AN

ILLUSTRATED WEEKLY JOURNAL

OF

HORTICULTURE IN ALL ITS BRANCHES.

FOUNDED BY

W. Robinson, Author of the "English Flower Garden."

" You see, sweet maid, we marry
A gentler scion to the wildest stock ;
And make conceive a bark of baser kind
By bud of nobler race : This is an art
Which does mend Nature,—change it rather : but
The art itself is nature."

Shakespeare.

MONS. B. LATOUR-MARLIAC,

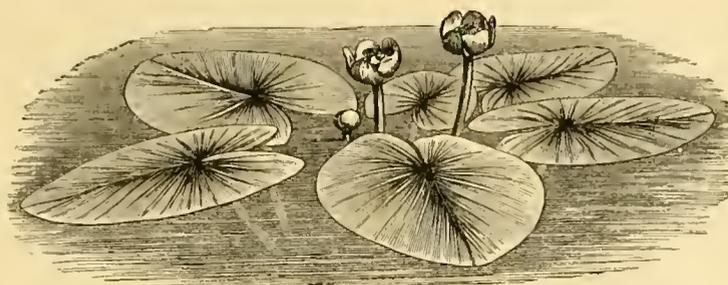

WHO HAS BROUGHT THE LOVELY COLOURS AND FORMS OF THE WATER LILIES OF THE
EAST TO THE WATERS OF THE NORTH,

THE FORTY-FOURTH VOLUME OF "THE GARDEN"

Is dedicated

BY ITS FOUNDER.

W. R., January, 1894.

INDEX TO VOLUME XLIV.

(Illustrations in Italics.)

A.

Abelia floribunda, 163
 Abutilon Anderken au Bonn, 296, 380; chrysostephanus grandiflorum, 216; Golden Gem, 602; vexillarium, 430
 Abutilons, 424, 459; dwarf, 402
 Acaena, False, and its varieties, 57; platyptera, 461
 Acalypha Macfeeana, 523, 600
 Acanthopanax richardsonii, 6, 94; scladophylloides, 6
 Acer pseudo-platanus atropurpureum, 94
 Acers, Japanese, and the drought, 207
 Acidanthera aquinoctialis, 521
 Aconeta Bakeri, 89; brysonia, 89; cryptocodonta, 89; densa, 89; erythroantha, 89; Humboldtii, 89; Hrublyana, 89; Schilleriana, 89; sella-turcica, 89; sulcata, 89
 Aconitum, 89
 Aconites, 89
 Acorus, 377
 Acorus calamus dryarioides, 552
 Adam's Needle, a fine, 86
 Adiantum cydoniaefolia, 485
 Adiantum cucullatum, 68; e. variegatum, 182; venustum, 20
 Adiantums, large-growing, 371
 Adiantum fulgens, 573
 Aerialis Ballantianum aureum, 221; crassifolium, 72; Fieldingii, 8; Godefroyanum, 72; Lawrenceana, 71, 266; obovatum, 72; quinquevulberum, 71; Sanderianum, 87, 156; Savgeanum, 71; suavisimum, 72, 324; virens, 71; Waineri, 156
 Agrostis ionoptera, 150
 Agapanthus, the, 114; Moorcanus, 131, 179
 Agave coelestis, 444, 459
 Agave Leopold II., 221; univittata, 221
 Aglaomorpha Meyeniana, 523, 552
 Aglaonema rotundum, 313
 Ailanthus glandulosus, 198
 Albert Nurseries, notes from the, 601
 Ailther, the golden-leaved, 6
 Allamandas, 162
 Allotment gardens and the drought, 4
 Almondsbury, notes from, 88, 219, 476
 Alonsoa Warscewiczii, 411
 Alpine plants, choice, planting, on sloping ground, 264
 Alpines, choice, 554
 Alstromeria aurantiaca, 61
 Amaryllis, a hybrid, 322; belladonna blanda, 174; seedlings, 419; vittata hybrida, 47
 Amaryllids in flower, 600
 Amasonia punicea, 410
 America, plants from, 531, 591
 American blight, 64
 Anianthium muscatoxicum, 186
 Anemobium alatum, 430
 Anemopa cinescens, 169; fruticosa, 57
 Anemophallus Titanum, 531, 574
 Anemopsis Boggi, 471; murais, 392
 Ansaesa sativa variegata, 601
 Andromeda japonica, 58

Androsace carnea, 466; Chamajasmine, 466; Charpentieri, 466; ciata, 466; cylindrica, 466; foliosa, 466; glacialis, 466; Hausmannii, 466; Heeri, 466; helvetica, 466; imbricata, 467; lactea, 466; Laggrii, 466; lanuginosa, 466; lanuginosa at Plympton, 527; obtusifolia, 466; pubescens, 467; pyrenaica, 467; rotundifolia, 466; varmentosa, 466; 493; sempervivoides, 466; strigillosa, 466; villosa, 466; Vitaliana, 467; Wulfeniana, 467
 Androsaces, 482, 465
 Anemosa adiantifolia, 136; caudata, 136; cheilanthoides, 136; collina, 136; Dregana, 136; lirsuta, 136; maudicea, 136; tomentosa, 136; tomentosa, 137
 Anemias, 136
 Anemioctyon phyllitidis, 136; phyllitidis, 136
 Anemone, Japanese, the, 280; japonica var. Lady Ardilaun, 337, 406; Robinsoniana, 84; sulphurea, 10; sulphurea, 10
 Angelica Tree, the, 551
 Angraecum arenaum, 59; caudatum, 497; Chaillouianum, 497; eburneum, 498; pulchellum, 410; sesquipedale, 454
 Anisals, dry-weather, 46, 197; border of, 188; in masses, 174
 Anthemis tinctoria, 11
 Anthurium crystallinum, 459; Dechardi, 255; flowers, 42; Wembeckianum, 357
 Antirrhinum, dwarf, the, 215, 279; Hendersoni, 364; Tom Thumb, 94
 Antirrhinums, 116
 Aphelandra nitens, 532
 Aponogeton distachyon, 509
 Apple Adams' Pearmain, 567; American Mother, 567; Annie Elizabeth, 319, 371; Bartlett's Glory, 270; Blenheim Pippin, 445; Brudick's Nonpareil, 579; Bramley's Seedling, 399; Byford Wonder, 502, 523, 567; Chatley's Kernel, 399, 447; Colonel Vaughan, 581; Devonshire Quarrenden, 115, 201; Duchess of Oldenburg, 401; Ecklinville Seedling, 354, 399; Ecklinville Seedling, 301; Flanders Pippin, 452; Frogmore Frolic, 242, 870; Gibbon's Russet, 228; Golden Harvey, 407; Gospatrick, 580; Hambledon Deux Ans, 301, 319, 354; High Cutlers, 581; Hollarbury, 370; Improved Bass Pool, 525; King of the Pippins, 408; Lord Suffield, 241, 275; Lord Suffield, fruiting branch of, 241; Maingtons Pearmain, 452; Newton Wonder, 580; Peasgood's Nonpareil, 273, 302, 319; Pott's Seedling, 273; Shepherd's Seedling, 301; the Pear, 611; the Pear, 611; Tibbett's Pearmain, 580; Tyler's Kernel, 581
 Apple crop, the, 2
 Apple tree, the Elephant, 180
 Apple tree bearing fruit and bloom, 405
 Apple trees, old, 274, 351; old, at Tachtrook, 340; re-grafting, 611

Apples, a big crop of, 129; blister on, 201; Crab, 446; culture of, 490; early, 39, 90; good, 303; keeping badly, 252, 582; late dessert, 579; little-known, notes on, 317; market, 317, 451; russet, 39; storing, 318
 Apples and Pears on heavy soils, 354
 Apricot Oullin's Early Peach, 579; the, in France, 191, 301; the, in London, 115, 174
 Apricot trees fruiting, 352
 Apricots, early, 38; on heavy soils, 273
 Aquatic plants and their culture, 506
 Arabis, 591
 Arad, Giant, the, 531, 574
 Aralia cordata, 5; Maximowiczii, 94; Sieboldi in Cornwall, 169; Sieboldi at Mount Charles, Truro, 169; spinosa, 551; spinosa var. canescens, 6
 Aralias, the Japanese, 5
 Araucaria bearing cones, 40, 112
 Arbutus alpina, 282
 Arctostaphylos alpina, 282
 Arctotis reptans, 269
 Arunaria balvarica, 512; norvegica, 436
 Arenarias, 512
 Aristolochia gigas Sturtevantii, 174, 293
 Arnicia cheioides, 187
 Artichokes, Globe, from seed, 466; Globe, protecting, 504; Jerusalem, 533
 Arum cristatum, 349; dioscoride, 348; Draconculis, 348; iaticum, 348; maculatum, 348; sanctum, 349; syriacum, 348; triphyllum, 348
 Arum Lilies, flowers of, 349
 Arum Lilies, 348; and drought, 346
 Asparagus europaeus, 444; tuberosa, 38
 Ash, Mountain, for towns, 203
 Asparagus, forcing, 463; on heavy land, 378; plumosus nanus, 410
 Aster acris, 231; alpinus speciosus, 436, 592; Amellus, 238; A. bessarabicus, 327; Amellus, seedling, 327; arcticus, 412; cordifolius, 430; c. Diana = Photograph, 436; corymbosus, 203; diffusus var. horizontalis, 492; diplotephioides, 16; dwarf, a, 493; grandifolius, 510; Novae-Angliae, 430; c. Novae-Belgiae, 595; paniculatus, 414; puniceus, 492; pyrenaicus, 482; tataricus, 412; Thomsoni, 186
 Asters, China, at Eynsford, 345; early-flowering, 197; at Kew, 288
 Athyrium Goringianum pictum, 183
 Aubrietia, 412
 Auriclea, the, 216
 Australia, flowers from, 521
 Autumn flowers from Newry, 833
 Autumnal tints, 392, 593
 Azalea indica, 42; linearifolia, 531; viscosa, 169
 Azaleas, 13; at Goodhurst, 205; hardy, 205
 Azara integrifolia, 615
 Azola caroliniana, 509; filiculoides, 33

B.

Babingtonia amphorosma, 180
 Baden-Baden, notes from, 500
 Balantium calca, 570
 Balbista verticillata, 342
 Bamboos, two interesting, 538
 Bambusa pyramidea, 182; Ragamowski, 182, 264
 Banana, cultivation of the, 496; fruiting plant of, 496
 Bananas, 239
 Barberry berries, 391
 Barberries in flower, 182
 Bartoniana aurea, 86
 Batatas paniculata, 120
 Batemanio Burti, 432
 Bean, a French running, 587; French, Ne Plus Ultra, 226; kidney, a running, 472, 504, 610
 Bean, Sacred, the, in New Jersey, 229; ways of growth of the, 229
 Beans, climbing, 587; French, 158; for autumn and early winter, 183; forcing, 536; in pots, 261; runner, 185
 Bedding plants and the drought, 227
 Bed, permanent, a pretty, 470
 Beds, mixed, 9
 Beech trees, unhealthy, 16
 Beet, Turnip-rooted, 56
 Begonia, a fine-leaved, 603; c. calina, 523; Erfordia, 531; fuchsoides, 323; Gloire de Lorraine, 460; Martiana gracilis, 323, 346, 364; Mrs. Bourne, 169; Octavia, 174; semperflorens atropurpurea, 96; s. Crimeon Gem, 96; s., seedlings of, 119; s., varieties of, 97; s., Vernon's variety, 159, 337
 Begonias as bedders, 154, 280; at Bexley Heath, 390; at Chiswick, 340; at Forest Hill, 327; at Swanley, 347; bedding, 469; double, an interesting race of, 198; fine-leaved, 603; in the open, 255, 888; tuberosa, 79, 418; winter-flowering, 461
 Bellflower, the Chinese, 162
 Bellium telidoides, 282
 Berberidopsis corallina, 341
 Berke, the scene in, 428
 Berries, autumn, 393
 Bernials, some tender, 140
 Bifrenaria vitellina, 128
 Birdweed, Blue Rock, the, 85, 411
 Bismarckia nobilis, 460
 Blight Scenas, the, 57
 Blight, American, 212
 Blood Flowers, the, 52
 Blue Berry, the Pennsylvanian, 420
 Boeconia cordata, 406
 Boilers and fuel, 500
 Bolbophyllum barbigerum, 72, 127; cupreum, 521
 Bomarea organtha, 521

The GARDEN.

VOL. XLIV.

ORCHARD AND FRUIT GARDEN.

GROWING STRAWBERRIES.

UNDER this heading (on page 506) Mr. Porch gives his experience with a quarter-acre plot of Strawberries, grown with a view to testing the expediency or otherwise of cultivating this popular fruit on a much larger scale in the future, and, further, asks for information as to the best methods of disposing of the fruit after it is grown. As I happen to be fairly familiar with the county in which Mr. Porch is located, and have also gained what may safely be considered reliable knowledge in the matter of growing Strawberries for the markets, I will give my experience in the hope it will be of some service to that gentleman as well as other readers of THE GARDEN who may stand in need of advice. All things considered, Mr. Porch succeeded fairly well, but very probably he would have done even better had he expended about £1 or rather more on rough or fresh strawy manure, this being applied in the form of a mulch not later than April. The Glastonbury soil must be of an even more retentive nature than ours in this part of Somerset, as it is very certain that if we had not both mulched and watered the breadths of Noble in these gardens, the crops would have been a failure. Then, again, if the season had been a wet one, or say only a few very heavy showers had fallen, the fruit, where no strawy mulch was not placed about the plants, must have been badly splashed and practically spoilt for market. I shall also be greatly mistaken if the unmulched plants do not fail to produce runners freely, red spider also being, probably enough, troublesome, and without a good supply of early, well-rooted young plants, how are the requisite new additions to be made cheaply?

Mr. Porch did well in starting with Noble, this variety succeeding better the first season after planting—it was very late planting in his case—than any other sort that I have had any experience with. It is also very early and of attractive appearance, though not a good traveller. Supposing a good-sized field with a slope to the south is available, then it might be possible to compete with the growers in the neighbourhood of Southampton, who are among the first to consign Strawberries in quantity to Covent Garden and other markets. In this case Noble might well be extensively planted,

or, say, to the extent of four acres or more, but, as it happens, May 11 was not particularly early this year, being probably a week behind the Hampshire and Cornish growers' dates of commencing to gather Strawberries in quantity. This being so, Mr. Porch would not have obtained high prices at Covent Garden, though he ought to have done better nearer home. Personally I am of opinion that Mr. Porch as well as many other beginners in the direction of growing soft fruits for marketing will do well to let Covent Garden alone, preferring to cater for the wants of towns within easy reach of their fruit grounds. The former is very well supplied with quickly perishable fruit, but this cannot be said of the majority of provincial towns. Instead, therefore, of relying exclusively upon Noble, and which no one considers of the best quality, therefore not in demand when better fruit can be had, a succession should be provided for. Sir J. Paxton is the market grower's most reliable second early variety, as it does well nearly everywhere, the fruit being large, of good form, very firm, and richly flavoured. President succeeds this, and being a tremendous cropper as well as good in other respects, it will be some time before it is wholly ousted by newer varieties. Both Sir C. Napier and British Queen, where they thrive, are grand varieties for market, and the old Eleanor or Oxonian is yet one of the best for the latest crop. Alice Maud seems to be going out of cultivation, but if Mr. Porch and other beginners can procure it true I should advise them to give it a good trial. It is a second early variety and most reliable. All the varieties named can be bought cheaply, or at any rate are anything but new in cultivation, but were I to commence Strawberry cultivation on a large scale a trial would be given most of the newer varieties as they came out. If they proved superior to older forms, then they would be grown to the exclusion of the latter, but if they failed to surpass those that had previously done good service, then the rubbish-heap would be their destination.

Now a few remarks as to the best methods of packing the produce. Mr. Porch asks if it will pay to pack each fruit (meaning those extra fine and early) in leaves and boxes, when you can gather 50 lb. a day and upwards from the open ground. He failed to state whether his trial consignments were thus packed or not, but should say they were not so well packed as that, or the price would have been near 1s. 6d. per lb. instead of 9d., and that, too, at Bristol, and I should think Wells. Instead, however,

of taking so much trouble with the packing, and which may or may not bring its own reward—for it is all a lottery—the better plan in most cases would be to pack in shallow punnets, fitting these, in their turn, closely together in light flat boxes. For fine early fruit of Noble the punnets that will hold about 1 lb. of fruit in a single layer are the best, these being lightly padded with dry Moss or wood-wool covered with leaves and laid together or even enclosed singly in these. Then paper them over, tying this to the punnets with a strip of raffia, and pack tightly in a single layer in a shallow box with a latticed lid. The railway officials, when they know what they are handling, are not so reckless as often considered, and that is why I recommend the latticed lid. These early fruits ought to realise, and would have done this season, not less than 1s. 3d. per lb., plenty being retailed at 2s. per lb., the prices gradually falling to 9d. I am of opinion that fine or selected fruit of Sir J. Paxton or other varieties might also be packed in shallow 1-lb. punnets with advantage to the sender, such retailing readily at 1s. or rather more per lb. As it happens, the bulk are packed in deep 1-lb. punnets, and these not being filled above the level of the rims, two layers, of either one dozen or two dozen, can be packed in boxes made to hold these numbers respectively. Shallow baskets are also largely used for sending Strawberries in, but I would strongly commend the Bath practice of packing Strawberries, when plentiful, in flat punnets or very cheap chip baskets with movable handles. These are sold just as received by the fruiterers and this is better in every way than handling the fruit. The same advantage attends the use of smaller punnets, and, besides, Strawberries travel badly in masses. There are times when Strawberries sell badly, and, in anticipation of this, arrangements should either be made for making fruit that will not sell readily for dessert into jam, or else there ought to be an understanding with someone to take all surplus fruit for a similar purpose. Mr. Porch ought to find a ready market for his fruit at Bristol, Bridgewater, Weston-super-Mare, Yeovil, Wells, and other local towns, and I doubt if Glastonbury and Street are any too well supplied. In each and every case arrangements should be made beforehand with fruiterers in the different towns to take the fruit when fit, and he and others similarly situated ought to claim to be able to send everywhere by rail at traders' rates. The difference between the latter and the ordinary

charges is very considerable, and unless the more favourable terms are conceded, Strawberry growers on either a large or small scale are badly handicapped. In any case, Strawberries should as much as possible be sold locally when the prices are falling below 5d. per pound.

The quotations of Covent Garden prices in the different papers, if not always absolutely correct, are as nearly so as the compilers can make them. To a certain extent they are misleading to inexperienced consigners, who have to learn that the fluctuations are in some cases very marked in a single morning, or far more so than the quotations denote. The latter are a fair average, but do not hold good a day after they are compiled. They show what has taken place, not what the prices will be subsequent to publication. Consigners ought always to be in touch with leading fruiterers and salesmen, and should arrange to have daily or frequent returns or notifications of the prices realised.—W. IGULDEN.

—Replying to Mr. Porch's questions *seriatim*, I may at once say that it will never pay to pack Strawberries from the open ground in small boxes. This form of packing is only practised in private gardens, or with forced or imported fruit sent from a long distance to the London markets. Some growers in the south-west of England send their fruit in this way to market, but they would not do so were it not for the risk involved in so long a journey. With forced fruit it is necessary to pack in a way that will ensure its coming into the salesman's hands without blemish; but there is no need to be so careful in the case of outdoor fruit. Where it is a question of sending off several hundred pounds of fruit every morning, the labour involved in packing the berries in leaves and the cost of boxes would be so great as to run away with the profits. The prime fruit is all sent in pound punnets, and various methods of packing these are employed. The boxes in which Oranges are imported are much used, they being roomy, light and sufficiently strong. The bottom of the box is filled with punnets, another layer being stood on them anglewise, so that there is not much pressure on the fruit. The box is filled in this way and covered with green bracken or anything of a like nature that will tend to keep the fruit cool and fresh in transit. Baskets, such as Peas are imported in, are also good for the purpose, especially for the earlier gatherings, as, being smaller, there is less danger of the berries being injured. Any Covent Garden salesman will send these baskets at request, the custom being to charge 1s. each for them, this being returned when they again come into the salesman's hands.

The area given up to Strawberries has of late increased so much and prices come down to such a low level, that a great bulk of fruit has to be put on the London markets in an even simpler manner than that above described. In a favourable year the output from the Strawberry farms is so great, that only the very finest fruit will make enough to warrant the expense of putting it into punnets. The price for prime samples will then often drop to 2s. 6d. per 12 lbs., so that second fruit has to be dealt with in a different manner. For this inferior fruit half peck and peck baskets are used, thus lessening the labour of packing. An enormous bulk of fruit is disposed of in this way at prices which would have struck terror into the hearts of Strawberry growers twenty years ago. Many London people never think of buying Strawberries until they can get them at 2d. per lb. The London Strawberry season culminates in the "smashers' week," when prices come down to their lowest point, and the "smashers," or jam manufacturers, buy what fruit they want. As regards sending the fruit to Covent Garden salesmen, there is no other way of disposing of any bulk of prime fruit, except by making arrangements with men of a like description in some of the large northern towns. I have been told by those who ought to

know that prices run somewhat higher in Manchester and Birmingham than in London, probably because the markets are not so liable to be glutted as is frequently the case in Covent Garden. I do know that some of the southern growers make a point of sending some of their produce to the north, and much of what is consigned to the London markets never reaches the salesmen, there being loads of fruit coming up by road which are diverted from their original destination and go on to one of the northern lines. It is certainly in the interest of a grower to put his fruit directly on to the northern markets than to let it pass first through a London salesman's hands, who naturally gets a picking out of it and lowers the grower's returns. In the case of large quantities of preserving fruit for the same reason it is preferable to make a contract with some jam manufacturer, who, as a rule, prefers to get his fruit direct from the grower than to buy in the London market. The prices as quoted in the London dailies I have found fairly reliable. The wholesale prices are certainly given much more accurately now than I have ever known to be the case. The weight of fruit, 220 lbs. from 280 plants, partly last season's runners, with no manuring and in such a trying season as the present, I should consider very satisfactory. Noble is, however, a heavy cropper, yielding more abundantly than the largely grown Sir J. Paxton. So far from considering 9d. per lb. a poor price, I should think it a good one now-a-days. Our large market growers would think themselves fortunate in getting an average return of 6d. per lb. Even in the favoured Hampshire grounds, where picking commences three weeks earlier than in the home counties, the price in an abundant year will come down to 2½d. per lb. To have made not less than 6d. per lb., Mr. Porch's fruit must have been very good, a proof, I should say, that the soil is just the thing for Strawberries. This, indeed, is the main point that has to be considered in connection with profitable Strawberry culture. If the soil is not naturally favourable, no amount of labour will make it so, and a man will only lose money on it. This can only be proved by experiments conducted through a period of several years. There is little difficulty in getting Strawberry runners to grow into good plants. That can be done in most soils, but it is not so easy to keep them vigorous and sufficiently productive over the second and third year to recoup the owner for labour of planting and loss of space, as the year following planting the crop taken from the ground will no more than pay expenses, the second year being the crop that should recoup the grower for his outlay and yield him a fair surplus, and the third season he ought to be able to count on a fair crop. Where the soil is not suitable the third crop will generally be more or less of a failure, and thus the grower's profits are much reduced; in fact, I much doubt if biennial planting would yield any profit. Many who have embarked in Strawberry culture have found this out to their cost. It is certainly an early district where picking commenced this year on May 11, being about a week later than the early Hampshire lands, where gathering in this phenomenally precocious season began in the first week of May, a week before the earlier Kentish grounds, and from a fortnight to three weeks in advance of the main crops in the home counties.—J. C. B.

The Phylloxera.—We learn that the Phylloxera has appeared in the vineyards of the province of Trapani (Sicily), in which Marsala is situated. This is the only province of the island which has hitherto been exempt from the visitation. The districts where the disease has been discovered are Alamo and Partinico. A Government commission has been despatched to the spot to combat the scourge.

The Apple crop will be very irregular and light. In grass orchards especially large quantities of Apples have dropped during the past few weeks, and they still continue to drop, the ground under those trees which set a heavy crop being thickly strewn with fruit of all sizes up to half-grown

samples. Very many trees failed to set any fruit at all, though the show of blossom was promising both in numbers and size of bloom, but the remarkably dry weather spoiled their chances of swelling. Trees on ground kept clean, and with no under-cropping, form a fine object lesson on the advisability of letting the trees have the full benefit of the soil they grow in. The growth of such trees, though rank in some seasons, is just of the right description now, while that on orchard trees is meagre and does not yet promise well for another year, though there is yet time for improvement, and the genial rains of the past day or two will help them, if more follow soon. Summer pruning will be worse than useless on light soil; this year.—J. C. TALLACK.

Cherry Hâtive de Prin.—Last year in the nurseries of M. Maquerlot at Fismes (Marne) we met with a very fine Cherry, known in that district as the Cerise Hâtive de Prin, and so named from the hamlet of Prin, in the commune of Serzy-Maupas. It is excellent in quality and valuable for its earliness, while its handsome appearance has caused it to be so much thought of, that it always commands the highest price in the market at Rheims. Except in some localities in Champagne, this variety of Cherry is so little grown that it may almost be considered a novelty, and yet we imagine that we came across it again lately, at Anizy, near Soissons, where we were informed that it is very highly esteemed throughout the entire district under the name of Cerise de Saint-Médard. It remains, however, to be proved whether it is the same variety which is known by these two names. As there were no leaves on the trees at the time of our visit to Anizy, we could not determine the point satisfactorily. The trees which we saw at M. Maquerlot's were of very vigorous growth, with bark of a glaucous brownish red colour. The full grown leaves were of a deep green colour, and had stalks about three-quarters of an inch long, the limb or blade of the leaf being about 4 inches long and 2 inches across, oval, abruptly acuminate, and margined with large, obtuse, unequal teeth. Flowers mostly in clusters of four, white. Fruit shaped like that of the Cerise de Montmorency, *i.e.*, a depressed spheroid about an inch in transverse and about three-quarters of an inch in vertical diameter, and of a uniform deep cherry-red colour; flesh of a deep pink colour, juicy, full flavoured, sweet and acidulous combined. We cannot say that this fine Cherry is certain to exhibit everywhere else the same high qualities for which it is distinguished in its native district of Champagne, but we should earnestly recommend our readers to try it.—*Revue Horticole*.

Canker in fruit trees.—It is now known that the cause of canker in fruit trees is a microscopic fungus named *Nectria ditissima*, which rapidly extends its ravages, but which can be effectively brought under control. For this purpose the cankered parts should be cut away and dressed with a pruning-knife, after which a mixture of the Bouillie Bordelaise containing 3 per cent. of sulphate of copper and 6 per cent. of lime should be applied to the affected parts with a paint-brush. This application may be repeated once or twice in the course of the summer.—*Revue Horticole*.

Making new Strawberry beds.—Every Strawberry grower has his favourite method of forming new beds, and so long as the results are good it does not much matter what particular plan is adopted. That followed by Mr. Camm, gardener to Admiral Egerton, St. George's Hill, Byfleet, seems, however, to me to be worthy of special mention. The runners are put out in rows, allowing just enough space to admit of development the first year. In the autumn they are lifted and put into their fruiting quarters. Some beds of President, Héricart, and King of the Earlies managed in this way look, in spite of three months' parching weather, remarkably well. One advantage of growing the plants the first year in this way is that by the time the hot weather sets in the foliage fairly covers the ground and helps to

keep the roots cool, mulching not being needful. Watering can also be attended to, if desirable, much better than if put out at once in their permanent quarters. I have at various times grown Strawberries much in this way, and I found that so far as fruiting went the plants bore almost, if not quite as well lifted at the close of the growing time as if put at once into their permanent position. President is found to be by far the most reliable Strawberry at St. George's Hill, and Waterloo is well thought of. Noble, in spite of its prolific precocious character, has been discarded, the flavour being so inferior. For forcing Mr. Camm prefers La Grosse Sucrée to all others.—J. C. B.

Roses and Peaches in the same house.—In a long lean-to house at Porter's Park, East Barcoet, I saw a fine lot of Roses growing in a house along with Peaches. The back wall was 10 feet high, probably more (I speak from memory in connection with a visit there three years since), and was wholly devoted to Roses. Cloth of Gold was especially noteworthy. The Peaches occupied the front of the house, and were trained over a rather low trellis. Judging from the crop of fruit and the quantity of Rose blooms, I could not but admit at the time that the combination was quite a success. I have frequently seen very fine examples of Maréchal Niel growing against the back wall of a lean-to vinery. The temperature required for successful Grape culture is necessarily higher than that required for Peaches, and for this reason less suited for Rose growing. We have here a Gloire de Dijon trained up the partition which divides two Peach houses, and well has it succeeded for the last twelve years. We can cut lots of flowers in the early spring months, and for this reason it is kept. True, the annual crop of green-fly makes its appearance, but the getting rid of this is a simple matter. While not advocating the combination of Peaches and Roses, the above shows that both can be successfully grown together.—E. M.

Jefferson's Plum under glass.—What a grand Plum this is for cultivating under glass. The fruits are large, of a golden yellow colour, and of excellent flavour. In fact, out of a goodly list of kinds of fruit at present in use this Plum is the most appreciated. My tree is planted out and trained up underneath the roof. In such a position it bears very freely, the fruits hanging in bunches. This checks the tree's vigour, although, of course, by this it must not be understood that the tree is overcropped. To cultivate Plums under glass the trees require to be kept cool and airy at all times, as any attempt at forcing would only end in failure. Our Plum house is a cool corridor connecting a range of vineries.—A. YOUNG.

GOOD DRY WEATHER STRAWBERRIES.

For the last three years the weather has been both hot and dry just at the time the Strawberry crop would have benefited by a heavier rainfall. No bardy fruit suffers more than the Strawberry if a lengthened period of drought is experienced directly the fruit has set. Not only is the fruit deficient in size, but it lacks flavour. These dry seasons, however, are not without their object lessons; they should teach us to make note of the varieties that succeed best under adverse conditions. Valuable information might be disseminated if others were to record the varieties that have given the best results during the present season, stating also the character of the soil in which the plants are growing, as so much depends upon this. In my opinion far too many sorts are grown; far better is it to ascertain those that succeed the best in any locality and plant freely of them. Within a mile of this garden the soil is heavy and too much impregnated with chalk for Strawberries to be grown successfully, as the foliage lacks that deep green shade so characteristic of vigour and productiveness that it has in sandy or heavy loams for instance where Strawberries grow so well. Outside of that radius

the soil is varied in character, being heavy and light loam, peat and gravel, in all of which Strawberries thrive wonderfully well. Hundreds of acres are cultivated for the market supplies. Sir Joseph Paxton is the one sort which succeeds above all others. Not only during such a season as the present, but in a wet one this sort is highly spoken of. The flavour is excellent in well-grown and thoroughly ripened examples. In our strong soil this variety is the best dry weather kind we have. Noble has borne a fairly good crop, having stood the drought remarkably well. In point of flavour, however, it has not improved, neither was it earlier than others. Vicomtesse Hélicart de Thury is a splendid variety for soil of this character. In point of cropping and quality it has no superior; the only complaint that can be made against it is the size of its fruit. We commenced gathering ripe fruit out of doors May 21. This is not an early garden, being so much exposed to east winds in addition to the heavy character of the soil. President is an excellent dry weather Strawberry both here and in lighter soil. The habit of growth is vigorous; the long leaf-stalks enable the leaves to extend a good way from the crowns, thus keeping the soil comparatively cool by affording shade for a distance around. British Queen and Dr. Hogg are not a success here in such dry weather. The latter does fairly well when the weather is less dry. Those who prefer a somewhat acid Strawberry will find it in the Captain; the fruit is borne on stout foot-stalks, but not in sufficient quantity to make it a profitable kind to grow. Sir C. Napier has a flavour peculiarly its own, but it also does not produce fruit in sufficient quantity.

E. MOLYNEUX.

Strawberry Stirling Castle—I met with this variety, certainly a very scarce sort, just recently at a jam manufacturer's in Kingston. It was spoken of as "Stirling," but is doubtless the old Scarlet Pine. The fruits were of the usual pointed or cone shape, rich in colour, very sweet, and of brisk pleasant flavour, one of the most pleasant varieties I have tasted for a long time. It should apparently make a good variety for breeding from to secure flavour. One jam-maker told me that he grew this variety and Elton Pine exclusively for jam manufacture, because the fruits are so firm and admirably adapted for boiling.—A. D.

KITCHEN GARDEN.

HOT WEATHER AND THE VEGETABLE SUPPLY.

VERY rarely indeed are vegetables so scarce as at the present time, and there will have to be a very early and marked change in the weather to effect an improvement in the supply. Peas, the most popular of all summer vegetables, are not at home in a tropical climate, and are behaving very queerly accordingly. Keeping them in a moist state at the roots does not sustain them in good health, and in no case that has come under my notice has the normal height of different varieties been approached. That is not the worst of it. Instead of the rows sown in March and April at intervals of a fortnight and still longer apart providing a succession of gatherings, all are fit to gather from, at nearly the same time. Even the late Ne Plus Ultra has developed into a second early variety, and we are also gathering from Duke of Albany, Criterion, Telephone, Success and Carter's Daisy, all being fit about the same time. Being kept moist at the roots, the pods fill well, but the contents are too old for picures before it is expected. Later rows are also flowering too soon, and in very many

gardens where space is limited there will be few or no Peas fit for use much later than June. All we can do is to sow as many late rows as possible, the first or second week in July being none too late in many localities to sow Ne Plus Ultra, Latest of All, Sturdy, Autocrat, and such like, English Wonder, William Hurst, Chelsea Gem, as well as the later-growing early sorts being sown up to the end of that month. Where Peas are not much crowded, have been kept well supplied with water at the roots, and the crops closely gathered, there is every likelihood of the haulm pushing out fresh side shoots, especially if there should, fortunately, soon be a change to dull showery weather, and very acceptable second crops be thus obtained. Do not, therefore, be in a hurry to pull up the haulm of Telephone, Telegraph, Duke of Albany, and other strong growers, as these are the most likely to grow afresh and give good gatherings. Only thorough soakings of water are of any service to Peas, and if they do not work downwards readily, bore holes at short intervals along the rows with a pointed iron rod or sharp stake. The value of heavy mulchings of straw manure can scarcely be over-estimated, especially during a hot and dry season such as we are grumbling about now.

Before these lines are in print I shall most probably have gathered kidney Beans from rows of plants on a warm border, and when once these become plentiful Peas can better be dispensed with occasionally. Luckily, this crop stands plenty of heat, but the plants ought not to be starved at the roots. Ours some time since had two thorough soakings of water and were then heavily moulded up. Later rows have been similarly served, and a very acceptable lot of Beans will apparently be had without much trouble. Runner Beans, again, seem to revel in the heat, as they are growing rapidly and strongly. As yet ours have not been watered, but they will soon have a thorough soaking, the dose being repeated twice a week during dry weather. These Beans are certain to be in great demand this summer, and none of the cultural details in the shape of thinning out, staking, training, mulching, or watering should be neglected a day longer than can be helped. Keep the pods closely gathered, whether actually wanted for use or not, allowing a number of them to mature seed having a most weakening effect on the plants. If some must be saved for seed, then set apart one end of a row for that particular purpose, and these few plants being well fed at the roots will produce a surprisingly good crop of seed, which maturing early and surely, the quality will be better than is often the case when saved in a more haphazard fashion.

Vegetable Marrows like plenty of heat, and in other hot and dry summers have been the principal green vegetable sent to the markets. Those numerous waggon-loads of Vegetable Marrows to be seen very early in the morning wending their way to Covent Garden and other markets are not grown on heaps of manure, but are produced by plants in the open fields with only a comparatively thin layer of solid manure under them. Under market growers' treatment the plants form only a moderate amount of haulm and abundance of Marrows, plants on heaps of manure behaving in an exactly opposite manner. They do not when grown on the level or nearly so require much water, and it could not well be supplied to them if they did. It is of the greatest importance, especially this season when the plants have grown as rapidly as Cucumbers in a frame and promise to be productive exceptionally early, that the

fruits be cut as fast as they are large enough for use. When this is not done, those left on the plants attain a great size, only to be spoilt, very probably, in the autumn, and the consequence of this neglect or thoughtlessness is a cessation of the growth of later fruit; whereas, if kept closely cut over, productiveness will be the rule up till the time early frosts are experienced. Vegetable Marrows are not considered very high class, and in very many establishments are not often seen on the dining-table. This, however, is either the fault of the cook or gardener, or, it may be, both of them together. If the ordinary Long White or Green Vegetable Marrows are cut when no more than 6 inches long and of about the same size round as a fully-grown Cucumber, cooked and served whole, they are then more worthy of being termed Vegetable Marrow, and would be far more often asked for by owners of large gardens than at present. This may seem an extravagant practice, but small samples are plentiful enough if only the big manure heaps are avoided and close cutting is practised.

This promises to be a good year for Tomatoes, and if the season continues hot and dry, they will ripen earlier than usual and be abundant and good from open-air plants. If the precaution is taken to protect those plants growing against walls and fences with frame lights, or glazed cases when the weather is dull and wet, disease might, to a certain extent, be defied and a lot of sound fruit be had accordingly. For salad, those ripened under glass are the best, but any moderately well ripened in the open air are suitable for cooking, and a very wholesome and acceptable dish they prove to most people. Being kept in a moist state at the roots, and I hold it is a mistake to starve them in hot weather, the plants are growing very strongly with me, the crops also setting most satisfactorily. If there is any drying off at the roots practically, it should only be done in dull showery weather, and in no case ought the plants to expend any of their strength in the production of side shoots for which there is no room or use. Lay in a few where there is room for them to form one or two bunches of fruit and pinch out the rest as fast as they form.

M. H.

Tomato Challenger.—I am greatly interested in a fairly large trial of Tomatoes under glass, all the best praised varieties and many that have as yet received no commendations in this country being grown. Up to the present time, none have given so much satisfaction as Challenger, and this excellent variety will be grown to the extent of a thousand plants next season. It is of good sturdy habit, the leaves not taking up a disproportionate amount of room, while the clusters of fruit almost touch each other from the ground up to a height of 6 feet, and the plants are still making good progress. The majority of the fruit is of a medium or most serviceable size, of good form and colour, while no fault can be found with the quality. It certainly resembles Chemin, but with me is a better cropper.—J.

Salt for Celery.—Would it be beneficial or otherwise to sprinkle salt on the Celery drills heavily before earthing with a view to killing the worms and slugs? Also would it be beneficial or otherwise to dust the ground heavily with lime before earthing the Celery?—T. C.

** Salt may with advantage be freely forked into the Celery trenches with the manure. Use enough to fairly whiten, but not wholly cover the surface of the manure, and well mix it with the latter, or a bushel of it may be mixed with every cartload of manure before it is thrown into the trenches. This will certainly benefit the Celery

and check, but not wholly keep away or destroy the worms and slugs. Prior to moulding up, a mixture of soot and lime may safely be dusted very freely about the plants, and also the soil brought up to them, soot in particular having a lasting effect. It will mean a little extra trouble in the way of cleaning the "sticks" when required for use, but better that than badly-eaten and disfigured stalks.—W. L.

ALLOTMENT GARDENS AND THE DROUGHT.

I HAVE been during the past two weeks engaged in awarding prizes to a large number of allotment gardens, and I have noticed in many instances the difficulties which have beset the cottagers in battling with the disadvantages of the drought. In a field of about 14 acres, of one-eighth and one-sixteenth of an acre allotments, though water is laid on, there are only two or three stand pipes, and some of the holders have to carry their water a considerable distance. Things are generally backward in development. Peas, Broad Beans, Cabbages, Lettuce, Turnips, Turnip-rooted Beet, and Vegetable Marrows are the only articles up to anything like their usual mark, and some of the best of the Peas will almost be over by the first week in July, when our local show is held. Some of our Ealing cottagers have been famous for the excellent Cauliflowers of the Erfurt type, they have made a practice of exhibiting during the first and second weeks in July, but this season there is scarcely a good Cauliflower to be seen, so much are they out of character and disfigured by blight, and anyone might be led to suppose from their present appearance the cottagers are growing a very indifferent stock. Then the plants are sadly affected with blight and caterpillars, and the club in the case of the Cauliflowers is this season a great pest. The use of lime and soot in the soil in which the club appeared last season and an entire change of crop have had little perceptible effect. It would be interesting to know if club is more prevalent in a wet season than in a dry one. Cabbages sown last autumn are quite out of character this season, and to judge from the appearance of some of them, a certain sort named Defiance, which is a great favourite among our Ealing allotment-holders, is this season so different as to look like a bastard, and yet I am assured that seed from the same packet has produced Cabbages of remarkable quality, and as inferiority is the result of the season and not of the strain, no one should be in a hurry to condemn the seedsman for supplying a bad article.

On light gravelly land, of which a portion of our allotment gardens consists, the crops are thin and poor, largely owing to want of rain and the difficulty experienced in procuring manure; indeed, this has now become in some of the suburbs of London a very expensive luxury. The allotment-holder scrapes together the very best materials in the way of manure he can, but it is too often a poor fertiliser. When last winter lecturing to allotment-holders in the county of Berkshire, I found that in the country as much difficulty is experienced in procuring manure as near London. I was questioned as to the best patent manure for allotment-holders, and, desirous of having the most reliable advice, I wrote to Mr. J. J. Willis, of Harpenden, who admitted that the problem as to suitable artificial manures for allotment-holders is a difficult one, not from want of materials, but for conveniences for their storage, preparation and application, and it is of little use to recommend anything that requires careful mixing by those employing it. The best all-round manure of this character is, in the opinion of Mr. Willis, undoubtedly guano, but its composition varies so greatly, that persons purchasing it may pay double its value. Probably the safest and most economical manure for general garden purposes would be a low grade manure, such as is advertised as Turnip manure, and which costs from £7 to £8 per ton. This contains about 9

per cent. of nitrogen, and should be sown broadcast and dug in at the rate of 2 to 3 cwt. per acre according to the crop for which it is intended, the Cabbage tribe requiring more than Onions, Carrots, Beet, Peas, &c. There are some good bone manures now to be had which are well adapted for Peas, Potatoes, Onions, &c. Soot is a good manure, but it is one that, while apparently ready to the hand of most allotment-holders, they appear to use very little of where it can be procured. Basic slag may be used with advantage on all soils that are not chalky.

The difficulty of getting a patent manure to suit allotment-holders is great, but capable of being overcome. If it were possible for a body of allotment-holders to club together and get one or two tons of Turnip manure direct from a good firm, they would find it come cheaper than going to an agent, and the firm would deliver it carriage free. Then come the storage and division, both of which might be arranged by hearty co-operation and mutual assistance.

R. D.

Deep cultivation.—When looking over an extensive range of allotments recently I could not help noticing the marked difference between the appearance of the crops in a few cases as compared with what was generally found. In relation to the latter I asked a worker to let me have his spade that I might ascertain how deeply his ground was worked, and found it did not exceed 10 inches. Below that the bottom was so hard, that it was most difficult to penetrate it. In the case of the few better cropped holdings I found that the soil had been worked 15 inches in depth. The allotments were all in the first year of cultivation, but the holders have all learned a rough lesson as to the value of deep cultivation, and it is to be hoped that the common 10 in. will be deepened to 20 in. during the ensuing winter. But there is not a garden in the kingdom where this season the value of deep cultivation is not being made manifest. If it be wise to advise the formation of trenches for Celery, Peas, and other crops, it is equally wise to advise that all the cultivated soil shall be treated as though it were one huge trench, as even single trenches ever so deep and well prepared by no means equal deep trenching of an entire area. It sometimes happens when moisture is too prevalent that on deeply worked soil the crops are too gross and leafy. That is much more seldom an evil, however, than is the existing one of excessive dryness, so that over large areas of cropped soil the produce will hardly pay the cost of the seed. Farm land just now is in a terribly barren, burnt up condition because it is so shallow worked. On the other hand, where ground is every few years trenched from 2 feet to 3 feet and well manured, crops in spite of the drought look fairly well, and for the season are almost the only successes. Such a season of drought as is the present should give a strong impetus to the deeper cultivation of the soil.—A. D.

Carrots dying off.—All the beds of Carrots in my charge are infested with a grub like a small maggot, which cuts the young Carrots across. What can I do to destroy them, and can I do anything another year to prevent their ravages (in the preparation of the ground, I mean)?—T. C.

** Once maggots take possession of Carrot roots there is no remedy other than forking them out of the ground and burning all together. Sand thoroughly impregnated with petroleum and sown broadcast over the beds or freely between the rows soon after the plants show through the ground, further dressings being given every fortnight till the roots are large enough for use, has a decidedly deterrent effect upon the fly that causes the trouble, but no applications of either diluted petroleum or other insecticides are equal to destroying the grubs once they are formed unless strong enough to kill the plants as well. Try the sand remedy on any plants that come up after the rains, and if any seed is sown soon with a view to having young Carrots throughout the autumn and winter months, distribute some petroleum-soaked sand along

the drills. For the attacks of grubs after the roots have attained a serviceable size, these disfiguring the roots, but not often causing the leaves to flag badly and die, a free use of wood ashes is the best lasting preventive. Instead of sowing this very freely in the drills with the seed and risk destroying the latter by an over-dose of it, completely cover the surface with good wood ashes, or the latter and soot in mixture and lightly fork it in. Nitrate of soda and salt are also deterrents of grub attacks, and excellent fertilisers in most cases. Ground intended for Carrots ought, as a rule, to be dug up deeply and roughly early in the winter, a second turn being given during a dry time in March. This will be the means of greatly improving the soil and getting rid of various insect pests. In extreme cases a complete change of ground should be tried, a compost of fresh sandy soil being substituted for ordinary garden soil. The less thinning out of seedlings there is needed the better, always provided there are enough plants, grubs being most often troublesome where much thinning has had to be done.—W. I.

CUCUMBERS FAILING.

WITH this I am sending stems and roots of Cucumbers and Tomatoes, which I shall be glad if you will submit to an expert to examine. The whole of the Cucumber plants in two long houses have collapsed just when they were beginning to do well, and no reason for this can be found. They are grown without bottom-heat in a light sandy loam, with solid manure and bone meal mixed with it. The progress up to the time of failure was most satisfactory, the root action being good and the top growth equally so. First a few leaves flag, then some of the branches, and eventually the whole of the plant goes. I can find no damaged roots and the stems are apparently sound, though the collars, I should say, are not quite as they should be. The water used is principally "town water," and very hard. It is run into tanks and warmed by means of hot-water pipes passing through them prior to use. The houses are new, and there may be something wrong with the paint. Only a few Tomato plants go wrong, but the symptoms are much the same, and the collapse of strong fruiting plants is very sudden. Strangely enough, another large house of Cucumbers in this neighbourhood failed similarly, the soil in this case being very different from ours, but the house was new. If you can help me to solve the mystery a great favour will be conferred.—G. W.

I enclose leaves and roots of Cucumbers from the house of a small grower for market. The plants flag and in a few days are what might be termed dead. There are two more places half a mile distant where the plants are similarly affected, and in one of them I am informed that the Tomato plants of one of the growers are going off in the same way. The house from which I pulled the enclosed plant up is, like the others, most suitable for Cucumbers, and the owner told me that a Rose tree in a pot at one end began to go wrong first, then a couple of Geraniums, then the Cucumber plants. I do not attach much importance to the death of the Rose and Geraniums, and I simply give the man's explanation. I saw he had a fine healthy Tomato plant in the place where he said the Rose stood. I shall be glad to know of cause and likely remedy for the Cucumber disease.—W. P.

* I am very sorry I have not been able to reply to the enclosed letters before, but I could find no cause of injury to the plants, so I sent them to Miss Ormerod, who was not more fortunate. The same reply applies equally to both letters. I am sorry to say that I am quite unable to say what has caused the death of the Cucumber plants. I have carefully examined the roots under a microscope, and, failing to find any cause of injury either insect or otherwise, I sent one to Miss Ormerod, who quite confirms my examination. There are some eel-worms present in the stem, but not enough to injure the plants. I think the very hot weather may have had something to do with

the mischief by drying the atmosphere or the soil more rapidly than was imagined, or was the temperature of the houses too high? Whatever the cause may have been, I think you may be quite certain that it was not an insect, mite or eel-worm or a fungus.—G. S. S.

THE PEA CROP.

WHEN Peas sold at public auction fetch £17 per acre, it shows that the crop is very scarce in some districts, especially when the buyer has to pay for gathering, carriage to market and other incidental expenses. This price was obtained in this district for a fine crop. In many instances the dry weather has proved disastrous, growers in several cases having had to plough up the crop as not worth retaining. Besides the drought to contend against, there was the Pea weevil, which played terrible havoc. Rarely have Peas been gathered so early in the season. In the case of some of the varieties, no sooner had gathering commenced than it was over. Those people who have hitherto put their faith in the early rounds for a first crop will eventually have to grow the better quality early marrows. The only gain as regards the early rounds is where they are sown in November or December; then with a fairly favourable time these afford the earliest gathering. This was the case this last season, as after a perusal of all published reports, it was those sown in November or December which were the earliest. Of these, Veitch's Selected Extra Early, good types of Ringleader and William I. were the best. I must admit that the season was all in favour of the early marrows, whether raised under glass and planted out at the first opportunity or sown in the open. On the other hand, the early rounds did not beat them for earliness when sown under like conditions. These are evidently what might be described as wet-weather Peas, as they take a surprising amount of moisture both in the atmosphere and at the root. The hot and dry weather this season was too much for them, as besides being abnormally short in the haulm, they were in and over in less than a week, the haulm turning colour rapidly. Those people who relied upon these for succession for the first two or three sowings must have been without Peas at some time and quite unable to keep up a succession.

The varieties which I have grown, and which also have done exceedingly well, have been William Hurst, Chelsea Gem, English Wonder, and May Queen. These are all of fine quality, come early into use, last a surprisingly long time in bearing, and give a daily succession of pods instead of one or two gatherings like the early rounds. In more genial seasons I have had William Hurst and Chelsea Gem keep lengthening out the haulm and forming pods. At one time it was customary to make the sowing for the first crop during November, and in many gardens this is still done with more or less success. Soil and situation have a great influence one way or the other. Many gardeners, I know, condemn this system, but I do not. By not sowing in November or December they make a mistake in relying, when they do sow, upon the more inferior rounds. I have quite given up forwarding the rounds in this way, as the haulm quickly lengthens out, and if an inclement time should follow to prevent planting when ready, they soon get spoiled. Another feature of the dwarfs is, that by being sown comparatively closely together the crop is far heavier.

A. YOUNG.

Tomato Early Ruby in the open air.—It is very seldom that ripe Tomatoes can be gathered from the open air in the third week in June. This has happened with a variety called Early Ruby. Good plants were put out against a south wall on a raised border during the first week in June, the first trusses being well set and the fruit swelling. This, of course, would be a help, but however this may be, it shows the remarkably early character of the season.—A. YOUNG.

TREES AND SHRUBS.

THE JAPANESE ARALIAS.

THE *Aralia* family has no representative in Eastern North America outside of the genus *Aralia*, and only one woody plant, *Aralia spinosa*, a small tree of the Middle and Southern States. In Japan the family appears in no less than eight genera. The Ivy of Europe reaches Japan, where it is rather common in the south, although we did not meet with it north of the Hakone Mountains and the region about Fugisan. *Helwingia*, a genus with two species of shrubs, remarkable in this family for the position of the flowers, which are produced on the upper surface of the midribs of the leaves, is Japanese and Himalayan. In Japan *Helwingia* ranges to Southern Yezo, where, in the peninsula south of Volcano Bay, in common with a number of other plants, it finds its most northern home.

In the flora of Japan, *Fatsia* is represented by the handsome evergreen plant *Fatsia (Aralia) japonica*, now well known in our conservatories, an inhabitant of the extreme southern part of the empire, although often cultivated in the gardens of Tokio, both in the open ground and in pots; and by *Fatsia horrida*, a low shrub, with stout, well-armed stems, large palmate leaves and bright red fruit, which is also common on the mountains of the north-west coast region of North America from Oregon to Sitka. In Japan we find it growing under the dense shade of the Hemlock forests on steep rocky slopes above Lake Umoto, in the Nikko Mountains, at an elevation of 5000 feet above the sea-level, and in Yezo. The third member of the genus, *Fatsia papyrifera*, from the thick pith of whose branches the Chinese rice-paper is made, and an inhabitant of Central and Southern China and of Formosa, is frequently seen in Tokio gardens, as it is in those of the United States and Europe. In Yezo is found a representative of the Manchurian and Chinese genus *Eleutherococcus*, a shrub still to be introduced into our gardens, and *Panax repens*, a delicate herb with trailing stems and bright red fruit, which manages to live on mountain slopes under the dense shade of Bamboos; while *Dendropanax*, a tropical genus of trees and shrubs of the New World, as well as of the Old, reaches Southern Japan with a single shrubby species, *Dendropanax japonicum*. *Aralia* is more multiplied in species in Eastern America, where six are known, than in Japan, whose flora contains only two, although a third, the Ginseng (*Aralia quinquefolia*), a native of Manchuria, Northern China, and the United States, has been cultivated for centuries in Japan for the roots, which the Chinese esteem for medicine and buy in large quantities, sometimes paying fabulous prices for them, especially for the wild Manchurian roots, which are considered more valuable than those obtained from North America or from plants cultivated in Japan, or in Corea, where Ginseng-cultivation is one of the most important branches of agriculture. Curiously enough, this North American and Chinese species was first made known to the outside world by Kämpfer's description of the plants cultivated in Japan.

Of the indigenous *Aralias* of Japan,

ARALIA CORDATA is a herb with large pinnate leaves and long compound racemose panicles of white flowers, which are followed by showy black fruit. In habit and general appearance it resembles our North American Spikenard (*Aralia racemosa*), but it is a larger and handsomer plant, and well worth a place in the wild garden. In Japan *Aralia cordata* is often cultivated in the

neighbourhood of houses for the young shoots which, as well as the roots, are cooked and eaten.

ARALIA SPINOSA VAR. *CANESCENS*, only differing from our American *Aralia spinosa* in its rather broader and more coarsely serrate leaflets and in the character and amount of pubescence which covers their lower surface, is a common tree in Yezo and in all the low mountain region of Northern and Central Hondo. It usually selects rather moist soil, and sometimes, under favourable conditions, rises to the height of 30 feet or 40 feet and forms a straight, well-developed trunk. In Hondo large plants are rare, probably owing to the fact that the forests on the low and accessible mountain slopes are frequently cut off, but the shrubby covering of such hills is almost always brightened in September by the great compound clusters of the white flowers of the *Aralia* which rise above it. The Japanese form does not appear to be much known in gardens, although young plants have lately been raised in the Arnold Arboretum from seed sent a few years ago by Dr. Mayr from Japan, and it is the Manchurian variety known as *Aralia chinensis*, or as *Dimorphanthus mandshuricus*, that is usually seen in our gardens, from which the American form, the type of the species, appears to have pretty nearly disappeared, although the name is common enough in nurserymen's catalogues.

But of all the *Araliaceae* of Japan, *Acanthopanax* is the most interesting to the student of trees. It is a small genus of about eight species of trees and shrubs, all members of tropical Asia and of China and Japan, where half-a-dozen of them have been found. The most important of the Japanese species are *Acanthopanax ricinifolium* and *Acanthopanax sciadophylloides*. Of the other species, *Acanthopanax innovans* is a small tree, of which I saw young plants only, on the Nagasendo, without flowers or fruit, and which is still to be introduced. *Acanthopanax aculeatum*, a shrub or small tree, with lustrous three or five-parted leaves, is much planted in Japan in hedges and is hardy in Southern Yezo, where, however, it has been introduced. *Acanthopanax trichodon*, of Franchet and Savatier, a doubtful species, which, from the description, must closely resemble *Acanthopanax aculeatum*, we did not see; but *Acanthopanax sessiliflorum* of Manchuria and Northern China and an old inhabitant of the Arnold Arboretum, we found evidently indigenous near Lake Umoto, in the Nikko Mountains, on the Nagasendo and in Yezo.

ACANTHOPANAX SCIADOPHYLLOIDES is still unknown in our gardens, and we were fortunate in securing an abundant supply of seeds. It is a handsome, shapely tree, sometimes 40 feet in height. The flowers appear in early summer on slender pedicels in few-flowered umbels arranged in terminal panicles 3 inches or 6 inches across, with slender branches, the lower radiating at right angles to the stem, the upper erect. The fruit, which is of the size of a pea, is dark blue-black, somewhat flattened or angled, and contains two cartilaginous, flattened, one-seeded stones. This handsome species inhabits the mountain forests of Nikko, where it is not common. Later we found it in great abundance on Mount Hakoda, in Northern Hondo, and in Central Yezo, where it is common in the deciduous forests which clothe the hill-sides. Here it apparently attains its largest size, and grows with another species of this genus,

ACANTHOPANAX RICINFOLIUM, the largest *Aralia* of Japan. I have followed the Japanese botanists in referring this tree to the *Panax ricinifolia* of Siebold and Zuccarini, although the plant cultivated in our gardens and in Europe as *Acanthopanax ricinifolium* or *Aralia Maximowiczii* is distinct from the Yezo tree in the more deeply lobed leaves with much broader sinuses between the lobes. A single individual similar to the plant of our gardens I saw growing in the forest near Fukushima, in Central Japan, but, unfortunately, it was without flowers or fruit. And as I

was unable to find any leaves on the Yezo trees with the broad sinuses of this plant or any intermediate forms, it will not be surprising if the forests of Japan are found to contain two species of simple-leaved arborescent *Acanthopanax*, in which case it will be necessary to examine Siebold's specimens to determine which species he called *Panax ricinifolia*. In the forests of Yezo, where it is exceedingly common, *Acanthopanax ricinifolium*, as it will be called for the present at least, is a tree sometimes 80 feet in height, with a tall straight trunk 4 feet or 5 feet in diameter, covered with very thick, dark, deeply-furrowed bark and immense limbs, which stand out from the trunk at right angles like those of an old pasture Oak, and thick reddish brown, mostly erect branchlets armed with stout, straight, orange-coloured prickles with much enlarged bases. The leaves, 7 inches to 10 inches across, are dark green and very lustrous on the upper surface, light green on the lower surface, which is covered, especially in the axils of the ribs, with rufous pubescence. The small white flowers are produced on long slender pedicels in many-flowered umbels. They appear in August and September, and are very conspicuous as they rise above the dark green foliage, giving to this fine tree an appearance entirely unlike that of any other inhabitant of northern forests. *Acanthopanax ricinifolium* is common in Saghalien and Yezo, and I saw it occasionally on the mountains of Central Hondo, where, however, it does not grow to the great size it attains in the forests of Yezo. Here it is associated with *Lindens*, *Magnolias*, *White Oaks*, *Birches*, *Maples*, *Cercidiphyllum*, *Walnuts*, *Carpinus* and *Ostrya*. The wood is rather hard, straight-grained, light brown, with a fine satiny surface. In Yezo it is highly valued, and is used in considerable quantities in the interior finish of houses and for furniture, cases, &c.—*Garden and Forest*.

The golden-leaved Alder.—A hot and dry season such as we are now having brings out the colour of the golden-leaved Alder. We have several trees growing on exposed banks and knolls in the pleasure grounds. In conjunction with these, we also have several specimens of the purple-leaved *Prunus Pissardi*; the two together making quite a harmonious blending of colour. Unfortunately, rabbits are very fond of peeling the stems during the winter months. A piece of wire netting bound around the stem will, however, protect it.—A. YOUNG.

The Clammy Locust (*Robinia viscosa*).—This is a charming member of the *Acacia* family, and makes a handsome tree, but, happily, we have not to wait till it attains tree dimensions before it gives us considerable beauty. Some specimens quite recently planted and less than 6 feet in height have been blooming this season, and will now continue (only more profusely) each year. It has some considerable resemblance to the False *Acacia*, but it is rather smaller in growth, more slender, and the bark of the young shoots is very clammy; hence the name. It is fast-growing, and on a lawn would soon make a handsome tree with a considerable spread of branches. The flowers are of much the same tint as those of the pink variety of the common *Acacia*, but they cluster more thickly in short racemes.—A. H.

Double-flowered Peach Clara Mayer.—This is a very fine and also a very rare and remarkably floriferous variety. The flowers, which are very large-sized, well formed, and of a very deep bright red colour, are produced in such abundance, that when the tree is in bloom the branches are completely hidden by the flowers and foliage, the contrasting colours of which have a very striking ornamental effect, more particularly so as the red colour which the petals of the flowers are suffused throughout never entirely leaves them, but sometimes becomes a little lighter or weaker in tint here and there. The culture and propagation are precisely similar to those which are practised in the case of all other fruit trees belonging to this group. The soil should be a somewhat tenacious

one, and light rather than too heavy. Propagation is effected by sowing the fruit stones, when such are produced, but more usually by shield grafting, the stock employed being the *St. Julien Plum* tree. In some soils or under special climatic conditions other kinds of stocks are sometimes preferred—the *Myrobella Plum* tree, for instance, which is especially employed when small sized or half standard trees are required. In some localities the *Damas de Toulouse Plum* tree is also used as a stock, and is valuable for this purpose in districts where own-root Peach trees do not succeed well. Elsewhere it is seldom used as a stock. We have no hesitation in recommending the double flowered Peach tree *Clara Mayer* as being one of the finest ornamental trees or shrubs. Moreover, it is hardy and possesses all the good qualities that an ornamental tree should exhibit, being robust in growth and never suffering from the severest frosts in winter. It also accommodates itself to every mode of training and does well under every form and in every position and aspect.—*Revue Horticole*.

Spartium junceum (the Spanish Broom).—There are few outdoor shrubs which better enjoy the present long and remarkable spell of semi-tropical weather than the old Spanish Broom. It is flowering now very beautifully. It is easily distinguished from all the hardy *Leguminosæ* by its green rush-like stems, devoid of leaves except when young. It grows to a height of 8 feet or more, but being of a lanky, gaunt habit is seen to best effect when planted in shrubberies where its base is hidden, and a suitable setting of greenery is provided for the profusion of blossom. The flowers are individually larger than those of most of the hardy shrubs of the same tribe, and the colour is a rich glowing yellow. It is a native of Spain and other parts of the Mediterranean region, and is also found in the Canary Islands. According to Loudon, it is chiefly found on gravelly soils in its natural state, and in this country it is useful for dry sandy soils where many other shrubs would not thrive. It is one of the earliest exotics brought to this country of whose introduction a record exists, the date being 1518. The plant seeds with freedom, and may by this means be rapidly increased. There is a double-flowered variety in cultivation which promises to be a valuable plant, but it is not common as yet.

Kalmia angustifolia and **Rhododendron hirsutum** are very pretty now. I think these deserve to be planted more extensively than they are. The ponticum and hybrid *Rhododendrons* are all faded and gone, and *R. hirsutum* and *Kalmia angustifolia* form a good succession. It is generally understood that *Kalmias* will only grow in peat bog, but we have some strong plants on clayey ground, which, I hope, is something in their favour. The three best sorts are *Kalmia angustifolia rubra*, *K. a. rosea* and *K. a. glauca*. The last-named is in bloom in April, the other two during the present month (June). The *Heaths* are coming into flower. There are four kinds of white *E. cinerea*. *Erica cinerea alba* is a strong-growing plant, best suited for a dry bank. It has light green foliage and blooms later in the year than minor or major. *Erica cinerea alba minor* is a pretty compact-growing variety—one dense mass of white blooms, similar in growth to *carnea alba*, only dark green foliage, the earliest of its class to bloom. *Erica cinerea major* is in bloom with minor, only makes stronger growth and larger flowers. *Erica cinerea alba multiflora* is the latest to bloom and resembles minor, only it is in bloom longer than the other and has light green foliage. Then there are the bright-coloured varieties of *cinerea*. *Purpurea* is a bright purple; *atro-purpurea*, a dark purple; *nigra* is dark purple; *rosea*, a flesh colour; *coccinea*, a bright scarlet; *atro-sanguinea*, a crimson; *pallida*, a pink. All the forms of *cinerea* do best on a dry bank. The same remarks apply to *E. tetralix* and *E. ciliaris*. The vulgaris varieties grow almost anywhere.—C. REEVES, *Flash Nursery, Two Dales, Matlock*.

The English Flower Garden.—Design, Views and Plants. Third edition, revised, with many new illustrations. London: J. Murray, and through all booksellers.

WISTARIA AT THE LARCHES,
EAST GRINSTEAD.

WE are indebted to Miss Brown, of The Larches, East Grinstead, for the very excellent photograph from which this engraving was made. The engraving tells its own tale. This district is not so favourable to this noble climber as many others in England, but still the hardiness of the plant and its freedom of bloom are well proved in this rather cool and hilly district. It is surely needless to say any more of a plant which everybody ought to know so well. Of its use for bowers and covered ways we spoke last week. Up to the present its most

fruit which are now employed in many parts of France, "the orchard of Europe."—*Revue Horticole*.

ORCHIDS.

EPIDENDRUM VITELLINUM MAJUS.

I AM in receipt of a letter from Major-General C. B. Lucie-Smith, of Worthing, in which he questions my remarks as to this plant preferring a shady situation, giving a case in point of a plant in his own possession which had been treated quite the reverse. He says :—

I obtained the plant when semi-established, having forty-five bulbs in April, 1891. In the May

sunlight is accountable for the depth and brilliancy of the colours. Take, for instance, *Cochlioda Noezliana* and *C. vulcanica*, *Ada aurantiaca*, and the *Masdevallias*, which have as bright colours as any Orchids, all of which grow best and flower most freely without sun in a north house. We are told that Roezl found *Epidendrum vitellinum majus* growing upon stunted Oaks in a district where it rains for about a couple of hours every day from May till October, and where from December to February the plants are enveloped in dense fogs and subject at times to frost. Lindley tells us the typical form is found on cloud-capped mountains amidst continual mists in the regions of Lichens, so that the plant in a state of nature is not troubled with much sunlight. I hope that General Smith's plant

Wistaria sinensis at The Larches, East Grinstead. Engraved for THE GARDEN from a photograph sent by Miss Brown

common use is as a wall plant on the houses around London. There are many noble specimens of it at Tooting and other pretty villages.

Dried fruit and vegetables.—A practical treatise on the drying of fruit and vegetables has just been published conjointly by M. Nanot, director of the National School of Horticulture at Versailles, and M. Tritschler, engineer of arts and manufactures. In the United States of America this branch of industry has become an important element of agricultural prosperity, and special apparatuses for the drying of fruit accompany the extension of the enormous orchards of the West. It will be at once seen how important is a work by competent writers which fully describes the stoves, the dryers, the peeling and paring machines, and the evaporators which ought to take the place of the antiquated methods of drying

following I put it in the full sun in the open air, protecting it from heavy rain and wind until the 16th of September, when it was removed to a cool house, placing it well up against the glass, where it could get all the sun available. In May, 1892, it began to bloom, and gave eighteen spikes bearing 172 flowers of exceptionally fine colour and substance. Would growing it in the shade give as good results, especially as regards brilliancy of colour?

I am glad my notice has called forth this statement. I saw the cut with an account of the plant in question in a contemporary last season, and I have been watching for a notice of it this year, but I have seen nothing; neither does the writer mention anything about it in the year 1893. During the year 1891 we had very little sun, but plenty of moisture, so that this plant had not much sunlight to put up with. I do not think such good results could be chronicled this season. I do not think

will continue to give a like amount of flower for many years, but I doubt its ability to pull through the present season in a like creditable manner.

WILLIAM HUGH GOWER.

Sobralia macrantha Princess May.—I have received a beautiful flower bearing the above name from Messrs. Pitcher and Manda, the United States Nursery, Hextable. The plant grows only about 1 foot or 15 inches high, the flowers being large and of good substance. The flowers resemble those of the variety *Kienastiana* in size and in being, like those of that form, of the purest white, saving the front lobe of the lip, which is suffused with a delicate and pleasing shade of heliotrope. It is an extremely delicate and desirable variety. —G.

Oncidium Lanceanum.—G. Simmonds sends me a flower of the above-named plant, with the erroneous name of *O. Lawrenceanum*. He says it

is from a plant that came to him last year from Surinam. Its leaves are getting very spotty, and he asks what he can do to prevent this. You have one of the grandest plants in the genus *Oncidium* and one of the most difficult to manage. I have grown it and have seen it doing well when well shaded from the sun's rays. It should be allowed to spread its roots wherever it likes upon a moist and stony bottom and be kept in a hot and very moist atmosphere. This is the best plan to prevent the spots which usually appear on its leaves if exposed to the sun. Yours is a very good coloured variety, with a rich dark purple lip, and the flower yields a delicious odour resembling vanilla.—W.

Cattleya Sanderiana, which I noted recently as being shown so finely by Baron Schröder at the Temple, and of which I also recently noted a fine variety sent me by Mr. Broome, of Llandudno, have both been eclipsed in richness of colour by a variety sent to me by Mr. Kerslake, gardener to the Rev. E. Handley, of Bath. It is of about the same size as the two referred to, the petals, however, being somewhat narrower than in Mr. Broome's fine flower. The colour of the sepals and petals is a deep, rich rosy purple, the side lobes of the lip of the same colour, and the large and finely developed front lobe of a very rich velvety crimson-magenta, with the two yellow eye-like spots at the side of the throat.—G.

Cattleya Schilleriana (*H. Parsons*).—A superb flower of this plant comes to me for my opinion, the sender saying he had always taken it for a strong-growing plant of *C. Aclandiae*, but from which it appears to differ. It does differ, and that considerably, for in *C. Aclandiae* the column is quite exposed, the side lobes of the lip being quite rudimentary; whilst in the flower sent these organs are very large and form quite a vaulted hood over the column. The flower, cut from a scape bearing five blooms, measures $4\frac{1}{2}$ inches across, sepals and petals of a bronzy purple, much spotted with purple of a deeper hue. It is a very fine form of this rather variable plant, but I cannot consider this as a natural hybrid between *C. Aclandiae* and *C. guttata*, as some do, and even if a hybrid, I do not think that the first-named plant is one of the parents. It flowers sometimes twice in one season.—G.

Houlletia odoratissima.—H. Parsons sends me a flower of this singular and beautiful species, which was introduced to cultivation by M. Linden, of Brussels, over forty years ago. The flowers are very fragrant, borne several together on an upright spike, the one before me being fully 3 inches across, the sepals broader than the petals, reddish brown. The curious lip is white and hastate in front. These plants have never been popular. They are easily managed, and some of them should find a place in every collection. They do well in either hanging baskets or pots well drained, using for soil good brown peat fibre or Sphagnum Moss. Water should be given freely when growing, much less being requisite in the winter. They may be grown in the *Odontoglossum* house, keeping them at the warmest end during the winter season.—G.

A giant Cattleya.—Mr. Holmes, gardener to Mr. G. Hardy, Pickering Lodge, Timperley, sends me a flower of *Cattleya Warszewiczii* Sanderiana, which is certainly the largest and most richly coloured that I have ever seen. It measures 10 inches across, the sepals and petals of a fine deep rosy purple, broad, the latter being prettily frilled at the edges; the large lip is 4 inches long and 3 inches broad, frilled at the margin, the colour an intense rich velvety crimson. At the side of the throat are two large eye-like blotches of a rich yellow.—G.

Cattleya Aclandiae in two varieties comes from Mr. Holmes, with whom the plant is a great favourite. In one form the sepals are broader than the petals, the former slightly waved at the edges, ground colour yellowish, with a tinge of green, tipped with bright chocolate, and profusely marked with spots and blotches; the middle lobe of the lip is bright rosy purple with deeper veins, side lobes very small, white; the other form is smaller, the colours paler. It is not a plant that seems to

be very amenable to cultivation, but I have had nice plants of it which were grown upon good-sized blocks of wood with but a very little soil about the roots. It requires a moist atmosphere and a high temperature, with a good deal of bright sunshine.—G.

Cattleya Warneri.—G. Wilson sends a grand flower of this for an opinion. It is a very fine variety, nearly as dark as some of those which I used to see about thirty years ago, and which one seldom sees now; the flower before me measures upwards of 8 inches across, broad, and of good substance, deep rosy purple in colour, the large lip deep rosy crimson in front, very much undulated and frilled, the base white, having a streak of orange in the throat, with numerous lines of white traversing it. It is a magnificent variety, first flowered by Mr. Robert Warner some thirty-three years ago.—W. H.

Limestone for Dendrobium Phalænopsis.—*Dendrobium Phalænopsis* apparently grows freely enough when potted in the same material as the majority of other *Dendrobies*, but at the same time it shows its extreme partiality for limestone, this being used both for drainage and mixed with the peat used for potting. By using the above material, the young growths from small pseudobulbs are remarkably strong and healthy, and the roots cling closely to the stone.—A. YOUNG.

Cattleya Mossiæ Hardyæ.—Flowers with this name also come from Mr. Holmes. He says he thinks it is quite distinct enough for a name. It is a chaste and beautiful variety. There are four flowers upon the scape, the sepals and petals being of the purest white; lip also white, the middle lobe of the lip beautifully crisped at the edge, has a ground of pure white, stained with orange in the throat and on the side lobes. It is a charming variety, even prettier than *C. Wagneri*, the first plant of which I exhibited at Regent's Park some years ago.—G.

Aerides Fieldingi.—For the general uses of the garden no species of *Aerides* has proved of so much value as this, commonly known as the Fox-brush Orchid. It is one of the most easily cultivated in the whole family, maintaining year after year a vigour of growth which, unfortunately, departs from a good many Orchids after two or three years' cultivation. Although I have frequently noticed a night temperature of 60° to 65° in winter recommended for this amongst other *Aerides*, my experience is that the *Cattleya* house is more suitable, choosing the warmest position. I believe Mr. Gower has in these pages recommended temperatures approximating those of the *Cattleya* house rather than those of the East Indian house, and from what I have seen I feel certain that as fine spikes will be produced with greener, sturdier foliage when this advice is followed. I have plants now in flower with spikes 2 feet in length. The flowers are $1\frac{1}{2}$ inches in depth and of a beautiful amethyst-purple, the lip and the rounded tips of the petals being considerably deeper in shade than the rest of the flower. The species comes near *A. multiflorum* (*A. Lobbi*) in botanical relationship, but is distinguished not only by its robust foliage, but also by the pointed apex of the labellum. *A. Fieldingi* is a native of the Sikkim Himalaya and Assam.—B.

Cypripedium spectabile.—It is interesting to see from the experience of Mr. Field that this beautiful plant can be grown with care in an ordinary garden, but anyone who has a piece of boggy ground may leave it to take care of itself. I have had it in the wild part of my garden for many years, and it comes up every season like a weed. It has never been finer than this year. I had nearly thirty blooms open at one time. It is useless, however, to attempt to cultivate it except under conditions similar to those under which it grows in a state of nature. My plants are in ground that is constantly wet, but I have noticed that the roots run about near the surface, and I should advise anyone planting it not to bury them too deeply. I have never seen it growing wild, but I fancy it grows on, rather than in boggy ground, that is, on the loose mossy surface of such places.

Some time ago we were clearing out some ditches in the winter, and my men threw the soil over where the *Cypripediums* were growing. They were not covered by more than 3 inches or 4 inches of soil, but none of those that were so covered ever came up again. Some of my plants are growing in the shade and others in the sun, but they are all protected against wind by trees. *Cypripedium pubescens* and *Cypripedium parviflorum* grow also in my wild garden, though not so vigorously as *C. spectabile*. They all increase very slowly, and I have never known any self-sown seedlings to appear. *Cypripedium acaule* I have tried again and again, but I have never succeeded in establishing it. I found it growing near Ottawa, in Canada, some years ago and brought a few plants home with me. They came up the next year and flowered, but they made no sign the year after. Perhaps the English summer is not warm enough to enable this form to ripen its bulbs for the next year's growth. If any of your readers have been more successful with this species, I should like to know how they have managed it. The European form—*Cypripedium Calceolus*—is not difficult to grow, but it requires different treatment. It is not a bog plant, but grows, I believe, in limestone districts.—F. W. HARMER, *Cringleford, Norwich*.

GARDEN FLORA.

PLATE 916.

RHODOCHITON VOLUBILE.

(WITH A COLOURED PLATE.*)

This interesting and attractive flowering climber is one of the many that are conspicuous by their absence in a great number of instances in our plant houses of to-day. Like others, it has had to give place in a measure to other and more showy plants. It is, however, none the less a most useful climbing plant for the cool greenhouse. Its position therein is almost indicated by the style of the growth as seen in the coloured plate. In any house, for instance, where it can be trained up the rafters, hanging therefrom over pathways, &c., it is seen to the very best advantage. There are other and likewise very useful plants of a similar habit, *Maurandya Barclayana* and *Lophospermum scandens* being cases in point. These are both better known in many gardens than the *Rhodochiton*. Each of them is, however, amenable to the same treatment, the last being the most vigorous grower of the three and at the same time the most free-flowering. Not being an enduring or lasting plant, it is needful for the sake of greater safety to strike a few cuttings every year. The best time to do this is towards the end of the summer, so as to have nice young plants to grow on the following spring. With good care such plants as these will go through the first winter afterwards with hardly an exception; after that, however, the young plants will be much the safer. The cuttings should be taken with a heel, being about 4 inches in length; these will strike best in nearly all sand under bell-glasses in a cool pit or frame, striking singly in $2\frac{1}{2}$ -inch pots being the best way to proceed. In after-potting I would advise the use of a little peat as well as leaf-mould and good loam, about one-third of each. After-pottings should be attended to before the plants are pot-bound so as to starve or weaken them, but anything beyond a 10-inch

* Drawn for THE GARDEN in the gardens at Burford Lodge by Gertrude Hamilton, September 23, 1892. Lithographed and printed by Guillaume Severeys.

pot will be rarely needed. Another mode of culture is to turn the young plants out into boxes, but planting out as it is generally understood is not to be recommended in this instance.

This Rhodochiton is a Mexican introduction of more than half a century back. It should further be added that where the seed ripens another good and easy mode of increase is afforded with a correspondingly vigorous growth. At Burford Lodge, Dorking, where the drawing was made, cuttings of this climber are taken in the autumn, and when rooted, kept in the greenhouse during the winter. They are potted on in the spring and planted out at the same time as the other summer occupants of the flower garden. It also seeds freely at Burford Lodge. The late Rev. Harpur Crewe used to have it grow and flower freely outdoors in his garden at Drayton-Beauchamp Rectory, Tring. G. H.

FLOWER GARDEN.

TRANSPLANTING LILIES.

EVERYONE who has a garden is obliged from time to time to transplant his flowers for various reasons, and it becomes, therefore, a matter of great importance to find out the best time for doing so. With imported plants this is one of our difficulties. Many years ago I sent for a large number of Hellebores from Holland; at the time I was very imperfectly acquainted with their peculiarities, and I lost them all. The gardener, knowing the hardness of the Christmas Rose, said, "Any place will do for these," and they were put where I wanted to have them in various corners, and soon withered off and died. If I were to try the same experiment now, probably I should not lose one, but this is a hard experience to gain.

I have had an interesting letter from M. van Tubergen, in answer to one from me about moving Lilies. I had said that I did not find the varieties of Martagon and some other Turk's-cap Lilies difficult to move. He replies, "I cannot help saying, but I do not agree with you about the moving of Lilies; not one variety bears it well, except umbellatum; almost all of them suffer much by lifting and planting." Now M. van Tubergen must be taken as a good authority, and yet practically I have proved that Lilies will bear transplanting in the very height of their growth. This season when the rain came after the first great drought, I took the opportunity to move *L. chalconicum*, *pyrenaicum*, and *Thunbergianum* Prince of Orange. They have all moved perfectly well, and if I live to see it, they will no doubt flower much better next season than if I had left them alone. The Prince of Orange flowered well after transplanting. I moved the *chalconicum* because it was not doing well where it was; *pyrenaicum* had just finished flowering. I am inclined to think that they move best just at the flowering season. I should not have ventured to move the above-named Lilies had I not tried the experiment before. I was visiting near London either at the end of May or beginning of June about three years ago and I was offered some *L. chalconicum*. The thought in my mind was they would surely die from the rough treatment; but, instead of that, they have grown and flourished, and a fine clump of this very beautiful Lily will this year give me abundance of bloom. The secret seems to be semi-shade

and abundance of water, and the Lilies will go on apparently almost indifferent to their change of quarters; but if their new situation agrees with them, they will rapidly improve and be finer and better next summer than if they had been left alone. *L. pardalinum* does appear to be very obstinate. I had some fine roots sent to me in 1890, and they do not seem to have recovered the shift yet. They did not bloom at all the first year, and they are only flowering scantily now. With more attention they would, no doubt, have done better. The season has been dead against *pardalinum*, but still it is evident that it resents any removal even when carefully performed. *Auratum* does well after removal, and so, of course, does *candidum*. With regard to this last Lily, I made a mistake in transplanting and culture which nearly caused the loss of a splendid bed of it. Seeing the roots pushed out of the ground, I took the bulbs up and replanted rather deeply and in rich ground. The next year was almost a complete failure, and this year the bed is only convalescent. I shall never cover deeply the roots of *candidum* again, but when they require it put some earth around them. I have watched the mode of culture in cottage gardens, where these Lilies generally grow better than in large gardens. The rule, where they do best, is to let them alone, except according to the rough, but successful, plan adopted by cottagers with regard to their perennials, when they put in autumn some manure around the roots.

I moved the common Christmas Rose (*H. niger*) this year about the middle of March—just in the driest time. It was not looking well when I moved it, but since that it has begun to throw up strong growth. Of course, in that case the exposure after taking up was very short, and I resorted to careful shading and watering. I did this chiefly for an experiment in transplantation. I know one grower of Hellebores who frequently moves his plants. I have no doubt that, on the whole, Christmas Roses do best when let alone, but they want good ground. They are prospering in a wild condition under the trees at Kew.

A GLOUCESTERSHIRE PARSON.

DWARF LILIES.

AMONG the earlier flowering Lilies are some of the dwarfiest of the entire genus, for some varieties of *L. elegans* or *Thunbergianum* are at the most little more than 6 inches high, yet they bloom with the greatest freedom. In no other Lily is there such a great amount of variation to be found as in the different varieties of *L. elegans*, for they vary not only in shape and colour of the flowers, but also in height and season of blooming. The nomenclature of most of these forms is in a very confused state, for varietal names are often given to individual fancy, and the result is very confusing. This practice seems to be on the increase, not only with Lilies, but in all classes of plants, and quite recently in *THE GARDEN* (p. 477) a protest was entered against the same principle being applied to Orchids. One of the dwarfiest and earliest of these forms of *Lilium elegans* is Prince of Orange, the flowers of which are of a bright yellow. A second variety—*alutaceum*, in which the flowers are more of a buff tint, is often seen mixed with Prince of Orange, though the two are perfectly distinct, as, apart from colour, the leaves of *L. alutaceum* are much shorter than those of the other, while the petals are less pointed. While noticing the difference between these two, it may on the other hand be pointed out that the varieties *alutaceum*, *aureum*, and *aureum nigro-maculatum*, are practically one and the same thing. A very pretty flower of a yellow colour, splashed more or less with crimson, is also known by the varietal

names of *bicolor* and *pictum*. Rather taller than either of the above is an early-flowered form with large, but somewhat irregularly disposed petals of a brownish red hue. This can be obtained from different dealers under the names of *latcritium*, *biligulatum*, and *aurantiacum multiflorum*. Again, in purchasing such varieties as *fulgens*, *sanguineum*, and *atro-sanguineum*, it will be found that the different dealers are by no means of one accord in their ideas of these varieties. *L. elegans* in variety is sent here from Japan during the winter months, and very superior forms they are as a rule, and quite distinct from the varieties cultivated by the Dutch. One that generally crops up in considerable numbers among these imported bulbs I take to be the variety *brevifolium*, the leaves being unusually short, thick, and of a very deep green, while the flowers are of a peculiar shade of light red. This grows about 18 inches high. A second variety from Japan is a bold grower, and in the bud state it is very noticeable by reason of a woolly substance around the unopened buds. The flowers are yellow, heavily spotted with crimson. This has at different times borne the names of *splendens*, *guttatum*, and *robustum*. Under this last name it was awarded a first-class certificate eleven years ago by the Royal Horticultural Society. H. P.

FLOWER GARDEN NOTES.

IN a gardening experience extending over thirty years I never remember such a trying time for bedding stuff, and doubtless many whose memory carries them back longer than this would have to make the same remark. Heavy and persistent watering is the only thing possible to encourage growth, and in many flower gardens this is hardly possible. At Cowdray, where tuberous Begonias enter largely into flower garden arrangements, Mr. Geeson has adopted the only method possible to secure rapid growth, viz., a surface mulching of cocoa fibre, a heavy watering, and then a slight shading with breadths of tiffany until the plants get established. Begonias will evidently be strongly to the fore in bedding arrangements for the current season, and it is gratifying to find the idea gaining ground of either planting thinly on a dwarf carpet or mixing with a nicely contrasting plant that is slightly dwarfer than the Begonia. *Koniga variegata* or *Geranium Manglesi* associates admirably with crimson Begonias, besides allowing space for the latter to develop into symmetrical plants. The efforts of the best growers, both nurserymen and private gardeners, to establish a more erect flowering race are bearing good fruit. Such a race will be infinitely more attractive and useful for outdoor purposes than the large flowering drooping section. True, we shall have, I imagine, to sacrifice size to a great extent, as flowers 5 inches and 6 inches across are hardly likely to be induced to assume and retain an erect position, but then, to slightly alter an idea already more than once broached in these columns, "the general beauty of a bed does not depend on the size of individual flowers." The shading of Begonias above mentioned is not only a help to quick establishment and growth, but also in weather like the present highly beneficial to the foliage, which if not thoroughly well hardened, is liable to blister and burn under a scorching sun. Some varieties seem much more susceptible than others to the sun's influence in the early season.

MIXED BEDS.—With the laudable desire to initiate a more free and natural style in the bedding operations, mixed beds are often to be found on rather an extensive scale in lieu of carpet beds; but, although one can appreciate the motive, it is difficult always to praise the execution. Whether it is that mixed beds are often the last to be done, and so get all the odds and ends left from others, I do not know, but certainly the result is often by no means pleasing. No greater mistake can be made than to huddle together indiscriminately zonal Pelargoniums, Fuchsias, Marguerites, Be-

gonias, Iresine, Coleus, such annuals as Stocks, Zinnias and Asters and even small shrubs and conifers. Such an assortment may seem impossible for one bed and an exaggerated statement, but it is not the case. I have counted all these different things, and planted, too, very thickly—from 6 inches to 9 inches apart. I suggested the bed would be a regular thicket so soon as the different things were well on the move, and was told they would be thinned out. I doubt very much if any bed could be satisfactorily worked in such a manner; the judicious blending of colours, so important in these beds, would be well-nigh impossible.

The advantage of a deep, fairly holding soil over one that is dry and shallow in a season like the present for herbaceous plants was early apparent, and each succeeding rainless week enforces the advantage. So far as Violas are concerned, for instance, it is impossible on our sandy soil to do justice to the plants or produce flowers in anything like the condition shown by Messrs. Dobbie, from Scotland, at the Temple. I was hoping to note a few special characteristics, both of habit and colour, of sundry new varieties on trial, but must reserve any such notes for another season. There is not likely to be the slightest chance this year of giving an accurate description, and, indeed, the remark is applicable to all new outdoor flowers. No fair estimate can be made of their worth unless they are specially favoured in point of soil and facilities for watering. The best thing just at present in the herbaceous borders (Countess of Paris Carnation—grand this year—excepted) is *Lilium candidum*, and it is a treat to see this old favourite throwing some of its good old-fashioned spikes. I write "old-fashioned" because it is a remembrance of the pre-disease era to find single spikes with a dozen and more good flowers. Very good also just at present are *Erigeron aurantiacus* and *E. speciosus*, the latter in the distance hardly distinguishable from an early Starwort. Both are capital subjects for cutting and stand well in water. To those readers who require large quantities of white flowers, I should like to recommend The Pearl variety of *Achillea ptarmica* fl. pl. For cutting in quantity this is specially valuable, and really beautiful wreaths and crosses can be made with a groundwork of this double white Yarrow, interspersed with Mrs. Sankey Sweet Pea or the white Everlasting Pea (*Lathyrus albus*), an occasional bloom of *Lilium candidum* and spikes of Princess Alice Stock. How acceptable, too, are all these flowers in making up baskets or nosegays for the yearly children's flower service. If the dry weather continue, it will be well to mulch and water any special beds where rapid growth is required. Beds of scented plants, for instance, comprising besides the lemon-scented Verbena and Eucalyptus all the best of the finely cut leaved Pelargoniums, furnish such a lot of cut foliage for the flower basket through the summer months that we are glad to get a profusion of growth as soon as possible. *Aloysia citriodora* is very subject to red spider when growth is at a standstill, and an occasional dose of insecticide or a heavy syringing with water, with which a handful of sulphur has been mixed, is highly beneficial.

Claremont.

E. BURRELL.

Lathyrus grandiflorus.—This is really a splendid Pea and of a most enduring character. All the perennial Peas seem able to adapt themselves to a variety of situations, but this species is, I think, the most accommodating of them all. I have met with it under a variety of conditions, and it always was showy and free flowering. Although not so popular as *L. latifolius* and its variety, it deserves to be most extensively grown, and no trailing plant of the early summer months surpasses it in brilliancy. I was especially charmed with it recently growing up the front wall of a cottage beside the road in a country village. It was quite 8 feet high and profuse in bloom from base to summit. Another plant blooming finely at the present time has its roots in nothing better than the garden walk. Amongst shrubs it will

hold its own vigorously. Its flowers are double the size of those of any other perennial Pea and bright in colour. Usually the spikes are two-flowered, but I have had it in a border of good loam with four and five flowers upon a spike. Care should be taken not to introduce it among choice things. For a temporary summer screen, nothing could be finer, and a line of some length would make a truly gorgeous effect. It goes on blooming for some weeks and does not exhaust itself in producing seed; sometimes a few pods swell, but generally none at all. It is easily increased, however, by the roots, which are very numerous, and the smallest piece appears to grow away on its own account if encouraged at the start.—A. H.

ANEMONE SULPHUREA.

This seems to abhor limestone of any description. Imported plants seldom become established under two years (these should be got in the spring). The sum and substance of its culture seem to me to be that autumn and winter transplanting are in most cases the cause

Anemone sulphurea.

of failure. Seed is the best method of raising a stock. It should be sown in November in the open ground in a partially moist, peaty situation, and the seedlings be allowed to remain for two years. Then, when growth commences in the spring, transplant to permanent quarters. It takes about the same time as a Christmas Rose to get from a small plant to a good specimen. Full exposure, ample drainage, and moisture in summer are its requirements.

MAURICE PRICHARD.

Christchurch.

The white Lily (*L. candidum*) is again unsatisfactory this year; at least, we have seen very few thriving masses. At Kew, where Lilies do so well and are planted in a picturesque way, *L. candidum* is far from presentable, and it is not easy to overcome this malady, that afflicts one of the most beautiful plants of early summer. Large groups are planted at Kew amongst shrubs and also in the open, but in both cases the growth is sickly and most disappointing. Perhaps some readers of THE GARDEN have had success with it, and we remember a few years ago seeing a splendid break of the flower in Bath. The gar-

den was near the railway station, and a hot, moderately dry, sloping bank was set apart for this Lily. The bulbs succeeded remarkably well, sending up vigorous stems crowded with splendid flowers. In wet and dry seasons *L. candidum* behaves alike, but its fine aspect in many cottage gardens seems to point to the fact that the bulbs are better in the open fully exposed and not disturbed.

NOTES ON SWEET PEAS.

THE familiar Sweet Pea has been much improved of recent years in the colour of the flowers, and the range of hue extended considerably. These notes are prompted by a collection in full bloom in the Chiswick gardens, and it is of interest, a number of kinds having been received from Mr. Eckford, Mr. Laxton, and Messrs. Barr and Son. We are concerned chiefly with the varieties of Mr. Eckford, who has done much towards getting new shades of colour in the flower, and the many rows, side by side, each variety kept quite distinct, give ample opportunity for comparison.

We notice that the several varieties are very true to name. A few "rogues" occur, but nothing worth speaking of, thinning out these leaving more room for the better development of the desired type. The plants, through the severe drought, are dwarfer than would otherwise be the case, but they are blooming freely. Such a collection is not often seen, as one can tell at once the more effective kinds for colour. The rows of mixed varieties are charming, but brilliance and boldness of colouring are derived from the rows of distinct forms, the carmines, pinks, and other shades showing to advantage. This suggests that in large gardens the Sweet Peas should be kept in some measure distinct, not mixed freely, as is the custom, the bold massing of decided colours being rich and telling. This system need not be carried out to an undue extent, but a line of a brightly-coloured variety, as *Ignea*, would make a decided change and keep in beauty over a long season. One could gather freely from such without destroying its beauty, although flowers for cutting should be grown in a reserve garden, and then those for effect are not interfered with.

There are many lovely things amongst Mr. Eckford's seedlings, and also a few that are certainly no advance nor justify their name. Princess of Wales is a type that we do not care in the least for, the flowers striped with a mauve-purple kind of colour, most objectionable, ineffective, and dead. Such varieties as these should not be grown when there are so many very beautiful forms already. A few kinds also approach closely to one another in colour, too closely to warrant their cultivation together. Princess of Wales and Senator have much in common, and in noting the various varieties we shall allude to those that appear synonymous, or at least practically so. Mauve or purple shades must always be used with extreme caution, and Mr. Eckford will do well not to get too many of this tone or of the striped varieties. Such a variety as Primrose scarcely justifies its name. The flowers are certainly not true primrose, but a cold creamy yellow, distinct, it is true, and the possible forerunner of a good primrose-coloured Sweet Pea. Such

a kind would be of great beauty and of value for cutting as well as in the garden. It is far from our wish to condemn such an acquisition, but it is scarcely good enough to name. We value it as a herald of better things. The varieties in this interesting collection at Chiswick range through many shades of colour. A gem is that named Mrs. Gladstone, the flowers of a pink shade, deeper in the upper than the lower petals. It should be grown freely for cutting, and might be used in many choice arrangements. Apple Blossom is another beautiful flower, large, and very free. Her Majesty has a large flower, and the colour is brilliant carmine-rose. It shows up distinctly, and would be valuable for cutting; Dorothy Tennant, violet-purple, and Countess of Radnor, a charming pale lilac shade, are of note. The colours of Sweet Peas are not very easy to define, the subtle shades of purple, maroon, and crimson melting one into another, but we give as near as possible the tint. It seems that we may in time get a blue Sweet Pea. It has not been raised yet, but several flowers are of this shade of colour; Captain of the Blues and Imperial Blue are too much alike to be grown in the same place, the flowers of the latter being the lighter of the two. The colour is purplish blue and the flowers large. Empress of India is similar to Apple Blossom, but White Queen is a desirable kind, the bloom large and rose-white in colour, a free, pretty variety. Amongst the brightest in the collection is Ignea, the flowers rich crimson, paler in the lower part; it is very effective and distinct. Valuable for its tender colour is Mrs. Sankey, the flowers of which are white just tinted with pink—a good kind to grow in the reserve bed for cutting. Very effective is the variety Boreatton, the flowers of deep colour, a crimson-purple shade, almost black. Such intense tones stand out conspicuously from other types. One of the brightest flowers is Cardinal, scarlet; whilst Splendour, also of a carmine shade; Princess Victoria, rose-carmine; Maroon, deep maroon, intense shade; Jennie Lea, rose; and Delight, white, are noteworthy. Mrs. Eckford is creamy white. We do not care for this colour, it is neither one thing nor the other. The Bride, white, and Isa Eckford, delicate pink, are two good kinds. A fine contrast of colour is got in Monarch, the upper part of the flower crimson, the lower violet-blue.

Mr. Eckford is doing good work amongst the Sweet Peas, but care is necessary not to give names to flowers that are not quite distinct from those already in cultivation, nor to praise the dingy striped kinds. There is a lamentable desire to get striped things now-a-days, and if the colour is a dull heavy maroon or purple, so much the better. But this is not correct; such things spoil an otherwise beautiful series of flowers.

Delphiniums from seed.—A few distinct kinds under name are all very well, but if a good strain of seed is not procurable, it is a good plan to grow a few of the best of the named kinds and save your own seed. The seeds should be sown thinly in the open air, and the year afterwards the seedlings transplanted where they are to flower. I grow hundreds about the pleasure grounds in the shrubbery borders, the towering spikes being now extremely handsome. Under good treatment it is remarkable the height the stems will rise to. On light soils the height of the stems during this season of drought is much dwarfer than usual, but on our heavy soil they are all that can be desired in this respect.—A. YOUNG.

A note on Foxgloves.—The homely Foxglove is not made half sufficient use of in English gardens. There are many beautiful varieties with

large flowers, finely spotted, and those pure white, with intense crimson, purple, or other coloured spots, are remarkably handsome. The name *Gloxinkedora* given to some strains is in allusion to the *Gloxinia*-like character of the flowers, their bold shape and charming series of colours, the spotted kinds being especially worthy of note. This paragraph was suggested by a large break of varied coloured kinds amongst shrubs, a perfect forest of spikes rising from the undergrowth, so to say, and presenting a splendid effect either close to or in the distance. Many positions in the shrubbery, border, and woodland might be brightened with this tall and graceful flower. It looks well on the higher tiers of the rockery, especially if the surroundings are of shrubs, the dark leafage of these throwing into bold relief the colours of the Foxglove. Few things are more easily grown, and it is not difficult to get a thoroughly varied and attractive type of plant. Those with pure white flowers relieved with deep-coloured spots are the more appropriate.

Anthemine tinctoria.—A perennial hardy and free enough to grow anywhere and with flowers like the yellow Marguerite Daisy should be a valuable thing in every garden, and a boon to gardeners that have to provide large quantities of flowers for cutting. Such is the above plant, and the reason for its comparative scarcity, I do not know. It remains in beauty for many weeks, and one may go to it again and again to cut flowers by the armful and still leave abundance to make the garden gay. It is very hardy even on a cold clay soil, has a tufted habit, and bears several flowers on a stem varying from 1½ feet to 2 feet in height.

Nemesia strumosa.—I was not much struck with the appearance of the above new annual at the recent Temple show. As exhibited, in pots, it shows none of the continuous blooming character that was promised. Possibly this character might show itself in plants grown in the open ground and in rich soil; but, judging from the habit of the plant as shown, I should rather depend on successional sowings for successional bloom than trust to its production from one set of plants. Again, there was but little promise of the range of colour in the blooms that one had been led to expect. The limited number of plants exhibited may be answerable for this, though there were several plants in which shades of orange prevailed. Altogether, I thought the exhibit disappointing, though this is not an unusual experience with new plants, when seen for the first time, after much has been read of their wonderful merits. It seems a pity that a greater range of colour was not shown at such a show.—J. C. TALLACK.

Heuchera sanguinea.—Will someone who has succeeded in flowering *Heuchera sanguinea* kindly inform me of his treatment of this pretty plant? I have tried every means of inducing it to bloom, but without success. I have it on rock-work, in the garden beds, in pots, small and large, but all to no purpose. It certainly must require some particular treatment or some special soil to induce it to flower. I recollect seeing it at Kew in the small greenhouse, some three or four years ago, flowering beautifully in rather small pots, and thought it a lovely plant.—W. R. B.

"Margaret" Carnations.—Would it not be wise to fix the name by which this useful class of Carnations shall be known? Up to now there seems to be some doubt about the matter, for we find them written of as Margarets, Margarita, Marguerites, as well as with other variations. When the Messrs. Veitch first introduced seed of this valuable strain, they gave it the name as written at the heading of this, and, personally, I think it the best because it is the simplest of all that have been given and there is no danger, in speaking of them by this name alone, of confounding them with the plants so long known as Marguerites. Though only of recent introduction, these fringed Carnations have long been grown in France, where they are valued very much for their free-flowering properties. Unless they are wanted absolutely true

to colour, they are best raised from seed, as their free-flowering character is all against their welfare when struck from cuttings, for only in rare cases do they make anything but flowering growth when grown from cuttings. This spring I had 500 cuttings sent from Monte Carlo in five different colours or shades, viz., white, yellow, red, pink and deep pink. All but the last struck very freely and have been planted out for some weeks, but most of them make but little grass, nearly all the growth made being flowering stems, and no amount of pinching will induce them to make any other kind of growth. I hear that this class of Carnations is grown very largely in the neighbourhood of Monte Carlo, and they succeed well as early spring-flowering plants under the sunnier skies and more genial climate met with there. Judging from their habit, it seems probable that they are grown from seed saved from flowers of selected colours, and that they come fairly true. Here it is impossible to grow them for spring flowering, except under glass, so that it is more than ever necessary to be careful in saving seed which will produce a large percentage of double flowers.—J. C. TALLACK.

Garden Pinks.—Most beautiful as well as sweetly perfumed was a big handful of the new Pink Ernest Ladham, which I brought away with me from Shirley the other day. I found it growing there in great abundance and blooming profusely. It has large solid blooms, white shaded rose, with dark maroon blotch in the centre, and seems to be one of the most beautiful of garden varieties. It is now possible, with the old white, Mrs. Sinkins, Her Majesty, Mrs. Welch, the old Paddington red, Anne Boleyn, Ernest Ladham, Lettie Dean, and other good forms, to have in gardens a really good collection, and to these hardy sorts may be added some of the best of the laced varieties, although just two or three of these suffice for ordinary culture. Now is the time to propagate Pinks by cuttings, and once a good stock is obtained, all other culture is easy enough.—A. D.

THE WEEK'S WORK.

THE KITCHEN GARDEN.

BROCCOLI.—The planting of Broccoli should now take place as the seedlings become ready. It is often advised that Broccoli should be planted on undug ground, but all soils are not adapted for this plan of planting. When the ground is rich, planting on undug soil may be practised, as the growth made will then be sturdy, and so able to withstand severe frosts. On the other hand, when the growth of the Brassica is not generally satisfactory, then the plot should be dug and manured if necessary. What must be avoided is planting on loose and over-manured soils. Where possible give Broccoli a well-exposed plot, setting out the plants 30 inches apart each way. If club is troublesome, do not neglect to dip the roots in a puddle formed of soil, soot and lime, also freely dusting the surface over with lime.

SELF-PROTECTING BROCCOLI.—This being one of the most useful of autumn and early winter choice vegetables, a large breadth of it should be planted. If the weather keeps good, heads may be cut from the open until far on in November, but if weather of an inclement nature should set in, then the whole of the plants may be lifted and bedded in in cold pits or any other available place, even to a sheltered border if protection could be afforded afterwards. My practice is to plant out after second early Peas, all that is necessary being to clear off all rubbish, levelling and chopping over the surface with a heavy hoe.

LEEKs.—Where this useful winter vegetable is in demand and the plants are strong enough, planting should now take place. The soil for Leeks must be both deep and rich, for, as the roots will be inserted deeply, manure just applied to the surface is useless. If a quantity is grown and the soil is in good heart the plants must be set

out in rows 15 inches apart and 9 inches in the rows. As the plants become established liquid manure may be freely applied. Planting in trenches should be adopted where the soil is poor and there is but little depth. In this case take out the trenches a foot or 15 inches in depth and the same in width. In these place some good manure, filling up with the best of the surface soil. Insert the plants deeply, and as they become established and are growing freely they may be further encouraged by the application of liquid manure. That made from cow manure and soot is the best. Being planted in the trenches, the soil should be levelled down as the Leeks become strong enough.

LATE PEAS.—Whatever effect the present weather may have upon the growth of Peas, as late a supply as possible should be provided for by sowing at the present time one or more varieties, such as Ne Plus Ultra, Sturdy, or any other approved variety; even the dwarf earlies, such as William Hurst, Chelsea Gem, or English Wonder, will answer. Being dwarf growers, these are easily protected from birds and early frosts. The soil must be both well worked and fertile, and if this should not be the case, then fork in a good dressing of manure and burned refuse. The rows for these should be drawn about 2 feet apart, and if dry at the time, the drills must be well soaked with water, this ensuring a quicker, and consequently stronger germination. For the taller growers the rows must be more isolated and also well exposed or mildew will attack them. Trenches should also be prepared, especially on light soils, as if the weather should prove dry, a soaking of water occasionally will be needed after the Peas have started well into growth. A. YOUNG.

FRUIT HOUSES.

RIPE AND RIPENING GRAPES.—In many instances colouring has been very rapid, too much so, in fact, for it to be perfect, but the Grapes were not so ripe as they appeared to be, another fortnight or longer exposure to a good circulation of warm dry air being needed to bring out a full rich flavour. Unless extra well coloured, Black Hamburgh bunches are liable to lose much of the blackness there may be about them, and if the foliage is thin, it is advisable to either shade the roof or cover some of the best bunches with squares of kitchen paper. A good covering of healthy old leaves is the best aid to colouring and a preservative of colour afterwards. Nor ought white Grapes to be unduly exposed to the full light and sunshine, or disfigurement is very likely to take place. Fire-heat is still needed in the case of Muscats, a circulation of warm dry air being needed both to swell the berries to their full size and to ripen them properly. The berries of Madresfield Court, and in a lesser degree Foster's Seedling, are liable to crack badly in dull wet weather, and nothing but plenty of air will quite prevent this. From the time colouring has well commenced till the bunches are cut the house ought never to be quite closed. If it is necessary to draw up top sashes when it rains, these ought not to be wholly closed, wooden caps being fixed over the openings at a distance of 10 inches from the coping, these keeping out the rain and not wholly hindering an escape of warm air, the requisite amount of fresh air being admitted through the front lights. If air can be admitted at the ends, a few squares of glass being taken out and half-inch mesh galvanised wire substituted, this will be found a very effectual preventive of cracking to some distance across the house. There should be no withholding of water at the roots, as that is no preventive of cracking, and may even be the indirect means of causing it directly water is applied. In dull showery weather fire-heat should be kept constantly turned on, this being needed to assist in the maintenance of a good circulation of dry air.

LATE GRAPES.—Lady Downe's is now sufficiently forward in most vineries to be liable to scald badly, and in some instances bunches have already been disfigured from this cause. Early and careful ventilation is the best preventive, a sudden

rise in the temperature while yet the berries are very cold and the air not changed being the primary cause of scalding. Keep the hot-water pipes just warm, very slightly open the top-lights late in the evening, and give air freely before the sunshine is very strong. None of the bunches ought to be exposed to direct sunshine, but all ought to be lightly shaded by their own first formed leaves. Sub-laterals should be early pinched back to the first leaf, allowing them to grow strongly and then cutting them back wholesale being sometimes attended by loss of berries by scalding, and is a faulty practice in any case. Gros Maroc is also liable to scalding, and occasionally a few berries of Muscat of Alexandria are lost from similar causes. The sun striking direct on bunches in the morning at the east end of a house, and again on those at the west end of a house in the afternoon, is liable to cause scalding, and nothing short of thinly shading the glass with lime water or whiting will prevent it. Now that the berries have attained a good size, it will perhaps be better realised in some cases that the crops are heavier than the Vines are capable of properly supporting, and it is not yet too late to reduce the number to reasonable limits. It should also be borne in mind that very solid bunches of late Grapes are by far the most difficult to keep, those most freely thinned usually hanging much the longest. Before it is too late, the bunches should be again gone over, and a few more berries be very carefully taken out wherever they promise to eventually press tightly against each other. The smallest, or those with the fewest stones ought to be cut out first as much as possible, and if the bunches of Lady Downe's, Alicante and Gros Colman do present a somewhat loose appearance when fully ripe, this will very probably be an advantage in the end.

PEACHES AND NECTARINES.—When the fruit is cleared from the trees in the earliest house they must still be well attended to, or next season may see a partial failure. After syringing ceases, this being when the fruit is on the point of ripening, the borders, previously constantly being moistened and, it may be, trampled on frequently, commence drying, cracking very probably following in due course. Lightly loosening the surface with a fork and mulching with straw manure is a good preventive of this, and if not carried out prior to the crops being gathered should be done immediately after, the mulching in this case following upon a thorough good soaking of water, or, better still, liquid manure. Newly-moved trees will continue growing after the crops are gathered, and this growth should be fostered by means of morning and evening overhead syringing. Older trees should have much of the wood that has just produced fruit cut out, and if there is any red spider on them, instead of daily syringing the trees and thereby keep them growing later than desirable, the better plan is to thoroughly coat both surfaces of the leaves with flower of sulphur. Squeeze a double handful through a canvas bag into a three-gallon can of water, and well syringe the trees with this mixture. If the first application does not suffice, repeat the dose. The house should be set widely open and the borders never become very dry. See that the borders supporting the successional trees are in a thoroughly moist state when the fruit commences ripening, allowing them to become dry and then applying water having the effect of forcing many fruits from the trees, and none are so large as they would otherwise have been. Every morning all fruits that are ripe enough to gather without actually dragging them from the trees ought to be collected and stored in a cool, dry room ready for packing or home consumption, the quality and keeping properties being improved by this timely attention. Let ripening fruit have plenty of air.

REWARDING PEACHES AND NECTARINES.—There is every likelihood of Peaches and Nectarines being somewhat scarce in the autumn. Instead of the open-air crops being late or affording a succession to any grown under glass, these promise to be a month or so earlier than usual. The heat reflected from or radiated by the walls is largely re-

sponsible for this, progress in the open being more rapid than in unheated houses, and if the latter are kept cool the latest supplies may be had from these. Ventilate freely in the daytime, close about 4 p.m., at the same time giving the trees a thorough syringing, partially re-opening the top ventilators in the evening. In some instances it would be a good plan to lightly shade the roof, especially over trees on which the crops are ripening faster than desirable. Deferring tying down or laying in the young wood also has the effect of keeping the walls and the fruit on front trellises cooler than they would be if more exposed to sunshine. Allowing the borders to become dry is a mistake at any time, and never more so than when those in charge are desirous of retarding ripening.

PRACTICAL.

ORCHIDS.

THE most beautiful Orchids now in flower in the Cattleya house are the varieties of *C. Warscewiczii*, or, as it is better known in cultivation, *C. gigas*. Sander's variety is much superior to *C. gigas* in richness of colour, and yet another quite distinct form was exhibited at the Drill Hall, Westminster, recently under the name of *Sandera*. It is said that this *Cattleya* grows chiefly upon trees, in the full sun sometimes, and that plants grown in the shade produce long, drawn pseudo-bulbs, which do not flower. This is just what might be expected, and bears out what I wrote about the growths of *Cattleyas* last week. It is certain that if we are to have free-blooming plants of *C. gigas*, *C. Sandariana*, *C. imperialis*, &c., the plants must be kept well up to the roof-glass and in a position where the light can get at them. I have in previous numbers alluded to the treatment required for these and hybrid varieties of them and *C. Dowiana*. One thing noticeable this year is the very early flowering of the *C. gigas* type and also *C. Gaskelliana*. The season is something like three weeks earlier, and the cultural directions must also be pushed forward. Instead of being in the first week of July, we are really in the third week of that month, and must go to work as if we were. All the *C. gigas* types of *Cattleya* may be repotted as they pass out of bloom, for roots are freely produced soon after that time from the base of the last formed pseudo-bulbs. Amateurs have an idea that to get such shy-flowering Orchids to bloom well, they must be starved into it. This is a grave error and utterly opposed to the physiology of plant life. Let the plants have the best fibrous peat and Sphagnum, intermixed with clean potsherds, to grow into. Encourage growth by a fair allowance of water and moisture in the atmosphere and give the plants plenty of light and warmth. When growth is complete the ripening period begins. Then is the time to keep the plants dry at the roots. Very dry they must be to prevent growth, but the roots must not be allowed to perish from over-dryness. I do not like to see the pseudo-bulbs shrivel much, but if the roots are kept in a healthy state, the bulbs will soon plump up again when the time comes to water freely.

During the next three months the houses will not be so well furnished with Orchid blooms as they have been, but many interesting and beautiful things will be found in all good collections. *Disa grandiflora* will be conspicuous in collections where it is well grown. It may be classed as a greenhouse Orchid really, but the main point in its culture is the condition of the atmosphere. This ought to be very moist, and the plants must be placed where they get sufficient air without being in a draught. They will sometimes succeed admirably in the coolest and best ventilated part of the *Odontoglossum* house. The garden variety *Disa Veitchii*, raised in the nursery of Messrs. Veitch and Son, by crossing *D. grandiflora* with *D. racemosa* is also very handsome and quite free in growth. Messrs. Backhouse, of York, have obtained the same cross. *Mormodes luxatum eburneum* and the spotted variety *punctatum* should now be in bloom, and they finish up their growth at this season of the year; but until the

flowering period is over and growth completed, they will require a good supply of water. *M. pardinum* is a distinct and curious variety requiring the same treatment. There is a variety grown under the name of unicolor. These plants require careful treatment when growing, for if water lodges in the centre of the growths the plants may be killed. The leaves will decay as the plants pass into the resting period, and at that time no more water than will prevent the bulbs shrivelling must be given. Some of the *Zygopetalums* will soon be showing their flower-spikes, their distinct growth and colours forming an interesting feature. *Z. maxillare* is a distinct and handsome species; it has frequently been imported since Gardner found it on the Organ Mountains in 1837, and always, as it was found by Gardner, growing on the stems of Tree Ferns. I observed a large batch of it in the nursery of Messrs. Sander at St. Albans some time ago, and in each case the growth of the Orchid had been equal to that of the Tree Fern. The plants are best grown on the stems, whether the Fern is alive or dead. There are now very beautiful garden hybrids of these *Zygopetalums*, the best known being *Z. Sedeni* and *Z. Clayi*, much resembling each other. They succeed in the usual peat and Sphagnum compost. *Z. rostratum*, which also flowers at this season, requires a rather higher temperature when making its growth.

Owing to the very high temperature, we have dispensed with artificial heat, but not for long do the very hot nights as well as days continue, and at any time there may be a change. The value of ample storage for rain water has been exemplified in our case, for we have enough in the underground tanks to last a week or two longer. Well water, of course, has been used all through for damping down. We grow a crop of early Melons in the house where most of the *Dendrobiums* make their growth; the plants have all been cleared out, and the Orchids which have taken their place are grown in a high temperature. When the house is shut up at night, or rather in the afternoon, the temperature on sunny days rises from 95° to 100°, but with this high temperature there is also excessive moisture in the atmosphere, caused sometimes by syringing the plants well and always by damping down the paths, stages, &c. The plants form roots with amazing rapidity in this heated and moist condition of the atmosphere.

J. DOUGLAS.

PLANT HOUSES.

GREENHOUSE PLANTS.—When *Ericas* of the hard-wooded kinds and other plants from the Cape and New Holland have done flowering, the mistake is frequently made of allowing them to remain housed too long. In this way the growth that usually follows quickly upon the full development of the blossom is considerably drawn, and becomes attenuated and weakly. If this course be adopted for two or three seasons, the plants will in a measure lose their compact habit. Immediately the flowers are faded, all should be picked off carefully, and the plants being thus relieved, there will be nothing left for them to perform but the perfecting of the young growth. When any are bearing an extra crop of flowers, the first to fade should be picked off in advance of the general clearance. Take for instance an *E. Cavendishi* or *E. tricolor*. By the removal of the earlier blossoms as soon as faded, there is no detracting from the good appearance of the plant. Another mistake is that of permitting any shading over such plants after the flowers are past their best. It is done at times when from special reasons a plant is required to be kept in as fresh a flowering condition as possible for a few weeks longer, but such treatment ultimately weakens the growth if persisted in. Again, houses that are shaded to any extent by climbing plants are not suited for this class of subjects; nor are those structures that are badly ventilated. No houses have surpassed the old-fashioned ones with plenty of side ventilation for these hard-wooded plants; houses, it is true, that were constructed with a lot of wood

and small panes of glass, no shading, however, being thought of or ever deemed necessary. Overcrowding amongst soft-wooded plants should also be avoided, or the same results as to weakly growth will follow. If hard-wooded plants are used in the conservatory, see that they are not packed together, as is now the fashion, to an inordinate extent. Against their use I have nothing to say, provided they have sufficient room given them with the maximum possible of light and air. If the foregoing conditions and suggestions be attended to, these plants will do useful service where now they are considered as unfit for the purpose.

As soon as the flowers are picked off, a few syringings freely given will put a stop to any possibility of insect pests, as red spider, which often attacks *Pimeleas*, *Boronias*, *Hedaromas*, and plants of similar character. With a few days of such treatment and not quite so much ventilation, the young growth will be encouraged to start off more vigorously. Then, after a short interval, the plants can be stood outside in favourable positions where they can receive a good proportion of sunshine. A deal depends, of course, upon the locality and surroundings. In some cases a slight artificial protection will be needed, as where fully exposed to winds, whilst in others sufficient is afforded by the natural surroundings. The plants where possible should be stood upon beds of coal ashes, or in any case have bricks placed under the pots to prevent worms from entering them to cause future trouble. Repotting in any needful case can be attended to by the middle of the month. Time must be allowed for doing this properly, whilst the best soil obtainable should in every instance be chosen. This will consist of the best peat, not soft and spongy, but full of fibre, with silver sand and some nutty charcoal; a little fibrous loam should be at hand for such as *Pimeleas* and a few other plants, which do all the better with a small proportion. The potting should not in any case be excessive, nothing beyond 2 inches additional diameter being required, whilst often less will suffice. Firm potting is of the utmost importance. Freshly potted plants may require to be kept indoors somewhat longer, more especially should there be a change in the weather. Complaints as to the state of the weather have been frequent enough of late, but growers of hard-wooded plants have had no reason to complain.

AZALEAS (Indian) will require looking after closely to see that thrips do not make any headway. Both large and small plants are liable to attacks. The plants may now be out of doors in all probability in favourable localities, and have brought a few of this insect with them. It will increase rapidly if not checked, and for this purpose a strong solution of soft soap and tobacco juice is still one of the best remedies, the mixture being made to do duty over and over again, when it is caught in a flat receptacle. In such seasons as the present the red spider must also be looked upon with suspicion, for when hardy plants out of doors are badly troubled with this pest, it will be no small wonder if the *Azaleas* escape. Sulphur water will be found the best remedy, combined with frequent syringings of clear water. Only those plants that flowered late, or others not in the best of health, will now need to be kept in a moist growing atmosphere, and the sooner this can be dispensed with the better. I have more than once noted that when the plants have been kept under these conditions too long they have not set their flower-buds freely, but have formed duplex crowns of wood-buds instead. As in the case of the plants previously alluded to, the potting in any necessary instance should have early attention, good peat being the best soil to use, more especially when dealing with those of only moderate vigour. Extra vigorous kinds, as *Fielder's White* and some others, will do with a little loam added to the peat, this being conducive to a more floriferous growth on the whole. In some instances a top-dressing of peat will prove beneficial; for instance, where the surface soil has been a bit washed or is sour looking, there will be room for a surfacing with advantage. In doing this the after-watering for a time

must be performed with a rose on the can or it will be labour wasted; allowance must at the same time be duly considered to see that the plants do not suffer, as the surface may not be dry when the lower portion of the ball is in this state.

JAS. HUDSON.

MARKET GARDEN NOTES.

TOMATOES.—The long spell of hot, dry weather, so unfavourable for many things, has been a disadvantage in favour of Tomatoes. The early crop came in much more quickly than is generally the case, and the plants are ripening a great weight of finely-coloured fruit. Large quantities of Tomatoes are grown in houses previously filled with Strawberries, which in a general way ripen off by the end of May and beginning of June. The great heat has this year ripened the fruit quite a month earlier than usual, so that the London market will be very abundantly supplied with Tomatoes in the early summer months. Plants are specially prepared for this purpose, so that even before the last Strawberries are gathered the Tomatoes are beginning to get hold of the ground. In this way the houses soon begin again to furnish produce for market. Tomato growers are this year likely to take a heavy weight of fruit from their plants, but much will, of course, depend on the weather later on. Extremes, it is said, meet, and we are likely to see this adage verified as regards the weather after the turn of the days. It is most unlikely that we shall continue to get this fine weather through the summer. July and August may be just as unfavourable for Tomatoes as the last three months have been beneficial to them.

CHRYSANTHEMUMS.—Comparatively few *Chrysanthemums* are grown in pots for cut bloom. The plants are put out from 1 foot to 18 inches apart in beds some 6 feet wide. The great trouble with them is during the first month after planting. Planting in most market gardens is almost or quite completed, and all that is wanted is a steady light rain to thoroughly moisten the ground and make it firm round the roots. One good natural moistening will put the plants in good heart, and then, if the hoe is run in among them, they will go ahead and will do with an occasional soaking. As things now are, it is impossible to discontinue watering for more than a day or two at the most. The plants having no great body of roots, the lower leaves would turn yellow and probably be attacked with red spider if watering is not continued until a change of weather takes place. A mulch of short manure would be of great help, but this cannot always be commanded in sufficient quantity.

PEAS.—There is a general belief among growers here that there will this year be a serious break in the supply. The earliest crop came in fairly well, as they got the benefit of the heavy rainfall in February quite up to podding time. No trace of this remains, and the main-crop sowings have to do their work with the ground in a dust-dry condition. On some of our light Surrey lands, which are in an ordinary year good for all but late Pea crops, the failure is so decided that acres of them have been turned in. At the present time the London markets are very well supplied, but when the early sown crops are done, and with this forcing temperature they cannot last long, the effects of the dry weather will be felt. Peas like abundant moisture, and will not fill well if they do not get two or three good copious falls of rain on them after they come into bloom.

The long period of dry weather and brilliant sunshine has produced a state of affairs in market gardens of a most unpleasant nature. The labour of watering has been enormous. One London market gardener has been paying £10 extra weekly for the last two months for labour rendered necessary by the hot weather. The temperature in plant and fruit houses was as high in April as is the case in an ordinary summer in July and August. Sometimes extra labour pays, but the forcing nature of the season brought fruits and flowers in with a rush, and so filled the markets as

to reduce prices to a phenomenally low point. One man told me that for bunches of flowers such as Pelargoniums and Roses, the ordinary market value of which range from 1s. 6d. to 3s., he had been obliged to sell for threepence. Pot plants have had to be cleared out at prices that could not bring back the expenses incurred in their culture, and thousands of them have not been worth taking to market. Roses seem to have come in all together, especially Maréchal Niel, which never has a long season. One man had to cut a large houseful which would in ordinary years have lasted some six weeks in about ten days. Rushed into market in this way the blooms naturally were sold for next to nothing.

It was simply impossible to keep things back. Fires were drawn out in April and houses shaded, and still the inside temperature almost daily ran up to 100°. It has been a short, but the reverse of a merry season for many who rely on the spring months to yield the major part of their income. It has been the same with fruit; the weather was favourable for bringing on early crops, but 2s. 6d. per pound for Grapes and 3s. per pound for Strawberries were good prices in May. The hardy flower trade has suffered seriously. A cool spring is much better for growers of such things as Pansies, Daisies, Carnations, &c., as it gives a rather longer period for disposing of the plants. Owners of small gardens, who many of them cannot give much time to their plants, were afraid to purchase on account of the semi-tropical heat and dust-dry condition of the ground. They waited for a change which, in the south of England at least, has never come. Many have quite a third of their stock left on hand, which in most instances will be of no further use. Desperate attempts to clear by lowering prices have been made, and probably never has the hawk's barrow been filled at such low rates as during the past month. The general depression in trade has, of course, made matters worse than would otherwise have been the case.

J. C. B.

STOVE AND GREENHOUSE.

PARIS DAISIES.

It is wonderful the amount of fine blooms that a few plants of these will furnish during the earlier months of the year. Cuttings put in in early summer will be well established in 6-inch pots by the end of the autumn, and these will yield flowers from March onwards. The more root-bound the plants are the better quality will the blooms have, as they can be frequently fed with liquid manure. Where large conservatories have to be furnished, specimens in 8-inch pots will be found very useful. Plants a yard or more across with several hundred expanded blooms are imposing, and the more they are cut from the more blooms come. It is this wonderfully free and perpetual flowering character that renders the Paris Daisies so valuable. Provided they are well nourished, one may cut from the same plants from March till November. In France they are sometimes grown in standard fashion, with clean stems 4 feet and more in length. There was, and may be now, a florist in Normandy who made a speciality of these standard Marguerites. It was curious to see a considerable space of ground covered with them during the summer months. Some of the plants were veterans that had done nearly ten years' service in supplying cut blooms. They were miniature trees, and were preferred for cutting from to young plants, as the roots being so cramped they did not make much wood, and with judicious feeding the blooms produced were of high quality and in the greatest profusion. I do not know if the French growers are troubled with the leaf-mining grub that torments the plants in this country. I

never saw any trace of it and never heard it complained of. This pest has become so difficult to deal with, that the value of Paris Daisies has been thereby seriously impaired. Plants that one might otherwise depend on to yield abundance of good bloom all through the spring and early summer months suddenly become quite useless when attacked. Syringing with paraffin would probably act as a deterrent, but as new leaves are constantly forming it would have to be used every week. The constant use of soot water from the time the plants begin to grow will, I am told, act as a preventive, but I cannot speak from experience as to its efficacy. The leaf-miner is such a scourge with me that I have had great difficulty in getting even a few plants into good condition for spring blooming. Although in the autumn they looked perfectly healthy, by the time the bright spring days came they were of little value, the whole of the foliage being ruined with this pest.

The worst of it is that, unlike many insect pests, the Daisy fly continues to breed all through the summer and autumn, the intensity of its attacks ranging according to the nature of the weather. If September is sunny, eggs are deposited which appear to remain dormant all through the dullest months, but are called into existence by the first warm days in February or March. If this is not the case, I cannot account for the way in which some large plants failed. They were as green and as healthy as one could desire up to March, and then to my surprise I found that all the older leaves were full of grubs. By the end of April they were quite ruined. It is evident that the eggs could not have been deposited in the winter, but the autumn previous had been very warm. The fly will, I believe, never work except in bright sunshine. I accidentally found that plants in shade were rarely if ever attacked, whilst others near by in the full sun were ruined. This gave me an idea that if the grubs could not be destroyed, the attack of the fly might be to a great extent avoided by keeping the plants in a rather shady place through the summer and early autumn. The best way I found was to cut down one-year-old plants in June, and when they came well into growth to stand them on a north border. This answered so far that they kept free from the grub till the following June. Young plants are not so well suited to this way of treating them, running overmuch to leaf, older ones, having a basis of hard wood and kept rather root-bound, remaining more compact and sturdy. J. C. B.

Clerodendron foetidum.—Bright lilac scarcely conveys a correct idea of the colour of this. There is a pot plant now blooming in the conservatory here; reddish lilac would be better if such a term is admissible. So far from the flowers being foetid, they are really fragrant, but the foliage when touched gives out a rather rank odour. I notice on the border where the pot stood last year that some small roots found their way into the soil; from these young plants are springing up. This seems a ready way of propagating it.—J. M., *Charmouth, Dorset.*

Ivy-leaved Pelargoniums.—A very interesting collection of Ivy-leaved Pelargoniums is in bloom in the Chiswick Gardens, and we picked out a few of the brightest and most pleasing kinds, as, like collections of any other flower, only a few are worth growing. One of the best is Souvenir de Charles Turner, which has a large full flower of a brilliant carmine-rose colour, with maroon on the upper petals. Very pleasing is Galilee, the flowers double, intense and shining rose in colour, with a silvery reverse to the petals, quite one of the finest in the collection. A pure carmine colour is General Gordon, a showy variety with bold trusses; whilst a note may be made of

Diamant, a variety of bushy habit, the flowers of a charming lilac tone, the upper petals crimson at the base. Several plants are grown of that fine kind Rycroft Surprise, which has been already noted in THE GARDEN. Louis Thibaut is worthy of note. The flowers are bright crimson, double, and several appear in the truss. A good variety for its freedom and colour. Gloire d'Orleans is very distinct. The plant is free and dwarf, whilst the flowers, borne in neat trusses, are rich rose-magenta in colour. All these are double, and we may add to the list Flambeau, the flowers of large size, brilliant scarlet and freely produced; Mme. Thuenir, rose-carmine; Gloire de Nancy, a well-known variety; Francisque Sarcy, white; Hoffgarter Exheler, scarlet, large; Mme. Cochin, flowers small, white, tinted with rose and very pleasing; Camille Flammarion, brilliant rose; Berthelot, rich magenta; Le Printemps, rose; Jeanne d'Arc, white, touched with pale lavender; and Beauty of Castle Hill, the flowers very large and of a rosy colour. These would form a good collection, all being of vigorous growth and the flowers of decided colour.

BOOKS.

BRITISH FOREST TREES.*

THE author of this book states in his preface that it "is specially intended for the use of land-owners and of those already engaged in practical forestry." His qualifications for the task of writing a book on "British Forest Trees" are original, not to say dubious. His book, he says, has "no pretension of being a work of original research or observation based on long experience in the treatment of forests in Britain," and "only professes to be, to a considerable extent, a compilation from the best German sources;" but the author vouches "for the correctness of the scientific principles enunciated from his personal observations made here, and also during fifteen years' active service in the teak forests of tropical Burmah." Most people would think that this was not the best of schooling for compiling a book on British forestry, but that does not appear to have occurred to Dr. Nisbet, and he has produced a book in which several German authorities are acknowledged in the lump "as having been chiefly utilised in the compilation" (p. viii. preface), besides "numerous other works" which have been acknowledged in a foot-note "wherever it has seemed desirable to quote the authority for any assertion." Beyond this it is exceedingly difficult to tell what is Dr. Nisbet's and what is from German sources, but we would hazard a guess, in justice to the latter, that a good deal of the book is the doctor's and the style exclusively his own.

British forest trees are divided into principal species and minor species for pure and mixed forests respectively. The first class includes eight coniferous and broad-leaved species, and the second class twenty-one species. Why the divisions are made is not apparent. The Austrian and Corsican Pines are classed among the minor species as synonymous, which is a blunder from the British planter's view. The Ash, Sycamore, Douglas Fir, and Elm are set down in the minor class, and the Birch, Alder, and common Spruce among the principal species.

The arrangement of the contents is orderly in its way. Each species is treated under the heads of "Coppice," "Distribution," "Ex-

* "British Forest Trees and their Sylvicultural Characteristics and Treatment." By John Nisbet, of the Indian Forest Service. London: Macmillan and Co.

ternal Dangers," "Fungoid Diseases," "Insect Enemies," "Maturity and Reproductive Capacity," "Requirements as to Light, Soil, and Situation," "Sylvicultural Treatment," "Tree Form and Root System," "Wood Formation," &c., and on any of these points the book will be a handy reference guide if it be a safe one. One wonders at such a book appearing now, because it has been more than anticipated by Schlich's "Manual" just out before it, but that is a consideration for the authors and publishers. As in Schlich, British authors on forestry are rather cold-shouldered, a thing not to be wondered at in anyone who aspires to write a book that is not a jumble of sense and prejudice. Mixed forest is advocated, as it appears to me, on slender grounds, in preference to "pure forest," and Sir Herbert Maxwell's advocacy of the latter is prominently cited as "entirely wrong," and as showing the "urgent need for some properly qualified instruction in forest science;" but I doubt if Dr. Nisbet's service in tropical Burmah has made him a match for Sir Herbert on his native heath, and with whom most foresters agree, for the pure forest is much the easiest to manage, the most profitable, and the profits of pure forest planting can be much more certainly estimated. Dr. Nisbet's advocacy of close canopy overhead in woods, as of much importance in the production of timber, will commend itself to foresters, but close canopy is not consistent with the mixed planting which he recommends, for close canopy is difficult to maintain in a mixed wood. Of course trees of similar habit and rate of growth may be mixed without danger.

There is a great deal of useful and instructive reading that foresters will not find in any English book on forestry at the same or even a much higher price, but on many questions affecting forestry practice and the habits of British trees grown for timber, the author is not correct. Take the Ash for example (p. 248). "Its chief sylvicultural importance," we are told, "lies in the production of the larger assortments of timber for cabinet-making and the like," whereas there is no tree that is so easily disposed of in assortments of all sizes down to 2 inches quarter girth, and it is not cabinet makers who are Ash consumers, but agricultural implement makers and manufacturers of a great variety of common and useful household and workshop utensils. Agriculturally, Ash is "a very useful" tree in fields, we are told; whereas, wherever its voracious, wide-spreading surface roots trip up the plough or rob the soil of the nourishment provided for crops, it is simply detested. It appears also that the Ash "is deservedly prized" for the formation of avenues, which will be news to landscape gardeners. Under the head of "Sylvicultural Treatment of Maple and Sycamore" (p. 257) we also get something new. These trees, it is stated,

are not naturally intended to be grown in *pure forests*, or even to be allowed to grow up in *clumps or groups*, as they are distinctly light-loving after they have passed through the pole-forest stage of growth; hence they soon exhibit a *tendency towards branching and sparse crown*, and with their *scanty broken canopy and light annual fall of foliage*, prove unable to protect the soil against ultimate deterioration.

The words I have italicised should just be read in the opposite sense. By itself, or crowded with other trees of similar habit, the Sycamore makes a magnificent trunk—tall, straight and sound, and I have valued many such. It is not in the least disposed to be branching under such conditions, nor sparse crowned with scanty broken canopy, and the annual fall of foliage is one of the heaviest in the wood—smothering

bottom vegetation and forming a thick layer of humus upon the ground, in which the surface roots rovel. Among broad-leaved trees we are also told that "no species equals the Beech in density of foliage;" whereas the Beech is a feather-weight compared to the Sycamore, Horse Chestnut and Spanish Chestnut in mass and weight of foliage. Statements like these, betraying lack of familiarity with British trees, shake one's confidence in the author's observations generally. Distinguishing the different species in respect of their "requirements as to light," as Dr. Nisbet does, is, I think, needless and fanciful. All British forest trees love light—the more of it the better, and the few species in his comparatively short list that endure shade better than others might have been enumerated in a much more concise and practical manner.

J. S. W.

The Illustrated Archæologist.*—This is a very nicely printed and a very promising publication. The processes with which the part is illustrated, and which for landscape work are generally so bad and shocking, will be found, when applied to illustrate level surfaces like stones and tables, as in the present instance, much more satisfactory.

NOTES OF THE WEEK.

White Pink Snowflake.—This is very much superior to all others. The habit is good. It is, as you will see, very free-flowering and pure in colour, and we are safe in saying that not five in a hundred blooms show the slightest inclination to burst. —DOBIE AND CO., *Rothsay*.

Annual flowers will be poor this year, judging from their aspect in gardens. The long drought has proved too much for them and the flowers are small. It is interesting to note the influence of seasons upon plants. Last year annuals were splendid, but this, the reverse is the case. On one very fine border of bulbs, but sown with annuals in the spring to create colour during the summer, scarcely a single kind is in proper condition.

Lilium concolor is a very pretty species when grouped with shrubs of dwarf growth. We noticed it thus used recently, and the effect of its brilliant scarlet flowers, spotted with black towards the base of the segments, was much enhanced. It is better for the outside of the bed and grows about 18 inches in height, the leaves narrow, abundant, and making quite, so to say, a little bush. The variety *Conidion* is a worthy kind, the flowers yellow, enriched with purplish spots.

Rose Cloth of Gold.—"Caledonicus" (p. 474) asks if any reader has good tidings to tell of Cloth of Gold this year. I am again able to give a good account of our plants at Hollywood, Boscombe. Although the blooms have not been up to the standard of excellence of last year, owing to the drought, the plants have flowered satisfactorily. Our plants are not in the least sheltered. They make good strong growth and flower well every year. I consider the success of this Rose with me is due to its being planted 1 foot above the level of the lawn.—F. H. AND.

Kämpfer's Iris is one of the principal flowers in beauty now, and makes a charming picture in Mr. G. F. Wilson's garden at Wisley, where it is planted by the margin of water. This is precisely the situation that best suits *I. Kämpferi*, and half the failures with it arise from a too dry situation. Many fine gardens in England might be beautified by this species, but the margins of ponds, lakes and streams are strangely ignored. This Japanese Iris varies greatly in both size and colour of the flowers, but the single varieties are more effective.

* "The Illustrated Archæologist" for June.—Edited by J. Romilly Allen, F.S.A. Scot. Charles J. Clark, 4, Lincoln's Inn Fields, W.C.

The segments are broad and compose a strikingly handsome bloom, robust and showy. It would be advisable to weed out the ugly semi-double kinds in many instances. For the sake of effect get those kinds of decided colours, not the mottled and ineffective shades, which make a poor show against the rich selfs. One of the most beautiful of all is the pure white variety, which we remember by the lake in the garden of the late Sir G. Macleay at Bletchingley.

Senecio macrophyllus is certainly not a plant for the border, but it is splendid in the rougher portions of the garden, where its massive character is seen to advantage. We recently noticed a specimen in the herbaceous ground at Kew, standing out by itself, a perfect picture of vigorous growth and bold, if coarse, beauty. The leaves are very broad, with conspicuous midribs, the stem sturdy and tall, bearing at the summit a crowded mass of yellow flowers. A well-grown plant thus displayed is a feature that will interest all who admire vigorous, stately growth.

Geranium balkanum.—In reply to the Rev. Wolley Dod's inquiry, I beg to state that *Geranium balkanum* was presented to the Imperial Botanic Garden at Vienna by Prince Reuss, the German ambassador there. He found the plant when on a hunting tour with Prince Ferdinand of Bulgaria in the Balkans. At Vienna the authorities were not quite sure whether it was *macrorrhizum* or not, and the intention was to call it *balkanum* in the case of sufficient distinctive character. I obtained a plant under this provisional name and distributed it as *G. balkanum*—MAX LEICHTLIN *Baden-Baden*.

Gladiolus Colvillei albus we have made note of as a very charming bulb to plant near to shrubs of dwarf growth or at the foot of the rougher parts of the rockery, where the Heaths and plants of similar character are grown. When in a garden recently this beautiful *Gladiolus* was thus used, and the white flowers against the green foliage stood out boldly. This *Gladiolus* is not so tender as some suppose. It will live through the winter. A common plan is to lift the bulbs, dry them, and replant again in autumn. A good group of this *Gladiolus* is charming when in flower.

A beautiful Flag.—We send you by parcel post a few spikes of *Iris Monnierii* which is now a grand sight, growing here side by side with *Iris gigantea*, which plant it resembles in habit. The spikes are each 5 feet high, carrying a number of flowers; the clear yellow of the blooms makes a fine contrast with those of *I. gigantea*.—WALLACE AND CO., *Colechester*.

** A beautiful *Iris* and quite hardy. We remember seeing this plant in the Garden of Plant, Paris, many years ago, and brought some to England. We often wonder why it is not more common in cultivation. The colour is clear and good.—ED.

Chærrops Fortunei.—This plant has proved itself quite hardy here. Our plants—a pair—are 13 feet high, and each produces every year three or four large spikes of bloom at the end of May. They are exposed to the east winds, and stood the blizzards of January, 1881, and March, 1891, without the slightest injury. Both are well furnished with healthy foliage to within 3 feet of the ground. This Palm deserves to be extensively grown, as it is as hardy here as the common Laurel. I used to leave the spikes on for seed, but they never matured any. Now I always cut the flowers off to strengthen the foliage.—J. G., *Kil'erton, Exeter*.

Lychnis Haageana is one of the finest hardy perennials in bloom now, and the bold flowers range from brilliant scarlet to pure white. The scarlet tones are most effective, but sunshine such as we have been favoured with during past weeks makes the flowers quickly fade. A plant in full bloom is very effective, as the flowers are individually broad, fringed and borne freely. Owing to the quick fading of the colours when the plant is exposed, a moderately sheltered position must be selected and not in full exposure to the sun. Ordinary soil, if it is light and well drained, will suffice, and it is also important to transplant often,

then this fine *Lychnis* will prove one of the showiest of perennials in bloom in the summer months.

White Lilies and dark-leaved shrubs.—When visiting nurseries and gardens recently we have seen the good effect of grouping the white Lily (*Lilium candidum*) with such dark-leaved shrubs as the purple Hazel or small trees of *Prunus pissardi*. The result is very beautiful, the deeply coloured leafage intensifying the purity of the bold spikes of spotless flowers. A very good way to plant *L. candidum* is amongst shrubs of varied toned foliage, but to get the chocolate-coloured kinds behind the Lily to throw into relief the dense masses of bloom. It is noticeable that this species succeed remarkably well thus planted.

The blue Himalayan Poppy is in bloom now, and in a cool recess in the Kew rockery it is seen to advantage. *Meconopsis Wallichiana* is not so fine this year as usual, owing to the drought, but its lovely flowers are always welcome. As suggested by the popular title, it is a native of the Himalayas, and when in suitable position grows several feet in height, forming a plant of great beauty and distinctness. It enjoys a deep well-drained soil and a shady sheltered spot. At Kew it is planted in a recess where Ferns luxuriate, and the surrounding greenery brings out the clear, soft, and distinct colour of the flowers. *M. nepalensis* is by the side of it, and the two make an imposing group.

Bech trees unhealthy.—You may possibly remember that I had a correspondence with you the spring before last, I think, concerning the injury done to the Beech trees. You thought it was due to the east wind. I have this year investigated the matter and have proved that the culprit is a weevil whose depredations have become serious with us, destroying the beauty of the trees, so that they can be recognised amongst the others by their withered leaves. The attack begins very soon after the leaf-buds open, when the eggs are deposited, the larva rapidly working their way with disastrous results. I should much like to know whether other districts have suffered.—R. L. ALLMAN, *Woodlands, Bandon*.

Aster diplostephioides is a lovely flower, not quite so vigorous and free in bloom as might be desired, but many fail with it through not giving proper treatment. This species is not new, although so little known that it may be regarded almost as a novelty. It was described by De Candolle as far back as 1836 under the name of *Heterochaeta diplostephioides*, whilst it was figured in the *Botanical Magazine*, t. 6718. It is unquestionably a remarkably handsome composite from the Himalayas, and last year was shown well by Mr. Marshall at one of the meetings of the Royal Horticultural Society. It enjoys a light, thoroughly well drained soil and open position, such as may be found on every rockery. The plant is not tall, but the spike rises quite 2 feet in height, bearing flowers about 3 inches across, the ray florets symmetrically arranged and intense purple-blue in colour, the orange-coloured anthers in rich contrast. Although shown occasionally, it has never become popular.

Two forms of our native Water Lily.—We lately had the pleasure of seeing a very lovely picture of our native Lilies in the lake at Middleton Hall, Tamworth, the residence of Mr. E. de Hamel. This lake, although nearly covered with the Lilies, does not show them in any overcrowded state, the flowers being superb. The effect, from many points of view of the lake in relation to the Manor House and a pretty orchard garden near, is charming. But what interests us the most is the fact that there are two distinct forms of the Water Lily growing there, one having a flower much larger than the other, wider, and with a delicate shade of pink through its central parts, and more distinctly on the outer petal. The other kind is no less beautiful, but the outer parts, instead of being pink inside and brownish purple outside, are a deep green outside and greenish white inside, the flower also being much smaller and a beautiful white. It is very interesting to know that there are two forms of the

native Water Lily, and for aught we know there may be other forms. We shall be very much obliged to our readers who may have made any observations of the kind if they would kindly communicate with us. We have been puzzled before by this native pink Lily, which is a handsome kind for the water, flowering freely and having very large blossoms.

Lilium Grayi is in bloom at Kew in a bed filled with *Azalea amena*. This beautiful form is a rear ally of *L. canadense*, and some American botanists regard it as a distinct species. It was first discovered by Dr. Asa Gray in the year 1810, he having found it near the top of Roan Mountain, in North Carolina. Dr. Gray and Professor Sargent re-found it in 1879 in the same locality, whilst Mr. A. H. Curtiss discovered it in Virginia. A figure of this Lily appeared in the *Botanical Magazine*, t. 7231, the drawing having been prepared from a plant which bloomed at Kew in 1891. It is likely to prove a thoroughly useful garden Lily, being as readily grown as *L. superbum* or its relative, *L. canadense*. The flowers are carried on tall branching stems, and the whole aspect of the plant is graceful and the flowers very rich in colour, the outside of the segments deep crimson, whilst the inner face is heavily blotched with purple on a yellow ground, reminding one of the *Tigridia*. At Kew there is quite a group of it, and note should certainly be made of this uncommon species, if such it may be called.

Lilium Martagon album in London.—This has been in flower with me ever since the 28th of May. It is now (June 26) almost over. It is much earlier than in previous years. Last year it was not in bloom till June 21, and the year before June 28. The bulbs which I planted in September, 1890, gave me forty flowers the next summer. Last year they sent up five stems with ninety blooms, and this year they have thrown up six fine stems, some 5 feet high, with no less than 167 flowers. Two of these spikes carry ninety-one blooms between them. The white Martagon is a very handsome Lily, and with but little attention soon forms a striking feature in any border. The above facts concerning plants now in my garden clearly prove that this is a Lily which does well in suburban gardens. Next summer I hope to have it in bloom in Kensington, where, although under less favourable conditions, I have no doubt it will render a good account of itself. While in Oxford during the past term I frequently visited the Botanic Gardens, but was surprised not to find the white Martagon included among the collection of Lilies there.—R. A. JENKINS, *Highgate*.

Crinum Powellii album is blooming freely in the nursery of Mr. Morse at Epsom. This is a rare and beautiful flower raised by Mr. Powell, after whom it is named. *C. Powellii*, it may be interesting to mention, is the only hybrid *Crinum* and was raised from *C. capense* and *C. Moorii*. It was raised about 1876 and is a most beautiful plant for a warm, sheltered and sunny position. The type is well known, and its rosy-coloured flowers are effective when several plants are together. Mr. Powell mentions that "Strange to say, the white-flowered plants were obtained from *C. capense* rosem; while those of *C. c. album* (which was also used as a seed parent) had flowers of the deepest shades of rosy pink." We think in time that this beautiful plant will become popular; the flowers, pure white, are produced from June until October. As yet it is expensive and never likely to get very cheap, as it does not produce offsets so freely as the parent. *C. Powellii* requires to be planted deeply—about a foot, with some manure beneath the bulbs, but not actually touching them. It is quite hardy, and in an open loamy border will prove satisfactory. The rose and white flowers are pleasing in contrast.

Notes from Chester.—The long drought has happily left us unharmed, as the many visitors we had during the week of the royal show would be able to say. The copious rainfall of the past few days will quickly put a fair fresh face upon the foliage and fill up the blanks with new growth, which was held in abeyance for lack of moisture.

In walking through the avenues and quarters flower-filled and bright with summer glory, the bold striking plants of *Romneya Coulteri* cannot fail to attract. We have a large lot of this fine plant, and the effect is very fine. It is a decided gain. *Philesia buxifolia*, with its beautiful wax-like flowers, is in splendid perfection. It is the outside *Lipageria* quite, so far as character and beauty of bloom are concerned. *Hypericum empetrifolium* is one of the prettiest of the St. John's Worts. It is a most valuable little plant for working in effectively with bits of rock garden planting. We planted out the borders about the royal pavilion on the show ground here with fine-foliaged plants of a hardy character, and the glints of gold we managed to get with this pretty *Hypericum* we found helped to brighten the effect without suggestion of intrusive gaudy patches of colour. But we must not overlook *Escallonia Phillipiana* in a list of the week's flowers. The little spray enclosed is from the open, unprotected, a position the plant has occupied for some years unharmed, and it must have endured up to 30° of frost. It is a beautiful little shrub, and is fragrant. It is the hardiest of all the *Escallonias*, if not the showiest.—DICKSONS.

SOCIETIES AND EXHIBITIONS.

ROSE SHOW AT EARL'S COURT.

JUNE 28.

THE second exhibition of Roses was held at the Gardening and Forestry Exhibition on Wednesday last. The competition was not very keen, and the flowers betrayed traces of the storms that have recently passed over the country. They were fresh, full of fine colour, but frequently much damaged, the Teas in particular, which were bruised and battered by the heavy downpour of rain. We noticed that the dark-coloured varieties came out conspicuously, especially *Horace Vernet*, whilst such kinds as *Xavier Olibo* and others of that type were seen to advantage. Besides Roses, a creditable display of fruit was to be seen, and the exhibition was on the whole very interesting.

The chief class was for forty-eight Roses, distinct, single trusses, and the first prize was awarded to Messrs. Harkness and Sons, The Nurseries, Bedale, Yorks. It is interesting to notice how at various times in the course of the summer certain firms come to the front; on this occasion the Yorkshire flowers were very successful throughout. This collection contained one of the finest blooms of *Gustave Piganeau* we have ever seen, large, solid, fresh, and of beautiful colour. It will be doubtless interesting to mention the finest of this prize lot, and they consisted of *Caroline Kuster*, *Mme. Haussmann*, *Earl Fitzwilliam*, *Horace Vernet*, *Comte de Raimbaud*, *Jean Ducher*, *The Bride*, *Fisher Holmes*, *Marquise de Castellane*, *Rosieriste Jacobs*, *Le Havre*, *Mrs. J. Lairg*, *Captain Christy*, *Marie Baumann*, *Pride of Waltham*, *Crown Prince*, *François Michelin*, *Dr. Sewell*, *Earl of Dufferin*, *Mme. G. Luizet*, *Barthelemy Jobert*, *Queen of Queens*, *Duchess of Bedford*, *Louis van Houtte*, *Mme. Cusin*, *Dupuy Jamain*, *Mme. Isaac Pereire*, *Chas. Lefebvre*, *La France*, *Dr. Andry*, *Xavier Olibo*, *Souvenir de S. A. Prince*, *A. K. Williams*, *Comtesse de Nadailac*, and *Senateur Vaise*; whilst the second place was occupied by Mr. Frank Cant, *Braiswick Nursery*, *Colchester*, the entries numbering five, not a bad competition therefore. *Ernest Metz*, *Ulrich Brunner*, *Duke of Wellington*, *Sultan of Zanzibar*, *Le Havre*, and *Mme. Cusin* were shown finely. It is always satisfactory to give equal first prizes, and this was the case in the class for twenty-four Roses, distinct, triplets. Messrs. Harkness and Sons and Mr. Frank Cant were bracketed together. They were practically equal, and the Yorkshire flowers of particular note were those of *Marie Baumann*, *Suzanne Marie Rodocanachi*, *Mme. G. Luizet*, *Countess of Roschery*, *Gustave Piganeau*, *Fisher*

Holmes, and a variety named Mrs. Harkness, which is a good flower, full, salmon in colour, and of a clear pleasing tint. The dark-coloured kinds in Mr. F. Cant's stand showed to advantage, particularly Horace Vernet and Sir Rowland Hill. We may mention that Horace Vernet was excellent in the third prize box from Mr. G. W. Barch, The Nursery, Peterborough. In the corresponding class for the same number, but single trusses, the Peterboro' flowers from Mr. Barch won premier place, there being seven entries. They were a very even collection, and the best shown were Her Majesty, which was good in many stands in spite of the dryness of the season. Again Xavier Olibo was worthy of note, and Exposition de Brie, Senateur Vaisse, Dr. Sewell, Ulrich Brunner, Mme. Lambard, Victor Hugo, Mrs. John Laing, Horace Vernet, Duke of Wellington and Mme. Chas. Crapelet. Mr. Cant's flowers were highly creditable, and Suzanne Marie Rodocanachi—a terrible name for a lovely Rose—was noteworthy. The best twelve blooms of any dark variety came from Mr. B. R. Cant, Colchester, who had splendid flowers, especially for colour, of Alfred Colomb, the second place being occupied by Messrs. Harkness with Charles Lefebvre; whilst in the corresponding class for light-coloured flowers, Her Majesty was shown well by Messrs. Perkins and Sons, Coventry, that now popular variety, Mrs. J. Laing, being exhibited well by Messrs. Harkness, who were second.

Amateurs came out well, showing very fine flowers. The chief class was for twenty-four Hybrid Perpetuals, distinct, single trusses, and the first prize was keenly contested, this award going to Mr. E. B. Lindsell, of Bearton, Hitchin, who had remarkably fine dark-coloured flowers, Horace Vernet in particular, whilst Mrs. J. Laing, Heinrich Schultheis, A. K. Williams and Dupuy Jamain were also well shown. The Rev. J. H. Pemberton, Havering-atte-Bower, Romford, who seems likely to stand well this year, was second, but equal first with Mr. Lindsell for twelve Roses, distinct, three trusses of each. In the two collections we made special note of the varieties Horace Vernet, Ulrich Brunner, Duchess of Bedford, Gustave Piganeau, Louis van Houtte, Alfred Colomb and A. K. Williams. For twelve single trusses, the Rev. H. A. Berners, Harkstead Rectory, Ipswich, was a good first, having very fine flowers for the season of Her Majesty, Ulrich Brunner, Baronne Rothschild and Earl of Pembroke; Mr. J. Gurney Fowler, Glebelands, South Woodford, Essex, second.

Tea and Noisette Roses were not so numerous, and as a rule disappointing because so much spoilt by the weather. The principal class was for twenty-four distinct single trusses, the first-prize-winner being Mr. B. R. Cant, who had very good blooms of the leading kinds. Especially worthy of mention were those of Mme. de Watteville, Ethel Brownlow, Mme. Cusin, Catherine Mermet, Souvenir d'Elise, Souvenir de S. A. Prince, Edith Gifford, Niphotos, Ernest Metz and Francisca Kruger, whilst Mr. Frank Cant was second. In the open classes there was one for eighteen single trusses, distinct, and here Mr. G. Mount came first with flowers of much beauty, although greatly damaged. It may be worth while to mention that throughout the show the finest blooms were those of Innocente Pirola, Comtesse de Nadaillac, Rubens, Souvenir d'un Ami, Souvenir de Paul Neyron, Jean Ducher, The Bride, Catherine Mermet, Marie van Houtte, Anna Ollivier, Niphotos, Mme. Cusin, Souvenir de S. A. Prince, Maréchal Niel, Mme. Lambard, Ethel Brownlow, Souvenir d'Elise Vardon, and Hon. Edith Gifford. Messrs. Prior and Son were second. In the amateurs' division for eighteen Teas the first prize went to Mr. H. V. Machin, Gateford Hill, Worksop, the flowers fresh and in good character, particularly The Bride, Cleopatra, a very fine exhibition Tea; Rubens, Marie van Houtte, Mme. Cusin, Jean Ducher, and Mme. Hoste, whilst Mr. Lindsell was a close second. For twelve distinct, the Rev. H. A. Berners won with a very charming box of flowers, the best being The Bride, Souvenir d'Elise, Mme. Bravy, Innocente Pirola, Comtesse de Nadaillac, Marie van Houtte, Anna Ollivier, Comtesse Panisse, Mme.

Hoste, Francisca Kruger, Princess of Wales, and E. Gifford; Mr. Lindsell second. Mr. H. V. Machin had the finest twelve blooms, showing Souvenir de S. A. Prince remarkably well, whilst Messrs. D. Prior and Son were second with Maréchal Niel.

The class for eighteen garden Roses was not the least interesting feature of the show, the first prize going to Messrs. Paul and Son, Cheshunt, who had a fine mass of them, the best being the bunches of Camoens, Mme. Pernet, Ducher, Aimée Yibert, the hybrid rugosa Mme. Georges Bruant, l'Idéal, and Waltham Climber. Mr. C. Turner, Slough, second.

Several miscellaneous classes were provided for things otherwise than Roses, but the competition was not severe. One class was for a group of tuberous Begonias arranged for effect, 12 feet by 8 feet, and although Mr. Ware, Tottenham, was the only competitor, his group was of much merit, arranged with Asparagus plumosus, and containing many fine varieties; want of space prevents individual description. A noteworthy class was for twelve bunches of Gloxinia flowers, and above all competitors was Mr. T. Bones, Heaton Gardens, Cheshunt, who had splendid flowers, Ruby, scarlet, Paragon, purple, white margin, and Princess May, white, being worthy of mention. Mr. Howe, Park Hill, Streatham, was second. Several very prettily arranged baskets of Roses were to be seen, and the first prize table decorations from Mr. F. W. Searle, Vine Nurseries, Sevenoaks, may be mentioned.

Groups and other plants not for competition were shown largely. The principal feature was a fine arrangement of Roses, representing great variety, from Messrs. Wm. Paul and Son, Waltham Cross, a rich profusion of flowers, especially of the variety l'Idéal, Maréchal Niel, Ma Capucine, Louis van Houtte, and Mme. Pierre Cochet, the flowers yellowish, shot with scarlet, a very fragrant and promising Noisette. These displays are most artistic. Messrs. Barr and Son, Covent Garden, had a large bank of hardy flowers, comprising a great variety of Sweet Peas and Poppies, besides various other things in season. Mr. J. R. Chard, Stoke Newington, had table decorations; Mr. J. Walborn, West Kensington, crimson Carnations; and Messrs. J. Cheal and Son, Crawley, tufted Pansies and other hardy flowers. Messrs. Jarman and Co., Chard, Somerset, showed Sweet Peas, and Cucumber Baker's Triumph, a very fine long ridge outdoor variety, also a new Tomato of promise. A very beautiful group of Cattleyas came from Mr. W. Davies, gardener to Mr. Danell, Stamford Hill, N. Mr. Anthony Waterer, Knap Hill, showed his splendid new Spiræa Anthony Waterer, which has been previously described in THE GARDEN. A new Rose named Merrie England was shown by Messrs. Harkness. It is a Hybrid Perpetual of the striped class. We do not care for it. The flowers are large, rose-pink in colour, with stripes of white. It is not pretty.

Fruit.

Some very fine fruit was shown, the competition in some of the leading classes being keen. Black Grapes were specially good, also Strawberries considering the dry season. Peaches and Nectarines were numerous and very good. Melons occupied a large space. The fruit was not allowed to be tasted. This acts injuriously, as it is impossible to judge Melons from appearance. In many cases fruit which would take some time to ripen was staged. Figs and Cherries were well represented, and there were several large exhibits in the miscellaneous classes. Several new fruits in the way of Strawberries and Tomatoes were staged, but only one secured an award. A splendid collection of fruit was sent by the well-known Sawbridgeworth firm.

A first-class certificate was awarded to

STRAWBERRY GUNTON PARK—This was certificated two years ago by the R.H.S., and has been exhibited several times this season. It is a very fine fruit, varying in shape from conical to cockscomb, colour dark crimson-scarlet, of brisk flavour, the flesh firm. From W. Allan.

For the best six dishes of fruit there were four competitors. Mr. J. McIndoe, Hutton Hall Gardens,

Guisborough, Yorks, was an easy first, having very good Muscat of Alexandria Grapes, a fine dish of Pear Clapp's Favorite, fine Stanwick Elruge Nectarines, Grosse Mignonne Peaches, large Brown Turkey Figs, and good bunches of Black Hamburg Grapes, the berries large, but of poor colour. Second, Mr. Ocock, Havering Park, Romford, who had good Black Hamburg Grapes, Elruge Nectarines, Bellegarde Peaches, and Brown Turkey Figs. For three bunches of white Grapes, any variety, very good bunches were staged; first, Mr. McIndoe, with large bunches and good berries of Muscat of Alexandria; second, Mr. T. Osman, Ottershaw Park, Chertsey, with very good bunches of Buckland Sweetwater. For three bunches of Black Grapes there was a strong competition, and very good; Mr. Osman secured the premier award with large well coloured Black Hamburg; second, Mr. Taverner, Woolmer, Liphook, Hampshire, the variety being the same as above, but smaller bunches, having good berries nicely coloured. Mr. G. Featherby, The Vineries, Gillingham, was third. An extra prize was given to Mr. W. Thomson, Huttonhurst, Hounslow, for three grand bunches of Madresfield Court, but wanting a few more days to finish. Melons were numerous, but the white-fleshed kinds predominated. For three fruits Mr. Poulton, Ivy Mount, Streatham, was first with good even samples of Hero of Lockinge; second, Mr. J. C. Mundell, Moor Park Gardens, Rickmansworth, who showed three varieties; third, Mr. S. Mortimer, Swiss Nursery, Farnham, with Hero of Lockinge. In the class for one fruit, Mr. Poulton was first with the new Gunton Orange, staging a pretty Melon nicely finished; second, Mr. McIndoe with High Cross Hybrid. Peaches were very fine, grandly coloured, and in quantity, Mr. C. Stocking was first with a grand dish of Bellegarde; second, Mr. W. H. Divers, Ketton Hall, with Crimson Galande. For the best dish of Nectarines Mr. W. Robins was first with very fine Spencer's; second, Mr. McIndoe with Stanwick Elruge. For the single dish of Figs, Mr. Allan, Gunton Park, Norwich, was a good first with Negro Largo; second, Mr. McIndoe. Some fine fruits were staged in the class for two dishes of Cherries, Mr. Fowler, Glebelands, South Woodford, being first with large fruit; second, Mr. W. H. Divers. For the best three dishes of Strawberries, Mr. Allan was first, staging two dishes of Gunton Park and one dish of Lord Suffield; second, Mr. Divers, with British Queen, Waterloo, and a fine dish of Laxton's Latest of All. The same exhibitors secured the awards in the order named in the class for single dishes.

Messrs. Rivers, Sawbridgeworth, had a very fine collection of Cherries, Peaches, and Plums, receiving a special award. Among the Cherries the best were Early Rivers, Bedford Prolific, Bigarreau de Schrenke, Black Bigarreau, Black Hawk, and Monstrueuse de Mezel. Waterloo, Amsden June, Alexander, and a seedling Peach were also fine. Mr. S. Mortimer had a grand lot of Melons, receiving a silver-gilt medal. Mr. Divers sent six varieties of Peaches, the best being Alexander, Barrington, Sea Eagle, and Princess of Wales (silver medal). Mr. Featherby had a similar award for Tomatoes, Cucumbers, &c.

A full prize list is given in our advertising columns.

THE GARDENERS' ROYAL BENEVOLENT INSTITUTION. ANNUAL DINNER.

THE fifty-fourth annual gathering of the subscribers and supporters of this institution was held on Thursday evening, June 22, in the Whitehall Rooms of the Hotel Metropole, London. Baron Schröder presided. There was a good company present, including Lord Teynham, Sir Trevor Lawrence, Rev. W. Wilks (Master of the Gardeners' Company), Messrs. H. J. Veitch, G. F. Wilson, P. Crowley, N. N. Sherwood, and other well-known patrons of horticulture. It will be remembered that the anniversary dinner of last year was unavoidably postponed from the usual month of June

until the middle of November. This year, however, the former time has been again adopted. The present gathering must be classed with the most successful the institution has ever held, and the executive are to be congratulated upon the financial result of the same. Baron Schroeder, in his after-dinner speech, ably advocated the claims of the charity and the great need there was for further and increased support. The chairman urged all who love their gardens, and who look to the garden as their greatest possible source of enjoyment, to do all that lies in their power to render assistance to the gardener in times of confirmed sickness, adversity, and old age. He stated from practical experience that there was nothing so soothing as to be associated with flowers after a hard day's work in the city. Further allusion was also made to the recent alteration in the rules (see new rules, more particularly rule 10), whereby votes were added to subscribers who became candidates for the pensions in proportion to the years they had subscribed, from four years upwards to fourteen, and from 50 to 550 votes. This, the chairman considered, was one of the very best alterations or rather additions that could possibly be made, one also that is mainly due to the excellent and practical suggestions of the treasurer. Mr. H. J. Veitch, as treasurer, replied, thanking the baron for his earnest support. Mr. Veitch pointed to the steady progress that was being made in days of hard times, the pensions being maintained and the institution worked at the lowest possible expenditure. He claimed for the new rules as drawn up by the hon. solicitor (Mr. Peacock), revised by the committee, and sanctioned by the special meeting, that they were second to none for their comprehensive character and the benefits they confer upon the community of gardeners. He further stated that in the election of pensioners there was no distinction as to nationality, all parts of the United Kingdom receiving the same consideration. The treasurer also added that there were a large number of pensioners over 80 years of age, two of 87 years, one of 88 years, one of 89 years, whilst two had been pensioners for 21 years. The letters that he and the secretary had received spoke of the untold blessings that had been conferred upon the distressed and infirm. Sir Trevor Lawrence, Rev. W. Wilks, Mr. Sherwood and other gentlemen in their remarks further urged upon the company the indebtedness due to the gardener and the need of provision in old age. The result of the evening's meeting, as announced by the secretary (Mr. Geo. J. Ingram), was most gratifying, the total amounting to the sum of £1500, amongst the chief contributions to this amount being Baron and Baroness Schroeder, 100 guineas; Messrs. de Rothschild, 100 guineas; Mr. N. N. Sherwood, £100; Mr. George Monro, £91 18s. 0d.; Mr. H. Williams (Messrs. B. S. Williams and Son), £35; Mr. Robert Tate, £25; and from the Bristol and Bath Auxiliary meeting, £35 15s. 0d. In addition to these amounts several new annual subscribers were added to the list. The chairman, in conclusion, expressed his pleasure with the decorations of the evening, these being of a profuse character, Orchids being largely employed, no less than fifteen stands being decorated therewith—plants of Orchids being also employed. The cut Orchids in large quantity and choice variety came from Messrs. Sander and Co., and the plants of same from Messrs. B. S. Williams and Son. The arrangement of the cut flowers was entrusted to Miss Hudson, Gunnersbury House Gardens. Other plants were supplied by Messrs. Cutbush and Sons and other firms. The pleasure of the evening was enhanced by the efficient programme of music, whilst, fortunately for the comfort of the company present, the phenomenal heat of the previous few days had greatly subsided.

The weather in West Herts.—The temperatures during the past week were considerably lower than those of the preceding one. Taken as a whole, however, the weather again proved warm

for the time of year; consequently this was the twenty-third unseasonably warm week that we have had in succession. During Sunday night the exposed thermometer went down to within 5° of the freezing point. Monday night, on the other hand, was the warmest yet recorded here during the present summer, the same thermometer falling only to 55°. During the last nine days the temperature of the ground at 1 foot deep has fallen 8°, and at 2 feet deep 4°, but at the latter depth is still warmer than at the same period last year. Rain has fallen on every day except Sunday, and to the total depth of about three-quarters of an inch. On several days the wind has been higher than at any time since the middle of March, and the air more humid than for some weeks. Although the recent showers have scarcely done more than wet the surface of the ground, yet their beneficial effect upon vegetation generally is very marked; in fact, the lawns are already beginning to look quite green again.—E. M., *Berkhamsted*.

SEED CATALOGUES.

TO THE EDITOR OF THE GARDEN.

SIR,—Will you use your influence against an abuse which was at one time moderated by your aid, but which has cropped up again? I mean the use of false names and descriptions in seed catalogues. I sent for my seeds this spring from one of the best firms, and amongst the rest for *Linum grandiflorum*, white. This turns out to be the white form of *L. usitatissimum*, perfectly useless for the garden. It must all be pulled up and thrown away, leaving an unsightly gap in the scheme of colour. Again, I read "Pea Lord Anson's, hardy climber from Cape Horn." I fondly imagined that *Lathyrus magellanicus* had been re-introduced and sent for a packet, but when the seeds came they proved identical with my own, saved from the common annual *L. azureus*, a native of S. Europe. Surely a great firm ought to be above such tricks or such carelessness. C. M.

Eucalyptus oil—a warning.—The essential oil which is obtained by pressure from the leaves of the *Eucalyptus globulus* appears to have properties of a poisonous nature, demanding caution in the use of it. Intelligence has recently come to us from Australia that a man residing at Geelong, who was suffering from influenza, died after taking a rather large dose (over an ounce) of this oil. From Tasmania also is recorded the death of a boy ten years old who had taken a spoonful of the same oil as a remedy for a cold in the head.—*Review Horticult.*

St. Anne's House, C.ontarf, Co. Dublin.—The herbaceous borders are now at their best, and the Delphiniums, 10 feet or more in height, among more lowly Lilies, Poppies, Irises, and other flowers are much admired. At St. Anne's garden culture is at its best; all departments are well done. Fruit and vegetables, Orchids and Ferns, hardy and alpine flowers, and choice aquatics are here to be seen in perfection as the seasons roll round. I lately saw a clump of the hardy *Cypripedium macranthum* bearing no less than seventeen of its great purple flowers, and on my present visit I noted *Habenaria dilatata* with spikes 2 feet high, and a choice bit of the rare *Phyteuma omosum* with six or seven clusters of its curious flask-shaped blossoms. In a shallow pool in the open air the "Zebra-striped" or "Porcupine Quill" Rush (*Juncus zebrius*) was 3 feet high or more, with quills as thick as one's little finger. At every turn rare and choice plants, both hardy and tender, are to be seen. In a warm greenhouse are Oranges of many varieties as fresh in leafage and as fertile as if under an Italian sky. The Egyptian Papyrus is here quite at home, luxuriant, 15 feet high or more, while *Bignonia grandiflora* was in splendid blossom. Amongst the Orchids the *Cattleyas* were especially gay, also *Odontoglossum Alexandræ* and *Epidendrum vitellinum majus*, with its

orange-red spikes. The enormous growth on *Dendrobium Dalhousianum*, 5 feet to 7 feet long, and the fresh and luxuriant leafage of the *Catasetums* and *Calanthes* were a treat to see, as also were the choicest sorts of *Cypripediums* here so well cultivated. In a cool house I noted the luxuriant growth and enjoyed the odour of the *Malmaison Carnations*, and the beauty of two or three varieties of the now too often neglected perennial *Daturas*, with their great pendent trumpet flowers. It is always pleasant to see St. Anne's under the guidance of Mr. Charles Smith, who has managed these gardens for no less than twenty-five years; and before leaving we happened by accident to see a very handsome practical token of the appreciation of his employers, Lord and Lady Ardilaun, in the form of a very handsome silver tea and coffee service with a suitable inscription.—F. W. B.

The white Camellia.—Can any reader inform me in what book recently published can be found a poetical description of the white Camellia?—FLEUR.

Tomato Challenger cracking.—Can any of your readers who are Tomato growers inform me if they find the new variety Challenger liable to crack. I have a house 60 feet by 24 feet planted entirely with this variety, and I find the fruits crack very badly. I shall be extremely grateful for any information as to the cause, and also if there is any cure. I may state that I am also giving Conference and Trophy in another house and find no sign of cracking there.—A CONSTANT READER.

"The Garden" Monthly Parts.—This journal is published in neatly bound Monthly Parts, in which form the coloured plates are best preserved, and it is most suitable for reference previous to the issue of the half-yearly volumes. Price 1s. 6d.; post free, 1s. 9d. Complete set of volumes of THE GARDEN from its commencement to end of 1892, forty-two vols., price, cloth, £30 12s.

"Gardening Illustrated" Monthly Parts.—This journal is published in neatly bound Monthly Parts, in which form it is most suitable for reference previous to the issue of the yearly volumes. Price 5d.; post free, 8d.

"Farm and Home" Monthly Parts.—This journal is published in neatly bound Monthly Parts, in which form it is most suitable for reference previous to the issue of the yearly volumes. Price 5d.; post free, 8d.

"Hardy Flowers."—Giving descriptions of upwards of thirty hundred of the most ornamental species, with directions for their arrangement, culture, &c. Fifth and Popular Edition, 1s.; post free, 1s. 3d.

"The Garden Annual" for 1893.—Contains Alphabetical Lists of all Branches of the Horticultural Trade. The Lists of Gardens and Country Seats (containing over 9000) have been very carefully and extensively revised, and are admitted to be the most complete ever published. Price 1s.; by post, 1s. 3d.

All of our readers who are interested in the improvement of cottage homes are invited to help us to make Cottage Gardening known. It is published at the very lowest price to meet the wants of those for whom it is intended, and copies will be sent for distribution, free, by the publishers, Messrs. Cassell and Company, La Belle Sauvage, Ludgate Hill, E.C.

"This is an Art
Which does mend Nature: change it rather; but
THE ART ITSELF IS NATURE."—*Shakespeare.*

CHRYSANTHEMUMS.

SEASONABLE NOTES.

MANY persons complain of the points of their plants being in some way injured, so much so, that many shoots are rendered totally blind and useless. One amateur cultivator said no less than two dozen plants in his small collection were, he feared, ruined by this cause alone. I have had some experience in the same direction. Plants that are grown on the orthodox principle of three shoots each, with a view of having that number of large blooms, seem to be the most susceptible to attacks. The injury is caused by an insect, which is about an eighth of an inch in length and very narrow, but which moves very fast. It punctures the skin in a longitudinal manner immediately below the lastly formed leaf. The puncture extends downwards about a quarter of an inch and appears to go through the tender skin into the fleshy part of the shoot, destroying the tissue and causing the shoot in a day or two to buckle over towards that side where the injury occurs. The extreme point of the shoot is thus rendered useless. Seldom can the depredator be caught in the act, it is so small and active.

No doubt the recent hot and dry weather is answerable for much of the damage done to the plants in this direction by the extra crops of insect pests. What I recommend is to employ the tobacco powder distributor freely in the points of the shoots, not, however, loading the tender leaves so freely with powder as to cause an injury to them by the hot sun when coated over with the powder, as is sometimes the case, but to scatter it lightly and often on the leaves. Another good remedy is to put a handful of sulphur or soot in the water two or three times a week when syringing the plants in the evening. Not only will the soot be objectionable to the insect, but it is useful in supplying lost colour to the leaves of the plants. It may be surprising to some to hear this, but it is a fact nevertheless that soot applied in a liquid form to the leaves will change their colour from light green to a deeper hue. The use of bones as crocks is a source of another complaint. Some writers go so far as to say that with the aid of bones as crocks the risk of the blooms damping is reduced to a minimum. This I am not prepared to substantiate, neither do I advise their employment for that purpose or any other. The objection this season to bones as crocks appears to be that they injure the roots directly they come into contact with the bones, which are, by the time the roots reach them, in a putrid mass. Bones that are simply ground without being bleached chemically are undoubtedly the most dangerous to use in this respect, but they are preferable when mixed properly with soil, as all bones should be. I do not advocate the employment of bones ground to half-inch size, or even quarter, for the reason they are not long

enough about the roots for the plants to derive sufficient benefit from them. Finely ground bones or those dissolved by the aid of sulphuric acid are what I advocate. The only remedy I can suggest is to remove the bones and replace them with clean crocks. This can be done without repotting the plants by holding the plant upside down in one hand, carefully lifting off the pot, changing the drainage and as carefully returning the pot to its former position. Another plan might be tried, that of well soaking the soil with lime water; this might cleanse the roots and probably the bones also by removing some of the offensive matter.

The persistent manner in which the plants have shown buds has been a source of great trouble to most growers of my acquaintance. The members of the Queen family have been the greatest offenders in this respect, although other sorts in many cases have formed an excessive number of buds. For the first time in my experience the Princess of Wales family has done the same, but not to the extent of that of the Queen. In the southern counties of England this has been more felt, owing to the extreme heat and dryness of the atmosphere. Happily, however, the plants are now showing a decided tendency to "grow out" of this freak. With a view to pick up lost time and to encourage the plants, I advise that a rather sharp stimulant be given them. Nothing is better than nitrate of soda given in a safe manner, purely with a view of elongating the sap vessels, to prepare them for future reception of more solid and stimulating food. Nitrate of soda may be applied in a raw state to the plants at the rate of half a teaspoonful to a 10-inch pot, watering it in. If, however, it is used in a dry state, it should be powdered fine, as when in lumps it is liable to burn the roots. In no instance, however, should it be given when the soil in the pots is in any way dry. A safer way to use nitrate of soda is to dissolve it in water at the same rate of strength and give the plants a thorough soaking. A second dose may be required in a fortnight if by that time a change is not clearly perceptible in the growth and general appearance of the plants.

It is rather early yet to commence with the regular feeding of the plants. They have not been sufficiently long in their flowering pots to absorb the whole of the nutriment in the compost, and to gorge them as it were with additional food would be to nullify the effects of a properly prepared compost. However, there is such a variety of opinions as to the proper time to commence to feed the plants that a note on this phase of culture may be of service to beginners. Many growers advise that stimulants be not applied until the flower-buds are formed. This is a mistake, because in some instances the flower-buds do not form till the middle and end of September, and even later than that. The time is too short from this stage for the plants to derive much benefit from stimulants, because these late-formed buds as a rule develop their blooms at the same time as those which set fully five weeks earlier. If the plants are not fed until so late a date, how can they retain their former vigour, as the roots quickly exhaust the soil given to the plants at the final potting in May? The plants ought to be fed before the buds form, so that they may be strong when that critical time arrives. Weakly plants never produce buds of the same quality as stronger plants of the same variety, and if the buds are not produced in proportion to the necessary qualities of each variety, how can the flowers be properly developed? When the plants are growing well do not let them de-

teriorate from lack of attention on this point, but keep them advancing, allowing no check to take place. Feeding should commence when the pots in which the plants are to flower are full of roots—that is to say, as soon as the roots have pushed through the new soil and have reached the sides of the pots.

E. MOLYNEUX.

Bones as drainage for Chrysanthemums.—A member of the National Chrysanthemum Society informed me a few days since that the Chrysanthemum plants he is growing for exhibition are nearly ruined in consequence of the broken bones he used for drainage some three weeks before the time of writing having become rotten and infested with maggots. He adds that the bones in a dry state appeared to be an excellent sample. I thought the matter of sufficient importance to submit it to the opinion of a well-known expert like Mr. Norman Davis, of Camberwell, who states that the experience of the writer is a not uncommon one, and that he is constantly hearing of plants of Chrysanthemums being spoilt by the injudicious use of materials, singly or in the form of compounds, which are totally unfit for the purpose for which they are recommended. The bones used in this particular case had been imperfectly prepared, or they would not have so quickly fermented. So far as the presence of the maggots is concerned, they would not be likely to live long in the soil. There is no other remedy but to repot the plants, replacing the bones with a mixture of broken charcoal and old lime rubbish, which will have a tendency to sweeten the soil. In addition to this, Mr. Davis advises watering the plants as soon as repotted with luke-warm water, having previously dissolved half an oz. of common washing soda in each gallon. This will have the effect of clearing away any particles of sour, fatty substance that may be adhering to the roots, and then there is every probability a healthy growth will be made. Bones should never be used as crocks to provide drainage. Even when they have been properly prepared they are always liable to ferment and create life, but when mixed with the potting soil the case is different. The crocking of pots, says Mr. Norman Davis, is somewhat of a science. Chrysanthemum growers used to waste (as they considered it) the space at the bottom of their pots with broken pots; now-a-days a grower is apt to consider he cannot afford to lose such space, so there is a tendency to employ many materials that will act as food and drainage at the same time. But it is a hazardous proceeding without experience in such matters, and a grower may run the risk of killing his plants. Mr. Davis considers there is some danger in the use of charcoal by itself, inasmuch as it stores too large a quantity of chemical gas, which may injure the roots by burning or otherwise injuring them.—R. DEAN.

Chrysanthemum names.—The way in which the names of new Chrysanthemums are bestowed by the Americans is certainly far less confusing than that followed by our continental neighbours, for, especially in the case of complimentary titles, the same name is often bestowed by different raisers on two distinct varieties. A system of registration of names, which could easily be carried out, would obviate all this difficulty, and such a principle, if followed in this country, might with advantage be adopted in the case of all florists' flowers. A fruitful source of confusion, which is nowhere more noticeable than in the case of the Chrysanthemum, is naming varieties after different members of the same family, for in most cases the initial letter only of the christian name is given, so that mistakes very readily occur. A good illustration of my meaning is to be found in the list of new varieties on page 530 of THE GARDEN, for we find there Mr. B. Spaulding and Mrs. H. F. Spaulding, while Mrs. F. A. Spaulding and Mrs. T. H. Spaulding are older varieties. Ludi-crous mistakes are often to be seen at exhibitions of Chrysanthemums, the French names especially

being a stumbling-block to many, but when the different names approach each other so closely as in the above examples, errors are at some time sure to creep in.—T.

FERNS.

TREATMENT OF FERNS DURING THE SUMMER.

FERNS, as a rule, receive good attention during the early spring months as regards potting, watering, shading, &c., but I fear the same amount of care is not always bestowed upon them throughout the summer. As the season advances and the earlier growths mature it does not pay to neglect the plants; they rather require looking after even more closely than in the spring.

INSECTS,

which in the early part of the year were not plentiful or that had been cleaned off either by the removal of old fronds or by other methods, will now be again giving trouble if not well looked after. Both thrip and scale will cause considerable annoyance if they escape notice until the plants are seriously affected with them. This work, on the other hand, if taken in time is easily kept under; not so, however, when in the ascendancy, the plants being frequently disfigured for the rest of the season, more particularly in the case of thrip. Such a season as the present one has been favourable to thrip, a hot and somewhat dry atmosphere seeming to suit it all too well; whilst where the scale gives trouble most fear need be apprehended in a warm house combined with moisture, not that it will cease to thrive under more adverse circumstances. I regret to say still the greatest amount of filth which accompanies it will be found in a warm and moist atmosphere. Where the oldest fronds are badly affected it is better by far to remove them at once, provided they can be spared; the cleaning in many cases of such is a waste of time with no compensating advantage. The under fronds will be those most likely to be attacked; these in most cases can be spared if seen to in time so as not to cause the removal of too large a quantity. For the thrips nothing surpasses a good syringing or dipping in a weak solution of soft soap and tobacco water, or where possible two or three fumigations. Either remedy should be given in time so as to avoid repeated applications.

OVERCROWDING

the plants is another source of evil; this may possibly result from a previous luxuriant growth or by reason of having a larger stock than can be conveniently accommodated. It is well to have the plants thriving as it is to have them in good numbers, but when it comes to crowding the plants there are drawbacks that point to plants of lesser size or fewer in numbers. A deal may be done towards remedying this by shifting the plants to other quarters. Those Ferns, for instance, which are wintered and grown in the spring in the stove and that are known to be tolerably hardy can be kept for some months in a cooler and drier atmosphere with advantage both to themselves and others remaining in warmth. Again, other Ferns grown as a rule in a temperate house can be accommodated in a cool house and others in frames and pits even; anywhere, in fact, that is at all suitable rather than allow overcrowding, with its attendant evils, to ensue. In this

removal to other houses there are many advantages to be derived. The plants, for instance, become hardier and more enduring in growth, whilst additional material is also afforded for the conservatory or show house when flowering subjects are neither so much required nor any too plentiful.

WATERING.

is a matter calling for increased attention now, the pots being (or at least should be) well filled with roots. Ferns at any time do not look well if in pots or pans of excessive size, nor are they any the better for overpotting. It is far preferable to have the plants well rooted, so that they will take a liberal supply of water without that fear of soddening the soil that is ultimately the case when overpotted. There is a wide difference in Ferns as to the quantity of water they will absorb, but in no case is a dry course of treatment now to be recommended. Gymnogrammas when healthy at the root take a large supply; they must, in fact, have it if healthy plants are to be maintained. When these Ferns suffer and the fronds begin to curl, it is a most difficult matter to resuscitate them. The Nephrolepis take a liberal quantity. These Ferns do not show symptoms of distress so soon as many when in reality they are suffering, the result being seen a few weeks afterwards in the pinnae turning yellow and dropping off. In no case is it advisable to let Ferns droop before they are watered; some may come round again and not feel the effects materially, but the majority do so. The conditions of the house or fernery as to atmospheric moisture have an immediate bearing upon the plants in this respect. In a dry, airy house the plants will require almost twice the amount of water at the roots that others of the same kind would do in a moist atmosphere, yet if well attended to the former would thrive as well. This results from the roots in the former instance having more work to do, less absorption taking place through the fronds than under more congenial conditions. Where Ferns are found to dry up rapidly, it is a good plan to stand the pots in pans of water. I have tested this and seen it also adopted by other growers with the best results. Maiden-hair Ferns, for instance, which are well rooted may be safely stood in such as Strawberry pans. Where even it is not desirable to actually allow the pots to stand in water, it is a good plan to let them stand over it and upon bricks or rough drainage. Any Fern for which fears are apprehended as to water supply may thus be kept secure.

DOODIA.

Odontosoria tenuifolia (G. Myers).—This is the name of the specimen you send marked No. 1, and a very beautiful form it is of this variable plant. As it has a very wide distribution, it is not at all surprising that it should take on various forms. The very finest that I have seen is known in gardens as *Davallia Veitchii*, a beautiful plant, well suited for basket culture.—W. H. G.

Onychium japonicum (G. Myers) is the plant marked No. 3. Those numbered 2 and 4 I cannot name, they being sterile fronds of some *Lastreas* or *Polystichums*. *Onychium japonicum* is found in China and Japan, as well as various parts of India, and it makes an excellent Fern for the cool house, and even does well in the open-air fernery in many parts of these islands. The fronds you send appear to be very finely cut.—W. H. G.

The Mountain Bladder Fern (*Cystopteris montana*).—J. Early sends me a fine frond of this Fern, which he gathered last year in Norway, asking its name, and if it can be grown in England. This species when dried much resembles *Cheilan-*

thes viscosa from Central America and Mexico, but it is a British plant, and I have specimens of it gathered on Ben Lawers, in Perthshire; it is also to be met with on several of the higher mountains in Scotland, although it appears to be everywhere rare. It is also found in various parts of Northern Europe and on the Rocky Mountains of North America. I have always found it a difficult plant to manage under cultivation. It likes a moist shady situation, an abundant supply of water, to have Sphagnum growing about it, and a nice cleft between the rocks for its roots. On the other hand, many assert it is not difficult to grow, but this does not accord with my experience.—W.

Adiantum venustum, from Messrs. Birkenhead, is a remarkably handsome Fern, which does well in the temperate fernery, but I do not think it will succeed in the open air in the winter. It is a common species in Northern India, growing at from 7000 feet to 10,000 feet altitude. The fronds are about a foot long, the pinnae firm, finely toothed, and of a somewhat glaucous green beneath. This species is not so often seen as it deserves to be. Its fronds are harder than those of the generality of Maiden-hair Ferns, thus fitting them for cutting.—H.

Lepicystis squamata (G. Todman).—You have in this a very elegant Fern, and you did quite right in allowing it to become fertile before sending it for a name. It is the plant more commonly known as *Polypodium squamatum*. The fronds, rising from a creeping rhizome to 2 feet or more high, are pinnatifid, the pinnae being divided nearly down to the rachis. They are from 6 inches to 8 inches in width, rich green above, densely scaly beneath. It is a fine stove plant from the West Indies.—G.

Cheilanthes capensis (G. Todman).—This plant partakes of the character of an *Adiantum* very much, and I do not wonder at you so naming it, for it has been called an *Adiantum* and an *Adiantopsis* by several Fern authorities. Your frond, which is about 4 inches long, is nearly its full size. It is a superb Fern, suitable for the cool house, and I used to think it adapted for a Wardian case, but I have found that when so placed the pinnae turn black from getting too wet. It is a native of South Africa.—W. H. G.

Ferns from Sale, Cheshire.—I have received a batch of Ferns for determination, and amongst them is a frond labelled *Adiantum pubescens*, which Messrs. Birkenhead say is called *hispidulum* in some other gardens. These two names apply to the same plant, and *hispidulum* appears to be the name having the preference. The plant called variety *tenellum*, a name given by Moore, is quite correct. The form called *hispidulum fulvum* is the true *fulvum* of Raoul, which comes from the Fiji Islands as well as New Zealand. This may be the reason of the other form, called *fulvum*, being different. The *Hypolepis* appears to be *H. amaurobachis*, which I do not think has been found in New Zealand, but is Australian. The two forms of *Davallia* called *pentaphylla* and *pycnocarpa* appear to be different, and if they keep as distinct when growing, I should retain the names, although I have seen *pentaphylla* with three pairs of pinnae besides the terminal one. Is there any difference in the growth of the plants? *Davallia elata* is quite correct, I should think, but I should be glad of a specimen when fertile. *Trichomanes humile* appears to be *T. angustatum* (Carm). It is broader in the pinnae than the specimen of *humile* I have. The other species appears to be *T. flabellatum*. I should like to see examples of the kind you had from New Zealand under this name. *Lomaria attenuata* appears to be the *L. gigantea* of Kaulf, a South African plant, but it is very difficult to name a species from a single sterile frond. The plant sent that has a creeping rhizome appears to be *Polystichum coriaceum*. The rest I will give my attention to next week.—W. H. G.

The English Flower Garden.—Design, Views and Plants. Third edition, revised, with many new illustrations. London: J. Murray, and through all booksellers.

COTEHELE, CORNWALL.

This is one of, if not the most unique old place in the west of England, and a paradise to the antiquarian. A local guide book says:

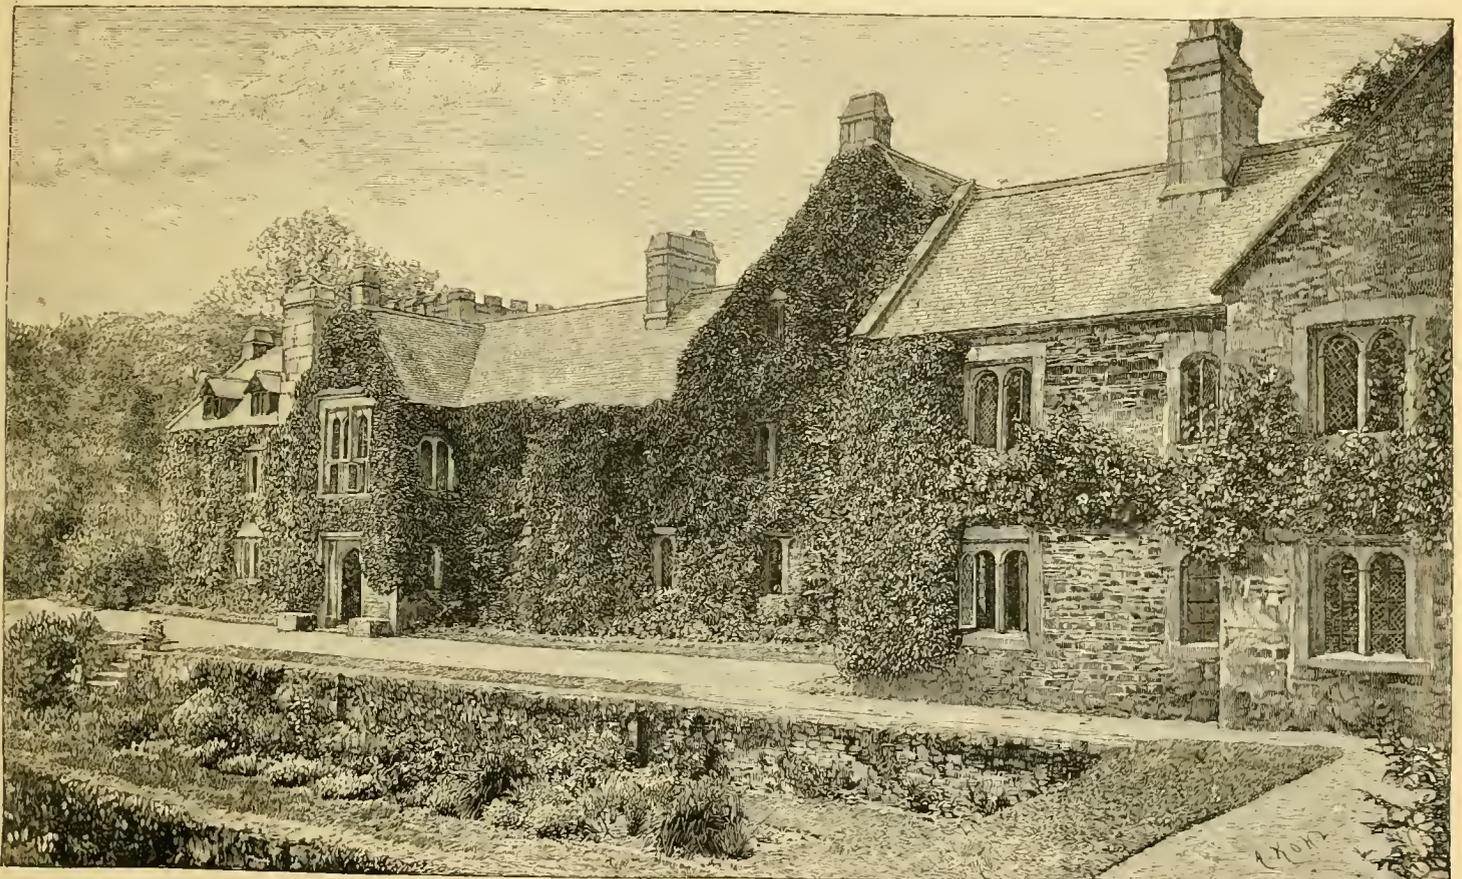

It is impossible, indeed, to conceive anything better than Cotehele as an illustration of the home life of our mediæval ancestors. The building, the furniture and appliances, as they are to-day, so were they 300 years ago; as it was in the days of Henry VII., so it is in those of Queen Victoria, and so, thanks to the preserving spirit of the Edgumbes—the Mount-Edgumbe family—it is likely to remain for centuries to come.

These remarks apply to the exterior (with which we are at present most concerned) with as much force as to the interior. The quaint old terraces—four in number—are laid out in

brated Morwell Rocks, about three miles distant, and a full view of the old town of Calstock, lying in a direct line with the Morwell heights and about half-way distant.

Cotehele estate appears to have suffered most severely in the great snow blizzard of 1891, thousands of large trees, including English Oaks and Spanish Chestnuts, having been torn up by the roots. A giant among the Chestnuts that had withstood the fury of the gale was still standing in a somewhat sheltered nook. This at 3 feet from the ground measured 21 feet round. One extensive hill-side exposed to the full force of the gale was quite stripped of all its magnificent timber. The whole of this hill is now (June

by road and river. The principal sorts grown are President, Paxton, and Alice Maud. Many of the newer varieties, including Jubilee, The Captain, &c, have been tried, found wanting, and discarded. Sir Charles Napier did well, but was too late to command the best prices. The present season appears to have been most satisfactory and the fruit has paid the growers well. At the time of my visit Cherry and Raspberry picking was going on, but both crops will be very light, not more than half the average, on account of the severe drought. One grower kindly showed me his accounts for last year, and amongst other items I noticed the sum of £147 odd as paid for Raspberries consigned to one buyer

Cotehele House, from the east. Engraved for THE GARDEN from a photograph sent by Mr. Hayman, Launceston.

old-fashioned beds and borders filled with hardy flowers. No carpet bedding or any other modern monstrosities have been permitted here. Very little masonry is seen in the formation of the terraces, and the old walls are mantled with various creepers, including Vines, Ampelopsis, Myrtles, Clematis, Magnolias, Jasmynes and Ivy.

The engraving gives a faithful representation of one side of the house, looking east. The house is used as a shooting-box and dower residence by the Earls Mount-Edgumbe. The building is situated on the summit of a high hill on the Cornish side of the river Tamer, commanding extensive views of its winding course, also of the distant ranges of hills in both Devon and Cornwall, including the cele-

brated Morwell Rocks, about three miles distant, and a full view of the old town of Calstock, lying in a direct line with the Morwell heights and about half-way distant.

This place is in the centre of very extensive fruit gardens, hundreds of acres being devoted to Cherries, Strawberries, Raspberries, Plums, &c. Strawberry picking commenced this year on April 18, eleven baskets having been despatched to London on that date. The last pickings took place the end of first week in June. Some idea may be formed of the quantities sent off to the metropolitan, midland, and local markets from the fact that this year 118 tons were sent from Beeralston Railway Station, besides the quantities sent

in London. In every direction I found abundance of fruit, but it will be impossible for the trees to mature their heavy loads unless we get a speedy change in the weather. A plague of caterpillars had swept over one part of the district, leaving the trees in their course stripped of all their foliage. Apples, Pears, Plums and Cherries, as well as bush fruits, seem to have suffered alike.

Cotehele Quay is situated in the centre of this extensive fruit growing district, and can be easily reached by steamboats which run from Plymouth every day at tide time.

W. S.

Saccolabium curvifolium.—This is not only one of the brightest coloured of Saccolabiums,

but may even in this respect be said to be surpassed by few Orchids. It produces short erect spikes, on which the flowers are thickly crowded, their colour being a brilliant orange-scarlet, the effect of which is heightened by the apex of the column being violet-purple. The species is easily distinguished from any other *Saccobolium* by its foliage. The leaves are narrow, about 8 inches long, and very markedly decurved, the apices being jagged. This plant is found in Assam and Burmah, but not in Ceylon or Java, as has been stated. From the latter island comes *S. miniatum*, a species very much like *S. curvifolium* in the shape and colour of its flowers, but always recognisable by the shorter, straighter leaves. According to my experience it also flowers a couple of months earlier than the one under notice. It has nevertheless been a good deal confused with *S. curvifolium*, a figure of which appears in the *Botanical Magazine*, t. 5323, as *S. miniatum*.—D.

ORCHARD AND FRUIT GARDEN.

SUMMER PRUNING AND TRAINING OF FRUIT TREES.*

It has been said that the principle of summer pruning of fruit trees is one of those phases in the successful cultivation of fruit grown in the open air upon which cultivators are not agreed. Certainly there is a great diversity of opinion as to the time when and the extent to which the trees should be operated on, and there are some people who go so far as to question whether summer—or, indeed, any—pruning is really needed. This being so, some would perhaps say, "If there is such difference of opinion, who is to decide which is the correct mode?" or, "If such differences of opinion exist, it can surely matter but very little whether summer pruning is practised or not." I am fully convinced that when it is judiciously performed summer pruning is one of the greatest possible aids towards the successful cultivation of fruit in the open air; and amongst really practical gardeners I do not believe there is any difference of opinion as to the system itself, but only as to the time and manner of performing it. At the same time there appears to be amongst some an increasing tendency to allow outdoor fruit trees to grow with far greater freedom, and to allow them to assume what is called a natural form, with but little, if any, pruning at all. This, I think, is an evil; for if trees are allowed to carry their whole natural free growth they will soon become so crowded that, instead of being able to produce fruit of fine quality, it will be small in size and poor in flavour, and only appear at the outer edge of the tree, and not equally over the whole, as it does when the growth is kept well balanced by judicious pruning, and light and sunshine have free access to all parts. There can be no mistake as to the ill effect, so plainly visible to all competent observers, of the rigidly pruned-in trees; but do not let us go to the other extreme and allow the trees to grow into a tangled mass for the want of a little timely attention and restraint. Considering how much the cultivation of fruit is now engrossing public attention, it will be as well perhaps to consider more at length which is the best system to adopt, and what advantages are likely to be obtained by what I may term a judicious system of summer pruning. Summer pruning is not by any means a new process,

for although the cultivation of fruit trees has advanced considerably during the past few years, summer pruning in some form or other was practised years ago, but whether judiciously or not is at present an open question, though until quite recently the past generation of gardeners, or rather their practice, was held up to younger cultivators as a beacon light towards which they should all steer. Those bygone gardeners prided themselves especially upon their correct methods of training fruit trees, particularly those growing against walls; but, however clever they were in their training, the fruit was often only conspicuous by its absence. It has indeed been said that the time and attention these old practitioners bestowed upon their trees were more for the sake of extreme neatness of outline than for the production of fruit, as the fruit obtained was, considering the time bestowed upon the training, practically *nil*. Their bush and pyramid trees gave one the idea of topiary work, so shorn were they of extending growth throughout the season. Now although I have a great partiality for a well-trained tree, yet I should not by any means commend a system or a tree which did not in due season produce fruit commensurate with the time and attention bestowed upon it. But, on the other hand, I say that those who denounce judicious training as being unnecessary are not advancing the best methods of manipulating fruit trees. With trees growing against walls, for example, the better they are trained, the easier they are to manage afterwards, and the little extra attention bestowed upon them in their earlier stages is well repaid when they are once established, as a man can see at a single glance which shoots want removing and which not, and so he will not have to waste his time in pondering over the work, as he almost necessarily must do with ill-trained trees. Leaving out of sight for a moment the argument that well-trained trees are beautiful objects in any garden, I maintain that fruitfulness may be made to run on parallel lines with training, although in one sense, of course, the form the tree is to take is only of secondary importance, as it is the quantity and quality of the fruit produced, by which its value will be gauged.

The dwarfing stocks now largely in vogue have helped to revolutionise fruit growing, or rather the pruning that is required, for with the advent of these stocks, which supplied a want long felt, trees suitable for the smallest gardens or for special positions could be grown of a small restricted size, and be also made fruitful without much pruning or pinching being necessary to produce them. It was the attempt to rigidly restrict the old trees grafted or budded on what is known as the free stock which led to the abuse of summer pinching, as any attempt to dwarf trees on these free stocks by summer pinching or pruning only led to disastrous results, the continual pinching or pruning only causing the trees to produce a thicket of shoots and unfruitful spray. Regularly as the season came round the trees had to undergo the same operation, with the same result of little or no fruit following. In the treatment of such trees as these grafted on free stocks we have made a decided advance, as it is now fully recognised that by allowing them freer extension fruit-buds are formed naturally, and the trees to a certain extent, and after a certain time abandon their free or semi-wild mode of growth. Any kind of fruit tree growing on the free stock may thus be made to assume a restricted form by being allowed a semi-extension growth. I have often been struck with the fruitfulness of Apples, Pears, and Plums growing in the open when allowed

to have more of a free growth accorded them, but not to the extent of running wild so as to appear unkempt. I cannot sufficiently condemn what is by no means an uncommon occurrence now-a-days, viz., the stepping right out of the groove of rigid pruning into the very opposite extreme of absolutely natural growth, without any attempt or thought of even thinning out the shoots, so as to allow light and sunshine to have free access. This is where fruit culture is in danger of being abused now, and it behoves those who undertake the culture of fruit in the open air to practise the best possible system whereby the trees may be made fruitful, and also produce it in such a form as will ensure good quality.

Before discussing the most suitable methods of summer pruning and training I will just refer to the treatment of trees which have in the past been subjected to the most rigid system, and which are consequently almost devoid of fruit. They may be trained to walls or growing in the open as pyramids or bushes; either will illustrate my point. Some time during the month of June a thicket of shoots will be seen growing from each tree, as the more they are pruned the more they appear to grow. The centres of those growing in the open will be found so thick, that light can barely penetrate, and the natural and obvious result is that the main lengths of the branches are utterly destitute of fruit-buds. With such trees as these—and they are by no means uncommon—the most judicious and sensible course would be not to cut these shoots off wholesale, but to well thin them out in summer, even going to the extent of cutting out some of the main branches, so as to allow direct sunlight to reach right up to the main trunk. There need not be any fear as to the future well-being of the tree through cutting out superfluous branches whilst they are growing, for the wounds will all become well callused over by the end of the season. By allowing the light to have free access at this early part of the year, instead of waiting until the trees are dormant, a season is gained, as the sun is enabled to exercise its benign influence on the foliage whilst in active growth; for, as is well known, no elaboration of the strength of the tree so as to produce fruit-buds can take place whilst the tree is enjoying its winter sleep. True enough, it is wise to look over the trees whilst they are at rest to shorten in or remove any obstructive branch, and with standards this is the most sensible course to adopt; but with what are termed bush or pyramid trees the case is different, as they are more easily got at, and one great advantage of pruning in summer is that what may appear a favourable distance apart for the branches whilst the foliage is off presents quite a different appearance when the trees are in full growth, so different, in fact, as sometimes to make them appear quite crowded. Trees which are pruned during the growing season certainly require to be looked over at the winter season, but only to thin out a growth here and shorten a shoot there, so as to balance the growth or shape of the tree, and nothing more. During the past few years I have allowed all our Plum trees, bush as well as standards, to go practically unpruned, save the shortening of a branch here and there to balance the growth of the tree, and I never saw trees in a more fruitful condition, fruit-buds forming right up to the tips of the two-year-old wood; and though very little annual growth is made under this system, yet what there is, is short and fruitful. Now if these trees were subjected to rigid annual pruning, a thicket of spray is all we should obtain for our pains,

* A paper read before the Royal Horticultural Society, June 7, 1892, by Mr. A. Young, Abberley Hall Gardens.

Cutting out branches wholesale after the fruit is gathered, where they appear too crowded, is a much better plan than shortening the shoots and spurring in the laterals, with the idea of producing formal pyramids.

As a general rule wall trees are the first to require our attention in the matter of summer pruning; and amongst these the stone fruits should have precedence, and the operator must be early amongst them, for if pinching, dis-budding, or pruning be neglected for any length of time, the trees very quickly become unmanageable, the basal leaves in many instances turning yellow and dropping off, on account of the exclusion of light. Trees growing against walls suffer from neglect much sooner than those growing in the open. These latter have light all around, whereas those on the wall get it on one side only. Peaches and Nectarines need not be very specially referred to, as with these the principle is more readily understood, even if not always acted upon, and cultivators are more agreed on how the trees should be managed. In passing, I would say that it entirely depends on how the shoots are treated during the growing season, especially during the months of May and June, as to whether Peaches may be successfully cultivated on open walls or not. Crowding the shoots in the early stages and the neglect of what is known as dis-budding are two of the main causes of failure, combined, of course, with the insects, for, as is well known, the Peach is prone to the early attacks of insect pests, and if their destruction is not persevered with during the first few weeks of the tree's growth, there will be very few shoots left to disbud. It is the retention of the earliest shoots which is needed, as when secured they have the whole season in which to make their growth and to become efficiently ripened. The dis-budding merely consists in taking off all shoots not required for the extension of the tree, and the retaining of one well-placed growth at the base of the fruit-bearing shoot, and another at the end to draw the sap. Never, however, lay in more shoots than will be required for the furnishing or extension of the tree, and all shoots retained should be well exposed to the light to ensure their being well ripened. After the fruit is gathered, the best course is to go over the tree and cut out what is known as old bearing wood and such as will not be required for the extension of the tree. By cutting out or pruning at this stage, if neatly done, the wounds quickly heal over and the shoots remaining are more fully exposed to the ripening influences of the sun and the air. Apricots, Plums, and Cherries—except the Morello, which requires somewhat different treatment—may all be referred to together, as the same general principle is applicable to each, all being adapted (when grown against walls) for the style commonly known as "fan" training. They are all subject also to the evil known as "gumming," a disease peculiar to stone fruits, but which is more prone to attack them when the trees are subject to hard winter pruning instead of to judicious pruning during the summer. The fruit-buds are formed on natural spurs, and also on the spurs formed by pinching or summer pruning, but the best course is to manage the trees so that these natural spurs will form plentifully, as they are more likely to produce both better and more abundant fruit than the pruned spurs are. What we have to consider, therefore, is which is the best system to pursue so as to cause these natural spurs to form. Commencing, then, with young trees, the cultivator should aim at securing a well-balanced tree,

with fruit-bearing wood equally distributed over the whole surface, bearing in mind to get the wall also well furnished. All young trees when growing against walls have a persistent habit of a few shoots or branches trying to get quickly to the top of the wall at the expense of the lower branches, and it is generally a few of the leading ones towards the centre of the tree which acquire this habit. This supplies its own lesson, viz., to check these strong shoots so as to throw the strength into the lower branches. The lower branches may require but little shortening when first planted, but the centre shoots must be checked, so as to secure a well-balanced tree. I think it is also a bad practice with trees of the stone-fruited section to train a shoot as a leader straight up the wall. If a young tree had six shoots I should train three on each side, leaving the centre open. If there should be an odd shoot, even if it be started in the centre, it should be cut back more severely than the rest, training the resulting growths right and left. Some people are of opinion that the shoots of a young trained tree when first planted should be laid in intact without shortening; but if such trees succeed in forming well-balanced growth, it will be found to be more the exception than the rule. It may appear out of place to refer to the shortening of these dormant shoots in a paper on summer pruning, but it is necessary to describe the formation of a young tree. In training the young shoots which are to form the main branches, each leader should be trained to take a straight course, so that it will not interfere with its neighbour. Sufficient shoots must be laid in to form the framework, and where they are too thickly placed they must either be pinched back to form spurs, or, if these are not needed, cut them clean out with a sharp knife. Sometimes a shoot or two may be forging ahead at the expense of the others, and be causing them to be weakened thereby; if so, pinch out the points, but not otherwise. It is these equally balanced shoots, laid in intact, which form natural spurs. Some would shorten all these shoots back again, if only to the extent of just taking off the tips. But this is not the best course to pursue. If a shoot should want shortening so as to equalise the growth or to form extra shoots, shorten it, but not otherwise. By merely taking off the tips it causes a mop-like growth to form at the ends, and the lower part becomes bare. Natural spurs are far more likely to form when the shoots are laid in their whole length. Secondary branches must also be encouraged from the leading branches, but the same principle holds good with the whole. The crossing of branches, or the running into each other, must of course be avoided; but with the framework of the tree thus properly laid the summer pruning may be very expeditiously performed. Allowing the young growing shoots of either Apricots, Plums, or Cherries to grow ahead until far into the season before being checked results in the trees becoming gross and unfruitful, and when in due course they are shortened back, instead of assisting in forming fruitful spurs, it only paves the way for other strong shoots to follow, and the trees gradually merge out of their fruitful habit, and probably gumming ensues. With young trees, and especially Plums, there appears to be a natural tendency for the shoots to form more thickly towards the ends of the branches; therefore, these should be pinched first, so as to equalise the sap more in the lowermost parts. All shoots not required for laying in must be pinched back to the fourth or fifth leaf, and after this first pinching any growth which may follow on

fruitful trees rarely exceeds what is needed for the health of the tree. The growth needed is a kind of semi-extension, and if this will not bring the trees into a fruitful condition, or if the growth should be extra strong through a too rich root-run, nothing short of root-pruning will bring the trees into a satisfactory condition.

PEARS ON WALLS.

These are trained chiefly as fan-shaped, horizontal, and cordon trees, though there are several other forms, but the pruning of each will be very similar, or more or less according to the different stocks the trees may be grafted on, as the Pear when on the Pear stock produces a far stronger tree, and pushes out more breastwood from the spurs, than when grafted or budded on the Quince. It is with Pears, I think, that the greatest errors of summer pruning have been practised, and it is the particular point which most needs clearing up. In their anxiety for extreme neatness, gardeners in days gone by commenced pinching the shoots as early in the season as possible, and the practice was repeated at intervals throughout the whole season, and the result was that fruit-buds were formed very sparingly. No amount of summer pruning or pinching will cause the formation of fruit-buds on the current year's growth. It is quite evident that summer pruning must be practised, or the fruit-spurs against the wall would be deprived of light, and this is what is needed to ripen up the buds. It will also be understood that any Pear trees which are growing strongly against walls, as old trees on the Pear stock are somewhat prone to do, will not be able to be brought into a fruitful condition through summer pruning alone. It is root-pruning which such trees require to bring them into a fruitful condition; and in passing I may say that I have seen some very successful experiments attending the root-pruning of old unfruitful trees. During the formation of the young trees, and whilst they are extending, it is one of the greatest possible mistakes to pinch or shorten the leaders of the main branches before they have filled their allotted space, be they on the Pear stock or on the Quince. Just shortening the leading shoot has a tendency to form a bunch of shoots at the end, and leaves a vacant space of perhaps 18 inches without one lateral shoot or fruit-bud forming. Shortening back also has a tendency—even when done sufficiently close to force all the latent buds at the base into starting—of giving the tree a gross habit, so that it does not come into a fruitful condition so early as it otherwise would; whereas by leaving the leader intact the buds will push out evenly, and, instead of growing into strong shoots, they will form natural spurs, and the tree will commence bearing much earlier. In the case of cordons, the leader must be left to grow ahead unchecked until the top of the wall is reached, which has the result, as previously noticed, of natural fruit-buds forming along the whole length; but if they are shortened back, coarse spurs are apt to form, and these during the growing season throw out a quantity of breastwood. When cordons are starting into growth and are fairly well advanced, there sometimes appears a shoot here and there growing strongly ahead, perhaps close to the top, and consequently the leader may be suffering on account of this strong shoot drawing away the sap. In cases of this kind it is much better to check these strong shoots, so as to equalise the sap and throw the strength into the leader. After a fairly long experience with cordon Pears, I find the best course is to go over the trees about the middle of June and shorten back the strongest shoots (not the leader) to about five leaves, allowing the

weaker to remain as they are, and then towards the end of August to go over them again, shortening back to four leaves or thereabouts. If the trees are carrying a fair crop of fruit, very little secondary growth will follow; but if it should, the bud at the end of each shoot will almost invariably draw off the sap, and so prevent the starting of what should be fruit-buds. The necessity of securing the leading shoots, so as to prevent injury from wind, cannot be over-estimated. This should be done early in the season, as if left for too long a time, they cannot be trained in so evenly and are also apt to be broken from not being so pliable. These are minor details, but they require close attention if well-trained trees are desired. Coming now to the larger trained trees, such as fan-shaped, horizontal, palmette Verrier, or whatever the form, the principle is the same even if the method be somewhat different. In training the trees, take particular care to lay the branches in straight. With fan trained trees in course of formation, it will be understood that a sufficient quantity of shoots to form the tree will not be able to start direct from the main stem, for if this were attempted the branches would have to be very close together to start with, and by the time they had reached the limit of the wall they would be very wide apart. It will, therefore, be necessary to shorten the leaders at convenient distances, so as to enable a well-balanced tree to be formed. With horizontals the central leading shoot should be shortened back during the winter to about 10 inches, when three shoots will probably form at the top; if more than three form, thin them out to that number. The centre shoot should be trained straight upwards, and the two others right and left of it. The branches are generally trained 9 inches apart, this being three courses of bricks. If by chance only two shoots form, insert a bud during July in the vacant space. In the southern counties of England it may be safe to shorten the leader as soon as it has become firm, so as to form an extra pair of branches in a season, and I have known such shoots to turn out satisfactorily, but in the north this would not be a safe method to follow. During the formation of the young trees, if there should be a shoot near the leader growing ahead and so acting as a "robber" to the main shoot, do not hesitate about shortening it back. As regards the summer pruning, it is the breastwood which most concerns us. Do not upon any account practise early pinching, thinking that by so doing fruit-buds may be formed. More probably such treatment will but add fuel to the fire, causing the growth of extra spray. The best course is to go over the trees about the middle of June, and shorten back all the stronger shoots to about five or six leaves, leaving the weaker ones untouched. Towards the end of August a general summer pruning should take place, all the shoots being shortened back to four leaves. Trees that are in a fruitful condition will not throw much breastwood, so that going over the trees twice will not take up much time. If the trees are only gone over once, there is the danger that if left too late it will cause the trees to become gross, and if done too early a quantity of secondary spray is certain to form, and by the end of the season the trees will have the appearance of not having been pruned at all.

TREES IN THE OPEN.

It is in the treatment of these that the greatest changes have occurred in people's ideas as to the extent of pruning necessary. There cannot be any gainsaying that, if we are to

secure fruitful trees, the old system of close pruning must be abandoned. The more we prune the more we shall have to prune. The amount of pruning really necessary will depend principally upon the formation of the tree during the first year or two after being planted. If it is allowed to grow ahead without any check, the growth will in most cases be unequal and crowded. But the early summer pruning of these open-air trees is a decided mistake, for when pruned or pinched early, secondary growths will almost certainly follow, and these cannot possibly have time to become well-ripened wood, so as to enable their being retained as permanent shoots. Occasionally a shoot may require checking early in the season, but only on quite young trees, which may, perhaps, have a shoot or two growing too strongly ahead, while the weaker are naturally suffering for it, or at least being checked in their progress of assisting in forming a well-balanced tree. Trees which are being allowed to form a semi-extended habit should not require pruning before the end of August, and the amount necessary will, of course, be determined by the kind of stock the trees are grafted upon. Where Apples on a free stock and Pears on the Pear stock are allowed to have freedom of growth, they early become of fruitful habit, which they retain without making gross growth. At the end of August the growths will have become of a woody nature, and then any spare shoots and those likely to crowd the centres, and so prevent light and air from having free access, should be pruned in to three leaves. Any extending leaders which are growing too freely must also be shortened. The style of tree will indicate the amount of pruning necessary. The time for removing any solid branches which are crowding up the centre will depend principally upon the fruit hanging upon them, as no one would think of removing them until the fruit is all gathered. This is the time when all bush or pyramid trees should have a general overhauling, as any crowded branches may then be seen at a glance, and should be removed forthwith. The wounds quickly heal over, and the remaining branches would derive the benefit of the extra sunlight and air. This pruning must take place before the leaves fall to be of any real benefit. As regards Cherries and Plums, the thinning or pruning necessary for them will resolve itself more into thinning out any crowded branches and shortening rampant leaders than to regular pruning, and by this course the trees will be enabled to become more fruitful than where close pruning is rigidly adhered to. By pruning during the month of September, the wounds quickly heal over and do not become subject to gumming—a disease Cherries and Plums are very prone to if pruned whilst in a dormant condition.

I am aware that closely pinched or pruned trees may be made fruitful by regularly subjecting them to root-pruning, but I think the course I have detailed will result in more fruitful and healthier trees.

Melons cracking.—I have a two light frame which I put on a hot bed of manure early in the spring, and planted Melons in it, Munro's Little Heath. They have gone on very well until now. They are nearly at their stage of ripening. They have been well attended to both as regards giving air and watering. Some of them are beginning to crack. I have only four fruits to every plant.—W. M.

* * * It is some years since I grew Munro's Little Heath in frames, but from what I know of it am somewhat surprised at the fruit cracking prematurely, or even cracking at all. In common with the Canteloups, of which I believe it to be

only a variety, the fruits are large, deeply ribbed, and have a rough, warty skin, their strong constitution and free-fruiting habit rendering them particularly well adapted for frame culture. In "W. M.'s" case the plants must have been somewhat highly cultivated and in the best of health when the fruits were beginning to ripen. When the drying-off process is commenced long before the fruit has arrived at its natural ripening period, or again when the foliage is lost from other causes, notably red spider, it is not often that any cracking of fruit takes place, or that it is fit to eat. In frame culture, however, there ought to be a certain amount of drying off practised both with a view to improving the quality of fruit and prevent cracking. When the fruit commences ripening or changing colour, there ought to be enough moisture in the manure underneath to keep the haulm fairly fresh, and no water should be applied from the surface, or any damping down carried out. Sudden increases of the temperature and accumulations of vapour in the frame should also be guarded against, air being given directly the sun strikes on the glass in the morning, and increased considerably before it becomes very hot, being gradually taken off in the afternoon, but not wholly, before 4 o'clock. On dull days also give a little air, or it may happen that a sudden burst of sunshine will bring about a state of affairs in the frame most prejudicial to the fruit before it can be remedied. When the foot-stalks of Melons are cracked all round, cutting may be practised as a preventive of cracking across the fruits, the latter being sufficiently forward to admit of their being well ripened where they are, but detached from the plant. It is the thin, smooth-skinned varieties, of which Victory of Bath is a good type, that are most addicted to cracking under frame culture.—W. I.

COLOURING WHITE GRAPES.

If the generally accepted theory that white Grapes require much more sunshine to colour and ripen them properly than do black varieties is the correct one, then ought the former to be exceptionally good this season. That all will ripen considerably earlier than usual is very certain, but it remains to be seen whether white Grapes will generally be much better than usual. At present they look remarkably well in several vineries that I have visited, but in others the prospect is anything but satisfactory, the excess of sunshine over and above what usually falls to our lot during the spring and early summer months evidently not having been properly dealt with. Black Grapes can be hurried along too rapidly for them to colour properly, and why are white varieties supposed to be capable of standing or being in need of different treatment? I hold that Grapes of any kind, white varieties included, should be given good time in which to colour and ripen, and all their good properties are then well developed accordingly. Doubtless very good produce can be and very often is had at the end of about four months from the time of starting them, but it is better for the Vines, and from a private, not a market grower's point of view, better also for the owner, that five and in some cases six months be allowed before many bunches are cut. Naturally, very much depends upon circumstances. For instance, some varieties mature more rapidly than others, inside borders being also in favour of more rapid forcing, while some localities have the benefit of much more natural heat and sunshine than others, nothing short of an extra free application of fire heat compensating for this.

All this is very well understood, in many cases being acted upon accordingly, but I have yet to learn why it is that white Grapes should receive such special treatment, more particularly during the ripening period. Why

are they so often much exposed to a strong sunshine when the black varieties are so carefully shaded from it? In one case the sunshine is supposed to lay on the colour and in the other to take it off, and to a certain extent the supposition is correct. I repeat to a certain extent, as the theory will not stand the abuse to which it is too often subjected when practised. If bunches of black Grapes are heavily shaded by a thick canopy of leaves and receive plenty of fresh air while ripening, there is every likelihood of their colouring very satisfactorily, but in all probability the flavour and keeping properties would have been better developed if much less shade had been accorded. As a matter of fact, they can be well coloured and most perfectly ripened under a thin covering of leaves, and what suits them is equally efficacious in the case of white Grapes. When the leaves are very carefully tucked or tied back from over the bunches of the latter, so as to let as much sunshine as possible strike full on the bunches, this apparently does hasten colouring considerably, but who has not been disappointed with bunches thus treated? They may appear very satisfactory when hanging, but when they are cut and fastened perhaps to a show board, the satisfaction diminishes considerably. The face of a bunch may be fairly well coloured, but the point and sides show a greenness not noticeable before cutting, and which cannot be got over or hid in any way. In very many instances the sunshine striking full on berries not previously exposed and, so to speak, hardened, disfigures them badly, the grizzled patches or rusty appearance denoting only too plainly that the attempt to hasten colouring in a somewhat artificial manner has failed badly. I have seen hundreds of bunches disfigured and practically spoilt, many berries being scalded, and have damaged a few score myself by exposing them prematurely to bright sunshine, and it is to be hoped my remarks will prevent many readers from commencing or persevering with the practice. According to my experience, the only time when the bunches should be exposed as much as possible to the full sunshine is previous to and during the flowering period. If this is done, the flowers are strong, open well together and simply set to perfection. Muscat of Alexandria thus treated may be set as surely in a mixed house as it can under any special treatment—a fact that I have frequently demonstrated, the bunches this year being as solid as those of Madresfield Court alongside. The rods being fully 4 feet apart, the laterals somewhat thin and all stopped at the second joint beyond the selected bunch on each, there is a slight division between each Vine or rod, and a certain amount of subdued sunshine reaches the bunches both from this slight opening as well as from between the uncrowded leaves.

If other conditions are favourable and good time allowed, or say not less than six months, from the time of starting (February 1 or thereabouts) the berries ought all to be of the clearest amber, and which I maintain is attainable by no other means. Six months may seem a long time for the growth and ripening of a crop of Muscats, but when the berries are extra large and solid, yet another two months is needed for colouring them to perfection, the true Muscat flavour also not being developed much under that time. This class of Grapes requires more heat during the ripening period than is good for black Grapes growing in the same house, at any rate as far as colouring is concerned, plenty of fire-heat and a free circulation of air being needed throughout. I am contented with

somewhat smaller berries, and which ripen surely enough in a somewhat airy house, the temperature of which where the Muscats are located seldom falls much below 65° or greatly exceeds 70°. In cooler parts of the same house, that is to say, at a well-ventilated end and along the front, Madresfield Court and Black Hamburg are grown, and a rod each of Foster's Seedling and Buckland Sweetwater is also worked in. Both of the latter white varieties receive treatment almost identical with the Muscats, and the former has done me good service repeatedly, Buckland Sweetwater also doing well. Neither of them will bear full exposure to fierce sunshine, but they will colour beautifully under a thin covering only of their own leaves. Golden Queen and Mrs. Pearson are quite as slow in ripening as the Muscat of Alexandria, and the only times I have ever had them both at their best were when they were started equally early or not later than the early part of February. This season, owing to the more rapid progress made, the chances are those started in March in a mixed house of late varieties will ripen more satisfactorily than usual or without the expenditure of much fire-heat in August or September. The same remarks apply to White Tokay and Calabrian Raisin, both of which are very slow in colouring, and when started late not unfrequently fail to colour properly.

Judicious ventilation and a moderate amount of light and sunshine alone will not, however, ensure the perfect colouring of white Grapes. Other essentials to success, notably a healthy root-action, sufficient moisture and food at the roots, a clean top growth, and the avoidance of overcropping, must not be lost sight of. Can it be denied that overcropping is more often resorted to in the case of white varieties than with black Grapes? At any rate, the consequences of this short-sighted practice are not sufficiently realised, especially in the case of Muscats. They will succeed well up to a certain point and then collapse badly, the berries shanking and shrivelling wholesale, not a presentable bunch being seen in the house by the end of August or thereabouts. Foster's Seedling overcropped is scarcely recognisable, the bunches being loose, the berries small, round, green and watery. Buckland Sweetwater is less often overcropped, for the simple reason that the Vines will not constantly produce more bunches than they are capable of properly ripening.

W. IGGULDEN.

RED SPIDER ON GOOSEBERRY BUSHES.

This has been very prevalent throughout the long drought, and has worked such havoc that some growers are quite discouraged. As Mr. Allan said in a recent number of THE GARDEN, not a few of the remedies prescribed with so much confidence either fail or prove as bad or worse than the disease. I also agree with this writer that the Gooseberry spider seems larger, different, and more difficult to kill than the usual form. But what I am most anxious to be more fully informed is Mr. Allan's remedy, viz., Bentley's soluble paraffin. Is it really soluble and easily applied, of uniform strength throughout without the usual risks of paraffin accumulating on the top, and so proving strong enough to scorch and burn, or weak enough to prove ineffective? There is no doubt of the potency of paraffin as an insect killer. The practical difficulty has been to make it soluble in water, so as to apply it of a uniform strength of half a pint to 3 gallons of water, as used so effectively at Gunton. As Mr. Allan says Bentley's soluble paraffin was equally effective in clearing Plums of green-fly, would he kindly add further in the pages of THE GARDEN whether it is equally so against Apple grubs,

Plum and Gooseberry caterpillars, &c.? Perfectly soluble paraffin should prove a great boon to cultivators and is a far safer remedy to use than the various preparations of sulphate of copper, which are also insoluble as well as virulent poisons. The latter properly used will kill every living thing, but unless kept in violent mechanical agitation to maintain a uniform mixture of substances absolutely insoluble in water, they will kill or seriously injure the trees or hedges as well, and a few such accidents are apt to arrest their use and leave the destructive insects in full possession of our gardens and orchards. It has been pitiable this season to note how little has been done to destroy insects, which have multiplied beyond all reasonable averages through the intense heat and dryness. Most fruits stood these wonderfully well and managed to set fair or very full crops of fruit, but when the pests of flies, grubs, maggots and caterpillars came, the majority of orchards were left to their fate.

D. T. F.

Insect pests in the garden.—At p. 507 Mr. Allan recommends Bentley's soluble paraffin for the destruction of red spider and aphid, and I can also testify to its value for black-fly on Cherries. I never saw trees so dirty as they are this season, no doubt owing to the drought. I note Mr. Young also advises the use of petroleum, but as a winter dressing, and an excellent remedy it is. I would advise the use of the same in a soluble state in the early summer months before the fruits get too advanced, and no injury will result. I prefer it to quassia, which will very soon spoil the flavour of fruit if advancing to ripeness. If trees are well cleansed in the winter and the roots do not suffer, there is less trouble during the summer. For red spider and green-fly on Rose trees, also mildew, I have found soluble paraffin the best insecticide. I have a quantity of standard Roses, and these had a dressing once or twice and the insects have given no further trouble. By thoroughly syringing Rose trees in this way one is enabled to enjoy the blooms in a cut state, as when placed in vases in rooms green-fly is most objectionable. I first tried paraffin for mildew in the Rose house early in the year, and it succeeded far beyond my expectations. American blight this season is rampant, but, as Mr. Allan explains, it may be got rid of by using soluble paraffin mixed like paint. We are now going over our cordon Apple trees, which are suffering from this pest.—G. WYTHES.

Jubilee Strawberry.—In a note on forcing Strawberries last year I named the above as doing well in the open. I intended growing some in pots for late forcing, that is, to come in at the end of May and first week in June, little thinking that the bulk of the outside fruit would be over at the last-named date and that forced Strawberries would be out of the question. Despite the early season, owing to the heat and drought, Jubilee still remains good. Being on a north border, it is now bearing freely and is wonderfully vigorous, the foliage luxuriant and there is neither spider nor lack of fruit. The fruit is smaller this season, owing to drought, but that must be expected on two-year-old plants, as all the runners we could secure we utilised for pot culture. The great value of this variety is its freedom of growth and long fruiting qualities. It does not produce a few large fruits and give over, but keeps up a succession. The flavour is also good, somewhat after the old Pine Strawberry. This note refers more to its value for late fruiting in pots than otherwise. As previously stated, I potted up a good number (some 500 plants). These were all intended for the last lot indoors, or, more correctly, in cold frames; but the season coming upon us so rapidly, the plants had not been pushed on, having other varieties. The result was they stood rather closely together in the frames and were kept cool. This variety came in very useful after the early and midseason sorts were over. I intend to grow Jubilee as a late variety for pots. By some mistake a score of plants were placed in heat along with La Grosse Sucrée, but the fruit did not finish well, and I do not advise it for pot culture, otherwise than for late

fruiting. I consider it a valuable Strawberry on light soils, or where Strawberries do not grow vigorously. Its constitution in such soils is much better than that of Waterloo, which is apt to go off in the winter. It is a bad dry-weather Strawberry, at least with me. I have Latest of All in close proximity. This is rightly named, as the fruits are only just colouring (June 24). I fear it is not so free in growth as Jubilee.—G. WYTHES

KITCHEN GARDEN.

TOMATOES FOR WINTER.

WHATEVER advance may have taken place during late years as regards improved varieties of Tomatoes, we have not as yet obtained a really good sort for winter fruiting, and, perhaps, never shall, but will have to rely more upon methods of culture by which to secure satisfactory results. A variety that was introduced last season with a great flourish of trumpets as being specially adapted as a winter fruiter has so far failed in this respect, it being no advance on others. The variety I refer to is Ladybird. I like the look of the variety as a summer fruiter, the fruits setting freely in bunches and the growth not at all too gross. Even from its seedling stage it showed its distinctness in this respect. The freest setting variety I have ever seen is the Pear-shaped. True, the fruits are not very large, but the quantity to a bunch makes up in this respect. The fruits, however, are as large as a fair-sized Plum. I had a couple of plants last season growing in a cool house, and the flowers set freely right up till Christmas. The structure was kept ventilated for Chrysanthemums, and if I could have kept the house warmer I am sure the flowers would have set right throughout the winter. My impression is that this would make a good parent to work upon to get a free-setting winter variety. As far as quality is concerned, it is everything that could be desired. As far as a supply up till Christmas is concerned, there is no difficulty in securing this from the summer fruiters, that is, where they are growing in light and well-heated structures, but it is after this time that the supply runs short. I have often been sorry to have to do away with plants in the early winter on account of the structure being needed for other purposes, as at this time it is impossible for the plants to prove satisfactory when subjected to a low temperature or, on the other hand, a too high and moist one. It is to meet such cases as these, where winter Tomatoes are needed, that it is highly essential to raise a fresh batch of plants and grow them on for the purpose of winter fruiting. On plants raised now and carefully attended to there will be time for a crop of fruit to set by the latter part of October. After this time the days are generally dull and wet, conditions not favourable for the setting of the flowers.

The best varieties to select are medium growers and free setters, such as Conference, Early Ruby, and by the appearance of Challenger under pot culture I should be inclined to think it would make a good winter fruiter. In pots the growth of Challenger is not at all gross, and it sets its fruit freely, these swelling off to just the size needed either for private use or for market. As regards the mode of increase, I prefer seedlings to cuttings, for although cuttings might naturally be expected to come into fruit earlier, and consequently be better adapted for winter fruiting, yet on the other hand seed-

lings under a judicious system of culture will fruit quite as early, and in every other respect most satisfactorily. Drawn and weakly plants are of no use whatever, as by the time these have become fit to produce fruit the season is too late for the bloom to set.

Pot culture is also preferable to planting out, as then the plants are more under control, and besides there is the advantage of having the structure at liberty for other subjects until Tomatoes are fit for housing. The best position for winter Tomatoes is those light houses or pits that are occupied with summer Cucumbers and Melons, for directly these are over and cleared out the Tomatoes can take their place. The plants should be in their winter quarters from the beginning of October or the middle of the month at the latest. A. YOUNG.

SHORT NOTES.—KITCHEN.

Cucumbers failing.—I have had the same experience as "G. W." and "W. I." re Cucumbers failing. About three years ago my plants went off mysteriously after making good root and top growth. I found it was caused through too close an atmosphere and dryness at the roots. I found that my plants were diseased at the collar, although as regards outward appearance they looked very healthy.—J. TARBET.

A purple-podded Pea.—Could you kindly inform me through THE GARDEN the name of enclosed Pea, as no one I have asked seems to know it?—E. WARD.

* * In reply to E. Ward, we beg to say that the Pea referred to is our purple-podded Pea, described in the "Vegetable Garden," page 110.—VILMORIN-ANDRIEUX AND Co.

TREES AND SHRUBS.

LAWN TREES.

I SUPPOSE there are few persons where the opportunity offered who have not gladly availed themselves occasionally during the late spell of exceptionally hot weather of the welcome shade of trees. A canopy of foliage more or less dense has been highly appreciated on lawns both large and small. In seasons like the present, the value of evergreen and dense-foliaged deciduous trees for lawn planting as compared with most of the coniferæ family is clearly demonstrated, and the remarks in that direction which have appeared from time to time in THE GARDEN receive ample corroboration, although one has only to walk through many, I might say the majority of pleasure grounds to realise the need for such persistent advocacy. There should, however, be a wise discrimination shown in the selection of ornamental trees, especially for prominent sites, as sometimes they are out of all proportion to their surroundings, or the nature of the soil may be all against their proper development. An instance of an oversight in connection with the first of the cases cited is furnished not many yards from where these notes are penned. A *Pterocarya caucasica*, that would have shown to splendid advantage on a lawn of anything over an acre, is hemmed in by a garden wall on the one side and by vineries on the other. Probably the planter of the tree had no idea of the size it was likely to attain, but it has appropriated the whole of the small piece of lawn on which it is planted, has a spread of branches some thirty yards in diameter, and, as I have said,

is rubbing shoulders on either side with surrounding buildings. On the other hand, *Laurus Sassafras*, which I have before recommended as a capital tree for small lawns (it makes a very nice specimen here, some 30 feet high, dense in foliage and well furnished), only seems to attain in some places the dimensions of a fair-sized shrub. Many admirable trees for small lawns can be found in those that combine sufficient density of foliage to afford a welcome shade with a fine display of flower and serviceable fruit. Strong-growing varieties of Apples, for instance, that make shapely trees, of which Cornish Aromatic, Scarlet Nonpareil, Beauty of Kent, Hambleton deux Ans, Blenheim Orange and Brownlee's Russet are half-a-dozen examples, may be planted with advantage, and so may the Mulberry, the Medlar and the Siberian Crab. Recent notes on Magnolias may tend to popularise these highly ornamental trees and lead to their occasional planting in situations where they would look remarkably well; some of them are very handsome and different to anything else we get in English gardens. They attain very fair proportions (our plant of macrophylla is over 30 feet high)—quite large enough for an average sized lawn. *Paulownia imperialis* and *Zelkova acuminata* may also be named as small trees with handsome deciduous foliage. The plea for greater variety in planting (and is it not needed?) so far as the smaller trees are concerned, which was the object of this note, might safely be extended to trees of larger size. No one would wish to debar our stately specimens of Oak, Beech and Chestnut, but a walk through many pleasure grounds shows that the rarer deciduous trees, often with highly ornamental foliage, are seldom met with. I was impressed the other day with a grand contrast in which the Copper Beech played a conspicuous part. A very finely coloured tree, not over tall, but with a shapely head, is backed and flanked by a group of Spanish Chestnuts; the latter are just now in full flower, and the contrast, as any tree lover will imagine, is wonderfully fine. Fine old specimens of the Tulip Tree are to be found in many gardens, but younger trees are seldom met with, an omission which if not speedily rectified will leave the majority of our gardens without any decent examples of this handsome tree when the old ones have died out. The foliage peculiar severally to such trees as *Ailanthus glandulosa*, *Gymnocladus canadensis*, *Magnolia acuminata*, and *Pyrus Sorbus* should secure them a place in all large collections, and all grow into handsome trees averaging from 50 feet to 70 feet in height. The maximum height mentioned was considerably exceeded by a fine Pear-shaped Service in the grounds here, which, unfortunately, came down in a gale during the winter of 1891-2. I must not forget a good word for the deciduous conifer *Taxodium distichum*, a very handsome tree, but, unfortunately, tender as a young tree; the leader is very apt to be crippled in severe winters, and all side growths die back. This is, I imagine, the reason why nice shapely young plants of this *Taxodium* are not easily obtainable. In addition to its stately appearance as a large specimen, its foliage is very useful for cutting.

Claremont.

E. BURRELL.

Abelia rupestris.—This is one of the most continuous flowering shrubs we have, and withal a very pretty one. Its usual habit is to form a neat twiggy bush, clothed with small oblong-shaped leaves, while the little pink tubular-shaped flowers are borne in clusters at the point of every shoot. In some districts it is just commencing to bloom, and it will, if untouched by frost, continue to

flower till November. It does well trained to a wall, and in such a situation will bloom later in the season than where exposed in the open ground. It is a native of China and was one of the many introductions of Robert Fortune from that region. Two species of *Abelia* have been illustrated in THE GARDEN, viz., *A. triflora*, a Himalayan species (Vol. X.), and *A. floribunda*, a native of Mexico (Vol. XIII).—T.

THE JAPANESE DOGWOODS.

CORNUS, which is exceedingly common in North America, where sixteen or seventeen species are distinguished, is less abundant in Japan than in the other great natural botanical divisions of the northern hemisphere. In the northern regions of Eastern America different species of *Cornus* often form a considerable part of the shrubby undergrowth which borders the margins of the forest or lines the banks of streams, lakes and swamps. In Japan these shrubby species, or their prototypes, do not exist. High up among the Nikko Mountains, on rocks under the dense shade of Hemlocks, we saw a few dwarf sprawling plants of the Siberian and North China *Cornus alba*, but did not encounter in any other part of the empire a shrubby *Cornel*. High up on these mountains, too, the ground is carpeted with the little *Bunchberry*, the *Cornus canadensis* of our own northern woods, which is also common in some parts of Yezo and on the Kurile Islands, where a second herbaceous *Cornel*, with large white floral scales, *Cornus suecica*, is found. This is a common plant, too, in all the boreal regions of North America from Newfoundland and Labrador to Alaska, and in Northern Europe and Continental Asia. Of arborescent *Cornels* the flora of Japan possesses only two species, *Cornus Kousa* and *Cornus macrophylla*, and neither of these is endemic to the empire.

CORNUS Kousa represents in Japan the *Cornus florida* of Eastern America and the *C. Nuttallii* of the Pacific States. From these trees it differs, however, in one particular. In our American Flowering Dogwoods, the fruits, which are gathered into close heads, are individually distinct, while in the Japan tree and in an Indian species they are united together into a fleshy Strawberry-shaped mass, technically called a syncarp. Owing to this peculiarity of the fruit, botanists at one time considered these Asiatic trees generically distinct from the American Flowering Dogwoods, and placed them in the genus *Benthamia*, which has since been united with *Cornus*. In Japan, *Cornus Kousa* is apparently not common; certainly it is not such a feature of the vegetation in any part of the empire which we visited as *Cornus florida* is in our Middle and Southern States. Indeed, we only saw it in one place among the Hakone Mountains and on the road between Nikko and Lake Chuzenji, where it was a bushy flat-topped tree not more than 18 feet or 20 feet high, with wide-spreading branches. The leaves are smaller and narrower than those of our Eastern American Flowering Dogwood, and the heads of flowers are borne on longer and much more slender peduncles. *Cornus Kousa* also inhabits Central China. It was introduced into our gardens several years ago, and it now flowers every year in the neighbourhood of New York, where it was first cultivated in the Parsons' Nursery at Flushing. As an ornamental plant it is certainly inferior in every way to our native Flowering Dogwood, and in this country at least it will probably never be much grown except as a botanical curiosity. The second arborescent Japanese *Cornel*,

CORNUS MACROPHYLLA, often known by its synonym, *Cornus brachypoda*, is also an inhabitant of the Himalayan forests, where it is common between 4000 feet and 8000 feet above the sea-level, and of China and Corea. It is one of the most beautiful of the *Cornels*, and in size and habit the

stateliest and most imposing member of the genus. In Japan, trees 50 feet or 60 feet in height, with stout well-developed trunks more than a foot in diameter, are not uncommon, and when such specimens rise above the thick undergrowth of shrubs which in the mountain regions of Central Japan often cover the steep slopes which descend to the streams, they are splendid objects, with their long branches standing at right angles with the stems, and forming distinct flat tiers of foliage, for the leaves, like those of our American *Cornus alternifolia*, are crowded at the ends of short lateral branchlets which grow nearly upright on the older branches, so that in looking down on one of these trees only the upper surface of the leaves is seen. These are 5 inches to 8 inches long and 3 inches to 4 inches wide, dark green on the upper surface, but very pale, and sometimes nearly white on the lower surface. The flowers and fruit resemble those of *Cornus alternifolia*, although they are produced in wider and more openly branched clusters; and, like those of this American species, they are borne on the ends of the lateral branchlets, and, rising above the foliage, stud the upper side of the broad whorls of green. *Cornus macrophylla* is exceedingly common in all the mountain regions of Hondo, where it sometimes ascends to 4000 feet above the sea, and in Yezo, where it is scattered through forests of deciduous trees, usually selecting situations where its roots can obtain an abundant supply of moisture. This fine tree was introduced into the United States many years ago through the Parsons' Nursery, but I believe has never flourished here. In the Arnold Arboretum, where numerous attempts to cultivate it have been made, it has never lived more than a few years at a time. Raised from seed produced in the severe climate of Yezo, *Cornus macrophylla* may, however, succeed in New England, where, if it grows as it does in Japan, it should prove a good tree to associate with our native plants.

CORNUS OFFICINALIS, as it was first described from plants found in Japanese gardens, has usually been considered a native of that country. But, although it has been cultivated in Japan for many centuries on account of its supposed medicinal virtues, it is probably Korean. It may best be considered, perhaps, a mere variety of the European and Asiatic *Cornelian Cherry* (*Cornus Mas*), from which the Korean tree is best distinguished by the tufts of rusty brown hairs which occupy the axils of the veins on the lower surface of the leaves. In the botanic garden in Tokio, which includes the site of a physic garden established in the early days of the Tokugawa dynasty, there is a group of trees of *Cornus officinalis*, which appear to have attained a great age. They are bushy plants, perhaps 30 feet high, with bent and twisted half-decayed trunks and contorted branches, which form broad, thick round heads, and in October were loaded with the bright, Cherry-like fruit.—*Garden and Forest*.

Deutzia gracilis is usually thought more of as a plant for pots and the greenhouse, but it is perfectly hardy. When massed together on the outskirts of the lawn this shrub presents a fine aspect at this season of the year. We noticed it thus grouped in the Royal Gardens, Kew, the plants about 2 feet or a little more in height, and covered with the pure white flowers.

Escallonia Phillipiana.—A very noticeable feature in connection with this beautiful *Escallonia*, mentioned on page 535, is its hardness, for frosts sufficiently severe to cut some species to the ground have little or no effect upon this. The pure white flowers are so distinct from those of any other *Escallonia* that it must be given a place in any collection of choice flowering shrubs. In especially favoured districts, another kind—the larger growing *E. montevidensis* or *floribunda*—is a very ornamental flowering shrub, one of the tenderest of the entire genus. It forms a free-growing, somewhat upright bush, that under favourable conditions will reach a height of 10

feet or 12 feet. The white flowers are borne in terminal corymbs, an arrangement very different from that of the better-known kinds.—T.

ORCHIDS.

DIPODIUM PALUDOSUM.

UNDER this name just now is flowering for the second time in Mr. Williams' nursery, Upper Holloway, a very curious plant with somewhat the habit of a very soft-leaved *Vanda*. It was introduced by the Messrs. Veitch, of Chelsea, some few years ago from Borneo, and more recently it was brought home to Europe by M. Regnier, of Paris, from Cochinchina. It was originally discovered by Griffiths in Malacca, and he named it *Grammatophyllum paludosum*, but with this genus it has nothing in common, neither can I believe it has anything in common with *Dipodium*, for we are told that this is a genus of terrestrial leafless Orchids of Australia and New Caledonia, having thick branching roots and stems 1 foot to 2 feet high, furnished at intervals with brown scales, and terminating in large racemes of nearly regular flowers. The plant in question is an erect growing one, having numerous two-ranked leaves, which are soft green in colour and thin in texture, bearing axillary spikes of bloom. Mr. Williams has figured the plant under this name in the "Orchid Album," t. 422. I rather think that this plant belongs to the genus *Wailesia*, and that the two genera ought never to have been merged together, for I can see nothing which could bring them together but the fact of their both being members of the same tribe. The genus *Wailesia*, we are told, consists of epiphytal plants with the habit of *Vanda*, with distichous leaves and lateral spikes of bloom. Here then is a description more in accordance with the plant under consideration, and which I would commend to the attention of Orchid growers, more especially to those who care for the curious species of this order. It is of erect growth and very much resembles a *Vanda*, saving that the distichous leaves are soft in texture, but they nevertheless are persistent. The spike is lateral, bearing from six to twelve flowers, each about 1½ inches across, sepals and petals nearly equal in size, creamy white, dotted with bright purple, lip white, streaked and blotched with rich purple. This plant appeared to require a moister atmosphere than is to be found in any of our plant houses, and for several years it was grown in large Wardian cases in the hottest stoves. The plant, however, has now got better acclimatised, for it grows at Holloway in the open stove. The pots are well drained, the potting material being simply *Sphagnum Moss*. It likes an abundance of moisture all the year round, but, of course, much less is requisite during the winter. It also likes a fair amount of sun and light.

WILLIAM HUGH GOWER.

Odontoglossum Galeottianum (*O. Clarke*).—The flower you send is that known as *O. Galeottianum*. It is a plant about which very little is known, and I should think you are very fortunate in getting it instead of *O. Cervantesi* roseum. Reichenbach appeared to consider it a natural hybrid, suggesting for its parents *O. Cervantesi* and *O. nebulosum*, but as all the flowers I have seen of it appear to be exactly alike, I am doubtful about its hybrid origin. You will find it figured in Williams' "Orchid Album," t. 423.—W.

Cattleya Warneri.—This is a very beautiful form of the original *labiata* section, and it more

nearly resembles the typical plant than any other, but its time of flowering is quite different. I have before me two flowers, both sent for my opinion of them. One from Mr. Law-Schofield is a very pretty and a good coloured variety, with a nicely frilled lip of a rich deep purple. The sepals and petals, too, are of a deep rosy purple, but being somewhat narrow do not give the flower such a bold and effective character as some I used to see about thirty years ago. The other flower from Mr. Temple is decidedly inferior, the colour on the lip being very poor.—G.

Odontoglossum Phalænopsis.—A superb variety of this charming plant comes from G. Cunningham asking what I think of it. I must certainly acknowledge it to be the very finest variety that has come under my notice. The flower is nearly 3 inches across and of the purest white, the lip being stained with deep rich and glowing purple, saving the white marginal border. This is a plant I have always succeeded best with when it was kept through the winter in a temperature which did not fall below 60°, keeping the atmosphere moist in the summer months. It thrives well with the other *Odontoglossums*, but it must not be overloaded with soil about the roots, and it will not live unless the atmosphere is kept moist.—H.

Luddemannia Pescatorei.—The genus *Luddemannia* is one whose position in the Orchid family has been the subject of considerable doubt and discussion amongst botanists. It was the subject of a paper given by Reichenbach at the Orchid conference in May, 1885, the genus, as it happened, being represented there by a fine flowering specimen of the rare *L. Lehmanni*, exhibited by Sir Trevor Lawrence. In his paper Reichenbach pointed out the affinity of the genus with *Acineta*, and this is borne out by the habit of the plant and the downward growth of the flower-spike. Bentham, however, had introduced some confusion into the matter by putting *L. Pescatorei* (now flowering at Kew) under *Cycnoches*, to which genus it certainly does not belong. The mystery surrounding the genus is further increased by Reichenbach recording that a plant sent to him by Messrs. Veitch "appeared" the first season to be a new species of *Luddemannia*, and the next turned out to be *Acineta erythroanthera*. This led him to suggest that *Luddemannia* might be a sexual form of *Acineta*, or, as surmised by Schlim, the collector, of *Peristeria*. But after all there seems to be no absolutely trustworthy evidence of these plants sporting, nor, on the other hand, have *Acinetas* or *Peristerias* ever temporarily assumed the characters of *Luddemannia*. *L. Pescatorei* was introduced in 1848 by Linden. It is a native of Ocaña, and was first discovered by Schlim at 9000 feet altitude. It appears to have been almost or quite lost sight of until a few years ago, when it was flowered by Mr. Moore at Glasnevin; from his plant the figure in the *Bot. Mag.*, t. 7123, was made. It is certainly a very handsome and remarkable Orchid. The flower-spike, which is as thick as a lead pencil, originates at the base of the pseudo-bulb, and hangs straight downwards for a length of over 2 feet. The flowers, between forty and fifty in number, are crowded on the terminal half. They do not expand to the full extent, and are about 1½ inches in diameter. The lip is shaped like a spear head and is of a rich yellow, the petals being of the same colour. The sepals, however, are brownish red, and dusted over with tiny black specks, the flower-stalks and the rachis of the inflorescence having the same character. It should, like the *Acinetas*, be grown in baskets, so as to allow the flower-spike to find its way through the bottom.—B.

Ceologyne Dayana.—Of this species, which was staged so well at the Temple show by Mr. Ballantine, gardener to Baron Schreder, T. Jamieson sends me a portion of a spike bearing five flowers. It much resembles *C. Massangeana*, but its flowers are very distinct. It bears about two dozen flowers upon its long spike; they are white or nearly so in the sepals and petals, and the oblong lip is three-lobed, the side lobes recurved

at the tips, where they are banded with streaks of brown upon a white ground, and blotched on the outside with the same colour. The front lobe also has a belt of dark brown with a marginal border of white. This plant comes from the hottest parts of Borneo.—W. H. G.

Miltonia Warscewiczii.—Flowers of this species come from Mr. Law-Schofield under the name of *Oncidium Weltoni*. This was the name under which Mr. O'Reilly sent it to Mr. B. S. Williams in January, 1868, with dried flowers. Some of these I sent to Reichenbach, and from him I got the correct name. The flowers now before me are past their best and I am unable to express any opinion upon them, but perhaps when the plant blooms again, Mr. Schofield will let me see the flowers before they have faded. The flowers vary considerably, but they all have a shining patch on the lip, as if it had been freshly varnished.—W.

SHORT NOTES.—ORCHIDS.

Oncidium pumilum.—This is an interesting species from Brazil. The plant grows best in a small pan, and bears a raceme of rich yellow flowers densely crowded together. It is very distinct.

Phalænopsis Marie is one of the most beautiful Orchids in bloom now. It is best grown in a basket, and the flowers are of distinctive colour, white, richly blotched with chestnut, the base purple, whilst the lip is wholly of this tinge.

Phalænopsis Esmeralda.—A good form of this beautiful Orchid is in bloom at Kew. The plant is grown in a basket, and bears flowers of a purple-rose colour, the lip, column and side lobes intense crimson. It is a Cochinchina species.

Ionopsis utricularioides is a delicately beautiful Brazilian species which was recently in bloom in the Kew collection. It is quite a small plant, growing in a basket, and bears a short raceme of flowers, which are white, with purple veins at the base of the lip.

Oncidium triquetrum (G. Temple).—It is just 100 years ago since this plant was first introduced, whilst the plant you take it for, *O. pulchellum*, was not introduced for a quarter of a century later. *O. triquetrum* is a native of Jamaica, whilst *O. pulchellum* is found in Demerara and various other parts of America. It is a very pretty and interesting species.—W. H. G.

Cypripedium Curtisi.—I am in receipt of a flower of this charming kind from Mr. Law-Schofield. It is a very nice variety, but I fail to see anything unusual in it. This kind has always been a great favourite with me, the petals being of such a pleasing colour. The flower now before me appears to have a broader white border to the dorsal sepal than many I have seen.—G.

Cattleya Mendeli.—Mr. Law-Schofield sends me a chaste and very pleasing variety of this form. I am very sorry it did not come earlier. The sepals appear to be white, faintly tinged with flesh, and the broad petals delicate satiny rose, the lip pure white, stained with deep orange in the throat, the front lobe faintly tinged with mauve. The name *delicata* would be very appropriate.—W. H. G.

Odontoglossum vexillarium superbum.—A spike of bloom comes to hand from Mr. Holmes, who has a grand lot of *O. vexillarium* in many varieties under his charge. The variety *superbum* is the best, saving the form recently shown by Mr. Sander at the Temple. This originated, I believe, with Sir Trevor Lawrence, and although Mr. Holmes says he has several plants now in full bloom, it remains scarce.—W. H. G.

Cattleya Gaskelliana.—A very fine flower of this variety comes to me from Mr. Holmes, who has charge of Mr. Hardy's unique collection. It is remarkable for its very fine colour and its large lip; the sepals and petals are soft rosy purple, the lobes of the lip being flaked with a much deeper and brighter purple, whilst the middle lobe is rich amethyst-purple, with a white frilled margin, stained in the throat with bright orange, and

having radiating lines of purple at the base; this is a magnificent form of this summer-flowering *Cattleya*.—W. H. G.

Mormodes luxatum eburneum (W. W.).—This is your flower, and a very beautiful variety it is, pure ivory white, with a brown streak in the lip, and very sweet-scented. The flowers of the typical plant are of a greenish yellow and yield a delicious perfume. I have generally seen this variety appear quite promiscuously, as if the bulbs had been collected when out of bloom, or without having been seen in flower. It is a very beautiful variety, deserving extended cultivation.—G.

GARDEN FLORA.

PLATE 917.

PLAGIANTHUS LYALLI.

(WITH A COLOURED PLATE. *)

This is a hardy, free-flowering and beautiful shrub, which, although introduced and flowered at Kew and figured in the *Botanical Magazine* in 1871, and since then noticed occasionally in the pages of *THE GARDEN*, has not yet obtained that notice from horticulturists to which it is fully entitled. Against a south-east wall at Kew it has grown into a large plant in about four years, and both last year and this it has bloomed with the same freedom and produced somewhat the same effect as a Cherry when in flower. A south-east wall is a trying position for plants of questionable hardiness, the morning sun after a severe frost being fatal. But the *Plagianthus* at Kew did not suffer at all during the severe weather of last winter; indeed, it retained most of its foliage till the spring. The wall is not, therefore, needed as a protection, but as I learn from Mr. Gumbleton that in his garden, where the *Plagianthus* is treated as a shrub in the open, it does not flower freely, the wall is probably needed to ripen the wood and induce a good set of flower-buds.

Mr. Moon's drawing gives an excellent idea of what a spray of the *Plagianthus* is like, and it is easy to imagine the beauty of the plant when bearing scores of such sprays. The flowers are snow-white, with golden yellow anthers. The shoots should be pruned and the young wood laid in as soon as the flowers are over, which is towards the end of June (the Kew plant has still a few flowers upon it). The flowers are produced on the ends of the last season's branchlets. Cuttings of this plant do not strike freely, only a small percentage of a batch put in last autumn having rooted. Probably autumn layering would be the best plan for it.

Plagianthus is a genus of about a dozen species, and belongs to the Mallow family. Three species are found in New Zealand, *P. Lyalli* being one of them; the others are natives of Australia and Van Dieman's Land. Five or six species have been introduced into English gardens, but *P. Lyalli* is the only one that has any special claim to a place in the garden. According to Hooker in the "Handbook of the New Zealand Flora," it forms a small branching tree 20 feet to 30 feet high in the mountain districts throughout the Middle Island, from Nelson to Milford Sound, fringing the Beech forests. It is said to be deciduous at and above 3000 feet altitude, and ever-

* Drawn for *THE GARDEN* by H. G. MOON, in the Royal Gardens, Kew, July 1, 1892. Lithographed and printed by Guillaume Severeys.

PLACIANTHUS LYALLI

green below that level. In autumn its naked branches and yellow foliage give a peculiar colour to the landscape at the higher elevation. In New Zealand it flowers in January, whereas here it flowers in June. The flower-stalks are fully 2 inches long, and this gives the clusters a graceful appearance, as some of the flowers hang downwards.

P. LAMPENI is, perhaps, the second best species of the genus in a garden sense. It flowered with Mr. T. Smith, nurseryman, Newry, about nine years ago, when a figure of it was published in the *Gardeners' Chronicle*. It is described as a perfectly hardy shrub against a wall, a prodigious bloomer, with sweet-smelling flowers and much superior to

P. PULCHELLUS, noted in THE GARDEN by Mr. Gumbleton in 1880 as having stood two unusually severe winters with him without any protection, and flowered when only 2 feet high. Sir Joseph Hooker makes both P. pulchellus and P. Lampeni synonyms of P. sidoides, which is figured in the *Botanical Magazine* (t. 2753, 1827) as *Sida pulchella*, and is a shrub 3 feet to 4 feet high, with cordate leaves and small axillary whitish flowers. It is a native of Tasmania. Mr. Smith's plant is vastly superior to that represented in the *Botanical Magazine*; so much so, that Dr. Masters preferred to keep it separate under the name of P. Lampeni. Is this plant in cultivation now? W. W.

THE WEEK'S WORK.

ORCHIDS.

THE exceptionally hot weather, which lasted for about two weeks, has apparently passed away, and a few refreshing showers have filled the underground tanks with fresh rain water. We had a good supply left, but on examination it proved to be almost as hard as well water, probably through the cement tanks acting upon the water. Had the tanks been formed of slate or galvaonised iron, the water might have retained its original softness. Allusion was made last week to the *Dendrobiums* being placed in their growing quarters, and, curiously enough, an amateur wrote lately to inquire why the young growths of *D. Paxtoni* continually damp off. This never happens with our plants, which are always placed in a heated house and grown rapidly, air being admitted as freely as possible and the house shut up every afternoon with a high temperature. I should say that the cause of the young growths damping is the want of artificial heat and an overmoist, close atmosphere. The plants would also be more liable to damp at a distance from the glass roof and crowded amongst other plants. It is the custom with most Orchid amateurs to remove the plants when in flower from their growing quarters and to place them together at the end of the house, or in some position where they would be most effective, more regard being paid to effect for a time than to the healthy condition of the plants themselves. They should only remain there until they pass out of bloom, and be at once removed to the place from whence they were taken. This removal may sometimes do harm, and cannot be conducive to the well-being of the plants. It affords a good opportunity to overhaul the plants in every compartment to remove all spent flower-spikes, and the leaves should be washed with a weak solution of soft soapy water to clear off any dirt or sticky substance which may have dropped from the flowers. In arranging the plants thus removed, a careful cultivator will place each specimen in the best position to ensure its most perfect development. It is useless to expect the small plants to make good growth if they are farther removed from the roof glass than the large ones. Small duplicates of choice specimens require more careful attention than the parent plant from which they have been removed, and if these large specimens make the

most satisfactory growth and form flower-sheaths more freely within a few inches of the glass roof, the small specimens placed in front of them, nearer the paths and farther from the roof glass, are sure to suffer from lack of light and air. It is better to place plants like these, together with any sickly specimens from which the old potting material has been washed, by themselves, as they require rather more shade from bright sunshine. Recently imported Orchids, too, are by no means attractive to some, and are too often pushed into some corner out of sight, where they are neglected and have a poor chance of ever forming healthy, sturdy specimens. Of course the Orchid fancier who cares for his plants will not trouble much how they look, but will place them in the best position, for nothing delights him more than to see the young growths starting from the base of the more recently formed pseudo-bulbs, and to see the young roots pushing freely amongst the fresh Sphagnum and fibrous peat. Newly imported Orchids are the delight of the Orchid fancier, but those who dislike their appearance and neglect them had far better form their collections with established plants; it saves time and trouble. Now comes a matter of considerable importance, that is, the watering of newly-imported plants. The mistake is often made of giving them too much, and as a consequence, instead of the plants making fresh roots freely, as they should do, they rather lose those they have, and never get a fair start. Every newly-potted plant should have a clean flower-pot to grow in, ample drainage, sweet and fresh potting material, and a thorough watering about every ten days. Lightly sprinkle the surface frequently to encourage the growth of new roots from the base of the bulbs. Newly-imported Orchids should have even more drainage than the established plants. The great complaint this year is of the abundance of insect pests, especially thrips. Fumigating the house with tobacco smoke may do more damage to the plants than to the parasites upon them. Soft soapy water, which will kill green-fly, does little harm to thrips, and if the soapy water gets upon the live Sphagnum Moss it will kill it. Tobacco water, at the rate of about half-a-pint of the liquor sold in the shops to a gallon of water, is an excellent wash for them.

At this season of the year there are numerous, distinct, and beautiful plants in flower. Amongst them *Grammatophyllum Ellisi* is conspicuous, a very nice specimen in rude health having been exhibited before the Orchid committee of the Royal Horticultural Society the other day. The flower-spikes comes with the young growth, and is sometimes as much as 3 feet in length. Importations of it sometimes come over in fairly good condition, but as a rule it must be placed with the Orchids difficult to import. If recently imported plants can be obtained at any time, plant them in teak baskets in peat and Sphagnum, well drained, and hang them up near the roof-glass of the warmest house. The young growths have a tendency to damp off unless care is taken to keep water from getting into the centre. The plants are now in growth and require plenty of heat and moisture. Amongst other occupants of the warmest house, *Miltonia Roezli* has passed out of bloom, and may be repotted now as the young growths are starting. I used to repot this in August or September, but it is much better, if time can be spared, to see to it now. It does well on the shady side of the house, but where it can get plenty of light. It is rather dangerous to overpot it, and it does not like too frequent disturbance at the roots. Before repotting see that the plants are quite free from thrips, which is their worst enemy. These plants are never at any time removed from the warmest house. The potting material should be quite half freshly-gathered Sphagnum, washed clean and chopped up. The best fibrous peat should be used with it with a liberal sprinkling of potsherds and bits of charcoal. About a month ago the plants of *Miltonia vexillaria* were removed into the cool house. A considerable number of them are yet in flower, but as soon as the plants pass out of bloom they will be dipped in the tobacco liquor solution already alluded to. Even if thrips cannot be seen

upon them, it is much better to do this as a precaution. Now is the time to pot these plants also, and the treatment that they receive should be the same as already advised for *M. Roezli*. The brilliant *Epidendrum vitellinum majus*, though not yet out of bloom, is also starting to grow.

The cool house must be freely ventilated, damped down frequently, and well shaded, leaving the ventilators open at night. The *Cattleya* house is now kept at a temperature of from 60° to 65° as a minimum with air on at night. The East Indian house temperature is about 70°.

J. DOUGLAS.

HARDY FRUITS.

PEACHES AND NECTARINES.—Never before probably have Peaches been gathered so early from trees against open walls, the variety *Early Alexander* being exceptionally precocious. *Hales'* Early and other comparatively early varieties are also commencing their final swelling, in the more favoured parts of the country at any rate, and in any case all ought once more to be gone over with a view to lightening the crops where still too heavy. Those worst placed for swelling to their full size should be the first removed, pulling off two or three dozen fruits from a fairly large tree greatly increasing the size of those left. Wall nails always seem in the way of swelling fruit, and if those dangerously near to the latter are not shifted now it will not be possible to draw them later on without damaging the fruit. If the daily syringings have been persevered with, there will not be much red spider about, the young growths being strong and healthy accordingly. Any shoots liable to break down should be laid in, the whole of them on early trees also being either fastened back with twigs, ties, or shreds and nails. Then if the leaves are further tucked back from the fruit the colouring of the latter should be perfect. Allowing the young wood to set out from the trees another fortnight or three weeks would serve to retard some of the later varieties, and a scrim canvas shading or blinds drawn over the trees during the hottest part of clear days may be desirable where fruit is particularly wanted late in September and till November. Birds are likely to attack Peaches and Nectarines badly this season owing to small fruits ripening and being over unusually early. Therefore net over the trees when the fruits are approaching ripeness. Wasps also are very numerous, though as yet they have not started eating fruit. The nests of these should be taken as much as possible.

WATERING PEACH AND OTHER WALL TREES.—Rainfall has been pretty general, but in but few places has there been enough to well soak the ground about wall trees. Nor is there much likelihood of a sufficiency of moisture reaching the borders, especially near to the walls. Advantage ought, therefore, to be taken of a dull, showery time, or it may be an improved water supply, for giving the borders a good soaking of water, or, better still, moderately strong liquid manure, soot water being a fairly good substitute for well-diluted drainings from farmyards and horse stables. If, on loosening the surface of the border prior to watering, it is found very dry, first well moisten it with clear water before applying liquid manure, this rendering the soil in a fit condition to absorb the manure, fewer risks of injury to tender roots also being run.

PLUMS.—*Rivers' Prolific*, *Morocco* and other early Plums are ripening fast on the wall trees, and the second early varieties are also commencing their final swelling. In very many instances the crops are still much too heavy, the thinning out requiring to be more severe this season than has been the case for several years past. If all still hanging are allowed to remain on the trees, the probability is none will attain perfection, and, seeing that half-ripe fruit makes excellent preserve or it can be used in pies, it is a great mistake to neglect still further lightening the crops. Immense quantities of half-ripe *Victoria* Plums are, in years of plenty, supplied to wholesale jam-makers by mar-

ket growers, and what are left on the trees then swell to a good size, fetching much better prices accordingly. Good care should be taken of any trees against cool walls, as these will carry on the supply to September and later. Cut all the strong growths starting from near the top of the walls cleanly out and thin out the rest where crowded, laying in some of those reserved to their full length wherever there is a blank space to furnish, and shortening the rest back to the fourth or fifth leaf. Curiously enough, some of the trees against quite cool walls are overrun with red spider, and these will greatly weaken them unless checked. A good-sized bandful of flower of sulphur squeezed through a canvas bag into a 3-gallon can of water, and the mixture well sprayed over both the upper and lower surfaces of the leaves, is the best remedy for red spider.

FIGS.—Plenty of strong sunshine is very favourable to the growth of Figs, and this should be a good season for this luscious fruit. As usual, the trees are growing strongly and forming far too much wood, especially about the base of those low stemmed. Much and in many cases the whole of this sucker growth should be cut cleanly away, and the trees ought also to be gone over, foreright shoots, unless no training of young shoots is resorted to, being cut off. Thin out the shoots better placed for training, only enough being laid in to thinly clothe the wall. When the shoots smother each other, they do not as a rule become sufficiently firm to be either hardy or productive, and the crops on the trees do not have a good chance of ripening properly. It is a mistake to top any of the young shoots, the points of well matured wood being where the Figs will be principally produced next season.

GRAPES.—Very rarely do Vines grown against sunny open walls and trailing over the roofs of outbuildings and such like present such a promising appearance as they are doing this season. Unless we have had all the summer weather for this year, the crops should be very heavy and early, the ripening being as perfect as in former days when this class of fruit was more grown in the open than now. The lateral growth being duly stopped at the first or at the most second joint beyond the bunches, and duly fastened back to the walls, all sub-lateral growths should also be prevented from smothering either the wood or bunches. Most of them ought to be cut out, a few, or where there is room for them, being stopped at the first joint. The small cluster varieties may well be allowed to bear as many bunches as they will, but in the case of the Black Hamburgh, a few Vines of which are still to be met with in the open air, and the common Sweetwater or Muscadine, the bunches may be reduced in number, and some of the best of those reserved thinned out with advantage. The berries of the last-named when thinned out will attain the size of Frontignan, and when ripe are very refreshing. In bygone days they used to be retailed in Kent at 10d. per pound, and may once again sell equally well. Mildew is the greatest enemy to outdoor Grapes, and on the first signs of this the affected parts and the bunches generally should be well dredged with flower of sulphur. This will, if persevered with, most probably check the spread of mildew, and can easily be washed off if need be under a tap of clear running water without prejudice to the Grapes.

PRACTICAL

PLANT HOUSES.

PROPAGATION.—This is a part of the necessary work of every establishment, but in none more so than where plants for decoration in small pots are in every-day demand. That this also is on the increase no one can deny who has had an opportunity of observing the tendency of the times in the use of plants. It must be, therefore, far better to provide as useful a stock in succession as possible rather than bewail the condition of plants which through repeated and constant use have become mere skeletons. The provision of a proper

propagating pit has been urged more than once, and need not be repeated beyond saying that it will soon repay for the outlay, at the same time making the raising of small plants a pleasure rather than otherwise. About this time there are many things that can be struck with ease provided a steady fire is kept going or other means employed to secure bottom-heat. Shoots of Crotons in variety can now be taken with clean growth of the current year, not forgetting that exceedingly useful kind of small growth and distinct habit, *C. van Oerstedii*, *C. Countess*, *C. picturatus*, *C. interruptus*, *C. Baronne James de Rothschild*, and *C. Andreanus* make up a capital half dozen of old and well-tried kinds.

The same advice applies to *Ixoras*. If any additional stock be needed of *Allamandas* and other flowering plants, these also should be secured whilst there is yet good time to get the young stock well rooted before the resting season comes round. *Poinsettias* can be struck as opportunity offers for another month, a few at a time being in my opinion preferable to the many, so as to have a nice gradation of height in the plants at the proper time. The same remarks apply to such dwarf growing stock as *Fittonias*, *Cyrtodeiras*, *Sonerilas*, and the useful *Panicum variegatum*. Such winter-flowering *Begonias* as *B. insignis* can still be propagated, allowing nothing in pot room for such a stock beyond $\frac{1}{2}$ -inch pots for blooming; pot them into 6-inch pots, and they would be failures in the majority of cases. Another exceedingly serviceable plant if propagated about this time is *Eranthemum pulchellum*, one with blue flowers it is true, thus not appearing possibly to such an advantage under artificial light. My plan with this plant has been to strike the cuttings in $2\frac{1}{2}$ -inch or 3-inch pots, then give one shift only as soon as they are well rooted, keeping them in heat with plenty of light. Such a stock will add to the attractiveness at Christmas-time when blue flowers are none too plentiful. Rather than store too many old plants of *Gardenias*, it will be found better to strike a fresh stock. Branches rather than single shoots of these can be taken with safety if good means for propagation in a rapid manner are at hand. I mean by this pieces of growth with half-a-dozen or more young shoots upon them. These, when struck successfully, are a decided gain in time, the groundwork of a good bushy plant having been secured in the cutting. In every case an excess of moisture will have to be guarded against. This may seem rather strange advice to give during the hottest weather, but as long as sufficient artificial warmth cannot be maintained without too high a temperature, any excess of atmospheric moisture cannot be dispelled in a proper manner.

SEED SOWING.—New seed of this season's harvesting of the choice hybrids of *Amaryllis* is now ripe and in a fit condition for sowing. Before these lines are in print mine will have been sown in shallow pans, each seed being inserted upon its edge. It pays to give extra pains to this little matter—little as regards time, but all-important in securing a good germination. A brisk heat is best until the young plants appear, when less will suffice. Note should be taken of this, sowing in good time; it is thus possible to save a season in the flowering. A sowing of *Cinerarias* made about now will provide one of the most useful lots of plants that can be grown of this showy greenhouse annual. The advantage of such a stock is the absence of the Rhubarb-like leaves, which no plant grower cares to see. Another sowing if made about the end of the month will provide a fine succession for late spring flowering in small pots. The earliest sowing of *Calceolarias* should be made about the middle of the month, these and the foregoing both being kept quite cool and in the shade if possible. Provided the soil be thoroughly saturated before sowing the seed, there will be no need of watering before the seedlings appear.

The earliest ripened seed of *Primulas* will now be fit for sowing, such a stock being the best for seed-sowing as well as for decoration in small pots. A close frame for this will be found the better place, with shading and a covering of glass to prevent evaporation. Another very useful sowing

that can be made now is that of *Mignonette* for autumn flowering and to carry the season on to nearly Christmas. Six-inch pots at the most will be a good size to use for sowing the seed, no future shifting being thought of. These pots will produce plants of large dimensions, smaller ones being used if correspondingly small plants are preferred. These latter, however, will necessitate closer attention to watering. *Humea elegans* has not been grown the last season or two to any extent through a failure in the seed crop. Now is a good time to sow, treating it in the same manner as the *Primulas*, more patience even being needed to secure a good germination. JAS. HUDSON.

THE KITCHEN GARDEN.

WINTER PARSLEY.—Arrangements for the winter and early spring supply of Parsley now demand attention. Where Parsley is dependent upon a sowing made in early spring, and which has had to be gathered from at all times, it rarely if ever gives a supply during the winter and early spring. Not only the sowing, but the position and means of protection when the time comes for such to be required must be attended to now. The beds should be formed of the size that will take portable lights, or whatever covering it is intended to apply. Low brick frames which are not now in use may also be put in order for sowing, the lights, of course, not being required until protection is really needed. The borders for sowing should be well exposed as a safeguard from damp, which often plays great havoc with Parsley in winter. The soil for the seed must be fairly fertile and also firm. Where Parsley does not succeed very well, work into the soil some pounded old mortar rubbish or a dressing of freshly slaked lime, as it is on soils where a fair proportion of lime is present that the Parsley succeeds the most satisfactorily. The seeds must be sown in shallow drills drawn 15 inches apart, and if sown in low open frames, the soil must be kept moist by watering. To prevent the surface from drying rapidly, cover with a mat until the seeds germinate.

SOWING IN POTS.—Plants may also be raised by sowing a few seeds in 3-inch pots, and as the plants become large enough they may be placed in shallow boxes or tubs with holes around the sides. These are kept out in the open air until the winter arrives, when they are transferred to frames, an airy greenhouse, or a vinery. Parsley grown in this way comes in very useful in times of deep snow and severe frost, and for small gardens it is a system to be commended.

SPRING CABBAGE.—It is quite evident that too much care cannot be taken in providing for an early supply of Cabbage, as during the past season or two this crop in many gardens has proved a veritable sheet-anchor. With such varieties as *Ellam's Early Dwarf* and *Mein's No. 1* there is no fear of their running to seed or being cut off by frost. It is more than a month too early to think of sowing such kinds as *Enfield Market*, *Nonpareil*, and some other kinds. I have specially mentioned the two above excellent early kinds, knowing their true value, and I daresay there may be others well worthy of attention. In the midlands and more northern parts of the country the middle of the month is the most suitable date. In earlier districts delay sowing another week. There is nothing like having plenty of plants, and as *Ellam's* is a small grower, it may be planted closely together.

RAISING THE PLANTS.—Select an open spot with the soil in a fertile condition, as it is useless to expect good plants from poor soil, and, moreover, if fertile soil is not provided for them they are very apt to be over-run with either fly or club. In my case the seed-bed for Cabbage follows on after early Potatoes, this being in good condition, a forking over previous to sowing being all that is needed. If at all rough after the drills are taken out, fill up with old potting soil. If at all dry, well water the drills previous to sowing, this

being far preferable to watering after the seeds are sown. Nor must coating the seed with red lead be omitted if small birds are troublesome. If club is likely to be troublesome, work in some lime and wood ashes previous to sowing, and as soon as the seedlings appear in the rough leaf, dust over with soot, this preventing the flies from depositing their eggs.

MAIN-CROP CELERY.—The trenches having already been prepared as advised in a previous calendar, proceed to put out the plants, as if allowed to remain too long they are apt to receive a check and cause bolting. See that the balls are in a thoroughly moist state before being disturbed, as if planted dry it is with difficulty that they can be moistened afterwards. Take up the plants with squares of soil, as then they will not receive any check. Also see that the sucker growth and small leaves clustering about the base are removed. After planting give a thorough watering, also sprinkling the plants over in the evening. As the plants commence to root into their fresh quarters plentiful supplies of water are needed, especially if the weather should continue dry.

LATE FRENCH BEANS.—A sowing of this most useful crop should be made now, or in the course of a week, so as to afford a late supply. Take care that the site is open and sunny and the soil rich. Canadian Wonder and Ne Plus Ultra are both good for late sowing. It is also advisable to arrange the rows so that they can be protected in case of early visitations of frost. A. YOUNG.

FLOWER GARDEN.

HARDY FLOWERS—A RETROSPECT.

IT must be five or six years since you did me the honour of publishing some remarks of mine under the above head, and since then lovers of hardy flowers have certainly had to complain of no lack of novelties, while the cultivation of many rare and choice things has, it may be hoped, become better understood.

The following notes refer mainly to plants that have come under my observation within the time named, and where other and older things are mentioned it is because I have at length succeeded with them where I had previously failed, or because they have continued to baffle all my attempts to make them grow. Many of the choice alpine *Ranunculuses*, especially the white sorts, remain with me as intractable as ever. The most beautiful of all, *R. amplexicaulis*, fortunately, does well almost anywhere, and *R. anemonioides* also grows strongly here, but many that I have had disappear after the first year, though I cannot quite say this of *R. glacialis*, a plant abundant on the tops of some of the Swiss mountains, and which has lived on for the last two years, though it does little good. I have heard that this has been successfully grown in English gardens in a compost consisting mainly of smashed slate, an imitation of its habits and habitat, which sounds likely enough. I regret much that I cannot get that very beautiful *Buttercup*, *R. montanus*, to flourish. I grew it apparently successfully for a year, and it flowered well, but then disappeared, and a second relay planted in common soil did no good whatever. Another yellow species, *R. granifolius*, seems easily grown. I do not apparently know how to grow *Anemone palmata*, though both the yellow and white varieties occasionally flower here, but pieces of *A. sulphurea* brought home from Switzerland in the autumn of 1890 have become established and have bloomed. It is not easy to establish this species when dug up and

transplanted from its mountain home, and although I am rather proud of my own success, I do not altogether recommend others to do likewise, as strong seedlings if they can be procured are more likely to succeed. This is one of the most beautiful of *Anemones* and of alpine flowers, and another sulphur-coloured species (of the *Pulsatilla* tribe), *A. albana*, is perhaps one of the ugliest, the pistil and stamens being too large for the corolla, and giving the flower a choked and over-stuffed appearance. Many of the varieties of the *Pulsatilla Anemone* appear to be somewhat difficult to establish, or at any rate to obtain in the shape of plants that are likely to grow, and the same may be said for *Adonis pyrenaica*, which is certainly a much finer thing than the commoner *A. vernalis* when doing well.

In the face of the magnificent modern varieties of perennial Larkspur, it is not perhaps a very wise thing for gardeners, especially if space is limited, to trouble themselves about botanical species. *D. Brunonianum*, however (which I do not possess myself), appears to be distinct, and is a handsome plant. *D. triste*, a plant seldom procurable, and probably with a bad constitution, is quite unlike anything else. The yellow Larkspur (*D. Zalil*) is a remarkable plant whether it be in fact perennial or biennial, but it appears to be radically weak in constitution, and is not likely to become common in English gardens. I am now struggling with my second venture—my first having died suddenly—but I doubt if it is alive next year. *D. nudicaule elatius*, sold as a true perennial, is very much the reverse of this latter, like all its sisters, its brothers, and its aunts of the scarlet persuasion. I have had no real opportunity of judging the merits of *Clematis erecta*, for the drought has prevented its doing well at the flowering season, but this has the high recommendation of the Rev. C. Wolley Dod, and I sometimes wonder whether there are not others among these herbaceous *Clematises* that might be worth introducing into select gardens.

A year or two ago I bought several of the species of *Pæony*, but the results hitherto have not been very astonishing; indeed one or two of them are so very much like some plants of single *Pæonies* which I already possessed, that I fancy I must for some time have been entertaining angels unawares. Mr. Ewbank (and I rather think Miss Jekyll also) having pointed out that *P. Wittmaniana* is a plant that "no gentleman should be without," I thought it better to do the right thing promptly and set up with it last autumn, but it has not yet flowered. The price of this species is truly appalling, but I managed to get a good piece from a Dutch nursery at just one-third of the price asked in this country. They seem to manage these things better in Holland.

Among the *Cress* family (*Cruciferae*) the most remarkable introduction, or, more strictly, re-introduction, of recent date is *Morisia hypogæa*, a plant that I have not yet ventured to plant out and expose to the vicissitudes of a Kentish winter. It is said to be hardy, and is becoming commoner, though still a dear plant. The best of the alpine *Alyssums* (and a good many of them are much alike) is one named *A. serpyllifolium*. *A. pyrenaicum*, interesting from its rarity and the inaccessibility of its only known habitat, is a poor grower here, though, being so cheap, it probably grows better in many other places. The *Æthionemas* and pink *Iberis*, lovely things when grown well and in abundance, do not seem to do well here; nor do they seem to be easily raised from seed. *Vesicaria græca* is sufficiently unlike the *Alyssums* to be worth grow-

ing, but I lost it some years ago, and have never succeeded in getting it again.

I do not trouble myself much about alpine *Pinks*, many of which are too much alike, and the best of which, such as *Dianthus alpinus* and *glacialis*, are hard to keep on cold soils and in wet winters. The very beautiful species figured in *THE GARDEN* (Vol. XL., p. 332) under the name of *D. callizonus*, a native of the Transylvanian Alps and said to be hardy, has not yet, I think, got into the market; at any rate, I have not observed it in any list. *Arenaria montana* (or *grandiflora*), a plant of this order, is one of the most beautiful of all white alpine, and one wonders it is not more common. A neat species (*A. tetraquetra*) grows here, but has not yet flowered.

I should like to see an extraordinarily pretty little Greek alpine (*Erodium chrysanthum*) again in M. Froebel's catalogue. I kept this on my rockery for two or three years, which is more than I can say for *E. Richardi*, another pretty little gem of the same order that I must some day set up with again. I am always looking for novelties among the *Pea* family (*Leguminosæ*), but not always with conspicuous success. I think the best thing I have at all lately come across in this way is the red variety of the commoner *Anthyllis montana*, a beautiful variety of a beautiful species. The exigencies of a new and altered garden compelled me to move *Orobus roseus*, one of the most beautiful plants of the order in cultivation, and I lost it thereupon, and have never succeeded again in getting a growable plant. *O. varius*, as its name implies, is, perhaps, really variable. The plant that I have under that name, and for which I paid 2s. 6d., is beneath contempt, but it is a good deal praised, and the right thing may exist somewhere.

The beautiful pale lemon *Oxytropis campestris*, so common in the neighbourhood of Zermatt, is growing and flowering well here. I wish I had some more species, but the difficulty of moving and establishing these plants is well known and seed does not germinate freely. The rare and distinct *Astragalus adsurgens* has died here, I regret to say, and a plant for which under the name of *Tephrosia virginica* I paid 1s. 6d. has not even attempted to live. In the appendix to his interesting lecture on hardy flowers delivered before the Royal Horticultural Society, Mr. Wolley Dod mentions *Baptisia australis* as a good plant that will not do in his Cheshire garden. I was afraid at one time that the soil and climate of Mid-Kent were going to have the same effect, but I see my plant is at length doing well. This is a very fine herbaceous perennial when well grown. The little alpine *Broom* (*Genista humifusa*) is a beautiful free growing thing, and so is the British *G. pilosa*. Still more beautiful it may be, but hard to move, and I fancy difficult to propagate. *Trifolium uniflorum* is a very distinct plant, and apparently very difficult to procure. I saw it in my friend Mr. Ewbank's garden, who tells me he has since lost it, which speaks ill perhaps for its perennial quality. It is, I believe, a native of the Apennines.

An *Oxalis*, given me some few years ago by Mr. Ewbank under the name, I believe, of *O. pulchella*, is a gem of rare beauty; it has only one fault (which some people may perhaps think a virtue), viz., it flowers in October at a time

When the rotten woodland drips,
And the leaves are stamped in clay,

and when, in fact, one does not want it. Of all the new plants I have seen this year, another *Oxalis*, *O. enneaphylla*, has attracted me

most—lovely white flowers and still more lovely glaucous green foliage. Mr. Ewbank tells me this is hardly in the Isle of Wight, but I learn on equally good authority that it is not so at Kew, and I fear Kent must take its cue from the latter and not the former locality. It comes from the Falkland Islands.

Some twelve or fourteen years ago I bought a dwarf brick-red Poppy under the name of *P. spicatum*, a name which, for all I know, may be authorised, but which certainly rather "savours of Sweet," not to say of the nursery gardener. This has since been named by the Kew authorities *P. rupifragum* var. *atlanticum*, and still more recently (judging from a label I saw on the Kew rockery last spring) *P. lateritium*. The peculiarity of my plant is that while it never reproduces itself by seed, it appears to become habitually hybridised from pollen of the common *P. orientale*, and has produced a remarkably good strain of garden Poppies, dwarfer and more floriferous than the male parent, having bright scarlet petals without any blotch and almost blue anthers. Another good Poppy is *P. pilosum*, which should be more largely grown, for it is very easily raised. The Himalayan *Catheartia villosa* has eluded me, nor have I ever succeeded in piloting the blue and yellow *Meconopsis* (*M. Wallichii* and *M. nepalensis*) between the Scylla of a cold winter and the Charybdis of a dry spring. The Chinese *Eomecon* (figured Vol. XXXV., p. 76) grows strongly with a wild and weedy growth. It is worth having, though less beautiful than its American cousin, *Sanguinaria canadensis*. It is needless to say that *Romneya Coulteri* is hopeless in such a garden as mine in the open, but it appears to be quite possible to grow this in large pots and keep it through the winter in a house. At any rate, I have done this with success during the last winter, and have bloomed it during the present summer. As I believe the flowers are produced solely upon young shoots, the plants need never become unmanageably big. This is a thing worth any amount of trouble.

A few years ago I had quite a good collection of *Cistus*, but these were all killed by the winter of 1890-91 except two, the variety known as *C. formosus* and *C. alyssoides*. As these two were both sent to join the majority by the short sharp frost of last January, I am not perhaps entitled to suggest that they are essentially hardier than others. The latter species roots at the joints as it spreads, which affords a ready means of propagating it, but it is inferior to most of these things in point of beauty. *Helianthemum tuberaria*, one of the few herbaceous rock Roses, is rare in English gardens; it is a beautiful thing and worth growing, and probably easy to keep through the winter in a cool house, for it has, I believe, no pretensions to be considered hardy in this country.

I never seek composite flowers, and seldom come across any new plant in this colossal order that much interests me. The *Inulas* of the Caucasus (*I. glandulosa*, for instance) are among the most beautiful and most distinct of the summer-flowering plants of the order. *Centaurea ruthenica* is also a graceful plant and very distinct, so much so, that I cannot help wondering if there are not other species (over and above what we already have) among the long list of the genus which might be worth growing in choice selections. These things attract me more than the Michaelmas Daisy tribe. The biennial Mexican Thistle (*Erythrolena conspicua*) I hope to flower next year. I have not seen it myself in any garden as yet. The rigour, not to say coarseness of growth, of the great majority of this order of plants is well

known, but it is noticeable, nevertheless, how extremely difficult to transplant and establish some of the alpine species are found to be, while many even of the strong growing Daisy flowers appear to be especially agreeable to slugs. *Celmisias* are distinct, but lack hardiness, I believe. They are New Zealand plants, I understand. I doubt if I have as yet succeeded in establishing *Ostrowskia magnifica*. I started this year with a decent plant, but it has gone under rather prematurely, I fear; however, it may come up again next year. This is finely grown by a neighbour of mine, who gives it the protection of a little manure and ashes during the winter. The New Zealander (*Wahlenbergia saxicola*) I had in abundance last year, for it seeded all about my rockeries, but this year there is not a single plant to be seen from which I am disposed to infer that here, at any rate, it is simply an annual, and the entire absence of rain for the last four months has prevented the seed germinating for this season. It is not of much value, being far inferior to most of the alpine Hairbells even when the blooms are open, which they seldom are for more than an hour or two during the day. I bought *C. Raineri* (vera), but I am not sure even now whether I have got the true thing. My plant gets smaller rather than larger, and has sickly yellow foliage like the hybrid *G. F. Wilson*, both which peculiarities no doubt speak well for its authenticity, but it certainly does not correspond with some description of this species which I read not long ago in THE GARDEN. The blooms of my plant are much like those of the common *C. carpatia*, and I cannot see that they are in any respect more beautiful—at any rate, this is not a species about which collectors need make themselves unhappy.

It may possibly be from some want of tone in my moral nature, but ever since I have interested myself at all in hardy flowers I have always had "gentian on the brain." Any sort of dog-Latin adjective attached to the word "gentiana" by way of a specific name attracts and tempts me at once. This is not an altogether desirable craze to have, for anyone acquainted with the culture of alpine and such things must be aware that the death rate is higher in this than in almost any other family. Some time ago (Vol. XLI., pp. 185, 240) there was a discussion in these pages about *G. verna*. I took no part in it myself, but I was inclined to agree at the time with Mr. Ewbank, who, if I recollect right, held a brief for the optimists in this little controversy. My own experience is that this species can be successfully grown up to a certain point, and, as far as I can see, it does far better in common soil than in any sort of compost that can be made for it; indeed, it has always disappeared at once with me when planted in any mixture of peat, while the finest plant I ever had grew in a dry border slightly raised. I am inclined to doubt, however, whether the same plant can be successfully grown for any great length of time; certainly here it seems to reach a zenith, after which comes a more or less rapid decline. Two or three years ago I had the common blue, the white, and the red-purple varieties all growing and flowering side by side, but the last is gone, and I fear the second will have followed it by next spring. Of the common *G. verna*, I observe that Irish plants flower considerably later than those hailing from Swiss habitats. Next to the common *Gentianella* (*G. acaulis*), by far the most vigorous *Gentian* in my garden is *G. bavarica*. A piece which I brought or sent home myself in 1890 spreads strongly and

flowers freely and continuously. I planted it originally surrounded with white sand, and occasionally give it a dressing of the same material, and during the recent drought I kept it surrounded by damp *Sphagnum Moss*. If this loveliest of alpine will grow in my soil and climate, there seems no reason why it should not do well anywhere. I took a hint from Mr. Ewbank last year, and made a sort of sunk bed with cement sides and bottom. In this several *Irises* and some six or seven summer and autumn *Gentians* appear to be doing well, though the prolonged drought of the spring and summer has been much against them. Among those apparently growing well and likely to live (besides *G. septemfida*, which remains, as far as I know, the best summer-flowering *Gentian* that we have) are *G. tibetica*, *G. Wallichii*, much like *G. septemfida*; *G. alba*, apparently a robust and genuine perennial; and *G. angustifolia*. *G. oregana* also seems likely to grow and thrive. Many others have failed—some, like *G. saponaria* and *G. ornata*, after flowering once; others, like *G. calycosa*, without even making any attempt to live. I have never succeeded in establishing permanently any of the choice varieties of *G. acaulis*, though I have had plants of the white and sky blue sorts that have flowered. There are, however, few alpine plants that show less inclination to accommodate themselves to English climatic conditions than *G. acaulis* when imported direct from its mountain home. One of the most distinct and remarkable summer-flowering *Gentians* that has ever been introduced is the American *G. sceptrum*. Some years ago there was a very fine specimen of this growing in the bog at Kew, and I should very much like to know what became of it. It has certainly disappeared long since, and I am pretty sure it was gone the next year after I saw it in bloom. I have no personal knowledge of how these things are managed, but as it is hardly to be supposed that a rare and choice perennial of this sort would be rooted out if once established, I assume that it must have succumbed either to the English winter or more probably to some want of perennial quality. The Chatham Island Forget-me-not (*Myosotidium nobile*) is one of the most beautiful blue flowers ever introduced, but as far as my experience goes, it will not grow in the open and dies in a house—a sort of vegetable sea serpent. The green-fly and other pests (all other pests, I think) are always with it.

Onosma albo-roseum is a choice and interesting plant. It is not a biennial (as I have seen stated somewhere), and it is not capable apparently of being permanently cultivated in the open. I had a very fine specimen under a hand-glass up to the end of last December, but it was turned into a black mass in one night. It broke again from the roots in the spring and has a second time grown into a good plant. I hope to raise it later on and keep it through the winter in a pot under glass. The name, though fairly descriptive, is, I admit, very shocking, but we shall not improve it by translating it into the "Whitey-rosey Asses'-sniff"; and as for the Silver Dropwort, the white is not at all silvery, while the name ignores the pink edge of the corolla.

The papers on hardy *Cypripediums* and *Orchises* contributed occasionally by your correspondent Mr. Webster are models of what such articles should be, for one may learn from them not only how these things may best be grown, but which of the species are the most and which the least likely to be successful. I at any rate have taken the hint to be cautious in these matters, and have only

lost one species (*C. candidum*) out of the few I have tried. The three yellow species (*C. Calceolus*, *C. pubescens* and *C. parviflorum*) are all growing vigorously here, the first in chalk, the two latter planted, according to Mr. Webster's plan, on decayed logs sunk about 9 inches in the earth. *C. spectabile* anyone apparently can grow. Kent, on the chalk formation, is the headquarters of English Orchises. I have never been guilty of the vandalism of digging up any species of *Ophrys*, but I have on one or two occasions tried to grow the great Butterfly Orchis (*Habenaria bifolia*) and the finest of all, the great brown Orchis (*O. purpurea*), said to be confined to Kent, but which is to all intents and purposes the same (except for some infinitesimal botanical distinction) as *O. militaris*, said to be confined to S. Oxfordshire. Neither of these, however, has ever done well, and if they come up at all, always disappear the second year. The *Cephalantheras*, or *Helleborines*, do better, though they lack the beauty of the Orchises above named.

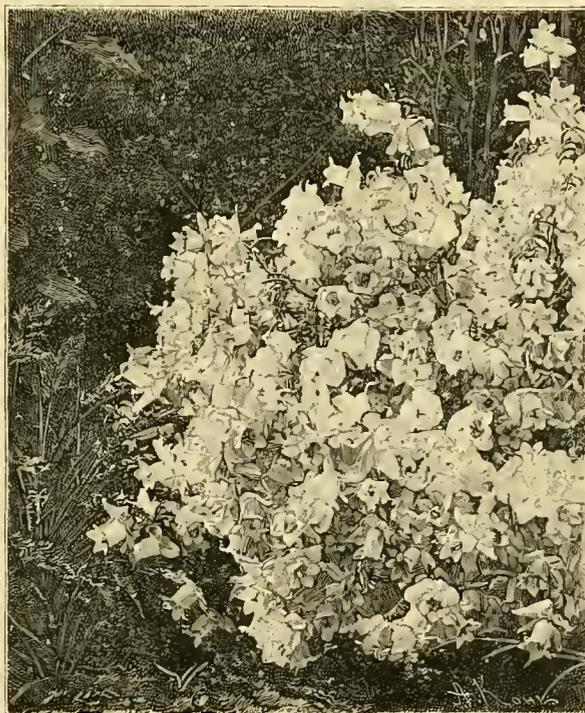

Now that the horticultural public has either finally embraced "pan purpurism" or else has sadly acquiesced in the conclusion that there is no such colour, I would suggest the "interesting plant" as a theme for an autumn controversy. What is an "interesting plant"? Gardeners of the "robust" type probably regard a plant said to be "interesting" much as some of us regard a young man said to be "very good," that is to say, as one to be avoided as far as possible. I confess for myself, however, to having a distinct weakness for plants—especially N. American plants—that will not grow in English gardens, and I suppose it will be admitted that for a plant to be "interesting" it should be difficult or next to impossible to grow. There is, for instance, the Pine Barren Beauty (*Pyxidantha barbata*), of which a kind American friend has sent me boxes—hopeless! There is my old friend *Rhexia virginica*, on which I have spent a small fortune, but have never seen in my own or anybody else's garden. There is *Aletris farinosa*, which I suppose somebody can grow, for it remains pretty cheap. However, if any of your readers have got this established I shall be interested to hear of it. There is *Polemonium confertum*, which, I am aware, is successfully grown by your correspondent Mr. Wood, but which I have never yet succeeded in making permanently happy in any soil or situation, though a morbid craz; for blue flowers has induced me to buy it about half-a-dozen times.

I fear I must reckon a plant I bought in the early part of the present year under the name of *Dasystoma flava* among "interesting" failures. Why this should have failed to grow is not quite obvious to me, for the piece sent me was apparently healthy and vigorous. The prolonged drought, which has made life to unestablished plants difficult, if not absolutely impossible, may perhaps account for it, but *Dasystoma* is, I believe, closely allied to *Gerardia*, a genus which has never taken kindly to English climatic conditions, and which I have never met with anywhere successfully grown.

The plant in my garden which at present, I think, affords me the greatest satisfaction is *Clintonia Andrewsiana*. This has not yet flowered here, but I have at last, I hope, got it permanently established in a shady position on the rockery growing in a little peat with a good deal of grit. As far as my experience goes, unestablished plants of this species are especially liable to damp off in early spring even when grown in pots, but there seems no reason to

doubt its hardiness when once established. I saw this (and I have never seen it elsewhere) in Mr. Ewbank's garden at Ryde in 1889, and although I do not say it is "the finest hardy plant in cultivation," as some anonymous enthusiast is said to have called it, it is beautiful and exceptionally distinct. It is a liliaceous plant, and the flowers are very dark red, something the colour of our own Figwort, the leaves rich green and glabrous.

Hesperochiron pumilus, given me many years ago by Mr. Wolley Dod, I have managed to keep, though for a year or two, if I rightly remember, it gave up flowering. I now grow it in a small pot permanently sunk in the rockery. The pot, of course, merely protects the tiny roots from being washed or scratched out of the ground, for the plant itself is perfectly hardy. It never increases, and I get about six or eight flowers yearly; these are not unlike *Oxalis Acetosella*. It has no value as a garden plant, and I am extremely proud of it and take everyone

Group of Canterbury Bells (*Campanula Medium*).

who comes to see my flowers in late April to see it. The name of *Scolopus Bigelowi* is itself much in its favour. I had it for years before it flowered, probably because nursery-men's plants take some time to grow into flowering size, but it bloomed well in March of last year and failed to flower in the recent spring. I cannot at all tell why. It comes among the very early spring flowers long before the *Trillium*, to which it is allied. *Galax aphylla* never did well here and has disappeared. *Jeffersonia diphylla* continues to live, but has not flowered for some years. The last time it did so, the sparrows, or some small birds, knocked the blooms all to pieces. My third (or it may be my fourth) plant of *Shortia galacifolia* is at present in a pot. I have lost so many, that I have not the courage to put it out, though probably plants strongly grown in pots have the best chance of success. I have seen this apparently growing well in the open in the gardens of one or two of my friends this summer, but I know no one who has as

yet satisfactorily established it and bloomed it in the open. *Lancea tibetica* is a very dwarf plant, something like a purple Musk. Mr. Wolley Dod tells me he finds its weedy growth objectionable, but here at any rate, perhaps owing to the impossibility of anything growing this year, it has maintained the habits of good society. I like it. It is said to be the only species of the genus. The white variety of *Ramondia*, which flowered here this summer, is worthless so far as I can judge at present.

Mid-Kent.

J. C. L.

ANNUAL AND BIENNIAL HARBELLS.

The *Campanulas* comprise annual, biennial and perennial species—an interesting and beautiful family, adapted for all kinds of situations and differing greatly in expression. The little *C. fragilis*, that spreads its growth over the rockwork, is different from the gay and gaudy Canterbury Bells represented in the accompanying illustration. A rock garden well planted with the Bellflowers is a mass of colour at this season, and obtained at little expense.

A very distinct section of the genus is that comprising the annual and biennial kinds. Annual flowers, we are afraid, are having a poor time this season, and where the rainfall has been practically *nil* since March last the seedlings are making slow progress. We were looking at an important collection of *Campanulas* recently, and the annual kinds had scarcely moved; but they must not be judged from their behaviour in a phenomenally hot season, when everything is hanging its head in the fierce sunshine. The most important annual species is *C. macrostyla*, which ranks amongst the finest of hardy annual flowers. A coloured plate was given of it in THE GARDEN, May 3, 1879, about two years after its introduction from its home at Lake Isauria, near Mount Taurus, in Asia Minor. It is remarkably distinct, possessing a character peculiarly its own and unlike all other members of the family. The habit of growth is rigid, and it grows about 1 foot high, whilst it assumes a candelabrum-like form, the much-branched, wiry stems embellished with very small leaves. One wants to see a good mass of it, and this applies to annuals in general. They are effective when in bold clumps or colonies. The distinguishing feature of this species is the style; hence the origin of the name, and it is remarkably developed, standing out erect from the flower, which is quite flat, salver-shaped, and the leaves and stem are ciliate. In the month of July this fine annual *Campanula* opens its handsome flowers, which are veined with blue on a white ground and shaded with purple. There is a variety named *roseiflora*, which, as suggested by the name, has rose-coloured flowers. One does not often see this *Campanula* in gardens, but it is worth growing for its distinct flowers. Another good annual kind is *C. Loreyi* and its variety *alba*, which are pretty kinds, easily grown, and last almost throughout the season. *C. Loreyi*, sometimes spelt *Lorei*, has been long

in English gardens. It is synonymous with *C. ramosissima*, and was introduced from Mount Baldi, in North Italy, in 1824. The plant grows about 1 foot in height, and has small shining leaves. The deep blue flowers are freely produced, and make a good show when one has a good mass of plants, as previously advised. This annual is not very common in gardens, but it is worth a place in the border, especially where there are other kinds. There are varieties of *C. Loreyi*, and the chief is named *alba*, the flowers of which are greyish white, and also *C. L. fl.-pl.*, besides a form called *stricta*, in allusion to the upright character of growth, the flowers light blue in colour. These are the best of the group, but a few others may be named. *C. Loefflingi* is quite a dwarf species from Spain, where it colours the cornfields with its flowers, which are solitary, funnel-shaped, produced in panicles, and of a blue colour. It is useful for the rockery, but is very dwarf, only a few inches in height. A good patch of it is showy, and the seed is easily raised. We may add *C. strigosa* and others, but the most important have been described.

Many *Campanulas* may be treated as biennials, but the chief biennial kind is *C. Medium*, a favourite old plant that is superb in masses, owing to the varied and splendid colours. It is the most useful of the family, showy either in the border or in pots, and there is much diversity of character in the several varieties. Cross fertilisation has done much, and amongst the large number of varieties are some very charming forms. We much prefer the ordinary singles to the duplex and double types. There are many good strains as they are called, and a mixed packet of seed will give many fine things. The plants bloom with the greatest freedom, each shoot heavily weighted with the stout bells, and when in perfection are perfect mounds of blossom. A glance at the illustration will show their freedom, but one need not describe such a lovely subject, which should be in every good garden, grown in masses to get effect from the flowers. Another point is that the plants even when in bloom may be lifted and potted for the greenhouse, conservatory, or to form groups in the house or at the exhibition. The *calycanthema* varieties are those in which the calyx has by selection assumed a very broad saucer-like character, and it is this type that gets coarse when too large, wanting in the refinement and beauty of the ordinary forms. The plants, it must not be forgotten, should be put into bold groups in large gardens, and the effect is finer if the colours are kept distinct, not mixed, these being very poor in comparison. Get a good blue, rose, purple, white, and try grouping them in distinct colonies, and we think that the result will be pleasing. There is plenty to select from, the colours varying greatly and the seed is easily raised. Keep the fading flowers picked off to promote continuous blooming. Get the young seedlings in position before autumn is far advanced. A succession of seedlings should be obtained, otherwise there will be a blank in the display.

C. persicifolia, *C. pyramidalis* and their respective varieties, besides many others, especially the trailing kinds, may be mentioned; but these have been often noted in THE GARDEN. Of biennials, the Canterbury Bells hold first place, and the interesting annual kinds add to the beauty of the garden in the summer months.

Eryngium alpinum.—Amongst hardy flowers nothing attracted so much attention at the recent Richmond show as did a cluster of heads of *Eryn-*

gium alpinum shown by Mr. Prichard, of Christchurch. It is said to have been introduced in 1507. Certainly it is one of the most beautiful of the perennial Thistles. The heads are large, bluish silver in hue, the bracts much larger than in giganteum, softer, indeed almost silky-like in texture, most elegantly lacinated and interlined with blue. Most certainly do we owe the rescuing from oblivion of large numbers of beautiful plants to the movement in favour of hardy flowers.—A. D.

Exhibiting hardy flowers.—I observed that at Richmond one trade grower followed the vicious example so fearfully set at the Temple show and elsewhere of setting up in bewildering profusion and confusion literally everything that a hardy garden could furnish—good, bad, and indifferent—without regard to the effect of such a show on the minds of sightseers. Did trade growers but limit their collections to the best and leave the rubbish at home, they would very materially help to attract the attention of visitors at shows, who want the best only. The two collections of twenty-four bunches, distinct, set up in a class by Mr. Prichard and Mr. Sage, were worth many of the ordinary trade collections. How much shows and gardening would gain were in these things trade growers much more self-denying and discriminating.—A. D.

Kempfer's Iris.—Unless in close proximity to water, Kempfer's Iris is this year by no means up to its usual standard, for even where the plants have been freely watered the foliage is wanting in colour, while the flowers are not so numerous as they are in most seasons. It is essentially a water-side plant, and though during a dry summer a good deal may be done (if they are planted in a sunk bed) by watering whenever necessary, it has been this year insufficient to maintain them in a satisfactory condition. Where too dry, the foliage is very quickly attacked by insect pests, especially red spider and a large black form of thrips. These last shelter themselves at the base of the leaves, where they are closely adpressed together, and from whence it is impossible to dislodge them. This Iris is sent here in great numbers from Japan during the winter months, mostly in the shape of small clumps containing about half-a-dozen crowns, that are well protected against damage by the stiff clayey soil in which they have been grown. If planted under suitable conditions these clumps of Iris can as a rule be depended upon to flower well the first season, and very beautiful varieties can be found among them. Many have the flowers splashed and flaked in a curious and striking manner. These are admired by some, but I prefer the self-coloured blossoms, two particular forms of which crop up as a rule pretty freely among these imported clumps. One is of a deep rich purple, just lit up with gold at the base of the petals, while the other is pure white. Both are very large flowers and have a double row of expanded falls, so that they form what is usually spoken of as double blossoms. These imported clumps afford a good opportunity for anyone anxious to commence the culture of these beautiful forms of Iris. From the adhesive nature of the soil and the shaking about they have undergone, the balls of earth are nearly as hard as a brick; consequently I prefer to loosen them somewhat with a pointed stick before planting.—H. P.

Lilies.—I have rarely seen in any one garden of such moderate dimensions such a collection of Lilies as Mr. Herbst has in his garden at Richmond. Like so many others, he does not find that Lilies have much of permanence. Still, bulbs are purchased by the hundred so cheaply, that a supply is easily maintained. In Mr. Herbst's garden I found *Lilium testaceum*, about 4 feet in height, blooming finely, the flowers pendent and of a sulphur-cream hue. This is said to be a hybrid between *L. candidum* and *L. tigrinum*. Wonderfully fine from last year's bulbs are growths of *tigrinum*. *Thunbergianum* had bloomed well and was over. *Croceum*, one of the hardiest of garden Lilies, was still flowering well. *Browni* was dwarfer than usual and the flowers imperfectly developed. *Longiflorum*, *eximium*, and *Harrisii* had all done

well. Various forms of the *lancifolium* section were about to bloom capitably, for these in clumps of three would form later a telling feature. *Auratum* was not in strong force, as it is seldom so satisfactory as some other varieties. The soil is a fairly deep-holding loam well prepared, but rarely are any of the Lilies good for much after the second year. Mr. Herbst has a capital collection of Irises—German, Spanish, and English; also good sorts of Gladioli. His garden is one in which many things are found that are far from being common, and there is in it more of bloom than may often be found in one of large area. Roses are in great abundance. Hybrid Perpetuals, Teas, Noisettes, Chinas, Polyanthas, &c., are all very beautiful. Limited as is the area, some good vegetables are grown too, and some standard Morello Cherries are carrying wonderful crops. The collection of Ivies is an excellent one, and they are encouraged to grow in all sorts of ways.—A. D.

THE CARNATION AND PICOTEE.

As a cultivator of the Carnation and Picotee for over thirty years, I have obtained considerable knowledge of the way in which the changes in the seasons act upon the plants.

In a hot, dry season like the present the rapidity of growth during the past month has been surprising. Those unacquainted with the action of excessively hot weather upon the blooms, whether the plants are grown in pots or planted out in the open borders, may be surprised that the flowers are much smaller than usual. When the weather is cool, especially at night, the petals expand slowly, but in hot weather the flowers open with astonishing rapidity, and the petals do not expand to their full size. Our garden is nearly full of Carnations; hundreds are grown in flower-pots and many hundreds more in the open borders.

The want of rain has been very much felt, especially with the border Carnations, green-fly gets upon the foliage, and the active little insect—the thrip, sadly mars the beauty of the flowers. Some persons may say, "Why do you not destroy these pests?" The answer to this is, "With so much work pressing and all hands at the pump, for we have had no rain to speak of since February, more than our usual share of sunshine, and now it is the 26th of June, there has not been time to do the work as it should have been done." The pity of it is that beautiful seedling varieties flowering for the first time become so disfigured, that it is impossible to say whether they should be propagated and grown on for another year. I have so frequently advocated the growing of seedling Carnations and Picotees, that no more for the present need be said on that point. At the present time, June 26, most of the border Carnations, seedlings included, have flowers fully expanded upon them; they will not be fully in flower for another week, but this is quite three weeks earlier than usual.

The flower-trusses have not been thinned out, and the seedling plants are quite laden with flowers and buds. When the plants began to show the effects of the dry weather, I had the entire surface of the ground amongst the plants dressed with manure obtained fresh from stables where peat litter is used for bedding the horses. I have used this in previous years and found it very effectual in promoting growth, but this season, after giving a thorough soaking of water over the manure, the effect was almost magical in promoting vigorous growth, and as the plants were well watered overhead with a hose, the insect pests were kept down better than might have been expected. The named varieties were treated in the same manner as the seedlings, and where large blooms were expected for exhibition, the flower-buds were reduced to three or four upon one stem. All the trusses have been tied to neat sticks, and the effect of the whole is exceedingly good, the masses of colour in the seedling beds having the best effect at a distance, and they are very interesting because of the daily development of the new seedling varieties of merit, expanding their flowers for the first time.

Many amateurs may have to purchase their seed, and it cannot be expected that a packet of seed sold for 1s. 6d. or 2s. 6d. can have all been saved from the best varieties after the most careful fertilisation, nor must the amateur expect, even when he has carefully fertilised the flowers of the best varieties, that the seedlings will all be good. My experience this year has resulted in the production of an unusually large number of plants producing single blooms merely, and this may be partly owing to the season hurrying them on too fast, but more, I expect, because the seed has been saved from rather thin, but well marked flowers in the bizarre classes. The result is interesting and sometimes amusing, the variety in form and colour being so varied. The removal of several barrow-loads of single flowered varieties has given more space for the development of the plants of the better varieties, and their ceasing to extract moisture from the ground will save watering to some extent. I alluded some time ago to the fact that the best purple self Carnation yet raised, named Purple Emperor, was produced by me from the purple-edged Picotee Her Majesty, crossed with another light purple-edged variety. We have a considerable number of plants this year from light purple-edged Picotees, and the result is a considerable number of purple Carnations amongst them. To many amateurs this may be a source of disappointment, but amongst them there will doubtless be a number of varieties in the class intended to be improved. No class contains flowers of such good colours or so perfect in form that further improvement is impossible. Every raiser of seedlings should set himself a high standard of excellence, and never rest satisfied until he has worked up to it.

I have given a good deal of attention to the production of yellow ground Carnations from seed, and in this class the variations of colour presented by the seedlings raised even from the same parents are truly surprising. The yellow Carnation and Picotee are no doubt accidental productions from the white ground varieties. The question has been asked, When or how was it produced? We do not know more than this, that the yellow Carnation was grown in England before the year 1597, as Gerard mentions in his "Herbal" that a merchant in London named Nicholas Leat obtained a Carnation with yellow flowers from Poland and gave it to him, and he cultivated it in his garden in London. Early in the seventeenth century the yellow ground varieties became popular, as Parkinson informs us in his "Paradisus," published in 1629. I have raised in some seasons and bloomed upwards of 600 seedling plants from yellow ground varieties, and amongst them many plants produce flowers with white grounds, also self-coloured border Carnations, rose, red, maroon, and scarlet. I was informed of one seedling raiser who produced 300 plants from seed obtained from the yellow self Pride of Peshurst, and the result was one variety with yellow flowers; the remainder presented every shade of colour but yellow. The time has now arrived to fertilise the flowers which are to produce seed, and the amateur must promptly decide what class he intends to operate upon. If self-coloured border Carnations are desired, choose a bright-coloured variety with well-formed flowers as the pollen parent. The seed-bearer should be of vigorous sturdy habit, producing stout flower-stems of moderate height. These are essential, and the results will be all the more satisfactory if the flowers are of as good colour and form as those of the pollen parent. Choose a fine day to fertilise the flowers, as the pollen is more potent and in the condition of a fine yellow powder. The stigma is in the centre of the flower in the form of two horn-like processes. Collect the pollen from amongst the petals with a fine camel's-hair brush, with which it is applied to the stigma. If the pollen has taken, the flowers will collapse in twenty-four hours. If they do not, the process must be repeated; but never use the pollen when in a sticky condition. Do not mix the classes. Cross self-coloured varieties with selfs, bizarres with bizarres, flakes with flakes, Picotees with Picotees, and yellow ground varieties with flowers

of the same colour. The seed will take two months or more to ripen, and this stage can be ascertained by the capsule assuming a yellow tinge and opening at the apex. Gather the pods and lay them out on clean paper in a dry place. The time to sow the seed is from the middle of March to the middle of April. I generally sow it about the 1st of the latter month. The plants for this year are now of large size and ready to set out in the open ground. They should be planted in June, and they like rich deep soil to grow in. Plant them 18 inches asunder, this giving ample space for the development of the plants. They do not require such careful preparation of the soil as rooted layers of the named varieties, which are not generally planted until the end of September. The plants in pots were all placed in a glass house about the middle of June, and in this position they were easily fumigated with tobacco smoke to destroy the thrips and green-fly. The flowers are much better developed and of surpassing purity when thus freed from insect pests, sheltered from the inclemency of the weather, and protected from too much sunshine by light, movable shading. Some weakly constituted varieties which will scarcely live out in the open borders will thus produce their flowers in very fair condition; moreover, in our uncertain climate seed can seldom be produced from plants grown out of doors, the shelter of glass being absolutely necessary to ripen the seed well and prevent the pods from decaying by damp before the seed is ripe. When the plants are grown under glass they should have ample ventilation.

J. DOUGLAS.

Early-flowering Gladioli.—Judging by the numerous examples of the early-flowering Gladioli that are to be met with this season, they are advancing considerably in popularity. This need not be wondered at, for the markings of the flowers are in some very bright, and in others very chaste and delicate, as may be seen by reference to a coloured plate in THE GARDEN, December 22, 1888. In a cut state their light and slender spikes fit them for purposes where the large massive ones of the *gandavensis* section would be inadmissible. Where a greenhouse or conservatory has to be kept gay with flowering plants at all seasons, these Gladioli will be found extremely useful, and for such a purpose the purple-flowered Colvillei, and more particularly its white variety *albus* or The Bride, has been grown for a long time. Gladioli of this section are largely grown in Guernsey, from whence considerable numbers are distributed every year. When needed for greenhouse decoration, the bulbs should not be potted singly, but about half a dozen in a 6-inch pot.—H. P.

Layia elegans.—Amongst annuals that are blooming fairly well this season is this charming kind. This class is remarkably good, considering the season, at Syon House, and we made special note of the *Layia* as an annual none too common in commons. *L. elegans* is much like *L. heterotricha*, the flowers produced very freely, and yellow, with a broad white margin. It is very dwarf, not unlike a Daisy, and charming for cutting. A large mass of it in the border at Syon is very beautiful.

Lilium testaceum.—This Lily is in colour totally distinct from any other member of the genus, the flowers being of a clear nankeen tint, while the anthers are bright orange. It is supposed to be of hybrid origin, the parents being the scarlet Turk's cap Lily (*L. chalcedonicum*) and the Madonna Lily (*L. candidum*). In growth it more nearly resembles this latter, while the flowers, which are as large as those of *L. candidum*, are prettily reflexed. The bulb is very much like that of the Madonna Lily, which is the earliest of all the Lilies to start into growth. *L. testaceum* comes next, or rather it appears above ground at much the same time as the pretty yellow-flowered *L. Hansonii*; while these two are closely followed by the scarlet Turk's cap (*L. chalcedonicum*). Though this last commences to grow so early, it is among the later blooming Lilies, as July is often

well advanced before it flowers. *L. testaceum*, on the other hand, usually blooms towards the latter part of June, though this year, in common with all outdoor subjects, it is earlier than that. The perfume of the flowers is very pleasing. *L. testaceum* will grow in a light sandy loam better than many other Lilies. Besides the above name it is also known as *L. Isabellinum*, *L. peregrinum* and *L. excelsum*. This last name is very suggestive, as when thoroughly established it is really a tall and stately Lily.—H. P.

ROSE GARDEN.

ROSES AT UCKFIELD.

IN such a season as the present one, June is truly the month of Roses, but during recent years a visit to a large Rose garden or nursery during that month would hardly have been repaid. Probably not within the memory of the majority of Rose growers has there ever been such a display during the last fortnight of June as there has been this year. It was in anticipation, therefore, of seeing many old favourites in full beauty, and perhaps of making the acquaintance of some new candidate for popularity, that I spent a day among Roses in East Sussex, and the centre of their cultivation there is the nursery of Mr. G. W. Piper at Uckfield. Here the pride and beauty of the Rose family, the Teas, find a congenial home, and I noted with special satisfaction that Mr. Piper entertained no erroneous notions on the score of tenderness, but inclined to the view that the Teas are as hardy as the Hybrid Perpetuals.

The two great families in any case were about equally balanced here, and the plants on all sides gay with flowers. But the season has been a trying one, and characterised by extremes which are sure to leave their mark; and whether one sees plants by the score in private gardens or by the thousand in nurseries, heat and cold and drought have all contributed to make them fall short of the usual standard of merit. Hot days and cold nights are most trying, and Mr. Piper pointed out to me flowers showing undoubted traces of having been touched by frost when the buds were but embryos on the growing shoot. After great heat by day the glass on several mornings in June went down to freezing point at 4 feet from the ground, and this would mean actual frost among dwarf Roses. All these things are factors of evil, more or less, and one has to remember them, nor fails to do so when it is seen how they spoil the good intentions of the best growers. The good old reliable kinds, Teas as well as Hybrid Perpetuals, were here in number, as, for example, Rubens, one of the earliest, yet still one of the best among Teas, with Alfred Colomb and Captain Christy in the Hybrid Perpetual section. These in fine form are always beautiful, but those who care for Roses know them and what they are. Mme. Hoste is a fine Tea with Mr. Piper, and I think with anyone who will give it a fair trial, it is certainly the best pale yellow for out of doors. Certain Roses require special years to bring them to perfection, and this has been quite the year for Jean Ducher, Francisca Kruger, and others, bringing out their full flowers in a matchless variety of tints. I am afraid Mme. Pierre Guillot will also have to be included among this lot. It came from the noted raiser M. Guillot with Ernest Metz in 1888, but whilst this latter kind has already made its name for fine form, freedom, vigour, constancy—in short, all the essential qualities of a first-

rate Tea—its twin sister, which from the name it bears must have been good in its raiser's estimation, has shown us but few flowers. Here were some of the brightest and best I have seen, and when good there is no denying that it is a taking Rose with a brilliant centre of rich rose colour, but externally coppery yellow, shading to white at the edges of the petals. Roses that make good plants and fail to flower regularly, or that open fine flowers freely, as in the case of Cleopatra, which I saw in good form, and fail to make a plant, are ever doubtful and not to be generally recommended. Dr. Grill is a growing favourite at Uckfield. It was hardly known till figured in THE GARDEN; our trade importers had overlooked it; yet it is hardy, vigorous, free, and constant, most charming in groups. Another sport from Catherine Mermet seems likely to come forth and take its place with those that have preceded it as the lovely offspring of a lovely parent. There are already The Bride in one direction, white, and Waban in the opposite extreme approaching red. This new sport originated with Mr. Piper, and has all the qualities of Catherine Mermet, the essential point being its distinct colour. It is intermediate between the parent and The Bride, white, or almost white, externally, but with a pink-coloured centre, the tint pronounced upon the edges of the petals in the half-opened bloom in the same way as characterises the lovely Souvenir de Paul Neron. The plant that produced the sport last year has given another shoot from the same place and with similarly coloured flowers this year, so that there is no doubt as to its origin and distinctness.

Kaiserin Friedrich, among Dijon Teas, looked very promising, and among Hybrid Perpetuals I saw nothing so fine as Gustave Piganeau, though in truth it must be admitted that it is of uncertain growth, and through this will fall short of the great destiny it otherwise deserves. I saw a good proportion of blooms on a row of plants, and it impressed me much more favourably than last year, when I saw it in another nursery and thought the flowers rather dull in tint. Probably then I did not see a fresh flower, but with Mr. Piper it was grand, the flowers of large size, full, well formed, and of a clear bright carmine-red colour. A word of praise must be given to Susanne Marie Rodocanachi, although it is not new. It has a dreadful name, but it is one of the brightest Roses, so clear and decided in colour; there is no mistaking it anywhere.

Having looked through Mr. Piper's Roses, he kindly led the way through pleasant fields for a couple of miles to the Framfield Nursery of the noted Waltham Cross firm, which is in charge of the veteran Mr. Ironside. Here, however, the aim is plants, not flowers, the latter being sacrificed for the plant's benefit. There is pleasure, however, in the sight of large breadths of the first rate kinds in rich and vigorous growth, fine stock for autumn distribution. Maresfield, too, is only two miles from Uckfield, and here Messrs. Wood and Son grow many fine Roses. The Teas, I believe, from some peculiarity of situation, are not grown, but Hybrid Perpetuals and other old garden Roses are plentiful. A. H.

Rose Gustave Piganeau.—This Hybrid Perpetual is in fine character again this season. It has been already shown well, and seems likely to prove one of the best exhibition Roses of the year. The flowers are too large to please everyone, and they are not free from coarseness, but the crimson

colour is decided, the petals large, and composing a full, handsome bloom. Last year it won many silver medals offered for the best H.P. flower in the exhibition. It is quite a Paul Neron in size, but more refined.

Polyantha Roses.—Too much praise cannot certainly be bestowed upon this charming race of garden Roses. Two or three years since I saw hundreds of pretty little standards of the Polyantha Rose growing in 5-inch pots for conservatory decoration. The stems were about a foot in height. Arranged with other plants in the conservatory they produced a charming effect.—A. YOUNG.

A splendid single Rose.—Not one Rose of the hundreds we have, whether species or varieties, single or double, has given such a delightful picture during the last few days as has a kind that came to us under the name of *moschata nivea*. Probably very little is known about it and few grow it, which is a pity, as, like many more of the single kinds, it has only to be planted and left alone. *Rosa moschata*, or the Musk Rose, according to Mr. W. Paul's "Rose Garden," is a very old introduction and the kind named *nivea* is a variety.

but it goes on blooming even till well into the autumn.

Rose M. Furtado.—This is a Rose that very few grow, but I recollect seeing a large quarter of it in Mr. Prince's nursery some years ago, and was reminded of it by a first-rate flower in a splendid box of twenty-four kinds of Tea Roses that was shown at the Drill Hall. Mr. Prince says that with him it is an excellent Rose, fine, free, and very constant, the colour a clear sulphur-yellow.—H.

SINGLE ROSES.

DURING the last few years many of our older single Roses have again become very popular. I have never seen our own native Briers prettier than they have been this season. They have indeed been handsome. Throughout the early part of June the plants of our largest single white variety on the banks of a stream in my neighbourhood have been clothed with bloom. Then, again, how many different shades

Flowers of *Rosa rugosa*. Engraved for THE GARDEN from a photograph sent by J. Mc Walters, Armagh.

Now more attention is being given to the singles, it is to be hoped that this will receive its due share. It produces flowers in clusters of from three to fifty, according to the vigour of the shoots. The clusters that crown some of the strong growths that spring up from the base of the plant are immense—often a foot in diameter. It has a splendid constitution, otherwise it could never have done so well with us, as the plants were placed in clay on a bank against a fence, upon the chance that they would just screen the fence, as we had no idea what a fine thing it was. The great bushes are covered with bloom, and the flowers are large, though so numerous. In the bud state they are of a pretty pink colour and shaded with that tint on a white ground. Still more commendable is its delightful odour.—A. H.

Rose Gloire des Rosomanes.—This is an old French Rose, now almost forgotten, but, happily, grown and much cherished in a few gardens, where we hope it will long remain. The place for it is in the shrubbery, as it can well take care of itself. It is sure to attract attention from its vivid rich crimson-red colour, and probably no sweeter Rose ever came into English gardens. In hot summer weather the flowers are fleeting,

do we find in the common Sweet Brier. The great drawback to single Roses is their lasting so short a time. Against this we must put their extreme freedom of flowering. The forms of *Rosa rugosa*, the Japanese or Ramanas Rose, represented in the accompanying cut, are probably the most free-flowering of all. These are so distinct from all others, so hardy and free from disease, that no collection should be without them. They are among the earliest to flower, and are invariably the last. From a fair-sized plant one may be certain of blooms from the end of May until the end of November during an ordinary spring and autumn. No sooner is one bloom over than another opens upon the same truss. But with *Rosa rugosa* and *Rosa pomifera* the interest is not confined to the flowers alone, as they are well worth growing on account of their handsome foliage, in which nestle large bunches of fruit, that have a very attractive and showy appearance. *R. rugosa alba* has deep orange-coloured berries, while those of *R. rugosa rubra* are deep scarlet when ripe. These two varieties have been intro-

duced to this country for upwards of ninety years. *Rosa ferox*, another name for them, is very appropriate, as they possess an enormous number of long thorns; is perhaps more so than any other Rose. It seems quite immaterial to them what soil they are grown in or what aspect they have. In the border they are the most constant and showy flowering shrubs we can have, and are beautiful for long after the majority of deciduous shrubs are bare.

Among other single Roses we must not fail to mention the Hybrid Sweet Briars of Lord Penzance. His lordship, by careful and persistent hybridisation, has succeeded in getting a highly coloured strain, a very fairly representative plate of which was given in THE GARDEN for January 21, 1893. Turning to the Austrian Briars, we find in Austrian Copper and Austrian Yellow two of the most useful, as well as oldest of our single Roses. The date of their introduction is not known, but they were grown in this country by Gerard as far back as 1596. The Austrian Copper has also been figured in THE GARDEN, December 27, 1890 (p. 600). The two Austrian Briars are single, while the Persian Briars, viz., P. Yellow and Harrisoni, are semi-double. Bardou Job, one of the Hybrid Teas sent out by Nabonnand in 1887, is a sweetly pretty Rose, and will almost rank as a single variety, scarcely coming under the term semi-double. Hébé's Lip, one of the Hybrid Sweet Briars in commerce, is white, with an edging of purple, in the style of a Picotee. *Rosa rubrifolia* is of very vigorous growth, the flowers being a pretty soft rose, while the wood and foliage both possess a very deep and beautiful shade of red. Other single Roses of great merit are *Rosa Brunonis*, *moschata*, *Rosa lucida*, *Rosa multiflora* (syn. with *Polyantha simplex*), and the Bramble-leaved or Prairie Rose (*Rosa setigera*). R.

OLD-FASHIONED ROSES.

I WAS glad to note "S.'s" note on Rose Aimée Vibert (p. 525). It is almost impossible to over-praise it. Probably "S." and most of your readers are aware there is a climbing and a common variety alike, which is often not the case unless in this broad distinction: that the one grows so much faster than the other. The clusters of blossom are of the purest white, and charming for the clothing of arches or pillars. This Rose, being perhaps the very hardiest of all Noisette Roses, also forms very rich furnishing for the tops of high red-brick houses and walls. I never remember to have seen William Allen Richardson so many and richly hued as this year. It would be quite impossible to describe the series of metallic tints covering all the ground between deep copper and rich gold, resting on the softest yellows that distinguished some of them. William Allen Richardson also seemed to enjoy the drought, for it seemed not only abnormally beautiful, but exceptionally crimson. Unique Jaune and Rêve d'Or were other coppery or metallic-coloured Roses that showed deeper tints than usual, and, in fact, the same was observable in the copper-coloured Austrian Brier. It is somewhat singular that though such colours are so popular, such Roses are very seldom grown and yet more rarely grown successfully. In most old-fashioned gardens the single and double yellow and several golden-coloured Roses will be found; but how seldom any bronze or Briars, or even Sweet Briars for that matter. Comparatively recently no rosery was considered complete without one or more plants of Sweet Brier, and many had the best of all fences for a Rose garden—a Sweet Brier hedge. Now the hedges, writing in general terms, have disappeared, and it is seldom one finds Sweet Brier in quantity either in beds or borders. It is hoped that Lord Penzance's seedlings will reverse all this.—D. T. F.

— I have now upon my desk a copy of "Hogg on the Carnation," which also includes some few pages on Roses. This book was published in 1839, and was then in the 6th edition. The classification of Roses was then very far removed from what it is at the present day. I note that the following distinctions were then made, viz., white Roses in seven kinds, Moss Roses in six, Scotch Roses in eight, blush Roses in twelve, red Roses in thirteen, bright red in eleven, dark Roses in twelve, purple in ten, yellow in two, red and white in three, and Sweet Briars in seven. I note, moreover, that English names were chiefly employed then, names easily remembered and as easily written. I was particularly interested in the fact of so many as seven kinds of Sweet Briars being described, most of which I doubt not are very scarce now. These were as follows: Semi-double Sweet Brier, double Sweet Brier, Manning's Blush Sweet Brier, Royal Sweet Brier, Monstrous Sweet Brier, mossy Sweet Brier, and double tree Sweet Brier. The introductory remarks upon the Rose in the following words very well express present day opinion: "To say anything in praise of the attractive beauty and sweetness of the Rose would be not only to insult the good sense and good taste of my readers, but absolutely to imply the want of both; suffice it then to say that the Rose is a universal favourite." Mr. Lee, of Hammersmith, and Mr. Loddiges, of Hackney, are therein given as two of the chief Rose growers. It is further more interesting to read the cultural notes; suffice it to note that layering is specially recommended as a mode of propagation, a fact that seems to be lost sight of in the present day rapid reproduction. I have myself, however, proved that it is a satisfactory mode of increase, and one that might be adopted even in these go ahead times. Layers, for instance, of the vigorous-growing Hybrid Perpetuals will strike root freely and make good plants in due course. But a few years after this edition was issued some of the oldest of present-day Roses were introduced from France, and thence onwards very rapidly have new kinds been raised and sent out, some to quickly fade into oblivion, others to remain, and that rightly so, for an indefinite time. Of these older sorts, when shall we see the last of the fine old Bourbon Souvenir de la Malmaison, the Hybrid Bourbon Charles Lawson, the Hybrid China Juno, still one of the sweetest scented of all Roses. La France cannot now be considered other than an old Rose, seeing that it was grown in this country as long ago as 1868.—ROSA.

— The stands of these, generally composed of large and striking bunches, were objects of much interest at the recent Rose show at Earl's Court. The stands being well furnished with bunches, in most cases having several expanded flowers, and being in addition fresh and bright at the time they were judged, illustrated to an extent seldom seen the great variety of old and some new-fashioned Roses suitable for garden decoration. The date of the show was just fitted to have them at their very best, and they must have appeared to many as a revelation of beauty and adaptability largely, if not entirely, previously unknown. The old Provence or Cabbage Rose, the type of which is supposed to have been introduced some 400 years ago, was represented by the red and the white, both having large and handsome blossoms, and also by the pretty Maiden's Blush with its light blush blossoms, all perfectly hardy and deliciously fragrant, and thriving best, it is said, when grown upon their own roots. Under the general head of striped Roses, the most prominent were York and Lancaster, *Rosa Mundi*, often called York and Lancaster, and considered the best striped red; and Perpetua, with bright red stripes on a white ground. Moss Roses were well to the fore, among them Blanche Moreau, pure white, extra fine, the buds well mossed; Celina, bright crimson and purple, very showy; the common Moss, very pretty in the bud; the Crested Moss, bright rose, large and full; the White Bath, a charming variety; Carné, pale flesh, large and full, the buds well mossed; and Luxembourg, a very old Moss Rose, in colour purplish crimson, a fine pillar Rose because of its vigorous habit of growth. The Austrian Roses

being early bloomers were nearly over before the 14th, owing to the earliness of the season, but the single yellow and copper and the double Harrisoni especially should find a place in every garden where old fashioned Roses are cared for. Of the evergreen Roses there were charming bunches of *Félicité-Perpétue*, with its small and full creamy white blossoms; and *Myrianthes Renoncule*, blush edged with rose, small, and fully double. Among the species of climbing Roses, *macrantha* was prominent, its large white flowers with yellow stamens being very showy.

The charming white H.P. *Boule de Neige* is a delightful garden Rose. It is of the purest white, the flowers produced in bunches, and it is of a vigorous habit of growth. That it has something of the freedom of the Noisette class there can be no doubt. The white and red forms of *rugosa* were also to be seen, but the habit of hiding the flowers among the leaves detracts from their value as garden Roses. Perpetual Moss Salet, bright rose with blush edges, is a good garden variety also.

Of the Noisette Roses, there were charming bunches of the old Aimée Vibert, probably unsurpassed as a summer-blooming pillar Rose, the flowers pure white, large and full and produced with marvellous profusion; Lamarque, a grand garden Rose on a warm south wall, the pure white flowers having shaded yellow centres; l'Idéal, singularly novel in colour, a mixture of metallic red and golden yellow; and William Allen Richardson, with its striking orange-yellow or apricot colour.

Of the China Roses, the common and old crimsion were very good, and they are also fine autumnal bloomers. Of Hybrid Tea-scented Roses, Bardou Job is almost single, but has finely formed petals of a bright crimson colour, and the deep carmine *Reine Marie Henriette* was very striking. On a south wall this Rose blooms with remarkable freedom. *Homère*, which is not included among the Hybrid Tea Roses, was represented by bold bunches of light rose flowers, suffused with deeper rose, and *Triomphe de Pernet père* makes a good garden Rose also, the colour red, the buds long and tapering, while it is remarkably free blooming.—R. D.

Roses from America on own roots.—The Americans rely chiefly upon own-root Roses, and rightly so, we think, after considerable experience and much vexation with grafted and budded plants. Messrs. Siebrecht and Wadley, New Rochelle, N.Y., recently sent us a large consignment of own-root plants, and we are agreeably surprised at their strength and vigour of growth. The kinds sent are chiefly Teas, such as Catherine Mermet, The Bride and Perle des Jardins—a trio of the highest merit, and whilst the trade growers of this country tell us they cannot get strong plants on their own roots, those now sent us, especially the two first-mentioned kinds, are stronger than any that we have ever succeeded in growing upon their own roots. It is the true way, and such Roses are imperishable. There is no doubt that the budded plants are often much worried by their stocks, not merely with suckers, but in other subtle ways. The strong stock results in a rapid growth, but we have found our best kinds go back and get weaker after two or three years, which they should not do. The own-root plant may be a little slower at first, not much, however, if started in the right way. It is certainly the healthiest and longest lived where the soil is warm enough for it and in other ways good for the plant.

Banksian and Noisette Roses.—Please say what constitutes a Banksian Rose and what a Noisette Rose? What is the time to prune Aimée Vibert? I have one which has grown very freely, but it has only produced flowers on shoots from the root late in the summer.—H. F. W.

* * * Your two questions are rather difficult to answer in the way I imagine you require. Banksian Roses are so called after their introducer; so, too, are the somewhat large class of Noisettes. The first Noisettes were strong growers and flowered in trusses. Miss Glegg, Aimée Vibert and others of

like habit may be taken as examples. But at present we have this class and the Teas approaching one another so closely that they are now usually classed together. There are but two varieties of the Banksian Rose, yellow and white. These grow very strongly, are almost evergreen, require a warm situation, and very little summer pruning. They usually flower in trusses, but I have sometimes seen a plant of the white variety produce solitary flowers. All of these extra strong growers, including Aimée Vibert, are best pruned in the summer. As they all produce their main crop of flowers upon wood matured the previous season, such growths are of little service after the crop is secured. They may, therefore, be removed, and so afford more room for the more useful growth. In the spring it is only necessary to cut away the foot or two of growth from the tip if immatured or frost-bitten, and to tie the shoots out a little from one another, so as to avoid undue cramping of the young lateral growths.—P.

NOTES OF THE WEEK.

Syringa japonica has flowered splendidly here this season. This is quite a different shrub from *Ligustrina amoorensis* and *Ligustrina pekiensis*.—V. LEMOINE AND SON, Nancy.

Azolla.—A Correction.—Kindly allow me to say that careful examination and comparison with Strasburger's and Campbell's figures make it almost beyond doubt that the species alluded to on p. 535 (last vol.) is *Azolla filiculoides*, not *A. pinnata* or *caroliniana*.—GREENWOOD PIM.

Potentilla nitida is a charming alpine plant in bloom now at Kew. It is quite dwarf, not more than 2 inches in height, and has an abundance of small silvery leaves, the flowers delicate rose in colour as a rule, but varying from white to deep red. This little gem is easily grown and should be on every rockery.

The scarlet Elder.—There is now in Clogher Park, Co. Tyrone, a fine specimen of the scarlet Elder. It is more than 15 feet high and wide, and literally covered with bunches of crimson coral-like berries. It is also interesting, as though more than ten years planted, it never fruited before, presumably the effect of this fine season.—E. M.

Strawberry Crimson Queen.—Till this year I was under the impression that Noble was the earliest Strawberry, but I found Crimson Queen was some few days before it. At Bridehead House, near Dorchester, Mr. Birkenshaw gathered good fruit of Crimson Queen at the end of the first week in May. This was very early to obtain Strawberries from the open air.—DORSET.

Calceolaria andina is a rare Chilean species of exceptional freedom. It is in full bloom at Kew in the hardy plant house, and worth noting by all who care for this class. The leaves are not large, but the comparatively small bright yellow flowers are produced with great freedom on the slender stems. Quite small plants are attractive, and they remain in beauty over a long season.

Erigeron speciosus superbus.—This fine plant is arranged in large masses in the Broxbourne nursery of Messrs. Paul and Son. The flowers are large, lavender-blue in colour, and produced with great freedom. For several weeks they have been in perfection, uninfluenced by the severe drought. In hot and wet seasons this *Erigeron* is alike happy, and should be planted freely in all gardens.

Chiswick Garden flower show.—On Tuesday, July 11, the Royal Horticultural Society will hold a special flower show in the Chiswick Gardens, which are close to Acton Green, Turnham Green, Gunnersbury, Chiswick, and Kew Bridge stations. The fruit, floral, and Orchid committees will meet at 11 a.m. precisely. Lady George Hamilton has kindly consented to distribute the prizes in the afternoon. The band of Her Majesty's

Royal Horse Guards (Blues), under the direction of Charles Godfrey, R.A. Mus., will perform during the day. The exhibition will be open to the public from 1 to 8 p.m. The Fellows of the society and special subscribers will be admitted at 12 o'clock noon.

Sambucus racemosa serratifolia is a lovely and interesting shrub, desirable both as to its tint and habit of growth. The shape of the leaves is graceful, but what I particularly wish to note as its distinguishing feature is that it is much more apt to berry well here than *Sambucus racemosa*, the ordinary scarlet-berried Elder. The latter flowers profusely with me. I suppose the blossoms get nipped by spring frosts, as I seldom find any fruit on the bushes.—M. A. R., Liphook.

Calandrinia umbellata we noticed in bloom a few days ago in the hardy plant house at Kew. It is a fine Chilean species. The flowers are of an intense shade of shining rose-purple and produced freely on the branching stems. In the evening the blooms close, and are fully open in the early morning, when the lovely satiny colour has a rich glow. This *Calandrinia* is a perennial, and easily raised from seed. A good tuft of it is very rich when the flowers are fully expanded.

Mutisia decurrens is very bright now against the wall of the museum facing the pond in the Royal Gardens, Kew. It is a Chilean plant, and has a fine effect during the summer months. The flowers are intense orange in colour with a touch of apricot in them and of large size, whilst the leaves are narrow and glaucous in colour. It succeeds well against a warm wall and in moderately dry soil. Against a plant house would be a suitable position, and this climber is of sufficient beauty to justify freer use being made of it.

Aeclepias tuberosa.—This pretty flower comes to us in good condition from Mr. Prichard, Christchurch, Hants, with other fresh and beautiful hardy flowers. It is curious that this plant, introduced so long ago and so much distributed, is seldom seen. We suppose it must die out frequently. In America it rejoices in the hot sandy barrens, and only in our warm Surrey soils does it get anything like the same conditions. Mr. Prichard also sends us the graceful white *Jacob's Ladder*, and a large and striking seedling form of *Chrysanthemum maximum*, to which he does not affix a name.

A new Bourbon Rose in the nurseries of Messrs. W. Paul and Son, Waltham Cross, is full of promise. It is named Lorna Doone, and several rows of it which we saw a few days ago show that the plant is vigorous in growth, with fine robust leafage, and the flowers full, quite of exhibition character, the colour intense crimson. Then they are deliciously fragrant, and in these days those who raise new Roses should not overlook this important point. Unfortunately, many new Roses are practically without scent, and therefore bereft of their sweetest charm. This Bourbon variety should become popular if it maintains its present high character.

Phyllocactus J. T. Peacock, which we recently saw in full bloom at Kew, is a fine example of a splendid genus. The flowers are very large, the outer segments crimson and the inner ones shot with a lovely pellucid satiny purple shade—a superb contrast of colour. Many of the *Phyllocactuses* are quite as handsome, and they are not difficult to cultivate in an ordinary plant house. We hear that this genus is getting popular, but there is no difficulty in purchasing fairly large specimens at an absurdly low price. Considering their easy culture, showy flowers, and freedom, it is strange that they are not more seen in private gardens. In the gardens of Alton Towers, the Earl of Shrewsbury's residence, *Cactuses* of the showier types are grown largely.

Seedling Gaillardias.—A very charming collection of seedling *Gaillardias* is in bloom in the nursery of Messrs. Paul and Son at Broxbourne. The flowers range through many shades of colour, sometimes self-yellow, then primrose and crimson, whilst one notices the same diversity in habit of

growth. We like those of compact habit, especially one seedling, which is smothered with flowers of bright crimson with a very narrow yellow margin. At this season of the year few things are more useful for cutting than the *Gaillardias*. They are free, easily grown, graceful, and bright in aspect. The wholesale naming of varieties is a mistake, and some kinds approach dangerously to those already in catalogues. At Broxbourne there is quite a pink kind, a relief from the prevailing tones of yellow and crimson.

Early Apricots.—To gather ripe Apricots from the open walls at the end of June, all, I think, will agree is an unusual occurrence. I gathered eighteen good ripe fruits from the open wall on June 26, and shall be able to keep on gathering from this wall for many weeks to come. I never saw the trees so thickly set with fruit as they were this year, and they look in the best of health. Our trees are growing in a raised south border, every inch of which has to be cropped twice each year. I have this year given the border three or four good soakings of water, first throwing a good sprinkling of guano over the soil. I observe it has had a good effect on the trees in causing them to make a good growth, although they are carrying a heavy crop.—J. C. F.

Nemesia strumosa.—Referring to the letter of J. C. Tallack on the above plant, we would point out that the flowers he saw at the Temple show were forced at an unusually early period under glass in order that they might be seen at that show. The range of colour was not so great as it was last year, doubtless owing to the weather and early season of flowering, which you are aware influence colours a good deal. Those who saw the flowers at our nurseries or at the Drill Hall last July will remember what an astonishing range of colour there was then, and which was admired by the many visitors who saw them. We saw only this morning a most exquisite bouquet of these flowers which we had photographed. We will send you on a copy in the course of a week or two.—SUTTON AND SONS.

The Sea Hollies.—The colour of the *Eryngiums* is very fine this year, although the plants are dwarfer than usual. It is the various shades of silvery grey that one admires so much in this class. We recently noticed a group of the several kinds on a hot, dry border, the common *E. maritimum* spreading out into a broad silvery mass. *E. giganteum* and *E. planum* were noteworthy; also *E. alpinum*, perhaps the finest of all, but a weak grower. When in full perfection the various Sea Hollies are remarkably beautiful, and *E. planum* in particular is attractive to bees. This was not in bloom in the border, but *E. giganteum* was in perfection. *E. Oliverianum* is another fine kind, which we noticed grown in a large mass in Mr. Paul's nursery at Waltham Cross. The *Eryngiums* are not grown sufficiently in gardens. They should be planted in colonies or masses to get the effect of the steel-blue bracts. In large gardens groups of them might well be formed in the more conspicuous positions.

The early season.—I thought it might be interesting to some of your readers were I to give a short account of the effects of the abnormally early season on flowering plants grown in the Botanic Gardens at Oxford. When last term began (April 20) the high stone walls in the gardens facing south-west were a mass of Roses. I particularly noticed *Reine Marie Henriette*, *W. A. Richardson*, *Ilomère*, *Mme. I. Perière*, and *Cheshunt Hybrid*. These Roses had quite fifty blooms apiece, some carrying twice as many. *Panacratium maritimum*, *Clove Pinks*, *Paeonia Moutan*, and actually some Spanish *Iris*es enlivened the border at the foot of this wall. Here also were *Tea* and *H.P. Roses* grown as dwarfs, which came into flower a fortnight later. The magnificent collection of tuberous *Iris*es in the gardens was coming into bloom and continued in flower all through May. By the 1st of June the following *Lilics* were in flower: *Pardalinum*, *Martagon*, *chalcidonicum*, *testaceum*, *croceum*, and *dalmaticum*. The English *Iris*es were also in bloom. A magni-

ficient *Wistaria* on a north-west wall came into bloom early in May. Its branches are trained horizontally along the wall, and extend over 40 yards. So early a season is almost unprecedented at Oxford.—R. A. JENKINS, *Brasenose College*.

Carnations from Claremont.—We have some beautiful self-coloured Carnations from Claremont, and remarkably well grown, among them being Countess of Paris, Mrs. Reynolds Hole, Murillo, and Mickleham. Mr. Burrell writes:—

These have proved fine border varieties, vigorous in habit, of good constitution, very free bloomers, and practically non-splitters, only Mrs. Reynolds Hole offending a little in that respect. I have had a good few more on trial, but they have been discarded. In my opinion no border Carnation should be sent out that does not possess the qualifications above-named; nine-tenths of them are worthless, except it may be for size, symmetry, or colour of flower. One or two good sorts not yet out are Raby, Ketton Rose, and two more seedlings. The blooms of Countess of Paris are only second-rate; this was the first out with me, and is now nearly over. I had a job to get these, we have had some very fine flowers. Touching constitution and habit of this particular variety, I should say "a little miffy," but decidedly superior to many sent out as good border kinds. I have sent fairly long bloom-stalks to let you see it is not a question of "one flower on the end of a stick." Most of our plants are throwing five, six, and seven good strong flower-stalks.

Early Apples.—The extraordinary heat and drought which we have had and are still experiencing have told on fruits of all sorts outdoors, and although such fruits as Peaches, Plums and Apricots have been gathered from the open, it strikes one as being more remarkable to have ripe Apples in the open garden and orchard. At the Clifton show last week, Mr. W. H. Bannister staged a dish of Red Astrachan Apples apparently quite ripe, gathered, it was said, from an orchard tree, and although they were small, as might be expected, they possessed their usual characteristic bloom and colour. In these gardens we have two trees of the variety Gravenstein. The fruits of this already show signs of ripening. The powerful scent pervades the air for some yards round and the fruit has already attracted the attention of the birds, which are driven by sheer necessity to the devouring of ripening fruits of all sorts, but it is very unusual for them to attack Apples by the end of June, as they have done this year. Beauty of Bath, another early August sort, too, is also showing signs of ripening; some fruits are falling, of course, somewhat prematurely from the dry state of the ground and its over-heated condition. Watering and mulching are quite out of the question, or they would have been practised as a relief to the strain upon the trees, which in most cases are carrying good crops. Our ordinary water supply is cut off, and we are dependent on a well of only moderate depth for everything, so that watering any outdoor trees is impossible. The oldest workman on the estate cannot remember such a short supply of water as that we now have. In many respects the crops are fully a month earlier than usual, but in the case of Apples it is even more so, because the Red Astrachan under notice were shown on June 28, and they are not usually in season till about the middle of August. The Juneating and other very early sorts must, I should imagine, be over. What is the experience of other fruit-growing contributors respecting early Apples this year?—W. STRUGNELL, *Rood Ashton Gardens*.

The weather in West Herts.—The past week was the twenty-fourth unseasonably warm one that we have had in succession. On Sunday the highest shade temperature reached 83°, and on Monday 81°. On the other hand, during Friday night in last week the exposed thermometer fell to 37°. The temperature of the ground at 1 foot deep now stands at 69°, and at 2 feet deep at 66°. On the same day last year the readings at these depths were respectively 64° and 62°. During the last four months rain has fallen on but twenty-five days, and to the total depth of only 2½ inches. There is but one other instance, during the thirty-

eight years over which the Berkhamsted rainfall records extend, where the total rainfall for any consecutive four months has been as small, and that was in those ending January, 1880, when it was exactly the same as this year. The average fall of rain for these four months is 8½ inches, and the average number of rainy days fifty-two. When digging up some Potatoes in my garden recently, the ground in which they were growing was found to be dust-dry to the depth of 17 inches.—E. M., *Berkhamsted*.

SOCIETIES AND EXHIBITIONS.

NATIONAL ROSE SOCIETY.

CRYSTAL PALACE.

JULY 1.

THOSE who attended the exhibitions in and around London during the past week or two could not fail to note that each succeeding one fell short of its predecessor. It was no surprise, therefore, to find that this, the chief Rose show, was also far behind its usual standard. The competition was not nearly so keen as usual. This is easily accounted for in the case of those whose water supply is all too limited for the garden to receive that amount needful in such an extraordinary season as the present one. Others situated in forward localities would, no doubt, be far past their best standard. The best show of Roses that we have seen this year as regards quality was the early show in the Drill Hall under the auspices of the Royal Horticultural Society. The Tea-scented kinds, which mainly comprised the exhibition on that occasion, were really grand in quality; since then there has been a marked falling off, save in a few special cases. On Saturday last some of the exhibits bore traces of the storm of a few days previous. This could hardly be avoided; the delicate colours always suffer if not protected from heavy rains, and protection in such a season could scarcely be entertained. Those who took the precaution to mulch their Roses early have had no cause to regret it.

Nurserymen's Classes.

In the large class for seventy-two distinct kinds in single trusses, Messrs. Harkness and Sons, Grange Nurseries, Bedale, Yorks, worthily won the first prize with a magnificent exhibit, which also carried with it the challenge trophy in this section. This exhibit also included the best H.P. in the trade classes, a fine bloom of Horace Vernet, other good ones being Mrs. J. Laing, Mrs. Reynolds Hole, Victor Hugo, General Jacqueminot, Exposition de Brie, A. K. Williams, Mme. Charles Crapelet, Dr. Andry, Comte de Raimbaud, Auguste Rigotard, Ulrich Brunner, Charles Lefebvre, Gustave Piganeau, Duc de Montpensier, Beauty of Waltham, Viscountess Folkestone, Mme. M. Verdier, Dupuy Jamain, Mme. G. Luizet, Earl of Dufferin, Mme. Victor Verdier, Merveille de Lyon, La France, Prince Arthur, Ernest Metz, Souvenir d'Elise Vardon, Cleopatra, and Mme. C. Kuster. The flower of Horace Vernet, already alluded to, was large in size, perfectly formed, and exquisitely coloured. Colour is always a strong point with these growers, and it always stands them in good stead. Mr. B. R. Cant, who took the second prize, also showed well, as he has already done this season on more than one occasion. He also secured the N.R.S. silver medal for the best Tea in the trade classes with a lovely flower of The Bride. His other best blooms were Duke of Teck, Mme. Lambard, Duchesse de Morny, Innocente Pirola, Fisher Holmes, Jean Soupert, Mme. de Watteville, Thos. Mills, Crown Prince, Mme. Cusin, and Paul Neyron. For forty-eight trebles, Messrs. Harkness and Sons were again placed first, showing in addition to several kinds already noted Mme. Willermoz, Comtesse de Nadaillac and Margaret Dickson, the same features characterising this exhibit as in the larger class. Mr. F. Cant was successful in gaining second place, he also showing well, the

finest blooms being Viscountess Folkestone, Mrs. J. Laing, Alfred Colomb, Horace Vernet, Gustave Piganeau, and Mrs. Reynolds Hole.

For forty-eight single trusses Mr. H. Merryweather, Southwell, Notts, was first with an extra good exhibit. Here were to be noted Catherine Mermet, Fisher Holmes, Ernest Metz, Earl of Dufferin, Duchess of Bedford, and J. S. Mill as specially good. Messrs. Burch, Peterboro', were a close second with fine blooms of Her Majesty, Anna Olivier, Niphetos, Innocente Pirola, Antoine Ducher, and Duke of Wellington. With twenty-four singles Mr. W. H. Frettingham, Beeston, Notts, was first, showing well, the finest blooms being those of Lord Macaulay, A. K. Williams, Louis van Houtte, and Ferdinand de Lesseps. Mr. John Mattock, Headington, Oxford, was second with fine blooms of La France, Sir Rowland Hill, E. Y. Teas, and Charles Lefebvre. In the class for twenty-four trebles Messrs. Burch were first, having in addition to kinds already noted Marchioness of Dufferin and Marie van Houtte, Horace Vernet and A. K. Williams also being prominent flowers. Mr. W. H. Frettingham was second, Baroness de Rothschild here being noted for the first time, and Her Majesty in good condition. In the Tea and Noisette division, for twenty-four single trusses, Mr. B. R. Cant won the first place with a very fine lot of flowers, the best being The Bride (extra good), Ethel Brownlow, Souvenir d'Elise, Mme. Hoste, Luciole, Mme. de Watteville, and Francisca Kruger. Mr. F. Cant followed closely with blooms nearly as fine, the best here being Mme. Lambard, Jean Ducher, Ethel Brownlow, and Innocente Pirola. With eighteen distinct kinds Mr. Merryweather won the first prize against Messrs. D. Prior, Colchester, the former having fine flowers of Souvenir d'Elise, Rubens, Souvenir d'un Ami, and Francisca Kruger. For twelve single trusses of any Tea or Noisette (Maréchal Niel excepted), Messrs. D. and W. Croll, Dundee, N.B., were first with fine blooms of Rubens; Messrs. Burch second with Innocente Pirola, and Messrs. R. Mack and Sons, Catterick Bridge, Yorks, third with Souvenir d'Elise. Mr. B. R. Cant was again first for eighteen trebles with Comtesse de Nadaillac, Souvenir de S. A. Prince, Souvenir d'un Ami, Catherine Mermet, Marie van Houtte, and Mme. Cusin as his finest selections; Mr. Mount, of Canterbury, showing well for second place with similarly good kinds.

Amateurs.

In the trophy class for forty-eight distinct trusses, Mr. E. B. Lindsell, Hitchin, repeated his previous triumphs and won with remarkably good flowers, including the finest bloom of an H.P. in the section, one of Ulrich Brunner, a splendid flower. His other best kinds were Ethel Brownlow, J. S. Mill, The Bride, Abel Carrière, Merveille de Lyon, Caroline Kuster, Horace Vernet, Maréchal Niel, Dr. Sewell, Alfred Colomb, Mrs. J. Laing, Prince Camille de Rohan, and Innocente Pirola. Rev. J. H. Pemberton, Havering-atte-Bower, Essex, was a good second, Ernest Metz being his finest flower, other good ones being those of Earl of Dufferin and A. K. Williams. In the next class, that for thirty-six kinds, Rev. A. Foster-Melliard, Sproughton Rectory, Ipswich, was first, his finest half-dozen being Souvenir d'Elise Vardon, Ethel Brownlow, Maréchal Niel, Lord Macaulay, Horace Vernet, and Duke of Wellington. Mr. W. Drew was a good second in this class, Louis van Houtte, Earl of Dufferin, and Eugène Verdier being the finest blooms. Mr. Gurney Fowler, Woodford, Essex, was first for twenty-four kinds, showing excellent flowers of Victor Hugo, Duke of Connaught, Chas. Lefebvre, Fisher Holmes and Black Prince. Col. Pitt, of Turkey Court, Maidstone, was second, showing well. With sixteen distinct in three trusses Mr. E. B. Lindsell was again first, this exhibit being a very fine one, Fisher Holmes (extra good), Duke of Wellington, and Horace Vernet being the best blooms. Mr. H. V. Machin, Worksop, was a fairly good second. For twelve trebles Mr. W. Drew, Ledbury, was first, Horace Vernet and A. K. Williams being the best. With twelve single trusses of any H.P., Mr. Drew was first with Mrs. J. Laing, the rest being only medium exhibits.

In the next division of the amateurs' section, with a limit of 2000 plants, Rev. H. Berners, Harkstead, Ipswich, was first for twenty four kinds, with fresh, but rather small flowers, the best being Prince Arthur, Horace Vernet and Mme. Hoste. Mr. Slaughter, Steyning, was second here. Mr. Whitton, Bedale, came first in this section for eighteen kinds, showing remarkably well, Duke of Wellington, Dupuy Jamain and Viscountess Folkestone being all first-class flowers, Mr. Parker, Oldfield, Herts, taking the second prize. Mr. Ough, Hereford, was first for twelve kinds, his finest being Sir Rowland Hill and Camille Bernardin, the former extra good. Rev. H. Berners was first for twelve trebles and also for nine blooms of one kind of Hybrid Perpetual, with Merveille de Lyon. In smaller classes for growers of lesser numbers, the most successful were Mr. O. Orpen, of Colchester, and Mr. C. J. Grahame, Croydon. Mr. Conway Jones, Gloucester, Mr. Hodgson, Croydon, and Mr. Parker, Headington, also showed well in various classes, as did Mr. Bateman, Archway Road, N., for Roses grown within eight miles of Charing Cross, Mr. Rivers, Langton, being second in this class, the finest flowers in the two exhibits being Ulich Brunner, Marie Rady, Cleopatra and Ethel Brownlow. In what are termed extra classes for amateurs, the most successful exhibitors were Mr. Arthur Bryans, Foot's Cray, and Miss E. B. Denton, Stevenage, who had a fine bloom of Charles Lefebvre.

In the Tea-scented and Noisette division of this section the trophy class was the most important one, and here Rev. A. Foster-Melliard was first, with very superior flowers, which included the best Tea or Noisette, a very fine bloom of Mme. Cusin. Other first-rate flowers were those of Ernest Metz, Maréchal Niel, Marie van Houtte, Caroline Kuster, Souvenir d'Elise, Comtesse Panisse, Hippolyte Jamain, and Souvenir d'un Ami. Mr. O. Orpen also showed well in this class. For twelve distinct kinds, Rev. H. Berners was again successful, Ethel Brownlow, Jean Ducher, Mme. Hoste, and Marie van Houtte being his best flowers—Col. Pitt, Maidstone, being also a worthy antagonist. In the class for twelve trebles, Rev. A. Foster-Melliard won again, taking the piece of plate offered as a first prize by the Hon. Mrs. Townshend-Boscawen, with similarly good blooms and varieties as in his previous exhibits. For nine single trusses, Rev. H. Berners was again first with an even hox. In the limited classes, Mr. Orpen was first for twelve kinds, Maréchal Niel and Catherine Mermet being included amongst the best. Rev. J. H. Pemberton came in first for nine sorts, showing a very superior lot of flowers, Mr. Orpen being again the most successful exhibitor in smaller classes.

Open Classes.

In the schedule several open classes are provided for specified varieties or colours; these usually create a large amount of interest, although, on the whole, the trade growers have matters their own way. The finest Maréchal Niel were shown by Messrs. D. Prior and Son, who have previously shown them remarkably fine; the next came from Mr. Mount. For any other yellow, Mr. B. R. Cant won with Mme. Hoste, and Messrs. Croll with Marie van Houtte. For Niphotos, Messrs. Burch were first, and Mr. Mount second, and for any other white, Messrs. Mack & Son won with Merveille de Lyon, Messrs. Harkness following with the same variety. For twelve blooms of Marie Baumann, Mr. Mount was first, and Mr. F. Cant second; and for the same of A. K. Williams, Messrs. Mack and Son won, Messrs. Perkins, Coventry, following. For any other crimson Rose, the English Fruit and Rose Co., Hereford, were first, and Mr. Mount second with Fisher Holmes. For dark crimsons, Messrs. Prior and Son were first with the last named kind, and Mr. F. Cant second with Xavier Olibo. For blooms of Her Majesty, Mr. B. R. Cant was first, and Messrs. Burch second. The finest flowers of Ernest Metz were those from Mr. B. R. Cant, and the next best from Mr. F. Cant. Mr. B. R. Cant won again with Ethel Brownlow, Mr. Mount following. For twelve trusses of any H.P. not named, the

finest were from Mr. F. Cant, of Fisher Holmes, the next best being the same kind from Mr. Geo. Mount. A class was provided for Catherine Mermet and The Bride collectively, in which Mr. Mount was first and Mr. B. R. Cant second. For twelve trusses of any new Rose, Messrs. Harkness and Sons were first, with grand flowers of Gustave Piganeau, Mr. F. Cant and Mr. B. R. Cant following with the same variety. For twelve new Roses, Messrs. Paul and Son came to the front, showing the following Hybrid Perpetuals: Dowager Duchess of Marlborough, Marie Magat, Gustave Piganeau, Duke of Fife, Violet Queen, Charles Gater, Paul's Early Blush, Bruce Findlay and Frère Pierre, with Bourbon Mrs. Paul, Noisette Gustave Regis and Tea-scented Waban.

For twelve trusses of any seedling Rose or distinct sport, Mr. Chas. Turner was awarded a gold medal for Crimson Rambler, which has been frequently alluded to in these columns and which loses none of its well-deserved popularity. Messrs. A. Dickson and Sons also received two gold medals for new Roses in this class; one called Marchioness of Londonderry, a white variety, rather loose, and Mrs. Sharman Crawford, a bright rose-pink, of good shape and with reflexed petals. For thirty-six bunches of garden Roses, distinct kinds, Messrs. Paul and Son were first, the best flowers being Reine Olga de Wurtemberg, Rêve d'Or, White Pet, Perle d'Or, Mrs. Bosanquet, Beauté de l'Europe, Mme. Pernet, Ducher, l'Idéal, Mme. Alfred Carrière, Mme. Pierre Cochet, and Gustave Regis. For eighteen bunches of the same, Mr. Alfred Tate, Leatherhead, was first, and Rev. J. H. Pemberton equal second with Mr. H. Machin. For twelve bunches in varieties Mr. C. E. Cuthill, Dorking, was first, the best being of the Polyantha section. A capital class was that for twelve varieties of button-hole Roses in bunches, the best coming from Mr. John Mattock. The finest were Catherine Mermet, Mme. de Watteville, Ma Capucine, Niphotos, Comtesse de Nadaillac, Innocente Pirola, The Bride, forming in all a fine box of well coloured and suitable blooms. Messrs. Keynes, Williams and Co., Salisbury, also showed well in this class. A very fine miscellaneous group of Roses was staged by Messrs. W. Paul and Son at one end of the building; these comprised the best and most serviceable kinds, forming in all a magnificent group, to which a special award was made. Miscellaneous groups of other than Roses were contributed by Messrs. J. Laing and Sons, Messrs. Cannell and Sons, Messrs. Cheal and Son, each firm exhibiting their specialities in their usual good style.

A full prize list is given in our advertising columns.

Royal Botanic Society's fête.—A very successful fête was held as usual at Regent's Park on Wednesday evening last. Fortunately, the weather was perfect for an affair of this kind, and the gardens and lake were illuminated with thousands of fairy lamps. The attendance, we think, was smaller than on previous occasions, doubtless owing to many counter attractions in the metropolis. There were the usual displays of cut flowers, and in the tent Messrs. W. Paul, of Waltham Cross, had a splendid group of Roses, Messrs. Cheal and Son Dahlias and Violas, and Messrs. Barr and Son, Long Ditton, hardy flowers.

The late Lord Calthorpe.—The name of Lord Calthorpe, who died lately, is associated with one of the earliest of the Birmingham public parks. His lordship's father in 1857 dedicated to the public use 31 acres of ground situated between the Pershore Road and the River Rea. Calthorpe Park was opened by the Duke of Cambridge, and was maintained as little more than a field until 1871, owing to the tenure not being such as to justify considerable expenditure of money by the corporation. Ultimately a grant of the park to the corporation was executed by Lord Calthorpe and his two brothers, the Hon. A. Calthorpe and the Hon. Somerset Calthorpe, who were next in succession. So far as they were

legally able to do so they divested themselves of all interest which they had in the land in favour of the corporation. The council were then able to undertake the outlay, which has rendered the park an extremely attractive place of recreation.

Sowing Canna seeds.—The advice to file hard seeds to assist germination is often given, but I am not in favour of such a mode of treatment, as the same end can be attained by soaking in water previous to sowing, and there is not the risk of injuring the embryo which is liable to be done in filing. Among the seeds for which filing is recommended are those of Cannas, yet if soaked in water and placed in the stove for forty-eight hours previous to sowing, all further trouble is obviated. The principal points to be considered with regard to seed treated in this way are that it should be sown as soon as it is taken from the water, and on no account must the soil be allowed to become dry afterwards, otherwise the delicate embryo will very likely suffer. Treated in this way I do not experience any difficulty with many hard seeds.—H. P.

Salvia cacaliæfolia.—"G.S." sends a specimen of this plant which I have not seen for about thirty years. In the colour of its flowers it reminds me very much of *Salvia patens*, which was sent out many years ago by Mr. T. Jackson, then a nurseryman at Kingston. It comes from Mexico, but I do not know from what part of that country. It was, I believe, introduced by M. Linden, of Brussels, and it is well deserving of cultivation, on account of its rich deep blue flowers.—W. H. G.

Araucaria bearing cones.—Is it uncommon for the *Araucaria* to throw out cones? I have a tree with seven, each about the size of a small sugar basin and quite round.—J. THORPE, *Argyllshire*.

The white Camellia.—"Fleur" will find a poetical description of the white *Camellia* under that title in W. H. C. Nation's "Prickly Pear Blossoms," recently published by Eden, Remington and Co., 15, King Street, Covent Garden.—READER.

Insects on Peas.—Can you tell me of a remedy for a pest that all my Peas are covered with to such an extent that the crop is entirely crippled? It is not unlike a little red thrip, and attacks the haulm and pods alike.—G. B.

* * * Please send specimens of the insect.—ED.

Names of plants.—*M. V. Charrington.*—We cannot name florists' flowers.—*Inlus.*—Not recognised.—*F. Talmur.*—Send better specimens.—*Anon.*—*Calycaanthus floridus.*—*S. H. B.*—*Justicia lucida.*—*C. A. L.*—*Spiraea arifolia.*—*West Highlands.*—*Azalea procumbens.*—*E. Semper.*—*I.* *Lysimachia clethroides*; 2, *Veronica subsessilis*.

"The Garden" Monthly Parts.—This journal is published in neatly bound Monthly Parts. In this form the coloured plates are best preserved, and it is most suitable for reference previous to the issue of the half-yearly volumes. Price 1s. 6d.; post free, 1s. 9d. Complete set of volumes of THE GARDEN from its commencement to end of 1892, forty-two vols., price, cloth, £30 12s.

"Gardening Illustrated" Monthly Parts.—This journal is published in neatly bound Monthly Parts, in which form it is most suitable for reference previous to the issue of the yearly volumes. Price 5d.; post free, 8d.

"Farm and Home" Monthly Parts.—This journal is published in neatly bound Monthly Parts, in which form it is most suitable for reference previous to the issue of the yearly volumes. Price 5d.; post free, 8d.

"Hardy Flowers."—Giving descriptions of upwards of thirteen hundred of the most ornamental species, with directions for their arrangement, culture, &c. Fifth and Popular Edition, 1s.; post free, 1s. 3d.

"The Garden Annual" for 1893.—Contains Alphabetical Lists of all Branches of the Horticultural Trade. The Lists of Gardens and Country Seats (containing over 9000) have been very carefully and extensively revised, and are admitted to be the most complete ever published. Price 1s.; by post, 1s. 3d.

All of our readers who are interested in the improvement of cottage homes are invited to help us to make Cottage Gardening known. It is published at the very lowest price to meet the wants of those for whom it is intended, and copies will be sent for distribution, free, by the publishers, Messrs. Cassell and Company, La Belle Sauvage, Ludgate Hill, E.C.

No. 130. SATURDAY, July 15, 1893. Vol. XLIV.

"This is an Art
Which does mend Nature: change it rather; but
THE ART ITSELF IS NATURE."—Shakespeare.

STOVE AND GREENHOUSE.

THE MALMAISON CARNATIONS.

PLANTS that were propagated from layers some-thing like twelve months since will this season have flowered fully a fortnight or three weeks earlier than usual. One large grower has just told me that his are all past their best. I have noted also from remarks made in a contemporary that others have experienced the same thing, the flowering being hastened without doubt by the conditions of the season. This does not matter materially, for we have the old Clove now in full beauty with other kinds as well. In some respects it is an advantage, for it allows of the propagation by layering to be attended to all the sooner. This in itself is a great advantage if a large stock has to be secured, and should not certainly be lost sight of. Propagation by layering is still the best course to pursue; it is the safest, as it is also the quickest, involving no more labour in the end. Where two-year-old plants are still in hand, these will make capital stock for propagation in this way, simply because the growths are longer, thus admitting of more effectual layering than in the case of yearling plants; besides which these latter will make fine plants for the earlier flowering next season. A good method to pursue is that of either planting out the old stools or plunging them in a frame. For instance, a frame that has been cleared of either early Potatoes or Carrots, and still is lying idle, will do well for the purpose. First level the soil and add a little fresh around the old ball if necessary as the planting is being done. Then give it a thorough good watering, and after that surface the soil all over with cocoa fibre to a depth of about 3 inches, this also being watered. The layering should then take place in the usual way, the layers being pegged into the cocoa fibre for rooting. This material is a first-rate rooting medium, keeping a regular moisture around the layers, encouraging thereby a speedy root-growth.

After the layering is completed, the fibre should be made firm and a sprinkling of silver sand be added as a surfacing, with another watering as a finish. The lights should then be placed over them, but do not keep them closed so as to cause a too damp atmosphere. Such a condition will only tend to engender fungoid growth and cause green-fly. Close if needful during the daytime, more especially when an easterly wind is blowing or the sun very bright and warm. This latter advice may seem an anomaly, but it works out well, shading being employed at such times as a matter of course. This latter should be removed as soon as the sun declines, and then air may be given, or if very quiet the lights can be left off entirely until the following morning, so as to have the full benefit of the dew. Being layered in the fibre, but little watering will be needed, and this will be found all the better. By adopting this plan the layers will be fit for potting in a month or five weeks' time, and this will allow a good interval for the young plants to become

well established before winter sets in. This fact is an all-important one in the future well-being of the plants. Late propagation, with a consequently late period before sufficient roots have been formed to carry the plants safely through the winter, means that a closer course of treatment has to be adopted. This is not at all congenial to the Malmaison or any other Carnation, for it must not be lost sight of that it is a hardy border plant and not a tender greenhouse one in any sense of the term. I am disposed to think that this is a point in the cultivation of this fashionable flower that frequently escapes notice. Anything approaching a close or stuffy atmosphere during the autumn and winter is decidedly injurious to the plants, as indeed it is at all times. It is of no use to attempt to make up in this way for time lost in layering.

The yearling plants afore alluded to, if not wanted for propagation, should at once receive a shift into one size larger pots. In doing this do not hesitate to make use of about half and half good peat and turfy loam. If the loam be at all close and wanting in fibre, then employ more peat. In fact, I would not hesitate to pot in peat altogether rather than use inferior loam. Add to the peat a little bone-meal or lime rubble and sand; this will make a very good mixture. Firm potting is quite essential, less watering being afterwards required. Slopping the plants frequently with water will cause them to go off at the base. Should any wireworm or other grub trouble the plants at any time, dust them over at once with soot in a light manner, leaving it to be watered in. This not only acts as a check, but as a preventive also, beyond which it is also a manure in which Carnations delight. These plants should have all the light and air that can be given them, but be screened from easterly winds and from the intense heat of the sun during the day in very hot situations. This can be easily managed with ordinary shading. Plunging the pots in a season like the present is a good course to pursue; it saves watering, too much of which is not beneficial at any time. During a wet period, on the other hand, the plants would be better not plunged, being merely stood upon a bed of coal ashes or upon bricks, so as to prevent worms from entering the pots. Just sufficient staking should be afforded after potting to prevent the shoots from breaking down; in doing this do not crowd the growths together, but rather draw them out. In the case of the young layers it will sometimes happen that an adventitious flower-spike will push up; rather than stop this, I would encourage it, for one good flower upon a dwarf plant is a pretty sight during the winter months. It is hardly necessary to allude to varieties now beyond saying that Mme. Arthur Warocque, of which such a good opinion was formed, is rarely seen in good form. If it were grown satisfactorily, we should, no doubt, see it shown beside the other fine varieties.

SOUTHON.

Campanula pyramidalis in pots.—This fine and showy species of Campanula, which was quite a fashionable plant some sixty years ago, can now be seen in fine condition at Gunnersbury House, Acton, where Mr. J. Hudson grows it largely in pots for decoration. Plants are raised from seeds sown at midsummer or a little earlier, and in a year from the time of sowing they are strong subjects in 6-inch and 8½-inch pots, and a few will blossom, though it is best for them not to do so until the second year, by which time they will have made very fine specimens. If the plants flower one year from seed, they do not make such fine specimens in the second year, when they can

be had in large pots with twenty or more spikes of bloom if they have not previously flowered, and are then well adapted for both indoor and out-of-door decoration. The Chimney Campanula, as it is termed, continues in bloom for a considerable time up to the autumn, and if the plants are to be grown on for another season they should be housed when they go out of flower. One remarkable feature about the plants at Gunnersbury House is the singular variation seen in the leaves, as they differ very widely, and it might be expected the flowers would, therefore, vary in colour. As soon as the plants are advanced enough they are stood out of doors upon a bed of ashes, and well looked after with water. A fairly light, rich soil and good drainage are essential. At present the shades of colour in the Chimney Campanula appear to be limited to blue and purple, with the addition of the white.—R. D.

Canna Comtesse de l'Estoile.—This, which has made its appearance in most of the various groups of flowering Cannas that have been somewhat largely exhibited this season, is one of the best of the spotted flowers, which by some are greatly admired, whilst by others the self-coloured blossoms are preferred. It is a bold growing variety, with foliage of a glaucous green tint, whilst the flowers are large and of a bright clear yellow, thickly spotted with red. With such a list of varieties as we now have a selection is absolutely necessary, and this can be depended on as a superior spotted form. When this class of Cannas first became popular, many of the new varieties had dark coloured foliage, but of late nearly all the newer forms had green leaves, and there seems to be a wider range of colour in the flower than there is among the dark-leaved varieties. The variety Comtesse de l'Estoile was raised by M. Crozy, and sent out in 1892.—J. P.

Hibiscus schizopetalus.—This is a great favourite of mine and a very striking plant when in flower, though it is not met with nearly so often as it was a few years ago. It does not possess the large gorgeously-coloured blooms of most of the forms of *H. Rosa-sinensis*, but is so distinct from anything else, that it is sure to attract attention when in flower. It is of a loose open habit of growth, and will not flower freely if kept dwarf. As a roof plant this *Hibiscus* is just at home, for the pendulous blossoms are borne on stalks 6 inches or nearly so in length; consequently the flowers are in this manner seen to the best advantage. The individual blooms are about 3 inches in diameter, and remarkable for the curiously cut and slashed petals, which are of a bright red colour, marked towards the centre with yellow. As in many of its relatives, the long projecting stigma forms a prominent feature. It is of very easy culture, for cuttings strike with the greatest freedom, and if potted off as soon as rooted, they grow away quickly. *H. schizopetalus* is usually regarded as a stove species, but it will grow and flower in a very satisfactory manner in an intermediate temperature, and in this way it is less subject to insect pests than in the stove.—T.

Himalayan Rhododendrons.—The flowering season of the various Himalayan Rhododendrons is spread over a lengthened period, for the stately *R. argenteum* or *grande* will open its blooms quite early in the new year where protected by a greenhouse or conservatory, and the different species will maintain a succession till midsummer, or nearly so. The last to flower, as a rule, belongs to a group upon which numerous names have been bestowed, but between all the members of which there are really but few points of difference. Thus the plants to be met with in this country under the names of *R. Jenkinsi*, *R. Maddeni*, *R. calophyllum*, *R. tubulatum*, and *R. virginale* are at the most but slightly removed from each other, and the names are often used indiscriminately. The usual habit of this section of Rhododendrons is to form a freely-branched, yet somewhat loose-growing bush clothed with oblong lanceolate leaves, deep green above, and thickly studded with ferruginous scales underneath. It flowers freely, but there are seldom more than

half-a-dozen blooms in a cluster. The individual flowers are funnel-shaped, about 3 inches or 4 inches long, and as much across the expanded mouth. They are when fully opened pure white. The form to which the name *R. calophyllum* is usually applied is of more sturdy growth, with rounder leaves, which are also of greater substance, while the flowers are at times somewhat larger. This sturdier type will often bloom in a smaller state than the looser-growing form. Seedlings of this section of *Rhododendrons* can be raised in quantity, and it will be found as a rule that there is a certain amount of variation among the progeny, though I have never raised the sturdier form from the more slender one, or *vice versa*. These *Rhododendrons* strike root far more readily from cuttings than most Himalayan species. There is no hair or wool on the stems, and this I have invariably found influences the production of roots, for not only in the case of *Rhododendrons*, but also most other plants, those with smooth stems strike root with greater certainty than the others. The *Rhododendrons* above alluded to are essentially conservatory plants, as they are far more tender than most of the Himalayan species, and unless in especially favoured localities it would be useless to plant them out of doors.—T.

The Cape Coast Lily (*Crinum giganteum*) (*C. Marendaz*).—The large bulb you received last season from Dahomey, West Africa, and of which you enclose a flower, is certainly the plant named above. It is said to occur in many parts of the west coast, and to make bulbs as large as a good football. The flower before me, pure white on the inside, tinged slightly on the outside, measures upwards of 6 inches across. I do not detect any perfume. The anthers are of a deep purplish black. It has long been known in England, but not much grown.—W. H. G.

Plumeria lutea (*G. Bacon*).—This appears to me to be your flower, but it seems to have more yellow in it than is usual. You say some stems were sent you from Brazil, but I do not think it is a native of that country. The plant was introduced by M. Linden, of Brussels, many years ago from Peru. The flowers are deliciously sweet, but the plants are ugly-looking and cannot be brought into any reasonable shape. I would not recommend any of the genus to the amateur with limited space.—W. H. G.

Anthurium flowers (*H. Bertrand*).—These are really very fine standing in water above some flowers of *Lælia purpurata* and have a very fine effect. There is, first of all, *A. Andreanum*, which is the parent of all these large-spined kinds. It is very brilliant in colour. To my mind it cannot compare with the smooth spathe and deep colour of *A. Archiduc Joseph*, which is of a rich crimson. The spathes of *Reine des Belges* are of a delicate rose colour, the two latter varieties being very fine. Of *A. Scherzerianum* there also come some fine forms, one called *Marie-Eugénie* being extremely rich deep crimson with a long yellow spadix. A very fine form of the variety called *Rothschildianum* named *andegavense* has a large spathe, the front creamy white, regularly and profusely blotched with crimson-carmine, whilst behind it is wholly reddish scarlet, with a few freckles and dots of white, the spadix yellow. I am told this is a robust grower and a free bloomer. There is a form marked *giganteum*, but which exactly resembles the form called *maximum*, sent out some years ago by Mr. Wm. Bull, of Chelsea. The spathe is oblong in shape, nearly 10 inches long, pointed at the end, 4 inches across, thick and fleshy in texture, and vivid scarlet. This, I think, accords with the kind named *maximum*, and whilst anxious to see these *Anthuriums* gain popularity, I do not wish to see a multiplication of unnecessary names.—W. H. G.

Show and regal Pelargoniums.—Now that the show and regal types of *Pelargoniums* are again being prominently brought before the public, it would be well if growers were to name the most distinct and beautiful amongst the newer varieties. Out of a dozen of the best kinds purchased last season *Empress of India* is a splendid variety, the

colour being better described as salmon-scarlet. This variety is very free, with a good habit. *Duchess of Fife* is another beautiful variety; so also is *Fair Rosamond*, this latter being of dwarf habit, the flowers pure white, the two top petals slightly spotted with pink. Amongst those described as show *Pelargoniums*, *Martial* stands out conspicuously, the lower petals being scarlet, the top ones deep maroon. I can also say a good word for *Jubilee* and *Dorothy*, as described in *THE GARDEN* (p. 510).—A. YOUNG.

Diplarrhena Moræa.—This uncommon Irid is a near ally of the genus *Marica* or *Morea*, for the different species are known under both generic names. It forms a tuft of dark green rigid leaves, while the flower-scapes which well overtop the foliage produce a great number of blossoms. The individual flowers are about a couple of inches across and of an ivory-white tint, but, as with several of its immediate allies, they only remain in perfection for a single day. This is, however, counterbalanced by the fact that each scape produces a considerable succession of blossoms, so that a specimen of it will be an object of beauty for some time. This *Diplarrhena* is a native of the southern portion of Australia and Tasmania, and in common with most plants from that region it needs the protection of a greenhouse in this country. A near ally of the above and a native of much the same region is *Paterosonia longiscapa*, with long narrow iris-like leaves and violet-blue blossoms, borne on scapes sometimes a couple of feet high. It frequently flowers at Kew, but I have not met with it in any of the nurseries.—T.

Azalea indica.—The saying "when doctors differ, who shall decide?" is as applicable to gardeners as to any other body. At a recent meeting of the Kingston Gardeners' Association a member read a short, but very concise and practical paper on the culture of the Indian *Azalea*, and stated that at certain periods of growth it was his practice to feed his plants by giving them twice a week liquid manure made from cow manure. He stated that the best results followed from this course, and other members conversant with his plants, many of them large bushes, corroborated him. Other members, especially some old plantmen, deprecated the employment of manure of any sort whether liquid or artificial, and said some of the finest specimens ever seen had been grown without the aid of any stimulant whatever. Then, again, with regard to repotting, the reader of the paper said that he never reduced the balls of his plants when repotting so as to remove any roots. Others agreed that was the right course, but then it was said by other members that many first-class growers of *Azaleas* would cut the large balls of roots hard down in repotting, so as to keep the plants in pots of moderate dimensions and yet obtain the very best results. Here is some excellent room for discussion as to the best methods of treating *Azaleas*. Whilst one occasionally sees in gardens plants so admirably furnished with leaves and flowers that nothing can be better, it more frequently happens that plants in a comparatively starved state are found root-bound, soil-exhausted, and badly needing complete renovation. No doubt at the outset very much of the future welfare of the plants depends upon the nature of the compost employed in potting.—A. D.

Propagating Javanese Rhododendrons.—It is now pretty generally known that these *Rhododendrons* strike root readily from cuttings, that is, if they are taken when in good condition and carefully treated afterwards. The present is a very suitable time for increasing them in this way, for the best cuttings are furnished by the current season's shoots taken when they are in about a half-ripened state, that is to say, soon after they have lost their succulent character. Most of the shoots of the present season will now be in just such a state, while another advantage of summer propagation is that the various appliances that are needed are less occupied than is the case during the spring months. Pots 4 inches or 5 inches in diameter are very suitable for the increase of these *Rhododendrons*, and to prepare

them for the cuttings they should be about half-filled with broken crocks; then the soil should be put in and pressed down very firmly to within half an inch of the rim of the pot. When a layer of clean silver sand is placed over this the pot is then ready for the reception of the cuttings. If the shoots are not more than 4 inches, or in some cases 5 inches long, the cutting may consist of the entire shoot, and this is an advantage, as that portion of the shoot close to the older wood produces roots more readily than any other part. Where the shoots are too long for such a purpose, it will be found an advantage to form the base of the cutting with a sloping cut, as a greater surface for the formation of roots is thus ensured. The cuttings must be dibbled in firmly and well watered afterwards. When this is done a good place for them is in a close propagating case in an intermediate house, thus carrying out a good general rule to put cuttings in a temperature a little (but not much) higher than that in which they have been grown. In two or three months they will be nicely rooted, when they must be hardened off, and as soon as sufficiently established potted into small pots, using for a compost sandy peat. In putting in the cuttings it is a very good plan to put from four to six around the edge of the pot, as when rooted the ball of earth can be conveniently divided up without injuring the delicate hair-like roots.—T.

Zephyranthes carinata.—This has flowered with me during the present season about a month earlier than usual. It merits more extensive cultivation, for though the flower-spikes do not exceed a foot in height and are often less, yet the blooms are nearly as large as those of the Scarborough Lily (*Vallota purpurea*). They are, however, borne on single stems, but as the bulbs are small, several can be grown in a pot of medium size. The flowers, which are 3 inches or more in diameter, are of a rich deep rose—a very pleasing tint. The colour of the blooms depends to a considerable extent upon the conditions under which the plants have been grown, for where fully exposed to the sun the flowers are brighter in tint than when in a partially shaded position. Like the *Vallota* and many other bulbs of this class, the *Zephyranthes* dislike being disturbed at the roots, and flower much better when they are quite pot-bound. Such being the case, a compost that will remain sweet for years should be chosen, and good yellow loam with a liberal admixture of sand will just meet the requirements of the *Zephyranthes*. They need greenhouse treatment, or at all events the protection of a frame from whence frost is excluded during the winter.—H. P.

Sandersonia aurantiaca.—This is a splendid plant, allied to the *Gloriosa*. I used to grow it in the stove, placing it when in flower in a warm greenhouse. I have not seen it for a long time until I noticed it recently at Sir Trevor Lawrence's, under the care of Mr. Bain. The flowers are of moderate size, bell-shaped, and of a deep orange colour. It is a native of Natal, and should be potted in equal parts of loam, peat, leaf-mould and decomposed manure made sandy. Drain the pots well, for the plant likes a good supply of water during the growing season. In the winter the tubers are dormant, and should be kept cool and dry.—W. H. G.

Pelargonium Ardens.—This is usually regarded as a true species of *Pelargonium*, but it is said to be of hybrid origin, though raised so long ago that little is known concerning it. The parents are said to be *Pelargonium fulgidum* and *P. lobatum*. It is certainly wonderfully bright and effective when in flower, as the blooms, though not large, are of a rich glowing crimson tint. Another somewhat in the same way is *P. Schottii*, whose flowers are of a velvety crimson-purple, shaded on the upper petals with blackish maroon. *Pelargoniums* of this class, that is to say the original species and hybrids but once removed therefrom, are very seldom met with, and may be sought for in vain in nurseries. Still a collection of them, or rather a selection therefrom, would form a very attractive feature far more in-

teresting to many, I should say, than the commonly cultivated forms which are everywhere met with. The rugged, spiny-stemmed *P. eclimatum*, with pure white flowers feathered in the upper petals with maroon, is very distinct and pretty, and so are some of the forms raised therefrom, such as Ariel and Pixie, with rosy coloured blossoms. The scented-leaved forms again yield a considerable amount of variety, the flowers of some being very attractive. Many of them are very useful for cutting, especially where the old-fashioned nosegay is required, while as specimen plants they will please many. Some large specimens of scented-leaved *Pelargoniums* that were exhibited at some of the principal shows last year by Mr. Hudson attracted a considerable amount of attention.—H. P.

CARNATIONS AT EDENSIDE GARDENS.

A FEW yards from the station of Great Bookham, in Surrey, is Edenside Gardens, where Mr. James Douglas, of Ilford, has a large house filled with the best kinds of Carnations. For many years Mr. Douglas has raised and shown Carnations, not a few of the finest kinds in gardens appearing first at Great Gearies. At present only one house has been erected, 100 feet by 18 feet, but two other structures of the same dimensions are to be built to accommodate the various florists' flowers, Auriculas, Calceolarias, Cinerarias, &c., that are to find a home here. The Carnations are in pots, and, arranged in the well-constructed house, are of more than ordinary interest. There is a wealth of new varieties as well as of old favourites, and the show, for such we may call it, is of importance to the lover of Carnations. Mr. Douglas has secured the finest seedlings raised by Mr. Martin Smith, even the recent Malmaisons, which have created a new interest in this section. The collection is rich in selfs, and the following new kinds we made especial note of as worthy of culture. It is gratifying to see that the protests made from time to time in THE GARDEN against "pod-bursters" are bearing fruit. Very few of the varieties mentioned possess this evil trait, and their decided colouring would tell well in gardens grouped in distinct masses, the best way, as we have frequently pointed out, to get the best effect from the flowers. We have given in each case the raiser's name, and amongst the selfs are several lovely things. Hayes' Scarlet (Smith) is a brilliant scarlet flower, full, the petals stout, smooth and handsome, the plant of strong growth. There are no signs of the objectionable split calyx. The Carnation raisers of the present day are working in better lines than those of old, and getting really fine varieties of distinct colours and robust habit. Duke of Orleans (Smith) is a yellow Carnation, a very lovely flower, a great improvement upon Germania, deeper in colour and stronger in growth. A great fault in this section, as a rule, is the poor constitution of the plants, and this kind is an advance. A yellow flower of clear colour, full, and well shaped is a decided gain. Another of Mr. Smith's yellow Carnations is named Corunna, the flower remarkably handsome and stout, but without an element of coarseness. Each variety is represented by a quantity of plants, and one can judge of their rich effect in the garden. The Hunter (Smith) reminds one strongly of the variety Mrs. Reynolds Hole, but the beautiful apricot colour is richer and the flowers keep quite intact. We could not discover a split bloom. Carnations that split and lack fragrance are not of great value. Louis Philippe (Smith) is a good yellow self, very distinct, the petals quite short, wavy at the margin, and composing a handsome, dense, effective bloom. It is exceptionally free, and in all respects a good Carnation. Oriflamme is a new scarlet flower raised by Mr. Douglas. It is a very brilliant colour, the petals stout, smooth, and held well together in the firm calyx. This variety, it will be remembered, secured the first prize offered for twelve bunches of a border Carnation by Mr. Martin Smith at the exhibition of the National Carnation and Picotee Society in 1892. The colour is as bright as in any

kind known to us. A large group of plants is to be seen of Niphetos (Smith), the flowers exceptionally pure, very little split, and remarkably free. It will be much valued, we should think, for cutting. The finest rose self is Lady Gwendoline (Smith), the colour clear and rich, the form of the flower neat, full, and pleasing. Like all the other kinds that have been mentioned, it is a good grower. Every colour almost is represented in the self Carnations. Abigail (Smith) is carmine-rose, a fresh charming tint, the petals broad, firm, and the calyx not split. Water Witch and Mephisto, both Mr. Smith's seedlings, are acquisitions. The former is a delicately coloured flower, blush-white, full and broad, bearing something of the Malmaison character, whilst the latter is deep maroon-crimson, an intense shade, the flowers large and not in the least split. A fine lot we noted of King of Scarlets (Douglas), one of the brightest kinds in the whole collection, the petals stout and the calyx perfectly unbroken. We should like to see a group of it in the open, where it would create an effect in the garden. Two varieties very similar are Alice Newman (Smith) and Mrs. Louisa Jamieson, raised also by Mr. Smith. The flowers in each case may be described as dull red, a distinct colour, but not so bright as one could wish for. Each bloom is of bold character, full, and of splendid form. A very pleasing variety, one of the gems of the collection, is Ruby, raised by Mr. Douglas. The compact, full, sturdy flowers are clear shining rose—a striking and welcome shade, whilst the plants are vigorous in growth and free. Splitting of the calyx quite spoils the kind named Royal George (Smith), which produces a very large flower of splendid rich purple colour.

The above are the names of the best selfs in this fine house of Carnations, and certainly we have here a precious collection, in which the colours are striking and the flowers bold in form, sweet and not split, except in one instance. Not many years ago such a place would scarcely have been given to this type, which is the chief feature of beauty, although there is a wealth of bizarres, flakes and so forth. We may mention yet another named Midas, which is very pale rose in shade and one of Mr. Douglas' seedlings. The colour is peculiarly soft.

The collection is rich in Picotees, and very beautiful are the following, which represent the highest type of this cherished flower: Mrs. Sydenham (Douglas) is a yellow ground, very pure, with a well-defined red edge, a full, handsome kind, the plant vigorous in growth. Mr. Douglas has devoted much attention to this class, as shown by his superb seedlings. Another fine acquisition is Lily Henwood, a yellow ground kind, heavily flushed with red, the habit of the plant conspicuously dwarf and compact. One of the most charming is Ganymede (Douglas), a heavy red-edged flower, full and rich in colour, a pleasing type. We saw a large group of it and were much pleased with the fine shape and decided colour of the flowers. A lovely new Picotee is Melpomene, a light rose-edged flower, the ground very pure white. It was a mass of delicate bloom and was amongst the novelties shown by Mr. Douglas last year. Another of Mr. Douglas' seedlings deserves mention. This is Desdemona, not a large flower, but, so to say, dainty, very free, light rose-pink shade, exquisite against pure white. No split blooms occur. We may also mention, amongst other Picotees, Mrs. Sharp, heavy rose edge; Brunette, heavy red edge; Thomas William, rose edged; Baroness Burdett Coutts, purple edged, and Muriel, bright purple, heavy edged. Then, of course, one gets here a rich selection of bizarres and flakes. The success of Mr. Douglas in these particular sections is well known, and the beautiful things he has given us are sufficient proof. A charming rose flake is Lady Marie Currie, the flower of fine shape and the flakes very distinct and clear, whilst the plant is a strong grower. Very beautiful is the variety Charles Henwood, a purple flake, bright and attractive, the flowers of the largest size, rich in colour, and the growth robust. It deserves praise. Not a few of the bizarres and flakes are objectionable in colour, but not such kinds as we here mention. Mrs. Constance Graham is a fine

type of the scarlet flake. This is one of Mr. Smith's seedlings, the colour most brilliant and the flake thoroughly well defined—a fine kind for colour. A scarlet flake that may be mentioned is named Dregorins (Douglas), not a very pleasing name for a pretty flower, the flake excellent and the flower of fine size with smooth, stout petals. Amongst the pink and purple bizarres we made note of the variety Harmony (Douglas), which was represented by a coloured plate in THE GARDEN, December 21, 1889. The plate shows well the beauty of the flowers in both form and colour. The growth is vigorous for a bizarre, and we were pleased to see that all the newer kinds and novelties were of robust habit. Phoebe (Smith) is another fine pink and purple bizarre—a lovely flower, full, the colours bright and clear.

It is needless to mention old varieties, which of course, are well represented, nor to refer at greater length to novelties. The Carnation is shown in its various phases, from the Picotee division to the Malmaisons, which we need not further refer to, as they were described recently in these pages. In winter the house will be gay with the best tree kinds, and in the future we shall expect many prizes from the 2000 seedlings for trial that are soon to be planted out. Upwards of 4000 plants are in the house, and when this home for flowers is in full working order, each season of the year will have its treasures—Carnations, Cinerarias, and so forth. We may mention that a number of beautiful seedlings are in bloom under numbers, and therefore could not be described.

Richardia Elliottiana.—Apart from its beautiful golden coloured blossoms this is a very distinct Richardia, for the leaves are much thicker in texture and of a deeper green than those of any of the others, though while spotted with white they are less so than those of Richardia alba maculata. The foliage, too, of R. Elliottiana is blunter than any in of the others. A very notable feature is, however, furnished by the leaf-stalks, which, especially toward the lower part, are mottled with green, brown, and white, after the manner of some of the Alocasias. This Richardia is altogether a firmer plant than the commonly cultivated forms, and it appears to be of slower growth, so that with the limited number sold at the time of its distribution, and the fact that it will take a good while to work up a stock, we shall probably see it realise a good price for some time. It is, however, said to come true from seed, so that the holders of the strong flowering plants will have the advantage.—H. P.

Mitraria coccinea.—Discovered on the island of Chiloe (which is situated a few miles off the mainland of Chili) in the year 1848, this gesneraceous plant promised at one time to become popular. Like a good many other things, however, discovered and introduced about that time, it almost entirely disappeared from cultivation until within the last few years, when a desire to grow these old greenhouse plants appears to have re-arisen. Mitraria coccinea is an evergreen plant with small deep green leaves and slender, woody, semi-scandent branches, altogether of very pleasing, graceful habit. The flowers are tubular, somewhat inflated, and of the brightest scarlet. A specimen planted in a corner of a peat bed in the greenhouse at Kew is flowering freely at the present time. Although Darwin, who visited Chiloe when voyaging in the *Beagle*, describes the native home of this plant as one of the moistest on the habitable globe, it is one that enjoys abundant sunlight; this season appears to suit it perfectly. It is easily increased by cuttings.—B.

SHORT NOTES.—STOVE AND GREENHOUSE.

Schubertia grandiflora.—This plant is flowering freely with Mr. Bain at Burford Lodge. It is in a small pot trained upon a trellis, the large umbels of white fleshy flowers being very sweet. I was not aware that this plant, which was figured in THE

GARDEN, July 30, 1887, could be so easily grown in pots.—W. H. G.

Tillandsia xiphioides (G. Schneider).—This plant has a greenish tomentum covering its leaves and an erect spike, which is remarkable for its pure white fragrant flowers. If the plants are kept clean and in good health, they will be found very interesting.—W. H. G.

Vriesia Duvaliana (G. Schneider).—This comes for a name. The leaves are smooth at the edges, sheathing at the base, and pale green on the upper side, with a tinge of purple beneath, spike erect, dense, clothed with distichous bracts, which are green on the upper part, deep red beneath, the stems also being furnished with scales of the same colour; it is these bracts that constitute its beauty.—W. H. G.

Scutellaria Mocciniana.—Mr. Riches, in sending a beautiful raceme of this asking its name, says it is rather a straggling plant, though very fine when in flower. The straggling habit can easily be remedied by pinching out the points and striking them, thus keeping up a stock. The raceme before me has forty-six flowers, each about 2 inches in length, of a rich deep scarlet, and the limb deep yellow.—W. H. G.

Cleome pungens is certainly not a stove plant. I have grown it for years under ordinary greenhouse treatment raised in heat in early spring. Last year two plants put out in June on a raised bed of very sandy soil grew most vigorously and showed flower-spikes, but the cold nights coming too soon, they never quite perfected. It is worth growing for its palmate foliage. To save seed, the pods require watching and careful handling, as they suddenly burst and the contents are lost.—J. M., Charmouth, Dorset.

NOTES OF THE WEEK.

Spigelia marylandica.—This pretty old flower, so seldom seen, comes to us in bright bloom from Mr. Prichard, The Nurseries, Christchurch, who, we are well pleased to see, is forming a nursery of hardy flowers in Hants.

Rose Gloire Lyonnaise.—We have a lovely photograph of this fine Rose from Mr. Grahame, Croydon. We have grown it several years now, and find it a great Rose, hardy, free to bloom, handsome in its Willow-like shoots, and most distinct in habit and flower.

Sweet-scented Lily.—I have brought you a stem with two flowers and one with two buds of *Lilium odorum japonicum*. If you smell it in the evening, I think you will agree that it is the sweetest of all Lilies. I have a clump with fourteen flowers.—G. F. WILSON, Weybridge.

The Peruvian Lilies, or *Alstroemerias*, brighten the borders in the nursery of Messrs. Paul and Son at Broxbourne. The chief kind grown is *A. aurantiaca*, which produces during the summer months a profusion of orange-yellow flowers, which are remarkably effective when the plants are in broad clumps. Too little attention is given to the *Alstroemerias* in gardens, the impression being that they are tender. This is true of some kinds, but not of *A. aurantiaca*, the handsomest of the family. The great point is to get it well established, and then leave it alone.

A fine dark Rose this year is *Louis van Houtte*, which still remains one of the best of its class, although sent out many years ago. This fine variety was raised by Lacharme, who distributed it in the year 1869, mentioning that it was a sport from the well-known *Charles Lefebvre*. It is a splendid Rose, very deep in colour, and, like the majority of the richly shaded varieties, very sweetly-scented. We have not seen it so much at the exhibitions this year, as is sometimes the case, but in several nurseries and gardens the plants have been in full beauty.

Spiræa Anthony Waterer, so finely shown by Mr. Anthony Waterer, of Knap Hill, Woking, at the meeting of the Royal Horticultural Society on

Tuesday last, is one of the most beautiful new shrubs that has appeared of recent years. It is a lovely thing for colour. It is a form of *S. Bumalda*, dwarf in habit, compact, strong in growth, perfectly hardy and blooms from early summer until frosts occur. The heads of bloom are intense crimson, and the plant is a picture of strong colour throughout the best part of the year. It is well adapted for pot culture, for which, as is well known, the type is largely used, but this eclipses it for its superb depth of colour. There is no doubt that it will be very largely grown in the future.

Funkia Sieboldi is the finest of the family. We were pleased to see a few days ago a border composed of this Plantain Lily alone in the Broxbourne nursery. A large specimen of it is remarkably handsome, and in THE GARDEN of July 19, 1890 (p. 69), particulars are given of an example in Ireland no less than 9 feet across and 5 feet in height. When in robust health the leaves are very striking, heart-shaped, and of a pleasing silvery glaucous tone. Even without flowers it is worth a note. The plants of *F. Sieboldi* were in full bloom, the creamy white spikes or racemes of flowers rising gracefully from the base of foliage. It likes a little shelter from very keen, searching winds. This year the display was not so long-lasting as usual.

Oenothera macrocarpa or *O. missouriensis* is one of the principal plants in full bloom at Broxbourne. It withstands the heat remarkably well, and a break of it is charming, the flowers very large and rich yellow in colour, whilst the stems are prostrate. When well placed the plants bloom with great freedom, creating a patch of yellow in the border or rockery during the summer months. A good mass on some rocky ledge is attractive, although it may be planted in the front of the border with advantage. A sunny spot and warm soil are most conducive to a robust growth. We have before remarked that to get the full beauty of a plant it should be massed together, and this principle is well carried out in this nursery.

Mauve tints under artificial light.—At the exhibition held at Earl's Court on the 28th ult., in relation to some centre pieces for table decoration, the question arose as to whether *Ceanothus Gloire de Versailles* with its charming silvery mauve-coloured flowers would show up well upon a dinner-table under artificial light. It is sometimes thought, and I think erroneously, that these delicate tints do not display themselves to advantage, but Mr. J. Hudson, who is a reliable authority upon the matter, informs me that *Erigeron grandiflorum*, which he grows largely for cutting, is an excellent subject under artificial light, and as its silvery-mauve tint is very similar to that of the *Ceanothus*, I think there can be no doubt as to the value of the latter for the same purpose.—R. D.

The hardy Gladioli of the *Lemoinei* race are getting more popular each year, and the reason is not only that they are hardy, but the newer varieties are a great advance upon those raised earlier. Recently we noticed a group of them in full bloom. These had remained out during last winter with no protection except a slight covering of cocoa-nut fibre refuse. This is evidence, if any were needed, of their hardiness, but there is an impression that they are tender. The soil should be deep, warm, and not too heavy. Amongst the varieties we noted as of good colour were *Cleopatra*, light red; *Marie Lemoine*, pale yellow, the lower segments blotched violet-purple; *Masque de Feu*, crimson, a deep, showy colour; and *Lafayette*, yellow, crimson in the centre. These hardy hybrids are very easily grown, and the flowers may be cut for decoration with advantage.

Hæmanthus Katherinæ.—There are very few stove plants, either now or at any season of the year, which excel in beauty this noble South African bulb. A fine example now flowering in the Palm house at Kew makes a very conspicuous and striking object. The habit is quite different from that of *Hæmanthus sanguineus* (the well-

known Blood Flower), and is more like that of a *Crinum*, the large bulb having a long neck and being surmounted by broad, deep green, Eucharis-like leaves. The flower-stem, upwards of 3 feet high, is as thick as a man's finger, bearing at the top a huge rounded umbel of closely-packed flowers that measures 10 inches across. The flowers are each $1\frac{1}{4}$ inches in diameter, the six segments of the perianth being narrow and of a bright red. The long stamens (which are also bright red) and the yellow anthers add considerably to the effectiveness of the inflorescence.—B.

Nelumbium luteum.—I note in your number for June 3, in an article on the Egyptian Lotus, that the writer supposes that *Nelumbium luteum* has disappeared from Jamaica. I beg to inform you that it still grows here. After I first came here in January, 1887, I searched for it without success where it was once known, in swampy ground between Kingston and Spanish Town. I was informed that it had not been seen in that locality for the last forty years, but in 1889 the seed-vessel was sent for identification from swamps in the parish of St. Elizabeth, and later on I received flowers. In 1886 I saw it growing in great abundance on an island in the Mississippi, near Davenport, Iowa. Possibly the difficulty found in growing it may be attributed to its having too much water. Try it with the ends of the roots in water only, and dry it off occasionally.—W. FAWCETT, Gordon Town P.O., Jamaica.

A note on Carnations and Picotees.—These are in perfection much sooner this year than usual. A very large collection is grown in Messrs. Paul and Son's Broxbourne Nursery, many of them raised here. We noticed several rows of that fine vigorous Picotee named *Redbraes*, and a large break of *Mrs. Reynolds Hole*, a variety much esteemed for its distinct colour. The flowers were not so split as usual, and this is as a rule their great fault. *Mary Morris* was in perfection, and the rosy flowers are welcome. *Conway* is of the old Clove class, the flowers not large, but produced very freely and sweet scented. In no case were the flowers large, owing to the dryness of the season, but they were not split. The most promising kind was called *Fireball*, the colour intense scarlet, the calyx not in the least split, the petals broad, stout in texture, and composing a large bloom. This is the type that is wanted in gardens.

Erythrina crista-galli.—This well-known plant, now grown in almost all tropical and semi-tropical countries under the name of the Coral Tree, was introduced to British gardens in 1771, and was therefore amongst the earliest of Brazilian plants to be cultivated here. It is useful both for the greenhouse and for flowering out of doors, its large, brilliantly red blooms being most effective in either case, especially in bright seasons like the present, when the flowers are unusually numerous and highly coloured. It is a plant of very easy cultivation, every year making long, semi-herbaceous shoots from a woody stool, to which it is annually cut closely back. If kept permanently for indoor use, the plants should be grown in pots, starting them into growth in a warm greenhouse as soon in spring as buds appear on the stools. When fairly started they should be kept cooler, an ordinary greenhouse temperature sufficing. They flower, as a rule, in July and August, but this varies according to the treatment they receive. After flowering they should be ripened off out of doors in full sunlight, and for the winter may be stored under the greenhouse stage, keeping them without water. In sheltered nooks in the southern counties, especially when planted against the south wall of a hothouse, it has proved capable of withstanding ordinary winters if well protected with litter during severe frost. In most cases, however, it is necessary to take up the stools and store them in a cool, dry place till spring, when they can be started in the same temperature as the pot plants and given their outdoor position when the late spring frosts are past. A coloured plate of this Coral Tree appeared in THE GARDEN for December 5, 1891.—B.

FLOWER GARDEN.

MARGUERITES FOR FLOWER BEDS.

The illustration which accompanies these remarks speaks for itself as to the effectiveness of Marguerites for bedding. They are not, one feels compelled to admit, nearly so much used in this way as they might be, and that with decided advantage. There is one good point in their favour which frequently escapes notice: it is that of their being fit for planting out extra early without that attendant risk so common to many plants. They are perfectly safe out of doors by the end of April either in pots or planted out, *i.e.*, speaking generally of the average English climate. A few degrees of frost will not hurt them nearly so much as it would the bedding Geraniums. We have had our plants outside by the end of April for some years past, and no injury has come to them thus far. On the other hand, there has been a marked advantage with respect to the fly and the attendant grub which buries itself in the foliage. I have noted repeatedly that where the

may be seen by taking note of the illustration. True, a pleasing combination may be obtained by mixing the white and the yellow varieties together. Or if an edging is really deemed desirable, then use something that is in character therewith. *Agathæa cælestis*, for instance, cannot be surpassed for this purpose. The use of scarlet Geraniums and white Marguerites is so common, not to say vulgar-looking, that I would always avoid this mixture by all possible means; the contrast is so sharp and garish-looking, affording nothing restful to the eye. Supposing the plants are planted in poor soil or to have in a measure exhausted its properties, after a time a weak solution of sulphate of ammonia will greatly assist them, this exciting stimulant being also good for pot or vase plants. It is hardly necessary to enter more fully into cultural detail. The Marguerites are not fastidious as to the soil in which they are grown; what is most needed is generous treatment both as to the soil and in watering. Young plants of the same spring striking will be found the best for planting out after one or two stoppings to procure a bushy base. By lifting these plants in the autumn,

At the nurseries of Messrs. Robert Veitch and Son, Exeter, *Heuchera sanguinea* also gives most satisfactory results planted in heavy soil fully exposed. The most brilliantly coloured flowers of this handsome species I noticed a few days ago in the gardens of Mr. Coulthurst, Southhill, Torquay. There it occupies a dry space in the rock garden, the soil being a red-coloured heavy loam exposed to the full sun all day long. The flowers are not only produced in the greatest profusion, but are of a larger size and deeper colour than I have ever seen before. It is possible that a lighter soil would suit this plant equally as well, but plenty of sun and sloping ground seem to be necessary to obtain plenty of flowers.—F. W. MEYER, *Exeter*.

—“W. R. B.” should try this plant in loam in his flower border. He can also try it in heat, in which it is said to do well. I have in a loamy border facing south a clump of about forty plants, which flower freely. *Heuchera sanguinea* is not a plant that will thrive if left alone for more than two or three years. After that time it requires division, which, I find, is best done in the spring.—G. H. C., *Brookfield*.

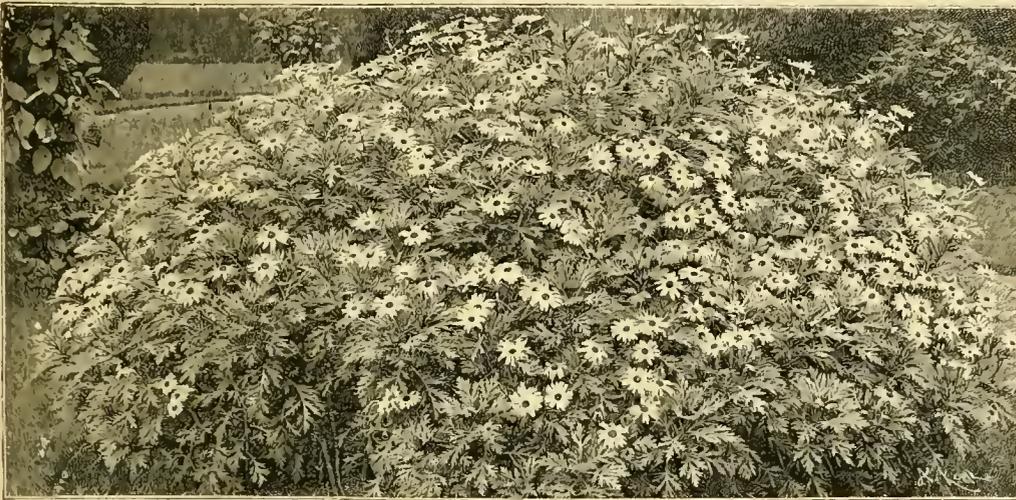

Pulmonaria saccharata.—What a delightful hardy summer ornamental plant this is, and it grows freely in any soil and position. During summer the large green leaves are so handsomely spotted with white as to appear as if inlaid with silver, and they are remarkably handsome. In early spring its shot-silk blossoms are equally delightful.—R. D.

A note on Canterbury Bells.—The large conservatory at Syon House is gay with Canterbury Bells, and it is interesting to notice that the range of colour is extensive, varying from pure white to deepest purple. The most pleasing of all is the rose-coloured form, a delicate shade, most acceptable in cut flower arrangements. Some of the flowers were of huge size, but we do not care so much for these as the smaller types.

Varieties of Spanish Iris.—In a large collection of this Iris we recently noted as of special beauty the varieties *Louis Philippe*, the flowers of a yellowish shade; *Venus*, yellow; *Alice*, the standards blue and fall white, and *Satisfaisantè*, in which the standards are blue and the falls yellow. They are all of distinct and attractive colours.

Mulching Carnations.—These plants have had a hard time, especially in light soils. I lately saw a quantity of plants in a sad state. These had been planted on a slope in front of fruit houses and were nearly all dead. I have found Carnations did much better even in the most favoured places if a mulch was given. I employed decayed leaf-mould that had been stacked for two years and found it of great assistance. Of course, it may not be considered the best mulch on light soil, but every bit of manure or litter was in request for vegetable crops, and so far the leaf-mould answered admirably. Spent Mushroom manure is also a good mulch where it can be obtained. A good grower told me it was the best thing one can use. When these plants get a surface-dressing in this way, a thorough soaking once a week will keep them growing freely, and though it would well repay the grower to damp over more frequently, the mulch will retain the moisture for some days and keep the plants growing vigorously. The ground was thoroughly dressed before planting to get rid of wireworm, which, I hear, has been troublesome this season.—G. WYTHES.

Forms of our native Water Lily.—In our rockery pool we have the two forms of our native Water Lily described at page 16. The pink form is remarkably beautiful, and I never remember to have seen the pink tint so decided as this year. These plants were gathered five years since from a large lake, 30 acres in extent, in a distant part of this estate, where they grow in great profusion. No exotic Lily could be more lovely than our

A bed of Marguerites. Engraved for THE GARDEN from a photograph by F. Mason Good.

plants had been badly troubled with this pest in the houses, they did in a large measure grow out of it when fully exposed. It is this pest undoubtedly that is the greatest deterrent to a more extended system of culture in the case of the Marguerites. Hand-picking has to be relied upon largely, but this involves a lot of labour. Syringing with soot water, with a weak solution of soft soap, or with water strongly impregnated with quassia chips are all good remedies. Some of either of these remedies should be kept available for the purpose; then it is not much trouble to damp the plants overhead once at least every day. Rendering the foliage distasteful to the insect prevents further ravages to a large extent, and is, all things considered, about the best course that can be adopted. By planting out early in the beds, say the last week in April, the plants soon take a hold of the soil. This also aids them in a large measure to stand against these insects. The beds also are thus filled in good time and give a relatively early yield in flower. Being so very distinct and flowering so very profusely under favourable conditions, it is no surprise that the market growers have a large demand for them in the spring. When planted out in beds in masses, there is an absence of that strict uniformity common to many plants, as

good pot stuff for another year will be secured if large ones are desired. PLANTSMAN.

Carnations at Syon House.—We have seldom seen Carnations in finer health than in the gardens at Syon House, Isleworth. Mr. Wythes has in one portion of the kitchen garden double rows of *Raby Castle*, whilst outside there is a row of *Gloire de Nancy*, the white *Clove*. The old crimson is flowering with great freedom, and its sweet, deeply-coloured flowers are always in request. Every Carnation is a picture of health, and the white *Clove* is remarkably strong, the growth sturdy, and the stems abundant, each carrying a wealth of bloom. These varieties where they can be made thoroughly at home are very useful, being of a type greatly in demand. *Raby* is a pretty flower, rose-pink in colour, fringed, and very free. It does not split, a common fault with so many otherwise good varieties.

Heuchera sanguinea.—In THE GARDEN, July 1 (p. 11), “W. R. B.” complains of being unable to flower *Heuchera sanguinea*. My experience with this plant is that it does best on sloping ground fully exposed to the sun. In the rock garden at Broadlands, Newton Abbot (recently illustrated in THE GARDEN), there is a large batch of this lovely perennial now in full bloom. It grows there in somewhat heavy loam sloping towards south-west, and it flowers most abundantly

native form, and where there are pools or lakes, means should certainly be taken to establish it. The rocky pool in these gardens is rather large of its kind, the bottom being cement concrete. The plants were procured just as they commenced to grow. Two or three were fixed in rather large wicker baskets, some good loamy soil being provided for them to root into. After being fixed in position, some large pieces of sandstone were placed around them, again filling up with soil. Some years ago I also established some in the large lakes at Holme Lacey, and this after attempts had been made for twenty years. The mistake which was always made was in procuring pieces whilst in full growth. I procured pieces just as fresh growth was starting and tied them round wicker baskets, filling in some good soil. These were placed at the edge of the pools at first, the crowns being just covered. As they commenced to grow freely, they were pushed into deeper water.—A. YOUNG, *Abberley Hall*.

The Madonna Lily.—In answer to the query in THE GARDEN as to the behaviour of *Lilium candidum* in other places, I may say that in this district, especially in the village of Great Whitby, it has been beautiful. There is hardly a cottage garden in which it is not growing to perfection. The natural soil is sandy loam on the old red sandstone formation. I have also seen it growing with extraordinary vigour on the chalk along the south coast. In this garden, although in the same district, it will not thrive at all well, the soil being a very cold limestone clay; consequently the bulbs lie too cold during the winter and perish. In some seasons the Madonna Lily is not nearly so satisfactory as in others, but I can confirm what you state as to its doing well in wet and dry seasons alike, as during the wet summer of 1888 it was equally as good as this season. In cottage gardens the bulbs are never disturbed.—A. YOUNG, *Abberley Hall, Stourport*.

FLOWERS AT SYON HOUSE.

THE flower garden facing the large conservatory at Syon House, Isleworth, is worthy of note, as the various beds are planted with a true eye to effect without undue formality in the arrangements. Rich colour is imparted by a judicious contrast of various things, and the rugged framework, so to speak, of this garden brings out the beauty of the plants. Standard Roses are a conspicuous feature, and when in luxuriant health, as they are here, crowded also with flowers, this type is effective. It is the weakly, miserable, mop-head specimens that are an eyesore and disgrace. A bed entirely of Fuchsias will soon be in full perfection, and we see with pleasure greater use being made of this fine flower. *F. gracilis* is disposed round the edge, and the centre is filled with *F. corallina*, the edging *Sedum Sieboldi*. The most original contrast, and one that those who have much of this kind of work to accomplish should think of, is the silvery *Centaurea candidissima* mixed with *Tropæolum Vesuvius*. The contrast is splendid, the small dark coloured leaves and brilliant flowers of this *Tropæolum* in rich association with the *Centaurea* leafage. We have never seen this mixture before, but it is very appropriate and not too stiff. One bed filled in the centre with Henry Jacoby Pelargonium has outside this a line of tufted Pansy Countess of Hoptoun, a pure white flower with a yellow eye, dwarf, compact, and free. Again, *Centaurea candidissima* is well used as an edging. In all bedding arrangements the great thing should be to get novelty. We noticed in one large bed the white Canterbury Bell used as a centre, alternated with the variegated Abutilon. Colour is therefore obtained early in the season, and when the Bellflowers have faded the Abutilon takes its place. In this bed Henry Jacoby Pelargonium is used to advantage, and the pretty *Cerastium tomentosum* forms the margin—very rich against an inner line of the *Lobelia*. Mr. Wythes plants the tufted Pansy Bluebell freely. It has flowers of a pleasing shade of blue and blooms profusely over a long season, hence in the London parks it is

more planted than any other kind. A very fine contrast is obtained by mixing it, as at Syon, with the yellow-leaved Pelargonium Beauty of Lauderdale, the brightly variegated Flower of Spring in the centre. In another arrangement the centre of the bed is the white Snapdragon, which is remarkably fine at Syon, edged with tufted Pansy Bluebell. It would be well if this beautiful white *Antirrhinum* were more used in gardens. Its flowers are of the purest white, produced very freely, and a succession is maintained for a considerable season. When in perfection a bed of this plant is a beautiful picture, and few things are more easily raised. Tuberosus Begonias are made good use of and enter into various beds, either massed or planted in conjunction with appropriate subjects. Although little has been written of the various beds so well laid out without a rigid system of arrangement, inartistic and objectionable, we have pointed out a few of the more important contrasts of colour.

FLOWER GARDEN NOTES.

THE best things in the flower garden just at present (July 3) are decidedly border Carnations and seedling Petunias, and as a good third Ivy-leaved Pelargoniums. Two large beds are planted sparingly with varieties *La France* and *Mme. Thibaut* on a carpet of variegated *Mesembryanthemum*, with occasional plants of *Grevillea robusta*. Anything of trailing habit as these Ivy-leaved Pelargoniums and the succulent that covers the ground quickly is likely to make the earliest and best show in a season like the present. Individual blooms of the double Ivy stand a long time, and in this matter are decidedly superior to the single zonals; the majority of them are also very free. Very large beds can be thoroughly well filled with these Pelargoniums, irregular pyramids and raised clumps being formed with the strong free-growing varieties, and the remainder of the bed carpeted with dwarfier sorts. Half a dozen plants of one of the large-leaved *Solanums* will complete the arrangement. Each succeeding year sees these Ivy-leaved Pelargoniums used more frequently for window boxes and vases. Planted at the edge and allowed to trail over, they come quickly into flower, and last in great beauty all through the season. Large vases can have the centres filled up with Fuchsias that would form a pleasing contrast to the different colours of the Pelargoniums. General Roberts and Mrs. Marshall are two good vase Fuchsias. Writing of Fuchsias reminds me that Dunrobin Bedder has quite come up to the expectations formed. It is a very dwarf variety of compact habit and wonderfully free. It has been employed, as a rule, in straight lines or patterns, but is not seen at its best in this way; it is too formal, too hedge-like. I like it associated sparingly with some nicely contrasting *Viola*. Tom Thumb Dahlias do not seem to be as yet generally known. They answer well for large-sized beds, and as there is now considerable variety in colour, charming combinations can be obtained. Those growing them for the first time must remember that to secure a continued and un-failing supply of flower, prompt removal of seed-pods is quite as essential as in the case of *Violas* and Sweet Peas. Probably the advisability, or shall I say necessity, of deep tilling for Sweet Peas has never been so fully manifest as in the present season. On herbaceous borders, where they were sown in clumps in shallow-dug ground, they are looking decidedly the worse for wear, although they have been watered and mulched and seed-pods promptly removed; but on a border that was heavily manured and bastard-trenched, they are doing well. The summary of new varieties in a recent number is interesting, but, as pointed out in a previous note, it is not everyone who can invest in novelties. A very nice combination of colour can be made with Mrs. Sankey, white, Princess Beatrice, pale pink, and Scarlet and Blue Invincible. I have always found a good strain of

the last-named one of the most vigorous of all the Sweet Peas.

A feeling of envy is engendered on reading the note on page 18 touching herbaceous borders at St. Anne's House, Clontarf. Everywhere in this neighbourhood, unless owners are blessed with a deep holding soil and have been able to mulch and water, herbaceous plants have for some time felt the effect of the prolonged drought, and have suffered severely. They bore up bravely until the end of May, but since that time the report must be premature and indifferent flowers and withering foliage. I referred last week to the early flowering of Starworts and Erigerons, and this week must chronicle a similar experience with *Zauschneria californica*, usually a late summer flowering plant. I have it close to a big clump of *Funkia ovata*, and as both are flowering at the same time the effect is very pleasing. Work for the past week in the flower garden has been the removal of seed pods and stalks from *Violas* and Pelargoniums, watering as much as possible, and lightly staking the Sweet Tobacco, *Humea elegans*, and *Gaultonia candicans*. "Such things should not be staked," is sometimes the verdict, to which I reply, "That all depends on the season." Such plants may sometimes go through a season without requiring support, but I have often seen them dashed to the ground in a few minutes when quite at their best if they have had to encounter without stakes a very heavy storm. A spell of excessive heat and continued drought must be recorded for the opening day of July, and to mulch wherever practicable (as well as water) will be sound advice. As soon as time permits, we shall mix up compost for *Viola* cuttings and for border Carnation layering. In both cases a similar compost will be advisable, viz., three parts leaf soil and one of common red sand; one or two barrowloads of old potting soil may also be added. Any *Daffodils* it is thought advisable to shift should be lifted as soon as possible. I find a few in different varieties ranging in season from the Tenby to the double poeticus, so useful for quick cutting that they are close to hand on a slip border, and their numbers will be increased this year. Any lifted may be stored in trays or boxes for early autumn planting.

Claremont.

E. BURRELL.

Dry weather annuals.—It was possible in looking over a large collection of annuals to note specially early in July what sorts or varieties seemed to thrive well in spite of the great drought. The minor *Convolvulus* are most beautiful, and even on a dull sunless day opened the flowers abundantly. The variety *sub-cerulea* is charming, having flowers of a pale or lavender blue. For a really true and superb blue nothing could excel a big breadth of the lovely *Phacelia campanularia*, one of the most glorious of hardy annuals. All the sturdy dwarf *Godeletis* stand drought well and bloom profusely, Lady Albemarle especially being effective. For a bright yellow nothing in annuals could well excel *Bartonia aurea*, quite a mass of flower, whilst a striking contrast is the dwarf and most beautiful *Linaria maroccana*. *Eschscholtzias* also all do well in the drought. These are but a few hurriedly noted out of many annuals, but they serve to show what may be relied upon for a dry season. Many others were late because the drought had checked germination, but under more genial influences now had made good growth, and will bloom abundantly a few weeks later.—A. D.

Three noble Irises.—The Iris family grows larger and more bewildering in numbers of both species and varieties, but I may safely select a trio of fine kinds and recommend them for general cultivation. They belong to the taller types—in fact, are some of the tallest, and of a decidedly ornamental aspect before and long after flowering by reason of their ample and graceful leafage. They should be planted in bold groups in sunny situations, preferably in a soil inclined to be moist. Associated with shrubs they are handsome, and it is the bold beauty of these three kinds flowering among Azaleas in a large bed that suggests this

note. Their names are *Monnieri*, *aurea*, and *ochroleuca*. In leafage they are somewhat alike, having long, narrow, rich green leaves. Their flowers are quite distinct from each other. Those of *ochroleuca* are white and yellow, the falls being margined with white, but orange-yellow in the centre and at the base, the standards being white also. It is tall and stately, and on account of this is called *Iris gigantea* by some, but I believe there is a form of *ochroleuca* named *gigantea* which grows more than 6 feet high, and is taller altogether than the type. This is a fine species for naturalising in a wet spot. I saw a group quite recently among Sedges and Rushes in a rather open clearing of a wet Oak wood. The effect was magnificent, the plants appearing quite at home and flowering freely. *I. Monnieri* has flowers of a rich soft yellow colour borne on stems quite 4 feet high, and is sweetly scented. *I. aurea* is of a very rich shade of deep yellow and quite self-coloured. Its flower-stalks are taller than those of the two preceding species, about 5 feet in height, the flowers being thrown up high above the rich leafage. They bloom nearly simultaneously, but *aurea* is a little the latest of the three.—A. H.

Lilium Martagon dalmaticum in London.—This dark coloured form of the Martagon Lily, often called the black Martagon, is just as satisfactory in London as the white variety alluded to on p. 16. I planted half a dozen rather poor bulbs in the autumn of 1890, and the first season there was, as is usual with most of the Martagon Lilies, but little show above ground. Last year, however, they flowered well, and this season have improved very much. The strongest spike has produced forty-seven beautiful blossoms, all prettily reflexed and arranged in a very symmetrical manner. Their perfume is, however, by no means pleasant. The unfolding of the flower-buds in this Lily very interesting, for when first visible they are arranged in a close, compact cluster, which is drooping, so that the flower-buds then really hang head downwards. As the stem lengthens the flowers expand and the stem gradually straightens, so that by the time most of the flowers are open they form an erect pyramidal-shaped head. The buds are covered with a white woolly substance, which gives them a very singular appearance, but in this respect individuals vary, as they do in the colour of the flowers, for some are very much richer tinted than others; indeed, under the head of *dalmaticum* may at times be met with every gradation in colour, from a few shades deeper than the ordinary Martagon to the richest tinted of all. To the palest forms of *L. dalmaticum* the varietal name of *Catanæ* is sometimes applied.—H. P.

Carnations at Maiden Erleigh.—In common with all gardeners who have to furnish large supplies of cut flowers, Mr. Turton grows very many Carnations out in the open ground, and of these I noted, not only doing wonderfully well in quantity, but flowering freely, that grand scarlet Rowena, one of the very best; Mrs. Reynolds Hole, so much favoured; W. P. Milner, a good white; Governor, creamy white; Colonial Beauty, a primrose ground, richly streaked with scarlet, very charming; and a crimson seedling of rich hue and a capital grower.—A. D.

Petunias.—These are revelling in the warmth and drought, indeed rank amongst the very best of dry weather tender annuals. The variety now found under the head "Petunia" is marvellous, though many of the flowers are of such surprising dimensions that they attract more by their size than beauty. Whilst the doubles come from seed generally wonderfully true, bloom very early and profusely, it is no doubt best when thus obtained from seed to propagate these from cuttings if it be specially desired to preserve particular varieties. The white-throated sirgles are really giants in flower, and when grown as pot plants in the greenhouse are beautiful. The striped forms, especially those having blooms of moderate dimensions and profusely borne, are the best bedders, and for small beds or edgings none are more pleasing than is the dwarf, compact growing dwarf rose, the flowers much excelling in form and colour those of the

old Countess of Ellesmere. Petunias are quite easily raised from seed if sowings be made in a gentle heat towards the end of March or early in April. I have raised great quantities from sowings made in a cold house or frame in April, but, of course, growth is slower, and when springs are cold, it is hardly fair to the small seed, whilst a little warmth ensures germination. Petunias when planted out do not require rich soil, and if employed for bedding, it is rather better to have the soil poor than otherwise. It not unfrequently happens in a dripping season that rich soil produces only growth and no bloom.—A. D.

NOTES ON HARDY PLANTS.

It sometimes happens that plants with which some find a difficulty are well grown and flowered by others, and even in the same garden a plant which will not succeed in one place will do so in another, even though there is apparently little difference either in the soil or the situation. Even such a common plant as *Saxifraga oppositifolia* I have found impossible to grow in some places, but at last by placing it on a small rockery, which seemed in its conditions to be like the others, I have found it to do well.

Verbascum olympicum.—This grand Mullein is worthy of a place in any garden, but it will be especially at home where shrubberies of any size are present. It attains to a height of 8 feet to 10 feet, and is profusely covered with its bright yellow flowers. Unlike those of the common Mullein and some others of the family which only open a few flowers at the time on each flowering stem, this species has a large number open at one time, and may well be described as a golden candle-brush of flowers, so that I was not a little amused at the observations of the "Gloucestershire Parson" recommending the growth of the common Mullein; not that I object to growing some of our native plants, which are really very beautiful; but whether for foliage or flowers this species so transcends our common ones, that I think it is useless to attempt to grow such a weed. I find that seedlings vary considerably both in the character of the flowering stem and in the foliage, the former being in some individuals much more branching and erect than in others, and the leaves, which are 3 feet in length, are in some specimens much more woolly than in others. There are other species which are also well deserving of cultivation, such as *Celsia cretica*.

Cypripedium spectabile.—I have been much interested in the remarks made in recent numbers concerning this beautiful N. American Orchid, but more especially in the paper entitled "Cypripedium spectabile at Home." In a depressed part of my small rockery, which I have filled with peaty soil, I have had a clump of it for the last thirteen or fourteen years. It is vigorous in growth and flowers very freely. Sometimes there are two flowers on a stem, of good size and colour. Close to this and in the same situation I have a good plant of

Orchis foliosa, which has now six flowering stems, and although they are not equal in size to those which I once saw with Messrs. Backhouse and Sons, or lately with Mr. Carrington Ley, near Maidstone, they are very beautiful. It is somewhat remarkable that it is much more easy, in my opinion, to cultivate these exotics than those native species which flower around us here on our chalk downs.

Lilium candidum.—The long drought has told severely on this beautiful Lily in my garden. The plants are not above one-half their proper size or height, and yet, strange to say, in a cottage garden in the parish, where the soil is very sandy and light and the clumps are planted on a sloping bank, the flower-stems have attained their usual height and the flowers their ordinary size. Why this should be, I cannot understand.

Lilium Browni.—A friend and neighbour who is a very successful gardener was very much surprised to hear I found this grow and flower well in the open and without any protection. He came

to see my garden afterwards, and was surprised at the vigour of this Lily. The oldest clump, which has been *in situ* some eight or nine years, is not so vigorous as usual, the fact being that I disturbed it last year and separated the bulbs, a treatment which the long drought of this season has caused them to resent, for although they have grown, they have not flowered. I have found with this, as with many Lilies, that they refused to move for a year, although the bulbs remained sound. The season has been a most trying one for all Lilies. In my own garden, with the exception of *Browni*, *speciosum*, and *dalmaticum*, they have all failed me. *Superbum* and *pardalinum*, as might have been expected, have suffered very much from the drought, while such kinds as *Humboldti* and *Hansonii* threw up weak flowering stems, which after a while withered away. On examining the bulbs I found them to be perfectly sound, so that I can only attribute this to the drought. It will be curious to see what will be the effect of heavy rains (if they ever do come) upon these ripened bulbs, whether they will start off into growth prematurely or remain quiescent.

Scabiosa ochroleuca is one of the prettiest of this interesting family. It is not by any means a new plant, but this is the first time that I have flowered it. Even in this very dry season its stems are 3 feet high, and I doubt not in moister seasons they would be higher. The flowers, of a delicate primrose colour, are borne singly.

Onosma tauricum.—I mention this well-known plant because some persons seem to find a difficulty in flowering it. It occupies in my small rockery a position somewhat elevated and fully exposed to the sun. There it has flowered freely, and I find now it is seeding abundantly. All this points to the fact that damp situations and heavy soils do not suit it.

Amaryllis vittata hybrida.—I have before now expressed my surprise at never seeing these gorgeous flowers in any gardens that I have visited. The few varieties I have, such as *Oriflamme* and *Adolphe Brongniart*, were obtained from Fontainebleau, where M. Souchet for a long course of years had hybridised and cultivated them. Mr. Kelway, of Langport, has done the same in this country, and they are certainly deserving of more attention—at least in the southern parts of the kingdom—than they have as yet received. Mine are grown in the border in front of my greenhouse facing south, and never have any protection during winter. They have now been there some ten years, and are thus entitled to the claim of hardiness; in fact, the same treatment as given to *Amaryllis belladonna* suits them exactly, but, unlike that plant, the leaves show themselves before the flower-stems.

Omphalodes Lucifæ.—I mention this because my neighbour, Mr. Carrington Ley, was somewhat surprised at the vigour of my plant, and said he could never keep it from snails. I have never had any trouble with it. Though it is not large, yet the plant is vigorous and flowers freely.

DELTA.

Lilies at Highgate.—The present early season seems to suit all my Lilies admirably. They are throwing up nearly double their usual quota of blooms, and almost if not quite attain their normal height. *Lilium testaceum* came into flower with me on the 27th of last month. It is over 5 feet in height, and with five to nine blooms to a spike. It is quite three weeks earlier than last year. The *speciosum* group promises to give a grand show of bloom by the end of next month. The early season is of great benefit to these Lilies, as in past years many did not flower till late in the autumn, and the blooms were dull and often injured by the cold rains. *L. speciosum* Krætzeri is doing well at the foot of a south fence. Two bulbs planted in 1891 have sent up six stems with forty-seven buds, one stem carrying twelve buds. The foliage is very healthy, and the plants revel in the bright sunshine. *Rubrum cruentum* has a shadier and moister position; three bulbs were planted in

1891 in loam, leaf-mould and sand, and have sent up eleven spikes with eighty-four buds. Some of the stems are already (July 1) over 5 feet high. This Lily (as well as the preceding) usually blooms early in October, but I believe it will be in flower by the end of August or beginning of September this year. *Macranthum* is very fine, with three stems to a bulb. This is one of the richest coloured of the speciosum group, and, moreover, is deliciously fragrant. *Roseum* and *rubrum* with its variety *multiflorum* are sturdy plants, and give good promise of early blooms. They are all in moderately light sandy soil, planted at a depth of 6 inches to 9 inches. They are top-dressed annually in May, 3 inches of the soil being removed and replaced by some rich compost. They are given abundance of water during the growing season, and kept dry in the winter by their position and the light soil in which they are planted. *Tigrinum* also is doing well, and is planted among my Roses. It is a very good Lily for such positions. Its varieties *Fortunei* and *splendens* are noble growers and very free flowering.—R. A. JENKINS, *Highgate*.

Hardy Crinums.—These plants make a noble show when planted so that they can have a little shelter from rough winds. C. Moorei and C. Powellii occupy a long bed in such a position at Burford Lodge, and are flowering profusely. C. Powellii appears to be the freest bloomer, but the flowers are not so massive as those of the first named, the petals being more pointed and the flower more tinged with pink. Both are well deserving of the attention of all who are desirous of stocking their garden with choice flowers.—W. H. G.

CARNATIONS.

THE prolonged drought would appear to have broken, as after a few intermittent showers, copious rain fell on June 27. The heat, however, has been a powerful factor in the rapid growth and development of Carnations, and with me they appear to have practically revelled in the bright, cloudless weather, and certainly they were never cleaner or more free from insects. This is the more remarkable, as green-fly has been such a persistent pest on the Roses, yet it has not affected the Carnations close by. Probably Carnations on lighter soils have suffered from the drought unless assisted by a suitable mulch of some moisture-conserving material. I used to mulch annually, and regarded it as an important and essential detail when I was dealing with a light soil, but it will not do to follow any special rule; one must modify practices and adapt them to the peculiarities of the place or season. For example, here in Sussex on heavy land a good preparation of the ground previous to planting is, during most years, amply sufficient to carry the plants through till their work is done. It must be borne in mind that the mulch, by checking evaporation, keeps the soil cooler, and soils in any way retentive need the sun's rays direct upon them in average years. This season, however, is a wonderful exception, and after 100 days of drought, with the thermometer registering 88° in the shade, even our Carnations—never more full of bud and promise—began to show signs of thirst, so a thorough watering was given at once and from half an inch to an inch dressing of clean peat Moss manure applied. This carried them through, and now at the end of June, refreshed with rain, they promise such a display of bloom as never before was seen, and that in all probability by the time these lines are in print, seeing that no less than forty kinds of magnificent selfs already have the first flowers open, and some are so numerous as to make quite a show.

The favourable character of the present season will be productive of good results that will last; in short, it is offering golden opportunities for another year, and the wise will embrace them. Early growth has not been all for flower; grass is abundant and strong. When shoots are ready is the time to layer, and many are fit now. I intend to begin at once, and in a neighbouring garden some layers have been put down a week. That

Carnations may be successfully planted over a long season I have repeatedly proved; but in this again the character of the soil is of some importance, and whilst early planting is always good, it is the essential element in success on heavy soil, no time being better than the first half of September. There will be no difficulty in having layers strong and well rooted by that time this year, and as all the details of culture since early spring have been performed considerably in advance of the usual date, planting may follow likewise by beginning in August. A. H.

Lilium Kramerii.—This Lily is not one of the easiest to grow, and it enjoys a place amongst shrubs. When looking through the Lilies at Kew recently we made note of this charming species, which succeeds admirably with Mr. G. F. Wilson in his Wisley garden. It is grown there amongst shrubs, a colony nestling amongst the Rhododendrons, a lovely break of delicate rosy flowers. Amongst shrubs is exactly the position that suits this type, as there it is sheltered from keen winds or screened from hot sun. The softly coloured flowers associate well also with the deep foliage of shrubs, and the best results accrue from planting in a deep loamy soil with which peat and leaf-mould are mixed. Under these conditions it thrives well, but is not one of the most satisfactory of the family as regards culture. Associated, however, with shrubs it succeeds better than in any other position. It is synonymous with *L. japonicum*.

Lilium odorum.—This is one of the oldest eastern Lilies in cultivation, having been introduced into this country as long ago as 1801, but after that it would appear to have been lost for many years, as it is only within recent times that it has been generally seen. The flowering display, too, is as a rule kept up by imported bulbs, as it is a difficult Lily to maintain in good condition for any lengthened period, being in this respect far more particular than its near ally, *L. Browni*. A limited number of grand bulbs of *L. odorum* is, however, usually disposed of at the auction sales of bulbs during the winter months, and if sound they can always be depended upon to flower well, at least the first season. *L. odorum* reaches a height of 3 feet to 4 feet, and a strong bulb will produce three or four blossoms. They are shorter and broader than those of the well-known *L. longiflorum* and of a more massive build. The exterior of the bloom is usually tinged with green and brown; this last is, however, very much less than in the allied *L. Browni*, while the interior of the bloom has in *L. odorum* a greenish shade. This Lily is usually disposed of at the auction sales under the name of *L. Colchesteri*, or *L. japonicum Colchesteri*, but seldom as *L. odorum*. The bulbs are quite distinct from those of *L. Browni* or any allied species. They are whitish, as in *L. longiflorum*, but in general appearance are widely removed from those of that kind. The blossoms possess a very agreeable fragrance, which is not of so powerful a nature as in many Lilies.—H. P.

SHORT NOTES.—FLOWER.

Primula imperialis has the foliage and somewhat of the general appearance of *P. japonica*, its erect spike of rich yellow flowers rising tier upon tier. This with many other fine hardy plants I saw recently with Mr. Bain in the Burford Lodge garden of Sir Trevor Lawrence.—W. H. G.

Gentians for the border.—Three species of this beautiful genus appear to do well in the open border even in the warm vale under Box Hill. The three species I recently noted were *G. cruciata*, *G. gelida*, and *G. septangulare*, and there was nothing round about which could compare in beauty with their exquisite shades of blue.—W. H. G.

Single Dahlia Scarlet Bedder.—Although it must be admitted that single Dahlias are not now in the height of popularity, yet they command much admiration where well grown and not too tall. One of the very best is *Scarlet Bedder*—full

height 30 inches, flowers of the best form, rich scarlet in colour, and most profusely borne. For filling centres of large beds few plants could be more fitting and effective.—D.

Pot Marigold Double Royal.—The flowers of this are of medium size, very double and perfect in form, the petals very closely interlaid and somewhat reflexed, in colour clear straw-yellow, with a distinct dark centre. These are borne on somewhat longer stems than is usual with pot Marigolds. Every flower comes true to character, and the strain seems to be the best so far as consistency is concerned.—D.

NOTES FROM FRANCE.

THE DRY WEATHER AND THE FRUIT CROPS.—The drought which prevailed through the spring and the early part of the summer has had a remarkable effect upon the ripening of various kinds of fruit. Generally speaking, everything is from three weeks to a month earlier than usual. In Touraine, on June 12, the Madeleine noire Grapes were commencing to colour, and the Précoce de Malingre Grapes were ripening. An old Vine grower told us that he has never known Grapes to ripen so early since the year 1822. On June 12 we also gathered in the open air Peach Apricots, perfectly ripe, yellow, perfumed, delicious. On June 10 we gathered our first ripe Amsden Peaches.

CITRON DES CARMES PEARS AND CALVILLE D'ÉTÉ APPLES.—It is a curious fact that in the southern districts of France this unwonted earliness of ripening is not observable to the same, or even a proportionate extent of what we find existing in the central parts of the country.

CHRYSANTHEMUM VICE PRESIDENT BARIIGNY.—This new variety, raised by Mons. S. Délaux, has a special value in that it comes into bloom in the latter part of September—a time when Chrysanthemum flowers are rather scarce—the early-flowering varieties being then over, and the late ones having not yet come into bloom. The plant is tallish and vigorous in growth, of pleasing habit, and very floriferous. Flowers erect, very large, of a rich brown-shaded crimson colour, the outside of the petals exhibiting silvery reflections and a deep golden yellow centre. The merits of this fine variety will, no doubt, be speedily and widely recognised.

ROAD-SIDE FRUIT TREES IN SAXONY.—In Saxony the sides of the public roads are planted with fruit trees, the produce of which yields the State a revenue which, during the last thirteen years, represents an average of 1,739,195 francs (= nearly £69,565) per annum. As may be seen from the following table, the yearly receipts vary in amount—necessarily so, accordingly as the season is favourable or otherwise; on the whole, however, they show a tendency to a steady increase:—

1880	41,776.25 francs.
1881	117,668.75 "
1882	112,618.75 "
1883	140,568.75 "
1884	132,026.25 "
1885	142,842.50 "
1886	109,730 "
1887	111,006.25 "
1888	106,425 "
1889	177,398.75 "
1890	188,278.75 "
1891	203,091.25 "
1892	205,753.75 "

THE ROSE-SCENTED GERANIUM (PELARGONIUM CAPITATUM).—This species, which was introduced into Europe from the Cape of Good Hope in the year 1690, is tolerably well known in our greenhouses as an ornamental plant, but in Lower Provence, Nice, Spain, Algeria, Turkey, Egypt, and the island of Réunion it is grown on a large scale for the manufacture of the Rose-scented perfume which is distilled from the leaves. The plant is of somewhat diffuse habit of growth, with stout stems 3 feet or more in height, and digitate, five-lobed or six-lobed leaves, which when bruised emit their characteristic odour of Roses. In districts very far south the plant exhibits a woody, shrub-like development. The flowers, which are

numerous and produced in umbellate heads, are pink or purplish in the lower petals, the two upper ones being marked with streaks of a blood-red colour. In very temperate latitudes the plant flowers from April to October.

In Algeria, where this Pelargonium is very extensively cultivated for the distillers, it is multiplied very readily from cuttings of the wood of the year taken off with a heel, and planted in rows 1 yard or so asunder and with a distance of 16 inches to 20 inches between the cuttings. A well-grown plant will yield an average of 2½ lbs. of leaves. These are not taken from the plant all at once, but are removed at three successive cuttings, viz., in June, July, and November; or at two cuttings only, in which latter case the first cutting takes place in April or May and the second in September or October. When distilled, the leaves yield on an average 1 per cent. of the essence, but as they are in practice always distilled along with the stems to which they are attached, the actual percentage falls short of this by about one-fourth, so that some idea may be formed of the extensive scale on which this plant is grown in Algeria where one is informed that about 6600 lbs. of the essence are annually pro-

duced it into that country. Personally, I cannot help thinking that Souvenir du Congrès is much too like Williams' Bon Chrétien to be considered distinct, the extra size of fruit on cordons and other young trees being misleading, and the difference is less striking according as the trees age, while the flavour is far from being distinct. I have gathered finer fruit of Bon Chrétien from old standards in Kent than I have ever seen of Souvenir du Congrès, these being formed principally on the top of the trees.

Although the Pear under notice is grown nearly everywhere, and was at one time very extensively planted by market growers, it is yet far from being a reliable variety. The trees either produce extra heavy crops or else very light ones. This is not because they fail to flower well nearly or quite every season, but rather because the leafy growth is somewhat sparse, and the flowers or fruit receive little or no protection from spring frosts. A good set may have taken place and the fruit have started swelling off only to be frosted through, the

None ought to be left on the trees till they are yellow and ready to drop off when touched or disturbed by wind, as these, though more attractive in appearance, are comparatively dry and flavourless, also keeping only a short time after being gathered. By gathering a few dozen or a basketful as the case may be at intervals of from four days to a week, it is possible to avoid a great glut of ripe fruit and the certain loss of the bulk of it, this also, as before stated, improving both the quality and keeping properties of the fruit. In this neighbourhood an extra large standard growing in a cultivated garden was at one time of little value—was apparently worn out, in fact—but two or three liberal soakings of fairly strong liquid manure applied during each winter has put new life into it, several sacks of fairly large fruit being gathered from this tree in favourable seasons. Those, therefore, who may have trees either in the open or against walls in a worn-out condition should first try what can be done towards restoring them to good health by feeding the roots before condemning them. W. I.

Pear Williams' Bon Chrétien.

duced by the forty eight distilleries which manufacture it in the Sabel district and the plain of Mitidja. When the essence is very pure, it sells for £8 to £10 per kilogramme (2½ lbs.). The odour of it very much resembles that of essence of Roses, with a slight admixture of lemon scent and an after-whiff of the aroma of Geranium leaves.—*Revue Horticole.*

ORCHARD AND FRUIT GARDEN.

PEAR WILLIAMS' BON CHRETIEN.

INSTEAD of being of French origin, as many people suppose, this very well-known and popular Pear was raised, according to the "Fruit Manual," at Aldermaston, a village in Berkshire, somewhere about the year 1770. Whether the name of the raiser is Wheeler or Stair cannot now be decided, Williams being the name of the Turnham Green nurseryman who first distributed the variety. It has but few synonyms, "Williams," the costers' term for it, being simply an abbreviation, while in America it is known as the Bartlett Pear, so named after Mr. Enoch Bartlett, who first in-

ground being nearly covered by them a few days after. The growth is sturdy enough, and good standards, pyramids, and bushes can be had without much trouble beyond cutting back what few extra long or straggling shoots form. It succeeds admirably on the Quince stock, cordons as well as bushes producing good crops of fine fruit. With me extra fine and, for the variety, highly coloured samples are produced by a fan-shaped tree on the Quince stock, but if large trees are desired, it is the Pear stock that gives the best results. As a second early Pear, ripening in succession to Jargonelle, this variety has no equal, but, in common with the latter, it keeps badly after it is ripe. If a fairly lengthened out supply is desired, and in some private places large quantities of fruit are wanted in August and September, trees should be planted in different sites. Here, for instance, we have trees against south-west, south-east, north-east, and a still cooler site, and they succeed equally well in each position. We commence gathering before the seeds are brown, and ripen the first batches in heat. Fruit thus treated frequently proves of better flavour and nearly as luscious as that ripened, presumably under more favourable conditions.

Shading Vines.—It must not be imagined that when I write of shading Vines I intend it for general adoption. The season such as we are now passing through is a most remarkable one, as in addition to the heat being very great, it has also been long continued. Under these conditions the foliage in many vineries will be sure to suffer, especially in those which are well exposed or with a south-east aspect. Some vineries, I know, on account of their position will not require shading in the least, while others will be decidedly benefited by a little shade. If it could have been applied earlier than this, so much the better; but if the foliage is now suffering, better by far shade a little than not at all. If shading is not done, the foliage may be prematurely lost, and the Vines will consequently suffer. A little whitening or flour and water syringed lightly over the roof will be quite sufficient. Some varieties are more apt to suffer than others. Those which suffer the quickest are Madresfield Court, Gros Marec, Gros Colman and Muscat of Alexandria. Black Hamburgh will also be benefited by a little shade. The vineries in these gardens are very much exposed, with a south-east aspect, but with a little judicious shading where needed, the foliage has not suffered nearly so much as might have been expected. The late house, in which I have growing Lady Downe's, Black Alicante and Mrs. Pince, has not required the least shade. Muscat of Alexandria I shaded slightly a short time since, and I never had the foliage look better or the Grapes more promising. This slight shade has certainly been of great benefit. Madresfield Court I wish I had shaded a little earlier, but, all the same, the foliage is good and the Grapes very satisfactory. Fester's Seedling has not suffered in the least, and Black Hamburgh only very slightly. These latter had a thin shade and the berries are as black as sloes. If the bunches of Black Hamburgh have to be kept any length of time, they must certainly be shaded, as I never remember to have seen this variety come along so quickly.—Y. A. II, *Abberley Hall, Stourport.*

Nuts.—There seems to be a heavy crop of Walnuts this year, and all who took the trouble to thin their abundance have found plenty to set aside for pickling. However, the Walnut is a somewhat catch crop, still not at all a costly one to grow, as the trees seem to thrive luxuriantly almost anywhere. I mentioned last year the heavy crop of Cesford Red, Kentish, and other nuts which was found on the tallish bushes that grow on the east side of one of the kitchen gardens at Maiden Erleigh. Again this year there is an enormous crop. The bushes are some 8 feet or 9 feet in height, moderately thinned, and perhaps some 6 feet to 7 feet through. Mr. Turton attributes

the remarkable success in fruiting which attends these bushes to the shelter which a belt of tall trees on the north-eastern side gives at the flowering season. At any rate, were small nuts so grown by acres, then the produce would be as enormous as the product would be profitable.—A. D.

THE WATERING OF FRUIT TREES AND BUSHES.

The few welcome showers that have fallen up to the end of June have proved most welcome refreshers to the leaves and branches of trees, but they have done little or nothing as yet for the roots; in fact, they have not yet reached the roots of the Potatoes, far less those of fruit bushes or trees. If the crops are to be finished of fair size and good quality, the roots must be helped through artificial watering and flooding—I had almost written—at once. Already it is too late to alter the results in bush fruits, unless with very late varieties and in backward localities, and in regard to autumnal bearing Raspberries. Few crops have suffered more from the drought than Raspberries, which are moisture-loving and also shade-loving plants. The crop has been plentiful in numbers, but small and hard. Gooseberries and Currants have suffered much also from the same cause, but not to the same extent. Something may yet be done to improve late varieties of both on north borders by one or more thorough soakings. Excellent crops of late Raspberries may yet be secured by liberally watering the current year's shoots with liquid manure. Drooping fruit bushes may also be cleared of spider, caterpillars in fact or in embryo, by a thorough overhead syringing with one of the many insect-killing mixtures and several soakings in succession of clear or manure water or sewage. This would enable Gooseberries and Currants to finish their young growths of wood, and also to plump up into fruiting size their myriads of pinched, half-shrivelled buds. The object is not to start them into new growth so late in the season, but to clean the wood and plump up the buds as much as possible without breaking them into new leafage. Hence it will be desirable in many cases of stunted growth to dispense with the usual summer pruning of Gooseberries or Currants. There is another reason: so many newly-planted cuttings and young bushes have got crippled through the drought or killed outright, that every inch of available wood will be needed for cuttings in the early autumn.

As to the main fruit crops, Apples, Pears, Plums, Cherries, Peaches, Nectarines, it is not yet too late to improve the current crops, as well as our prospects for the next and succeeding years through copious root-watering. We all know that the dropping of fruit may be caused by grubs, spring frosts, and other troubles, but no one can look at the semi-jaundiced fruits that so thickly strew the ground this year without seeing at a glance that most of these are the victims of drought at the roots of the trees. From March 1 till now, it is no exaggeration to write, these trees have not had a drop of water come within their reach. Nor is that all. During most of that time their wide spread of leaves, their myriad fruitlets have had to bear the brunt for months of unbroken, unclouded sunshine from dawn to dark. The dissipation of vapour, the strain on all the forces of life and growth, have been unprecedented. The trees have appealed to us by all the natural symbols at their command, such as drooping leaves and shootlets,

withered branches as early as May, and dropping fruitlets, for water for their roots, and overhead drenchings to cleanse and cool their sun-parched tops. As a rule, and in a wholesale way, they have appealed in vain. Neither individual possessors of large orchards, parishes, boards of guardians, corporations, county councils, nor the Government have taken means to water, and so save the fruit crops and the trees. In many cases there were no great difficulties in the way of doing so. On the whole there has been no general dearth of water. Within the area of town mains and a virtually unlimited amount not only of water, but of means of conveyance and of distribution, tens of thousands of fruit trees and bushes and other trees and shrubs have drooped, suffered irretrievable loss of crops and of health or have perished. These might have been saved through simply putting the pumping engine on double time and using the mains at night for saving the crops and the trees. Not a few parishes or rural districts have fire brigades and engines; each county council should have one or more; almost every provincial town has such. All these might have been turned to profitable as well as most beneficent account in keeping our fruit trees clean, saving the current year's crops, and in laying the solid and sure foundations for equally good or better crops in 1894.

D. T. F.

Late Strawberries.—A note at page 524 called attention to the early ripening of Strawberries this season and to the probability of a second crop. Growers in most cases will be more concerned about the production of runners and the forming of strong crowns for next season than a second crop. If the plants crop a second time there will not be time to make new growth or crowns. Runners in most cases will be scarce, and those who require them will do well to order early if purchased. If the stock is home grown, much time will have been saved if the runners are secured from plants grown for the purpose, that is from runners planted early last August, and the flower-spikes kept removed. Even with this special culture we have been obliged to flood the plants weekly in our light soil during the severe drought to keep them in a healthy state. Of late years I have noticed the division of old stools has taken the place of runners. It is anything but a satisfactory mode of propagation, as divisions never do so well as the runners, and though it may be done in the case of new varieties, in older kinds it is not necessary and of no value to the private grower. With regard to late fruit on the young plants, I should prefer to remove the flower-trusses—I mean from those plants that are expected to produce the best fruit next season. In the case of older beds it would not be so necessary. Still if fruit is desired in the autumn it may really be obtained from forced plants. If forced plants of such varieties as Vicomtesse Hélicart de Thury, La Grosse Sucrée, or Keens' Seedling are planted out in rich soil and well supplied with moisture, there will be no lack of fruit during August and September. Many can afford to replot their forced plants, standing them on a north border, or keeping them sheltered in a cool frame. These soon fill the pots with roots, and will give a lot of late fruit in the autumn months.—G. WYTHES.

Canker in Melons.—Enclosed please find part of Melon stem. Would you kindly let me know the disease and how caused? This is now the sixth lot I have lost the same way. You can see it starts about a foot from the soil. The house is kept on the dry side, as also the border. The variety is from seeds I got from India.—C. F.

* * This is not a case of canker at the collar, but rather of gangrene at the joints—a far less common occurrence. In all probability it is largely due to the variety not being adapted for house culture. Melons that succeed well in the

open air in tropical countries do not, according to my experience, give satisfaction under house culture in this country. At the present time I have six packets of Melon seed in my possession that were sent or brought principally from India, but previous experience in a similar direction has convinced me that they are of no value whatever. One or more varieties of Melons were brought from Cabul about forty years ago and successfully fruited in this country, and it may be some of our best English-raised varieties have a little Indian blood in them, but Indian varieties pure and simple are as a rule failures with us. If other well-tried varieties of English origin had failed in a similar manner, then I should say it was a case of too much sap, ruptures being brought about by the sudden removal of a quantity of rank growth. I have seen plants literally drop all to pieces from this very cause, the whole of the plants suddenly becoming a mass of putrefaction, or quite as bad as the specimens under notice. Grossness had been engendered by a very free use of sewage water, and the man in charge neglected stopping for about eight days, afterwards, acting according to instructions, cutting away haulm by the armful. The decay is too rapid for any effective remedy to be applied in the case of affected stems, but when it is the branches that go first these may be cut back to a sound part and the wounds dressed or dried with newly-slaked lime, with just a chance of arresting further progress. A free circulation of air, accompanied by plenty of fire heat so as to dispel the extra moisture, usually present in our atmosphere, is the only preventive measure I can suggest, rankness of growth being guarded against as much as possible. It is my opinion, however, that Indian Melons are no more fit for house culture in this country than are either ridge Cucumbers or Cantaloup Melons.—W. L.

NOTES ON CHERRIES.

At the meeting of the Royal Horticultural Society on June 20 some good dishes of fruit were staged from wall trees and from trees in the open ground. Some of the kinds grown in the open were the same as those on walls. The Morello type of Cherry, of which Kentish Red, Flemish Red and the Ostheim are now more commonly grown as bush trees and kept within bounds, are valuable, as they greatly prolong the season, make valuable preserve and are easily grown. Indeed, some bushes of these varieties in the kept grounds are lovely objects in the spring when in bloom. Even the Morello does not thrive in some gardens. This is in some measure owing to the stock, as often it is grafted on a dwarfing stock, which does not thrive in all soils; indeed, how often do we see a tree start vigorously, and when it has attained a fair size and laden with fruit succumb. In some cases the whole tree collapses and in others large branches die off, disfiguring the tree so much that removal is necessary. With failures of this kind I have had my share, and of late have endeavoured to get trees on the free-growing or wild stock. Even on the wild stock it is useless to grow this fruit unless due attention can be paid to extension and the giving of moisture. I would point out the advantage of a few trees in various positions. For instance, in late localities a south-east wall is desirable, and a succession is secured by some trees on a west and north aspect. We have a few trees (early varieties) on an aspect nearly south, and the fruit in such a position was literally roasted.

In the pages of THE GARDEN last year the system of planting Cherries on north walls was considered wrong, but I would advise it. Where wall space is limited the Morello would succeed admirably in bush form, provided attention was given to thinning the wood and supplying food and moisture. Some of the early kinds do not hang long, but others, such as the St. Margaret, a grand late black, Black Tartarian or Circassian, and Bigarreau Napoleon, are excellent for late use and keep some time on a south-east wall; whilst Governor Wood, Florence, and Late Duke are good white varieties for hanging. Many of the dessert

varieties succeed well in warm soils as bushes or pyramids, but they suffer much from frost. This may, however, be minimised to some extent by growing small bushes only having a very short leg or stem. These can be readily protected. Some years ago I adopted the dwarf bush form, planting some of the best kinds along the side of a walk on a north border, and found the trees did grandly. I netted when the fruit began to colour, mulched heavily twice a year, and lifted the trees every third year as soon as the leaves began to turn colour. In lifting or planting Cherries it is important to get the trees planted early and, as previously explained, before the leaves fall; indeed, in light, dry soils before they change colour if the roots are thoroughly saturated with water when planting. If the ground is at all dry there is no fear of the bark shrivelling; the buds retain their plumpness, and there is less anxiety as to their well-doing the following season should the weather prove hot and dry. W. S. H.

THE STRAWBERRY SEASON.

LOVERS of Strawberries have not had a good time of it this season. The supply has been short and, as a rule, the quality not satisfactory. So much fierce sunshine caused the fruit to colour rapidly, and, no matter how well the roots may have been supplied with moisture, there is sure to be an acidity and dryness about any Strawberries that ripen in too much heat. When, as was the case in many gardens and fields, no water could be applied, this, coupled with the fierce sunshine and heat of May and June, completely spoilt the crops. Thousands of Strawberry plants in various localities have died from want of water, red spider also being responsible for many losses, and this looks rather like a scarcity of runners for planting. Rain may yet save the bulk of the old plants, but all the same they will be badly weakened. To a certain extent the short duration of the Strawberry supply can be remedied, no matter how hot and dry the weather may be during the ripening period. For instance, I am practising fruit-growing in a warm south-western county, where the rainfall has been even less than in adjoining districts, yet the Strawberry season, independent of what is done under glass and in the open with the plants after forcing, will extend over a period of not less than nine weeks, probably even longer than that.

In order to be certain of a two months' supply of fruit an early start must be made, and this season I commenced picking fine fruit of Noble on May 5. Another year it may be fully a month later before the first Strawberries are fit to gather, but they would then be early, the season of 1893 being altogether abnormal. Raised borders, either extemporised at the foot of sunny walls of any kind, or those in front of fruit walls, are the best positions for the plants to produce extra early fruit, and, seeing that earliness is of primary importance, only quite young plants should be retained in such favoured positions. Mine, directly the first and only crop is gathered, and the requisite number of rooted runners are obtained from them, are cleared off the ground, as being no longer worth retaining. Sometimes the same sites are freshened up with soil and manure, and replanted with rooted runners, but more often than not a complete change of site is afforded. Noble is not a high-class variety, but it has no equal for precocity of fruiting, size of individual fruit, and weight of crop produced by young plants, and it will be some time before it is discarded.

When once Strawberries are gathered in quantity from open-air plants, there ought to be no break in the supply; but this may yet occur if the precaution is not taken of giving plants that are to produce second early crops a good position. Young plants invariably produce ripe fruits earlier than do older ones, and each season a fresh bed ought to be planted in a sunny, open position. The ground being well prepared and the plants given good room, it usually pays well to take three crops from these breadths of plants before destroying them, each season seeing a new bed formed and a worn-

out old one cleared off. For the second early crops La Grosse Sucrée is a good variety, but if quality rather than great size is most thought of, then ought Vicomtesse Héricart de Thury to be planted, this very heavy cropping early variety also affording good supplies of preserving fruit. Sir J. Paxton is also moderately early, and in every other respect the best variety in cultivation. Nor ought Alice Maud to be lost sight of. For planting on lower ground or in a good level quarter, the two last named, with President, a very heavy cropping variety; Sir C. Napier, a grand old sort, of superior quality; and Dr. Hogg, a large fruited, richly flavoured variety, are all suitable. The supply obtained from these breadths or rows would be the main crop, and to succeed these, British Queen, Frogmore Late Pine, Eleanor, and Waterloo ought to be grown, though the first and last would perhaps be sufficient for most places.

In many gardens no attempt is made to grow crops to ripen later than what may be had from the foregoing varieties planted in the open, but that is a mistake that should be rectified if possible. Without the aid, however, of cooler sites, a supply of Strawberries extending over a period of ten weeks will not be had in many places during a hot season, nor often during the average summer. Instead of the borders in front of garden walls with a northern aspect being devoted to common vegetables, herbs, and such like, these ought largely to be cropped with late Strawberries. It is surprising how well some of the latter succeed in such positions. For instance, Loxford Hall Seedling fails badly in the open, but with me on a north-east border it produces good crops of fine, richly-flavoured fruit, the supply usually lasting till late in July. Latest of All and Royal Sovereign are also admirably adapted for these cool borders, and I find Waterloo of the greatest service when grown in similar positions. Next season I hope to have a few score plants each of the last-named and Loxford Hall Seedling on quite a north border, and from these to be able to gather up to the end of August, or say till forced plants of Noble are producing a second crop in the open.—I. M. II., in *Field*.

Gooseberry caterpillar and the cuckoo.

—Some few weeks ago I noticed in THE GARDEN that Mr. Strugnell, of Rood Ashton, in his notes on the Gooseberry caterpillar, said that in his garden he had noticed the cuckoo frequented the bushes and destroyed the insects. He asked what was the experience of others in this matter. I never observed these birds frequenting our garden before this season. Previous to noticing Mr. Strugnell's remarks I had seen the cuckoo come and pick the insects off the bushes. On Sunday when it was quiet, I could frequently see three or four birds at a time in the Gooseberry quarter. During the third week in June, after the nets were put on to keep out the birds, one morning I found a cuckoo under the nets where there was a quantity of caterpillars. It is quite clear that the cuckoo is not to be despised in gardens, the more so in seasons like the present, when caterpillars have been so numerous. I have been obliged to syringe the bushes four times this season with quassa water and soft soap mixed, and even now caterpillars are appearing. I thought ours was an exceptional case, but on a recent visit to Bath I saw many bushes leafless.—J. C. F.

Scarcity of Strawberry runners.—Owing to the long-continued drought there is a great scarcity of runners, especially on light or thin soils. This will make Strawberry forcing more costly, as many purchase their plants, and runners being scarce, prices will rule high. This will not be the only difficulty, as growers will find a difficulty in securing enough for their customers, and in some cases old stools will have to be divided. No doubt if heavy rains were to come, the plants would push out strongly. This will not be the case with all varieties, as some kinds, notably President, are so badly injured by red spider, that it will be almost too late before runners are

secured. I plant specially for the production of runners, and on the variety named and Auguste Nicaise I have not a fourth of the runners required. Strawberries with thick leathery or shining foliage resist spider and grow more freely, whilst those with soft and hairy leaves are more subject to this pest, and soon feel the effects of drought. This is not quite true in all cases, however, for Vicomtesse H. de Thury possesses a soft, woolly leafage, but resists red spider. In the case of Vicomtesse H. de Thury it is not so necessary to layer in June for early forcing. I am no advocate for late potting, and always push on the layering at the earliest opportunity, but Vicomtesse H. de Thury so soon makes headway, that layering may be left longer than in the case of the others. Such varieties as Auguste Nicaise, James Veitch, and President one cannot layer too early, especially if the plants are to be wintered in the open. Last season I potted up a new variety later than the main lot, and could not force it owing to the scarcity of roots. To force early it is essential to get abundance of roots, so that those who can give the plants some help in the way of liquid manure to strengthen the runners would do well to apply the same. It is also an excellent plan to damp over in the evening on dry days, this greatly assisting growth and checking red spider. The earlier Strawberries are planted in their permanent quarters the better able they will be to resist severe weather or periods of drought.—S. H. B.

STRAWBERRIES IN THICK BEDS.

I HAVE long been convinced that the old-fashioned or "lazy-bed" system of growing Strawberries is the one best calculated to give a plentiful supply of fruit with a minimum of labour. Except in soils very favourable indeed to this fruit, the plants need renewing every third year. On soils of a porous nature the third year's crop is generally scanty and the quality of the fruit very indifferent. This quick wearing out of the plants, necessitating yearly planting with careful preparation of the ground, renders the production of Strawberries both costly and laborious. There is by our modern system of culture at least more trouble involved in keeping up a good supply of Strawberries than is the case with any other hardy fruit. The old-fashioned plan as taught me by one of the old school of gardeners consisted in putting out two rows of runners 2½ feet or thereabouts apart, allowing all the runners to come and remain, and restricting them to a width of not more than 5 feet. If the ground is well prepared, the whole of the surface will be fairly covered with plants the first season. The great objection to this way of growing Strawberries is that the berries in beds so crowded with foliage do not attain to such fine proportions as when they are more exposed to light and air. I have, however, gathered very excellent fruit from these thick beds, quite good enough for market, and therefore sufficiently good for private gardens. The extra weight of fruit, moreover, taken from the space more than compensates for some little deficiency in quality. In very hot, dry seasons, such as that just passed through, the shelter afforded by the foliage is even an advantage.

In many instances the berries on stools 2 feet apart were so hardened by the burning sun and parching winds, that they could not come to their full size. This was the case with mine; whereas, some beds of President, so thick that not an inch of ground can be seen between the leaves, ripened off perfectly, the berries being highly coloured, large, luscious and immeasurably superior in flavour to those fully exposed. All through three months of heat and drought these beds had but two moderate waterings, and it is an instructive fact that when the plants stand so thickly the soil is completely shaded by the foliage. The effects of such a dry season as the present are not nearly so marked as under the ordinary form of planting, even with the ground between the plants well mulched. I have invariably found, too, that the

blooms suffer less from frost in these thick beds. Where any quantity of preserving fruit is needed, and such kinds as Elton Pine and Vicomtesse Héricart de Thury are grown for the purpose, I am convinced that the old-fashioned way is the best. I remember over thirty years ago seeing large beds in private gardens which bore quantities of fruit for some years without showing signs of exhaustion. Mulching is not practicable, neither is it needful, as there is little or no danger of the fruit coming on to the ground or getting in any way gritty. Where Strawberry culture, owing to the over-porous nature of the soil, is fraught with some difficulty, I would advise some portion of the ground devoted to this fruit being cropped in this manner, as I know that the plants will last more than double the time than in the ordinary way.

J. C. B.

Good dry-weather Strawberries.—It must not be taken for granted that because a variety of Strawberry has gone through the trying ordeal of the past dry weather in some districts it should be stamped with the hall mark of superiority as applicable to all districts alike. I quite agree with Mr. Molyneux that much valuable information might be disseminated if growers were to give results as to the variety or varieties they have found succeed best, and also the character of soil. Among the varieties which are grown here, Sir Joseph Paxton has given the least satisfaction; so much so, that I shall not grow it again. This I entirely attribute to the soil. Knowing how well it succeeds in some gardens, and also having had it succeed well in other gardens I have had charge of, I decided to give it a fair trial here. I procured it from different sources, but always failed, and as a last resource Mr. Iggulden kindly sent me some runners for further trial. It succeeds excellently with him. Last year I thought I saw an improvement over the old state of things, but this season it is as bad as it well could be. Strawberries generally succeed well here, but I cannot get either Sir Charles Napier or Loxford Hall Seedling to succeed, let the season be what it may. Although the weather has been so abnormally dry, this has been a good Strawberry season with me, the plants being most vigorous. True, the fruits have not been quite so large individually, but they have been good. I commenced gathering on Whit Sunday, and now, the first week in July, Dr. Hogg is in splendid condition. The soil is a heavy limestone clay, consequently we have not felt the drought. This season, just as the plants were starting into growth, I gave them a good dressing of soot. This imparted a vigorous and healthy tone to the foliage, and which they have not lost. Vicomtesse Héricart de Thury does splendidly; so also do President and James Veitch. This season, I should think, has shown the value of young plants. For Strawberries to succeed well, healthy and well-rooted runners must be planted annually. The plants must be set out on firm, but well-cultivated and fertile soil, when they will surely succeed whatever the nature of the soil may be. In addition to working in a good dressing of solid manure, I find burnt refuse of great benefit.—A. YOUNG.

The vagaries of exhibiting cut flowers.

—Some few weeks back those who visited our London shows were treated to the rather novel and quite unnatural idea of setting up the florists' Tulip upon white paper. Then we shall now, I suppose, soon see what elegant frillings, &c., can be added to the Carnations—white paper, of course, probably miniature bouquet papers. Why not use the growths instead of a common kind that makes grass freely? Then later on both show and fancy Dahlias to be orthodox in the setting up must be upon boards painted green, and no foliage on any account used therewith. Asters, too, must have the frills or collars to make them compact, and of course later on Chrysanthemums must have either wires, cups, or papers (small) to keep as far as possible different from what they appear upon the

plants. As a contrast to this, it is a treat to look at a few stands of Gloxinia flowers in a setting of Malden-hair Fern or Begonia blooms with their own foliage. Hardy herbaceous cut flowers have fortunately escaped these barbarisms thus far, whilst the method adopted with Cactus, pompon and single Dahlias is quite within keeping and pleasingly effective, hence more popular with visitors.—SIMPLEX.

GARDEN FLORA.

PLATE 918.

THE BLOOD FLOWERS.

(WITH A COLOURED PLATE OF HÆMANTHUS COCCINEUS. *)

THE species of *Hæmanthus* represented in the accompanying plate is one of the oldest and best of the garden representatives of the genus. It was cultivated at Chelsea by Philip Miller in 1731, and according to the *Botanical Magazine*, in which it was figured in 1808, it was grown by the Dutch gardeners probably a century before Miller had it. There are thirty-eight species of *Hæmanthus*, according to Mr. Baker, and so far as we know them they are every one sufficiently attractive to be classed with select garden flowers. But, unfortunately, a considerable proportion of them are not easy to manage, and this is no doubt mainly the cause of the genus being comparatively poorly represented in gardens. There are, however, a few which we know to be satisfactory under ordinary treatment, and of these *H. coccineus* is probably the best. At Kew there are two large pans of it, nearly a yard across, packed with large bulbs which every year are crowded with long, broad fleshy green leaves and, after they have faded in autumn, with large heads of bright blood-red flowers, such as are shown in the plate. These plants are kept in an ordinary sunny greenhouse, except for about two months, usually July and August, when the leaves fade and the bulbs require a rest. This is provided by placing the plants in a sunny frame and keeping them quite dry until the flowers show through the top of the bulbs. They are then well soaked and fed with manure water. When at their best these plants are a gorgeous picture. It takes many years to grow a specimen, such as those at Kew, as the bulbs produce offsets slowly; still a single bulb in a 5-inch pot is worth a place in any greenhouse. There are twenty species belonging to the section *Diades*, characterised by usually large bulbs formed of thick fleshy tunics arranged in opposite series, and producing a pair of broad fleshy leaves every year, followed by a flower-head. These all like greenhouse treatment and restricted root room, the latter point being of some importance. We only give our plants a shift into larger pots when they become too crowded, and threaten to burst their pots or pans. They like manure water when they are making new leaves, and also when the flower-heads are developing, which is really contemporaneous with the starting of new leaves.

Besides that here figured there are several other good species in this section of the genus, viz. :—

H. ALBIFLOS, which has white flower-heads and variable leaves, sometimes smooth and glabrous, sometimes hairy (var. *pubescens*), and sometimes with a very distinct marginal fringe of white hairs

* Drawn for THE GARDEN in the Royal Gardens, Kew, by Gertrude Hamilton Oct., 1892. Lithographed and printed by Guillaume Severeys.

(var. *Burchelli*). This old garden plant has lately been re-introduced and distributed under a new name.

H. ALBO-MACULATUS is like *H. albiflos*, but differs in having the leaves spotted with creamy white. It is in cultivation in a few botanical collections.

H. TIGRINUS is very similar to *H. coccineus*, differing chiefly in having spots of red-brown on the back of the lower part of the leaves.

H. CLARKEI is a hybrid named in compliment to Col. Trevor Clarke, who raised it some years ago from *H. coccineus* and *H. albiflos*. It is in the Kew collection, where it annually produces its rosy red flower-heads.

Next in value to *H. coccineus* as a garden plant I would place

H. KATHERINE, which was sent to Kew in 1877 by Mr. Keit, and named in compliment to Mrs. Katherine Saunders, an enthusiastic amateur botanist residing at Natal, who has collected and forwarded to Kew many interesting plants during the last twelve years. There are several forms of it, one named Alice Barr being exceptionally large in inflorescence and rich in colour. Another fine variety is called *superbus*. This species pays for liberal treatment in regard to soil, moisture when growing, and sunlight. It produces flower-scapes 1 foot long, bearing heads of large size, one grown, I think, by Mr. Gumbleton measuring 9 inches in diameter.

H. CINNABARINUS is nearly as good if grown in a stove and treated well. It flowers freely at Kew, usually in spring.

H. MULTIFLORUS is a beautiful species, but it does not as a rule thrive under cultivation. It has numerous synonyms, viz., *delagoensis*, *abyssinicus*, *tenuiflorus*, *Kalbreyeri*, &c. Mr. Baker says it occurs throughout Tropical Africa, from Sierra Leone to Kordofan, Abyssinia and Delagoa Bay, and that it was first described by Vallet in his "Jardin du Roi" in 1608, having been sent to Paris from Guinea by the younger Robin in 1603.

H. FILIFLORUS is very near to, possibly identical with, some of the forms of *H. multiflorus*. These are all referred to here because the names occur in gardens.

H. MAGNIFICUS is another very fine sub-tropical species, which was introduced from Natal fifty years ago. It has Onion-like bulbs, leaves folded at the base, and forming a stem-like neck and lateral flower-heads, the stalks a foot long, the heads 4 inches or 6 inches in diameter, and coloured bright scarlet. There are several named varieties of it, *insignis* having long outer bracts; *Gumbletoni*, heads coloured reddish brown; and *superbus*, with narrower leaves and no distinct neck.

H. NATALENSIS is a big, rather coarse growing species with a globose bulb, a neck a foot long, large ovate leaf-blades, and a drumstick-like inflorescence a foot long, the head being very densely packed with bright yellowish red filaments, surrounded by dull red-brown bracts. It is worth growing, as it flowers every year and the heads are remarkable.

It may not be generally known that the genus *Hæmanthus* is confined to Africa, and is a near relation of *Clivia* (*Imantophyllum*), also African. The heads of flowers in *Hæmanthus* are made up of a large number of small, narrow tubular flowers, packed closely together in an umbel on the apex of a stout scape and surrounded by large petal-like bracts called spathe-valves, which are often the most attractively coloured part of the whole inflorescence.

W. W.

Garden abominations.—At the risk of offending many people, I would class among these—cable and other tile edgings, double Pansies, double Cinerarias, double Begonias, carpet beds, clinker rockeries and edgings, crested Ferns, common Musk (it stinketh), standard Roses, half-standard Roses, the muck heaps called Rose beds, Roses pruned back to the ground or near it, Grass

HEMLOCKIA OF MINNESOTA.

slopes suddenly going off at an angle of 15° with flat ground above, prim florists' and the exhibition standard. Some of these things may be good in themselves as being either horticultural triumphs or leading to them, but a museum of curiosities is the place for them, not the garden, which should be a place of refreshment for eye and mind, an abode of peace, and not a spot for the contemplation of monstrosities.—J. I. R., London.

THE WEEK'S WORK.

FRUIT HOUSES.

PINES—It cannot be too often pointed out that if the final stage of ripening is completed in a comparatively cool, airy house, or even in a deep Potato frame blocked up sufficiently high to hold the plants, the quality of the fruit will be very much better than would have been the case had the ripening taken place in a strong heat and moist atmosphere. Pines that are swelling fast should still be kept in a brisk heat, the time for transferring them to cooler quarters being when colouring commences. Plants recently placed in their fruiting pots should now be growing strongly, or otherwise they will not be fit to fruit early next season. Avoid stewing them in a very strong heat and over-moist atmosphere, as this would cause them to form soft spindly leaves. Should the weather continue hot, little or no fire-heat will be required, but it must be given directly a change to dull or colder weather takes place. Open the top ventilators rather early or soon after the temperature exceeds 70°, giving more air as the day lengthens, and closing early enough to run up the heat to 85° for a time. Syringe overhead very lightly when the houses are closed, and generally keep up a fairly moist atmosphere. These growing plants must still be very carefully watered, the soil being kept as near as possible just moist. Some of the strongest of the spring-rooted suckers might also be shifted into pots now with a view to fruiting them next season. The bulk of suckers from Queens that have recently fruited ought now to be quite fit for taking off and striking. Only the very largest should have 7-inch pots, the rest being placed in 6-inch pots—all being clean and well drained. Use nothing but the best brown fibrous loam, adding to every barrow-load a 6-inch potful of bone-meal and a 5-inch potful of soot. Fix the suckers very firmly in the soil and plunge in a brisk bottom-heat. Do not water at first, but keep them close and shaded from bright sunshine. Directly roots are being formed, give a good watering and gradually withhold shade. Those who have a good batch of strong Cayennes and other winter-fruited varieties that have been duly rested and kept a little on the dry side should start these now with a view to having good fruit next winter. If they are plunged in a brisk bottom-heat and subjected to a higher temperature and moister atmosphere than formerly, this should soon cause them to show fruit. In many instances probably, the extra top heat and moisture only would have the same effect.

ORCHARD HOUSES.—This has been a very trying season for trees in pots, it being scarcely possible to keep them properly moist at the roots during the very hot weather experienced, more especially in June. Plunging the pots and allowing the roots to strike out into a rich border save the watering-pot considerably, but are not so well in other ways. For instance, unless the pots can be turned round frequently some of the fruit will be badly coloured, and then, again, it is a risky matter to turn out the trees before the leaves are on the point of falling. The better plan is to keep the pots set on slates and to give the plants abundance of water and liquid manure, even if these mean two or three applications a day. If it can be tolerated, some strawy litter might be scattered over the pots to prevent their being badly heated and the roots dried by direct sun-

shine. Peaches and Nectarines require the most exposing to light and sunshine, the fruit colouring badly if much shaded. Much can be done by tucking back the leaves from some of the fruit and propping or slinging up some of the fruit that falls away too much for the sunshine to reach it. The earliest varieties will have already given some ripe fruit, Early Alexander, Hale's Early, and A Bec forming a good succession in the order named, these being followed by Royal George, Crimson Galande, Bellegarde, Noblesse, Grosse Mignonne, and other high-class varieties. Any trees cleared of their fruit may be turned out in a sunny position, but must not be neglected. Cover the pots with straw litter or else plunge in ashes. Keep the soil well supplied with water and the foliage free of red spider by means of the syringe. Most of the Cherry trees will also be cleared of fruit, and these should also be turned out and treated

Hamanthus natalensis.

similarly to the Peaches and Nectarines. This will admit of those left inside (and also Tomatoes in pots or boxes) being given more room. Keep the trees with swelling crops well supplied with liquid manure, and syringe freely with clear water every morning and afternoon or evening when the house is closed. Those trees with the fruit nearly ripe should receive plenty of clear water only, and syringing should cease in their case. Plums ripen and colour best under a thin covering of leaves, but Apples and Pears should be exposed as much as possible in order to colour them properly. Avoid over-cropping either of these kinds, and then the fruit will be extra fine in addition to being clearer in the skin and probably better coloured than the same varieties ripened in the open. Give plenty of air during the daytime. Keep the shoots pinched back, superfluous growth being freely cut out, thinly furnished trees being the most productive under orchard house culture.

PRACTICAL.

THE KITCHEN GARDEN.

LIFTING EARLY POTATOES.—Very seldom have early Potatoes ripened off so quickly as this year. The sooner now the early Potatoes are out of the soil the better, as after the long spell of drought the check will have been so great that if not taken up and a spell of wet weather should occur, the tubers would be in danger of second growth and also very likely be overtaken with disease. Those required for seed for another season's crop should be put on one side at once. When taken up, spread them out in a layer of about 9 inches or 10 inches in thickness on the floor of a cool shed and away from the light, or the tubers will quickly turn green. If placed in large heaps and closely covered with straw the tubers are apt to become heated.

TURNIPS FOR WINTER.—So far this has not been a good season for Turnips, that is unless the sowings have been on east borders. The time has now arrived to make preparations for the winter crops. The season being so dry, it is all the more desirable that the ground should be in a thoroughly fertile state. Manure in its rotten state holds moisture, and this is what is needed to assist in seed germination and also in supporting the young plants. A dressing of lime would be an advantage to old gardens rich in humus through years of manuring. Burned refuse is also an assistance, but work this well into the surface, not scattering it along the drills. Salt is also a capital stimulant for Turnips, and would be especially beneficial this season in keeping the soil cool and moist. Not much is required, just a mere sprinkling, it being applied to the surface before the latter is broken down. For early winter use Snowball is a good Turnip. Red Globe is valuable for succession and keeps well, but for late use the Orange Jelly and Chirk Castle Blackstone are invaluable; 15 inches apart is wide enough for the rows of the latter and Snowball, allowing an extra 3 inches for Red Globe on account of its larger leafage. Before even the young seedlings appear dust the surface over with soot every morning, that is if the weather should be dry, as a safeguard against fly. If one sowing fails, follow up quickly with another. Timely hoeing and also thinning must be strictly attended to before the seedlings become crowded.

PREPARATION OF GROUND FOR WINTER SPINACH.—This useful crop cannot have too much attention in the preparation of the soil, so as to get it both insect-proof and in a well-pulverised condition by the time it is needed for sowing. Ground which has been cleared of Peas and Cauliflowers will suit this crop admirably, and if it was well manured for these crops, no further addition will be needed. The surface in the meantime might well be forked over twice, this exposing the soil readily, so that birds may pick it over for grubs. As a further preventive and also as a stimulant, work into the surface both a dressing of burned refuse and soot.

SHALLOTS AND GARLIC.—The tops of these bulbs are changing colour earlier than usual, but by their present condition a fine crop should be harvested. If these are allowed to remain in the ground and a spell of wet should follow, fresh root-action would quickly commence, when, of course, the quality would be lowered and the keeping qualities spoiled. If when harvested the weather should be dry, lay them out on a gravel path or even boards in order to get them thoroughly ripened.

GATHERING AND DRYING HERBS.—All herbs which are required for drying should now be cut

and prepared for storing. As they are cut, tie up in small bundles and hang them up in an open shed so as to become thoroughly dry. When the bundles are too large they are apt to turn mouldy in the centre.

LETTUCE.—Good Lettuce for coming into use during the autumn months is often very scarce, but this need not be if sowings according to the demand are made at intervals of ten days. The Cos Lettuces are useful for transplanting, and in the selection of varieties do not omit Hicks' Hardy White, as well as a good selection of a summer form. The former is a capital autumn Lettuce with the quality of the summer Cos, and remains some time before running to seed.

A. YOUNG.

PLANT HOUSES.

THE CONSERVATORY AND SUCCESSIONAL PLANTS.

Owing to the hot weather and so much sunshine many plants now in season in the ordinary way will have been considerably hastened, if not already past their best. Late show Pelargoniums by good management will give a good display in most seasons up to the middle of the month; hardly so this year. Fuchsias will, however, come on quickly to succeed them; these like the Pelargoniums should be worked in batches, having at least three distinct stages; this is easily effected by stopping and not allowing the plants to become pot bound too soon. The Pelargoniums should now be laid on their sides where of no further use, so as to rest them and ripen the wood. The Fuchsias, on the other hand, will require liberal supplies of water, with stimulants also, as they advance into flower. To keep them at all on the dry side is simply ruinous, the plants going quickly out of flower, leaving thrips with red spider in the ascendancy instead. Early-sown *Celosia pyramidalis* in variety will form a pretty mixture with the Fuchsias. These very showy plants are not grown nearly enough; they can be had in flower from the end of June to the end of September with ease, the period of blooming being regulated according to the circumstances. This can be effected in either of two ways; the seed can be sown at intervals, or stopping the shoots as they show for flower can be practised. We are now following the latter plan, the plants being kept meanwhile in a brisk heat with plenty of moisture to keep red spider in check; some of these plants have been stopped twice, and where needful another stopping will be given. This method keeps the plant compact, the so-called variations in habit being more in reality variations in cultural detail than anything else. We shall pot some of the most vigorous of these plants once more; they are now in 6 inch, 7-inch, and 8-inch pots. Then from the end of August onwards we hope to have a good display of plumes. Where the plants are now growing in warmth, it is necessary to lower the temperature as the flowers show colour, and the syringe must be dispensed with also. Cold water from wells, &c., should not be given these plants; it is a check to them; rather take that from rain-water tanks or where fully exposed to the sunshine. In this respect, and as regards culture also, the Globe Amaranthus comes under the same heading. In either case plants will droop and die off from no apparent cause, but the watering in excess when in flower, and that with cold water, is more often than not the reason of this. Cockscorns can hardly be regulated as the *Celosias* are, but with care in watering these also will last in good condition considerably longer. If the red spider is troublesome upon these plants, it will pay to sponge the leaves with a mixture of soft soap and sulphur.

Liliums in sorts will now be useful additions to the conservatory list of plants. *L. Harrisii* is mostly over, but *L. auratum* under cool treatment can only be considered as just coming into flower, late potted bulbs being even later still. This latter kind should be securely staked as the tops increase in weight; for this purpose slender Bamboo sticks are as good as anything. Up to the time that the flowers are fully expanded a liberal supply of water is needful, but thence onwards rather less

should be given. *L. lancifolium* in variety will form a later succession, and *L. tigrinum splendens* a later still. This latter variety should be more grown in pots. It is quite hardy and need never be under glass until in bloom. All of these Lilies should be fully exposed to light and air until the earliest flowers show, when protection may be given, all needful staking being done before the stems grow crooked, no sticks being inserted near the bulbs. Zonal Pelargoniums will make a good display also, but it is hardly advisable to use many of them now. Enough of these (and frequently too many) are seen in the flower beds just at present. Later on in the summer and autumn these will be of more service. For the time being it will be a better plan to pinch out all the trusses and encourage growth instead. Gladioli in pots can be retarded if necessary by keeping them under a north wall, but let them have a plentiful supply of water all the same. In every change now effected in the conservatory arrangement see to it that a free use is made of the syringe or, better still, the garden engine, so that every nook and corner are reached to dislodge insects of various kinds, as spiders in variety, thrips and green-fly, and perchance mealy bug also. Mealy bug is no lover of cold water, and a deal may be done towards keeping it and the other insects in check by these opportune syringings, besides which these washings will cleanse the plants of dust and refresh them also. All permanent conservatory plants, whether planted out or not, must have regular attention given them in this way and at the root as well; otherwise in their proper season they will not be up to the mark.

JAS. HUDSON.

ORCHIDS.

AMONG Orchids now in flower numerous plants of *Cattleya Gaskelliana* make an exquisite display, and the sweet perfume of the flowers is very pleasant. The recently-introduced *C. labiata* is also coming into flower, and the two will keep up a good display for about six weeks. The early-flowering summer *Cattleyas* are now in full growth. Some of the earliest of them have formed their flower-sheaths. They still require heat and moisture to fully develop the growths, but the cultivator has to be very careful not to force the growth beyond a certain point. The more vigorous specimens have a tendency to start into growth again from the same lead. This is not desirable, as this second growth is seldom strong enough to flower, nor is there time for it to ripen sufficiently by the end of the season. To prevent a second growth in the case of fully-developed sheaths, place the plants if possible in a house with a lower temperature and a drier atmosphere, keeping them, of course, drier at the roots. The *Thunias*—a class of plants easily grown and which do not take up much space in the Orchid house—have mostly passed out of bloom, and as growth is completed they also must be moved into a house where they are well exposed to the light and where the ventilation is better. Less moisture both at the roots and in the atmosphere of the house is desirable. When the growths are fully matured no water is needed. The deciduous *Calanthes*, of which the varieties are now so numerous and the flowers so very beautiful, require to be grown in the warmest house. They may now receive liquid manure water about twice a week. Being now well rooted, they can take larger supplies of rich food. This increases the size of the spikes and deepens the rich rose-pink colour of such fine garden varieties as *C. Veitchii*. With a high temperature, much moisture is needed, and the plants ought to receive as much sunlight as they will bear. Now is the time to develop and finish up the pseudo-bulbs, and if the plants are well managed now and the leaves kept perfectly clean, the cultivator will be rewarded with a rich harvest of flower-spikes at mid-winter. I omitted to say anything of *Miltonia Phalænopsis*. Some of the plants, or all of them, may require repotting. If so, they should be seen to at once. Drain the pots well, and be careful not to over-pot them

This pretty species is not now so much valued as it used to be since the more showy *M. vexillaria* and *M. Roezli* have been so common in gardens. Keep the plants close up to the glass roof and water freely. Several other species of Orchids in the warmest house may now be repotted if they require more root room. All recently imported plants should at once be placed in their teak baskets or flower pots. The new *Eulophiella Elisabethæ* is sure to be a free-growing plant. It will probably succeed best in teak baskets suspended from the glass roof of the warmest house, but it would be well for the present to place the plants on the shady side of the house where they will receive the least amount of sunshine. As a general rule in Orchid culture the plants require the least amount of sunshine when the growths are in course of development. When they have grown to their fullest extent, heat and sunshine are necessary to their maturation. *Dendrobium Phalænopsis* is also being imported, and requires very much the same treatment. Orchid amateurs would do well to obtain plants of this fine species, as there are so many distinct and beautiful varieties, the colours varying from pure white to a deep, rich rose-purple. The great charm of Orchid culture to amateurs is anticipating the flowering of imported specimens. The spikes of this species may be grown to 2 feet in length, with a score of blooms upon each, and not the least of its good qualities is the length of time the flowers remain in beauty.

In the cool house there is plenty of work to do keeping the plants clean, as insect pests increase rapidly during the hot weather. The handsome *Disa grandiflora* will now be producing its flowers, and these are liable to the attacks of green-fly, which should be removed before the flowers open, as this checks their development and sadly mars the purity of the colours. The brightness of the colour of these flowers comes out best in clear sunshine. If we could expose the flowers to light and shade the lower part of the plant, the result would be the most satisfactory. I have previously urged the importance of supplying these plants freely with water. Never at any time even when in flower and later on when they may be in the resting period should they be allowed to become dry at the roots. The continued dry, hot weather is anything but conducive to the welfare of cool house Orchids. With an outside day temperature of from 80° to 90° and a scorching sun overhead, it is very easy to make a mistake in opening the ventilators of the cool house. Some cultivators think the best way is to throw them open to their fullest extent, but this is a very grave error; the house should be shaded and the ventilators should be opened in such a way that the heated air cannot blow directly through the house amongst or over the plants. Our front ventilators are kept shut all day, only those at the top being opened.

The plants may be syringed overhead daily in the hottest weather, and watered sufficiently to maintain the Sphagnum Moss in a healthy growing condition. Many of the *Odontoglossums* which have just passed through their flowering period have been considerably weakened thereby; in many instances the bulbs have become visibly shrunk, and require very careful management to bring them back to the condition they were in before flowering. To make things worse, there is little or no moisture at night; we have no rain, no dews, so that all the moisture must be obtained from within. There is none without, so that even at night admitting air through the house may not be desirable. If the nights are warm and dew falling, the ventilation may be more ample. One of the handsomest occupants of the cool house flowering at this season is *Odontoglossum coronarium*. When good plants of this can be obtained and if they do well and flower freely, no Orchid will give more satisfaction; the handsome spikes, which produce as many as thirty blossoms, cannot fail to please. Its peculiar habit of growth cannot be made to conform to pot culture; a long narrow teak basket suits it best, and the plant roots freely amongst moist and living Sphagnum. Keep the plants up near the roof glass, and when they

are strong enough they will be sure to produce their flowers. During this hot weather much attention must be given to *Oncidium macranthum* and *O. Marshallianum*; they must be freely supplied with water to encourage a strong, healthy growth, and both of them do best near the roof glass of the cool house. The vigorous growing *Odontoglossum Edwardi* is now making its growth, and may be placed with the plants in the same house. The temperature of all the houses is now at the highest point, and artificial heat can be dispensed with.

J. DOUGLAS.

KITCHEN GARDEN.

THE GROWTH OF ENDIVE.

ENDIVE must be considered the best substitute for Lettuce we have, and, taking into consideration the comparative ease with which a good batch may be raised, it should certainly demand attention, although the growing of the plants is only one part of the routine. Before raising and planting out the Endive it should be considered what means will be available for storing, as it is useless to provide a quantity for which when the cold rains and frosts of autumn arrive there will be little or no means of protection. The protection of the plants from both early frost and wet is of the greatest importance, as if only slightly injured by either of these causes the work of destruction quickly commences, when they are soon a mass of decay. In some instances the plants may be protected where grown, and for the earliest supply of Endive this is certainly the best method to adopt, reserving the space at command for storing for the later or winter batch. Long or isolated rows are the most difficult to protect where grown, and in providing the plants for this purpose arrange them in beds, as in this way protection may quickly be given on the shortest notice, either by the use of portable lights, oiled canvas, or clean mats.

Endive succeeds equally well either when transplanted or left alone. In the former case the plants do not grow so large certainly, but for lifting are more suitable. The non-transplanted ones often grow to a very large size and come in for early use. Endive is certainly a sun-loving subject; therefore, do not crowd the plants near fruit bushes or in low-lying damp parts of the garden, but expose them as much as possible. Although this exposure is needed, the soil must be both fertile and in a pulverised condition, or the growth will be slow and of poor quality, and when this is the case Endive is not worth eating. The Improved Round-leaved Batavian is the best for winter use, and is not as susceptible to damp as the curled forms. A portion of a good green-curl'd form should also be grown for earliest use, as it is also useful for garnishing. For raising the plants I generally utilise the south borders which have been cropped with early Potatoes, and as these had a fair dressing of old Mushroom-bed manure and burned refuse at the time of planting, the soil is just now in a capital condition for growing a crop of Endive. Poor soil Endive will not thrive in, and in these cases fork in a dressing of manure, but not too deeply.

Broadcast sowing may be all very well, especially where sown thinly, but, taking all points into consideration, sowing in drills is the best method to adopt. Direct light is thereby enabled to reach the plants on all sides and there is less work in attending to the plants, especially where the seedlings are

not going to be transplanted. The drills should be drawn quite 15 inches apart, this width being needed for the plants' development. Endive seed generally germinates very freely, but during this abnormal season of drought the drills must be watered previous to seed-sowing. As the plants grow, hoeing must take place, and as soon as large enough transplanting must be attended to, leaving the surplus plants in the rows 1 foot apart. If the weather should keep dry, transplanting will be carried out with difficulty unless precautions are taken to moisten the seed rows before drawing the young plants. Lift with as much soil as possible, also taking care that the roots are fixed firmly. If arranged in conveniently sized beds the plants may be easily shaded for the time being, supplying them plentifully with water at the same time.

A. YOUNG.

Early Potatoes.—It is seldom one can dig good early Potatoes in Scotland during the month of June, but this season being exceptionally early I was able to dig them in the first week of the month. The tubers averaged from 2 inches to over 3½ inches long, and of fair quality. There are many schemes and simple methods of stealing a march on time (many useful experiences I received when a youth employed in a London market garden have often been of much value to me during many years spent in private gardens). I have this season had many useful crops brought on early by throwing up a sharp ridge facing the south. On this, which was well cared for and improved by additions of light soil and manure, I had early Potatoes, Turnips (Early Milan), Spinach, Carrots, Radishes, Cauliflowers, &c., at least three weeks earlier than on the adjacent plots. The varieties of Potatoes were the old Ashleaf and Veitch's selection of that old favourite. A crop of Turnips was had from between the rows of Potatoes. Since the Potatoes and other crops have been removed this steep border has been filled with autumn crops, thus economising ground.—M. TEMPLE, *Carron House, Stirlingshire, N.B.*

Tomato Challenger cracking.—Some varieties of Tomatoes are certainly addicted to cracking more than others, but as yet I have not found Challenger affected. In fact, up till now I have considered this an ideal Tomato in every way. By taking care that the structure is not closed so as to cause a sudden rise of temperature, cracking will not take place. Care must also be taken that the air is increased sufficiently early in the morning to prevent a sudden rise. I know it is the custom of some people to keep the structures close and warm, so as to hasten on the ripening, but this is not a wise proceeding.—A. YOUNG.

The Carrot grub.—When a crop of Carrots is attacked by grubs there is no other remedy than picking them out by hand. Many acres of Carrots are grown in this part of Surrey for the London markets; in fact, within an area of ten miles I should say that quite one half of the bunched Carrots for winter use in the metropolis is produced. The light leam bordering on sand is favourable to the growth of finely coloured, well-formed Carrots. In seasons like the present growers are sure to be troubled with grub. Preventive measures are sometimes tried, but the results have never been sufficiently marked to warrant their repetition. A dressing of gas-lime put on early in winter and a fair sprinkling of salt to the young plants are supposed to act deterrently, but hand-picking is the one thing that Carrot growers have faith in. The dangerous time is during July when the little roots are tender. Get them through this month and they will then be too tough for the grub. There is only a certain number of grubs in the ground, and if these can be taken the crop will be safe. In the case of a very bad attack there will be a grub to the yard, and this is enough to clear off all the plants if nothing

is done. Late in the evening and early in the morning are the best times to find the grubs, as they are then near the surface, and wherever an ailing leaf is seen a grub will be found. Taken in time and persevered in, a crop even when badly attacked may be saved. When June happens to be very dry, thinning out should be cautiously done. Many growers here do not cut out the plants with the hoe in a dry time, but merely pull out some where the plants are very thick until a change of weather comes. If the season keeps dry they are left unthinned. In this way even if the grub does attack them enough is left for a crop. There is another advantage, too, the young plants shelter each other from the hot sun and grow away more freely. I have just been looking at two fields, in one of which the plants were "cut out" when quite young. For yards one cannot find a plant, whilst in the other, which has only been kept clear from weeds, there is a nice crop of very healthy young plants.—J. C., *Blyth*.

The Pea crop.—What are the best kinds to grow for a private garden, supply, quality, and productiveness combined? This is a fair question to ask in a season like the present when we take into consideration that the Pea does best in medium or rather moist seasons. I grow Chelsea Gem as a first early. There are others a few days earlier, I know, but the quality is not so good. To follow this I depend upon Criterion, a really splendid Pea with pods of medium size, but produced in abundance. Then follow Duke of Albany and Autocrat, both grand Peas with large pods, the latter of the two the finer in very hot and dry weather. To finish the season, Ne Plus Ultra is my most reliable kind; there is not a Pea to surpass it in flavour or in constitution. Sturdy is a dwarf form of the preceding and well suited for windy localities.—G. H.

POTATOES.

ALTHOUGH we have lately had some refreshing showers, not enough rain has fallen to have much influence on the Potato crop. The earliest varieties are too far advanced on our light Surrey lands to benefit by a copious rainfall. Beauty of Hebron, for instance, began to turn yellow several weeks ago, and in a good many instances the crop has been dug and marketed. There was a danger of the tubers growing out if left in the ground until a change of weather took place and no chance of their improving. Anxious to make as good a price as possible and to make room for winter greens, market growers have been clearing the ground of early Potatoes as rapidly as the demand would allow them.

One result of this premature ripening is that the London markets have been so bountifully supplied with English new Potatoes in addition to large foreign imports, that consumers would hardly look at old ones. Large growers are in the habit of holding over a considerable portion of their stocks till late in spring on the chance of a rise in price. In ordinary years, and especially in late springs, this answers very well, for it will pay to keep them for an additional sixpence per bushel. This year these old stocks have been almost valueless, hardly paying the cost of carriage to the London markets, and being sold in rural districts at about £1 per ton for feeding pigs. It is quite certain that in the south of England the main crops are in danger. If we do not get copious rains during the month, the yield of Magnum Bonum and other late kinds must be lighter than has been the case for years. Had the ground been moist when they were earthed up there would not have been so much to fear, but it was almost dry, and the young tubers are now in soil as dry as a dust-heap. In gardens where deep culture is practised the effects of the severe drought will not be so apparent; but it is not there that the bulk of Potatoes is grown. In a general way field culture is not nearly so thorough, the ground being ploughed in the ordinary way, which does not give more than 6 inches of soil for the roots to work in—in fact, hardly that, as the plough does not go in quite to that depth, and

subsoiling is not so generally practised as it ought to be. When the land verges on sand—and we have a good bit of such ground in Surrey—even the late crops have suffered to a serious extent.

J. C. B.

DOUBLE CROPPING.

By double cropping is generally understood the planting or sowing of two or more crops concurrently, so that one or the other is cleared off in time for the later one to be fully developed. The main object is to make the most of the ground, and in doing this there are several points to be considered. The character of the crops to be thus amalgamated must be considered, so that one does not injuriously affect the other during the process of growth. The preparation of the ground likewise should be such as to suit each kind as nearly as possible. There is an old-fashioned system of double cropping which rarely succeeds well, at any rate I have never succeeded to my satisfaction, nor have I seen others do so. I am referring to the planting of Brussels Sprouts, Broccoli and sprouting Kales between the Potato rows. Either of these crops, when so planted amongst the Potatoes, will become unduly drawn unless the latter be early kinds; between such it is never needful, for other crops can quickly follow these, so that no time is lost. It does not follow that simply because the ground is covered it is therefore well cropped. Lessons as to the value of double cropping can be learned wherever market gardening is carried on in the best possible manner. The best instance that I have ever seen was that practised by a market gardener, the same mode of procedure being also applicable to private gardens. This was a combination of three crops rather than two, between the times of planting of each there being hardly any interval. These three crops were Brussels Sprouts, Scarlet Runner Beans, and Cos Lettuce. The first to be got in was the Lettuce, the rows being 2 feet apart, these rows forming guiding lines for the next two crops. The Scarlet Runners followed these, and, lastly, the Brussels Sprouts, these being put in alternately between the rows of Lettuce. This covered the ground at 1 foot apart for each row, there being 2 feet between the sprouts and the runners. Before either of these crops had grown to any extent the Lettuces were cleared. The runners were then soon fit for stopping, as no staking was thought of. By clearing off the runners as soon as nothing was left upon them to pay for picking, the sprouts would be left at 1 foot apart from row to row, which is really none too much for comfortable picking, whilst at the same time the extra room afforded a free circulation of air between the sprouts. As soon as the Lettuces were cleared, there was room to stir the surface soil and clear it of any weeds, at the same time benefitting the two remaining crops. Another capital plan is to occupy the same plot of ground with Brussels Sprouts and Lettuce only. These two crops, if both are planted at the same time, will go well together. Three feet should be allowed between the first-named, with one row of Lettuce between each. The Lettuce then came away in time for the sprouts to be earthed up and the ground well worked with the hoe. In some places Parsley does not thrive nearly so well as one likes to see it. Where such is the case, I would advise a system of double cropping arrived at by sowing the seed in the same drills with the Onions. The ground for the latter crop should be well trodden preparatory to sowing the seed. This firm condition is at the same time congenial to the Parsley. Where the ground is fairly clean and the hoe not likely to be required frequently, the Parsley seed may be sown broadcast instead, but this necessitates more care on the part of anyone working the hoe. I have only just noted a combination of two crops which in an ordinary season, with more moisture in the soil, would have been successful, no doubt. This was the planting of the ground with Cos Lettuce at about 1 foot or a little more apart, the intervening crop being one

of Seakale by sets. As it is, the latter looks starved and weakly up to now, although the Lettuces were nearly all cleared by the end of May. The ground was well manured, as is the usual practice, and this may tend to recuperate the Kale in time. The time-honoured plan of sowing Spinach between the rows of Peas cannot well be improved upon, but when Brussels Sprouts are added on either side of the Spinach, it cannot be considered good gardening, nor is Celery as an alternate crop with tall Peas a commendable method. To grow Scarlet Runner Beans for staking in rows of 5 feet or so apart is a waste of ground, to say the least. The most of the ground can be made for such as French Beans, which turn in quickly. Such root crops as Beetroot, Carrots, Turnips, and Onions, save in the case mentioned, should occupy all their allotted space. When a young Asparagus bed is first formed, or when it is grown in rows upon the French system, it is possible for the first season or two to take such crops as Cabbage, Lettuce, or Radishes, but in no instance should these intermediary crops be at all overcrowded, it being borne in mind that the Asparagus is one of the most enduring of all vegetables, being, therefore, worthy of all possible attention.—H. G., in *Field*.

Early Peas.—To have Peas as early as possible most cultivators adopt some system of forwarding them, and I notice that Mr. Gilbert, at Burghley, still practises a system long known in Scotland, and adopted by some growers still, viz., sowing the earliest Peas during November. I never find that by these early sowings one saves labour, has finer crops, or gathers Peas earlier. Those which I sowed at the beginning of January, kept from frost and heavy rains, and coddled at no time, have done best this year, and always do. When Peas are being raised under glass the error of keeping them too close is very common, and when they are planted out in March or April, the plants being so tender they are liable to injury from frost and cold winds. I gathered William I. at the end of May, and during the first week of June Peas were plentiful. Those sown during January were not more than a week before the earliest sowings, and the crops from them extraordinary, William Hurst taking the lead as second to those raised under protection. Notwithstanding the long drought, we have watered no Peas, but instead depended on deep tith and liberal manuring, with thoroughly decayed material from the rubbish heap.—M. TEMPLE, *Carron House*.

—This year I sowed American Wonder on a warm south border on the 6th of February, and Carter's Lightning in the open quarter two days later. I gathered my first dish from the latter on June 7. American Wonder was just ten days later. Carter's Lightning is a heavy cropper and of fine flavour, much superior to either William I. or American Wonder.—THOS. COCKERILL, *The Gate House, Wirksworth, Derbyshire*.

Turnip-rooted Beetroot.—In shallow or poor soils the Turnip-rooted Beet possesses great advantages over the ordinary kind, as it may be sown where the longer-rooted kinds would not thrive, and coming into use so quickly there is much gain. The Turnip-rooted varieties keep solid for a long time, and if desired may be sown at different dates so as to keep up a succession. There are several varieties of the Turnip-rooted Beet, such as the Egyptian dark red, Crimson Ball, Eclipse, and Bassano. I prefer the first-named, as it possesses a rich colour, is of excellent quality, and comes to maturity earlier than some kinds. Sown April 12, it was fit for use the first week in June, and though not the largest variety, it is of good quality. The last-named is often grown for sale on account of its being larger, but I do not think a coarse Beet of any kind is an acquisition; it usually lacks colour and does not keep so well. The well-known Dell's Crimson, one of the best coloured Beets we have, and a small variety, cannot be beaten for keeping. In the salad bowl the Turnip-rooted Beetroots are valuable, as they may

be sown much earlier than the older kinds. When fully grown it is not advisable to leave them exposed to the hot sun for any time, but to lift and store in a cool place, or lay the roots in a north shady border. I prefer the latter, not cutting or removing the foliage till required for use. By sowing these early Beets, ground may be utilised for other crops as the roots occupy the ground so short a time. When sowing, it is best to sow on land not recently manured, as the roots crack if in too rich soil; a rapid growth is required and plenty of moisture at the finish to swell the roots.—S. H. B.

Mulching kitchen garden crops.—If ever the value of mulching was apparent it has been during this dry and hot season. So treated, we have had no real break in our Pea crop. French Beans are all the better for being so treated in hot and dry localities, and Scarlet Runners should by all means have a good mulching. These latter should be so treated before the first flowers expand; then, by liberal applications of water, the earlier blooms will set. If dry at the root, there is frequently a failure in this respect; hence a considerable loss ensues. If I had the time and material I would mulch Brussels Sprouts also, but this seems to be out of the question. Vegetable Marrows ought to be mulched; they are thus only half the trouble and give double the return. If anyone is driven into a corner for material for mulching, I would advise him to use the lawn mowings where these have not been looked up for the cattle through the scarcity of food. In our case these are taken straight away to the cows.—G.

FLAVOUR IN VEGETABLES.

WITH an absence of rain for three months it must be expected that the flavour of vegetables will be impaired. In the case of roots much may be done to retain the flavour. In the case of Turnips, Carrots, and Beet, when once a certain size is attained it is useless to allow such to remain a day longer on the parched ground than is necessary, as they soon lose their flavour. This season we had our early Turnip Beet fit for use at the end of May. The seed was sown at two different dates, and the first sown was ready for use at the time named. It was useless to allow the roots to remain to be dried up, so they were lifted with the tops intact and laid in in heavy soil on a north border shaded by a high wall. These roots at this date are much better in colour and flavour than those from a later sowing, and now occupying their original position. Last year, seeing the great advantage in lifting early Turnips when fully grown I adopted the plan more largely this season. I do not advise the lifting and laying in of any root till growth is nearly finished, as to do so would be as disastrous as leaving too long.

Early vegetables are more readily affected by heat and want of moisture than later ones, as they have not got hold of the soil to such an extent. The Short Horn or Forcing Carrot soon suffers if left in exposed positions when of a good size; also the early Turnips, of which Early Milan is a type. This if left after it is fully grown is not worth eating, as it so soon deteriorates, but if lifted or stored in a cellar or root store it remains sweet and solid. Radishes are soon hollow and worthless if not attended to. In some places Radishes are required regularly, and are sown on north or cool borders. In such seasons as we have just experienced they are difficult to keep of good flavour. Much may be done to assist them by sowing thickly in rows, and when above ground mulching with spent Mushroom manure or even leaf soil, this retaining the flavour, as the mulch is kept moist if watered once or twice a week. I have adopted this last-named for Lettuces with much success, and find it a great saving of labour on light soils. In the case of green vegetables there is more difficulty. I have not hesitated to lift such crops as Cauliflowers to a cool border. Peas are much improved in flavour if mulched. The same remark applies to French Beans, as if litter is placed be-

tween the rows the pods are more succulent and last much longer. Potatoes are much worse as regards flavour if left in the soil when the tubers are ripe. There is considerable gain by lifting early roots of various kinds, as the ground can be utilised for later crops. As summer vegetables of most kinds will soon be over, there will be much advantage in securing good breadths of later crops to fill up the void. W. S. H.

TREES AND SHRUBS.

LEGUMINOUS SHRUBS IN BLOOM.

By the commencement of July, especially during such a season as the present, the flowering period of most of our hardy shrubs is past, and of those that are still in bloom several belong to the order Leguminosae. Some of them are very fine, and as a rule they have not suffered so much from the excessive drought as many other classes of plants. This is no doubt owing to the deep rooting character of most of them, for though the roots are not particularly numerous, they penetrate to a considerable depth. While this feature renders them more independent of the drought, it at the same time militates against successful transplanting, especially among the Broom family. One of the showiest of all the Leguminosae now in bloom is

GENISTA ETNENSIS, the general appearance of which is well shown by means of a coloured plate in THE GARDEN of March 18 of the present year. It reaches a height of from 10 feet to 12 feet, and the long slender bright green shoots laden with golden blossoms form a very showy specimen. It forms an admirable succession to *Genista virgata* recently noted in THE GARDEN.

SPARTIUM JUNCEUM, here illustrated, is exceedingly showy at the present season, and in many instances, judging by the buds yet to expand, it will continue in beauty for some time. It is of free growth, and is especially attractive when so situated that it springs from a bank of foliage, as it is naturally bare at the base. A double-flowered form of the Spanish Broom has been at times mentioned, but the flowers of this that I have seen are poor, and not nearly so attractive as those of the common kind.

CYTISUS NIGRICANS, recently mentioned in THE GARDEN, is beautifully in flower, and a very pretty shrub it is. It is a much-branched bush whose slender twigs are clothed with trifoliate leaves, and terminated by erect spikes of clear yellow flowers of quite a different shade from those of any of its allies now in bloom.

CYTISUS CAPITATUS, now in full flower, forms a neat, compact-growing bush about a yard high, clothed with trifoliate leaves, which, in common with the stems and unopened flower-buds, are so thickly covered with hairs as to give the entire plant quite a hoary appearance. The flowers, which are borne in rather compact terminal heads, are of a light yellow colour and produced in great profusion. This will often bloom till the end of August or even in September, so that it must be included among the best autumn-flowering shrubs.

THE BLADDER SENNAS (*Coluteas*) will flower throughout the summer, and at the present time they are very interesting, being studded not only with blossoms, but also with the large inflated seed-pods from whence the popular name is derived. These last are the product of the earlier blossoms.

INDIGOFERA GERARDIANA differs widely from all the above in the flowers being of a rosy purple tint. In the open ground it is usually cut down each year, but the slender shoots which spring from the base ultimately reach the height of a yard or so, and flower well the first season. A specimen of this is very attractive just now, as the pretty pinnate foliage imparts to it a light and

elegant appearance, while the entire mass is studded with spikes of pretty pea-shaped blossoms. With the protection of a wall it is seldom cut down during the winter, and therefore attains a larger size than it will in the open ground. There is a white-flowered variety, less showy it is true than the typical kind, but still very pretty.

NOTOSPARTIUM CARMICHAELLE (the pink Broom of New Zealand) has been so often described in THE GARDEN, that nothing further need be said on that point.

AMORPHIA FRUTICOSA (the Bastard Indigo of the United States) is just opening a few of its ear-

ly beauty of the richly coloured petals; while the golden anthers, which protrude slightly from the mouth of the flower, are very striking by contrast with their surroundings. There are several forms, but all closely resemble each other, except the Lead Plant (*Amorpha canescens*), which is of smaller growth, while the pinnate foliage is of a peculiar hoary character.

The next to mention as being now in flower is quite a tree, though it blooms freely when not larger than a good sized shrub. This is

CLADRASTIS AMURENSIS (see illustration, p. 58), which forms a low-growing tree, clothed with pinnate leaves, which when unfolding in the spring are covered with a silky pubescence, which imparts to it a very distinct appearance. The flowers are borne in erect, densely packed racemes, and being of a whitish tint are not particularly showy, but noticeable from their numbers and the uncommon appearance of the specimen. T.

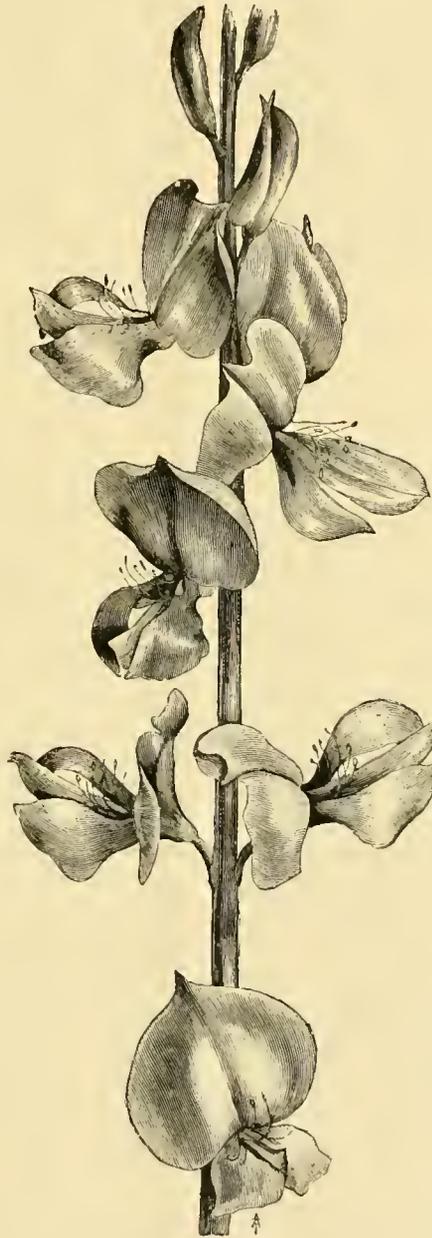

The False Acacia and its varieties.—

Lately in the drought, when trees in some soils began to look very doubtful in health, we often admired the colour of the leaves of the common Acacia. This beautiful tree is too little planted with regard to effect; we mean, it is so distinct in its beautiful green from our own trees, that it ought to be planted in picturesque groups as well as singly. Last year in France we were interested very much in some of the prettiest varieties of this tree which have been raised and are rather freely employed in gardens there. We particularly remember seeing a very beautiful kind in the public gardens at Orleans, with leaves as fine as those of the finest Sensitive plant. It was the variety *mimosæfolia*. Other good varieties are mentioned in our own and foreign nurserymen's catalogues. The old Italian round headed form, so well used in the north of Italy in places like Novarra, is valuable, but some of the elegant and free forms we speak of are still more so for our gardens. These are all forms of the Acacia about which Cobbett made such a noise. If his hopes concerning it came to so little, it and its forms are none the less most precious for our parks and pleasure gardens.—Field.

Garrya elliptica in Scotland.—The value of this old plant is becoming more widely recognised. At one time this useful ornament of our shrubberies was considered too tender to be planted in the ordinary shrubbery, and was confined to walls and sheltered positions. To show how hardy the plant is, there is a hedge of it in a villa garden at Bannockburn, in Stirlingshire, growing in a position exposed to north and east. This hedge was formerly cut in as required with a knife. But while passing the garden (which is near to the main road to Stirling) a short time ago I was sorry to observe that some ruthless hands had attacked this hedge with shears and cut the plants into the form of a sharp-pointed ridge, rendering the hedge as formal as hands (guided by a vulgar taste) could do. After such a severe winter as the past, the *Garrya* shows that no severe weather can injure it. In our shrubberies it is uninjured.—M. TEMPLE, Carron House.

AMERICAN NOTES.

THE JAPAN *VIBURNUMS* are now all pretty well known in our gardens with the exception of *Viburnum furcatum*, a common northern and mountain plant, so similar to our American Hobble-bush (*Viburnum lantanoides*), that some authors have considered the two plants identical, and *Viburnum Wrighti*, a distinct, black-fruited species of Northern Japan, where the American botanist Charles Wright detected it when the Wilkes' Expedition explored the shores of Volcano Bay. *Viburnum furcatum* is distributed through the mountain regions of the empire, and is one of the commonest species. Sometimes it grows to the height of 15 feet, and it is always conspicuous from its great, thick, reticulate-veined, nearly circular

Spray of the Spanish Broom (*Spartium junceum*).

liest blossoms, but it will not be in full bloom for some little time. It forms a free-growing clump of upright shoots that reach a height of 6 feet to 8 feet and are clothed with pinnate leaves, while the rich bluish purple coloured blossoms are borne in spikes on the points of the shoots. These flower-spikes usually consist of one long and three or four shorter ones, all of which are densely packed with bloom. The individual flowers are small, and unless closely examined appear to be dull and uninteresting, but closer inspection reveals

leaves, which in the autumn turn to marvellous shades of scarlet or to deep wine colour. If this fine plant takes kindly to cultivation, it will prove a real acquisition to our gardens.

ANDROMEDA JAPONICA, now common in our gardens, is properly a tree, for in the temple park of Nara, where it grows in profusion, there are specimens at least 30 feet in height, with stout, well-formed trunks 6 feet or 8 feet in length. *Andromeda campanulata*, another arborescent species, may be expected to become an ornament in our gardens of much interest and beauty, and as it grows as far north as the shores of Volcano Bay, in Yezo, and up to over 5000 feet in Central Hondo, it may flourish in the climate of New England. *Andromeda campanulata* is a slender, bushy tree, sometimes 30 feet in height, with a smooth, light red trunk, occasionally a foot in diameter and thick, smooth round branchlets. The leaves are deciduous, and in the autumn, before falling, turn clear light yellow. The flowers are pure white and are borne on slender stalks in many-flowered drooping racemose panicles. By Japanese botanists it is spoken of as one of the most beautiful flowering trees in Japan, and we considered ourselves fortunate in securing a supply of ripe seed, for, so far as I know, this species is quite new to cultivation. There is but one other Japanese plant of this family which can pass as a tree. This is the handsome *Clethra canescens*, or, as it is more generally known in Japan, at least, *Clethra barbinervis*, a more recent name. It is a beautiful small tree, occasionally 25 feet or 30 feet in height, with a slender trunk. The flowers are white and produced in slender, upright terminal paniced racemes 6 inches to 12 inches long, and open in succession for several weeks in August and September. In Southern Yezo *Clethra canescens* grows nearly down to the sea-level and along the mountains of the southern islands. In Central Hondo, where it is a common forest plant, growing usually near the borders of streams and lakes, it reaches an elevation of over 5000 feet, so that there is reason to believe that this fine species will thrive in our climate if plants are raised from seed produced at high elevations, although up to the present time those which have been sent to the Arnold Arboretum have never been very satisfactory. *Clethra canescens* grows not only in Japan, but in China, Java, the Philippines and Celebes.—*Garden and Forest*.

ORCHIDS.

LÆLIA CRISPILABIA.

This plant appears to have been named by A. Richard, and is said to be a native of Mexico. It used to be grown in our gardens under the name of *Lælia Lawrenceana*, and the only plant that was then known of it came from the gardens of Mrs. Lawrence at Ealing Park, where it was under the care of Mr. Frankling. This plant is nearly allied to *Lælia cinnabarina*, and it made the same flask-shaped bulbs as that species, which, together with the single leaf at the top, grew about 1 foot high. I think I remember the Messrs. Low, of Clapton, importing the plant some few years ago. Now this plant grew freely and flowered profusely, throwing up a spike 1 foot in length and bearing as many as six blooms, each nearly 3 inches across, of a uniform purplish lilac colour in the sepals and petals, the lip being small, the sides lobes rolled over the column, the front lobe being bent sharply backwards and much crisped at the edge. If this plant is now flowering with any of my readers, I should be very glad of a flower for comparison. I saw a plant bearing the name of *crispilabia* recently in Sir Trevor Lawrence's collection at Burford Lodge. This in its growth did not bear the slightest resemblance to the

type, for instead of a long pear-shaped bulb, or, as I said before, a flask-shaped growth, gradually decreasing upwards to a slender point, it had a short, thick, ovate pseudo-bulb and a broad ovate leaf, thick and fleshy in texture and light green. The flower is about 2 inches across, the sepals and petals being nearly equal, of a uniform bright rosy purple. So far the flower accords with that of the species, but the lip is very different. It is three-lobed, the side lobes forming a hood over the column, of a rich orange-yellow, the front very crisp at the edge and wholly orange-yellow, which colour runs up to the base, where it is prettily flaked with crimson, and it bears upon its surface four raised fleshy lines of a rich orange. That such a distinct plant in its growth, and apparently so very distinct in its bloom, should bear the name of *crispilabia* appears to me quite wrong, and I should propose the name of *Lælia Lawrenceana* for it if it is new. I am well assured it is not the same plant as grown by Mrs. Lawrence, which is figured in "Select Orchidaceous Plants," ii., t. 6. Mr. White grows this plant upon a block of wood, and it appears to thrive well under this treatment.

WILLIAM HUGH GOWER.

Grammangis Ellisi.—This is another Orchid which does not appear to find much favour with Orchid growers, for no one keeps the plant long in a thriving condition. It has large four-sided pseudo-bulbs, and too many growers appear to think that these large bulbs are a sure indication that the plant will stand a good drying with impunity. Mr. Ellis, its discoverer, says, "He found it growing upon a branch of a tree hanging over a river, about 25 feet above the water," so here one gets quite an insight into the life of the plant, for with the moisture derived from the water and the heavy dews which arise from it, the plant in all probability does not have a very great amount of dryness. Therefore, I say cool treatment and less water are a far better style of resting than drought and a high temperature. The plant, like many others, is flowering fully a month before its usual time, and I have seen it passing out of bloom. I was just in time to see the last of a beautiful variety in the Burford Lodge collection, where this plant continues to thrive and do well.—G.

Grammatophyllum Fenzlianum Measuresianum.—This is superior to the typical plant, and is now flowering at Burford Lodge. The several varieties of this species would appear to be very free-flowering, and consequently should receive the attention of amateurs more than they usually do. It produces a long and many-flowered spike of bloom, each flower measuring about 3 inches across, the sepals and petals being of a yellowish green, heavily blotched and spotted with deep brown; the lip is small, light yellow with brown lines. *G. Seegerianum* is another variety which comes near this plant, and is equally free-flowering. Both like the hottest position in the East Indian house, with a great deal of moisture both to their roots and in the atmosphere.—W. H. G.

Pecatorea Klabcchorum (T. S.).—The flower sent appears to be the species named above. You should have sent it sooner, before it had lost its beauty, and have packed it more securely, so that it could have been more easily recognised. This is still a somewhat rare plant in collections. *Pecatoreas* being destitute of pseudo-bulbs do not carry their leaves well, and thus the plants do not attain any great size. If they are kept in the cool house in the summer-time with a moist atmosphere, and removed to a house kept at about the same temperature through the winter with a moist atmosphere, the plants will grow and flower well. The flower before me measures about $3\frac{1}{2}$ inches across; the sepals and petals are white at the base, broadly tipped

with deep brown; the centre of the flower and its lip are smashed, but they appear to have been white and of the same colour as the tips of the sepals and petals, and to have been much spotted and dotted with rich brown. The plant is a native of Ecuador, but I am not aware that the locality has ever been divulged. I should much like to see these plants more frequently grown.—W. H. G.

Phalænopsis Mariæ.—I am always pleased to see this charming Orchid. Mr. Burbidge found this plant on an island where it was rare, and could not collect many plants, but other collectors at a later date found it more plentifully on some neighbouring islands. It comes near to *P. sumatrana*, each flower being about 2 inches across, the sepals and petals creamy white, banded with bright brown, the spots at the base magenta-coloured; lip wholly bright magenta, with a narrow marginal border of white. It is one of the most charming of the small-flowered kinds, and was recently to be seen in Sir Trevor Lawrence's collection growing in a somewhat shady position.—W.

Phajus Sanderianus.—This, which I have seen flowering from time to time for the past twelve months, I had taken for a very large form of the old *P. Wallichii*. My attention was, however, called to it when at Burford Lodge. The flowers each measure 6 inches across, the sepals and petals being nearly equal, of a rich deep bronzy brown, the back of the sepals tinged with a yellowish hue; lip large, rich bronzy brown, the front lobe stained with rosy purple and broadly bordered with white, which becomes yellow with age. The base of the lip on the outside as well as the furcate spur is rich yellow. It makes a very long erect scape bearing many flowers. I have not observed a forked spur in any other species.—W. H. G.

Vanda tricolor.—"H. H." sends three very handsome forms of this. No. 1 represents an excellent form of the variety known as *planilabris*. No. 2, an excellent form of *V. suavis*, commonly known as the *Chatsworth* variety. No. 3, *V. tricolor Patersoni*, figured in THE GARDEN, Vol. XXIII., t. 375. I am very pleased to find these *Vandas* are again becoming popular, for no better and sweeter flowers can be found in the whole Orchid family. They are plants which no amateur should hesitate to grow, because they stand well in a temperature of 60°, and even less, for although they come from Java, which is considered very hot, they are not found in the low places, but generally at considerable elevations.—W.

Cymbidium Devonianum.—C. Forrester asks what he shall pot some plants of this species recently purchased in and what treatment it requires. The plants should be potted in well drained pots in a mixture of fibrous peat and turfy loam, but do not over-burden the roots with soil. Water freely during the summer and keep the plants in the warmest part of the cool house, where they will succeed quite well. Keep them fairly moist until they begin to root and grow, when they may have a larger supply of water. It must also be borne in mind that during the winter the plants must not be dried off, but be kept fairly moist.—W.

SHORT NOTES.—ORCHIDS.

Cattleya Gaskelliana albens.—This is a very handsome variety of the original type, having flowers of a beautiful white, slightly tinged with lilac-mauve. It was flowering recently in the collection of Sir Trevor Lawrence at Burford Lodge, Dorking.—W. H. G.

Dendrobium binoculare.—This, now flowering in the Burford Lodge collection, is seldom seen. It has a drooping spike of deep rich yellow flowers with two velvety blackish spots on the lip. This comes near to *D. fuscatum*, from which it differs slightly. It was discovered by Col. Benson some twenty-five years ago in Burmah, and is a bright and pleasing kind.—G.

Lælia purpurata.—A. Cochrane sends me a flower of a very dark variety of this species, which he says "on account of the lobing of the petals he

proposes to call lobata." The name lobata was given by M. Linden to a flower a description of which was printed in THE GARDEN of June 10 last. It was an infinitely better variety than the one you send.—W. H. G.

Lælia Lindleyana.—G. Tomlinson sends me a flower which has been left until nearly past. It appears to be this variety. The flower is a little more than 4 inches across, white, suffused with lilac; the lip of the same colour, spotted with purple. It has been suggested that this is a plant of hybrid origin, but I do not fall in with this view. It thrives well with other Cattleys and Lælias.—W. H.

Angræcum arcuatum.—"T. S." sends me flowers for a name. I think the name is that given above, more especially as "T. S." says the plant was sent him from South Africa. The flowers are white and the spur is greenish. This plant requires strong heat and moisture. I am of opinion that there are a great many other species to come from the interior of Africa when we get to know it better.—G.

ROSE GARDEN.

BUDDING ROSES.

JULY is the month *par excellence* for this important operation, and although it can be carried on from June until September, it is by far the best plan to do it some time during the present and following months. With an apparent return to very hot and dry weather, it will be well to water the stocks before commencing budding. This will cause a freer supply of sap, and the bark will lift more easily and keep the bud moister than if comparatively little sap was on the rise.

Stocks.—These are not looking very well, owing to the excessively dry spring and summer; in many cases the losses reach a high percentage both among dwarf Manetti and seedling or cutting Briers. But perhaps the most disheartening results are to be found among the hedge Briers, especially if not planted early in the winter. There is a great advantage in planting these early as regards moisture and early striking off upon new roots. On the other hand, we have the danger of frost. It may be said, "Why fear frost, when the Brier is one of our hardiest native shrubs?" Granted it is hardy, but when a young sucker-like shoot has sprung up in the midst of a hedge or thicket of Brier and other plants, or been growing in a copse, it is much protected and in a comparatively tender state to what it would or should be later on when turned into a standard Rose tree and planted in the open. The past severe winter had much to do with the death of my Briers, and excessive drought following this completed the injury. Most stocks, like the Roses, have made little growth for the time of year when we compare them with past seasons, and in several instances it will be necessary to wait later than usual before inserting buds. We do not want gross growth, nor must we bud upon too weak and puny a stock.

The operation of budding is exactly the same, whether it be dwarfs or standards. We can also bud any other desired kind upon a variety of Rose equally as well as upon a properly prepared stock. For example, let us suppose you have a Gloire de Dijon on a wall, and wish to convert it into a Maréchal Niel, l'Idéal, or William Allen Richardson; it is only necessary to insert a bud in a young shoot near to the base, and having secured a successful take with your bud or buds, cut away the upper growth in the same manner as I will presently

describe for the stocks proper. Or you may bud two or more varieties upon a strong grower and still retain the characteristics of each Rose. It is wonderful how so small a germ as the bud of a Rose can contain its originality and convert the sap of Rose, Brier, or any other suitable stock to the support of the same. In a back yard near to me there used to be a half-standard Maréchal Niel. The winter of 1890 killed the Rose, but the Brier threw up a strong sucker of some 12 feet. This was budded with, I think, thirteen different varieties, most of which grew. There have been some fairly good blooms of Souvenir d'un Ami, Mme. de Watteville, Marie van Houtte, &c., upon the plant this season, it scarcely ever having been quite out of bloom, each variety retaining its originality to a remarkable extent.

Standard Briers have, of course, been confined to two or three of the most promising shoots or breaks coming from the stock at the nearest point to the height you desire your future standard Rose to be. Be very careful not to break or cut off the point of such shoots, nor yet to thin out any just before budding. If you do, the sap will receive a check, and the bark will not lift so easily and smoothly as is desirable. This is a great point, because the more easily you can insert the bud the less bruising it causes, and consequently you have a greater prospect of success. I have known Briers let go rather wild, then they have been gone through and superfluous shoots trimmed off. Where this has become necessary it should be done at least a fortnight before budding is commenced. The above comments will, I trust, effectually stop my readers from another absurd practice often carried out by amateurs. I allude to shortening back the shoots to about 2 feet as soon as the bud is inserted. If the recent mutilation of young growth checks the sap so effectually that it is impossible to lift the bark without using undue force, it must also check it sufficiently to rob the bud of nourishment. Remember that the bud is removed from a full supply of sap, and will soon wither up and dry if a good flow is not provided by the foster stock. This is why I advocate a good supply of water overnight if this dry weather continues and budding operations must be carried on at once, as they must be where a large lot of stocks is to be done, or where only a very limited number of buds of the desired variety can be obtained. To those who have not so experimented, much surprise will be felt as to how quickly a stock will take up the moisture and its sap become in full flow.

Dwarf stocks will have been slightly earthed up if my previous hints have been followed. The great advantage of this will be more than ever apparent during the budding season this year. It keeps the bark soft and moist, less brittle, and in a far better condition to receive the bud. Besides, one can plant them less deeply if soil be drawn up around them to protect the crown of the roots. Dwarfs must always be budded as near the crown of the roots as possible, and by simply removing the raised earth we secure this without an additional stoop of 2 inches to 3 inches.

Buds.—These, like the stocks, must be in the proper condition if you are to realise a high percentage of success. Too old or too young will make all the difference. The shoots they are taken from should be about three-parts ripened; that from which a flower has been cut about a week is generally in the right condition. Buds from plants growing under glass are rather better than those from the open, they being better matured, especially among Tea and Noisette varieties.

In about three weeks after budding look over your buds. By this time you should be able to see which buds are dead, and they may be replaced by budding again. In a dwarf stock you can easily insert a second bud on the opposite side to the first. In a standard it is best to choose another shoot or shoulder if possible; if not, then bud as nearly as you can to the other. Always leave your stock to grow at will for the rest of the summer after it has been successfully budded. Some few growers trim away a great portion of the wood in the autumn. With the exception of when a large number of stocks is needed for another year, and this growth is removed for cuttings, I do not see any advantage in cutting away that which would form a considerable amount of protection to the bud during winter. At pruning time cut away the whole of the stock close to the bud and give the young Rose growth the support of a stick as soon as it commences to shoot.

RIDGEWOOD.

ROSES OF THE SEASON.

ANYONE who has taken note of the kinds which have been shown in first-rate condition the past few weeks must have observed how well some sorts have been staged, whilst others have not been nearly so good as usual. At the early June show of the Royal Horticultural Society the finest Tea-scented Rose by far was Souvenir d'Elise Vardon, finer than which has rarely ever been seen. Innocente Pirola is another variety that has been shown well, better than usual. Ethel Brownlow has undoubtedly increased in popularity also. This is a really splendid and distinct Tea Rose. Souvenir d'un Ami has repeatedly been staged very fine; so have The Bride and Niphetos, whilst it is doubtful if Maréchal Niel was ever seen finer than at the show above quoted. As a contrast to all this, what a falling off there has been in Comtesse de Nadaillac, Mme. Thérèse Levet and Mme. de Watteville, whilst of Reine Marie Henriette and Cheshunt Hybrid not a flower have I seen. Marie van Houtte has held its own in no uncertain manner, and it is open to question if there is now a more serviceable garden variety. Catherine Mermet has not been altogether happy; nor have any of the Dijon section. These latter will probably be finer in the autumn.

Turning to the Hybrid Perpetuals and others, the same remarks can be borne out. Horace Vernet has this season been seen at its very best; it was the Rose of its section at the National from all quarters. A. K. Williams has also held its own, and the Earl of Dufferin has well maintained its popularity. That splendid new Rose Gustave Piganeau has risen in favour by its form and colour; at the National it was amongst the best. Mrs. J. Laing, although not quite so plentiful, has been shown remarkably well. That fine old Rose Charles Lefebvre has rather added to than diminished in favour; it has been repeatedly shown in the best condition; so also have Mrs. Reynolds Hole and Fisher Holmes, and no fault can be found with Alfred Colomb. Others might be quoted, but beyond a word in favour of Her Majesty, room will not permit; this is a grand Rose in such a season as this, but it is a pity that it is not really a perpetual. What has become of Sénateur Vaisse? This is a distinct old Rose, and well worthy of a premier place when well grown. The earlier Roses, as Charles Lawson, Paul Ferras, and others, have with me flowered well, but there is not much of a prospect for another season, no good wood having thus far been developed. La France escaped notice; this I have not seen nearly so good as usual. Other growers' observations would be most interesting.

ROSA.

The National Rose Society's annual exhibition.—Anyone visiting this show on Saturday, July 1, could not but be struck with the districts

from which the best blooms came. Taken on the whole, Colchester held its own, whilst Ipswich was well represented, and Essex also as a county; thus the eastern counties have fared better by far than some districts. This was also the case at the early exhibition in June at the Drill Hall. Yorkshire came well to the front, and when this is the case, the colour and freshness of the flowers always tell effectively. From the northern side of London, Hitchin was a victorious quarter; so also was Canterbury on the south. It was a pleasure to see such fine Roses also from as far north as Dundee. This shows what a phenomenal season the present has been. The districts that failed to hold their own in most cases were Berkshire, Wilts, Herts, Surrey, and as far west as Bath. It is just as well that the show was not put forward. It would have been manifestly unfair to do this as far as it pertains to those exhibitors who have on the present occasion shown what they can do in such dry seasons as 1893 has proved. What the quality will be at shows yet to be held may be fairly predicted from the results also recorded, but we may have a fine autumn display.—ROSA.

NOTES FROM THE CRYSTAL PALACE.

I CANNOT say I was disappointed with the show held by the National Rose Society last Saturday (July 1), because only a very few districts in the country have been favoured with suitable weather for Roses during the past three months. One might reasonably expect that such double varieties as La Boule d'Or, Etoile de Lyon and Ernest Metz among the Teas, with The Puritan, Comtesse de Serenye, Marie Rady and others among the Hybrid Perpetuals, would have opened well during the recent dry weather. But it has not been the case; in fact, I saw very few of these more double varieties exhibited. One noticeable feature about the show was the persistency of the old and well-tried kinds like Alfred Colomb, Baroness Rothschild, Charles Lefebvre, Duchess of Bedford, Fisher Holmes, &c. These came out much better than the majority of newer kinds, and again proved how generally useful they are. Mrs. John Laing, Earl of Dufferin, Jeannie Dickson, Suzanne Marie Rodocanachi and Gustave Piganeau among the newer H.P.'s were also good. I am more pleased with the last than I was last year, because it has stood the test of a season almost dead against weak growers. It is very free-flowering and constant, and if not vigorous, seems consistent in its growth. Very large and bright, thoroughly distinct and of good shape, Gustave Piganeau is perhaps the greatest acquisition among Hybrid Perpetuals since the advent of Mrs. John Laing. I carefully examined the boxes, and, with the exception of those from about three exhibitors, could only find here and there a bad flower. The premier bloom among the H.P.'s in the nurserymen's class was a grand Horace Vernet, found in Messrs. Harkness and Sons' stand of seventy-two. This stand also gained the 60-guinea trophy presented by amateurs, and was in every way the finest exhibit in the whole show. There was not a bad flower in it. Among other good blooms in the premier stand I noticed a magnificent example of Duc de Montpensier (a very vivid Rose, small as a general rule and very seldom seen in a first-class exhibition stand). Mrs. John Laing, Dupuy Jamain, Earl of Dufferin, Mme. V. Verdier, Alfred Colomb and Duchess of Bedford were also good. The Yorkshire champions were also first for forty-eight trebles, and I think it is now proved beyond doubt that during an ordinary season the first Saturday in July is the most appropriate date for the metropolitan show. This year, of course, exceptional, and instead of the northern growers having cause for complaint, this time, when the date falls on July 1, it is much too late for most of the southern growers. Returning to Horace Vernet, this grand exhibition Rose was good all through the show. I should say it was the best exhibited variety throughout. Dr. Tucker, Swanley Junction, staged six Her Majesty, that were very large, and a couple of them were really fine flowers. I noticed several good Sultan of Zanzibar. In Messrs.

Mack and Sons' stand was a good Marie Baumann, while Earl of Dufferin and Xavier Olibo were perhaps the two best Roses in Mr. Frank Cant's stand of seventy-two. In the forty-eight trebles, Messrs. Harkness had grand examples of Fisher Holmes, Duchesse de Morny, A. Colomb, Sir Rowland Hill (very deep in colour), and C. Lefebvre. A grand bloom of Duke of Wellington took my attention in the stand put up by Messrs. Burch, of Peterborough. In the class for the amateurs' trophy, a bloom of Ulrich Brunner in the winning stand (E. B. Lindsell's, Hitchin) and one of Auguste Rigotard in the second (Rev. J. H. Pemberton's) were very good. A Comte de Paris in Mr. Pemberton's stand of thirty-six singles was also good. This is a peculiar and very distinct Rose, deep crimson with a distinct shade of lilac, and mottled with deep scarlet, somewhat in the way of Duchess of Bedford.

In the class for six trebles, Mr. E. B. Lindsell had another grand Fisher Holmes, and A. Whitton,

Flowering shoot of the Anoor Yellow-wood (*Cladrastis amurensis*).
(See p. 17.)

of Bedale, Yorks, had a splendid bloom of Thomas Mills—at least that was the name attached, but I have not much hesitation in saying it was really Alfred Colomb, and many other growers were of the same opinion.

In the numerous classes for twelve of one variety the same general inferiority prevailed. Take Mrs. John Laing for example. There were ten twelves of this, and I do not think one could pick out more than six fairly representative blooms of this grand variety.

The Teas and Noisettes were very bad. If one had gone all through the show, it would probably have been found impossible to discover sufficient good blooms to have made up such a stand of trebles as Messrs. Prince, of Oxford, and the Messrs. Cant, of Colchester, have frequently exhibited in past seasons. "Baked up," "no rain since the end of March," &c., were the complaints from almost all quarters. Besides this, the majority of the blooms showed the stained and dirty appearance so common during a bad autumn.

What I consider by far the best bloom in the whole show was a grand Mme. Cusin in the Rev. Foster-Melliar's stand of Teas and Noisettes. It gained the medal, and was even in advance of Messrs. Harkness' Horace Vernet, bearing in mind the natural size, &c., of the two varieties. This stand was good, and was well ahead of its competitors, carrying off the amateurs' trophy for Teas in a far more decisive manner than that of last year. I assisted in judging both, and shall not soon forget the difficulty we had last season, when after several countings of points we only made one in favour of the winner.

The medal Tea in the nurserymen's class was a grand The Bride shown by Mr. B. R. Cant, of Colchester. Mr. R. Orpen, of the same town, had a good Maréchal Niel, and Messrs. Prior and Sons, also of the same district, were a good first with twelve of this variety. There was not a good bloom of Comtesse de Nadaillac, Souvenir d'Elise Vardon, Innocente Pirola, Ernest Metz, Cleopatra, or Catherine Mermet throughout the whole show.

New Roses.

Mrs. Harkness and Merrie England were again exhibited by Messrs. Harkness and Sons, but I cannot help thinking it was a pity to do so, for they were not nearly so good as when seen at Chester last summer. These two varieties are both sports from Heinrich Schultheis, a Rose that the present season has not suited in the least. By the way, I do not think there was a single bloom of it exhibited in the whole show. Mrs. Harkness is a grand flesh-coloured Rose, very sweet-

scented, free flowering, and particularly good during a dull season. Braiswick Beauty from Mr. Frank Cant, of Colchester, was much admired. This is somewhat after Bardou Job, and may be described as a larger type of it. It is semi-double, very free, and a good grower. The blooms were each from 3 inches to 5 inches over, while the colour was a glowing scarlet-crimson, suffused with the purple shading found in Horace Vernet. It is a grand Rose as shown here, and must rank as one of the best garden Roses.

In the class for twelve new Roses, Messrs. A. Dickson and Sons, of Newtownards, Ireland, had a good example of H.T. Kaiserin Augusta Victoria. This is a most promising Rose, free flowering, and a good grower. The colour is cream with a lemon shading. It may be described as a combination of The Bride, Innocente Pirola, and Medea. The seedlings in this stand I did not much admire, but one must remember that the present season is altogether against Roses, new and over-propagated varieties in particular. However, Messrs. Dickson and Sons gained the only two gold medals awarded to new Roses with Sharman Crawford and Marchioness of Londonderry. Helen Keller was also exhibited, but no ground plant being on view, it was not entitled to compete for a medal. Sharman Crawford is a good Rose that I shall describe as a combination of Marie Finger, Duchesse de Morny, and Marguerite de St. Amand. Marchioness of Londonderry is pure white, very double, and large. The flowers had evidently been knocked about, and, like the majority in the show, gave unmistakable signs of the season. It is a short grower, and from the buds on the ground plant may be somewhat difficult to open during wet or cold summers.

A grand box of Crimson Rambler was exhibited by Mr. C. Turner. It is small, semi-double, and very free-flowering. A grand plant was shown in a basket. It must have been some 8 feet to 10

feet high before the lips were cut off. It was one mass of flowers. Now that these old-fashioned Roses are in such favour, Crimson Rambler is certain to take a very prominent place.

SOCIETIES AND EXHIBITIONS.

ROYAL HORTICULTURAL SOCIETY.

CHISWICK SHOW.

JULY 11.

THIS society had a very interesting and beautiful show at Chiswick on Tuesday last, in conjunction with the National Carnation and Picotee Society. We may mention that the Chiswick local society was dissolved in 1891, and the R.H.S. held a show in its place. The continuance of this new feature in the society's programme depends upon the support received from residents in the neighbourhood. We have not sufficient space to deal with all the exhibits outside the general committees, but point out the leading features of interest.

Orchid Committee.

An award of merit went to each of the following:—

CYPRIPEDIUM MASSALIANUM.—This is of peculiar interest as the first hybrid Orchid, of which one of the parents is the famous *C. Rothschildianum*. It is a cross between that type and *C. superciliosum*, the plant partaking chiefly of the character of the latter parent. It is a bold and handsome kind, the flowers large and broad; the dorsal sepal green, striped with crimson-brown, and the petals green, blotched with quite a chocolate tone, whilst the lip is brown. This interesting hybrid evidently possesses a strong habit of growth. From Messrs. Sander and Co, St. Albans.

CYPRIPEDIUM STONEI CANNARTE.—This is a remarkably fine form of a well-known species. The flower is very robust, both dorsal and lower sepals broad, stout, white, striped with chocolate, the petals yellow striped with a similar colour, going off into self crimson, the lip dull crimson, veined with a deeper shade. From Mr. T. Statter, Stand Hall, Manchester.

Orchids were not very numerous, but sufficient were shown to make an interesting display. A very fine group came from Messrs. Sander and Co. This comprised a number of excellent species and varieties. *Aerides Picotianum* is a pleasing kind, the flowers large, creamy-yellow, the lip rosy purple, and the sepals and petals tipped with the same colour. A good form of *Brassia* is *B. Lanceana longissima*, the plant bearing two spikes, four flowers to each. The lip is yellowish in colour, and the sepals and petals green blotched with brown. *Cattleya granulosa* was represented by a good form, also *Lælia Schilleriana*, the sepals and petals touched with magenta, the lip crimson-purple. A lovely *Cattleya* is *C. Gaskelliana* (Cook's variety); it was quite the gem of the collection, the flowers of a delicately soft rose colour, the lip touched with yellow at the entrance to the throat. Several *Cypripediums* were exhibited; a hybrid named *Umlaufianum* is the result of a cross between *C. Lawrenceanum* and *C. Chantini*, the flowers very attractive and of a highly polished character. The lip is deep brown, the dorsal sepals green striped with brown, white at the margin, and the petals of distinctive colour. *C. Youngianum* is another acquisition and of attractive colour, whilst a note may well be made of the beautiful *Sobralia xantholeuca*. *Odontoglossum vexillarium* var. *superbum* is a beautiful form, remarkably free, the flowers small, but brilliantly coloured, rose blotched with deep crimson at the base of the lip and surrounded with pure white. *Epidendrum vitellinum majus* was very fine, also the white-flowered and free *Burlingtonia pubescens* (silver medal). Messrs. H. Low and Co., Upper Clapton, had a small and pleasing group of Orchids, comprising several rare kinds. *Aerides l'Ansoni* is a charming form, the

flowers of a rosy purple shade; whilst of *Cattleyas*, *C. Gaskelliana*, *C. Eldorado splendens*, *C. Wallisi*, pure white, yellow in the throat, and *C. Schilleriana* were well represented. We were pleased to see in full bloom the creamy white *Stanhopea Amesiana*, which is of distinct beauty (silver medal). Flowers of *Cattleya Rex*, which has been described before in THE GARDEN, came from Mr. W. C. Clark, Orleans House, Sefton Park, Liverpool. Mr. T. Statter had a number of interesting Orchids. *Lælia monophylla* is very charming, the flowers small, clear orange or apricot colour. Messrs. W. H. Lewis and Co., Southgate, showed *Cypripedium Bradshawianum*, which is of various shades of brown, the petals of polished character, deep green at the base, the lip similar to that of *C. Spicerianum*. *Cattleya Gaskelliana* var. *southgatensis* is beautiful in colour, the sepals and petals touched with rose, the lip white, crimson-purple at the base, with a suffusion of yellow within the throat.

Floral Committee.

First-class certificates were given to the following:—

LILIUM ALEXANDRÆ.—This was provisionally named thus, and exhibited both by Messrs. Wallace and Co., of Colchester, and by Messrs. J. Veitch and Sons, Chelsea, under the Japanese name of *L. Ulkyuri*. It is supposed to be a cross between *L. auratum* and *L. longiflorum*. It is quite distinct, and, judging from several plants exhibited, a useful and certainly handsome Lily. The flowers are large, open, of the *auratum* character, carried freely on sturdy stems, and have deep brown anthers. It is quite dwarf in habit and excellent for growing in pots, whilst it may also be used to advantage for planting amongst dwarf shrubs in the garden.

LILIUM LOWI.—This is a remarkably distinct and beautiful Lily. We know nothing like it. The plant is evidently tall, judging by the specimen shown, which bore two flowers, each of refined and delightful colour. They are not very large, somewhat campanulate in shape, and white, freely spotted on the under side with crimson-purple, this colouring showing up strongly against the white ground. We shall hope in time to see this Lily tried in the open. It is evidently a great gain to the already long list, and merits attention from all Lily lovers.

An award of merit was given to each of the following:—

ALSTREMERIA AURANTIACA.—We need not describe this further than by saying that it is a very large and richly coloured variety of the type. Valuable for the size and superb colour of the flowers. From Mr. G. H. Cannell, Sheffield.

NICOTIANA COLOSSEA VARIEGATA.—This is a remarkable distinctly variegated plant, which we remember was finely shown by the same exhibitor at the Ghent quinquennial. It has very large leaves, broad, long, and handsome in colour, the centre deep green, surrounded with a lighter shade on a creamy white ground. A showy, but not garish variety, which we heartily commend for its distinctness and bold colouring. From Mr. J. Sallier, Neuilly, Paris.

DRACENA INDIVISA AUREA VARIEGATA.—A well-variegated plant, the leaves green, striped with creamy white, and of robust growth. From Messrs. J. Laing and Sons, Forest Hill.

CALADIUM BARONNE DE MAIMORE.—A distinct variety, the leaves well coloured, the ground creamy white, margined and variegated with deep green, the centre rich crimson with ribs of the same intense shade. From Messrs. J. Laing and Sons.

A botanical certificate was given to

FERRARIA ANTHEROSEA.—This is a very singular plant introduced from the Cape in 1800. The *Ferrarias* are allied to the *Irises*, and *F. antherosa* has much the expression of an *Iris*, the segments deep sea-green in colour, crimped at the edge, the base yellow with spots of deep chocolate. Exhibited by Messrs. Veitch and Sons.

The finest exhibit before this committee was unquestionably the splendid group of Ferns from Mr. H. B. May, Dyson's Lane Nursery, Edmonton, to which a silver-gilt medal was most worthily given. Want of space prevents enumeration of many kinds, but we may mention that conspicuous were *Adiantum rubellum*, *A. Farleyense*, *A. lunulatum*, *Pteris Victoriae*, *Gymnogramma schizophylla gloriosa*, *Nephrolepis davallioides multiceps*, the beautiful *Pteris Mayi*. Besides the Ferns were the variegated *Phrygium variegatum*, *Dracena Prince Mamouk Bey*, crimson-leaved; *Aralia elegantissima*, and *Croton Burgmani*, green and cream-white. A superb mass of colour was made by the varieties of *Begonia semperflorens* from Messrs. Sutton and Sons, Reading. The several kinds were grouped in distinct batches, and made an exhibit of great beauty. They were sturdy examples in full bloom and only six months from seed—a noteworthy point. Very fine were *Reading Snowflake*, the flowers pure white; *Crimson Gem*, bright crimson, free and pleasing; *Duchess of Edinburgh*, white, with broad edge of pink-rose, very robust, the leaves of deep green colour; *Duchess of York*, rose-carmine, exceptionally bright and free; *Coral Gem*, lovely pink shade, the flowers borne in clusters; *compacta rosea*, rose in colour, the plant compact in growth and with deep green leaves. Besides the above also shown were *Achimenes Rosy Queen*, bright rose; *A. longiflora*, deep blue, and an excellent strain of double bedding *Stocks* (silver medal). A silver-gilt medal was awarded to Messrs. C. Lee and Son, Hammer-smith, for a group of shrubs with ornamental leafage, the majority variegated. Messrs. B. S. Williams and Son, Upper Holloway, had a large and interesting group, comprising a variety of things. Amongst Orchids we noticed *Brassavola Digbyana* in full bloom, a good type of *Cypripedium superbiens* named *Demidoff's* variety, *Dracena indivisa variegata* and numerous other things in excellent bloom (silver medal). Mr. T. S. Ware, Tottenham, received a similar award for a large collection of Carnations and Picotees cut from the open. The flowers, if not large, were fresh, especially those of *Arcadia*, *Prince George*, the fine old *Alice Ayres*, *Danger*, *crimson self*; *Florence Emily Thoday*, pure white; *Horace*, scarlet; *Raby*, Mrs. F. Watts, an excellent white, and *Countess of Paris*. We have referred to Mr. Martin Smith's group of Carnations under the Carnation and Picotee Society's report. A silver medal was given for the display. The specimen Ferns from Mr. Porteous, gardener to Mr. E. H. Watts, Devonhurst, Chiswick, were awarded a bronze medal. Other interesting exhibits before this committee were numerous. Messrs. J. Laing and Sons had a fine double yellow tuberous *Begonia* named *Lady Balfour of Burleigh*, also *B. Sunbeam*, the flowers single, large and rich orange-yellow. Messrs. Jas. Veitch and Sons had *Strobilanthes Dyerianus*, described recently in THE GARDEN; *Begonia decora*, moderately large leaves of deep colour; and *Pitcairnia amaryllidiflora*, the flowers densely crowded in the spike and brilliant scarlet in colour. The tuberous *Begonias* from Messrs. H. Cannell and Sons, Swanley, were noteworthy. They were well-grown plants, and raised from seed sown last February. The flowers were double and of splendid colours. Mr. Waterer, Knap Hill, Woking, had a boxful of *Spiraea Anthony Waterer*, the flowers intense crimson. M. Victor Lemoine, Nancy, had a group of hybrid *Begonias* of great value and interest. No medal was apparently given to them, although well deserving such award. The finer kinds were *B. Schmidt rosea*, dwarf and very free; *La France*, brilliant carmine-rose; *B. Schmidt alba*, dense and compact; *B. Abundance*, pink; *Diademe*, bright carmine-rose; *Sieberiana*, the flowers large, and pick; *Illustration*, crimson; and *Bajocensis*, tinted with pink, very pleasing. *Lobelia Lewry's Beauty*, a bedding variety, with remarkably intense blue flowers, was shown by Mr. Lewry, gardener to Mrs. Blake, Duppas Hill Terrace, Croydon. Messrs. H. Veitch and Son, Exeter, had an interesting exhibit, comprising such things as *Cytisus nigricans* and other flowering shrubs.

Fruit Committee.

Some fine collections of fruit were shown. Messrs. Veitch staged 160 dishes of hardy fruit, comprising a great variety of Gooseberries, Cherries, and Apples. The best dessert Gooseberries were White Champagne, Bright Venus, Greengage, Hedgchog, Early Sulphur, Rumbullion, Red Champagne, Ironmonger, Keens' Seedling, and Warrington. Amongst the large cooking varieties (green) were Stockwell, Matchless and Green London; yellow—Ringer, Trumpeter, Pretty Boy, Railway (very fine), and Admiral Boxer; white—Whitesmith, King of Trumps, Queen of the West, Alma and Progress; red—Napoleon, Clayton, Slaughterman, Forester, Companion, Highlander, and Whinham's Industry. There were also some branches heavily laden with fruit cut from cordon trees. Some very fine Morello and dessert Cherries, Raspberries, Currants (Red and White) and early dessert Apples were also shown (silver-gilt Knightian medal). Messrs. Rivers, Sawbridgeworth, staged some magnificent Cherries, also very fine Early Rivers' Nectarines, Princess of Wales Peaches, and a very large seedling Peach with yellow flesh, with Early Transparent, Monarch, Victoria, Grand Duke, and Jefferson Plums (silver Knightian medal). Mr. Miller, gardener to Lord Foley, Ruxley Lodge, Esher, staged well-finished Peaches, the variety being Royal George, Violette Hative and Elruge Nectarines of good colour and size, and a fine dish of Ponderosa Tomato. Mr. Thomas, The Royal Gardens, Frogmore, sent a very fine dozen of Walburton Admirable Peaches. Mr. Leach, Albury Park Gardens, staged two dishes of Black Hamburgh Grapes, two dishes of good Grosse Mignonne Peaches, Early Orleans, and Rivers' Early Prolific Plums, fruiting branches of Bradley's King of Damsons to show its bearing qualities, and a new seedling Raspberry of much merit named Mrs. Clarke. Mr. Hudson, Gunnersbury House, Acton, sent six large bunches of Black Hamburgh Grapes cut from a vine in a 14-inch pot; these were most meritorious. Mr. Douglas, The Gardens, Great Gearies, sent a new seedling Grape somewhat like Buckland Sweetwater. It is a thick-skinned, large-berried variety, and should prove a good keeping Grape and a good traveller.

A seedling Melon was staged by Mr. Thomas, who had six fine fruits of a scarlet-fleshed variety, but lacking flavour. A nice-looking green-fleshed Melon was sent by Mr. Crawford, Coddington Hall, Notts, but over-ripe. Mr. J. Barkham, Longford Hall, Isle of Wight, and Mr. Brook, Red Rice, Andover, also sent Melons, but of no special merit. A new seedling Vine, with variegated or white foliage and fruit, but certainly a step backward as far as appearance went, was shown in a pot by Mr. South, Neasdon. Seedling Red Currants were sent by Mr. Lowe, Shirenewton Hall, Chepstow, a dark red large variety, being named Lord Llangattock, and a lighter red—Jubilee. As only a few bunches were sent, it was impossible to form any opinion as to them. Messrs. Rivers also sent a fruiting branch of a sport or seedling Red Currant of great merit, but too much like La Versailles. Tomatoes were shown in quantity, Mr. W. A. South, Neasdon, sent five dishes of seedlings, but none found favour with the committee. A very fine plant in a 12-inch pot was sent by Mr. T. Berridge, Southall, heavily laden with fruit, but too much like Conference to get an award. A nice-looking Tomato, round and smooth, with crimson flesh and very few seeds, was sent by Messrs. Hurst. This was considered a good addition to the list of these fruits, and was asked to be sent to Chiswick to test its fruiting qualities, the flavour being very good. Twelve varieties of Peas were sent by Mr. Gilbert, Burghley, some past their best, but fine pods. A new Broad Bean named Taber's Perfection was shown by Messrs. Taber, Cooper and Co., Witham, Essex. It was requested to be sent to Chiswick for trial. A new Pea about 9 inches high was sent by Messrs. R. Veitch and Son, Royal Exotic Nurseries, Exeter. This is quite distinct and is named Lotus tetragonolobus, or Asparagus Pea, the pods of which are cooked whole. The flowers are yellow and the foliage is small and

hairy. In the classes for Messrs. Sharpe's prizes for Peas, Mr. H. Balderson, Corner Hall, Hemel Hempstead, was first; Mr. Waite, gardener to the Hon. Col. Talbot, second, and Mr. T. Watkins, Grove House, Merrow, third.

Local Show.

We cannot refer to this at great length. Many of the classes were not of much interest, comprising small cottagers' exhibits. Reference is made to the more important. Roses were shown well considering the season. The chief class was for twenty-four distinct, triplets, the first prize being a silver challenge cup value £26 5s., presented by Mr. J. Mantell, of Gunnersbury. This cup becomes the property of any exhibitor winning it three times, not necessarily in succession. Mr. Benjamin Cant has won it twice, but on this occasion the Yorkshire growers, Messrs. Harkness and Sons, Bedale, secured the award with flowers of remarkably fresh and bright colour, especially fine being May Quennell, Duke of Bedford, Charles Darwin, E. Y. Teas, Susanne Marie Rodocanachi, Duke of Connaught, and Mme. Haussmann. Mr. B. R. Cant was a good second, and Mr. Frank Cant, both of Colchester, third. For twenty-four blooms, distinct, Messrs. Harkness and Sons were again first, showing well such kinds as Mrs. Reynolds Hole, Susanne Marie Rodocanachi, Louis van Houtte, Horace Vernet, Gustave Piganeau. The best twelve bunches of hardy perennials came from Mr. Sage, gardener to the Earl of Dysart, Ham House, who had Gypsophila paniculata, Coreopsis lanceolata, and Eryngiums in good condition; whilst for eight bunches, Miss R. Debenham, St. Peter's, St. Albans, was first.

Another important division was for plants, but the competition was not very keen. The chief class was for an arrangement to occupy a space not exceeding 100 square feet, and the first prize was given to Messrs. Fromow and Sons, Chiswick, for a good group. In the amateurs' class for a group, Mr. Porteous, Devonhurst Gardens, was first. The group of Pelargoniums from Mr. Chas. Turner, which was the only exhibit in this class, and the twelve remarkably fine tuberous Begonias from Mr. Ford, gardener to Sir C. Pigott, Bt., Wexham Park, near Slough, call for special notice. Mr. W. H. Davis, gardener to Mr. T. E. H. Hodgson, Chiswick, showed Gloxinias well; also Mr. A. James, gardener to Mr. E. Hyde, Hillcrest, Ealing. The stand of flowers for a hall and table, in each case from Miss Lilian Hudson, won the first prize. The flowers were arranged with rare taste.

There was only a limited competition in the fruit and vegetable classes. Mr. T. Osman, Ottershaw Park, Chertsey, was first for white Grapes, showing nice bunches of Mrs. Pearson well finished; second, Mr. Payne, Neasdon. Mr. Osman was also first for black Grapes, staging good Hamburgs, the berries large and finely finished; second, Mr. Waite, Esher. Mr. Divers, Ketton Hall Gardens, Stamford, had the only dish of Strawberries, staging a good dish of British Queen. Mr. A. Pears, Springrove, Isleworth, was first with Peaches, showing nice Violette Hative. Mr. Waite was an easy first for Messrs. Carter's prizes for six dishes of vegetables; second, Mr. A. South, Neasdon. There was fair competition in the class for three dishes of Potatoes, Mr. Waite being first with nice tubers of Ashtop Fluke, Sutton's Seedling, and Reading Giant; Mr. Farmer, Blenheim Road, Gunnersbury, being a good second. In the Tomato class, Mr. Sage was first with medium-sized well-coloured fruits of Conference, Perfection, and Sutton's A 1. Mr. Hodgson, Grove Park, was first for a brace of Cucumbers. The cottagers' vegetables showed the effect of the long-continued drought both as regards numbers and size. Only one collection of hardy fruit was staged. This was sent by Mr. Farmer, Gunnersbury, and was most creditable considering the season. Mr. Farmer and Mr. J. Gale were the most successful exhibitors in the classes for vegetables.

United Horticultural Benefit and Provident Society.—The quarterly meeting of this so-

ciety was held on Monday evening last at the Caledonian Hotel. Three new members were elected, making thirty-five in the six months. The death of a non-paying member occurred in May last, and the amount standing to his credit (£21 7s. 4d.) was paid to his widow. The late member ceased to contribute in 1886. One member only is on the sick fund at the present time. The treasurer reported having invested £200 in West Bromwich 3 per cent. stock since the last meeting.

NATIONAL CARNATION AND PICOTEE SOCIETY.

This society held its annual exhibition on an earlier date this year than usual by reason of the hot summer, which has brought flowers rapidly to perfection. We were surprised to find that the exhibits generally were of great merit, and the border kinds formed a feature of marked interest, a contrast to the array of blooms in paper collars stuck into boxes. We were pleased to see throughout a keen competition, and a number of beautiful novelties were shown.

The chief class in the Carnations was for twenty-four blooms, not less than twelve dissimilar varieties. The premier position was taken by Mr. J. Douglas, The Gardens, Great Gearies, Ilford, who had excellent blooms, fresh, large, and of fine colour, a smooth even collection. They comprised Tim Bobbin, c.b., Mrs. Constance Grahame, s.f., Mrs. Douglas, p.f., Charles Henwood, p.f., Harmony, p.p.b., Edward Adams, s.b., Edward Rowan, c.b., Arthur Medhurst, s.b., Agricola, p.f., and Robert Lord, s.b., besides a number of very beautiful seedlings. A very good second was Mr. C. Turner. The more conspicuous were Charles Henwood, p.f., Lady Mary Currie, r.f., Billy Henderson, p.f., and Harmony, p.p.b. Mr. F. Hooper, Bath, third. Several exhibitors competed in the class for twelve blooms dissimilar, Mr. Martin Rowan, Manor Road, Clapham, winning first prize with a pleasing box, the flowers pure and especially noticeable because grown almost in the metropolis. This shows what may be done with the Carnation in large towns. We may mention that the finest blooms were Robert Houlgrave, s.b., J. D. Hextall, c.b., Sportsman, s.f., and Rob Roy, r.f. Mr. Arthur R. Brown, Handsworth, Birmingham, won the second prize. It is scarcely necessary to remark that the flowers in the classes such as six, seven, eight are not of great merit. Another class was for six blooms, dissimilar, and the first prize-winner was Mr. J. J. Keen, Southampton, who had very good flowers of Squire Potts, s.b., Alisemond, s.f., Robert Houlgrave, s.b., and J. Douglas, p.f. Mr. A. Greenfield, Sutton, Surrey, was second.

The premier Carnation was Robert Houlgrave, the splendid scarlet bizarre flower, in Mr. Rowan's first prize stand of twelve blooms.

The Picotees, we think, were the more beautiful feature of the show. There was, as in the case of the Carnations, excellent competition, and the first prize in the class for twenty-four blooms, not less than twelve dissimilar varieties, was well won by Mr. Chas. Turner, of Slough, who had refined blooms, smooth, and pure white in colour. Especially fine were Sylvia, l.p. edged, Esther, l.p.e., Favourite, l.r.s.e., Brunette, h.r.e., Madeleine, h.r.s.e., Little Phil, h.r.s.e., and Lady Holmesdale, h.r.s.e.; Mr. Douglas second, he having amongst others the old, but still beautiful Liddington's Favourite, one of the best of the rose and scarlet-edged class. For twelve blooms there was again splendid competition, and Messrs. Thomson carried off the first prize for excellent blooms, whilst Mr. A. R. Brown was second. Several competed in the class for six blooms, dissimilar. Here Mr. A. W. Jones was the most successful with very smooth examples of Little Phil, h.r.s.e., Clara Penson, l.p.e., Campanini, h.r.s.e., Norman Carr, h.s., Mrs. Payne, r.s.e., and Brunette. Mr. J. P. Sharp, Birmingham, was a good second, and Mr. A. Greenfield third.

An interesting class is for twelve yellow ground Picotees, dissimilar varieties. The first prize in this class was gained by Mr. Chas. Blick

gardener to Mr. Martin Smith, Hayes Common, Kent, with remarkably fine flowers of, amongst others, Stadtrath Bail, Alisemond, Dorothy, Annie Douglas, Remembrance, Almira, Chrysolora, Lohengrin, and Cowslip. Mr. Turner was an excellent second, Agnes Chambers and Almira being of note. A large number of competitors showed in the class for six yellow ground kinds, the premier award going to Mr. A. W. Jones. The classes for single specimens were also well filled. The premier Picotee in the exhibition was the variety Mrs. Payne, a fairly good flower, from Mr. A. W. Jones.

The selfs and fancies produced good competition. We care much for this class, and the twenty-four blooms, not less than twelve distinct kinds, from Mr. Chas. Turner, were splendid for colour; Gladys, blush—a lovely tint, Rose Unique, Ruby and White Lady were conspicuous. Mr. J. Douglas came second with very smooth blooms, and Mr. Chas. Blick third. For twelve, dissimilar, Messrs. Thomson were a good first; Mr. A. R. Brown second. In the class for six blooms, dissimilar, Mr. A. W. Jones came first, showing well the varieties Norman Carr, Stadtrath Bail, Germania, Almira, Lord Rendlesham and Gladys; Mr. J. F. Kew, Southend, second.

There was one class for pot plants, twelve distinct kinds, and Mr. J. Douglas was first, Niphetos, a beautiful white self, being amongst those shown; Mr. Chas. Turner second. Unlike former years, no card or "paper collar" was permitted at the back of the flower, freedom of flowering and cultural excellence being the chief points.

One class was for six Carnations and Picotees, open to those who have never won a prize, and the premier award went to Mr. C. Harden; whilst for a vase of any kind of Carnations, Mr. Douglas was first with a tasteful arrangement. Messrs. Thomson were first for three sprays. Messrs. J. Douglas and Thomson were first and second respectively for six button-holes.

We come now to the most interesting section of the show, the "Martin Smith" prizes, and the chief class was for not less than twelve trusses of the best border self-coloured variety. We may remark that in these classes the flowers must have been cut from plants wintered without protection in the open, not dressed in any way, and shown with Carnation foliage and buds. It is also stipulated amongst other things that a burst calyx signifies disqualification—one way to discourage this objectionable type. The first prize in the class named above was won by Mr. Sage, gardener to the Earl of Dysart, Ham House, Richmond, who had a splendid scarlet self, the flowers full, quite intact, and remarkably effective; Mr. E. C. Goble second, Mr. Douglas third with a fine rose self, and Mr. Divers, Ketton Hall Gardens, Stamford, fourth with Ketton Rose. It is a pity that many of the flowers are shown as seedlings or under numbers. It is impossible to describe them thus shown. Mr. J. Douglas was first for six varieties of selfs—a good selection of fresh, well-coloured flowers. For nine varieties of flake, bizarre or fancy Carnations or Picotees, not less than six trusses of each variety, Mr. Douglas was again first with lovely flowers, Mr. F. Hooper second.

The miscellaneous exhibits of Carnations and Picotees are dealt with for the most part in the report of the Royal Horticultural Society. A beautiful white self named Alice was brought from Gravetye Manor, Sussex. The flowers are very pure, full, serrated at the edge, and not in the least split. The bunch was loosely and simply arranged in a Munstead glass. A large collection was shown by Mr. Blick, gardener to Mr. Martin Smith, seedling Carnations and Picotees of many kinds being exhibited. A first-class certificate was granted to each of the following: Sirius, a fancy Picotee, full, and heavily splashed with bright scarlet on a buff ground; George Cruickshanks, also of this class, buff ground, edged and splashed with scarlet; Rosa Bonheur, scarlet flake, very bright and decided; Sir Garvain, yellow, stained with apricot (a distinct and handsome Carnation); Tom Sayers, a good type of Carnation, the flowers

full, not split, buff, striped occasionally with crimson. Bendigo is a rich purple self, intense shade of colour and full, striking flower; Aubry Campbell, yellow self, fine grower, vigorous, and with bold compact flowers. Other kinds thus honoured were The Dey, yellow ground Picotee, heavily edged with rose; Water Witch, blush self Carnation, very pleasing; Mephisto, similar to the old Clove in colour, but deeper, a fine self; and Ellen Terry, a very large white self Carnation, sweet and useful for cutting, besides valuable in the garden. Cardinal Wolsey, yellow ground Picotee, a great improvement on Victory; Duke of Orleans, yellow self Carnation, fine shade; Hayes' Scarlet, self scarlet kind, very bright, and The Patriot, a crimson bizarre of great merit, the colouring clear and distinct, may be also mentioned. A very beautiful seedling of Mr. Douglas is Agricola, a rich purple flake, full, and of rich colour.

GARDENING AND FORESTRY EXHIBITION, EARL'S COURT.

JULY 12.

A show of Roses and Carnations, besides miscellaneous plants and fruit, was held at Earl's Court on Wednesday last. The exhibition was not large, but many interesting things were to be seen.

Roses.

The competition was not keen in this section, except in one or two classes, but the flowers were fresh and of splendid colour, especially the dark-coloured Hybrid Perpetuals. The chief class was for forty-eight blooms, distinct, three trusses of each, and the first prize went to Mr. Chas. Turner, the Royal Nurseries, Slough, for very fine blooms, conspicuous being Ulrich Brunner, Jeannie Dickson, Pride of Waltham, Charles Lefebvre, Crimson Rambler, Marie Baumann, A. K. Williams, Duke of Teck, Suzanne Marie Rodocanachi and Merveille de Lyon. Messrs. D. Prior and Son, Myland Nurseries, Colchester, were the leading exhibitors throughout. They were first for twenty-four varieties, distinct, triplets, and exceptionally fine for colour were the blooms of Fisher Holmes, Anna Ollivier, Lady Sheffield, Suzanne Marie Rodocanachi, Alfred Colomb, Black Prince, Gustave Piganeau, Marie van Houtte and Souvenir de la Malmaison; Mr. George Mount, The Rose Nurseries, Canterbury, second. In the corresponding class for single trusses, Messrs. D. Prior and Son were again first, La Rosière being well shown, also Mrs. John Laing; whilst Mr. Geo. Mount was second.

The best competition was in the class for twelve Hybrid Perpetuals, in which the first prize was taken by Mr. A. Gibson, gardener to Mr. T. F. Burnaby-Atkios, Halstead Place, Sevenoaks. The flowers were brilliant in colour, and the finest were those of Baroness Rothschild, Mlle. Marie Rady, Capt. Christy, Marie Baumann, Maréchal Vaillant, Charles Lefebvre and Francois Michelon. A very good second was Mr. J. Parker, Oakfield, Hitchin. We ought to have mentioned that there was yet another class for forty-eight, distinct, single trusses, in which Messrs. Paul and Son, Cheshunt, were first with splendid blooms fresh and highly coloured, A. K. Williams, Eclair and Grand Mogul in particular.

In the Teas and Noisettes the best box of twenty-four blooms was from Messrs. D. Prior and Son, and included very good flowers of Catherine Mermet, Souvenir de S. A. Prince, The Bride, Comtesse de Nadaillac, Mme. Hoste, and Edith Gifford; whilst for eighteen of the same section, the first prize went to Mr. G. Mount, who had excellent examples of Edith Gifford, The Bride, Innocente Pirola, Ethel Brownlow, Princess of Wales, Mme. Chartas, and Catherine Mermet. Mr. J. Parker had the finest twelve.

We have often referred of late to the garden Roses, and we need not do more, therefore, than mention that Messrs. Paul and Son had the finest twenty-four bunches, the varieties much the same as those hitherto recorded.

Carnations and Picotees.

The Carnations were much the same as those shown at the National Carnation and Picotee show on the previous day at Chiswick, the prize-winners also being practically the same. The chief class was for twenty-four blooms of Carnations, not less than twelve distinct kinds, and the first prize went to Mr. Rowan, Clapham, who had remarkably fresh flowers of r.f. Rob Roy, s.b. Robert Houlgrave, p.p.b. Wm. Skirving, p.f. George Melville, c.b. Master Fred, p.p.b. Sarah Payne, and s.f. Sportsman. Mr. C. Turner and Mr. J. Douglas were second and third respectively. For twelve distinct, Mr. G. Chaundy was to the front, followed by Mr. F. Hooper. It is needless to mention names. The leading kinds were represented. There were similar classes for Picotees. The best twenty-four were from Mr. C. Turner, who had delightfully fresh flowers of r.e. Brunette and b.r.e. Lady Ponsonby; Mr. Douglas a good second. The best twelve blooms, and they were very fine, were from Mr. F. Hooper, of Bath.

The classes for selfs were pleasing, and a very good collection of twenty-four blooms, not less than twelve distinct kinds, came from Mr. Chas. Turner, King of Scarlets, White Lady, and Rose Unique being exceptionally fine. Mr. J. Douglas had an excellent second-prize stand, Mr. J. Walker Thame, Oxon, had twelve fine selfs and fancies, in which class Mr. Rowan was second; whilst the most meritorious yellow ground varieties, distinct, were from Mr. Douglas.

Miscellaneous Classes.

The most important of these was for twelve bunches of stove and greenhouse flowers, and equal firsts were awarded to Mr. G. Wythes, gardener to the Duke of Northumberland, Syon House, Brentford, and Mr. J. Prewett, Swiss Nursery, Hammersmith. The premier award might have been given to the larger and more varied clusters of Mr. Wythes, Hymenocallis macrostephana, the old Gloriosa superba, and the rich crimson Canna Franciscue being of note.

Several charming groups were arranged not for competition, and a gold medal was given to Mr. H. B. May, Edmonton, for his beautiful arrangement of Ferns and foliage plants. The several kinds were noted at Chiswick on the previous Tuesday. Messrs. Cheal and Sons, Crawley, received a silver-gilt medal for a large and very fine display of Sweet Peas, tufted Pansies, and other hardy flowers. Want of space forbids mention of individual species and varieties. It was one of the best groups we have seen from this firm. Messrs. Barr and Son, Long Ditton, had an extensive display of hardy flowers, Phloxes, Lilies, Gladiolus brencleyensis, and a charming group of rock plants disposed in a natural way, the little things creeping over stones. This is the way to exhibit alpine (silver medal). Mr. Wythes must be highly praised for his splendid display of Carnations in bunches, the flowers of the best border kinds, and exquisitely arranged with Maiden hair Fern, Raby, Amber, a lovely carmine colour, and the Crimson Clove were conspicuous. A silver medal was worthily given. A similar award was made to Messrs. Jackman and Son, Woking, for a large collection of Hybrid Perpetual and button-hole Roses, not forgetting a splendid box of the H.P. Mrs. John Laing. Mr. John Walker, Thame, had a meritorious group of cut Carnations, representing great variety, and was given a silver medal. Messrs. Paul and Son, Cheshunt, also had a charming collection of Carnations in bunches and a boxful of Canna flowers of the varieties introduced by this firm. Mr. Sage, gardener to the Earl of Dysart, Ham House, Twickenham, had a group of large bunches of the best hardy perennials, and was awarded a silver medal, the same exhibitor having the rich scarlet self Carnation named Jim Smyth. A group of Anthuriums and fine-foliaged plants was exhibited by Mr. W. Chuek, gardener to Mr. P. Thellussen, Brodsworth Hall, Doncaster. Messrs. Wallace and Co., Colchester, showed Lillium Alexandra, described in R.H.S. report. A new Carnation named

Mrs. Anst'ss, a large-flowered light self apricot colour, was shown by Mr. Anstiss, of Brill.

Fruit.

The display of fruit was superior to that of previous shows both in quality and quantity. Messrs. Rivers staged the very fine collection of Cherries they put up at Chiswick the day before with additions, and there were some good collections of other fruit not for competition.

A first-class certificate was awarded to

MELON EARL'S COURT HYBRID, of medium size, nicely netted, the flesh scarlet and of good flavour. It much resembled that good old variety Turner's Scarlet Gem. From T. Elisha, Old Windsor.

There were nine lots of three bunches of black Grapes. Mr. A. Maxim, gardener to the Hon. Miss Shaw-Lefevre, Heckfield, Hants, was first with B. Hamburg, large bunches and berries, and nicely finished, Mr. Osman, Ottershaw Park, Chertsey, being second with bunches of perfect shape, but a trifle smaller in berry. In the class for white, any variety, Mr. W. Lane, King's Ride, Ascot, was first with Muscat of Alexandria, nicely coloured, the bunches of medium size. Mr. W. Tidy, Stanmore Hall, was second with three very nice bunches of Foster's Seedling; this lot would have secured the premier award had they been riper. There was a great number of Melons staged in the class for three fruits (not to be cut), and with such restrictions the nicest looking fruits stand best chance, flavour, the chief point in a Melon, not being considered. Mr. Little, Milton Court, Dorking, was first with three fruits of Hero of Lockinge; second, Mr. Mortimer, Swiss Nursery, Farnham, with the same variety. For one Melon, Mr. T. Elisha, Old Windsor, was first with a large seedling variety. Peaches were numerous and good, ten lots being staged. Mr. T. Billings, Ham Hall Gardens, Ashbourne, Derby, had a grand dish of Barrington. Mr. Wallis, Keele Hall, Staffs, had a fine dish of Bellegarde, but not quite ripe enough. Nectarines were very good, Mr. Billings, Ham Hall, Ashbourne, securing the premier award with good, well-coloured Lord Napier. Mr. Wallis was a close second with Victoria. There was only one exhibitor for three dishes of Strawberries, Mr. Chuck, Brodsworth Hall Gardens, Doncaster, having very good Jas. Veitch and rather small fruits of Sir C. Napier and Dr. Hogg, the same exhibitor taking the first prize for a single dish of fruit with Sir C. Napier. There was only one dish of Cherries, this being staged by Mr. Mortimer. Messrs. Rivers received a silver-gilt medal for a very fine collection of Cherries, Peaches and Plums. Mr. Maxim had a silver medal for two large baskets of very good Hamburg Grapes. Mr. R. Grindrod, Whitfield Gardens, Hereford, had a similar award for a nice collection of fruit. Mr. Jinks, Fairlawn, Cobham, Surrey, showed fifteen dishes of Tomatoes, a nice even lot of fruit and distinct varieties, Ham Green, Conference, Dedham Favourite, Chiswick Red, Acme, and Golden Perfection being noteworthy. Mr. Elisha secured a bronze medal for a collection of fruit and vegetables. Mr. McDonald, Norgate, Chichester, had a stand of Cucumbers. A new Grape named Lady Hastings, shown by Mr. Shingler, Melton Constable, was not nearly ripe. It should, however, be seen again, as it is a noble-looking Grape.

A full prize list is given in our advertising columns.

Rose show at Manchester.—About a fortnight earlier than usual, owing to the advanced season, the annual Rose show, under the auspices of the Royal Botanic and Horticultural Society, was held in the gardens, Old Trafford, on Thursday, July 6. York was to the fore in the exhibition, inasmuch as Messrs. Harkness and Sons, of Bedale, were very successful prize-winners. The entry list was extensive, and included the names of well-known Rose growers in different parts of the country. In all classes the competition was strong. The prize list will show how many awards went to a few leading firms in Yorkshire, Nottinghamshire

and beyond the border. The southern growers were little in evidence, and this arises from the weather, which has been too hot and dry for the Rose. A full prize list will be found in our advertisement columns.

PUBLIC GARDENS.

Proposed addition to the Paddington recreation ground.—The following recommendation of the Parks Committee was by the Council's Standing Orders postponed until next week: "That the Council do purchase at a cost not exceeding £6000 the 2 acres 2 roods 17 perches of land adjoining Paddington recreation ground, which is under the control of the vestry of Paddington, for the purpose of adding to the recreation ground, conditionally on the vestry giving an undertaking, in terms to be approved by the solicitor, that two members of the Council representing the division shall be members of the committee of management."

Open spaces.—At the monthly meeting of the Metropolitan Public Gardens Association, held at 83, Lancaster Gate, W., the Earl of Meath, chairman, presiding, it was agreed to ask the Queen to extend her patronage to the association. It was stated that St. Thomas's Square, Hackney, and Duncan Terrace Garden, Islington, had been opened to the public during the preceding month, and progress was reported with regard to the laying out of Victoria Park Cemetery, E., the Brompton Road Triangle, and Goldsmith Square, Shore-ditch. It was agreed to put in order and open for the summer months St. Olave's Churchyard, Silver Street, and St. Katharine Coleman, Fenchurch Street, to endeavour to secure a public playground in Deptford, to place seats in a space in the Earl's Court Road, and to communicate with the vestry of St. George's, Hanover Square, respecting the burial ground in the Bayswater Road. Among a very large number of matters under consideration were the preservation of the Leyton Marshes, the acquisition of a recreation ground in Earl's Court, of a part of the site of Millbank Prison, of a riverside space in Battersea, and of the land of the New River Company opposite Canonbury Villas, the laying out of Whitfield's Tabernacle burial ground in Tottenham Court Road, and the purchase of a plot of vacant land in Hampstead.

The weather in West Herts.—Although the weather has lately been at times comparatively cool, still the past week taken as a whole proved very warm even for July, thus making it the twenty-fifth consecutive week of unseasonably warm weather. On Thursday and Friday in last week the temperatures in shade rose in the hottest part of the day to 85° and 86°. The nights were also warm; in fact, during the present month nearly all the nights have been more or less warm, and on those of Friday and Saturday the exposed thermometer never fell lower than 52°. At 1 foot deep the temperature of the ground now stands at 67°, and at 2 feet deep at 66°, or respectively 5° and 6° higher than on the same day last year. On Friday, the 7th inst., the temperature at the depth of 1 foot rose in the evening to 74°, and at 2 feet deep to 67°, both of which readings are higher than any previously recorded here during the eight years over which my observations extend. During the present month rain has fallen on six days, but to the total depth of only about half an inch. On Friday in last week 13½ hours of clear sunshine was recorded.—E. M., *Berkhamsted*.

American blight.—"W. P." is mistaken. The insect is dark brown, and reveals itself by the cotton thrown off for protection. I have almost lost Apple trees entirely by it before discovery, but I consider I have mastered the difficulty by painting with a strong solution of paraffin and soap-suds or Gishurst compound, not less than half paraffin, the first time with a tar brush, and then daily with a paint brush at every leaf-joint, or wherever the cotton can be detected. It is an

endless job at this season of the year, but not onerous. A quarter of an hour at each tree will do it, but the wood swarms with them, and so fresh discoveries occur every day, and it needs a sharp eye. The cure can, I hope, be completed when the trees are bare by a general painting of every inch; meantime the damage can be materially checked, as where you paint, there you kill, and I have proved it by the aid of the microscope.—T. PEARSON, *Putney, S. W.*

Dianthus neglectus.—Allow me to rectify an error in THE GARDEN of July 24 (p. 532). "Delta" says about *Dianthus neglectus*, "A pretty little Pink about which there is some dispute, and I believe M. Henri Correvon, of Geneva, asserts that the true *D. neglectus* has not yet been introduced to England." I do not believe that I ever said this, and can assure you that the true *D. neglectus* is cultivated at Exeter by Messrs. Robt. Veitch and Son, where I saw it lately, and at York in Messrs. Backhouse's nursery. I believe, too, I saw a plant sent from Messrs. Paul and Son, Cheshunt, and I suppose there are many other nurseries who cultivate it now. What I wrote about this plant was that the plate you published in THE GARDEN, and which was considered wrong by some of your readers, was, if not quite right, as good as it could be for a chromo-lithograph. *D. neglectus* has the outside of the petals of a greenish bluish colour and the inside like those of *Dianthus alpinus*, with the foliage of *Dianthus casius*. *Dianthus neglectus* I found frequently upon the Lautaret last year when travelling there with my friend Mr. H. Kitson, of Leeds. The plant is the characteristic species of the Alps of Dauphiné, M. Cenis, and Lautaret. It grows nowhere else, but I got seeds of a very nearly allied species of the Caucasus from Messrs. Levier and Sommer, of Florence, under the label *Dianthus*? Tieberdinski prival, Caucase, 9/90. The Caucasian form is so nearly allied to *neglectus*, that I would not be surprised to hear from M. Sommer it is the same plant.—H. CORREVON, *Jardin Alpin, Geneva*.

Wasps eating Grapes.—I find flies and wasps are just beginning to attack my Grapes. They had more than half of them last year. Can any reader tell me of a preventive?—J. W.

Sweet Sultan.—Can you kindly inform me through THE GARDEN what is the cause of my plants of this going off? It is a yearly occurrence with them. As soon as the plants come into bloom they die off. Mixing lime rubble with the soil does not make any difference. The stems appear to have been eaten just at the ground level, but I have not been able to find anything eating them. If you can give me any information I should be greatly obliged.—G. H. B.

Names of plants.—*Belton*.—*Fuchsia procumbens*.—*W. D. R. D.*—*Lilium Batemanianae*.—*G. B.*—Your Peas are suffering from red spider and thrips, caused through the dryness of the season.

"The Garden" Monthly Parts.—This journal is published in neatly bound Monthly Parts. In this form the coloured plates are best preserved, and it is most suitable for reference previous to the issue of the half-yearly volumes. Price 1s. 6d.; post free, 1s. 9d. Complete set of volumes of THE GARDEN from its commencement to end of 1892, forty-two vols., price, cloth, £30 12s.

"Gardening Illustrated" Monthly Parts.—This journal is published in neatly bound Monthly Parts, in which form it is most suitable for reference previous to the issue of the yearly volumes. Price 5d.; post free, 8d.

"Farm and Home" Monthly Parts.—This journal is published in neatly bound Monthly Parts, in which form it is most suitable for reference previous to the issue of the yearly volumes. Price 5d.; post free, 8d.

"Hardy Flowers."—Giving descriptions of upwards of thirteen hundred of the most ornamental species, with directions for their arrangement, culture, &c. Fifth and Popular Edition, 1s.; post free, 1s. 3d.

"The Garden Annual" for 1893.—Contains Alphabetical Lists of all Branches of the Horticultural Trade. The Lists of Gardens and Country Seats (containing over 9000) have been very carefully and extensively revised, and are admitted to be the most complete ever published. Price 1s.; by post, 1s. 3d.

All of our readers who are interested in the improvement of cottage homes are invited to help us to make **Cottage Gardening** known. It is published at the very lowest price to meet the wants of those for whom it is intended, and copies will be sent for distribution, free, by the publishers, Messrs. Cassell and Company, La Belle Sauvage, Ludgate Hill, E.C.

"This is an Art
Which does mond Nature: change it rather; but
THE ART ITSELF IS NATURE."—Shakespeare.

ROSE GARDEN.

ROSES AT WALTHAM CROSS.

THIS is a poor season for Roses, at least as regards the flowers, which are not proof against burning sunshine that quickly expands them without, unfortunately, that fine substance in the petals one gets in a cooler year. But in Messrs. Paul's nursery at Waltham Cross the plants are in remarkable health, and though the blooms last only a brief season, there was a great show a few days ago. In such a collection as this, there are old and new kinds upon various stocks. A large break is upon the seedling Brier, comprising the Tea and Noisette varieties. We noticed a new Hybrid Tea, as it is called—but the truth is the Teas are getting much mixed—named Grand Duke Luxembourg, that seems of great promise as a garden Rose, a little thin, perhaps, very free and with something of the Viscountess Folkestone character. The flowers are very sweetly scented, deep rose in colour, with still deeper buds, the inner surface of the petals quite silvery in tone. It is a strong grower and bright. Gustave Regis was succeeding well on the Grefferaie stock. This is a comparatively new Rose, very charming in the bud, the colour canary yellow, the margin of the petals touched with carmine. It is a strong grower and very free. Christine de Nouë is a pleasing new Rose of the Hybrid Tea order, the flowers rose-crimson, large and sweetly scented. One of the most conspicuous Tea-scented Roses at Waltham Cross is White Lady, which, it will be remembered, is a sport from the well-known Lady Mary Fitzwilliam. There is a very fine row of it, the growth strong and each shoot bears a burden of bloom. It is a better thing than its parent, the flowers very large, sweet and creamy white. A good group of it would make a great display. Too little regard is paid to the Rose for grouping in distinct masses, and we are pleased to see that this plan is followed largely by Messrs. Wm. Paul and Son—a system that gardeners should copy. A full, rich effect is obtained from the flowers, even those of such delicacy as Mme. Hoste, a very precious kind, the colour clear yellow. This is a good grower here, and in all respects a useful and beautiful variety. Francisca Kruger was well represented, and it is one of the most charming of this class; whilst a note must also be made of Viscountess Folkestone, which is a lovely flower, quite one of the best things raised by the late Mr. Henry Bennett. It is delicate in colour and very sweet. One always prizes Roses that are richly fragrant, and it would be well if raisers paid even more attention to this attribute of the flower. A large break of the variety Grace Darling was a mass of bloom, and in bad and good seasons alike this fine Rose is in character. It continues to bloom until late in the season, and commences early. The growth is exceptionally strong, and the flowers are creamy white in colour, margined with a peach tint. We like it for its constancy, vigour, and freedom even near to large towns. Some Roses, although full of charm, are often overlooked. Camoens

is one of this class. It is a delightful Tea, not useful for the exhibition, but that is of little moment when it stands high amongst those kinds for the garden. It is a good grower, and a quantity of it at Waltham Cross is smothered with bloom, the flowers light rose in colour, touched with yellow in the centre. Two rows each of Anna Ollivier and Ma Capucine, a bud Rose of great beauty, may be mentioned, as both were in full beauty. A Tea-scented Rose of importance is Mme. Charles, which has very large flowers, full, and of an apricot shade.

The climbing Teas are worthy of attention, and the Climbing Niphotos is conspicuous. This is called a climber, it is true, but all the plants will not develop an upward tendency. It is stronger in growth than the ordinary kind, but there distinction ends. Mme. Chauvy belongs to this section, and the flowers are distinctly handsome, the colour yellow touched with rose, and the petals coppery on the outer surface. Amongst the best known is Mme. Eugène Verdier, which is a very fine climbing Tea, and deserves to be more widely known. The flowers are rich yellow, well shaped, and very fragrant. Not far from this is the familiar W. A. Richardson, and although the lighter coloured flowers in particular have suffered much from the sun, this Noisette is exceptionally rich, quite of a deep apricot. L'Idéal was exceptionally fine. It is a very distinct and welcome kind, comparatively new, but becoming largely grown for its beautiful colour and neat bud. The flowers are a mixture of coppery orange and red, and make a great show, as they are produced with exceptional freedom. All who have not yet got this variety in their collections should make a note of it forthwith. Marie van Houtte is very fine this year; the flowers are large, and their distinctive colouring has been brought out to perfection. The plants on the cutting Brier are in rude health, but not with that deceptive vigour displayed by the Manetti. The

HYBRID PERPETUALS

are in fine character this year, especially those varieties which bear dark coloured flowers. We may make note with advantage of a few of the more important kinds. May Quennell is a Rose that one does not hear sufficient of. The flowers are produced freely and of a full crimson colour, whilst the growth is strong. Duchess of Albany, the sport from La France, was in full beauty. It is of a deeper tone than the parent, and maintains this distinctive character. Mrs. Jowitt, as seen at Waltham Cross, is worthy of note. The flowers are crimson in colour, full, handsome, and solid. Amongst the finest of the dark Roses this year are the following, and they have been shown well at the exhibitions. Without them indeed many shows would have presented a sorry aspect. Xavier Olibo, a well-tried favourite, is in excellent character, the flowers of remarkably strong and sweet fragrance, full, and of large size. When it is in condition, few Roses are more beautiful. Another variety that is very conspicuous this year is Fisher Holmes, one of the finest of the dark-coloured kinds. The flowers are of fine shape, full, even, and deep velvety crimson, remarkably rich in scent, and the plant is a sturdy grower. We have seen several good boxfuls of it at the shows, and we always admire its rich lustrous colour. A very brilliantly coloured Rose is Duke of Teck, the flowers bright scarlet, symmetrically formed and conspicuous at a distance. A few plants of this in full bloom make a great show of colour. Again, we may record a triumph for that new Rose named Gustave Piganeau, which undoubtedly is

one of the finest Roses in cultivation. It has been exhibited well this year, and was very fine at Waltham Cross. The flowers are quite as large as those of Paul Neyron in size, full, and crimson or rather carmine in colour, very bright and attractive. A valuable Rose is Caroline Testout, and coming, we think, rapidly to the front. The flowers are clear rose in colour, and there is no want of them on the vigorous plants. We get fragrance very pronounced in the variety Margaret Dickson, but the plant is almost too strong in growth. The flowers are white with a tint of flesh colour in the centre, full, and exceptionally sweet. Ulrich Brunner, the now well-known Spenser, Mrs. John Laing, and Silver Queen were of note; the last of the four has large well-shaped flowers of a silvery pink colour, very bright and attractive. Mme. Bois reminds one of Victor Verdier, the flowers of a pleasing rose colour. The new Bourbon Lorna Doone is likely to prove of much value, and we have already made a reference to it. A very sweetly scented Rose is Auguste Guinoisseau, sometimes called not inappropriately the white La France, although the flowers are not strictly white, but touched with a pink shade in the centre. They are borne very freely, and possess a very sweet scent. It is one of the best new Roses for the garden, and a group of it is exquisite. We have seen it on many kinds of soils and in more than one county, but always good. One Hybrid Perpetual Rose to which we would draw attention is Clio. It has been exhibited freely, and received many certificates. These are not worth much, but this variety is of great merit. A number of plants were in full bloom; the foliage abundant and of fine colour, the flowers large, sweet, and light salmon or a shade of pink in colour. It should be made a good note of for the garden and exhibition. The

POLYANTHA CLASS

is, we are pleased to see, getting more popular, and it is a pleasure to find that other classes besides the Hybrid Perpetual and Tea-scented are grown largely in gardens. This is a welcome sign that a love for these fine old types is reviving. The Polyantas are on the Grefferaie stock for the most part, and form a delightful section of Roses, making little mounds of blossom in spite of an abnormally dry soil and fierce sun. A break of them is full of colour, and amongst the best kinds are the following: Gloire de Polyantha was a mass of rose, the flowers full, rosette-like in shape, and so free, that almost every trace of leafage is hidden. It is a kind that should be planted in a group to get the full effect of its profusion of bloom. Blanche Rebatel is remarkably rich. We made special note of it for its colour, a shade of crimson-purple, the flowers, as in the others, being borne in dense clusters. It is in truth one of the most striking kinds in beauty now. Another lovely variety is Anna Maria de Montravel, one of the freest of the section. The flowers are imbricated, of the purest white, and valuable for cutting. A good way is to get a few of the best of this class and group them. Then they have an effect in the arrangements, and in ordinary soils and positions they succeed and bloom well. There is a number of varieties belonging to this group. Clothilde Soupert is apt to vary, but it must be mentioned. The flowers are white and rose-tinted in the centre, also well imbricated in form. Paquerette is a dainty little kind, the flowers not large, but perfectly double, and of the purest white, whilst another good kind is Mignonette, which has delicate rose-coloured flowers, passing to white, and produced in clusters.

This is merely a brief review of the Roses in this nursery. There are varieties of every section; of each class a group is represented in its fulness. There is a large collection in pots, and in one house the variety *Corinna*, which has been previously described, was in full bloom.

Rose Persian Yellow.—I never saw this Rose flowering so freely as it has done this year. I allow it to grow somewhat in a natural manner. The long branches are allowed to remain their whole length, and the following year these are wreathed with lovely golden-yellow blossoms. All the pruning our plants get is to remove the weakly shoots to admit of the stronger ones having more space.—E. M.

Tea Rose Clara Watson.—This is a new kind of which flowers were exhibited by Mr. G. Prince at the Drill Hall on June 6, and it looks very promising. In character the form of the flower very much resembles that of Hon. Edith Gifford, being full and double, the colour flesh. Perhaps it may come too near Edith Gifford, which is often decidedly flesh tinted, but time will show. Blooms of it compared with those of Edith Gifford in Mr. Prince's fine box of Teas were distinct enough.

Rose Princess of Wales.—There is something in the soil of Mr. Prince's nursery that specially suits those lovely tinted, but uncertain Tea Roses that all of us admire and few can grow. A box of a dozen good blooms of this kind was recently exhibited by Mr. Prince. The flowers were fine and the colour exquisite in its blendings of rosy pink and soft yellow. It is one of the late Mr. Bennett's raising, and was sent out in 1882.

Own-root Roses.—The great majority and all the best Roses are certain to succeed upon their own roots. In this matter we can learn something from the Americans. I am forced to come to this conclusion, that, given suitable conditions for growth and sufficient time, a plant on its own roots will grow as strongly as upon any other roots. I do not believe any stock promotes vigour over and above that natural to the kind. Upon this question, writing on p. 174, "Ridgewood" cites Marie van Houtte, Mme. Lambard and Anna Ollivier as examples likely to thrive on own roots, presumably because of their vigour, the still stronger climbers only "thriving fairly well in this form." This is not so. The best *Rêve d'Or* I ever had I struck from cuttings, and after a year in the cutting bed in a frame they were planted out. For the first two seasons they made a perfect forest of growth and then settled down to profuse blooming, in which state they continue. It is a pleasure to see the suckers coming up from these reach 12 feet in a season, and to lay them in in the place of old wood that has given its quota of flowers. With *Gloire de Dijon*, *Bouquet d'Or* and others I had the same success, and saw enough to prove that with these again there is no need whatever for a stock of any description. It is quite true, as "Ridgewood" remarks, that when suckers spring up from worked Roses many amateurs do not notice the difference. One would think that anyone who cared for Roses enough to grow them would be able to distinguish these robbers, but the fact remains many do not. A friend of mine was once called in to give advice to an ardent Rose amateur who was in despair at the non-flowering of many of his Roses. He discovered that the Roses had long since disappeared and that there were splendid plants of *Manetti*.—A. H.

Mme. Berard a good fence Rose.—The right place for *Mme. Berard* seems to me to be a fence. Perhaps my experience of this kind on walls may be unique, but certainly no Rose that I ever grew was so addicted to mildew as *Mme. Berard*. I had fine plants on the walls in one place, and they were always the first to become infested with mildew and the hardest to keep clean. Copious waterings at the roots seemed to hold the pest in check at times, but sooner or later each season it

appeared and greatly marred the beauty of the plants. I was so convinced that this kind was always the beginning of mildew among the Teas, that had I remained longer I should have removed and replaced *Mme. Berard* with some cleaner kind. Here, again, I find something confirmatory, for of many *Dijon Teas*—true, but of last year's planting—against the house and other walls, the only kind showing mildew is *Mme. Berard*, and the plants are smothered with it. On the other side of the house—drier and more sunny—is a fence clothed with *Dijon Teas* and other climbing kinds. Here *Mme. Berard* has been established six years, and it is quite free from mildew. There is a good length of the kind and it proves most free and constant, throwing splendid blooms in quantity and long succession, and, excepting *Bouquet d'Or*, there is no better Rose on the fence. I remember another and even longer fence in a garden where I spent some years when a boy—in fact, where I first made the acquaintance of *Mme. Berard*. This fence was planted with *Mme. Berard* and *Gloire de Dijon*. The former kind was by far the better and used to give a wealth of blossom. In one year when frost came late I remember cutting a score of good, partly opened buds of this kind at Christmas, and after a night in warm water, which opened them a little more, they were used in the church for the Christmas decorations.—A. H.

THE STAGING OF ROSES AT EXHIBITIONS.

Those who exhibit Roses have a far more rational and natural method of staging than have some other florists. For instance, we shall now in a week or two have the *Carnation* presented as usual in its hideous deformity with the paper collars, reminding one of those worn by the upper society in the *Elisabethan* era. Anything more inconceivably ridiculous could scarcely be imagined than these aids to malformation, for such it is when a flower is made to appear under artificial manipulation what it really is not when presented naturally. How much longer this is to last I do not attempt to predict, but might not the *Carnation* and *Picotée* Society make it penal for adding these embellishments (so considered)? It will not do, however, to dwell further upon this point considering the subject heading of these remarks. It is the *Rose* more particularly upon which I wish to say a few words. This season has been a most trying one for many of us. The procuring of fresh green Moss has been almost an impossibility for many growers. When this material can be had fresh there is nothing better both as regards effect and the moisture it contains, which tends to keep the flowers fresh for a greater length of time. When it is brown, however, it does not look well by any means, but brown-looking Moss I have seen greatly improved by preparing the boxes a week or so in advance, then keeping them cool and well moistened until required. When Moss is used it is a customary plan to fill up under the Moss with something that is dry, as hay or straw or dry Moss. This when moistened greatly adds to the weight, and when such has to be considered as a question of excess by the railway companies, one has to pay dear for the packing. What is far better is to fit galvanised wire netting as a groundwork for spreading the Moss upon. But it may be said by some that this is impossible, for the tubes have to be considered. If the netting, however, be strained upon a lightly made frame, it can rest upon the tubes, and these latter can be moved in their slots as desired by merely lifting the framework. I noted one exhibitor recently at the metropolitan shows who had recourse to black velvet as a groundwork to his flowers, and it did not look at all bad, the light colours more particularly being shown up well by its use. The colour, however, was a wrong one to employ, although it is used with effect by floral decorators for wreaths, crosses, &c. The better colour would have been a green one, the particular shade approaching as nearly as possible that of the *Rose* foliage. If this shade of colour were used when it is impossible to obtain Moss sufficiently good, it would be

as good a choice as could be made. This colour would greatly relieve the dark reds and crimsons, and in my opinion the whites and pale colours would not suffer in any way by its use.

In the arrangement of the flowers there is room still for improvement. It is very rare that one has the pleasure of seeing any wood-growth along with the flowers, and as to buds, these are still scarce; but this cannot be wondered at when the thinning down to one promising bud is so much in vogue. Yet the popular expression in schedules is "trusses," not "blooms"; this in itself is absurd upon the face of it. At times both the *Teas* and *Hybrid Perpetuals* will push up an adventitious shoot beside the flower. This should be allowed to remain, in my opinion, as it adds to the effect. I would also permit one shoot, not leaves, to be added both with single blooms and trebles. Why trebles, I would ask? Would not a pair of good blooms be quite enough of one kind of what are termed "exhibition" Roses? Of those classed as "garden" Roses and shown as they should be in real trusses of not less than three or more than six, a deal more use might be made. The way these have been taken up this season is a sufficient proof of this. Take, as an instance of the added *Rose* shoots, the light *Teas*; these look much more beautiful, I think, with some of the bronzy shoots. Against this I know it may be urged that this cutting would rob the plants; to this my reply is, grow a few plants for this purpose alone of the kinds best suited. When baskets or vases of *Roses* are staged the competitors are not slow to take advantage of this addition.

In the opening remarks I alluded to the doctoring up of the *Carnation* for show purposes. This failing is, I regret most exceedingly, now spreading amongst *Rose* growers. At a recent metropolitan show I was in conversation with a veteran *Rose* grower, raiser, and exhibitor, who stated that he had that morning stood and watched the manipulation of the petals to improve the flowers, or rather to make blossoms out of buds chiefly of the *Tea*-scented kinds, which appear to be the most amenable to this unjustifiable process. I have repeatedly noted its adoption by the decorative florists; this can be detected with a tolerable certainty when one knows what a bloom should be and not what it has been transposed into. Gummung the flowers to prevent them falling cannot be justified, but I would prefer this to the artificial dressing. There is, furthermore, sufficient room for an improved name card as regards colour; instead of white cards I would much prefer to see green ones adopted altogether.

GARDEN ROSE.

Rose Ernest Metz is one of the finest *Tea*-scented *Roses* this season. It is one of *Guillot's* raising, and sent out in 1888. The flowers are of fine form, the petals broad, and composing a splendid exhibition bloom. They are delicate *carnation*-rose, brightening towards the centre, and held on a sturdy stem. Although a first-class exhibition variety, it is good in the garden, robust, free, and pleasing in aspect.

Rose Hon. Edith Gifford.—*M. Guillot* has sent us many fine *Roses*, but surely none better than this. It is a wonderful picture at the present time, the flowers so numerous and fine. It never makes a big bush like *Marie van Houtte*, but it makes a handsome group, and the quantity of flowers it produces is surprising. It may be planted at little more than a foot from plant to plant, and when so closely massed it has a grand effect.

Rose Claire Jacquier.—This is a lovely cluster *Rose*, and some fine trusses of it have recently come to hand from a plant that grows on a fence in the garden at *Betteshanger Rectory*. I have had my attention called to it on more than one occasion, and have always had to confess to knowing nothing about it. By its strong habit and profuse blooming, it always seemed to me to belong to the *Polyantha* family, and after a diligent search through many catalogues, but in vain

I find it in that of Mr. George Paul. It has similar great clusters to those of the Polyantha, but the flowers are double, prettily shaped, pale externally and at the edges of the petals, but deepening into a rich almost orange-yellow. I think it is of comparatively recent introduction, and certainly deserves to be better known. I have only seen it in this one place.—A. H.

Rose Prince Arthur.—In the great heat and drought one Rose deserves a special note, and that is Prince Arthur. It is, I think, about the only Rose ever sent out by that veteran grower, Mr. B. K. Cant, and although its advent now dates back some eighteen years, we cannot afford to put it on one side. I know it stands high in Mr. Cant's estimation at the present day as a good show Rose, but the number of good shaped blooms the plants are bearing and its fine colour in the mass prompt this note. In colour it is a rich deep crimson, and the scent is powerful.—A.

Rose Dr. Grill.—I am not at all surprised that this should specially have attracted Mr. Camm's attention in a garden at Bournemouth, for where it does well it is a most attractive Rose, telling in colour and delightful in scent. It has a good vigorous constitution, too, so that anyone able to grow Tea Roses at all can grow Dr. Grill, which is much more vigorous than many Hybrid Perpetuals that I know. It is not a show kind, but it is a Rose of the highest merit for grouping in the garden, most free in bloom and altogether distinct from any other. It is almost useless attempting to describe its subtle blendings of a variety of tints, but I notice that all who see it admire it. During the past week it has been very fine, but at its best in the early morning, being then full of rich and wonderful colour, growing paler by night after the scorching cloudless days, of which we have had so many.—A. H.

EFFECT OF HOT WEATHER ON ROSES.

THERE can be no two opinions about the Rose season up till now. From all parts comes the report that the first crop of blooms was not only unusually early, but also of remarkably short duration. Very many blooms never got beyond the bud state, and those that did open scarcely lasted the day out. It must have been a great disappointment to those who, having expended so much trouble on their Roses in the hope of having some good ones for exhibition, to find, now the shows are being held, that they have nothing, or next to nothing, fit to show. The great majority of growers who never think of showing, but who may be equally fond of their Roses as those who do show, will have no such vain regrets, though the disappointment may be equally as keen. Roses are not at home in a tropical heat, and all the while it lasts it is not many serviceable blooms that will be produced, in the "sunny south" at any rate. All we can do, therefore, is to "hope on." When the change comes, and come it must before very long, Rose growers will perhaps recover their spirits more quickly than farmers generally. As far as well-cared-for Roses are concerned, it is not so much a case of suffering from want of water; but, as before hinted, the heat is too excessive for them. Those who could afford to temper the great heat by means of canvas or cotton blinds and other temporary shading ought to have been able to cut some good blooms, but in all other cases only very early risers have been able to cut anything worth having. Unless the present tropical weather lasts several weeks longer, the prospect of good second crops of bloom is decidedly encouraging. Already Teas growing against warm walls have formed a strong second growth, and if only the sunshine was less burning, a lot of good blooms could be cut daily.

So well are they growing, many great sappy shoots being formed, that I have good hopes of being able to cut a profusion of Roses at a time when they are usually very scarce. Those Teas in the open are also breaking strongly, and these, again, may give us many excellent blooms during the next two or three months.

It is somewhat early to write confidently about the Hybrid Perpetuals, but these may also give us a better second crop of blooms than usual. The young growth was not strong, but it is very firm, and I strongly advise lightly pruning all that were not cut over for the sake of cut blooms. Any that were not mulched in the spring will have suffered most, and will continue to suffer from the drought, and if a serviceable lot of successional and late blooms is desired, the ground about them ought to be lightly forked up and a thorough soaking of water given, this being followed by a heavy mulch of strawy litter. It is not rotten manure that is wanted, though amateurs seem to think that it is, and tiny mounds just round the stems are also of little or no avail. Rotten manure cakes badly, and soon fails to exclude sunshine or to prevent the loss of moisture from the soil; whereas, strawy litter spread all over the beds, or to a distance of not less than 18 inches from the stems, keeps the ground cool and moist without actually excluding air. A rather risky proceeding, but one that I shall recommend all the same, is to prune most of the strong, well-matured growths that were not previously shortened when blooms were being or might have been cut. They should not be hard pruned, as that would force out the back buds that ought to remain dormant till next spring, but if they are shortened to the seventh or eighth bud, there would be few or no risks run of forcing these out, and yet several good flowering shoots be obtained. At one time Roses generally were very dirty, aphides being especially numerous. These latter are not nearly so abundant now, but unless a thorough cleansing is given the trees or bushes, there is every likelihood of young broods being forthcoming directly there are soft young shoots for them to feed on. In addition, therefore, to being freely watered and lightly pruned, something in the way of cleansing also ought to take place. Frequent syringings with clear water would be very beneficial in several ways, but they would be still more effective if they were preceded by a thorough drenching of the top growth with either soapy water, soapsuds, diluted tobacco water, or a decoction of quassia chips and soft soap. Thus treated, there is every likelihood of the trees and bushes producing more good blooms in August and till frosts intervene than has been the case for many years, thereby compensating for disappointments earlier in the season.

Thanks to the firmness and early maturity of the young wood, Rose cuttings properly treated should strike root very readily this summer. Of the value of a good stock of own-root Roses little need here be said. Most rosarians would like to have a good stock if only they could raise or procure them in quantity. In the autumn well-matured growths cut into lengths and in every respect treated similarly to Gooseberry cuttings will usually strike root quite as freely as the latter, and so also can cuttings of a different description be struck easily at this time of year. Hand-lights or large bell-glasses are necessary for summer cuttings, those being set on a north border, about 3 inches of fine gritty, loamy soil being substituted for the ordinary ground. The best cuttings are young shoots that have only a short time previously produced a bloom or blooms, these being taken

off with a heel or thin piece of old wood attached, and the tops shortened to about three leaves. They must not be allowed to flag, but should be dibbled in moderately thickly and firmly fixed very much as they are prepared. Being kept uniformly moist at the roots, close and carefully shaded from what sunshine reaches them, the majority will strike root, and may eventually be placed singly in small pots or transplanted to nursery beds. Cuttings of Teas and Noisettes are very clean and good this season, or equal to what can be had from trees under glass, and it is not often that such a good chance of raising a batch of own-root plants offers itself. I. M. H.

A RIVAL TO GLOIRE DE DIJON.

I HARDLY expected that "A. H." would have gone to the Noisettes for a rival for the magnificent old Tea Gloire de Dijon. I agree with "A. H." (p. 525) that both are grand Roses with high and distinctive merits, but cannot follow him to the end of the sentence that Bouquet d'Or is the better of the two. True, it flowers in clusters, grows as strong or more strongly, but few will contend that it is as hardy as Gloire de Dijon. Whereas, as to forming a fine bush in the open, have not many complained that in not a few localities Bouquet d'Or needs a wall or a very sheltered spot to enable the flowers to open freely? But in any case these two Roses are almost too distinct to be pitted against each other. And as to rivals in the same family of Teas, one searches in vain for them in such more or less close imitations as Mme. Gerard, Belle Lyonnaise, Beauté de l'Europe, &c.

As to the Gloire de Dijon, I can only say the longer I know it the more I love it. We have just passed through an exceptional season for Roses. Among the last to leave us last December and the first to greet us this April and May was the Gloire de Dijon. Those, however, who are content to grow this Rose only on south or warm walls hardly realise a tithe of its charms of form, colour, and fragrance. Grown on every available aspect of walls, houses, and outbuildings, there are few houses that might not be enriched and enlivened from the open air most of the year. Then what a bed, border, group, mass, bush, pillar or pyramid it makes! Give this Rose a rich root-run below and sufficient area above, and mark what a blaze of golden and salmon it shoots across the most sombre landscape. If so much golden beauty needs a foil, it had better be found, not in other Roses of similar colour, but in such fine varieties as Paul's Pink Rover, Turner's Scarlet Rambler, or La France.

Even as a wall closter, a climber of church steeples, a draper of church walls, as a rule the squarest and ugliest objects in landscapes unless covered with Ivy, Gloire de Dijon has, as a rule, been far too much cribbed, cabined, and confined.

The writer has seen a few on churches, has heard of more, and hopes to see them all clothed with grace and beauty. Homère for the highest heights, Gloire de Dijon with William Allen Richardson and the white Banksian or Climbing Niphetos for white-robed purity and rich bronzes, with Marie van Houtte for soft creamy basement lines, would convert every church, house, or large building into a thing of beauty and a joy for ever. How our Roses, cut down into mere skeletons, that their solitary units or bunches of threes with buds and foliage may fill our show boxes, must fret and fume to have their heads in the pure air and their roots in the richest soil we can furnish them. Let Gloire de Dijon and other free-growing Roses have free course and uplift the dreary pall of monotony from the face of so many of our dull, monotonous landscapes. D. T. F.

Sweet Briars.—I have not yet read a word but of praise in favour of these, but as an interested observer of all that is done among Roses, I must confess to thinking that the naming is decidedly over-done. I saw and carefully examined the col-

section described by "G. II." in THE GARDEN of June 21 (p. 525), and though freely admitting that there were pretty things with distinct colours, there was also too much similarity. I had that morning seen the common Sweet Brier in a place where it has been planted by the thousand, and noticed a fair amount of natural variation in tint, so much so in fact, that the merest diversity of shade in the hybrid forms hardly justifies another name. These hybrids will not be great garden Roses in the sense that the fine Teas and other kinds are. At present mostly single, their value for planting is only equal to that of other single kinds; therefore let us have them in fewer numbers and absolutely different from the parent and each other.—A. H.

A good garden Rose is the variety Augustine Guinoisseau, raised by the French rosarian Guinoisseau in 1889. It is a beautiful flower, very free, and deliciously fragrant. Of the many varieties in collections, this is one of the more noticeable for its powerful scent; hence its common name of the white La France. The colour is white, with just a trace of delicate rose, and the plant blooms over a long season. It is not an exhibition Rose really, although that matters little. We can afford to do with a few more such Roses, free, vigorous, and with delicately tinted flowers of strong fragrance. It is quite time that raisers paid some attention to scent—the most acceptable virtue in a Rose, but often overlooked.

Rose Gloire Lyonnaise.—This is a grand Rose, especially when pegged down. That is the way to obtain the maximum quantity of flowers from strong growing Roses. This kind is the best of all for pegging down, as the flower shoots are very erect and usually long enough to hold the flower high up and prevent splashing with dirt during rain. When pegging down was largely advocated a few years ago, doubt was expressed by some who recognised the merits of the plan as to whether a Rose would go on year after year sending up shoots strong enough for the purpose. The group in question was planted in 1887 on a bank of deeply trenched soil. The plants have been pegged down yearly since, and this season some of the shoots put down were over 6 feet in length, whilst others that will be put down next year are now nearly a yard high. No feeding or manure has been given the plants, but most of the time the ground has been surfaced with the mossy Saxifrage.—A. H.

Rosa lucida.—In selecting single Roses this North American species must not be overlooked, as it forms a handsome bush that flowers with great freedom. It is very effective when from 3 feet to 5 feet in height, as it forms a dense bush clothed with bright green glossy leaves, nestling among which are the deep rose-coloured blossoms. Apart from the flower's other distinctive features are the shining foliage, from whence the specific name of *lucida* is derived, the bright red fruits so conspicuous in autumn, while at that season the decaying leaves are very noticeable. They die off richly tinted with various shades of brown and red, especially if the plant is growing in a spot fully exposed to the sun.—T.

Tea Rose Ethel Brownlow.—Ethel Brownlow is fast proving to be the best of the recently introduced Teas. This Rose was sent out in 1887 with Earl Dufferin and Lady H. Stewart, a grand trio which have met with no small success at the shows. Ethel Brownlow is a Rose of perfect form and colour. Its blooms, imbricated with a pointed centre, are salmon coloured, sometimes much flushed with rose, with the base of the petals of a yellowish hue. One of the best qualities of this Rose is its perfect lasting powers. At the recent show at Earl's Court, Ethel Brownlow stood erect and had not turned a petal, while nearly all the Teas around it were drooping from the heat. It has lasted over ten days in a cut state with me, and is an ideal button-hole Rose in all respects save for fragrance, which unhappily it does not possess. This year I notice Ethel Brownlow had the honour of a separate class for twelve blooms at the Crystal Palace show. The blooms staged were uniformly

good all through the show with two or three superb examples. It bore no slight resemblance in some cases to Comtesse de Nadaillac and Mme. Cusin. Ethel Brownlow is very free blooming, nearly every shoot being crowned with a bud, and as such is a good garden Rose. Its exhibition qualities have already been proved beyond a doubt, and it is a Rose which everyone should grow.—R. A. JENKINS, *Highgate*.

SHORT NOTES.—ROSES.

Rose Magna Charta.—This deserves a note for its specially sweet scent, and it is quite the type of Rose to have in a good group. It is free in growth and bloom, with flowers of a clear soft rosy pink.

Tea Rose Narcisse.—This is a charming kind and very free blooming. It is almost like *Lamarque* in miniature, dwarf, compact, and with every shoot terminated by a cluster of flowers. In the bud state it is specially charming. In colour it is of the palest sulphur, fading to cream-white as the flowers expand fully.

Rose Augustine Guinoisseau.—This, of the more recent new Roses on trial, has been the most striking, and appears to be a decided acquisition. There have been many fine flowers of it lately, and upon own-root plants, too, happily. It was sent out in 1889 as a nearly white *La France*. It is white externally, but tinged with rose which deepens towards the centre of the flower. The flowers are of charming form with pointed petals. It will be a fine Rose for grouping, and capable of producing a fine effect. Anyone intending to add new kinds in the autumn may safely include this.

FERNS.

MAIDEN-HAIR FERNS (*ADIANTUM CUNEA-TUM*) IN THE SUMMER.

It is not everyone who has favourable houses for the growth of this popular old Fern so as to provide a supply of cut fronds of enduring character. The growth made when mixed up with other plants is not always of the best description. It may look better, it is true, darker in colour and so on, but this is not the kind of material to last fresh when cut. What is wanted is a light, well-ventilated house with good control over atmospheric moisture, the plants being as near the glass as possible and in no sense overcrowded, otherwise the lower fronds, and others where the growth is dense, will either turn yellow or damp off. Damping off spreads rapidly in a humid and close atmosphere with possibly no fire-heat. This latter accessory cannot be considered essential by any means, being all the better for the plants if dispensed with entirely, provided other means are equal to the case. By this I mean a proper system of ventilation both by night and day, with no overshadowing from other plants. At all times should air more or less be left on; by this means there should be no signs of moisture deposited upon the plants in the form of dew in the morning. The greater part of the watering should be done early in the day, with no late evening damping down. By this means a good lasting growth will be obtained, the fronds of a pale green, with small pinnae as compared with others grown in more moisture, more warmth and more shading, these having larger pinnae and fronds possessing a deeper shade of colour that is not nearly so beautiful as the former. What may be termed the cool treatment as aforesaid is not nearly enough seen in practice. Many growers do not, I think, sufficiently realise the fact that this Fern is but little removed from a greenhouse plant as to its actual needs.

On the other hand, it is also possible to grow it thoroughly well in houses with heat and moisture, but in order to do this in the best possible

manner two or three points have to be considered. Firstly, the position should be one with a large amount of light, for I would rather shade plants in cool houses than in those heated at all, so as to act as a deterrent to over-luxuriant growth. Secondly, the plants in warmth should of the two be in smaller pots proportionately to those in the cool, and for the same reasons; and thirdly, the watering ought not to be excessive, nor overhead syringing be permitted. In this way it is quite possible to so manage the plants as to make them in every way valuable. In no case should over-potting be permitted. To fancy that fresh potting is needful every year is altogether a fallacy. It may be urged by some that they cut such a quantity of fronds, and therefore the plants need to be repotted; whereas, in fact, quite the opposite is the case. Take two plants, for instance, in health and of equal conditions in all respects; pot the one, giving an average shift and treat in the usual manner, leaving the other not potted at all, but assist it, if needful, by manure water and clear water also in plenty. When the growth is fit for picking, treat both plants the same, cutting them hard if needful, and after this note which plant of the two will afterwards recover itself and be presentable in a given space of time. The plant that has been repotted will stand the greater risk of losing its roots, or at any rate of having them weakened considerably. Given two such examples, methinks I can fancy how the fronds of the non-potted one will be sought for first, simply because they are the most suitable for cutting. I am not going to assert that repotting is to be reduced to absolutely no potting at all, but if the plants had about half as much of it as they frequently receive, it would be all the better for them after they have arrived at a serviceable size, and even prior to that less would often suffice.

When the house room is not sufficient to accommodate the plants satisfactorily, and there are pits or frames at disposal, let these be turned to account for their occupation. We have a large stock that cannot now be accommodated in any other way than in this manner. The surface is a bed of ashes, the depth being sufficient to allow of the plants standing upon 6-inch pots inverted, this being much better than close upon the ashes. Top and bottom air is left on all night to prevent any damp, and a very light shading is laid on the glass during bright sunshine, as the plants are close up to it. Here these plants will and must remain until the middle of September at the least, and they are better off than if shaded in houses by either plants or fruit trees. I have seen them also done well in pits with a northern aspect, but here they could remain later, as pipes were provided to keep out frost. If only a more rational mode of culture were adopted with this popular Fern, we should not hear so many complaints of the fronds not keeping in a satisfactory manner when cut. What is wanted is hard fronds, to use a popular phrase, and these can only be had by what may also be termed a hard course of treatment. A young stock of plants should also be coming on to supply the place of those becoming exhausted, as any plant will do in course of time when the utmost possible return is extracted from it.

GROWER.

Platyloma rotundifolia.—I have from John Margotten, of Shropshire, some nice healthy last year's fronds of this pretty New Zealand Fern, which he says has been out of doors in a somewhat sheltered rockery. Although I have tried this plant out of doors upon several occasions, it always died. There is another species which I would advise my friend to try in the same position as *rotundifolia*, and that is *Platyloma Browni*, a fine bold plant. In answer to your inquiry, I do not look upon *Pellaea* as synonymous with *Platyloma*, although the two genera approach each other very closely.—W. H. G.

The English Flower Garden.—Design, Views and Plants. Third edition, revised, with many new illustrations. London: J. Murray, and through all booksellers.

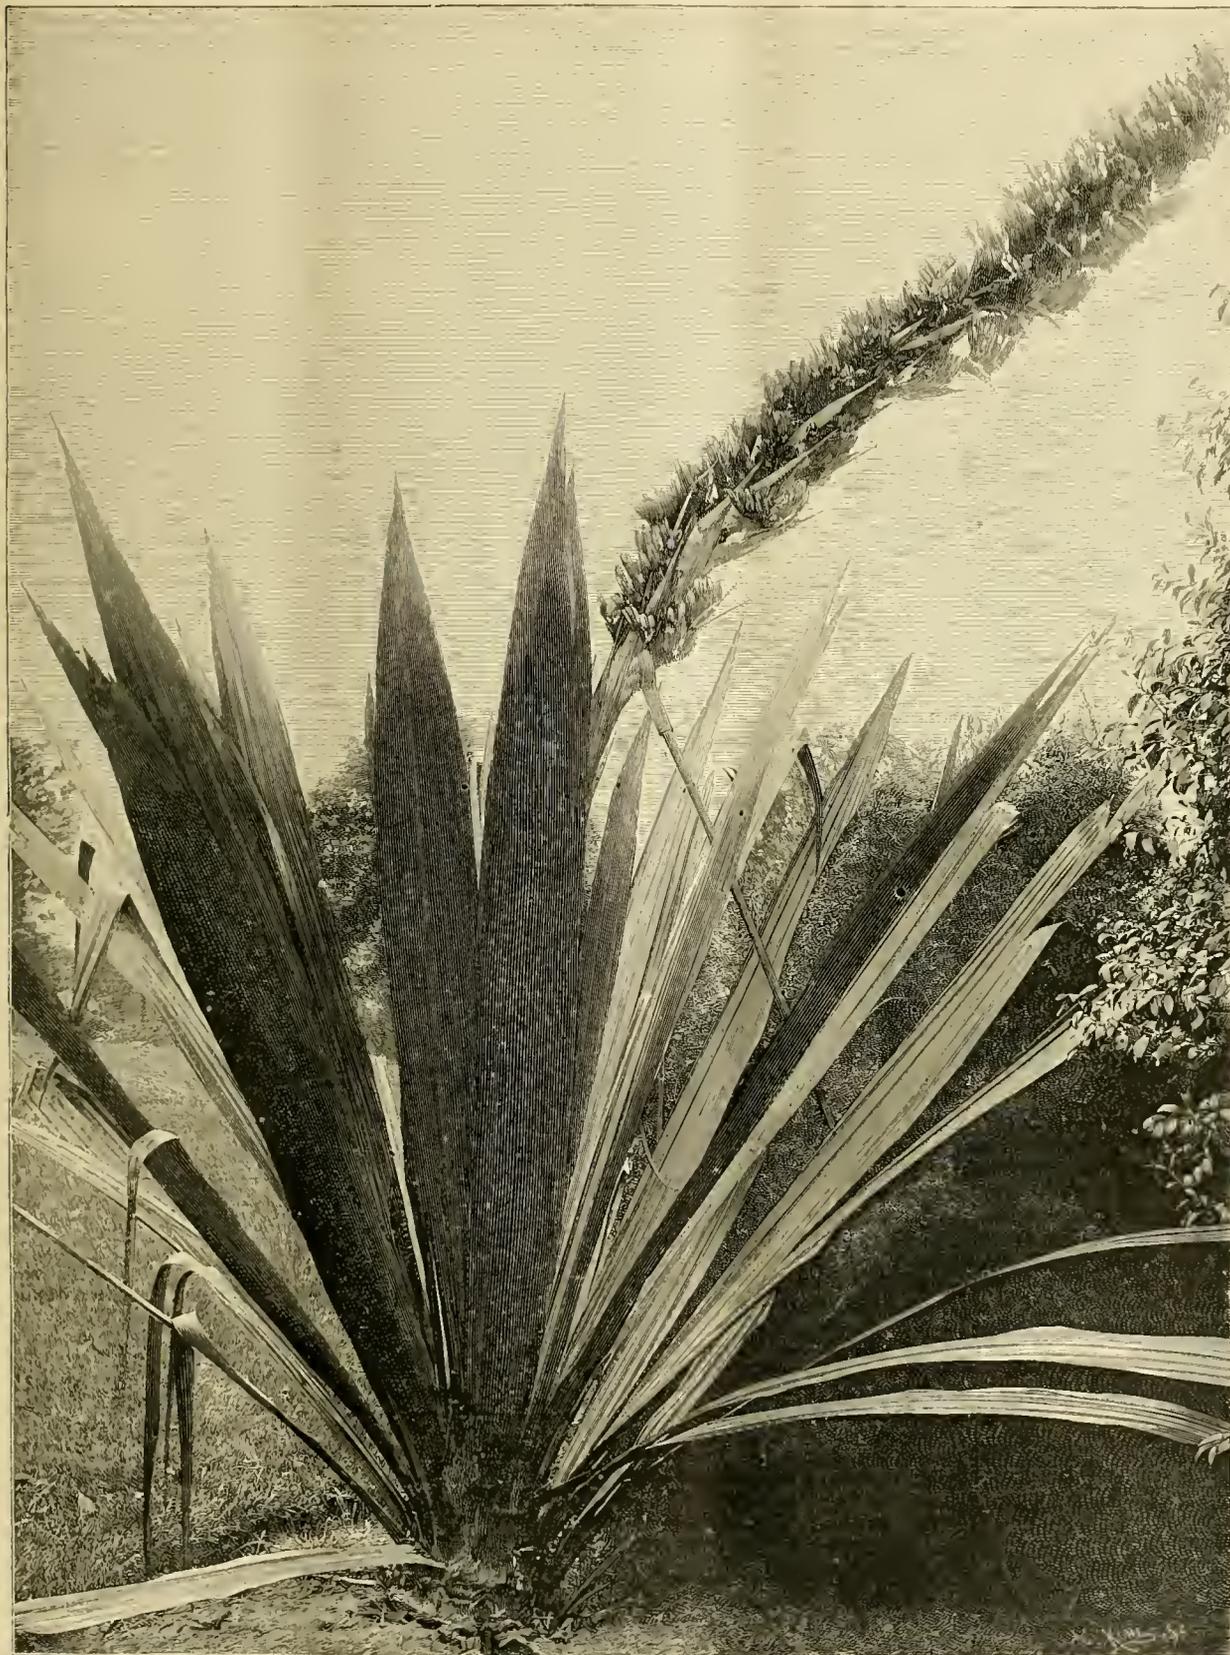

DORYANTHES GUILFOYLEI.

THE engraving here given shows a most magnificent species of *Doryanthes*, which flowered for the first time in cultivation

some five or six weeks ago in our garden. The plant was the admiration of thousands of visitors who flocked here from the city and country places to see it. There are now

four species of *Doryanthes* known, namely: *D. excelsa*, the well-known "spear Lily" of New South Wales, *D. Palmeri*, *D. Larkini*, and this new one which has just been named

D. Guilfoylei by the government botanist of Queensland, Mr. Frederick Manson Bailey, F. L. S. *D. excelsa* is the only species of the four not found in the northern colony. *Doryanthes Palmeri* was hitherto considered to be the most gigantic and showy Amaryllid discovered in Australia, but it is eclipsed in size and beauty by this later discovery. The leaves and flower-spikes are enormous. The leaves are each 9 feet long, over 8 inches wide, and of a brilliant green. From the base of the flower-stalk (which is $15\frac{1}{2}$ inches in circumference) to the apex of the inflorescence is 16 feet 2 inches. Of this, 7 feet 8 inches is a compound spike of rich crimson Amaryllis-like flowers, each 4 inches in length, and supported by 8 feet 6 inches of stalk. The plant was discovered by a brother of mine in the Upper Burdek in Ranges, North Queensland, and when sending the seeds he remarked that it was by no means plentiful, only one patch of it occurring above a cleft of huge rocks, and a solitary specimen about a mile away, from which he fortunately secured fruit. From the leaves a valuable fibre is obtained. This is of great strength, and with proper appliances could no doubt be

Doryanthes Guilfoylei in the Botanic Gardens, Melbourne. Engraved for THE GARDEN from a photograph sent by Mr. W. R. Guilfoyle.

converted into cloth, ropes, &c. Our gardens were aglow a week or so ago with the beautiful *Eucalyptus ficifolia* and numerous specimens of *Jacaranda mimosifolia*. We find that there are no less than ten varieties of the former, including deep and light crimson, bright scarlet, orange-scarlet, rosy pink of several shades, a pure white, and several others. Masses of these trees are a gorgeous sight against a dark green background.—WILLIAM R. GUILFOYLE, *Director Botanic Gardens, Melbourne, March 28, 1893.*

KITCHEN GARDEN.

AN IMPORTANT CROP.

CABBAGE, though a somewhat homely vegetable, is yet of the greatest service. Not merely is this the case in large gardens, but it is even more indispensable in the gardens of the middle and working classes. For two springs in succession, Cabbages have been comparatively scarce, being complete failures in many cases, and to make matters worse other winter and spring green vegetables have also been scarce. Nor must the Cabbage be despised as a summer vegetable. During the latter part of June and up to the present time it has been the only green vegetable available in quantity. In some cases what might be termed famine prices have been realised for spring-raised breadths of Cabbage, and it would have paid well to send them from the western and midland counties to the metropolitan markets. It may be that neither trying winters nor excessively hot and dry late spring and summer months will be experienced for some time to come, but, all the same, each ought always to be prepared for. In bygone days the greatest importance was attached to the spring crops, and after the sharp lessons we have had there ought to be no further need to remind my readers that present-day gardeners should attach quite as much value to Cabbages as former generations of growers did.

It seems to me we have done well in discarding some of the more robust varieties in favour of those less reliable if better in quality. Undoubtedly Ellam's Dwarf Spring and one or two more forms which greatly resemble that popular variety are a great advance as far as quality, neatness and even early hearting are concerned, but there is rather too much of a lottery pertaining to their culture. One season they succeed admirably, while during the next, under precisely the same treatment, disappointment ensues. By all means grow a good breadth of one or more of the neat-growing forms, including the variety most popular in the south-western counties, this being Wheeler's Imperial; but do not altogether ignore such reliable varieties as Enfield Market, Heartwell Marrow, Imperial and Defiance. These stronger growers, in addition to being quite hardy, produce good hearts, not merely in the spring, but throughout the following summer and autumn, always provided they have something underneath to support them. It may not be considered "high culture" to leave Cabbage on the ground long after the first heart has been cut, or say after having given a good early supply, but not many growers are prepared to go to the trouble of forming fresh beds in the spring. This season those who have preserved their beds intact have good reason to congratulate themselves upon so doing, and may again be

fore the year is out. If these old beds are further supplemented with a few hundred Coleworts, or even only a few score in the case of small gardens, there will be no lack of good wholesome green vegetables up to Christmas. By Coleworts I mean any variety of small, quickly-hearting Cabbage, including Rosette, Little Pixie, Shilling's Queen, Nonpareil, and such like. These ought to be raised in quantity, the seed being sown late in June or early in July, and the plants should be put out thickly wherever space can be found for them.

As before pointed out, it is the spring crop of Cabbage that is most valued, and whether this shall be a success or not is largely determined by the time of sowing the seed. In my younger days, and when practising in one of the home counties, about August 12 was thought a good time for sowing Cabbage seed in quantity, and the results were quite satisfactory. Since the introduction of the neat, early-hearting varieties already alluded to, this date has been found too late, the middle or not later than July 20 being the proper time to sow these. In the midland and more northern counties even this comparatively early date might be anticipated by a week or more, but in every case it is a good plan to make a second sowing from a fortnight to three weeks later, this time including rows or beds of the stronger-growing, later-hearting forms. So great is the necessity for plenty of plants, that a good open piece of ground ought to be given up to the seed-beds, and not some small corner or patch of warm border. An early and successional sowing having been made, more seed being sown directly it is seen there is likely to be a partial or complete failure from any cause, there will be plenty of plants for putting out and some to spare for neighbours should they, as they usually do, need some assistance. Sometimes it happens that the earliest raised plants run to seed prematurely, and it is then when the value of two separate batches of plants is most apparent. Should the season be unfavourable, those plants obtained by sowing in August may fail to attain a size fit for planting out, and once more the prudent cultivator who does not depend wholly on one sowing is on the right side. M. H.

VEGETABLES FOR NEXT SPRING.

THERE will be no lack of ground this season, so that planting need not be unduly delayed, as the Potato crop and early vegetables will be cleared long before the usual time. In my opinion late crops will be valuable on account of the short season. Those planted for the early autumn and winter supply will be required sooner than usual, and thus make later lots more valuable. In this locality Potatoes are quite three weeks to a month earlier than last year, and ground often occupied with crops at this date (early in July) is now vacant and ready for late winter vegetables. I fear in some gardens, unless due attention has been paid to the seed-beds, there will be poor plants, especially where thick sowing is practised. I do not advise too late planting, as unless there is time for the plants to grow it is labour thrown away. On the other hand, by planting quick growing crops and those which resist extremes of weather there will be less anxiety as to the supply of spring vegetables. I am fully alive to the advantages of resting the soil that has borne a crop, but I cannot do it, and I fear there are few who can. That, however, need not prevent good culture, as if the land is well prepared and the rotation of crops of diverse kinds properly carried out, there will be few failures if climatic influences are favourable. One often sees green crops fail simply because one succeeds the other. On land cropped heavily without

a rest, much may be done by varying the crops as much as possible, changing the manure, and digging in green vegetable refuse. This season I have dug in all the Spinach and small or succulent vegetables as soon as done with, and the ground being in a dry parched condition is much benefited. For late winter or long standing vegetables excess of manure does not give the best results, as a hard sturdy growth able to resist severe weather is required.

Coleworts are invaluable for late use if grown in quantity, and though these do not approach the size market growers require, they are valuable in the spring, just at the time other vegetables are running to seed. The hardy greens sown now will furnish good plants, and these may be put out very closely. I usually make three sowings: one in June, another in the first, and the last in the third week in July. These sowings give nice material for six months (from October till April), and for the March and April supply the plants are given a north border. For the autumn supplies the Rosette is sown. This requires more room and is less hardy. There is another point worth attention, and that is these plants seldom fail, being less subject to grub and caterpillars than others of the Brassica family. The Kales should be largely planted where late vegetables are required in quantity. For hardiness, the Cottager's, Buda and Asparagus Kales are valuable. The curled Kales are, perhaps, better known than the first-named. I prefer the dwarf Late Curled to the tall growers. This is hardier and one of the last to run to seed, forming a close compact head and short stem. Leeks may be grown where Onions fail for late spring use; for flavouring or as a vegetable they are serviceable. I prefer a dwarf thick Leek to a long one, the latter being difficult to cook unless cut, more trouble to grow, and, in my opinion, of inferior flavour. Turnips will be none too plentiful this winter, but with genial rains there will be no difficulty in getting a good supply for early autumn and winter use. I prefer Veitch's Red Globe, a variety of great merit. Large bulbs are not the best keepers. For late winter and spring supplies there are none better than the yellow-fleshed varieties, of which Golden Ball and Petrowski are good keepers, and for tops or cutting in the spring Chirk Castle Black Stone is best. This will stand very severe weather, and should be sown in August or early in September. Carrots, owing to the drought, have failed in many gardens, and I would advise sowing this month a short-rooted kind. Those who have Celery plants left over would find these useful if planted on the flat, merely drawing a deep drill to retain moisture and moulding up with a hoe as growth increases. These roots will stand frost and give useful material for soups, or even be valuable as a vegetable late in the spring when the other plants are exhausted. G. WYTHES.

Peas.—Last year I sent to you a note on the value of Prodigy as a second early Pea, but, considering its exceptional qualities, even in such a trying season as the present one I may be forgiven for again drawing the attention of your readers to its merits. I do not think that it is well known, for it was sent out about the same time as some other fine Peas, notably Duke of Albany, and got overlooked in consequence. But I believe it to be the finest variety in its season sent out for some years. In spite of the terrible drought experienced this year, I have been able to pick daily supplies for at least three weeks from two rows sown on March 23. These are now (July 3) over, but filled the gap between early kinds and another old favourite of mine, Champion of England. Most of the early kinds, of which the best was Chelsea Gem, came in practically together, and, in addition to the one named, I grew Veitch's Select'd Early, William I., and Exonian. These were sown at different dates, but the very hot weather brought them in within a few days of each other. Champion of England will last until Ne Plus Ultra is fit to gather, and on this latter I shall

depend until the latest kind (Sturdy) comes into use. I used to grow Criterion as a second early, and there is no doubt about its being a very fine kind; but it requires great care in gathering, as its appearance is deceptive, looking fuller than it really is, and unpractised hands are tempted to gather many before they are ready. Returning to Prodigy, it is a very fine Pea, each pod being packed with very large Peas averaging from nine to twelve in a pod. No other kind I grow is liked so much for the dining-table or pays so well for market, as it sells well and, what is rare with large-podded Peas, the crop is very heavy. It is not over-tall, as it averages about 5 feet—just the height that a good cropping Pea should grow.—J. C. TALLACK, *Livermere Park, Bury St. Edmunds.*

NOTES ON THE SEASON.

GARDENERS in particular will have good cause to remember the abnormally dry spring and summer of 1893. With many the difficulties must have been insurmountable, for what with a sandy or gravelly soil to contend with, and this not worked to any great depth, and also a poor water supply, little could be expected in the way of succulent vegetables. Personally, I have not so much to complain of, as the soil being a cold clay, I have been able to keep up a fair supply. The water supply with many is a serious consideration. In many gardens, no doubt, a ready supply could be obtainable at a comparatively small cost. I daresay that some people would think it quite incredible when I state that several thousands of pounds have been expended by my employers for only a very meagre supply; in fact, it is quite a failure. To meet such cases as these, the only panacea is deep cultivation, with a free addition of manure. In fact, I am sure that well-worked soil amply manured will give much better results than that which is poorly worked, deficient of manure and well watered. I have met with several cases this season where Peas and Cauliflowers have been quite a failure on account of the soil being so shallow worked. The old form of double trenching is not needed, for although there are exceptions, there are certainly numbers of cases where kitchen gardens have been quite spoilt for several seasons through the abuse of trenching. Very likely no trenching had previously taken place, but when this did occur, what little good pulverised surface soil there was buried 2 feet beneath the surface, and the crude subsoil placed on the top.

The value of prepared trenches for Peas was never more apparent than this season, the haulm and crops holding out surprisingly well. This season I made the most of the old Celery ground for the main-crop Peas, the rows being in exactly the same position, and as these were freely manured for the Celery, with an application or two of salt during the growing season, the condition of the Peas shows the value of so growing them. Where such precautions were not taken the crop must have suffered seriously, and although nothing can be done now, it supplies a wholesome lesson for another season. Potatoes as a whole are looking remarkably well. The south borders, of course, yielded the earliest Potatoes, but it is not this site this season which has yielded the heaviest crops; in fact, the tops ripened off remarkably quick, the quality not being so good on this account. In the more open quarters the crop is good and the quality first-rate. In many gardens, again, there has been a great outcry from the failure of the Cauliflower crop, and I am sure it would prove valuable if growers would give their experience as to the best plan of raising this. With me the autumn-raised

has been much the best. Of late years I know with many people there has been an outcry against raising the plants in the autumn on account of the time and other imaginary details, but I am sure good Cauliflowers can be grown by this method. A variety which has done good service this season is the large Asiatic. It is not grown nearly so much as it deserves, but all the same it is an excellent variety and well worthy of extended culture. It has withstood the drought remarkably well, the colour and quality being first-rate. On lighter soils certainly the results might not have been so good. I always take the precaution to set out the plants in deeply-drawn drills; in fact, cut out as if for Potato planting, plenty of manure being also worked into the soil.

This has been an ideal season for French Beans, the plants growing away without the slightest check. Grown on well-manured soil, French Beans are a good dry-weather vegetable and prove a veritable sheet anchor to a gardener. So also are Vegetable Marrows. These have simply luxuriated in the dry and hot weather, that is, where amply supplied with water when planted on prepared stations. Small seeds have done much better than might have been expected, and with the genial rains which are now falling at the time these notes are being written, will after all, it is hoped, lead to satisfactory results. Some few weeks since I sent a note as to the great benefit which would accrue by dusting over every morning with soot the seedling Brassica crops for winter use. The result with me is an abundant supply of plants of all kinds, the plants also being a mass of fibrous rootlets, the roots having ramified after the soot.

A remarkable feature of this season is, that although in some parts there have been quite refreshing showers, in others there have been practically none. It is to be hoped that the rain now falling is general, and this being so, it will lessen all anxiety as to the future of winter crops. A. YOUNG.

THE CABBAGE APHIS.

It is but too obvious that all the Cabbage tribe are terribly infested with aphis just now, and that only tremendous washings by means of heavy rainstorms can get rid of the pests. Pending this desirable consummation, which is not yet general, it seems as if great good would be done could anyone devise a remedy which could be safely applied to every form of Brassicae. The most difficult to deal with just now are Cabbages that are either now or fast becoming hearted, and therefore ready for use. Some of these heads are so foul with aphis, that they are literally smothered and quite unfit for eating. To keep them in the garden is simply to encourage the spread of the aphis, whilst they may be acceptable as cattle food when grass is so short. Where they cannot be so applied the best course seems to be to cut them off, but not too low down; remove carefully also all leafage, tread the Cabbages into a large hole, and cover over with a thickness of several inches of soil. When the Cabbages decay, the aphis would probably die also. Even to Cabbages that are only partially affected with aphis it is very difficult to apply any remedy for the destruction of the insects that may not be obnoxious. Insects are especially troublesome, too, in respect of the Turnip crop. So far it has been found exceptionally difficult to preserve the young plants from the fly or beetle. In this case, however, obnoxious dressings may be applied without danger to the plants or to their future use. There is no reason why the Bordeaux mixture, if there be added to it a strong infusion of soft soap to render it adhesive to the leafage, should not be applied with advantage, and where

the sulphate of copper and lime are omitted a strong solution of soot water and soft soap, to which is added as a dusting later, dry soot, will prove powerful aids to the preservation of the plants. Summer-sown Cabbage plants, Lettuce, Radishes, &c., seem to need similar protection from the fly. Some recent showers have been helpful, but a day's hot sun seems to dry up the ground and leafage and leave the myriads of insects as harmful as ever. A. D.

ORCHIDS.

AERIDES LAWRENCEÆ.

I REMARKED when looking through the Barford Lodge collection of Orchids a few weeks ago that *Aerides Lawrenceæ* was showing its spikes, and now having received some flowers from "A Lover of *Aerides*" asking various questions respecting this genus, a few words upon these plants might be acceptable to many of the readers of THE GARDEN. This plant, introduced by Mr. Sander about ten years since, is nearly allied to *A. odoratum*, but of gigantic size. The original plant was bought by Sir Trevor Lawrence in the sale rooms for 235 guineas, and a figure of it was given in THE GARDEN, Vol. XXXV., t. 702. It still remains the most superb and gigantic member of the genus *Aerides*. The distichous leaves are about a foot long, 2 inches broad, and of a rich deep green; the spike is long, and carries a many-flowered raceme, the flowers being large and very fragrant; sepals and petals pure white, tipped with a rich purple blotch; lip also white, fringed in front with rich purple, the large incurved spur being tipped with green. I have seen the species blooming in the months of November and December, and indeed at any time between the month of August and the last month in the year, and now in July I have the variety *Sanderianum* sent me. It appears to be most natural for it to bloom during August and September. It varies somewhat in its depth of colouring and in the density of the raceme, but in all the colour of the flowers is waxy white, marked with rich purple, whilst in the variety *Sanderianum* now before me the spur appears to be slightly more incurved and the ground colour more of a yellow hue, marked in a similar manner to the typical plant, with a few purple spots on the front of the lip. *A. Sanderianum* has been made a variety of *Lawrenceæ*, and justly so, I think, for I really can see nothing but colour to separate them. Other plants belonging to the same section well deserving culture and attention are the following:—

A. QUINQUEVULNERUM.—A plant with long deep green leaves, which are folded together at the base. This bears a very long spike, carrying a dense raceme of showy flowers, which are waxy white, tipped with very bright purple, the incurved spur green. This appears to be a very slow plant in making a stem, but it is one of the most beautiful of the family. It was sent to the Messrs. Loddiges, of Hackney, by Hugh Cuming fifty-seven years ago, so that it is not by any means a new species.

A. SAVAGEANUM is a newer plant, having been introduced by Mr. Sander some four or five years ago. It is a very richly coloured species, and it also appears to be very free flowering. The sepals and petals are of a crimson-purple, and the lip deep crimson with a small, straight green spur.

A. VIRENS comes near to the old *odoratum*, but it has longer racemes and the flowers are more loosely arranged. There are several named varieties, varying mostly in the depth of colour of their flowers and in their size, but all of them have the

spur much incurved. The flowers are pure white, tipped with bright purple and very sweet-scented.

A. SUAVISIMUM.—This is more lax in growth than odoratum, and the flowers, more distantly set upon the long spike, vary considerably in size in the different varieties and also in the colour. All, however, are more or less white, tinged with mauve or lilac, with a slightly deeper blotch on the tip of each sepal and petal; the lip flushed with a shade of orange or buff. The best and most distinct varieties which I have seen of this plant were in the collection of Mr. J. Jones, Whalley Range, Manchester, where many fine specimens of the distichous-leaved East Indian Orchids were grown.

A. ODORATUM.—This, the plant upon which the genus was established, was discovered in Cochinchina upwards of a hundred years ago. It appears to be widely distributed in the East, and many varieties have been named which do not differ much in general character from the original type. The form called *purpurascens* would seem to differ the most in appearance, having stouter growths, with larger and broader leaves; the raceme, too, is more dense and the individual flowers brighter in colour. Besides the above there is a form called *Dayanum*, which bears a more massive flower, another called *majus* having longer racemes and more brilliant flowers than the ordinary type. The variety *birmanicum*, introduced recently by the Messrs. Low, of Clapton, has smaller flowers, with fewer markings on the lip.

All the *Aerides* will do well if kept in a house the temperature of which does not fall lower than about 58° or 60°. *A. quinquevulnerum* and some few others require a little warmer position through the winter months, but care should be exercised in giving them moisture in order to prevent the leaves shrivelling and falling off.

WILLIAM HUGH GOWER.

Disa grandiflora.—Fine flowers of this superb plant come to hand from "E. J.," who says he has one spike bearing five flowers. In its native country it flowers about the end of February and the beginning of March, at which time the plant is just beginning to grow nicely with us. During the growing season it likes a nice moist atmosphere. "E. J." says the old name of *D. uniflora* would not apply to his plants, for he has none with less than two flowers, some three, a few with four, and one with five blooms on the same raceme. This I have seen several times, and upon one occasion I saw seven flowers upon one spike. The flowers vary a good deal in colour, some being, as in those now before me, bright crimson, flushed with rosy purple, while others are rosy pink and orange-red.—W. H. G.

Galeandra Devoniana.—A charming variety of this plant is now flowering in Sir Trevor Lawrence's collection, its large flowers being exceedingly handsome and uncommon. I cannot think why this plant remains so short-lived under cultivation. When I was with the Messrs. Rollisson at Tooting we imported a quantity of it from the Rio Negro district with the white form of *Cattleya Eldorado*, and many of the pseudo-bulbs were 5 feet or more in height and few less than 3 feet. These had been growing in a thick, deep vegetable mould, which induced me to grow the plant in leaf-mould, and with good results. The plants were placed in the hottest house we could find for them and kept nicely moist through the winter months, and I cannot but think if similarly treated it would become a permanent occupant of our plant houses. The flowers are large, helmet-shaped and borne upon the top of the stem in a large cluster; the sepals and petals purplish brown, with a narrow border of green; lip large, the colour white or creamy white, flushed at the apex with rosy purple and pencilled with lines of deep purple.—W.

Vanda Hookeriana.—An extremely fine variety of this very beautiful species is now flowering in the collection at Burford Lodge. It stands

along with *Anthuriums* and other stove plants, but in a position where it constantly obtains the full sun. The plant was first introduced some time in 1862 by the Messrs. Low, of Clapton, from whom I had a plant, but I failed to establish it. I am glad to see it flowering and doing so well with Mr. White with apparently so little care.—W.

Cypripedium Rothschildianum.—A flower of an excellent variety of this superb Lady's Slipper comes from Mr. Deacon, Bowdon Hall, Cheshire. He says it is from a plant which is bearing five flowers upon two spikes. I do not think this is anything extra, for I have seen the same number of blooms upon one spike, and these were all open at the one time. The variety is apparently very good and I have not the slightest doubt but it will improve. It should be repotted as soon as possible, which will cause it to gain strength, and from this plant another year you may get two spikes, each bearing five flowers.—G.

Thunia Bensonia.—This beautiful species is now flowering freely in Sir Trevor Lawrence's collection. The flowers grow in large terminal racemes or umbels, and are of a fine light magenta colour, the lip being open and veined with a very deep magenta, having a deep stain of orange on the disc. *Thunias* are very useful for stove decoration. After the leaves have fallen, remove the plants to a cool stove and keep them dry, but not to shrivel the bulbs, until about the month of March, when they should be shaken out, the roots trimmed, and be repotted. Drain the pots well and use for soil good peat fibre and Sphagnum Moss.—G.

Bolbophyllum barbigerum.—This very singular plant was imported between fifty and sixty years ago. It is now flowering in the Burford Lodge collection, where its long purple threads, which form a brush on the lip, are set in motion by the slightest current of air, rendering it a very curious and interesting plant. This and many others, which are considered by the majority of growers as unworthy of their notice, but many of which are most beautiful when examined, find a home at Burford Lodge.—G.

Epidendrum vitellinum mejus.—"W. H. G.'s" remarks as to the successful growing of *Epidendrum vitellinum majus* are to the point, and I think he has hit the mark exactly in drawing attention to shading and moisture. Some Orchid growers put down my success to the sea air, but if so, how is it my neighbours do not succeed? And how about growers actually on the sea coast? My *Odontoglossum* or cool house in which these plants are grown is shaded almost the whole day long by my residence, which does not allow the sun to shine upon it except in the early morning. I have two open tanks in the house, one occupying the whole space under the central stage. These are the contributors to my success, shade and moisture, as so ably pointed out in "W. H. G.'s" notes.—REGINALD YOUNG, *Liverpool*.

SHORT NOTES.—ORCHIDS.

Epidendrum alatum (J. H. Reeve).—The flowers you send are evidently of this species. I cannot think what caused you to imagine it to be an *Oncidium*. It has little to recommend it saving its slight fragrance.—G.

Cypripedium Curtisi.—From the Rev. E. Handley's collection comes a really fine variety of this species, the dorsal sepal being larger than usual, whilst the lip is enormous. If this was only a little brighter in colour the variety would be valuable.—G.

Aerides Godefroyanum (J. Inwood).—Yours is a fine variety of this plant, and not, as you suppose, a form of *Houlletianum*, which is nearer to *A. falcatum*. This was introduced from Cochinchina by M. Godefroy, after whom Reichenbach named it, and it is figured in "*L'Orchidophile*" for 1887.—G.

Cypripedium Parishii.—"M. M." sends flowers of this species, which are not, as far as I can see, out of the way. This Lady's Slipper likes plenty of heat and moisture. It grows naturally on the branches of

trees in the company of a Fern (*Drynaria quereifolia*). It enjoys plenty of heat and moisture, and the pots should be exceptionally well drained. It also likes full exposure to the light, but it should be carefully shaded from the sun's rays, or the leaves will suffer in colour.—W.

Oncidium leucochilum.—This distinct species, introduced from Guatemala as far back as 1823, is blooming freely at Syon House. The spike is of great length, and a considerable time elapses before full development. The colour of the flowers is charming, the lip of the purest white, the side lobes pink, whilst the sepals and petals are green, barred with chocolate.

Aerides crassifolium.—Andrew Cochrane sends me a portion of a spike of this fine Burmese plant, which was first found about thirty years ago by the Rev. Mr. Parish. The flowers are large and of a very bright rosy purple; the plant itself is a robust grower, with stout leathery leaves. I should be very glad if the grower that informed me last season that he possessed a pure white form of this species would let me know if it is flowering with him this year, and if so, would he spare a blossom for identification?—G.

Miltonia Regnelli purpurea.—J. Fletcher sends me a flower of this variety for a name. The species, I believe, I flowered first in England, and this was called Mr. Rucker's variety when it was first known. The colours are very rich, the sepals and petals being soft rosy purple usually with a white marginal border. In the flower now before me the colour runs right through, and the flat lip is rich purplish magenta. This plant comes from a warm part in Brazil and thrives best in the *Cattleya* house.—W.

Masdevallias.—"J. B." cannot think why these plants produce such small flowers this season. His plants of the various forms of *M. Harryana* do not produce blooms more than half the size they did last year. This, no doubt, is owing to the great heat of the season, and I have heard the same complaint from growers having a far better place for their plants, viz., a north house and in constant shade. The flowers are bright and rich in colour, but the complaint about them is that they lack size.—W. H. G.

Top-dressing Calanthes.—At this season of the year, when *Calanthes* are in active growth and the roots working freely, I find they are much improved by a little top-dressing composed of dried cow or horse manure rubbed through a sieve, some turfy loam and Sphagnum Moss. This should be spread over the surface to the depth of half an inch and pressed on rather firmly. A top-dressing of this kind will be much better than gorging the soil with manure water, as this is apt to make the soil sour. Liquid manure may be used, but only in a perfectly clarified state.—A. YOUNG.

Petroleum as an insecticide.—Although petroleum as an insect destroyer has been prominently before the public for several years past, yet many people still look upon it with doubt. Extreme care is needed in its application, and from the want of this no doubt many failures have occurred. Now that it is being recommended as an effective insecticide for summer use on fruit trees, yet more information will be needed as to its use and effect on various subjects. As to its being effective in killing red spider on Gooseberry bushes there can be no doubt; but, on the other hand, there is the flavour of the fruit to be considered. Those who may have used it for this purpose will perhaps tell us whether any ill effects follow when used in this way. I note that Mr. Wythes for the last year or two has written in favour of Bentley's soluble paraffin. Upon the strength of this, last year I procured some, and although I did not use it during the summer on fruit trees, but only at the dormant season, it quite bore out what Mr. Wythes has stated in its favour. The ordinary petroleum of commerce was also used, and I must say that both proved efficacious. Petroleum has also been recommended as a winter dressing for Vines, but extreme caution is needed with these.

I have heard of two or three instances where Vines were totally ruined, the eyes failing to start. I used it some years ago on all our Vines with no ill effects.—Y. A. II.

ORCHARD AND FRUIT GARDEN.

GRAPE LADY DOWNE'S SEEDLING.

COMPARED with twenty years back, this fine Grape is not now grown so extensively as then. This, no doubt, is caused by the extended culture of Gros Colman, which may be a better Grape to look at when it is well coloured, that being none too frequently. The larger berries, the freedom with which they set, and the heavy crops that the Vines will carry have also told in favour of Gros Colman. When, however, we consider flavour as being the most essential feature, which it should be in all private establishments, then the preference must be given to Lady Downe's Seedling; whilst at the same time it will keep better late into the spring. Where it is requisite that the old Grapes should meet the new ones in the latter end of April or of May, then the subject of this article must likewise be placed in priority to Gros Colman. I used to have a span-roofed house filled mainly with Lady Downe's, in which about 500 bunches would be hanging at Christmas-time every year. This crop made the matter of lasting out until new Grapes were ripe an easy matter, and year after year no difficulty was ever experienced in keeping the fruit when well ripened. Whilst upon this point it is as well to add that there is at times a tendency towards shrivelling if the fire-heat be carried on too late in the autumn at too high a standard. For my own part, I prefer to ventilate quite freely and lower the temperature also by the end of September. Soils and situations have also undoubtedly influence in this matter of shrivelling. In one instance where the greater portion of the border was inside I rarely found shrivelling give any trouble, but in another house with staging and brickwork in plenty, both tending to a drier atmosphere, I have had some trouble at times to keep it in check. I consider, moreover, that any tendency in the Vines to make a late growth, which Lady Downe's will oftentimes do, should be checked as far as possible. Upon this also depends the good keeping of the fruit without a doubt, for not only should the Grapes be well ripened, but the wood also; otherwise the foliage, which is not beneficially affected by the fully ripened wood, will remain green the longest and thereby draw its sustenance in a manner from the bunches themselves. On reference to the engraving accompanying these remarks, it will be noted that the bunch is a well-thinned one with daylight here and there showing between the berries. This is as it should be, so as to ensure a good state of preservation when less favourable weather sets in with the fall of the leaf. It is far better to thin well at the proper time than to leave the berries sufficiently thick for them to press each other tightly when they are coloured and swelling has ceased. Where scalding gives any trouble a little allowance can be made for this failing, but not much, for with top and bottom air left on all night in just sufficient quantity to prevent accumulated moisture upon the berries there need not be much fear of it. The thinning where done with a sparing hand at the proper time will almost inevitably have to be done later on when the berries are coloured,

for here and there a berry will show symptoms of decay and give a lot of trouble in extraction. No inside berries in berries of Lady Downe's should ever be left at the last thinning. My practice is and has been for more than twenty years to cut and bottle the bunches the first week in the new year, but I have rarely found it requisite to commence using them before February or even March, when the flavour is considerably improved; at any rate, such has been my experience of this Grape. Something more than twenty years ago I on more than one occasion exhibited boxes or baskets of 12 lbs. weight in March and April, when I

of the stock of fruiting plants. Some of them were much injured by the severe frost of last December and January, but the crops are generally good. I notice that Duke of Edinburgh (Moffat's) is much favoured by market men. It certainly is of hardy constitution, very productive, and of large showy appearance (always an item of much importance with market fruits). While some have suffered from the effects of drought, I have no complaint to make from the absence of moisture. Liberal mulching with half-decayed manure in early spring has saved us from all trouble of watering, and plenty of fine fruit is being gathered. —M. TEMPLE, *Carron House, Stirling, July 6.*

Feeding Vines.—The value of liquid manure is not sufficiently known, as often unsuitable soil may be made fertile by abundant supplies of liquid either from the cow yard or stables. Having a very light soil to deal with, I have found cow manure of great value, especially for young Vines. As is well known, such manure applied in a green state clogs up the soil, and it should either be mixed with loam (spent Mushroom manure in a dry state is excellent) or be placed in heaps and allowed to get partially dried. In such a state it is valuable as a surface-dressing on light soils. When applied to the surface of the border, in a few weeks the soil will be full of white healthy roots that will be ready for a surface-dressing of heavier material in the winter. Not only is the cow manure good for the roots, but it retains moisture and keeps the houses at a more even temperature, thus preventing the spread of insect pests. In stiff, heavy soils another manure equally valuable for top-dressing is night soil, provided it has been thoroughly prepared. It is a valuable manure when mixed with loam, or, what is better, with burnt refuse, wood ashes, or charcoal refuse, allowing it to remain a few months after mixing before applying it to the Vines as a top-dressing.—G WYTHES.

Grape Lady Downe's Seedling.

was offered 15s. a pound for the lot, and all I could supply of like quality. What a contrast this with the prices now ruling at the same season. GROWER.

Strawberries in the north.—Notwithstanding the great numbers of new Strawberries which have been raised and sent out of late years, I find that in most Scottish gardens the varieties cultivated are few. The northerners retain those (if ever so old) which give the best returns and which can be depended upon for hardiness and good constitution. None as far as I have seen (while visiting gardens very wide apart) are valued so much as President and Vicomtesse Héricart de Thury. Rarely can one visit a garden where these two well-known varieties do not form a large portion

STRAWBERRIES.

To have a full supply of Strawberries for at least two months in the summer should be the aim of everyone in possession of a garden of even moderate dimensions. There are varieties now which will succeed in almost any soil, and although in some situations it is a difficult matter to secure late Strawberries, it is worth some trouble to extend the season by planting the latest varieties in borders kept cool or shaded by some artificial means. Other fruits may be getting more plentiful in August, but Strawberries never come amiss. I have a variety grown from alpine seed which only requires more size to make it really valuable, being a continuous and heavy cropper all through the summer and autumn.

In a season like the present, when the crop was over by the time (middle of June) we generally commence picking, the variety Héricart de Thury will probably be fruiting again in the autumn. In a warm situation this Strawberry generally throws up a second lot of bloom, but rarely early enough to set a crop before frost comes. Noble has done remarkably well; in fact, it is far ahead of any other fruit crop this season as regards profit. It is evidently a variety well suited to

stand drought, and the quality was on that account much improved. This successful crop was grown on land sloping towards the south, which has had nothing but artificial manure for many years. It is the third season from planting, but the runners have been allowed to partially cover the ground. The most profitable way of growing Noble, where it can be managed either by stocking out the old plants or well thinning the runners, is to allow the runners to grow and keep up a succession of young plants, as the fruit comes much earlier and larger from one or two-year-old plants. The reason the crop has been so good this season on beds managed in this way is no doubt partly owing to the small quantity of leafage, which allowed the sunshine full play amongst the berries, to their great advantage in quality and colour.

To ensure a clean sample of fruit some kind of mulch is absolutely necessary. Where a sufficient supply of stable manure can be secured, nothing will beat a good dressing put on in winter or early spring. This will be a sufficient mulch, but there will even then be a difficulty with the weeds. The best time for planting Strawberries depends a good deal on the character of the season. In the garden, no doubt August or as soon as rooted runners can be secured is the proper time, seeing that a good crop of most varieties may be gathered the following season if the plants are placed in beds 1 foot apart, to be thinned after fruiting, but in the field, where we have to deal with plants by the thousand, either autumn or early spring is to be recommended. As a rule, I prefer spring, but in a season like the present, spring planting, where the plants could not be watered, has been of little use unless done very early, say in February. If delayed till autumn, plant if possible before the middle of October, to give time for sufficient root-hold before winter. If looked after and kept well trod in, plants may be successfully removed in open weather all through the winter. For a late Strawberry Laxton's Jubilee is worth growing, being hardy and a prolific cropper. It is a pleasant surprise to find a nest of the sweet, firm fruits of this variety weeks after other kinds are over.

If asked what was most necessary for the successful growth of Strawberries, I should say firmness of soil. Make your soil as rich as you like before planting, but afterwards tread firm and keep it firm, applying all manure on the surface only. The same soil and even the best of Strawberry soils will not suit every kind alike. Growers will find out by experiment which sorts suit best. In a mixed plantation where the Strawberries are planted between bush fruits, to be cleared away as the bushes require room, of four varieties planted five years ago, Noble (on the original plants) did best, Héricart de Thury suffered from the drought, but the old plants still bear well where sufficient moisture is available, while Paxton after the first two seasons has been of little good, and President a comparative failure from the first. Laxton's Competitor has stood the drought well, and is worthy of trial as a mid-season Strawberry. The runners do not bear as with Noble, but the grown plant is full of fruit and foliage. It appears to be hardy, as I noticed the blooms withstood frost when those of Noble were cut off.

E. W. B.

Raspberries.—The variations of growth found in these fruits in diverse gardens are remarkable. In not a few cases the canes are only fairly stout at 1 foot in height, in others they are stout and full of fruit 6 feet in height. Where such very strong growth ensues, it is a matter of necessity that ample room between the rows be given, and of course very tall, stout stakes are needed to sustain them. On the whole, I very much doubt whether such very tall canes so wide apart produce larger fruit or average crops than do canes that range from 3½ feet to 1 foot in height, and are in rows about 3½ feet apart. Perhaps it may be pleaded that canes so short fruit closer to the ground and the fruit is in such case in danger of getting soiled. That evil, however, might be easily remedied by mulching the rows with long

manure, and whilst the lower fruit is thus kept clean, weeds are checked, so also is evaporation in dry weather. It is not easy for everyone to have plenty of tall stout stakes, whilst shorter canes need only very trifling support, as between planting in stools and in rows trained up to wire supports there is perhaps not much to choose, for both ways are excellent, but the wire support if secured to stout Oak posts is of great endurance, and gives very little trouble in the matter of tying. It is a good time now to thin out young suckers, and should some be needed in the winter for transplanting, to select and preserve the remotest from the stools as being the best rooted.—A. D.

FRUIT TREE PRUNING.

I SHOULD think that paper read by Mr. A. Young on June 7 before the Royal Horticultural Society and published in THE GARDEN of July 8 would be about the stiffest conundrum ever propounded in that quarter. What the author of the paper means I cannot make out, but he is neither an "extensionist" nor a "restrictionist," nor anything between the two, I think. Here are two extracts from the same page quite opposing each other—

NO.

I am fully convinced that when it is judiciously performed summer pruning is one of the greatest possible aids towards the successful cultivation of fruit in the open air; and amongst really practical gardeners I do not believe there is any difference of opinion as to the system itself, but only as to the time and manner of performing it. At the same time there appears to be amongst some an increasing tendency to allow outdoor fruit trees to grow with far greater freedom, and allow them to assume what is called a natural form, with but little, if any, pruning at all. This, I think, is an evil; for if trees are allowed to carry their whole natural free growth they will soon become so crowded, that, instead of being able to produce fruit of fine quality, it will be small in size and poor in flavour, and only appear at the outer edge of the tree, and not equally over the whole, as it does when the growth is kept well balanced by judicious pruning, and light and sunshine have free access to all parts. I cannot sufficiently condemn what is by no means an uncommon occurrence now-a-days, viz., the stepping right out of the groove of rigid pruning into the very opposite extreme of absolutely natural growth, without any attempt or thought of even thinning out the shoots, so as to allow light and sunshine to have free access.

Readers will see from the above extracts that the "opposite extreme" which Mr. Young "cannot sufficiently condemn" is his own practice, and is attended with unqualified success in "all" his Plum trees, which are no exception to the rule, and shortening a tip "here and there for balance" is not pruning for fruit. In one extract it will be noticed this "extreme" causes "crowding," and in the other a paucity of shoots—"very little annual growth." A more illogical and inconsistent "paper" I never read.

YES.

The dwarfing stocks now largely in vogue have helped to revolutionise fruit growing, or rather the pruning that is required, for with the advent of these stocks, which supplied a want long felt, trees suitable for the smallest gardens or for special positions could be grown of a small restricted size, and be also made fruitful without much pruning or pinching being necessary to produce them. It was the attempt to rigidly restrict the old trees grafted or budded on what is known as the free stock which led to the abuse of summer pinching, as any attempt to dwarf trees on these free stocks by summer pinching or pruning only led to disastrous results, the continual pinching or pruning only causing the trees to produce a thicket of shoots and unfruitful spray. During the past few years I have allowed all our Plum trees, bush as well as standards, to go practically unpruned, save the shortening of a branch here and there to balance the growth of the tree, and I never saw trees in a more fruitful condition, fruit-buds forming right up to the tips of the two-year-old wood, and though very little annual growth is made under this system, yet what there is is short and fruitful. Now if these trees were subjected to rigid annual pruning, a thicket of spray is all we should obtain for our pains.

J. S. W.

EFFECT OF HANDLING FRUIT CARELESSLY.

A GREAT deal of fruit is annually either spoiled or much disfigured by careless handling. In some instances the blame rests with the grower or those responsible for the fruit, and in still more cases it is either the owners or visitors who do the mischief. Peaches and Nectarines approaching ripeness would seem to tempt the latter class, and if not watched very closely or repeatedly checked, they cannot resist giving those that are coloured a squeeze. They little know, and probably heed still less, what an effect those squeezes have upon the fruit. Not only does the outline of the thumb and second finger show very plainly when the fruit is fully ripe, but this disfigurement is quickly followed by decay. Ripening Peaches and Nectarines ought to be touched by no one but either the owner or the person responsible to the latter, and the inexperienced among these are warned not to press them in a careless fashion. On no account should a squeeze be given on the upper surface of a fruit, or a bruise may be unwittingly caused. A very light pressure with the forefinger on the base of the fruit, or close up to the foot-stalk, ought to be all that is necessary to determine the ripeness or otherwise of the fruit. If it is just soft there, then the rest of the fruit is fully ripe enough for gathering, though a few hours or a day or two in a cool fruit room would in most cases improve the quality. After a very little practice it becomes an easy matter to test the fruit in the manner indicated without bruising the fruit in the slightest. A Peach or Nectarine may, however, be quite fit to gather and yet not part freely from the tree; in fact, if they part very readily, the chances are the fruit is either over-ripe or not of good quality, owing probably to over-cropping. They ought to be gathered before they quite reach the dropping point, allowing them to drop into fish nets suspended underneath being a great mistake and a frequent cause of bruised, flavourless fruit being sent to the table. The fruit certainly should not be dragged forcibly away from a tree, but ought to require just enough pulling to part with a slight click. Here, again, practice makes perfect. If grasped too firmly in the hand, this may lead to bruising, and those who are unable to grasp the fruit without thus disfiguring it should have a pad of cotton-wool in the hand. After the fruit is gathered, it must still be handled very carefully. Finger or thumb marks may not show directly, but they do in a few hours. Whether the fruit is to be sent to a long or short distance, it ought to be still handled and packed carefully, never resting on or pressing hard against each other. This may to the uninitiated seem very trivial, but it is nothing of the sort, large numbers of soft Peaches and Nectarines being disfigured between the time they are gathered and the time they are eaten, housekeepers and other indoor servants spoiling much soft fruit by careless handling. Half the fruit that is sent to a dining-room and not eaten in the usual course is of little value the next morning, owing to the ordeal through which it had to pass. Even those who test the fruit at the table will do well in every way to press that part where finger marks will not show.

Apricots are quite as susceptible of injury as are Peaches, and should, therefore, be quite as carefully handled. Some varieties, notably Moorpark, and which happens to be the best of all Apricots, are very difficult to gather, and if it is to be kept two or three days after gathering

the fruit should not be fully ripe when pulled, and should be detached from the tree by means of a good pair of Grape scissors. Figs should also be very carefully handled. They do not, as a rule, part readily from the trees even when fully ripe, and break to pieces if gathered carelessly. When gathering grasp the fruit boldly, yet with a hand of velvet, and with the thumb detach the foot-stalk from the tree. The most richly flavoured fruits are those that are left on the tree till the skins are much cracked and on the point of decaying, but this stage must be anticipated if the Figs are to be sent to a considerable distance, the handling in any case being very carefully done. Plums are of a harder nature, the skins being more elastic than in the case of the other fruits mentioned, but, all the same, there ought to be no careless handling of the fruits. They are most tempting and pleasing in appearance when the bloom that invariably forms on them remains intact, and it is this that should be preserved as much as possible. Curiously enough, judges at flower shows frequently quite ignore this addition to the appearance of a Plum, much-polished fruit being given the prizes for no other reason than because it happens to be fully ripe or extra large, as the case may be. Yet the same men insist upon Grapes, rightly enough, having a good bloom on the berries. The foot-stalks ought also to be saved on dessert Plums as much as possible, and not many will be lost if the fruit is gathered before the dropping point is reached, being detached with the aid of scissors. As they are gathered, lay them in either a flat box or basket with a paper-covered padding of some kind in a single layer and just clear of each other, careful subsequent handling being necessary. Even Cherries show the effects of careless handling. Instead of being dragged away from the trees by the handful, choice fruit ought to have the foot-stalks cut through with scissors, the foot-stalks also serving as a handle for shifting the Cherries with. Apples, like Plums, have fairly strong, elastic skins, and therefore are not particularly liable to bruising. Too often, however, this good quality is strained unduly, as the fruit will scarcely stand being shaken down or otherwise roughly handled. When bruised, they keep badly and are of far less value than would have been the same fruit if less badly used. Pears are among the fruits that are the most injured by being squeezed at the wrong place. At all times they ought to be carefully handled, and when tested as to ripeness, the fruit should be taken in the hand and the thumb pressed against the thin end next the foot-stalk. If it is soft there, then the fruit is quite fit to eat. Should Pears not be used at the time they are tested, the slight bruise caused will not be noticed, nor will it impair the keeping properties of the fruit. Press them anywhere near the thickest part of the fruit and disfigurement is certain.

As already hinted, Grapes are thought but little of if minus bloom, and I need hardly point out how very careful those responsible should be to preserve this as much as possible. No thoughtless or irresponsible persons ought to have free access to a vinery, for the simple reason that very many of them cannot resist pressing some of the berries. Once the Grapes are fully grown, not necessarily ripened, every rub and every squeeze will show, this heedless removal of bloom showing even more plainly when ripeness is reached. It may not be possible, nor is it necessary, to send bunches to the table without a rub of any kind. The best side ought to be kept well laid up, whether the bunches are only to be sent a short dis-

tance or are packed for a distance, and when dished up with the same care, few or no marks of handling or rubbing will be noticeable.

W. IGGULDEN.

YOUNG VERSUS OLD STRAWBERRY PLANTS.

Old Strawberry plants, by which I mean any that have borne more than two good crops of fruit, were the first to feel the effects of the prolonged drought, not a few of them being burnt up beyond recovery. Under good cultivation, and on soils suitable for Strawberry culture, the plants are seldom purposely destroyed before they have produced three crops, and I have known them remain in a profitable state very much longer, this being principally due to a very free use of sewage water both during the winter and spring months. There are also soils so unsuited to Strawberry culture, that it does not pay to attempt taking a second crop from the plants. Not that a second crop could not be had, but the quality was so very inferior, that the fruit was comparatively worthless. The question is, Do we attach sufficient importance to the value of young Strawberry plants? In other words, are not the older rows still left on the ground longer than they ought to be in very many cases? Old plants, as just previously admitted, can be and very often are made to produce heavy crops of fruit, but what about the quality? How does this compare with that of the fruit of young plants on fresh ground? According to my experience, in the majority of instances the finest and also the best flavoured Strawberries are obtained from plants fruiting for the first time. It is also an indisputable fact that the first gatherings are obtained from young plants, and for this reason I have consistently advocated planting Noble on warm borders afresh every summer, taking one crop, and that an early and heavy one, from the plants, and then, after the requisite number of rooted runners is obtained, clearing off all together. I am not prepared to argue that Noble is of fine flavour under any circumstances, but from young plants the fruit is presentable enough and seldom found fault with. It is the crops from older plants that find so little favour either on the dining table or in the markets. Alice Maud is sometimes condemned for its inferior quality, and there may be good reason for the complaint in some cases. Young plants on fairly strong soils, however, produce grand fruit of superior quality, too. Sir Joseph Paxton does not vary so greatly, but I am yet of opinion that the most luscious and certainly the finest fruits are produced during the first two seasons after planting. Much the same rule holds good in the case of another popular variety—President. British Queen absolutely refuses to fruit a second time on some soils and in some situations, and very rarely do other than quite young plants produce heavy crops of superior fruit. Loxford Hall Seedling, grown on a cool border, yields a fairly good crop of extra fine, richly-flavoured fruit during the season following planting and a good full crop during the second year, after which it is a mistake to leave the plants any longer on the ground. I shall make no further attempt to multiply these examples in favour of my contention that the best flavoured fruit is obtained from quite young plants, enough being adduced to bring home the fact to all who like to have or to grow the best of everything.

In addition to young Strawberry plants being the first to produce ripe fruit of superior

quality, they are also hardier than the majority of those that have lost much of their pristine vigour, or any, say, that have given three good crops. The short spell of wintry weather, that is to say, the three weeks' frost of last winter, was much felt by the Strawberries generally, but although it undoubtedly weakened the younger plants, it did not kill any hereabouts. The older breadths, however, did not come out of the ordeal at all satisfactorily, not a few large plants having been killed outright, while those that survived had not recovered much ground before the severe drought set in. The hardiness of old plants, therefore, being doubtful is another reason why fewer of them should be saved. It is sometimes urged in favour of their being retained longer than I advocate that the third and in some cases the fourth crops are much the heaviest, and if only a few of the fruit are fine enough for dessert, the rest are very acceptable for making into jam. That large quantities are required for the latter purpose there is no disputing, but why not grow one or two varieties especially for supplying this class of fruit? Instead of keeping the finer or high-class varieties on the ground longer than they continue to give the best dessert fruit, would it not be a better plan to clear them off the ground after producing two heavy crops and to grow either Stirling Castle, Vicomtesse Héricart de Thury, or the old Grove End Scarlet solely for giving preserving fruit in great abundance? The fruit of either of these three varieties can be made into much better jam than any obtained from choice sorts, and which may be much mixed both as regards size and quality.

Doubtless where extra pains are taken in the preparation of ground well suited to Strawberry culture, good room also being allowed between the rows and the plants in the rows, the third and even fourth crops are remunerative enough, but in how many cases are all the conditions favourable to this end? In very few, I think. Too often deep culture and a free use of solid manure are followed by a rank growth of the plants, a plentiful crop of leaves and not very much fruit being the outcome. In other instances the fruit is produced freely enough, but owing to the plants running into each other it fails to ripen properly, especially in a wet season. If ground is trenched for Strawberries, this ought always to be done in time for a crop of early Potatoes to be taken off, and it will have settled down considerably accordingly. It is not the adoption, but the abuse of the practice of trenching for this crop that I often condemn, and shall continue to do so as long as instances of the latter come under my notice. Now, trenching is not possible in all cases, and, fortunately, is by no means an indispensable preparation. Young plants will produce good crops on untrenched ground or any equal to what are obtained by the more expensive and laborious preparation, and there is less likelihood of failure from the looseness and richness of the root-run. Most soils that have been well manured, dug a spade deep, and got into a free working condition will answer well for Strawberries, while if well-rooted plants are got out by the end of July or during the first week in August and well attended to, they will become sufficiently strong to produce a valuable first crop. On moderately strong retentive soils I have not seen properly mulched plants fail any the more quickly from not having a very deep run, and heavy waterings were quite as much needed in the case of those on light trenched soils as by those not having the benefit of this extra preparation, always provided they had not been on the ground

more than two seasons. This season both early and second early Potatoes will be fit for lifting very much sooner than usual, and Strawberry runners, though none too plentiful, are also early. This will give a good opportunity for putting out more young plants than in previous years and of testing my theory as to the superiority of the produce from young plants.

GROWER.

PECULIARITIES OF THE SEASON.

Few people living can remember having experienced such a trying, and in many respects so disastrous a year as that of 1893. Whether we have seen the worst of it remains to be proven. It may be, redeeming features will yet be found, but at present the gains are badly over-balanced by losses, gardeners having nearly as much to complain of as farmers. Curiously enough, the dwellers in nearly every district that I have visited or heard from seem to be under the impression that they have suffered the most both from the heat and drought; but if notes could be compared, it would most probably be found that Dame Nature's favours have been pretty evenly divided. Thunderstorms are frequently very partial. They seem to fall heavily in some localities and pass round others, but then the chances are those who miss the rains on one day come in for their share a few hours, or it may be days, later on. As far as all the counties south of Durham are concerned, the rainfall since February has been disastrously light. What rain has fallen at different times was of little avail against the powerful and constantly sustained sunshine and heat, this almost amounting to what is usually experienced in tropical countries. Those who are on light gravelly soils are by far the greatest sufferers, even if the water supply has not failed, the coolness attending clayey sub-soils being of the greatest benefit, and which no amount of watering in the case of gravelly or chalky soils seemed capable of producing.

Excessive heat, whether or not accompanied by moisture at the roots, is not good so early in the year for the majority of the fruits, flowers and vegetables we cultivate, and if the seasons changed permanently, then we, too, would have to take a lesson out of our American brethren's book and grow selections that would better suit the climate.

FRUIT.

It is very certain the great heat did not suit Strawberries. Although being able to gather ripe fruit during the first week in May was in some respects a boon, I would rather have dispensed with these early pickings and had later, heavier and more richly flavoured fruit. Gooseberries, Raspberries and Currants again have been far from satisfactory as regards flavour, all ripening very early, and the shortness of the season is much felt in many quarters. Caterpillars and red spider have been great enemies to the first and last named, and in many gardens not a healthy bush or any good fruit can be found. In cooler positions and where the bushes are well protected the fruit is fairly large, and hanging will, perhaps, remove some of the acidity from the Currants. Very early also were the dessert Cherries, Morellos likewise being ripe fully a month earlier than usual. The latter are among the best fruit crops of the year. Never before were ripe Peaches gathered from the open walls in the south of England by June 19, and in all probability if standards had been grown these would have given good crops of fruit. The

trees of double-flowering varieties flowered grandly this spring, and so would also standards of the sorts cultivated for their fruit if only they were given the same chance. Not only are Peaches and Nectarines ripening very early, but the fruit promises to be finer and better in quality than often seen in the open. Especially is this the case where the borders have been heavily mulched and watered occasionally, red spider being kept down by means of frequent syringings. Apricots, on the other hand, though equally early in ripening, are smaller than usual. These, in spite of the severe frosts experienced when the trees were in bloom, are exceptionally abundant, and in but few instances has thinning out been severe enough. The most luscious fruits are those shaded by foliage, and it would have paid well to shade the trees during the hottest part of the day. What few standard Apricots are grown should do well this season. During the average English summer they are of no service whatever in any but the most favoured districts. Plums—Rivers Prolific, Morocco, July Green Gage, and De Montfort, none of which ripen during an ordinary season much before the first week in August—were fairly ripe by the first week in July, and if the change to cool weather lasts for two or three weeks, then a long succession of superior fruit should be obtained. We gathered the first ripe Pear (variety Doyenné d'Été) on July 1, Citron des Carmes being about a week later. Pears, where they have not suffered greatly from the drought, in addition to being very early, also promise to be extra fine, Jargonelle and Williams' Bon Chrétien being particularly good. Apples, on the other hand, though more plentiful than at one time thought possible, are yet very small, the exceptions being where the trees have escaped blight and are thinly cropped. Birds are already very busy among them, the soft Codlins suffering most from their depredations. Beauty of Bath and Irish Peach are now ripe enough for use, these forming a close succession to Early Julien and Early Harvest. In the "good old days" August 10 was considered fairly early for the latter to be ripe. This year there will be none left by July 16.

FLOWERS

generally have been very early and short-lived this season, and that is not the worst of it. Not a few have been lost outright and very many more are badly crippled. Annuals even when sown where they were to bloom either came up badly or else failed to attain anything approaching their proper size before they flowered. Herbaceous plants, especially where they have not been transplanted lately, have also suffered very much from the heat and drought, and the Sunflowers and Phloxes are in full bloom, this being a month earlier than usual and before they are wanted. Most probably many of the border flowers will behave as queerly as some of the flowering shrubs are doing, these latter flowering again in several instances. Quite recently all the ends of the young branches on Laburnums were furnished with a flower raceme, and very pretty they looked, too. Roses against walls have given one early crop of blooms, and by the time these lines are in print a good second lot will be at their best. Nurserymen complain bitterly of their losses among newly-moved trees and shrubs generally, and of Rose stocks in particular, one putting the number of the latter lost by himself at about 30,000. Carnations were never more plentiful or much better than they are this season, and these grand border flowers will be more extensively grown during

the next few years than for a long time past. Clematises, again, have been gorgeous, but were far earlier than desirable. Some few things seem to like the hot and dry weather. For instance, the shrubby Hibiscuses, whether grown against a wall or in the open, are unusually fine and very beautiful; so also were Gum Cistuses, but, unfortunately, in both cases the flowers are very fragile and last but a short time. I never saw the common Jessamine flower so beautifully as it is doing this season, the charming white flowers quite scenting the place. Banks of St. John's Wort have been and still are very gay, no amount of dry weather apparently checking either the free spreading habit of the plants or their free flowering.

This has been a very bad season for

VEGETABLES,

and probably there will be no marked improvement for some time to come. Everything has been very early, and in many cases also too quickly over. Peas are the worst failure of the year, no amount of watering apparently saving the crops. The heat was too excessive, and as a consequence the haulm became badly blighted, the Peas in the pods also hardening more rapidly than desirable. I am afraid the change has come too late to save the later rows, most of which are flowering prematurely. Kidney Beans stand the heat well, and if kept moist at the roots prove one of the best of hot weather vegetables. Very promising also are the rows of runner Beans. Cauliflowers are a complete failure, and so also have Lettuces been in many gardens. As far as quality is concerned, Potatoes were never better and rarely so good at this time of year. The crops are not quite so heavy in some cases as desired, but there is no disease nor many faulty large tubers. Really good crops of Ashleaves have been dug that have been grown without any rain having fallen on them from the time the seed tubers were got in, but in these instances the ground was very well prepared for them. Other root crops have proved most unsatisfactory, while Globe Artichokes are both scarce and small, this being largely due to the pinch the old stools had last January. Vegetable Marrows revel in the heat, and some have already been sent to the markets.

M. H.

GARDEN FLORA.

PLATE 919.

SOLANUM CRISPUM.

(WITH A COLOURED PLATE.*)

THIS free-flowering, hardy climbing shrub has found a congenial home in Ireland, where it is frequently seen clothing the fronts of houses and walls, and is even a favourite with station-masters there who have a taste for gardening. It also occurs in Ireland as a large bush; for instance, in the Glasnevin Botanic Garden there is now a fine example of it supported by a large stake, and forming a mass of dark green foliage and graceful corymbs of purple flowers which are attractive all through the summer. At Kew it is planted against a south wall, where it grows very rapidly, and would soon cover a large space if not freely pruned. It is a most useful plant for covering walls and buildings—a spring-struck cutting

* Drawn for THE GARDEN by Champion Jones, June 4, 1892, from specimens sent by Mrs. Robb, Liphook. Lithographed and printed by Guillaume Severeys.

SALANUM CRISPUM

if planted against a wall in May or June extending 3 yards or 4 yards high and wide before the frost stops it. Although almost an unknown plant in gardens, it is not by any means new, for it was introduced into England by Mr. Anderson from the island of Chiloe about the year 1830. It is said to be common in waste places, hedges, &c., in Chili, occupying the same place in the native vegetation there as our Bittersweet (*S. Dulcamara*) does here. When introduced, it at once attracted the attention of gardeners, and pictures of it were published in the botanical and horticultural magazines of that period. Dr. Lindley saw it exhibited by Mr. Hugh Low, of Clapton, in 1831 at a meeting of the Royal Horticultural Society in April, when it was greatly admired. The plant shown had been grown in a pot and had formed a pyramid with a great number of lateral branchlets, at the end of every one of which there was a bunch of flowers.

If planted out in a rich soil the shoots are very vigorous, and sometimes it is better to cut out the strongest of the new shoots, or there will be less flower than is desirable. It thrives in poor soil, and unless a large specimen is wanted I would recommend a poor soil for it.

The leaves at the base of the stems are much larger than those on the flower branches, being 5 inches or 6 inches long and 2 inches broad. I have been informed that this plant is a magnificent shrub in a few gardens in the south of France.

Another species of *Solanum* which is hardy against a wall in the south of England is *S. jasminoides*. There used to be a fine example of it against a south-west wall in the Pendell Court garden, and I have seen a beautiful picture formed by it against an old building and encircling a tall chimney in the garden of Miss Talbot at Margam Park, Swansea, where Mr. Muir, finding a shoot of it had crept through a broken pane of glass from the greenhouse, had encouraged it to grow outside.

These two species, with *S. pensile*, *S. Seaforthianum* and the king of all climbing *Solanums*, *S. Wendlandi*, are worthy climbing representatives of the Potato family, and deserve a place in every good collection of garden plants. W. W.

THE WEEK'S WORK.

HARDY FRUITS.

EARLY STRAWBERRIES.—There is yet time to form fresh beds of these with a good prospect of success. If strong well-rooted young plants of the favourite early variety or varieties are at once put out on a raised border in front of a south wall and well attended to, they ought to attain a size nearly or quite equal to the production of one pound each of extra early fruit. No other crop better repays for good culture. Seeing that these borders are usually somewhat limited in extent, none but the earliest Strawberries should be grown on them, one good crop from the plants being enough. If the space cannot be had for a change of site, then change the soil, substituting either a loamy compost or else the best fresh garden soil for the best part of top spit that is moved. For these somewhat hot and dry positions, good rotten stable or mixed farmyard manure is the best that can be used, and if this was not dug in freely for the preceding crop, fork it in now. Make the ground perfectly level, all lumps being broken down, and well trample it prior to putting out the plants. As the latter are only to fruit once, 15 inches apart each way will be found enough room for them.

SUCCESSIONAL AND MAIN-CROP STRAWBERRIES.—Unless some of the first early varieties are

planted in a good sunny, open position with the main-crop sorts, there is a risk of a break in the supply. Therefore plant a few rows of both Scarlet Queen, Vicomtesse Héricart de Thury, or other favourite early variety, and follow on with Sir J. Paxton, La Grosse Sucrée, or any other variety that ripens moderately early. Another plantation should be formed in a cooler position, some of the second earlies accompanying Sir C. Napier, Countess, Dr. Hogg, British Queen, and other comparatively late ripening Strawberries. Room ought also to be found for Empress of India, Lord Suffield, Gunton Park, Commander and other newer varieties that are rightly considered worthy of a trial. In low-lying or backward districts it answers best to plant Strawberries on raised beds, these being 4 feet wide with 2-foot alleys between, three rows of plants going to each. If the site for these beds was first staked out and then prepared very much as for Asparagus, the best portion of the top spit being thrown out and then returned to its original position after a good dressing of solid manure has been forked into the subsoil, success will most probably be assured, let the weather during the fruiting season be what it may. In all warm or moderately warm localities, growing on the level is the plan that is most generally adopted. Deep cultivation should be accompanied by extra firmness of soil, this being especially necessary if manure has been freely dug in, or otherwise leaves may be too strong and plentiful for good crops to form or ripen well. If winter trenching took place and a crop of Potatoes be first taken from the ground, it will have settled considerably, but if the trenching has been done recently, then must a heavy trampling or rolling be given, a dry time being chosen for this operation. In all cases where the soil is of a somewhat strong loamy character, ordinary digging and a moderate dressing of manure given to the preceding crop of Potatoes or other quick-maturing vegetables are sufficient, subsequent good top culture keeping the plants in a healthy productive state quite long enough. In any case make the ground firm and level, no lumps being tolerated, and well fix the young plants, taking good care not to bury the hearts of these nor, on the other hand, to expose a portion of the stem. The roots should be spread well out and not cramped up in a hole made with a dibber, while if they have been layered into small pots, see that these are in a moist state before planting. The rows of that strong grower, Sir J. Paxton, and any other equally vigorous variety ought to be fully 30 inches apart, 2 feet dividing the plants in the row. Moderately strong growers, of which President is a good type, may well be put out 2 feet apart each way, while Dr. Hogg, Alice Maud and such like neat growers may be arranged 18 inches apart in rows 2 feet asunder. The planting ought all to be completed by the end of July. If the weather is dry, water the plants occasionally till well established; also keep them free of runners and the ground clear of weeds. If these cultural details are properly carried out, the crop next season should be both heavy and of extra good quality.

LATE STRAWBERRIES.—If Eleanor, Oxonian, Waterloo or other fairly robust late varieties are planted in the open with the main-crop Strawberries, they will give a fairly late supply of fruit. When Loxford Hall Seedling and Latest of All—the two best late varieties—are grown well in the open, red spider is almost certain to spoil them. For these, then, a cooler site should be chosen, and with them Waterloo may well be associated. They succeed admirably on wide wall borders with a northerly aspect, a north-east border answering remarkably well. Two crops are enough to take from these, old plants rarely doing well in cool positions. Seeing also that none of them are strong growers, there is nothing to prevent putting out the plants 18 inches apart each way. If a suitable fresh site cannot be found, change the soil and manure freely as advised in the case of early Strawberries, and start afresh with strongly-rooted plants.

OLD STRAWBERRY PLANTS.—It rarely pays to

preserve the plants in the open after three good crops have been taken from them, some growers being content with two crops. Runners are best obtained from younger plants, and it is unwise, therefore, to leave old clumps that have done their work any longer than necessary on the ground. If they are cut off with a spade, cleared off and burnt with the rest of the rubbish, a good site, without any further preparation, is early available for late Broccoli. The ground being solid, yet not poor, promotes an extra sturdy, frost-resisting growth. Those rows of Strawberry plants that are to be reserved for another year ought not to be neglected for several weeks longer. Directly the requisite number of well-rooted runners has been taken from them, all the oldest leaves and the rest of the runners should be cut away and removed with the roughest of the mulching material. Do not, however, leave the ground quite bare, or cracking and the loss of many surface roots may be the consequence. Leave some of the mulching to decay where it is, this assisting the plants to form strong crowns for next year, and keep the beds free of weeds. This summer those who last season took the precaution to place a few hundred runners into nursery beds will have been able to form fresh beds much earlier than would have been the case if they had been obliged to wait for this year's runners, and there is much to be said in favour of this time-honoured practice. It is also the simplest way of making sure of a sufficiency of well-rooted young plants for pot culture.

W. IGGULDEN.

THE KITCHEN GARDEN.

OPEN AIR TOMATOES.—The fact of ripe Tomatoes being already plentiful from plants growing against sunny walls augurs well for a good Tomato season. Care must be taken that the plants are well attended to as regards watering and stopping. Instead of Tomatoes in the open requiring to be kept dry at the roots, they must be kept well watered, especially if the season should still continue dry and sunny. Whenever the foliage commences to curl it is a sure sign that moisture at the roots is deficient. Plants carrying several trusses of fruit may, if the soil is not over-rich, also have some liquid manure, or a little approved fertiliser may be sprinkled upon the surface, afterwards watering it in. Although good crops may be secured from single cordons, yet if necessary a few secondary branches may be laid in. All that is necessary is to see that each shoot is freely exposed, all secondary side laterals being pinched out as soon as perceived.

PLANTS IN FRAMES.—These are also doing well this season, large quantities having already set, with others to follow. These are more likely to suffer from overcrowding, as on account of their position they are apt to be overlooked. If the plants were set out at the front of a frame, as I have advised in a previous calendar, the growths can be easily trained into position. All the shoots must be freely exposed, and these must also be stopped to prevent further growth, or they will quickly grow into a tangled mass. Do not upon any account close the frame at any time to hurry on the ripening, or an attack of disease may follow. What is wanted is a free circulation of air at all times, the ventilation being increased as the sun gains power and decreased at the close of the day. The plants will require to be kept well watered, and also fed if necessary. The foliage must not be wetted.

GLOBE ARTICHOKE.—As this is now looked upon as one of the most important crops, every care must be taken that the plants are attended to. The Globe Artichoke is a gross feeder. Where large heads are needed, the lateral heads in their earliest stage must be removed. If by chance any of the heads are not cut, do not allow them to flower, but remove them at once, also all old stems. This year's seedlings or suckers will be in especial need of support if the weather should remain dry, a mulch also being desirable. Any old plants which it is not intended to retain for future stock

may have all old rubbish cleared away and the tops cut over about a foot from the surface. These come in useful for Chards, and are blanched in the autumn like Cardoons.

PREPARING FOR MUSHROOMS.—Where a regular supply of Mushrooms has to be kept up, the collecting of the material should now commence, and especially is this necessary where droppings from the stables are only forthcoming in small quantities. It is not necessary that the material should be wholly droppings; quite a third of short strawy litter should be collected with it. Nor must the mistake be made, where only a small quantity is available, of laying it out so as to become dry and hard, as if so, its virtue is wasted. It is best laid under cover of a cool, open shed, and in sufficient thickness to prevent drying. If at any time it is apt to become over-heated before a sufficient quantity is collected, it should be turned. When sufficient is gathered together it should be thrown in a heap, and be well turned and separated as often as occasion requires. In the preparation of the materials, it is highly essential that the manure should not become over-heated at any time.

OPEN-AIR BEDS.—These I can also strongly recommend, and one or more should be formed in every garden where manure is forthcoming, even if only as an adjunct to the usual beds formed under cover. Quite one half may be of strawy litter, or such as may be obtained from stables after the longest has been shaken out. This is necessary, or the material would not hold well together after being made up. In the preparation of the material, and which is what I shall refer to for the present, it is much the safer plan to make some provision against wet; that is either by large shutters or sheets of corrugated zinc.

A. YOUNG.

PLANT HOUSES.

GREENHOUSE HARD-WOODED PLANTS.—**POTTING.**—Where this work has not been attended to earlier in the season, no time ought now to be lost in going through all of this class of plants save in the case of late summer and autumn-flowering kinds, as the late *Ericas*, the potting of which just prior to blooming is not advisable. Those plants which flower from the end of March to the end of June are those which in the due order of things require most attention to potting now. Any flowering earlier should have been attended to some time back; nevertheless, rather than let them stand over and thereby run a risk in their case of a weakened constitution, it will be far better to repot, although the benefits arising therefrom will not be so perceptible the first season afterwards. Early-flowering *Ericas* and *Epacris* belong to this latter order, which from the new year onwards for three months are in their very best condition. The safest time to pot such of these as are annually pruned is soon after pruning. Where it is done now there is more risk of injury to the roots if any sour soil has to be removed therefrom.

With regard to other *Ericas*, as *E. Cavendishi* and similar free-growing kinds of the same season, with the hardest wooded sorts, as the varieties of *E. tricolor* and others, no better time than the present can be chosen for potting, whilst there is still plenty of time before winter sets in for them to establish themselves. Other useful hard-wooded plants, as *Pimeleas*, *Eriostemons*, *Hedaromas*, *Aphelexis*, and *Boronias*, should all receive this same careful attention. Avoid by all possible means the deferring of this work for many weeks longer; it is not then so safe to do it nor is it nearly so well for the plants. In nearly every case above quoted peat will be the staple soil to be employed, and this should be chosen as good as possible, not soft and spongy with Braeken roots in it, but of a harder kind, as that with roots of the Heather in place of the Braeken. It pays well to give good attention to the procuring of the best peat in every case, but in none more so than in that of hard-wooded plants, many of which will need no further shift if they be specimens for several years to come, whilst smaller ones will make infinitely

better progress if potted in the best soil. The difference is all the more perceptible when the watering is not attended to in the best possible manner. With care in this particular work it is quite possible to run the plants along for a season or two, but it cannot continue. Use good peat and do the work of potting well, then the plants so treated will stand a season or two longer without additional shifting.

It is of no use to think the work of potting can be rushed through as in the case of *Coleuses*, *Balsams*, and other rapid-growing plants. To do this means failure in the near future, although it may possibly be attributed to some other and secondary cause, as over-watering, which in the case of these is rather the outcome of bad potting than anything else. Overpotting must also be guarded against, nothing beyond an inch additional around the old ball being necessary, whilst often it will be better to do with less than this. If a potting stick of about one-quarter of an inch in thickness be chosen, one size larger pot will in most cases be found ample. With a thick potting stick there is always the risk of injuring the roots, it being at the same time a difficult matter to do the work so effectually. Firmness in potting is almost as important as good soil. If this be not adhered to, the properties of the soil are sooner deteriorated, at the same time holding the moisture in suspension similar to a sponge, to the palpable injury of the roots. A free use should be made of silver sand, and clean crocks should be chosen, and, of course, clean pots. The very slightest amount of surfacing should be made to suffice, and this may be of a rather more sandy character than the rest of the soil. The peat itself should not be broken up too finely. Small plants will need it rather more so than larger ones; but do not err on the side of fine soil on any account.

After-treatment should be regulated in accordance with the locality. Where at this season these plants are grown out of doors along now they may still remain there, but bear in mind that heavy downpours of rain are most injurious to newly-potted plants, specimens in particular being at the same time deceptive as to watering. Should the weather on the other hand be warm and sunny, then a few light syringings will be decidedly beneficial as the sun declines. Watering is in itself a subject that requires practice and close observation; it should not be a matter of changing from one pair of hands to another, but be rather performed always by the same person. By so doing it is far easier to gauge the exact requirements of the plants than if done first by one and then by another. For some little time after potting a rose should be used upon the can, a steady watering being palpably better. Nothing in any case betokens carelessness in work more than pouring out the water in such force as to wash away the soil as if it were of no material importance. It will not be advisable in any case to plunge the plants in ashes; it may be done with plants that have their pots well filled with roots, but not in the case of newly-potted ones. Allow the plants plenty of room also, shading the outer ones at the roots if needed with other and dwarfier plants or by means of thin boarding, so that the sun does not shine directly on the pots.

JAS. HUDSON.

ORCHIDS.

MANY of the *Dendrobiums* have almost completed this year's growth, and should be placed in a position where they can obtain light and warmth. As soon as growth is completed it is usual to remove the plants into a cooler and more airy position, but it will be observed that the roots are in a very active condition; consequently it is not desirable that they should have a sudden check, and it would be well to see that the growth is quite completed before their removal. Over-dryness at the roots at this season of the year might give the plants too much of a check and cause them to finish up suddenly, and might be one reason why such species as *D. Wardianum* starts into a second

growth at this season of the year. It is only by careful attention to the minor details of the work that success in their culture is obtained. Many species and varieties of *Dendrobium* lose their vigour owing to some fault in culture which may escape the notice of even an experienced cultivator. One point of primary importance is this—that a plant should make but one set of growths in a year, and they should be gradually ripened. When it is thought the growths are fully matured, the plants may be removed to a vinery from which the Grapes are being gathered, or have been gathered. The plants should be in a light position and receive sufficient water to prevent the roots from shrivelling. Even *D. Wardianum*, which above all others is most liable to go wrong, rarely starts to grow a second time under this treatment. We manage our *Dendrobiums* in this way: As soon as the house is cleared of the early Melons, the *Dendrobiums* which are in early stages of growth are placed in it, a very light shade only is put over the glass in bright sunshine, and it is removed early in the afternoon, so that the plants have a very high temperature with abundant atmospheric moisture. They do not, of course, all ripen their growths at one time, and here it is where the thoughtful cultivator, who watches his plants and knows exactly when they have arrived at the stage for removal, has the advantage, for scarcely two of them are ready for removal at the same time. The plants which are removed first are *D. Wardianum*, *D. nobile*, *D. Leechianum*, *D. crassinode*, *D. heterocarpum*, and seedlings raised from them. Considering that a succession of bloom is maintained by those species and varieties from January to June, it is quite impossible that they can be ripened at the same time. The evergreen species of *Dendrobiums*, especially those of the nigro-hirsute section, require rather different treatment from the deciduous kinds. *D. formosum*, for instance, requires a very warm house to grow in, but the very nearly allied *D. Jamesianum* should be grown in the cool house, where it makes splendid long growths in a position not far removed from the roof glass. When growth is completed they require much less water of course, but over-dryness is injurious rather than otherwise. *D. formosum giganteum* will soon be producing its large handsome flowers, which last at least six weeks in good condition, and if allowed to remain on the plants for that length of time may cause exhaustion, unless water is freely supplied.

Another section of *Dendrobiums* is comprised in the *D. thyrsiflorum* group, the best of which are *D. densiflorum*, *D. Farmeri*, *D. Griffithianum*, *D. Schroederi*, *D. Paxtoni*, &c. These are grown with the deciduous species, but few of them have yet reached the middle of their growing season. When growth is complete they are best removed to the intermediate house, where water is gradually withheld, but not to the extent of causing the growths to shrivel. They are kept in the intermediate house, and receive much the same treatment as the *Cattleyas* all the year round, except for the two or three summer months when making their growth.

A very pretty plant flowering at this time is the elegant *Dendrochilum filiforme*. The flowers are fully open before growth is completed; consequently water must be freely supplied to it, not only to support the flowers, but also to assist the plant to complete its growth. The plant has a beautiful effect raised above the others and placed in a light position in the warmest house. The spring-flowering *D. glumaceum* grows even more freely under the same cultural conditions. It has not yet finished its growth, and also requires a plentiful supply of water. A good time to repot either of them is just before they start into growth. An equal portion of Sphagnum Moss and brown fibrous peat is the best material to plant them in. One of the more important details of the gardener's work is repotting and attending to seedling Orchids, and they require a very great deal of attention to keep them in life and health. The potting material is apt to become sour from frequent watering, and in this state it cannot but be injurious to the plants; therefore

they must be repotted. Thrips will also attack them at this season and sadly disfigure them. The plants must either be dipped in a tobacco solution or fumigated with tobacco smoke, and when in the early stages of their growth should never be allowed to become dry. At this season the Sphagnum Moss is apt to become dry, and frequently dies off altogether. This can only be avoided by careful attention to the atmospheric conditions of the house. The outside temperature has fallen considerably, and copious showers of rain have made quite a change in the external conditions. There is not so much danger of dry heated air getting into the cool house and injuring the plants, so that air may be more freely admitted both over and under the plants. Green fly had become very troublesome amongst the *Odontoglossums*, and to avoid the trouble of dipping them the house was fumigated. A freer ventilation will maintain a more healthy condition. All the houses may be now more freely ventilated when the weather is mild, but avoid exposing the plants to drying east winds.

J. DOUGLAS.

STOVE AND GREENHOUSE.

TUBEROUS BEGONIAS.*

The origin of many old garden plants is involved in obscurity, and it is doubtful whether the account given of several of them is anything more than the merest supposition. This is not the case, however, with the garden race of tuberous Begonias. In no other class of plants has the improvement been so rapid or so extensive, a fact due, no doubt, to the diligence of hybridists, combined with the readiness with which the wild types lend themselves to hybridisation, and the progeny to cross-breeding. Six species have been utilised in the creation of the summer-flowering race, and the difference in the foliage of the parents, in the habit of the plants, and in the colour of the flowers, together with the new conditions created by cultivation, has enabled such rapid progress to be made. The number of seeds that a plant, or even a single pod, will yield enables the raiser to multiply Begonias at a greater rate, perhaps, than any other garden plant. Rarely is it given within a lifetime to accomplish such magnificent results as have been achieved. Twenty years ago no one could have predicted, and far less believed, what would have been accomplished in the time, judging, at least, from the first hybrids that were sent out. All the varieties of Chinese Primulas, and of Carnations and Pinks, for example, have been raised in each case from a single species, and, consequently, the variation and selection of seedlings has been a slow process. Zonal Pelargoniums, on the other hand, furnish an example in which a vast number of garden varieties have been raised by the hybridisation of two or more species; but as they produce comparatively few seeds, a long time has been required to achieve present results. A large proportion of Pelargonium seedlings, again, is useless for bedding; but the seedlings of a good strain of Begonias can always be depended on to make a good display, as the quality is relatively even. Therefore, with this facility for raising seedlings, only the most rigorous selection should be made of varieties worthy of a name, and to be propagated by cuttings for pot culture. *B. boliviensis* was the first species introduced; it was brought to this country in 1864. The characteristics of the plant are its narrow leaves and drooping, elongated cinnabar-

scarlet and Fuchsia-like flowers. A large number of my double varieties at one time showed the influence of this species by their narrow leaves and elongated, many-centred flowers. It was also the seed parent of the first hybrid, *B. Sedeni*, sent out in 1870. Even now it is something more than a botanical curiosity. The next species introduced was *B. Pearcei*, in 1865. It was the chief factor in the production of the yellow, buff, and orange-coloured varieties. Its broad, oblique, olive-green leaves, more or less ornamented with silvery or pale green veins, can be distinctly traced in a large number of the choice modern kinds. *B. Veitchi* followed in 1867, characterised by its broad, orbicular leaves, and large round flowers of a brilliant vermilion. Many of the finest varieties, both single and double, now in existence owe their origin and their fine qualities to it. In the same year *B. roseiflora* was brought home, and was utilised to a small extent only in the production of some of the earliest hybrids. Light-coloured seedlings of it gave rise to *Queen of Whites*, put into commerce in 1878, and destined to be a most important factor in subsequent varieties of the same colour. *B. roseiflora* has broad, orbicular leaves and pale red flowers like those of the Sweet Brier. *B. Davisi* reached this country in 1876, and was much utilised, for a time at least, in the production of new kinds. Its neat dwarf habit and warm scarlet flowers, carried well above the foliage, made it a favourite with hybridists. It gave rise to numerous dwarf, erect-habited kinds, with small but brightly coloured flowers. *B. Clarkei* was introduced in the same year as *B. Veitchi* and *B. roseiflora*, but, like the latter, was not much used as a parent. It resembles *B. Veitchi* to some extent, and is of tall habit, with rose-red flowers. It was, moreover, the seed parent of *Vesuvius* and *Emperor*, two important varieties which long held their own, either as pot plants or for bedding out.

Leaving out of consideration the race of winter flowering kinds, the present race has sprung from these six species; but the first three are most in evidence to-day. The parents have been left so far behind that there is no occasion to use them further for improving the race; and the types are in danger of being lost to cultivation, unless they be preserved by enthusiasts or others of a botanical turn of mind. The first five of the six species above named were introduced by Messrs. Veitch, who put them into commerce, together with some of the first noteworthy hybrids they had made, and they were thus the pioneers in the great work which was on the eve of taking the horticultural world by surprise. Other eager workers, both in this country and on the Continent, were soon in the field, helping forward the great movement at a more or less rapid pace. I commenced hybridising and cross-breeding in 1875, with *B. boliviensis*, *B. Veitchi*, and *B. Pearcei*, together with the varieties *Vesuvius*, *Dr. Hooker*, *Dr. Masters*, and *Mrs. Masters*; but

The best laid schemes o' mice and men
Gang aft agley,

and nothing very striking resulted in the following year. But as "sma' beginnins hae sometimes big endins," I set to work in earnest by obtaining the finest of continental as well as of home-raised seedlings, and was encouraged by considerably better results. In January, 1878, I sowed seeds of fifty-seven different crosses, obtained by cross-breeding with the best sorts I could secure. The seedlings, when they flowered, foreshadowed possibilities I never dreamt of before, and I was awarded the gold

medal of the Royal Horticultural Society for a group of seedlings, as well as some first-class certificates. The astonished public also began to appreciate the "coming flower." That same year I secured *Queen of Whites* and *Henderson's White Queen*, and made numerous reciprocal crosses, from which, in 1879, I obtained 500 white-flowered seedlings; the tall ones I assorted under the name of *Reine Blanche*, and the dwarf ones I named *Stanstead Bride*. The greatest improvement, *Stanstead Rival*, having orbicular flowers and erect flower-stems, came out of the same batch. Besides other fine types, a small-flowered, nearly black variety made its appearance, and was kept for breeding purposes. It is represented in such modern types as *Duke of Edinburgh* and *H. M. Stanley*, with maroon-crimson flowers. By the autumn of that year I had made 161 different crosses of carefully selected parents, single and double, using *Stanstead Rival*, *Reine Blanche*, and *Lady Hume Campbell*, the first-named most extensively on account of its stiff upright habit.

Although it is interesting to know the first steps in the progress of development in this fine race of garden plants, the subsequent records of cross-breeding would be as futile to science as bewildering to anyone who might wish to trace the genealogy to the present time. Suffice it to say, the best types only were and are used as parents to sustain the onward march of progress. Size, shape, texture, and colour of the flowers, as well as the habit of the plant, were always kept in view. As far as size is concerned, the legitimate or desirable limit has been reached in the eight varieties named *Royal Begonias* sent out in 1886, particularly in *Victoria*, which has flowers measuring 7 inches across when well grown.

SINGLES.

The aim in this section is to get as many distinct and well-defined colours as possible, as well as an upright habit, with a profusion of flowers that do not require staking. Naturally the dwarf-habited and freely-branched sorts are the best parents to select from for the latter purpose. Some few there are, such as *Leviathan*, with stems like miniature hop poles, but their admirers are few. The texture of the flowers has made wonderful strides within the last few years. Orbicular flowers, as round as the compass could make them, have always been the aim of the florist, and are well represented by *Mrs. R. Ballantine*, *E. G. Hill*, *H. M. Stanley*, *Lady Scott*, *Fringed White*, *Lord Hillingdon*, *Lady Pigott*, and others. These are some of last year's acquisitions, and *Duchess of Leinster* and *Duchess of Westminster* are also quite recent. The last-named is one of a white-centred race; and I am now working on a dark-centred strain, with promising results. *Lady Whitehead* bears six to eight large flowers in a truss and represents a floriferous type. I still believe that improvement is possible, after all my previous efforts.

DOUBLES.

Good double varieties are more difficult to obtain than single ones, on account of the difficulty of getting pollen. The continental growers were the most successful with this section in the earliest stages of its development, but home-raised varieties are now far superior to the earlier types. My varieties of to-day show a marked improvement upon those of as recent a date as 1887. They were then globular, densely crowded with petals, lumpy and heavy, although better than the ragged and unshapely flowers of previous years. Those that obtained first-class certificates five years ago would not now attract

* Paper read by Mr. John Laing before the Royal Horticultural Society, August 23, 1892.

attention, far less merit approval. During the early days of the development of the flower we had to be content with size and colour, with little regard to either shape or refinement. One named Glow was a great acquisition in its day, being large, globular, and bright scarlet, but it consisted of numerous centres or secondary flowers resembling a truss of a double Pelargonium. Many of the largest-flowered varieties I have recently obtained have short, stout stalks and are self-supporting, bearing their huge blooms erect without staking. My aim is now to select and perpetuate only varieties with broad, even petals, arranged round a common centre, and having the refinement of either the Rose, Camellia, or Picotee, or displaying the crimped petals of the double Hollyhock. The first is represented by Princess May, white; Lady Wantage, rosy-pink; Laing's Rosebud, blush-pink; W. Clifford, rose; Laing's Triumph, rosy carmine; and Sir Trevor Lawrence, like a bunch of crimson Tea Roses when half expanded. The Camellia and Picotee types are represented by varieties bearing those names. A great many of the single-centred flowers may be compared to double Hollyhocks or Petunias, on account of their wavy, undulated, or crimped petals, and people appreciate these forms. They are well exemplified by Glory of Staustead, white flushed pink; Lady Brooke, salmon-red; Duke of Fife, salmon; Lady Dorrington, blush-pink; and Baroness Burdett-Contts, salmon-rose. The Duchess of Teck is like a bunch of Primroses. Various other comparisons might be made, but enough has been said to indicate the present lines on which double Begonias are being refined and improved, for the variation of colour seems endless.

USES.

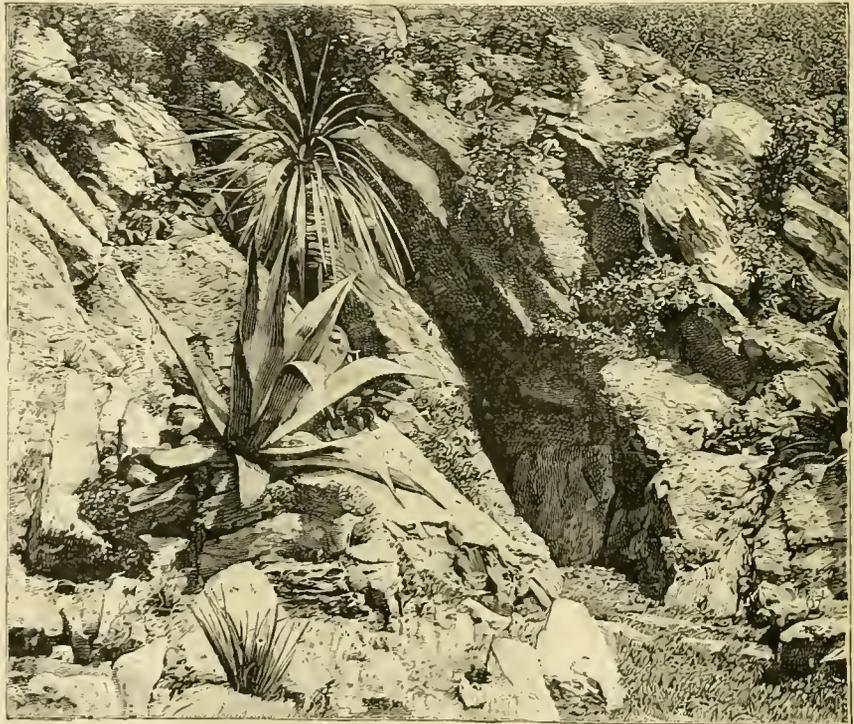

One of the most important uses to which Begonias can be put is for indoor decoration in pots, and to a smaller extent in baskets. A fine display may be kept up from April to November by starting them in batches at different periods, retarding some, and raising seedlings for late blooming. Single-flowered varieties are the showiest, but a batch of choice and refined doubles is an acquisition to any establishment, and gives most satisfaction under glass. Some of the more floriferous and drooping habited kinds, after the style of *B. boliviensis*, are very effective when grown in pots or baskets and suspended from the roof of the house. Even here choice kinds may be used, having medium-sized and not too heavy flowers. Some are decidedly fragrant, and if encouragement is given to their selection, a scented strain might yet be a reality. Maréchal Niel and Fragrant Rose have this quality.

For exhibition purposes Begonias are most effective in tastefully and judiciously arranged groups; but even here quality is often overlooked, and preference given to mere display. Only medium-sized plants are capable of being worked into arrangements of this kind, with dwarf and erect-flowering kinds for the front. Large specimens are not so popular as they might be, for they are bold and effective when well grown and tastefully manipulated, so that the staking is hidden.

There is a promising future for tuberous Begonias as bedding plants. Pelargoniums in a wet season grow like Cabbages, but are as green as Kale. Whether it rains or shines, Begonias flower abundantly, and they are always dwarf and short-jointed out of doors. Of course, to make sure of a good display early in the season, tubers at least one year old should be employed. They may be started sufficiently early in pits or heated frames, so as

to have them fairly into growth, but not showing bloom, and hardened off so that they may be safely planted out about the beginning of June. Thus treated, they do not experience the check that plants in bloom are certain to get if the weather immediately after should prove cold or dry. Seedlings selected as to colour are most suitable for this purpose, and those of stiff, erect habit and free-flowering character produce the finest display. Double varieties are more adapted for pot work, as the flowers are generally too heavy to withstand the effects of storms or wind or pelting rain. They will be still more extensively grown for indoor decoration, while the singles will be grown in thousands for bedding purposes. Figures would fail me to give exact data as to the number I have raised since I commenced the culture of this noble race of plants; they may safely be computed by hundreds of thousands, if not millions. About half a million

make the best cuttings, and may be inserted any time during the growing season, but the earlier they are taken the better will they root and form tubers. A few of the young growths that arise from the tubers in spring may also be taken; but the fact must not be overlooked that to take the same liberties with them as with Dahlias would be ruinous to a good display of bloom on the old plants for a season. The cuttings should be inserted singly against the side of 2½-inch pots, in a compost consisting of loam, leaf-soil, and sand in about equal proportions, and plunged in cocoa-nut fibre in the bed of a propagating pit or frame, and shaded till they have emitted roots, when they may be grown on if required for late blooming; but the young plants should preferably be kept in the cutting pots until the following spring, and this is the more essential in the case of late-struck cuttings, though, where practicable, these latter should be potted and kept growing.

No. 1. A cleft in the rock.

were pricked off into boxes last spring, and two-thirds, consisting of seedlings of single kinds, were planted out in June, besides several houses 100 feet in length filled with pot plants, and several ranges of frames.

A pleasing feature of the nomenclature of Begonias is the rational method of giving purely garden names, which, although not rigorously adhered to, is very generally adopted.

PROPAGATION.

There are at least four different methods of propagating tuberous Begonias, namely, by seeds, cuttings, leaf cuttings (as in the case of *B. Rex*), and division of the tubers. I approve of the first two methods only, for they are certainly the best, most practicable and profitable. Increase by cuttings is only essential in the case of choice standard kinds requiring to be preserved true to name. These are mostly used for pot culture, and are regarded as the most improved or advanced types of the race from whence the finest strain of seed is derived. Young shoots from near the base of the plants

Propagation by seed is at once the most legitimate, speedy, profitable, and certain mode of increasing this class of Begonias, either for pot culture or for summer bedding. There will always be a certain amount of speculation with regard to the colour, habit, and character of the seedlings the first year; but, if derived from a good strain, they seldom fail to give satisfaction, and may be assorted for future work as they come into bloom. They may be sown almost at any time of the year, according to the convenience and requirements of the grower. For my own purpose, I find that the third or fourth week in January is the most suitable; and those who have a sufficient command of fire-heat will find it advantageous to sow early in the year, as the seedlings are less liable to damp off than when they are raised in May, June, or July.

The seeds are sown in pans or in shallow wooden boxes, in a compost of light, porous material, consisting of flaky leaf-soil, a little loam, and plenty of sharp sand. This is mixed, and used in a rough state, with some finely

sifted material on the top to form a smooth and level seed-bed, which is pressed firm, watered, or more suitably dipped, and then the diminutive seeds carefully sown upon it. The pans or boxes are placed in a temperature of 65° to 70°, with more bottom heat. As soon as they can be handled, the seedlings are pricked out from time to time into other boxes with a finely pointed piece of wood, divided at the point so as to lift the seedlings. As they germinate very unequally and in succession, the work of pricking them off employs some men and boys for weeks together. When the pricked-off seedlings begin to get crowded, they are transplanted into other boxes at a greater distance apart. By the middle of May they are ready for hardening off. During the first three weeks of last June a staff of men and boys was constantly employed in planting those now in the open ground. By that time a large proportion of them had commenced to bloom, and several thousand of the most promising doubles, some of them gems, were transferred to 4½-inch pots, and placed in new houses specially built for their reception.

The ground in which the seedlings are planted out is heavily manured and roughly dug up to the action of frost in autumn. Old tubers intended for bedding out should be started about the last week in March or the beginning of April; small-sized pots will be quite sufficient for them. A warm and showery month of June, with rather drier weather in July and August, is the most favourable to Begonias in the open ground.

POT PLANTS.

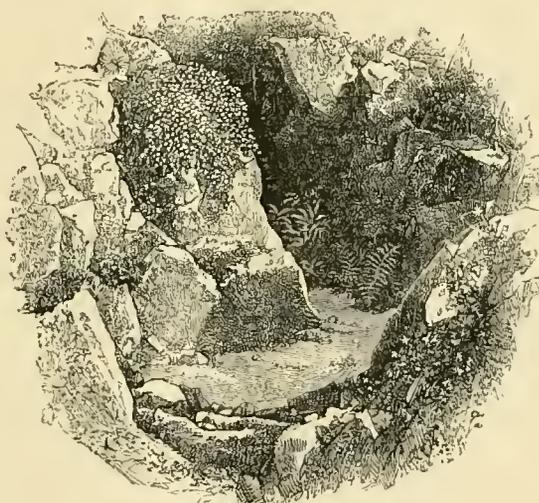

One-year-old tubers are the most generally useful for pot work; but those of two or three years' growth make the finest specimen plants. When four years old they begin to degenerate, some sooner, some later; hence the necessity of raising young plants to keep up the standard of perfection. The first batch of plants may be started about the end of January or the beginning of February, and they will flower in April or May, according to the amount of sunshine they enjoy and of artificial heat used. Successional batches of tubers may be put into heat during March or April to flower in June or July, and be it observed that the more slowly they are brought forward the more sturdy and durable they will be. Put them singly into small pots proportionate to the size of the tubers, in a compost consisting of equal parts of fibrous loam, leaf-soil, and sand, in a rough or lumpy condition. Press the soil rather firmly if short growth and a long season are desired, merely covering the top of the tuber. Stand the pots on a bed of cocoa nut fibre or plunge them in it, and keep the temperature of the house at from 65° to 70°. Should the soil be dry at potting time give it a watering; after that water should be applied with discretion till the plants begin to grow freely. Tubers that have been wintered in pots may be put into heat, watered a little, and afterwards damped down with the syringe till they start into growth, and then repotted into suitably smaller sizes. Light is of great importance in the early months of the year, and it is all-important that the plants should be kept as near the glass as possible after they have started into growth, to encourage a short-jointed and sturdy growth. Repot the plants before they become root-bound, and as the season advances and the temperature outside becomes milder, gradually give more and more ventilation, as upon a cool and airy atmosphere a great deal of the success in Begonia culture depends. Low span-roofed houses give most satisfaction. The soft and watery tissue of Begonias soon

responds to favourable or unfavourable conditions; therefore, let them have a house to themselves where possible, and no make-shift permitted. The smaller plants may be grown on the side shelves on ashes or cocoa-nut fibre, while all the larger and taller specimens may be elevated on shelving—staging tier above tier in the centre of the house and near the glass. A free play of air amongst the foliage keeps it fresh and healthy, and a dry atmosphere prevents the spotting of either flowers or foliage, as the weather gets warm about April and onwards. More or less shading during the heat of the day will be required after that month. When the plants have finished flowering, or become useless for decorative purposes, stand them out of doors in a sunny position, but sheltered from wind, and keep them watered till the leaves show signs of decay, after which water may gradually be withheld till the tubers ripen and the stems drop away. Remove them indoors on the approach of frosty nights.

THE ROCK GARDEN.

CAVERNS.

AMONG mountain scenery no rocks have a greater fascination for the lover of the pic-

No. 2. Rocky passage leading to cave.

turesque than those cleft asunder by violent convulsions during bygone ages, or pierced by mysterious caverns, which latter not only in themselves enhance the grandeur of the scene, but offer a welcome retreat to the tourist seeking repose within these shady recesses. The desire of possessing the delights of a natural cave in the rock garden has probably induced many an amateur to attempt the construction of a more or less elaborate cave in his own garden. It is seldom, however, that we meet with artificial caverns of which it can be said that they are true to Nature. Oftener than not such structures are merely a hideous arch of the beehive or baker's-oven pattern unless the work was carried out by skilled hands. From past experience I may venture the assertion that the construction of a cavern possessing the requisite stability and having at the same time a picturesque interior and exterior (apparently formed by Nature) is more difficult and requires more thought and skill than any other part of the rock garden. At the same time it cannot be denied that, if really well done, a cave should be the crowning point of the work and a most attractive feature, calculated to enhance the

charm of a rock garden, not only by its outward appearance, but by providing a delightful resting-place among the plants we love.

A natural appearance must be above all things the first consideration, and when this is wanting, a repulsive, instead of an attractive feature must be the inevitable result. I have seen artificial caves built with stones of the sandstone formation ornamented (1) with stalactites. Such an absurdity would be impossible in Nature. From Nature, therefore, we must again seek information and study the laws which governed the

FORMATION OF NATURAL CAVES.

Nature's caves among rocks of the unstratified class are generally the direct result of violent volcanic action, which by, perhaps, repeated upheavals from the direction of the interior of the earth caused huge blocks of rock to topple over and fall in such a manner as to leave a large irregular hollow space beneath. Subsequent floods of water may have lent their aid in widening the passage by abrasion of the rocks, but the primary cause in most cases is only too plainly evident. Caves among stratified rocks may sometimes be formed by water dissolving and removing the softer and more soluble portions of rock. Especially is this the case with limestone; but even here we have often plenty of evidence of primeval convulsions which caused the rocks enclosing the cave to show the strata almost horizontal in one place and almost vertical, or forming angles of various degrees, in another. Caves in Nature are thus formed sometimes by mechanical and sometimes by chemical action, or a combination of both, and I will now apply the practical lessons taught by Nature to the

FORMATION OF ARTIFICIAL CAVES.

In my opinion caves in the rock garden should be suggestive of that powerful and stupendous agency which formed most caverns in Nature, viz., volcanic action. An artificial cave, which has the rocks around it arranged in horizontal strata built with painful accuracy, looks stiff and unnatural when compared with a cave which has the appearance of large blocks of rock having been hurled together so as to form a natural self-supporting roof over the hollow space beneath. It is not necessary that both sides of the cave should have this appearance of having tumbled together, but sometimes it would look even more realistic to let it appear as if the rocks on one side of the cavern had remained stationary, while through some violent disturbance the other side had been thrown against them. If the rocks are of the stratified nature, we might in such a case show the strata in the part supposed to be stationary, and the strata in the rocks which are supposed to have fallen, almost in juxtaposition, just as we would often find them in Nature. If such a cave can be arranged beneath a waterfall, the effect is bold and extremely picturesque.

In constructing caves in the rock garden much must of course depend on the extent of the work and on the purpose for which the cave is to be constructed. It is, therefore, of importance to know beforehand whether the cave is to be accessible, or to be seen only from a distance, whether it is to be furnished with plants or not, and whether water is available.

If the rock garden is on a large scale, there is no reason why several caves of different shapes and sizes should not occur, some serving the purpose of a cosy retreat, others being mere clefts in the rock furnished with plants, and calculated more for distant effect.

A CLEFT IN THE ROCK.

This kind of cave is not generally intended for access. Outwardly it should appear as a large open fissure, the exact depth of which cannot be gauged owing to the end being hidden from view. This is easily arranged by constructing this cavity so that the darkest part of the recess is extended around a corner, and that the exact extent of it can never be seen from the outside. This will have the effect of making the dark recess appear very much deeper than it really is. The illustration No. 1 shows a cave of this kind which I constructed a few years ago. The plants used for the decoration of such a place must of course be shade-loving kinds only, and it would be necessary to arrange the rocks in such a way that rain falling outside the little cave could penetrate through specially made crevices in order to supply the plants within with the necessary moisture. By choosing thin flat stones for the construction of the interior of such caves, this is easily provided for. Where these thin stones do not fit exactly, the crevice between them is covered from behind with pieces of tough peat or turf and then filled up with other soil, so that light would be excluded except that reaching the recess through the cleft itself. Where space permits, the pieces of peat and turf just referred to may be planted with Ferns and other suitable plants. Sometimes a cleft of this kind can be made so as to branch off into several smaller recesses constructed on the same principle, and if well arranged and suitably planted, a very natural effect may thus be produced. It should be borne in mind, however, that such recesses, if not accessible, might easily become a safe and convenient hiding place for all kinds of vermin and garden pests, and it would be well to make them wide enough at least for a boy to be able to enter them occasionally.

LARGER CAVES.

The chief object of an accessible cave in the rock garden should be to form a cosy recess for seats, &c. It should, therefore, be shady and large enough to allow several persons to be able to find rest and shelter at the same time. The roof should be such as to form a safeguard against a shower of rain or the rays of a scorching summer sun. A decoration of the interior with suitable plants would be most desirable, and for this purpose it can often be so arranged that the roof of the cave, though apparently formed by large boulders, is fissured here and there, and admits light, air, and even rain to the places where the principal plants are to be grown. It would, of course, be a mistake to leave such rain-admitting fissures in that portion of the cave which is intended for seats, but farther away, in the irregular recesses at the sides, the partial admission of rain, light and air is most desirable, and would tend not only to lessen the labour required in looking after the plants in the cave, but also to purify the air, making the cave a more pleasant abode on that account. It must be pointed out, however, that these air holes require to be carefully arranged and distributed so as to prevent draught. A charmingly refreshing and cooling effect can be introduced into such a cave by water dripping from the roof here and there, and wetting

with its spray the Ferns and other plants without interfering with the comfort of visitors in that part of the cave which has been reserved for seats. As I have already treated the subject of a dripping waterfall, I need here only add that water thus dropping from the roof of the cave should be collected in a small irregular pond from which it might be dipped up as required for watering perhaps such plants in the cave to which rain and dripping waterfalls would have no access.

As already hinted at the beginning of this chapter, the construction of such a cave is not altogether an easy matter, and as the greatest difficulty consists in the combining of bold effects with stability, a few words on this subject may not be amiss. If the cave is an extensive one it will be found difficult to construct a firm roof of natural appearance, as stones of enormous size and particular shape would be required. The boldest roof is that appearing like a huge solid block which has fallen against other rocks. But a block of stone of the required proportion would be in most cases very unwieldy and most difficult to obtain. An arch of masonry would be a substantial support, but to hide its stiff and artificial appearance would be very difficult. I will, therefore, recommend two other methods based on experience and often employed by myself when constructing caves.

The first method consists in building the large boulder which is supposed to have fallen so as to form the roof of the cave on the same principle as explained in the article on "Stability" when treating on the subject of constructing projecting or overhanging rocks. The manner in which rocks of this kind are best built by means of large flat pieces of stone is best explained by sketch No. 5 on page 209 (see THE GARDEN of March 18). But sufficient stress cannot be laid on the fact that stones used for this purpose must be absolutely free from flaws or faults of any kind which might endanger their stability.

The second method consists in forming the desired large boulder or boulders artificially by means of strong iron supports embedded in concrete. If the length of the required boulder is not more than 12 feet or so, a few iron rails, such as used for railway metals, will answer the purpose very well, but if a still larger size should be necessary, iron girders, specially constructed according to the weight, would be best. After these irons have been placed in a position showing the desired angle of inclination, they are connected by other pieces of iron placed crosswise, so as to distribute the pressure. A firm scaffold is then built reaching within a foot or two of the irons. This scaffold is next covered with soil, which must be pressed firmly, and into which depressions or elevations are made here and there to produce irregularity. The whole surface is then covered with cement concrete consisting of four or five parts broken stones and sand mixed with one part of cement. During this operation care must, of course, be taken to have the irons well surrounded with the concrete, which should be packed very tightly. A layer about 12 inches in thickness should be sufficient for this concrete, which after two weeks will have hardened sufficiently to bear an enormous weight, and the soil which formed the mould and the scaffolding supporting it can now be removed. When this artificial boulder is sufficiently dry, it is coloured the same shade as the other stones used in the rock garden, and if really well done anyone not in the secret will never suspect the artificial origin of the boulder thus formed. An additional

feature should be graceful creepers, which might hang naturally over the entrance to the cave, and of which more will be said anon when speaking of plants.

A cavern, to look natural, should not be too open and conspicuous, but other rocks should if possible be in front of the entrance and a rocky passage, such as the one here illustrated (see illustration No. 2, "rocky passage leading to cave") will enhance the charm. When a cavern is introduced into the rock garden, care should also be taken to have higher masses of rocks than those forming the cave arranged in the background, as without such an arrangement the cavern will look unnatural and out of place.

STALACTITE CAVERNS.

That stalactite caves or grottoes in Nature are as a rule furnished with the most exquisite and weird ornaments is only too well known. They occur almost exclusively in limestone. The water, on percolating through these rocks, becomes charged with carbonate of lime, which is precipitated and forms more or less icicle-shaped deposits hanging down from the ceiling (stalactite), or cone-shaped or fantastically expanded masses on the floor of the cave (stalagmite). So delicate and lovely are often the shapes of these crystalline formations, that they have been termed Nature's drapery.

Cox's cavern and Gough's cavern at Cheddar, Somerset, are, perhaps, the best examples in the country, not for the size of the caverns, but for the beauty of the weird formations decking the interior. Plants are never found in caves of this kind, and could not live in them. As a general rule, therefore, the introduction of stalactites into our rock gardens should be avoided. When, however, the rock garden is on a very extensive scale, and contains caves and subterranean passages never intended for plants, there is no reason why such places should not be turned into caves for stalactites, provided the work can be done so as to resemble the work of Nature. I have myself constructed such a cave at Bystock, near Exmouth, where it was desirable to form an underground passage through the boldest and most massive part of the rocks. This cavern is about 60 feet in length and divided into several chambers. It is delightfully cool on a hot summer day, and is occasionally lit up with electric light, throwing a red glare over the drops of water falling from the stalactites to their corresponding stalagmites below. The foundation consists of brick arches, columns, and iron girders, the masking of which with grotesque formations has been so successfully carried out as to look perfectly natural. But it is only when such work can be carried out on a somewhat elaborate scale that stalactite grottoes can be introduced into our rock gardens, and to associate such caves with small rock gardens cannot be too strongly condemned.

F. W. MEYER.

Exeter.

(To be continued.)

Hardiness of bulbs.—The comparative hardiness of bulbs not in general culture is of interest to those consulting the by-pages of catalogues. Under cap glasses on a southern border *Freesias* and *Calochorti* were planted in October, and in due time appeared. The glasses were not covered during the winter. The *Calochorti* grew and have bloomed excellently; the *Freesias* were killed. The foliage of the former is thin and sparse, of the

Freesias fleshy and full; hence the different result. Near these were plants of *Ixiolirion* and of *Anomatheca*. This latter is a very pretty button-hole flower, and the patch had been in the same spot for years. The *Ixiolirion* flowered charmingly, but the *Anomatheca* has disappeared. Three *Crimons* have thriven in one spot for years; only one has recently appeared, and now only exists. Such are the uncertainties of winter frost.—*J. S. B., Bath.*

FLOWER GARDEN.

HARDY FLOWERS.

I CONSIDER a paper like that written by "J. C. L.," July 8 (page 31) on hardy flowers a most useful contribution to floral knowledge. It gives the writer's failures, his hopes and fears, his likes and his dislikes, and enables others to compare notes as to what they can do with the same plants. I propose to run through his paper and note those plants I have had any experience with. First of all come alpine *Ranunculi*. Let me, however, premise. My soil is of a light very brashy character, quite unretentive of moisture. I find these quite unmanageable. *R. amplexicaulis* grows and blossoms fairly, but it does not take at all kindly to my soil. I saw it growing rampantly once in stiff clay, and I have clay under mine. *R. anemonoides* is growing well in a friend's garden here, planted in partial shade on a raised rock-work, chiefly peat. Both he and I have tried various other alpine *Ranunculi*, but they invariably die after one season. *Anemones* of all kinds do well with me. I find no difficulty whatever with *A. palmata*; the secret is, I think, in planting it quite deeply; therefore the roots should be got in the dormant season and planted at least 6 inches or even 9 inches below the surface. *Anemone sylvestris* is one of the gems of my garden. I had some trouble to get it established; now, however, it is quite at home. In burnt earth and shade *Anemone sulphurea* grows well, but has not blossomed yet. *A. patens* flowers yearly, and *A. Pulsatilla* grandly, and so it ought, for its native home is on the Wolds, not a hundred miles away. *Delphiniums* of the "species" I find very uncertain. *Brunonianum* and *cashmerianum* are both with me biennial; on the other hand, *nudicaule* is, and has been, for years on a raised rockwork composed of road scrapings and scorched by the sun. Here it never fails to show its vivid colour. I cannot praise *Clematis erecta* too much, it is perfectly hardy, growing about 4 feet high, looking not unlike *Thalictrum aquilegifolium* in habit; it is not scented, otherwise like *Clematis Vitalba* in flower.

Dianthus, unlike "J. C. L.," I am very fond of. *D. alpinus* does very well in a raised position amongst crushed limestone, making a good clump; it is easily raised from seed or cuttings. It is apt to go off unaccountably sometimes. I lost a fine clump in the winter of 1892. I know several plants of *D. neglectus* doing well in a hot position

on a ledge of rock covered with a bare sprinkling of earth. *D. callizonus* I am keeping my eyes open for, but *D. cinnabarinus*, with its salmon-scarlet blossoms, is quite hardy and certain. *D. caesius* I have in a wall, immense tufts hanging down, as it does on its native Cheddar cliffs. *Orobus varius*—what is the true plant? I have tried many nurseries, but the descriptions I get do not by any means accord. I saw it in the nursery of a man who has it in its true form if anyone has, and I fell quite in love with its salmon-coloured blossoms, but I consider the price too high, as I have no doubt, like others of its family, it seeds freely. *Orobus aurantiacus* does grandly in a neighbour's garden, and did in mine till I moved it; now, alas, I fear the heat has settled it. However, I have seed, and it comes up freely. I grow a lovely lilac *Vicia* I should be glad if anyone could name for me; it is almost like the rare wild *Vicia sylvatica* (which grows here), beautifully pencilled, but not more than a foot or 18 inches high. *Meconopsis* and *Romneya* I get up from seed easily, but never get a plant through a winter. *Polemonium confertum* I do not consider at all difficult; it is growing splendidly on the top of a raised rockwork in full sun. *Galax* and *Shortia*, alas, I cannot give a good account of. I saw half a dozen plants of *Shortia* here in bloom in a peat rock bed quite shady, but I should be sorry to say how many plants had been bought beforehand. After this hot weather they do not look at all comfortable. Close by it *Veronica cypressoides* is growing rampantly, raising its altogether *Veronica*-unlike foliage about a foot high and wide. *Gentians* I love, especially *acaulis*, though I can never get it to grow. It lives, and that is all I can say, and blooms occasionally; yet within a hundred yards, used like *Box* as an edging in a front garden, it grows luxuriantly. I am quite unable to grow the American bog plants "J. C. L." names. My soil being so dry, I have made a small square pit, filled it with leaf-mould and peat, and keep it continually moist. Here *Cypripedium spectabile*, *Primula rosea*, *P. Munroi*, *P. sikkimensis*, *Chrysobactron Hookeri*, and some *Arisæmas* grow freely. I feel quite proud to say I have *Tropaolum speciosum* covering a rustic arch, with its roots in the deepest shade between the arch and a wall, and there are many more plants of it growing in a still more rampant manner on another house. I will conclude these notes by saying *Lilium testaceum* appears to be everywhere good this year, and the hot weather has suited *Eryngiums* to perfection.

North Gloucestershire.

J. R. N.

Hollyhocks.—Amongst the various floral attractions at Hampton Court Gardens just now are some excellent spikes of Hollyhocks. Not that the flowers are perhaps of the finest quality, but they are very good, and there are few gardens where such plants in bloom would not be eagerly welcomed. It is perhaps all the more interesting to find such sturdy, healthy Hollyhock plants at Hampton Court during such a hot, dry season as is the present, for the pestilent

fungus which preys so severely upon the plants is usually far more harmful in dry seasons than in moist ones. If there be any particular evidence of the presence of the fungus now on the stoutest of plants, at least the recent rains should do much to keep it in check. I have observed in many directions that single Hollyhocks are now grown. It may be that these are less liable to the attacks of the fungus than are the double forms, but pretty as these singles may be, the doubles, so long with us, have spoiled our taste for them, and they will hardly again find considerable favour as garden flowers. It is not too late yet to sow Hollyhock seed, even out doors, for it will soon germinate and give nice, stout plants in October for transplanting. These would certainly bloom the following year, and if a little late, so much the better, as they will then follow the *Delphiniums*. It is of no use to be particular as to doubleness. It is much to get a strain that seems at once to be free from fungus, and has bright, variously coloured and fairly double flowers.—A. D.

GARDEN SCENERY.

IN the view at Baycliffe Hall in THE GARDEN of May 13 there is a harmonious blending of forest trees with others of more shrubby growth, the effect being likewise enhanced by the lake scene, as well as that portion devoted to the lawn and the combination of hardy flowers interspersed amongst the shrubs. Herein is a happy association of woodland scenery with that of the garden proper. Our landscape gardeners would do well to study such examples as that now given ere they attempt to further enhance the appearance of a garden or proceed to lay out an entirely new one. Too much reliance is oftentimes placed upon what may be termed future effect without taking due advantage of present surroundings for immediate effect. At a glance one can note in the picture the grand appearance possessed by the forest trees in the distant view on the banks and down to the water's edge. These are trees of no formal outline (fortunately, they have for many years been beyond the reach of the clipping fraternity or the geometrical gardener), giving a massive appearance, and thereby greatly adding to the effect as a whole. Suppose for one moment these trees were removed, and then replace them in one's imagination with *Fir* trees of pyramidal outline, the effect would be spoiled in a large measure, as it would not blend with the foreground. Again, remove any other and put in their stead others of erect growth, as the *Fir* trees or those conifers possessing the same outline, and the harmony would be lost. I consider the grouping and the wavy appearance of the trees as seen in this example of a landscape scene to be in good accord. In no part of it could a tree of erect pyramidal growth be introduced without detracting from the whole. True, the majority of the trees are deciduous, but many of these are the finest we possess; evergreens, however, play an important part in the foreground, and compensate for any deficiency in that respect.

In making these remarks, it must not for one moment be inferred that I am condemning the use of trees of erect growth as *Firs* and other conifers; far from it, for they are indispensable, but it is the mixture I object to in distant scenery. Group the *Firs*, making them the leading and prominent features, and then will be seen their true value, not when planted individually between or mixed up with trees of more massive growth. Those who have viewed an alpine or a Norwegian scene can rightly estimate their value, or, for an instance, nearer home we have the same effect, but in a somewhat lesser degree, in the *Fir* forests of Scotland, more particularly in the Highlands. It is only when such trees are seen towering aloft and in masses that their true grandeur can be fully appreciated. In a smaller degree I have seen them to advantage in North Wales. It is the dotting about here and there without any due regard to the surroundings which should be avoided in the

case of trees of somewhat formal outline, as many of the *Abies*, *Piceas* and *Pinuses*.

Some would suggest, perhaps, that a flower bed (of formal outline, of course) should be introduced upon the expanse of turf. Not so, however, by any means, for such an addition would spoil the effect in the foreground. It will be at once noted that there is no encouragement given to plants of a tender character. This also is a happy thought in the arrangement, the constant attention in planting and replanting not only taking time, but valuable room also in the glass department when not in the beds. By relying more upon hardy plants, these being chosen to suit various soils and localities, then planting them in groups or masses, avoiding, again, the dotting system, the charm of a garden would be enhanced and the resources of a gardener not nearly so much taxed as in the production of tender plants by the thousand. Another feature in the picture is the employment in certain parts of plants of low or bushy growth; the view is not, therefore, detracted from, but added to, and an idea of greater expanse is given to the view. The planting of suitable aquatic plants along the margins of lakes is not nearly enough studied. This is obvious in the case of sheets of water that are not in any sense formal; but where there is a formal edge or outline, and this left bare, it is offensive to the eye of anyone who admires the natural and informal. Again, such plants as are in harmony with water scenes should be more used. Bamboos (hardy, of course), Pampas Grasses, the *Eulalias* and other plants of similar character should be more employed in landscape scenery.

I have one fault or two to find, however, with the view new under consideration. These are to be found in the foreground, the most immediate part of which is a path. Next this path is a narrow verge of turf of uniform width and a clearly defined edge to the shrubbery border. These are two mistakes that should be carefully avoided. The turf should lose itself amongst the shrubs, or else the margin should not run parallel with the pathway. These are matters that can be avoided in a fairly easy manner. Such examples do, however, slip in at times, but are more plainly visible when the line is straight or prolonged in an easy curve. Paths are oftentimes introduced in too free a manner, and that without any justifiable reason whatever. They do not add to the charm of any view, but rather obtrude upon the sight.

SIMPLEX.

Clematises.—Possibly attributable to the unusual heat of the season, but most certainly, in whatever position or on what aspect growing, *Clematises*, and especially *rubella* and *Jackmanni*, have flowered most luxuriantly this summer and also unusually early. I saw the latter variety in abundant bloom by the middle of June, and still plants look as if they would flower for several weeks longer. In the suburbs of London these *Clematises* have been flowering superbly and apparently irrespective of aspect, as they are doing equally well on either side of the streets. It is a matter for surprise that with so many other good summer bloomers we should see *Jackmanni* chiefly and any other sort very rarely. Perhaps it is, after all, the best general doer; still, its popularity and exceeding beauty this year should help to call greater attention to hardy *Clematises* for house or porch decoration. Very beautiful are they, too, when employed, as at Isleworth, to cover posts and form festoons beside garden walks or to cover arbours, or, indeed, be employed for decoration in many ways. The very worst use to put these charming climbers is to make of them globe-shaped plants, as sometimes seen, but, happily, rarely. *Clematises* are cheap. They can be purchased in pots and be planted out where desired to be grown just as well now as at any time. The only thing is to secure strong growing varieties.—A. D.

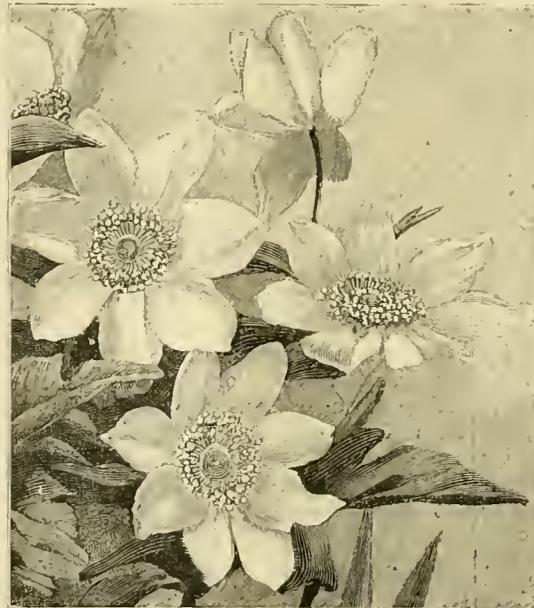

Chamærops Fortunei.—A question has been asked and a notice written about this plant lately, so it may be of some interest to state that one I planted in South Oxfordshire many years since

on a by no means sheltered lawn has flourished well, and flowers continuously and abundantly. I cannot remember exactly how old it was when it took to flowering, but considerably under twenty years (the age mentioned by your correspondent). For many years it used to be protected by matting in winter, not, however, overhead. Now it is never covered with matting and seems perfectly hardy. The soil where it is planted is one where *Rhododendrons* refuse to grow and but few conifers flourish. Here, where both the latter do well, I have tried it repeatedly, but severe winters like 1879 and 1890 kill it outright even when planted near a wall. A *Palurus* (rather a tender thing) was planted close by the last Palm. The Palm died, but the *Palurus* escaped the winter of 1890.—M. A. R., *Liphook*.

THE SKY-BLUE WINDFLOWER.

(*ANEMONE ROBINSONIANA.*)

THIS *Anemone*, well known to our readers who care for hardy flowers, has been charming with us this dry year. In well-exposed beds, in

Anemone Robinsoniana.

which we had many of it, it went rather quickly, as all spring flowers have done this year; but in places where it was used as a carpet under evergreen and other shrubs rather openly placed, the slight shade kept the blooms a long time fresh, and the leaves in some cases are not yet withered, whilst in the sun they are quite gone. We have grown it largely in dry positions, and, in comparison with many other things, it is, perhaps, the most charming of all spring flowers.

Notes on Lilies.—In the culture of Lilies we do not take into consideration the differences of soil; some thrive anywhere, while others are more fastidious. The green sand suits to perfection the *auratum* and its allies, which cannot be perpetuated in many other soils, take what pains you may. The white Lilies were recently referred to, but nowhere have they been more beautiful than those I recently saw in the gardens of East Kent. *L. Hansoni* has increased and done fairly well with me, but in five years I have not yet seen a blossom, and where *L. Szovitzianum* and the varieties of *speciosum* refuse to live *pardalinum* has much multiplied, though very dwarf compared with

specimens in the Dorking sands. The observations recently made on the removal of this Lily I can quite confirm; the patch was so crowded I lifted the bulbs, and as carefully replanted them in fresh soil. This year none have had more than one blossom; many have had none. Leave it alone, is the lesson.—J. S. B., *Bath*.

Heuchera sanguinea.—In THE GARDEN of July 1 "W. R. B." asks for information about growing *Heuchera sanguinea*. I find it flowers best when planted in very narrow deep crevices of the rocks, in soil containing a large proportion of sharp sand and leaf-mould. In our rockery we have two plants which have had twelve and twenty-eight spikes of flowers respectively. We have about twelve more strong plants, but they had only two or three spikes between them; these are planted in large pockets. Writing to THE GARDEN a few weeks ago, I mentioned two plants of *H. sanguinea* as having twelve and twenty spikes respectively, but since writing, one has thrown up eight more spikes. I should advise "W. R. B." to plant in narrow crevices, or if in large pockets to put a number of large stones in the soil so that the roots have only very narrow places to run through.—R. W. HOSIER, *Swaylands*.

—"W. R. B." complains (page 11, July 1) of this not flowering, and inquires if it does not surely require some special treatment. Here it flowers year after year brilliantly and abundantly without the slightest attention being paid to it either in rock garden or border. The soil here is of the nature which suits *Rhododendrons*.—M. A. R., *Liphook*.

—For some years I have been in much the same case as "W. R. B." with respect to the above plant, but did not care to give up trying, so when I was at the recent show at the Inner Temple I asked the advice of Mr. Maurice Prichard, of the Christchurch nurseries, who was exhibiting a nice lot of this plant. He strongly advised me not to give it up, but to try dividing the plants into single crowns in August, replanting in the sunniest spot at command. If this should meet the eye of Mr. Prichard I should be thankful if he would add some further hints as to soil, and whether elevation above the surrounding soil would be likely to do good. I have grown it in quite a sunny spot at the foot of a south wall, but in a rather rich soil prepared especially for Roses. Here the plants make strong growth, but never flower. The same thing has occurred with those tried in pots.—J. C. TALLACK.

I quite agree with the remarks of "W. R. B." in THE GARDEN of July 1 as to the shy blooming of *Heuchera sanguinea*. I have seen it in very many gardens, and in one where I have seen it flowering well I have seen a dozen where it is just the reverse. I have tried it in many positions and various soils—light loam, heavy loam, gritty soil, leaf-mould—and in various aspects; but in no case can I depend on its flowering freely. I have been at some trouble to try and get a good result and have experimented with quite young plants up to three and four years old, but in my garden and in the majority I have seen, it is, alas! undoubtedly a shy bloomer. I sometimes think that atmosphere has a good deal to do with the shy flowering of some plants: Certainly it often has as to their thriving. Do what you will to imitate the conditions as to soil, aspect and position of some plants that you see doing well, you cannot arrive at a like result. You can to a great extent alter and make any soil and position, but you cannot change the atmosphere.—M. C., *Loxwood House, Billingshurst*.

Phyllocactuses.—The note on these plants in THE GARDEN, July 8 (p. 38), referred rather to the prices we have seen them realise at auction sales.

At the late Mr. Peacock's sale of Cactuses not many years ago the prices were absurd; in fact, the plants were practically given away. In some catalogues doubtless they will be priced high, but by keeping a sharp look-out for sales, or going to less pretentious firms, there should be no difficulty in getting them very cheap.

A large form of the white Everlasting Pea.—One of the best of hardy garden plants is the old white perennial Pea, but a form of it now flowering with us—a plant that has been in its position several years—is superb and altogether in advance of the type. There is no mistaking its superiority; it is too evident in the bold racemes of flowers, which are very long and numerous flowered. Others were planted at the same time, all having been raised from seed, but the remainder show no advance upon the ordinary kind. These Peas are usually shy seed-producers, but this year is favourable and there is a fair crop of pods, so that we may hope to get some seed. Increase in any other way is a slow process with these things.

FLOWER GARDEN NOTES.

As a slight addition to the reference to border Carnations in a recent paragraph in "Flower Garden Notes," I should like to note the fact that when well grown these flowers pay very well indeed, and a fair-sized piece of ground will, if planted with them, give a very fair return to the planter. If thoroughly well rooted, sturdy layers of the free flowering varieties are put out say early in October one can depend on an average of at least twelve good blooms per plant the following summer; these will sell readily at 6d. per dozen, and given plants at 18 inches apart, the conclusion as to the good return obtainable is obvious. It is gratifying to record this year the return to form of the old crimson Clove. I have had it for the last two or three seasons growing side by side with other border varieties, with its foliage completely wrecked by the disease peculiar to it and to the tree Carnations; indeed, so bad was it last year, that I decided to have nothing more to do with it. Some score of layers were, however, planted out, and are this year doing admirably, throwing some capital flowers with the grass perfectly clean.

Various plants raised from seed, besides the seedling Petunias referred to in last week's notes are doing very well. East Lothian Stocks, especially autumn-sown stuff, are making a brave show. Buds of Margaret Carnations are plumping fast, and to all appearance will furnish plenty of bloom before the border varieties are over. There is, I think, still existing an impression that all, or nearly all, summer-flowering plants raised from seed are necessarily short-lived, but that is not so, for in addition to the Stocks and seedling Carnations already mentioned, we have such things as the Sweet Tobacco, Verbenas, Petunias, French Marigolds, Phlox Drummondii, and Sweet Peas, all of which will, if sown early, come quickly into flower and bloom profusely until the end of the season. Perhaps I should add if properly attended to, for in some cases (notably in that of Sweet Peas and the Marigolds, especially the varieties of Calendula) they will not keep up a continuous supply of flower unless seed-pods are promptly removed. Gardeners are alive to the necessity for such an operation, but amateurs need reminding of the fact. Only the other day, for instance, in looking round some gardens I came across what had been a remarkably fine row of Sweet Peas, and was told "they are over for the season." There was no doubt of the fact under the existing circumstances, for the row was simply loaded with seed-pods.

As the season for cottage shows is now close upon us, I should like to draw attention to the value of exhibits of hardy cut flowers. I have for some four or five years dropped at our local show the groups of stove and greenhouse plants (of no particular interest to cottagers), and in lieu thereof have staged a large collection of cut hardy flowers suitable for cottage gardens. They make of them-

selves a brave exhibit mixed with feathery Asparagus foliage, and a light and graceful effect can be produced by introducing between the vases or jugs employed for the flowers occasional plants of Fern or *Isolepis gracilis*. We shall run rather short of subjects this year; many things employed on previous occasions will, owing to the early-flowering season, be almost or quite over. Still, there will be Gaultheria, hardy Fuchsias, Starworts, Erigerons, Gaillardias, Spiræas, Campanulas, Everlasting Peas, Veronicas, Peruvian and Day Lilies and plenty of border Carnations and Violas.

An important lesson to be learnt from the present season so far as herbaceous borders are concerned is the absolute necessity of making any proposed alterations in the way of lifting, division and replanting early in the autumn, not later, at any rate, than the middle of November. Sometimes the operation gets delayed from week to week until the verdict goes forth, "We will leave it until after Christmas." Frost sets in probably with the new year, and it is nearly February before one can get on the ground. The work is run through rapidly—too fast by half, and if a season like that of 1893 follows, one half the transplanted stuff does no good at all; the other half just manages to struggle along, but there is no grand summer and early autumn display of flower. Let all such work by all means be finished by the middle of November, and then if a good mulching follows careful planting, things are not likely to suffer in any average season. Several new things likely to play a prominent part in the flower garden are on trial this year, but it is impossible to give an impartial judgment as to their merits, handicapped, as they have been, by the exceptional weather. Among the new seedling Carnations is a flower very like Ruby, only several shades darker, Clove scented and with very vigorous Clove foliage. If it proves free and a non-splitter, all layers will be secured.

Claremont.

E. BURRELL.

NOTES ON HARDY PLANTS.

Cypripedium spectabile.—We must feel much indebted to E. Laney for the interesting remarks on the culture of this flower, but, after all, though some of us, indeed very many of us, have managed to rear fine groups, yet it is not a plant that may be set and left to itself in the off-handed manner implied with good results. It may be so in the native country of the species, but surely all the experience of so many of us cannot go for nothing, and we have the stubborn fact that many of our best plantmen have only succeeded with the utmost trouble in getting the plant to live healthily for years in succession. Moreover, do we not know well how hard it is to get even some of our own native orchidaceous species to settle and flourish in gardens but a field or two's distance from their self-found home? We may be told that we have merely to set the plant in such and such soil and it is sure to grow, and we may be told so in good faith, but hundreds will bear me out that this is a plant hard to succeed with. Our American friend must not forget that one fact alone may be of some moment in hindering success. To have to deal with imported roots that have been mutilated and otherwise badly treated, at once seriously handicaps the English grower. I do not by any means wish to discourage the culture of this grand Slipper-wort; neither do I wish it to be believed that aught will be gained by indifferent or off-handed planting, which is rather implied when we are told that we pamper the plant too much.

Heuchera sanguinea.—"W. R. B." (July 1, p. 11) is not alone in his experience of this plant not flowering well; indeed, many have grown it, and grown it well, year after year without getting a single flower. May I suggest that the bulky flower-buds which form in the previous summer become injured during the winter owing to the shape of the stipules and their somewhat rough character. They are capable of absorbing and holding a deal of moisture during winter, and the bulkier the buds the more liable they are to injury

from wet and frost, and it is no uncommon thing to see all the prominent buds or points go black in spring. Then, instead of flowers, new growth must begin, often in the form of numerous and somewhat weakly side shoots, so that there is but a verdant mass of foliage without flowers. Supposing this to be the cause, the remedy would be to shelter the crowns from wet during winter. It is certain that the plant wants no protection from cold. Another thing that the plant wants is very liberal mulchings, for it makes a somewhat rhizomatose stem, and when the rhizomes can find a good rooting medium to the extent of their verdant parts, they are all the more vigorous, and without vigorous foliage you can have no flowers. As already hinted, flowers may fail to appear when there has been vigorous growth in the event of a changeable and wet winter.

Streptopus amplexifolius.—This is a charming Solomon's Seal-like plant, but with paler green leafage and more slender habit. The flowers are small and somewhat greenish yellow in colour, and as such of no account. Later, however, a most pleasing and desirable feature develops. Berries set freely. They are of large size, bright scarlet, and hang in beautiful array underneath the arching stems and foliage. The plant proved quite hardy with me last winter.

Gaultheria tricophyllea.—Under this name I have grown a charming little creeper not more than an inch high, with crisp leaves and woody stems, the former being scarcely larger than the leaves of common Thyme, but thickly beset with bristly hairs. The plant is evergreen, but the flowers are small and not easily found, though freely produced. The chief attraction about this plant is its wonderful berries. They are bigger than the biggest black Currant, and the colour is even more remarkable. It is a delicate sky-blue, or as some would say, turquoise-blue, but perhaps the most familiar comparison that can be made for colour is its resemblance to the rich and beautiful blue Delphinium Belladonna. The berries are somewhat egg-shaped, the apex being slightly puckered or clawed. They rest on the surface of the ground, and are borne on the underside of the flat twigs. I see it is an Indian species, and that it has been growing here since the year 1888. I received it with another Gaultheria under the name of carnea, but carnea proved less hardy. The plants have stood in pots plunged in cocoa-nut fibre and sand. Two or three winters ago one pot became split, the roots escaped with the plunging material, and the result has been more vigorous growth and fruit. I have taken the hint and planted the whole stock in the fibre and sand, which, being very old, is well rotted, but also quite sweet. Supposing we can grow this plant vigorously on our rockeries, what a charming little evergreen it must be, with its bright blue berries that remain on the plants for many weeks. My memoranda in connection with this plant are somewhat incomplete, and I remember that I had at one time its habitat and altitude. If anyone identifying the plant meant can furnish these particulars, they together with any other might prove interesting in connection with such a distinct and charming creeper.

Geum parviflorum.—This New Zealand plant promised well from its neat habit and dwarfness, but I believe it is not destined to long hold a place in our gardens. The flowers are few and small, the bulky centres are disproportionate to the small thin petals, but the worst feature of all is that the white flowers are extremely fugacious. It may be that the present summer has been too hot for it; anyhow, I had quite a little colony of the plant, and all the flowers were over in a few days.

Woodville, Kirkstall.

J. WOOD.

The blue Rock Bindweed (*Campanula mauritanica*).—It is curious how a plant sometimes behaves altogether contrary to our notions and expectations, and this one certainly does to our gain. A native of South Europe, in this country it requires, or is supposed to require a free,

light soil and a sunny situation; but in a favoured garden with such a soil it never lived through the winter, and I only kept it by taking cuttings each autumn and planting again in spring. It is worth this trouble, but it is best where it lives in the ground, and to my astonishment it does this in a border of close, heavy soil, where one would have supposed it must inevitably perish. Plants of several years' standing have been magnificent for weeks, and some of them spread over quite a square yard of ground. It makes a perfect mat of grey-green, studded with soft mauve-blue flowers, which come profusely and in succession all through the summer.—A. H.

SHORT NOTES.—FLOWER.

Epimedium colchicum.—What are the distinctive characteristics of this plant? Nurserymen listing it appear to disagree amongst themselves as to the plant which goes under that name.—NORTH CORNWALL.

Platycodon grandiflorum.—Flowers of this come from "C. H." for a name. The flowers are of a rich deep blue colour and each nearly 3 inches across. It is a plant which I would recommend my readers to plant more often than appears to be done. It grows to the height of 1 foot or 18 inches, and the growths are surmounted with large clusters of these large rich blue flowers.—G.

A charming flower bed.—On the terrace at Gunnersbury House, Acton, can be seen a very pleasing and effective circular bed, showing some evidence of originality in design. In the centre is a standard plant of *Prunus Pissardi*, and round this a few plants of *Acer Negundo variegata*, admirably variegated, with the branches of the *Prunus* rising above them. The centre of the bed is carpeted with yellow *Calceolarias*, round them is a ring of blue tufted Pansy, with an edging next the Grass of a white Pansy.—R. D.

NOTES OF THE WEEK.

Ruellia longiflora is worth a note for the bright crimson or rather scarlet colour of its tubular-shaped flowers. A number of plants are in bloom in the Cape house at Kew, and the flowers stand out conspicuously from the abundant shining green leaves. It is a native of Peru.

The Oswego Tea (*Monarda didyma*) is a familiar plant, but one does not often see a fine mass of it in gardens. This note was prompted by a colony of it at Kew, where in a moist recess in the rockery the plant has quite established itself, making at the present time a brave show of bold crimson heads of flowers. It is a suitable thing for moist, even quite wet spots.

White Fairy Rose, one of the *Polyanthas*, is represented largely at Kew, where there are single beds of it. This variety justifies such liberal planting, as the plants have been a mass of bloom for several weeks past, whilst there is no evidence of a decrease. The flowers are not large, but of neat, compact shape and pure white.

Bartonia aurea is a well-known annual, but we draw attention to it this year as it is remarkably fine, whilst annuals, as a rule, are very poor. This kind is of great beauty when in perfection, as we saw it a few days ago in the Broxbourne nursery of Messrs. Paul and Son, where a long row of it was in full bloom. *B. aurea* makes a spreading growth, the flowers rich golden yellow and of bold form. It is effective in a group.

Chrysanthemum Lady Fitzwigram.—This first-rate new white is likely to become as popular as the early-flowering *Mme. Desgrange*. In several respects it is an improvement on the older sort, the blooms being of greater size, the growth of the plant also being stronger. It may be had in bloom from July, and perfects a dozen really fine flowers on a plant of a peculiarly dwarf nature.—H. S.

Plumbago capensis for bedding.—This charming plant is usually thought more of as a

greenhouse climber, but it is a good plant for summer beds, as testified not only by the large specimens in Hyde Park, but by the small beds of it in the Chiswick Gardens. It is used here with excellent effect, and the light sky-blue flowers are plentifully produced, making a pleasing effect, also a change from the usual things seen in bedding arrangements.

A fine Adam's Needle.—Mr. R. W. Hosier, in sending us an excellent photograph of *Yucca gloriosa* growing in the garden at Swaylands House, Penshurst, Kent, says:—

The flowers were past their best when the photograph was taken. The spike is 4 feet 6 inches in length, and about 1 foot 6 inches through, and is flowered to the bottom. It would probably have been much higher, but is in a very dry position. I think a good clump of *Yuccas* looks well on a high position in the rock garden.

The pink Broom of New Zealand, botanically known as *Notospartium Carmichaeliae*, we recently noted in flower in the nursery of Messrs. J. Veitch and Sons at Coombe Wood. It is a very distinct species of the Pea tribe, and when in full bloom not without decided beauty. The flowers are of a pretty pink shade and appear in dense racemes—a contrast to the rich green branches. Although not so hardy as one could wish, it is worth planting in the more southern districts of England.

Rudbeckia purpurea is a very fine hardy plant in full bloom now. It gains in interest and beauty when seen in a large group, as we recently noted it in the nursery of Messrs. Paul and Son, Broxbourne. The stems, rising about 3 feet or 4 feet high, are terminated by large flowers. In a well-drained, deep soil it makes splendid growth, and is a fine thing to associate with the *Eryngiums* or plants of similar character in the border. Another name for it is *Echinacea purpurea*, but it is more usually classed with the *Rudbeckias*.

Two good Yuccas.—All the *Yuccas* are fine in form and aspect, but the larger species flower only occasionally. There are two species, however, for which a place should be found in the smallest garden of hardy flowers. These are *filamentosa* and *flaccida*. If there is a small group of each, several plants will flower annually. One of the best features in the garden at the present time is these two *Yuccas*. Their spikes, nearly 5 feet high, are bearing numerous large flowers, ivory white in colour, and most conspicuous at all times, but especially in the evening.

Lilium pardalinum is superb at present in the Royal Gardens, Kew, and it is worth a journey to see the two large beds of it near the Palm house. We have never seen a finer mass of this Californian Lily, the tall, graceful stems rising from a groundwork of dwarf shrubs and bearing a profusion of flowers, orange, heavily spotted with chocolate. The tall stems swinging gently in the summer breeze are delightful. It would not be easy to find two such masses in any garden. Hard by *Lilium longiflorum* is in full beauty, its ivory white flowers appearing just above the shrubs.

Spiræa gigantea by the waterside.—We were admiring recently this fine *Spiræa* planted by the side of a lake. The *Spiræas* are too little used for this purpose, but they are exactly the type of plant to use, *S. palmata* in particular, which makes a glow of crimson in summer. *S. gigantea* is well named. It is the giant of the family, and was first shown under the name of *S. kamschatica*. When in good soil it will grow fully 8 feet in height and bears large white clusters, like those of *S. palmata*, much magnified. It is not exactly the type of plant for the border, but has a fine effect by the waterside or in the wilder parts of the garden.

Terrific storm.—About 4 p.m. on Saturday, July 8, the district of Snaith, South-west Yorks, was visited by a storm of thunder, lightning, rain and hail, lasting about an hour, during which hailstones, some as large as pigeon's eggs, fell, breaking a large amount of glass in the extensive vineries

here. At the end of the storm the Vine borders were covered with hail as if there had been an inch of snow. Great damage has been done to the Apple, Pear and Plum crops, quantities falling to the ground, and of those left on the trees many are shattered and useless. In and around Snaith some hothouses had every pane of glass broken, and fields of Peas, Potatoes, Swede Turnips, Mustard and Barley are quite destroyed.—W. S. CAMPBELL, *Cowick Park, Snaith, R.S.O., Yorks.*

Solanum Wendlandi, illustrated by a coloured plate in *THE GARDEN*, February 1, 1890, is in full beauty in the Water Lily house in the Royal Gardens, Kew, where it has been blooming since the spring. But it is during the summer season that it is in perfection, and then one may see how much beauty is lost to large conservatories by not planting this noble climber. The flower-heads are of very large size, and the individual blooms, lilac-blue, touched with purple, are also of great breadth, making a rich effect. We do not see this much in gardens, and the reason is possibly that it is insufficiently known. Such a fine climber, free in bloom and vigorous in constitution, should be made good note of by all who have large plant houses to clothe with beauty.

Hippeastrum procerum, popularly called the "Blue Amaryllis," is in bloom in the succulent house at Kew. A group of it is planted out and forms one of the more interesting features in the Royal Gardens at this time. It was figured in the "Flore des Serres," t. 2077, as *Amaryllis proceræ*, and in the *Botanical Magazine*, t. 5883, as *A. Rayneri*, but whatever its name, it is a beautiful thing, the flowers refined, mauve-blue in colour, the segments spotted with red towards the base, the abundant glaucous leaves being margined with white. Even for its evergreen foliage alone it is worth growing. *H. procerum* was introduced from Southern Brazil in 1863, going first into Belgium, so that it is by no means new.

Delphinium Belladonna, one of the most beautiful of the perennial Larkspurs, was represented by a large group in bloom a few days ago in Mr. Gifford's nursery at Tottenham. This fine variety is not grown so largely as formerly, although more charming than many of the newer kinds that have been raised of recent years. The colour of this kind is exquisite—a soft, bright and distinct sky blue, the flowers appearing throughout the summer. It is naturally dwarf in height, not more than 3 feet, vigorous and useful for grouping in the front of deep green-leaved shrubs. This *Delphinium* should not be overlooked in the search for mere novelties. Its flowers are of value for cutting and may be used in the choicest arrangements.

Carnation Alice.—We have tried hundreds of Carnations at different times with a view to finding out the freest and best for planting in bold groups in the flower garden. The least success was with whites and yellows, but happily in white we now have Alice, which for garden decoration surpasses by far anything we have ever seen. It is a grand kind, as hardy as any, full of vigour and amazing in its exceeding profusion of bloom. Among other whites Mrs. Muir has been much praised, but we find it comes very short of Alice, and it is a florists' variety with the regulation flower, smooth and intensely formal. The petals of Alice are much fringed, and in colour a pure unspotted white. The opening bud has a tint of cream about it. In all respects it is first-rate and never splits. It was raised by Mr. Rogers, of Whittlesea, Cambs.

Nymphæa Laydekeri rosea.—This is another great acquisition to hardy Water Lilies, and very rich and bright in colour. The flowers are not so large as those of most of the newer hybrids, but doubtless will be larger when the plants are quite established. The plants were only put out in April this year. All the other good kinds were planted at the same time, but this was the first to flower, and it has continued for several weeks. M. Marliac says it blooms freely and uninterruptedly from April to October. It has a very showy appearance, the petals being sharply

pointed. On the first day of expanding it is of a clear rosy pink, but it deepens in tint daily for several days, and when at its best is of a rich carmine-rose hue with bright orange centre. From a considerable distance it looks quite red as it lies upon the water.—A. H.

The Tigrdias, or Tiger Flowers, as they are popularly called, are in bloom now in gardens. We saw a group of them recently, and in the full sun the gorgeous colour of the flowers is most pronounced. The type, *T. pavonina*, was the species used, and this year it is blooming, like all things, earlier than usual. Many fail in their culture through not planting them in suitable positions. They like a warm, light, dry soil, and we have seen them to best advantage in a sunny south border. There are many kinds, but the type must not be overlooked. The Tigrdias make variety in the border at a season when a change is required, and the splendour of the flower colouring is in its way unique. *T. conchiflora*, which has a yellow ground spotted with scarlet; *T. speciosa*, deep scarlet, and other kinds in cultivation are all worthy of attention. When planted put the bulbs in clumps to get effect from the gorgeous flowers.

Aerides Sanderianum.—Although described by Reichenbach as a species on its introduction in 1884, this Orchid is now looked upon as a variety of *A. Lawrenceae* by botanists. It is, no doubt, the finest of all the *Aerides* in the odoratum group. There is a good specimen now in flower in the warm Orchid house at Kew. The stem is 3 feet high clothed to the base with strap-shaped leathery leaves a foot long. The two flower-spikes are pendent, considerably longer than the leaves, and carry about twenty-five flowers each. The sepals and petals are creamy-white, conspicuously blotched at the tips with rich magenta-purple, whilst the remarkable horn-shaped lip is yellow marked with small spots of purple. In addition to its beauty it has the further attraction of a very pleasant fragrance. The flower measures $1\frac{1}{2}$ inches in depth, scarcely so much in width. Both this plant and its ally, *A. Lawrenceae*, are to be counted amongst the Orchid treasures added by Mr. Sander to our collections. The native home of both is in the Philippine Islands.—B.

Lilium longiflorum var. formosanum.—For about three weeks during the latter part of June and the beginning of July a group of this beautiful Lily has made a charming picture in the Bamboo garden at Kew. It consists of about 200 plants, which had been raised from seed ripened in the autumn of 1891. This is one of the rarest as well as one of the finest forms of *Lilium longiflorum* in cultivation, but its easy propagation as evidenced by these plants should soon make it one of the most popular of Lilies. Although the bulbs are only two years old, some of the stems have borne four flowers, the majority two and three. These flowers are trumpet-shaped, 5 inches long, pure white inside, but strongly tinged with reddish purple on the outside. The anthers are yellow. All these plants were raised from seeds produced on a single stem, which flowered in the temperate house two years ago. The seeds were sown early in 1892 on a bed of soil in a cool, light greenhouse, and they grew so freely that some of the seedlings developed one flower the first season. After they had died down in the autumn the bulbs were taken up and planted in rich open loam in the Bamboo garden. The graceful stems of the Bamboos with their wealth of feathery foliage have made a perfect setting for the flowers.

Crinum Powellii.—This *Crinum* is a hybrid raised from *C. longifolium* and *C. Moorei*. In the south of England (from London downwards) it is quite hardy, but for the cool or unheated greenhouse it has also proved a valuable acquisition, flowering as it does some six or eight weeks sooner there than outside. Wherever it is grown it should if possible be planted out, pot culture being unsuitable for it on account of the length of its bulbs, which require to be planted a foot or so deep. The flower-spikes are about 2 feet high and carry some six or eight flowers, which vary considerably in colour. In the typical form they are of

a rose-tinted white, whilst in the var. *roseum* they are of a clear pale rose. On June 20 last the pure white variety known as *album* was exhibited at the Drill Hall by Mr. F. W. Moore, of Glasnevin, and received a first-class certificate. It is also in flower at the present time in the large temperate house at Kew, planted in one of the beds; it is certainly a lovely thing. There is yet another form, and in this the flowers are white, striped with rose. But in any variety this *Crinum* is a most delightful plant, none of the forms being poor. When planted out of doors, a sheltered position with a southern aspect should be selected, giving it a rich, yet open leam to grow in.

New Lilies.—We have to welcome two Lilies that promise to get popular when better known and more plentiful. They were both shown at the meeting of the Royal Horticultural Society on July 11, and in each case a first-class certificate was given. *Lilium Alexandre* came from Messrs. Wallace and Co., of Colchester, and Messrs. J. Veitch and Sons. It is a hybrid form and has for its parents *L. longiflorum* and probably *L. auratum*; at least the flowers betray close affinity to this species. It has been already described in our report (p. 61), but justifies another allusion to it. A great point is its dwarf habit, which adapts it well for cultivation in pots. The other Lily that deserves mention is *Lilium Lowi*, which is of a different type. From the description one will see that its flowers are of distinct colour, white, freely dotted with a purplish crimson colour, that shows up to advantage on the pure ground. In time this will prove a useful, and we think popular Lily.

Too many Sweet Peas.—We welcome the improvement of any fine garden flowers, but the wisdom of giving so many names is at least doubtful. It tends to confusion and distracts attention from the things that are really good and distinct. Taking up a few seed lists, there would not be the least difficulty in compiling a list of thirty or forty named varieties, all of which are claimed to be distinct, but many are too much alike. Within the past few years great advances have been made and many new colours brought out among Sweet Peas, but the naming is overdone. Anyone who has time and space can test this by growing a collection. A few good things will be discovered, and many that rightly should never have been named at all, as, for example, Princess of Wales, a mauve-shaded, but altogether undecided colour, changing from day to day, hardly ever pretty, and of no value whatever. On the other hand, there is Princess Beatrice, than which no better kind has been sent out since the improvement first began. It is very clear, bright in colour and popular apparently, as it may often be seen in the London flower shops. We are greatly indebted to those who have spent so much labour among Sweet Peas, but it is to the interests of all concerned that those sent out as new should be distinct, and only when this is the case can the interest and popularity of the flower be sustained and extended.

PUBLIC GARDENS.

NOTES FROM THE PARKS.

ALTHOUGH the season has not been favourable for flowers, the parks are bright with colour, and each year the arrangements of various things undergo a pleasing change. It is worthy of note that the usual rigid style of bedding out, carpet designs, and set patterns of severe type are practically abolished. A few reminders of a once debased fashion remain, and whilst similar plants are used as formerly, they are set out in a wholly different way. As usual, the flowers in Hyde Park are very fine, distressed somewhat by the drought, but not seriously. Such things as *Plumbago capensis*, Fuchsias, Pelargoniums, Palms, Bamboos, and fine-foliaged subjects of like character are

boldly grouped. This feature of the Hyde Park summer arrangements should be followed also in other parks, where, however, we are pleased to see that hardy perennials are largely used. A very familiar flower is the Carnation, and both along Park Lane and in Regent's Park it is well planted. A few days ago the flowers were rapidly expanding, and in Hyde Park the variety *Alice Ayres* occupies one bed, the groundwork *Lysimachia nummularia aurea*, and the edging tufted Pansy *lilacina*, of a pleasing shade of blue. The Carnation has a large, full, white flower cut into with rose. It is pleasant to see that the edgings to the beds are diversified as much as possible, not the same things repeated until one gets weary of them, and in Regent's Park especially the London Pride, Creeping Jenny, and mossy Saxifrage are more largely planted than the Pyrethrum or other familiar edging things.

One of the most beautiful beds we have seen is in Hyde Park. The groundwork is *Alternanthera*, and the edging *Antennaria tomentosa*, whilst the surface is broken in a charming way by raised plants of blue *Lobelia*, *Carex riparia variegata*, the variegated *Phalangium*, scarlet tuberous *Begonias*, *Draena indivisa*, and *Grevillea robusta*. The colouring is of quiet beauty, and a relief from more gaudy arrangements. We think a little more variety might be introduced amongst the tufted Pansies, as there is a host of kinds, strong in growth, free, and representing considerable range of colours. The distinct beds of them are very fine, and show what may be accomplished by a free and bold use of this plant. Pelargoniums are a leading feature in the majority of beds, but garish effect is prevented by suitable contrast. A pink-flowered Pelargonium mixed with tufted Pansy *lilacina*, then a line of *Iresine Lindeni*, and an edging of white *Lobelia Snowball* form a very distinct and attractive bed. Again, the same tufted Pansy is used with Pelargonium *Aspasia*, the flowers of which are white, and the contrast is distinctly pleasing. It is not often one sees the Rose succeeding creditably in London, but a bed of several varieties is not without attraction, Harrison's Musk covering the surface of the ground, and the edging is blue *Lobelia*. The familiar Musk is a delightful flower for bedding, covering the surface and harmonising well with the majority of things.

Where the space to be dealt with is large, it is essential to get variety in the various beds. A tufted Pansy named *Beauty of Chipping Norton*, which has deep blue flowers, looks well in association with white Stocks. Of recent years *Lobelia cardinalis* has been largely planted, and a bed in which it is a feature mixed with tufted Pansy *Mrs. Turner*, the flowers light lavender in colour, and the edging of *Fuchsia Cloth of Gold*, results in a fine contrast. There is also now a departure in the matter of edgings. In one arrangement the bed has three rows of tufted Pansy *Snowflake*, a very good kind, of sturdy habit and throwing its white flowers well above the leafage. We greatly admire this way of planting the tufted Pansy. The groups of *Heliotropes* and the various other things that have been mentioned will have a hard time against the drought and hot sun, which in London, even in the parks, is intense. Artificial watering does something, but nothing atones for genial showers and shade at times.

The flowers at Regent's Park are planted in quite a distinct way, and this has become a very charming spot in summer. We have already referred to the edgings of hardy plants

used well and in perfect agreement with the subjects associated with them. In the outer portions and against evergreen shrubs large masses of *Lilium croceum* were, at the time of our visit, in full beauty, also of *L. umbellatum*—two species that succeed remarkably well under such conditions.

Another plant in full bloom was *Erigeron speciosus*, the flowers making a sea of light lilac-purple. The beds in this park are boldly planted. In one we see tufted Pansies of distinct colours, and in another Pink Her Majesty, associated with Carnation Guiding Star. A succession of bloom over a fairly long season is thus secured, the stems of the Carnation appearing freely from the dense mass of glaucous leafage as a groundwork. Around the border are standard Fuchsias, tuberous Begonias, *Pelargoniums*, and other plants arranged in distinct blocks to get rich effect. A very pretty contrast is obtained with white Canterbury Bells and blue Cornflower. *Delphiniums* with flowers of various shades of blue are imposing in front of dark leaved shrubs, and we hope that this vigorous style of flower gardening will be still further extended in the future. A very pretty arrangement is that in which the leading features are *Asparagus plumosus*, the variegated *Dactylis*, and *Begonia floribunda rosea*, the flowers rose in colour edged with a lighter shade. There is room still for further development in the way of hardy perennials, but we must say that the contrasts of colour to be seen are in good taste, rich, and effective, yet not garish. The beds of large-flowered *Petunias* are, however, a mistake. We have noted them on more than one occasion. The big, flabby flowers are quite wanting in vigour and the purple shades of colour most displeasing. If *Petunias* are used, the varieties should have small, brightly coloured flowers, which are far more effective than the later productions of the raiser.

Lincoln's Inn Gardens.—On Monday next, according to a custom which has prevailed for some years past, the gardens of Lincoln's Inn will, by permission of the Benchers, be thrown open for the benefit of the poor children inhabiting the surrounding neighbourhoods from 3 o'clock until dusk; and on and after August 14 until September 15 the gardens will be open from 5 o'clock until dusk.

Open space for Shoreditch.—On Saturday evening, outside Hoxton Church, a demonstration, convened by the local workmen's clubs, was held to demand, for the people of Shoreditch, the site of the Haberdashers' Schools as an open space. A representative local committee, headed by Mr. Stuart, M.P., is urging the desirability of granting the school site as a public garden and playground, there being at present absolutely no such open space in Shoreditch. The following resolution was proposed by Mr. J. Field, seconded by Mr. Knight (O.B.S.), supported by Mr. C. Freake, L.C.C., and carried unanimously, "That this meeting of inhabitants of Shoreditch respectfully urges the Charity Commissioners, in dealing with Aske's charity and the Haberdashers' Schools, to take into consideration the great need for an open space for the people of this densely-populated district." Another resolution, desiring the local M.P.'s and other elected representatives to press the matter forward, was also passed.

The weather in West Herts.—The past week has been the first week which has been in any way unseasonably cold since the middle of January. An unbroken record of twenty-five consecutive warm weeks, or six months, is certainly very remarkable, if not unprecedented in the present century. I call last week a cool one, but after all, the mean temperature was only slightly below

the average for the month. The ground still remains very warm even for midsummer, the temperature at 1 foot deep being 65° and at 2 feet deep 64°, or respectively 7° and 6° warmer than at the same time last year. Although rain has fallen on most days this month, the aggregate amount measures less than three-quarters of an inch, which, after such a long spell of dry weather, is almost valueless. The lawns are certainly greener than for some months past, but vegetation generally, notwithstanding the warmth of the ground, makes little progress. Even heavy waterings in such a season appear to do little good while the atmosphere and subsoil remain so dry. Mr. G. J. Symons, F.R.S., states in this month's *Meteorological Magazine* that only 1.12 inches of rain fell at Greenwich during the 113 days ending June 22, making this the longest partial drought on record in this country. During the same period 1.94 inches of rain fell in this part of Hertfordshire.—E. M., *Berkhamsted*.

Notes from Almondsbury.—A *Crinum* seedling is blooming well with me in the greenhouse. I have cared for it eight years. This year it has burst its pot and rushed up a spike of bloom. The spike is 3 feet long; there are fourteen blooms, six out now; the leaves are 4 feet long. Next to it stands a fine old plant of *Schubertia grandiflora* in bloom. Some persons like its nutty odour. On the surface soil of the pot I grow several plants of *Streptocarpus* hybrids. How charming these are! In a sheltered bed outside the greenhouse I grow choice Daffodils, *Stuartia virginica*, Fortune's Yellow Rose, *Iris aurea*, *Lapeyrousia grandiflora*, *Abutilon vitifolium album*, *Habrothamnus elegans*, and a carpet of the variegated white-leaved Strawberry, with the variegated Blackberry. I fear there is hardly room for all, but the combination at present is interesting. I can confirm all the praise given to *Iris aurea*, *Monnierii*, and *ochroleuca*. With me they have resisted nobly the great drought of 1893. *Alstroemerias* are my great failure this year, except *aurantiaca* in a damp spot. I believe a sunny ditch is the best place for most of the *Alstroemerias*; very rich soil, and yet not to be too wet in winter. It is these happy combinations of soil and position that are the trouble of the gardener. To make places suitable for all plants "passes the wit of man." Mulleins have been very fine; also Carnations, but as many leaves are falling and many Michaelmas Daisies are over, what shall we have in our gardens in September? All *Delphiniums* should be cut down and mulched and great care taken of Dahlias. An old clump of *Iris Milesi* was crowded with bloom this year. A warm wall in the south of England suits this well. *Antholyza paniculata* is blooming freely now.—C. O. MILES.

Rosa lucida in Berks.—I send a photo of *Rosa lucida plena*. The plant, a standard, is some twenty years old, 7 feet through the head and about 8 feet high, and forms a lovely object when in bloom. It is on a Brier stock budded by my father at Sulhamstead, near Reading.—J. E. STRANGE, *Aldermaston, Reading*.

BOOKS.

"Further Recollections of a Happy Life."*—Those who read Miss North's earlier book will welcome a further issue of what is in fact the autobiography of a remarkable woman. The present volume is a record of some of Miss North's earlier journeys in remote parts of Europe and in Egypt and Palestine—journeys of thirty years ago, when travelling was not made so easy as at present, but when the places visited were fresher and better worth seeing. The power of keen and shrewd observation that is evident throughout Miss North's writings, and the genial and widely sympathetic human kindness that endeared her to all who knew her, are as conspicuous in this as in the larger book.—G. J.

* "Further Recollections of a Happy Life." By Marianne North. London: Macmillan and Co.

Royal Horticultural Society.—The next meeting of the Royal Horticultural Society will take place on Tuesday, July 25, at the Drill Hall, James' Street, Victoria Street, Westminster. The fruit, floral, and Orchid committees will assemble at 12 o'clock as usual, and at 3 p.m. a paper on "Alpine Houses and Plants" will be read by Mr. H. Selfe-Leonard.

Wasps as gardeners' friends.—It is seldom that a good word is said concerning wasps; but this season they have proved quite gardeners' friends, as they have destroyed many of the insect pests so prevalent this season. Although fruit is ripe much earlier than usual, wasps have not yet attacked it. In a gentleman's garden close by a Morello Cherry tree had a bad attack of black aphides, but the wasps soon cleared them, leaving the Cherries, which were turning colour fast, unmolested.—A. YOUNG.

Salt as a manure for Celery.—I have used salt for Celery for some years and generally give two dressings, the first just after the plants have become established. Only a mere sprinkling is given along each side of the rows, keeping it away from the plants. At the same time the soil is broken down so as to form a top-dressing of about an inch. Into this the roots work very freely and the plants take on a healthy growth. The other dressing is given at the first earthing-up.—A. YOUNG.

English gardeners for India.—The Government of India have under consideration (says the *Bombay Gazette*) a scheme by which European gardeners for gardens in the various provinces will be regularly supplied from Kew, and will be retained on conditions more satisfactory than at present.

Lilies from Weybridges.—I have brought you up a few Lilies, including *L. Martagon dalmaticum* in four distinct varieties. This Lily has been unusually fine this season; one stem had thirty-nine flowers, another thirty-eight. I have also brought you *L. Humboldtii*, three varieties, and *L. Batemannii*, a fine growth with thirteen flowers and buds.—G. F. WILSON.

BOOKS RECEIVED.

"Bulbous Irises." By Prof. Michael Foster. R.H.S., 117, Victoria Street, S.W.

"A Synopsis of the Genera and Species of *Musea*." By G. Baker, F.R.S., F.L.S., Keeper of the Herbarium, Kew.

"Catalogue of Plants in the Broome Botanical Garden, Royal Victoria Park, Bath." By J. W. Morris, F.L.S. F. Curtis, X.L.C.R. Press, Bridge Street, Bath.

"Handbook of the Flora of New South Wales." By Chas. Moore, Government Botanist and Director Botanic Gardens, Sydney, assisted by Ernst Betche, Botanical Collector. Charles Potter, Philip Street, Sydney.

Names of plants.—*Dunum*.—Send better specimen.—*H. May*.—Please number specimens.

"The Garden" Monthly Parts.—This journal is published in neatly bound Monthly Parts. In this form the coloured plates are best preserved, and it is most suitable for reference previous to the issue of the half-yearly volumes. Price 1s. 6d.; post free, 1s. 9d. Complete set of volumes of THE GARDEN from its commencement to end of 1892, forty-two vols., price, cloth, £30 12s.

"Gardening Illustrated" Monthly Parts.—This journal is published in neatly bound Monthly Parts, in which form it is most suitable for reference previous to the issue of the yearly volumes. Price 6d.; post free, 8d.

"Farm and Home" Monthly Parts.—This journal is published in neatly bound Monthly Parts, in which form it is most suitable for reference previous to the issue of the yearly volumes. Price 6d.; post free, 8d.

Hardy Flowers.—Giving descriptions of upwards of thirteen hundred of the most ornamental species, with directions for their arrangement, culture, &c. Fifth and Popular Edition, 1s.; post free, 1s. 3d.

"The Garden Annual" for 1893.—Contains Alphabetical Lists of all Branches of the Horticultural Trade. The Lists of Gardens and Country Seats (containing over 9000) have been very carefully and extensively revised, and are admitted to be the most complete ever published. Price 1s.; by post, 1s. 3d.

All of our readers who are interested in the improvement of cottage homes are invited to help us to make Cottage Gardening known. It is published at the very lowest price to meet the wants of those for whom it is intended, and copies will be sent for distribution, free, by the publishers, Messrs. Cassell and Company, La Belle Sauvage, Ludgate Hill, E.C.

"This is an Art
Which does mend Nature: change it rather; but
THE ART ITSELF IS NATURE."—*Shakespeare.*

ORCHIDS.

ACINETAS.

ALTHOUGH only a small genus of Orchids, the *Acinetas* known in gardens are, with scarcely an exception, well worthy of cultivation; yet they cannot be said to occupy so prominent a position in collections now as they appear to have done forty or fifty years ago. This, of course, is easily accounted for when we consider the remarkable success which has since that period attended the labours of Orchid collectors in South and Central American regions in introducing to European gardens species of other genera with which, in showiness and wealth of colouring, the *Acinetas* cannot compare. Nevertheless, during July and August, when the best of them are most frequently to be seen in bloom, there are few Orchids more welcome than they are, not only because of their large and striking racemes of handsome flowers, but also for the interest which attaches to their curious method of flowering, as is hereafter described. There are now probably about ten species known, all of which are natives of Central American countries either above or below the Isthmus of Panama. The identity of one or two is, however, somewhat confused with members of the closely allied genera *Læcena* and *Luddemania*, which are very similar in leaf and pseudo-bulb. In regard to habit, *Acinetas* may certainly be included amongst the handsomest of Central American Orchids, having large, leathery deep green leaves, frequently from 1 foot to 1½ feet long, and stout, angular pseudo-bulbs, also dark green. The flower racemes in every species known to me are pendulous, issuing from the base of the pseudo bulb. As a rule they push straight downwards through the soil, coming out through the bottom of the basket in which the plants are growing. More than once I have noticed plants growing in pots where the flower-spike had pushed through the soil and drainage and found its way through the hole at the bottom, the large raceme of flowers presenting in that position an extremely curious appearance.

In regard to their cultivation, *Acinetas* present no particular difficulty. They should, on account of the peculiar method of flowering, be grown exclusively in baskets, and for the same reason large flat pieces of potsherds for drainage should not be used, preferring instead rather large lumps of charcoal, arranged so that the spike has no difficulty in pushing between them. I have seen *Acinetas* described as shy-flowering, but my experience with them has been the contrary, healthy plants flowering regularly every year. I believe that this description of them has arisen through their being so frequently grown in pots, for, notwithstanding the marvelous knack the flower-spike has of finding an outlet, I have on several occasions noticed the remains of old spikes curled up amongst the crocks in pot-grown plants. Above the drainage a layer of good *Sphagnum* should be placed, using, finally, as a compost sound peat-fibre and *Sphagnum*. On account of the inadvisability of using much drainage, it is better to select baskets that are rather broad and

shallow. From March to July or August the plants may be grown in the East Indian house, the coolest part of which is preferable. If such a position be not available the intermediate house will do, and in any case during the time the plants are in flower and at rest they should always be kept in this house. Water is needed in abundance during active growth, but after flowering the supply should be gradually reduced until in winter no more is needed than will keep the pseudo-bulbs and leaves plump and fresh. They like a position near the glass, but should be carefully guarded from the hottest rays of the sun. When in flower it is, of course, necessary for them to be suspended from the roof.

The following are the sorts generally grown—

A. BARKERI.—According to Mr. Bateman, who figured this species in his magnificent work, "The Orchidaceæ of Mexico and Guatemala," it was discovered in 1837 by Mr. J. Ross in one of the many dark ravines which occur in the neighbourhood of Xalapa, in Mexico. It was first flowered in this country in 1838 by Mr. Barker, whose collection of Orchids near Birmingham was at that period one of the most renowned in England, and in honour of whom Lindley gave it the name it bears. The last specimen I had in bloom bore a raceme of nearly twenty flowers, which were bright yellow, spotted with brownish red.

A. CHRYSANTHA.—This is one of the rarest of *Acinetas*, and, after having been lost to cultivation for nearly fifty years, re-appeared at Kew in 1888, having been sent there from New Granada by M. Patin and recognised on its flowering the next year by Mr. Rolfe. It has flowered several times since that date. The raceme is pendulous as in the other species, the flowers being bright yellow, the lip alone heavily blotched with crimson. Mr. Rolfe says it is distinguished from all other *Acinetas* by the strong curved horn at the base of the crest. In one of the continental figures of this plant the raceme is depicted as erect, an error which has led to considerable confusion in regard to not only the characters of this plant, but also those of the genus, none of whose species, so far as I am aware, have other than pendulous racemes.

A. DENSA.—This species and *A. Humboldtii* are probably the best known in gardens, yet neither of them can be described as other than comparatively rare Orchids. *A. densa* was introduced from Costa Rica about 1850, having been discovered by Warscewicz. It carries (generally during the month of August) a long raceme of handsome flowers, each of which is 2 inches across. They are somewhat cup-shaped by reason of the incurving of the sepals and petals, which also overlap each other. The sepals are entirely of a rich yellow, the petals, which have the same ground colour, being spotted with brownish crimson, a character that is still more markedly present in the lip. All the parts are singularly thick and fleshy in texture, and the flowers remain in good condition about a fortnight. The raceme as a rule is a little over 1 foot long and carries sixteen to twenty flowers.

A. HRUBYANA is a little-known species introduced for the first time by Mr. Sander, of St. Albans, about twelve years ago and flowered in 1882 by Baron Hruby in Bohemia, after whom it was named by Reichenbach. That botanist describes it as a fine plant, distinct from all other species of *Acinetas*, the flowers being white, with a few purple spots on the lip.

A. HUMBOLDTII.—Lindley first figured this species in the *Botanical Register* for 1843 as *Peristeria Humboldtii*, and he there stated that the plant was imported from Porto Caballo, in Venezuela, by Mr. J. Wilmore, of Oldford, near Birmingham, three years previously. It first flowered in March, 1842, carrying a spike 2 feet long. It had, however, been discovered many years previously by Humboldt and Bonpland in Peru both wild and cultivated. In the typical form of the species the flowers are reddish brown, spotted with dull

purple; in the variety *fulva* the ground colour of the sepals and petals is a tawny yellow, and a brighter yellow on the lip. A variety known as *staminea* has pale straw-coloured flowers. All the forms are extremely handsome, but, unfortunately, the flowers do not last many days in perfection.

A. SULCATA is a very rare species; it is, however, given in the list of Orchids which flowered at Kew in 1890. It was first seen in Mr. Christopher Sykes' garden at Brough, in East Yorkshire, and although no definite information appears to exist respecting its origin, Reichenbach concluded that it came from either New Granada or Ecuador, as he had a sketch made by Wallis which agreed with the flowers sent him from Brough. The flowers are yellow, spotted with brown-purple, and resemble those of *A. Humboldtii fulva*; it is, however, distinguished by having a hairy column. It flowers during July.

Other species which may be mentioned as completing the list of known *Acinetas* are *erythroantha* (occasionally seen in cultivation), *Schilleriana*, *cryptodonta*, and *sella-turcica*. None of them are of importance to gardeners.

B.

Orchids at Cheltenham.—A gathering of beautiful flowers comes to hand from Mr. Cypher, Queen's Road Nursery, amongst them being the grand and lovely *Sobralia xantholenca*. The flowers, which are large and showy, last several days in beauty, and when they go off they are succeeded by others from the same sheath, so that a good display is maintained. The sepals and petals are of a primrose-yellow, the large lip being somewhat frilled, of a deeper yellow, which passes into deep orange at the base. With this also comes a good flower of *Catasetum Bungei*, which was introduced a few years ago by M. Linden. This, with its pure ivory white flowers, has done much to popularise this genus of plants. It appears to be a very free bloomer. Mr. Cypher also sends a very good form of *Lælia tenebrosa*, with its bronzy sepals and petals and its richly coloured lip. Amongst the Slipper family is a very fine form of *Cypripedium cardinale* and one of its near relatives, the ivory-white *C. Sedeni candidulum*. *C. Curtisii* was also included. The first bloom this season of a fine dark form of the beautiful *Dendrobium Phalenopsis Schroederianum* was also sent. Of this plant Mr. Cypher says he has some wonderful growths, much finer and stronger than on the imported bulbs.—G.

Masdevallia Dayana.—This plant flowered for the first time in the famous collection of Mr. John Day, of Tottenham, nearly twenty years ago. It has recently been taken from the genus *Masdevallia*, and the almost unpronounceable name of *Cryptoparantus* has been given it. The plant is now in flower in the Burford Lodge collection of Sir Trevor Lawrence. The flowers, like those of all the *Masdevallias*, depend for their beauty on the sepals, which are joined together at their points, leaving an opening or slit at the sides; they are greenish white, spotted reddish brown, below wholly deep brown. This is a charming companion to the *M. fenestrata* which I used to grow and flower some years ago.—G.

Maxillaria Sanderiana.—G. Horrocks sends me a flower of this the grandest of all the plants known in the genus. It was introduced from Ecuador by Mr. Sander, of St. Albans, about ten years ago, and is now getting strong and established, and flowering very freely in many gardens. The flower sent, with a question as to its being a new variety, differs from that figured in THE GARDEN of July 23, 1887, inasmuch as it has a yellow lip. It is over 6 inches across, and a massive dark bloom. I cannot say it is a new variety, for I have seen it before flowering in the collection of Mr. Measures, The Woodlands, Streat-ham. This gentleman remarked that the lip was yellow, while the figure in THE GARDEN showed a white lip, but he did not deem it of much importance; neither did I, but what I did note with pleasure was the freedom with which the plant

was flowering. It was grown in the same house with the *Laelias* and *Cattleyas*, and this fact I would wish to impress upon the minds of my readers who have been trying to grow this plant in the cool house.—W. H. G.

Coryanthes maculata.—J. Buckley sends a flower for a name which I think must be a variety of this species, which is very variable in colour, and has received several names. He says this plant was sent to him by some friends in Demerara, and it was there or in some other part of British Guiana that it was first found. The flower now before me is tawny yellow without any spotting whatever; still, by the shape of the helmet and the bucket I think it belongs to this species. The genus comes very near to *Stanhopea*, but the flowers are infinitely more curious and interesting. The *Coryanthes* require the hottest position in the East Indian house with full exposure to the sun coupled with a nice moist atmosphere, and at no season of the year should the plants be allowed to become dry.—W. H. G.

Dendrobium canaliculatum.—D. Maurice sends a spike of a very fragrant species, which I had some difficulty in naming at first. He said it was sent to him by a friend from North Australia. The sepals and petals are not so pale as usual, being of a greenish rose and the lip rosy purple. This plant, introduced by Mr. John Gould Veitch, was figured in the *Botanical Magazine*, and described by Bateman under the name of *D. Tattonianum*, but it had been previously described by Robert Brown under the name given above. It is one of the most fragrant species of this genus, and although the spike sent had but six flowers we are told that it sometimes has as many as eighteen to twenty. It requires to be grown in considerable heat, for although from Australia, it must be borne in mind it is from the north of that country.—W. H. G.

CATTELEYA GUTTATA LEOPOLDI.

This species, which appears to have been introduced over sixty years ago, was first figured in the "Transactions of the Horticultural Society." It now, however, is seldom seen in our gardens, larger and more richly coloured kinds taking its place. The variety we now have under consideration was introduced some forty years ago by one of the *Verschaffelts* then in business in Ghent, and named by him in honour of the King of the Belgians. Of this variety I have received two splendid forms from M. Linden, of Brussels, the fine spikes making really quite a gorgeous display, and showing what a fine plant this is for decorating stoves at this season of the year. M. Linden informs me that these varieties were sent to him from Pernambuco, but as this is a province covering a greater surface than the whole of England, it does not give any clue to its whereabouts. The varieties are of great merit and the flowers richly coloured. The larger flower of the two measures 4 inches across, and the spike carries twelve of these flowers, the sepals and petals having a ground colour of tawny yellowish-green profusely spotted with crimson. The side lobes are white, suffused with rose, middle lobe clawed and of a deep rosy purple. In the other variety the blooms measure half an inch less across, the spike carrying fourteen flowers, which are richer and warmer in colour, the sepals and petals being of a rich bronzy hue, liberally spotted and blotched with deep crimson, the lip similar to that of the last named, but the side lobes of a deeper colour, and the front lobe of a rich amethyst-purple. I also received a fine spike of this variety from Mr. Seeger, of Dulwich, bearing twenty-five flowers. This variety comes about midway between the two forms sent by M. Linden. This plant Mr. Seeger tells me was imported

with others from the province of Santa Catharina, which is again larger than England, and from the same district I received some years ago the very finest form of this variety I have ever seen. This plant appears to have a wide distribution in Brazil, and, like many of the Brazilian *Cattleyas*, it requires considerable care to maintain it in a healthy condition for many years in succession. This comes about in a great measure from importing the plant in too large masses, and these having to be so much divided, many of them break from latent eyes only, and consequently the growths from these eyes are very weak. Some twenty years ago I remember cutting a fine plant out of an imported mass; it had thirteen growths, nine of which had the leaves entire, and last year I had the pleasure of seeing the same plant which had grown into a remarkably fine specimen. The old stems are pruned away when they became leafless, and this is the only system of pruning that I believe in. The plant turned out to be a very nice variety of this *Leopoldi*, and it proves that the plant is capable of being kept for some years in a state of cultivation. *Cattleya guttata Leopoldi* requires to be potted in good brown peat fibre, mixed with chopped Sphagnum Moss, or in the fibre of *Polypodium vulgare*, some flakes of which I recently saw which quite astonished me. It requires to be potted on a little cone or mound of soil above the pot's rim, and the pot itself should be exceptionally well drained. The plant should be grown along with *Laelia elegans*, and such like plants that require slightly more heat than do the New Grenadian *Cattleyas*, but they are at one with these plants for the supply of water during the summer months, but during the winter they like to be always just moist, for I believe this plant has been destroyed principally from being kept too dry, and in not being kept warm enough in the winter. It grows and flowers well with the usual occupants of a stove, requiring only to occupy a nice, light and sunny spot, and never to be syringed overhead.

WILLIAM HUGH GOWER.

SHORT NOTES.—ORCHIDS.

Cymbidium canaliculatum (*D. Maurice*).—This came home with *Dendrobium canaliculatum*, and, curiously enough, it has the same specific name, but it is not a very showy species. It nevertheless shows that the different genera which are prevalent in the Indian Islands extend also to the coast of Australia. This species has been found in New South Wales as well as in Queensland.—G.

Cynoches chlorochilon (*G. Snell, Etceter*).—This is the name of the flower you send. The yellowish green fragrant flowers are the male ones; I have never seen the female blooms. It is not new, having been introduced between fifty and sixty years ago, and is popularly known as the Swan's-neck Orchid. It appears to be a native of British Guiana. You may keep it dry during the winter.—G.

Cattleya superba is worth a note for the rich colour of the flowers. It is appropriately named "superba," and is a native of British Guiana. We noticed a good plant of it in bloom a few days ago at Kew. The flowers are compact in shape, sepals and petals rich purple-rose, except the lip, which is intense crimson, touched with yellow at the base, on which appear veins of a purplish tone. It is a bright and handsome species.

Epidendrum Frederici-Guilielmi.—This comes from Charles Roberts, and I am pleased to see so fine a variety of this plant. It was first introduced as a living plant some years ago by M. Linden, of Brussels, but it remained very scarce for some time afterwards. The flowers are each some 2 inches across and of a deep reddish purple

hue. They are produced in a many-flowered panicle, and they last long in full beauty. This plant does best in the cool house with the *Odontoglossums*.—W. H. G.

ORCHARD AND FRUIT GARDEN.

PLANTING OUT POT STRAWBERRIES.

THE present season has been most unfavourable for planting out Strawberries that have been fruited under glass. Many have doubtless delayed doing this work in the hope that a change of weather would render the prospect of success more certain. The earlier they are planted, however, the finer will be the crop next season. If the ground is in good order the roots will go down quite 9 inches by the close of the autumn, that is if planting is done sufficiently early, and by the time the berries begin to swell the plants will have got such a hold of the soil as to ensure the ripening off of a heavy crop of fruit satisfactorily. In the case of plants that have several crowns, I see no great advantage in keeping all the foliage. It is a peculiarity of the Strawberry that picking off some of the old leaves induces the production of new ones. If all the leaves are allowed to remain where the plants are turned out of doors they will remain for some time in the same condition, but cut all the foliage off and a new crop of leaves will immediately push up. This complete defoliation I do not, however, advise being done, but some of the oldest leaves may be taken off when the plants have done fruiting. This will be beneficial in more ways than one, diminishing the labour of watering until the plants can be put into the ground and rendering cleansing, also much easier. As all know who have had anything to do with Strawberry culture under glass, red spider is sure to attack the foliage in the latter stages of growth. If the weather should happen to be hot and dry after the plants are put into the open ground they will make little or no progress when this is allowed to remain. They will also be a source of danger to everything near them. Every plant should be dipped in soft soap water at the rate of 3 ozs. to the gallon, with enough sulphur to thoroughly coat the leaves. I much prefer black sulphur for this purpose, as it is much stronger than the yellow, and there is little danger of injuring the matured foliage, especially if dipping is not done till the plants have been a week or two in the open air. In any case it is preferable to run the risk of injuring a few leaves to leaving any spider on them. When the black sulphur is used the mixture must be kept well stirred, as it, unlike the yellow sulphur, does not float, but sinks to the bottom. There is some danger of the plants suffering from want of moisture after being put into the ground, as water does not easily penetrate the old ball of soil. I have always made it a practice to pierce the ball in several places with a skewer, as this allows of the freer entry of water, both from rain and the watering pot. Before planting, the ground should be rolled or trodden as hard as possible and made very firm round the old balls, leaving a shallow basin round each plant. If put into the ground in a rough-and-ready manner the old balls of soil are apt to get very dry, the water passing away round them, and when this is the case they never start away into free growth. Should the weather be very hot and dry, a few Pea sticks laid over the crowns will be very beneficial, affording grateful shade to the foliage and helping to keep the roots cool and moist. As soon as the plants start into growth the hoe should be used freely among them, and they will give no further trouble. J. C. B.

Early Apples.—No doubt Red Juneating, Mr. Gladstone, Red Astrachan, Yellow Harvest, Beauty of Bath, Red Quarrenden, Lady Sudeley, and others will be ripe and gathered by the end of August,

so fast have they been pushed on. It seems very doubtful whether in any way we shall improve upon our earliest summer sorts. Perhaps they are not worth much trouble being taken to do so. It does seem so evident that we can get little of flavour into Apples until cooler weather prevails, that we shall always have to be content with indifferent quality in the summer varieties. Very few trees of any of them suffice, usually about one tree of a sort, just to give an occasional dish at dessert.—A. D.

Jargonelle Pear.—This Pear, like most other fruits, has ripened unusually early this year. I was able to gather good large fruit of this Pear quite yellow and soft on July 18 from some old trees growing on a south wall of the abbey. This is fully a month earlier than in 1891 and a fortnight earlier than last year. It is strange how large the Pears are from these trees this year, although the weather has been so abnormally dry, with the roots under turf and in a carriage drive.—J. CROOK, *Forde Abbey.*

NECTARINES FAILING.

I SHOULD very much like to have your opinion regarding the failure of the Nectarines which I enclose for your inspection. The trees have been very much neglected, not having been pruned during the winter previous to flowering and fruiting this summer. The trees then being one mass of brown scale, to clean them I had them gone over with a brush dipped in paraffin, and was careful not to touch the leaves or any joints. In the house are two Peach trees either side of this Nectarine, and the fruit got to a fair size. The branches of the trees have kept dying here and there during the summer. I have used cow manure water to them, half manure and half clear water. The bed is 2 feet 6 inches in depth and 3 feet across. The soil is very strong loam, called wharpe, made from the river overflowing. The bed has not been dry in the least to my knowledge.—S.

* * * The trees not having been pruned had nothing to do with this failure, though it may have been responsible for the weakness of the growth. I have seen some enormous crops taken from trees that received no more pruning than might be given to a Quick-set hedge, but it was a bad thing in the end, such trees soon failing. One year's neglect of pruning is also ruinous as far as the form of the trees is concerned, it being a very difficult matter to recover them to a more satisfactory state. Alluvial soil is usually considered very good for all purposes, and in this case was not the cause of failure. If it had not been suitable for them, the Peach and Nectarine trees would never have started well in it. The cow manure water—and which I presume is simply the draining from a cow-yard or stalls—naturally varies in strength considerably, very much depending upon the amount of water that may be run down. As a rule it ought not to be used so strong as "S." seems to have applied it. Probably it would have been safer and more effective if diluted at the rate of 4 gallons of water to one of the manure. Even if this had been used too strong the consequences would have been different or more nearly approaching a wholesale collapse. Personally, I have no doubt the mischief was brought about by the use of crude paraffin, or, more properly speaking, petroleum. The symptoms are exactly the same as when Vines have been injured by a too free use of this powerful insecticide, laterals or branches failing at intervals and after the first growth has been made. Petroleum is of a very penetrating nature, and the bark of Peach and Nectarine trees, though less porous than that of Grape Vines, is far from being proof against it. Not till the supplies are cut off or, in other words, not till the decay first started by the petroleum has spread completely round a branch do the leaves flag and the fruit shrivel. A dry brush would have been quite as effective against the scale; at any rate using the petroleum did not save time. When petroleum is used as an insecticide the trees ought to be at rest, and even then it is not safe to use it

undiluted. I have repeatedly warned the readers of THE GARDEN against a reckless use of petroleum, and as often stated how it might be safely and effectively applied as a remedy for brown scale, mealy bug, and such like. For the benefit of "S." and other readers, I will once more give the formula. To every 3 gallons of water heated to 120° or thereabouts add 2 ozs. of soft soap and 6 ozs., or three wineglassfuls, of petroleum. Stir it well by means of a syringe, and apply to the trees while hot. The petroleum should be prevented from collecting on the top, the usual plan being to discharge every second syringe full forcibly back into the can, or two syringes can be employed, one being kept constantly discharging its contents back into the can. Petroleum is not nearly so effective when used with cold water. I ought perhaps to add that if I am right as to the cause of branches dying there is no remedy, and most probably new trees will have to be planted next autumn or winter.—W. I.

Pears and the drought.—The crop of Pears is this season exceptionally abundant, and where the means for keeping the trees well supplied with moisture at the roots has been at hand the fruit ought to be very fine, for up to the present I find but very little cracking of the skin, and trees that on several occasions have had their fruit crack badly are this year quite free of this. On well-drained soils Pears require a very heavy supply of water and liquid manure, and it is useless looking for anything beyond the ordinary run unless extra feeding is given. Luckily for the Pear crop generally, some heavy rains have fallen lately, which, although too late to help the early kinds, will be of great assistance to the late ones, and should be supplemented by artificial waterings and mulchings as well. With me Pitmaston Duchess, one of the best market Pears grown, is swelling up well. Beurré d'Amanlis, very heavily cropped, as usual, promises to be very good; also Beurré Bosc, Beurré Diel, Beurré Superfin, Beurré Clairgeau, Marie Louise, Seckel, and others. I find that the exceptionally forcing weather early in the summer brought on the very early kinds like Citron des Carmes, Jargonelle, &c., considerably in advance of their ordinary season, but with cooler and moister weather the later ones have a far more favourable opportunity of attaining their full size, and doubtless those who continue to apply plenty of liquid stimulants will have the best results, for my own observations lead me to think that Pear trees seldom (even in wet seasons) get enough moisture at the root.—J. G., *Gosport.*

Wasps eating Grapes.—In reply to "J. W.'s" inquiry with regard to flies and wasps eating Grapes, I would suggest that he hunt up all the wasps' nests he can find in his neighbourhood and destroy them, as there is no remedy that he can use in the house that would do any good. He will not find the flies destructive if the fruit is not punctured by the wasps. In this district the wasps' nests are very strong as well as numerous on account of the favourable weather we had in March. Cyanide of potassium is the best thing to use for destroying them, three ounces in a pint and half of water. Put about half an ounce in each hole. It is best done in the daytime. Within half a mile of here over 200 nests have been destroyed, but there is still a great number left.—J. C., *Bilting.*

HARDY FRUITS AT HAM.

IN the matter of Apples, Pears and Plums, but especially in connection with the two former fruits, Mr. J. Walker's market fruit farm at Ham Common presents most useful study, and is an admirable object lesson. The soil is, if deep, at least very sandy, and generally all sorts of trees thrive well in it. I was the other day much surprised to see how well the trees had stood the long drought, but still it is fair to say that as many trees carry but exceedingly light crops, they have not been distressed in the same way that heavily fruited

ones are. Still, there are many trees of particular sorts that have good crops, and in every case whilst the fruits may be somewhat smaller perhaps than usual, yet the trees seem to have made as good growth as ever; indeed it is most marked in this respect that for the time of year with yet some three months of growing season before them, the appearance of the trees should be so robust and healthy. Now whilst Apples generally are on the Paradise stock, and have on that in this soil made growth that may be described almost as luxuriant, yet Pears on the Quince certainly do not thrive so well as do those on the Pear stock; indeed the sandy soil seems to suit the Pear stock admirably, and no trees could well be cleaner, healthier, or more perfect in every way than are Marie Louise, Fertility, Marie Louise d'Uccle, Louise Bonne, Doyenné du Comice, and Williams' Bon Chrétien, although some other excellent Pears could be named. Several of these named are fruiting very well, others sparsely, but at Ham, Pears are not abundant, and it is worthy of note that in almost all cases the bloom was profuse and the set considerable, but the fruits fell soon after. If the aspect of the Pear crop here were to be taken as indicative of its general state, the return would be a poor one, but I have seen splendid crops on older or standard trees about the country; indeed, between my house at Kingston and Ham there is growing on a spare building plot between two villas a tall Marie Louise that has on it a really good crop of fruit; a finer for such a tree I have rarely seen, and all round Reigate recently I found splendid crops of Pears. So far as Apples are concerned, at Ham the crops curiously enough are best of large-fruited and large-leaved varieties, all small fruited being very sparsely cropped. The only exception is Yellow Ingestre, but that is cropping very moderately. Here one is surprised to find that so good a variety as Warner's King is being displaced by Lord Grosvenor. All the former have been beheaded and grafted with the latter, whilst Lord Suffield, here somewhat disposed to canker, is being grafted with Bismarck. Sorts that are fruiting fairly well are Lord Suffield, what few trees are left; Grenadier, always a good cropper; Stirling Castle, heavy crop; New Hawthornden, good; also Lord Grosvenor and Peter the Great. Prince Albert does well and is cropping freely. Manks Codlin also has been good. All Apples are ripening very early, and unless heavy rains come soon the fruits must be small. Mr. Walker first planted his trees at 8 feet by 9 feet apart, but the distance at which he plants now is 12 feet by 8 feet. Naturally the first planted trees now need much more room and moisture badly. All the same growth and leafage are good, and whilst wood is being early matured, fruit spurs are being rapidly formed. In the case of Apples, as of Pears, the heaviest crops seem this year to be on the standard trees. A. D.

Wasps as gardeners' friends.—The note from A. Young (page 88) contains the first notice that I have come across of these pests being in any way aids to the gardener. Mr. Young is very much favoured, too, by the wasps not molesting his fruit. Here they attack Peaches and Pears long before the fruit is ripe, and this year they have also attacked the Red Currants, which in other years I have gathered in October. At present to all appearance we shall have a difficulty in obtaining any in August. Surely it is not necessary to depend upon these pests for the cleansing of the trees from black fly when the removal of this insect is so simple a matter.—S.

Cherries on north walls.—Like "W. S. H." (p. 51) I consider it a good plan to plant a few sweet Cherries on north walls. It is in seasons like the present when these planted on north walls prove doubly valuable. In this garden I have two or three trees planted in this position, and during the last five years they have not failed to bear well. This year they kept up the supply three weeks after those on west walls were over, and I find they hang far better than when on walls which are warmer. It is the Bigarreau class that

are mostly prized here, and of this we have one tree and a Late Duke on a north aspect. Again, there is another advantage in having trees on different aspects, namely, often when the blooms are forward and destroyed by frost on warmer walls, those on the colder aspects escape from the trees being later in blooming. Cherries enjoy plenty of moisture at the root. In proof of this I have a large Morello on a north wall which has borne abundant crops for several years. Last summer when it was in full bearing and stoning it began to look distressed. Accordingly, I made a large bay of soil round it and deluged it three or four times with manure water with the best results. Again this year we treated it in like manner, and now we are gathering a splendid crop from it.—DORSET.

NOTES OF THE WEEK.

A seedling Crinum.—This was sent to Sunny Hill, Shirehampton, by Sir C. Strickland. If very near C. Powell, kindly say so.—C. O. MILES, *Almondsbury, Bristol.*

* * * A pretty flower. No doubt near C. Powell, but more delicate in colour.—Ed.

Cape Coast Lily (p. 44).—Surely not giganteum which has pure white flowers without tinge and a very moderate-sized bulb, with short, broad spreading leaves. If the plant has long, erect, smooth leaves and tall flower-stem it may be longilorum (Baker), or your correspondent may be lucky enough to have got the rare and superb Forbesianum.—R. T. C., *Wellton Place, Daventry.*

The Bamboo garden at Kew.—Visitors to Kew should not miss the newly-formed Bamboo garden, which leads into the Rhododendron walk near the river. The plants are getting thoroughly well established, and this new feature is one of the best additions that have been made to the outdoor attractions of the Royal Gardens.

Carnation Celia.—This very pretty, fragrant, and good Carnation comes to us from Mr. Allan, of Gunton Park Gardens, whose good judgment in raising plants we are pleased to see turned to the Carnation. There is room for a vigorous race of fragrant kinds, as most of the Cloves are not continuous bloomers or good growers on all soils.

A pleasing annual flower is *Linaria reticulata anrea purpurea*. We noticed a line of it in the Chiswick gardens, and it is a useful kind for edging, or a good mass of it would be a bright and distinct feature. The flowers are crimson-purple and yellow, the leaves quite grass-like. It is a charming annual and not grown so much as one might expect.

Antirrhinum Tom Thumb is not the type of *Antirrhinum*. Several plants of this class are in bloom in a bed at Kew, but merely, we think, to show how completely this plant can be spoiled by this absurd system of dwarfing, and thus changing its naturally graceful habit. The growth is only a few inches in height, and the flowers are produced immediately above the leaves.

Hippeastrum brachyandrum is flowering in an open border at Kew. It is an interesting species and well worthy of note. The flowers are of a rosy lilac shade enriched with crimson at the base of the segments, and they measure about 4 inches in length. Each sturdy scape produces one bloom, and when several specimens are in perfection a pleasing display is made.

Strobilanthes Dyerianus, of which we made a note in Messrs. J. Veitch and Sons' nursery at Chelsea, and also in Messrs. Sander's, St. Albans, is a strikingly handsome stove plant. It is likely to be largely grown in the future for the rich metallic-purple colour of its leaves, veined and margined with deep green—a fine contrast. The growth is very free, and the whole aspect of the plant reminds one strongly of a *Bertolonia*.

Streptocarpuses are largely grown as pot plants, but those who have big houses like the

succulent house at Kew to embellish with flowers should make a note of them for planting out as an edging. At the edge of the beds and in a peaty soil they form a distinct and attractive margin, producing a wealth of the finely coloured flowers. The long distance from the glass seems to have no effect upon them.

Annual Larkspurs—These have done uncommonly well with us here this season. We have much pleasure in sending you a few spikes. Perhaps you may consider them worth figuring in THE GARDEN. We do not recollect having seen a plate of annual Larkspurs. The Larkspurs have been in fine bloom for some weeks, and will continue some time longer.—DOBBIE & Co, *Beaulieu.*

* * * Beautiful things, extremely soft and rich in colour. There are so many things in our gardens that people are interested in, that they often forget some of the most interesting annuals. These are even prettier in the shape of the spike than double Rockets, while in addition to white they have delicate mauves, pinks and rich purples.—Ed.

The Brush Bush (*Eucryphia pinnata*) is one of the most precious flowering shrubs that adorn English gardens. We recently saw a photograph of the specimen in the Coombe nursery of Messrs. J. Veitch and Sons which was upwards of 10 feet in height. One can well understand that such an example would be of unusual beauty, and it also shows that the shrub is quite hardy. It is a native of Southern Chili, the flowers being produced in great profusion and pure white. They are not unlike those of the St. John's Wort in expression and size. This large specimen in the Coombe Wood nursery was smothered with bloom, a picture of vigorous growth and flowers, in fine contrast to the deep green leaves.

Carnation Leander.—Almost all who have grown Carnations in quantity out of doors have had failures with the yellows, and there was hardly one really reliable kind in this colour till Germania appeared. Mr. Gifford, of Tottenham, however, who, happily, is concentrating most of his attention upon the fine selfs, which are the most important in the flower garden, sent us last autumn some plants of Leander. It appears a most promising yellow kind. Its flower-spike has run up tall, but the flowers have been very full and fine, not bursting, and of a clear soft yellow colour. It seems to have a robust habit and good constitution, and doubtless will prove a decided acquisition. With the Carnation so satisfactory in its other varied shades, it is strange that yellows as a class are scarce, weak, and disappointing.—A. H.

Solanum Seaforthianum is very beautiful in the Water Lily house at Kew. A coloured plate was given of this fine climber in THE GARDEN, December 10, 1892, p. 519. It is one of the most useful stove climbers that can be planted, the growth being rapid, whilst it is evergreen and exceptionally free. One hopes that such climbers as this and *S. Wendlandi* will get popular, but at present they are very little known outside botanic gardens. *S. Seaforthianum* is not really new, although rare. Mr. Watson, in his description accompanying the coloured plate, says that it has been introduced into England several times, as shown by the figures of it published at the beginning of the present century and again twenty-three years ago. It was then figured in the *Botanical Magazine*, t. 5823, under the name of *S. venustum*. This species is a native of the West Indies, and is very common in Trinidad, climbing up bushes and festooning them with its masses of purplish flowers. All who have stoves should make note of this fine climber. There is far too much sameness in the plants in these structures.

Epidendrum vitellinum majus.—I beg to enclose a spray of *Epidendrum vitellinum majus*. You will see besides the main stem there are five branches from it bearing altogether forty-one flowers. The plant newly imported was bought in January, 1891. Last year it blossomed well, one spray having besides the main stem four branches. Is not this unusual, and are not the flowers very rich in colour and large in size? This spray has

been over two months in bloom. It is grown in an intermediate house, falling to 50° in winter, with a roof of ground glass in which Orchids in flower are kept. I have kept it constantly growing since I have had it, and the bulbs are of a very large size.—W. A. G., *Trewyn.*

* * * *Epidendrum vitellinum giganteum* is the name under which the variety sent by you is figured by Mr. Warner in the third volume of "Select Orchidaceous Plants," but the figure, if I recollect it right, is not so much paniculate as this plant—in fact, I have never seen a plant carrying such a spike, and it should be carefully preserved; the flowers are large and of a very rich colour, and its growing under a roof of ground glass does not point to its requiring much sun.—W. H. G.

Renanthera matutina.—Amongst the rarest and most interesting Orchids exhibited at the recent show in the Chiswick Gardens was a flowering specimen of *Renanthera matutina*. Although discovered as long ago as 1824 and introduced by Messrs. Veitch twenty-two years later, it has never become a common Orchid. Recent importations may, however, make it better known. The plant at Chiswick was about 2½ feet high, with narrow, leathery leaves 8 inches long, notched at the apex and arranged on the stem in two opposite rows. It carried a pair of long, slender, branching spikes, the flowers being 2½ inches across, yellow, blotched with reddish crimson, the older flowers, however, having almost entirely changed to yellow. The beauty and distinct character of this Orchid certainly entitle it to notice from cultivators, especially as the only other representative of the curious genus to which it belongs that is common enough to be generally available is *R. coccinea*, and this can scarcely be recommended for most establishments on account of its inconvenient habit and shy-flowering character. *R. matutina* is a native of Java, and, not coming from high altitudes, should be placed in the East Indian house, growing in Sphagnum alone.

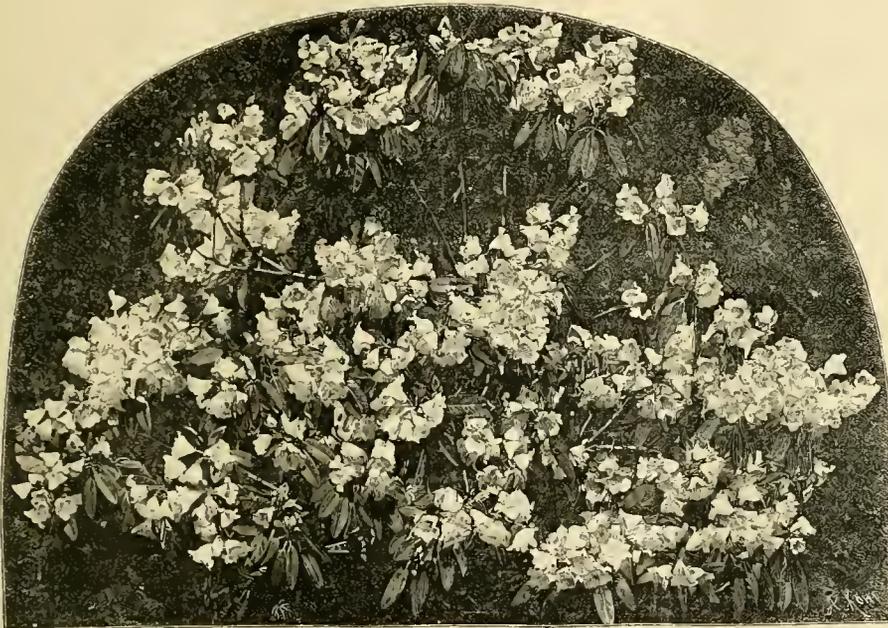

Brassavola Digbyana.—In a group of plants staged by Messrs. Williams, of Holloway, at Chiswick on July 11 was a good representative of this remarkable Orchid. It has been known in English gardens since 1846, having in that year been sent from Honduras. In habit the plant is very like a short-stemmed *Cattleya*, having dwarf compressed pseudo-bulbs, each carrying a single, fleshy, grey-green leaf. The flowers are produced singly on the spike and measure 5 inches in diameter. The sepals and petals are pretty nearly alike, being narrow and of a dull yellow, tinged with green. It is the creamy white lip which gives to the flower its remarkable character. At its widest part it is close upon 4 inches across. The central part is heart-shaped, with the upper edges folded above the column. It is, however, almost entirely surrounded at the margin by a fringe three-quarters of an inch in depth, which gives it a most striking appearance. In this respect it may be classed with *Dendrobium Brymerianum* and *Nanodes Medusa*. It should be grown in a compost such as is in general use for *Cattleyas*, but requires during the period of growth somewhat warmer conditions than the majority of that genus. One of the most striking as well as the most beautiful hybrids ever raised owes its parentage to this species and *Cattleya Mossiæ*. It was raised by Mr. Seden in the Chelsea nursery, and was first exhibited in flower at a meeting of the Royal Horticultural Society in May, 1889. Uniting as it does the striking peculiarity of lip displayed by the *Brassavola* with the colour of *Cattleya Mossiæ*, it may with certainty be considered one of the greatest triumphs ever obtained by Orchid hybridists. It is known as *Lælia Digbyana-Mossiæ*, Bentham having placed this *Brassavola* under *Lælia*.—B.

Lilium elegans armeniacum is one of the most charming of the dwarf Lilies. If planted amongst quite low shrubs, the bold, clear apricot flowers appear just above the dense massive leafage. Its appearance a few days ago was very fine.

TREES AND SHRUBS.

RHODODENDRON AUCKLANDI.

It is not generally known, I believe, that this species is fairly hardy, but that it is so I was able to prove last winter. Having a plant which had become too large for the houses, it was allowed to remain out all the winter, just protecting the roots. We had nearly six weeks of frost, and during that spell of severe weather the frost varied between 14° and 18° where the plant was standing, and I was delighted to find on the frost giving way to more genial weather that *R. Aucklandi* had borne the ordeal without apparently receiving the least injury. Early in April I had the satisfaction to find that the buds almost without exception were

Rhododendron Aucklandi in the gardens at Upcott House, Barnstaple. Engraved for THE GARDEN from a photograph sent by Mr. W. Harris.

going to open, and by the middle of the month the plant had on it in buds and expanded flowers as near as could be counted about eleven hundred. I then had it photographed, and, as will be seen by the annexed engraving, it presented a fine head of bloom. The plant is a half-standard, having a clean stem of 2 feet or 3 feet, the head being about 8 feet through. It is now planted out permanently, and it will be interesting to watch how it will behave. For a large conservatory it is a grand subject. In a small state it does not appear to bloom freely, but on attaining age and size it flowers very freely. The plant was brought by Sir R. Williams, Bart., from Tregullog, in Cornwall, about six years ago on his leaving there to take up his residence in N. Devon, and must be from sixteen to twenty years old or more.

WM. HARRIS.

Upcott, Barnstaple.

Genista tinctoria.—I should have included this native species of *Genista* among the leguminous shrubs in bloom on page 57, for it is now flowering beautifully in many places, and there are really few subjects that yield so showy a display at this season. It reaches a height of 2 feet to 3 feet, and when at its best it is quite a mass of golden blossoms.—T.

Wistaria sinensis.—I was very much surprised the other day to see a plant which I had seen flower before earlier in the season again in bloom. This plant is not one of the fine old trees mentioned in your note, but it has stood in the spot it now occupies, in front of a cottage, for at least twenty-five years. Has anyone remarked the *Wistaria* flowering twice in other quarters?—H., *Tooting*.

. We lately noticed a large plant in Chiswick flowering in the same way, and another plant in the same district we have frequently noted producing a second crop of bloom.—Ed.

Golden Elder.—This is very effective when suitably placed. It ought never to be put among tall growing things, but rather among shrubs of

the flowers and otherwise destroying it, this makes one of the best and prettiest I know. Planted in a young state about 2 feet apart and allowed to grow from 3 feet to 4 feet high, at which height it can be kept by careful knife-pruning, which may be done immediately after flowering or in the early spring, it forms a most charming hedge. The foliage is at all times green and pretty, and at this season the plants when covered with masses of the small white flowers are most effective. The other day near Exeter I saw it used as a short dividing hedge between two gardens, and here standard Roses had been planted between and allowed to peep just above the top of the hedge, together forming a novel yet very effective boundary.—W. MKY.

FLOWERING AND ORNAMENTAL TREES AND SHRUBS AT EXETER.

By this post I send you a few branches of flowering shrubs culled in the nurseries of Messrs. Robert Veitch and Son, Exeter.

COLUTEA ARBORESCENS PURPUREA.—This novelty has flowered all the summer and is still in full bloom in spite of the exceptionally dry weather. The flowers are much darker than those of the better-known type, *C. arborescens*, the vexillum being of a bronze-purple colour with a distinctly divided yellow spot at the base. The keel is also of a bronze colour, having a yellow stripe at the base shading into dark purplish brown at the point. The leaves are glaucous and very distinct. Not the least ornament of this handsome shrub is the large bladder-shaped seed-pods, which are very freely produced. Messrs. Veitch find it a free grower, and no garden should be without it.

CYTISUS NIGRICANS.—This is most valuable on account of its late flowering habit. The pendulous racemes of bright yellow flowers are nearly a foot in length, and often last till September. Owing to the abundance of bright sunshine it is flowering earlier than usual this year.

CLETHRA PANICULATA.—The white fragrant flowers of this variety seem larger and more robust than those of *Clethra alnifolia*. It should be a useful shrub where sweet-scented white flowers during the latter part of the summer are required.

ROBINIA SEMPERFLORENS.—This is now blooming most abundantly, the flowers being white and very sweet-scented. I also send you a flowering branch of the beautiful Rose Acacia (*R. hispida*).

DIPLOPAPPUS CHRYSOPHYLLUS.—The flowers of this, which are white and produced in great abundance, though small in size, are, as you will see, not quite open. Perhaps the best ornament of this handsome evergreen shrub is the minute dark green leaves, the underside of which as well as the stems is of a golden-yellow, giving the whole plant a more or less golden appearance. It is perfectly hardy in the west of England.

CYTISUS CAPITATUS.—The stem, leaves and even the calyx of the flower of this pretty shrub are covered with a dense pubescence. It is only just coming into bloom. The bright yellow flowers are produced in large heads at the end of upright branches, and appear almost like an umbel. It is of dwarf habit, and should be a most useful plant for the front row of a shrubbery.

CEANOTHUS GLOIRE DE VERSAILLES.—Of this I also enclose a bunch of flowers. It seems to be blooming much earlier than usual this year, but its handsome large blue flowers are always welcome.

I also send you branches of the following trees and shrubs, useful on account of their ornamental foliage. These specimens were also obtained at Messrs. Robert Veitch and Son's Royal Nursery, Exeter:—

SORBUS ARIA LUTESCENS.—The foliage of this is very distinct and handsome, quite different from that of the typical *S. Aria*. The serrated leaves are round or oval and covered with a thick pubescence of a glaucous tint, shading slightly to yellow.

low. The tree seen from a distance appears more like a variety of Eucalyptus than a variety of the Service Tree.

SIRBUS ARIA LACINIATA.—This is not so distinct as the former when seen from a distance, as the leaves are not so light in colour, and therefore less conspicuous. They are, however, deeply lobed and handsome when seen close at hand.

PTELEA TRIFOLIATA AUREA.—The brilliant sunshine of the present season seems to bring out particularly well the bright golden foliage of this telling shrub, which should be a desideratum where contrast of foliage is required.

CORNUS SPATHI.—This is another shrub with golden foliage. The portion of the leaf which is close to the midrib is mottled with green, but the greatest part of the leaf is of a deep golden yellow colour.

ACER PSEUDO-PLATANUS ATRO-PURPUREUM.—The leaves of this variety are large and of a bronze-green colour on the upper side. The lower side of the leaf, however, is of a distinct bright purple, which is very telling, especially if the tree is planted on an elevation so that the under side of the leaves can be easily seen.

SAMBUCUS CANADENSIS FILICIFOLIA.—The foliage of this cut-leaved variety of the Canadian Elder is very distinct and Fern-like in appearance, and as it is easily grown it should soon become as popular as the cut-leaved Sumach.

ARALIA MAXIMOWICZI (syn., *Acanthopanax ricinifolia*).—This is of a decidedly sub-tropical appearance, and though not ornamental in winter (when it looks more like a dry stick than a plant), it is highly ornamental when the large palmate leaves are fully developed. It is not particular as to soil. The stem is erect and covered with spines. F. W. MEYER.

Exeter.

HARDY HEATHS.

I WAS looking over the Heath borders the other day, and I thought it would interest your readers to know some of the kinds that are in bloom; also the strongest growers of the vulgaris varieties:—

Erica vulgaris alba Hammondi is a tall light green-foliaged variety; blooms in August.

E. v. Alporti is a tall, dark-foliaged, crimson variety; blooms in August.

E. v. tenuis is a dark-foliaged compact grower; flower a bright scarlet; free bloomer; blooms in August; not so tall as Alporti.

E. v. alba rigida.—A light green compact grower; free-blooming variety; blooms in August.

E. v. alba minor and *E. v. a. minor pumila* are free-blooming, compact, light green varieties; bloom in August.

E. v. alba Serlei is a tall, light green, rough-foliaged variety; blooms in September and October.

E. v. fl.-pl. is a dark-foliaged, strong grower with pretty double flowers, and blooms in September and October.

E. v. alba tomentosa.—A tall, light green, woolly-foliaged variety; blooms in September and October.

E. aurea is a bright golden variety; free grower. It ought to be in every collection; blooms in September.

E. v. cuprea is a copper-coloured variety; free-growing; blooms in August and September.

E. v. argentea is a silvery-foliaged, free-growing variety; blooms in August and September.

E. vagans is a free-blooming and distinct kind. There are several colours of this, and it is in bloom from August to October.

E. tetralix.—There are several sorts and colours. The best white is *tetralix alba mollis*, and the best crimson is *Mackiana*. They are in bloom from July to October.

E. ciliaris is a very good kind, but it is not so hardy as some of the others.

Hardy Heaths are among the most beautiful of small-growing plants, and by having a good assortment it is possible to have them in flower from March till October. There is a great variety of colour and foliage, and there can be nothing more beautiful than a bed of Heaths when in bloom. The best time for removing them is September or

October. They thrive best in peat or leaf-mould, but will grow and bloom well in maiden soil and prefer airy situations. C. REEVES.

Two Dales, near Matlock.

Lonicera japonica.—There are different forms of these Japanese Honeysuckles, but it is very probable they could all be included under one species. That to which the above-named is usually applied is a free growing climber, with hairy branchlets and large ovate pale green leaves. The flowers, which are borne in terminal clusters, are creamy white when first expanded, but become yellow as they fade, the contrast between the two tints being very noticeable. In one form the exterior of the bloom is suffused with pink. In one respect, however, they all agree, and that is in the delicious fragrance of their blossoms. *Lonicera japonica* should certainly have a place among the best Honeysuckles. Being a vigorous climber, it is well suited for arbours, arches, trellises, or similar purposes. It needs a spot fully exposed to the sun, as it will then bloom freely, while in the case of the flowers suffused with pink that hue is intensified when in full sunshine.—T.

Moving Cydonia japonica (H. O'B.).—The best time for transplanting this is in the autumn, as if delayed too late it will probably have commenced growing. It is by no means a difficult subject to propagate, and this can in some cases be done to a limited extent by detaching a few suckers that have roots of their own when a specimen is being removed. Cuttings, too, will strike in the open ground if they are taken at a length of from 8 inches to 10 inches and inserted firmly for the greater part of their length in a fairly moist, yet somewhat sandy soil. Again, if cuttings of the growing shoots are taken now at a length of about 6 inches, cut off at a joint, and inserted into well-drained pots of sandy soil, they will, if kept close in an ordinary garden frame and shaded during bright sunshine, often strike before the winter and be well rooted by the spring. *Cydonia japonica* may also be readily increased by layers, but such a mode of propagation cannot always be carried out.—T.

FLOWER GARDEN.

HARDY FLOWERS.

LILIES AND LILIACEÆ.

I RECOLLECT some time last spring that there appeared in THE GARDEN (Vol. XLIII., p. 158) an article by Dr. Wallace entitled "Lilies v. Roses." I read it at the time, but I have not again referred to it except to identify the vol. and page; neither do I propose to criticise any part of it except the heading, which I mean to take as the text for a little sermon of my own. Why *versus* Roses? or, indeed, why *versus* any large and important class of hardy garden plants? Apart from any idea of direct opposition in the word *versus*, and which, I daresay, may have been disclaimed, the term obviously implies that the two are matched on equal terms, more or less, and that the ordinary gardener may get with Lilies the same or nearly the same variety at the same or nearly the same expense, and under the same or nearly the same ordinary conditions. If, however, any such proposition as these be put forward, I for one meet them with a direct negative for the benefit of your readers (if any such there be) who may be still sufficiently backward in gardening knowledge as to accept them for sound. In horticulture, as in other matters, it is no use crying "peace" when there is no peace, and in writing on gardening there are few things that are more the reverse of useful

than lumping into the same category and serving up to the public as "desirable and easily grown" plants of the same genus some of which are easy and some of which are difficult or impossible to grow or keep. You may say, for instance, of Crown Imperials and *F. recurva*, that both are Fritillaries, both are hardy and both are desirable, but if you omit to say that the one will grow almost anywhere and that the other will probably grow nowhere at all, you have not told possible purchasers all that it is good for them to know. It is not my object to disparage

LILIES

nor to discourage their cultivation, and if Dr. Wallace or anybody else thinks these the most beautiful of all flowers, I am ready to agree with them. They are unequalled in beauty of form and in texture and are not surpassed in colour, and although most people would probably rather be without the scent of Lilies in a room, there is no denying there is plenty of it. But there is probably no class of hardy plants, at once so large and so desirable, that occasions so much trouble and disappointment to those who try to cultivate them in any quantity or variety. Lilies, it is true, when growing in the open are not covered morning and evening with green-fly, as were the Roses day after day during the present season; but the drought and east winds and late frosts are more absolutely fatal to them than to anything else in the garden that is at all worth caring about. The common white Lily (*L. candidum*) does well here, but the great drought (no rain fell in my garden from March 1 to May 15) damaged even these to a considerable extent, and except these and a good clump of the white Martagon (*L. Martagon album*), which I have at last got to do well, I have had scarcely a decent Lily in the garden during the summer of 1893. As a matter of fact, the Lilies here have distinctly deteriorated where they have not disappeared altogether, though I am in hopes that some of them in another year, with a more favourable season, may again come to the front. *L. Hansonii*, a Lily that increases so fast that one wonders its price remains so high, grew into such a clump that it ceased to flower, probably from having exhausted the soil, and I was obliged to dig it up, divide, and replant it. The plants look healthy enough, but I have had no flowers this year, for, like all Lilies, and especially Martagons, it greatly resents moving. For some years, and up to 1891, I had several fine bulbs of *L. colchicum*, the prince of all yellow Lilies, but the late May frost of 1892 ruined and killed the finer and stronger plants of these, and I have had to replace them, and consequently shall have to wait a year or two before I can hope for good blooms. This, however, is one of the easiest Lilies to grow, and it must have loam, for, as far as my experience goes, it dies out at once in peat. I had at one time three or four strong clumps of *L. pardalinum* in variety, though the varieties by the way (except perhaps the one called *californicum*, which is of a richer colour than the others) are not worth noticing or preserving, but these, too, appeared to me to grow too thick together and to have exhausted the soil, for they gave up flowering; so I dug them up, replanted what I supposed to be some of the strongest and best rhizomes and gave the rest away to two ladies of my acquaintance. I have since heard that one of these lots has been highly successful; of the history of the other I am ignorant, though I fancy I should have heard of it if it had come to any good. My own selection never again appeared above ground in any shape or form, and if the study of modern philosophy had not

convinced me that "matter is absolutely indestructible." I should have supposed that they had vanished into thin air. I am in hopes, however, that they may have contributed something to the nutriment of some strong pieces of the same species sent me by Mr. Wolley Dod with his usual kindness, and which are growing well, though the drought or perhaps recent planting has prevented them from flowering very freely. The moral of the above is—and it may be as well to call the attention of the unwary to the fact—that in dividing this Lily the exterior or leading shoots of the rhizomes must always be preserved and planted, for they and they alone are capable of producing flowering spikes, the matted interior masses being mostly or entirely barren. *L. Parryi*, of which I once possessed a fairly good specimen, has, I regret to say, disappeared here, and though I have bought it again once or twice, I have not again succeeded with it. It is one of the choicest and most distinct of Lilies, and worth a good deal of trouble to get to do well. The scarlet Turk's-cap Lilies (*L. chalcidonicum*) take a deal of establishing. I have had to move mine lately and have bought some new bulbs, but I have never yet been really successful with these, though I see them doing finely in one or two cottage gardens in the neighbourhood. There is no better Lily than this when well grown, but I doubt if my soil suits it. The dark purple Turk's-cap (*L. Martagon dalmaticum*) is buried somewhere in my garden, and has been for the last year or two; however, it may turn up some day, as may also that most unsatisfactory little Lily, *L. pomponium verum*, as the nurserymen call it, the cultivation of which "no fellow can understand," as poor Lord Dunsore used to say. The Tiger Lily (*L. tigrinum*, called, I think, *splendens* in the catalogues) does well here. I doubt if the individual bulbs are very long-lived, but this species, either by seed or bulbils, maintains itself in my garden, and comes up here and there at odd places. It is one of the best of the later flowering sorts. The erect hybrid orange Lily, usually sold under the name of *L. davuricum*, is one of the best as well as the cheapest of all Lilies. They are best bought in mixture, as the "varieties"—slight differences in shade of colour—are of little value from the gardener's point of view. They do not appear to increase here to any appreciable extent, though they are hardy anywhere.

Anyone who reads the foregoing remarks, and who is at the same time familiar with the gist of the articles on the same subject that have appeared in this and other gardening papers within the last eight or ten years, will probably be of opinion that little or nothing is added (at any rate from the positive side) to what he knew before. The more or less common Lilies are named as doing more or less well, while other rarer sorts which he might like to hear of as successfully established are not mentioned at all. A glance back, however, through a few volumes of THE GARDEN will convince anybody that this is the way with all amateurs' communications on this subject, and the moral, of course, is that there is nothing else to tell. Nevertheless, it is obvious that only communications from private gardens are of much value when dealing with the history of established plants. There are many other lovely things—some of them "quite too awfully too-too," as the young ladies say—which regularly appear in Lily catalogues, but which as regularly disappear when transferred to the garden the second year after planting, if indeed (what is by no means always the case) they come up at all. There is, for instance, what I

daresay the editor will like me to call "the Silver Lily" (*L. Washingtonianum*) and its variety *rubescens*. There is *L. Humboldtii*, a very fine type of orange Lily, if it would only grow, and there are a good many others. You see these exhibited from time to time in horticultural shows, and they regularly figure in the catalogues, though if you order them at once when these latter first appear in early autumn, you will have to wait, for you buy not home-grown, but imported bulbs of these. But where, I want to know, can we see these things permanently established? I should myself have classed that lovely thing *L. Brownii* among these fugitive nymphs, who only show themselves, but are too coy to be caught, but my friend "Delta," your well-known correspondent, who shares with me the east winds and other privileges incident to a residence in the premier county, has shown me that he has induced her to stay and dwell permanently in his borders, for he has at least two fine clumps of this species well established and likely to flower strongly even in such a fatal year as this. This at least is comforting.

People with walled gardens (and the garden above named is not walled) and light and warm subsoil are probably likely to be most successful, but I regret to say that neither of these advantages is mine. This is pre-eminently not a bulb garden, though there are a good many bulbs, of course, in it; but I never heard of any bulb that dies in the gardens of my friends that I can boast of being able to keep. In the death-rate I am always up to date. I have never had the Daffodil craze at all badly, and the mild attack I had some years ago has left me quite well and sane. I can read *Narcissus* catalogues without being at all upset with vain longings and imaginings (and oh, how I wish I could say the same about lists of *Oncocyclus Irises*!) Here, as in all cold soils, as is now, I conclude, well understood, the bicolors (among trumpet Daffodils) are the only sorts that do well. I can grow some of the white kinds in artificial soil, largely composed of grit and road scrapings. All, or almost all the sorts of self-coloured yellow Daffodils take themselves off after the first year. I cannot induce the common Hoop-petticoat to survive here under any conditions of soil or situation. On the other hand, the pale lemon-coloured variety (*N. Bulbocodium citrinus*) appears to have an excellent constitution. Queen of Spain is a very distinct and beautiful new type, which, as it is considerably cheaper, is, I presume, more robust than its near congener, *N. Johnstoni*; but I have not had it long enough to test its durability with me.

There are few things in the gardening line which I personally should be more interested to get together than a good collection of

FRITILLARIES.

Some year or more ago we got up a little discussion (GARDEN, Vol. XXXVI., pp. 544, 574) on the subject, and not long afterwards Herr Max Leichtlin in the R. H. S. contributed a paper on the same. But the magician of Baden-Baden has not, I suspect, yet taught the Egyptians (many of whom are empirics, not to say impostors) to do likewise with their enchantments. I have had several of them, such as *F. bucharica*, *F. liliacea*, *F. acmopetala*, and others, and have tried them both in pots and in the open. Some of them never appear above ground, while others if they put their noses through for a short time go down again with an alacrity which shows they do not like my soil, my climate, or my company. *F. Meggidgei* (a south European form which should know better)

invariably does this. *F. Barnati* bloomed prettily well last year and came up this, but withered away almost before the leaves were through the ground, no doubt from the effect of the drought. The management of the black Lily (*F. sarana* or *kamtschatica*) is an art that has altogether escaped me. I used to bloom this well on the top of a rockery, but although it continues to grow and run about in its well-known weedy style, it has ceased to flower here for some years past, although, taking a hint which I believe I saw somewhere in this paper, I dug it all up and replanted it, thereby detaching the bulbs one from another. I suppose I must get a new stock, for it is a remarkable and interesting species. There is this to be said for the Fritillaries, however, that some of the very best of the species are among the easiest to grow. The common *F. Meleagris* itself is a beautiful plant, and its white varieties are lovely. I have here a very dwarf snow-white variety, given me without name some years ago by a friend, which never fails to bloom well. The new *F. aurea* is one of the very best of early spring bulbs, and apparently quite hardy in ordinary soil, though my own experience is that only a percentage (and not by any means a large percentage) come up and flower. I have found the same tendency to failures, too, in planting half dozens of *F. latifolia* from Holland. Then there is *F. pallidiflora*, a great favourite of mine; the colour is "high art"—the very highest art, I imagine. It is a pity indeed this does not bloom later in the summer, for it would serve admirably as a sort of æsthetic smelling-bottle for any high-strung soul a little upset by catching sight of *Calandrinia umbellata* unawares. However, whether or no on "art" grounds, this is a charmingly vigorous plant that is in my judgment well worth growing.

Among Tulip species I regard *Tulipa Greigi* as one of the most magnificent hardy bulbs in cultivation. The plants vary considerably in colour, some having a tendency to become orange or yellow; but the idea of naming these as varieties is much to be deprecated. It is, indeed, one of the worst forms of gardening tomfoolery. *T. Greigi* does better taken up in summer and replanted. The dwarf *T. persica* (figured in THE GARDEN under the name of *T. australis*) is a capital garden plant, like a yellow Anemone. It is very hardy and increases rapidly, as does also the beautiful *T. sylvestris*, the English Tulip to which some of the botany books assign the habitat "old chalk pits," but which I fancy is confined to Selborne, where it seldom or never flowers. Some of the red and crimson Tulip species appear to me to be too much alike to be of much value from a gardening point of view, but I noticed at Kew the other day a pale yellow species, called, I think, *T. retroflexa*, which struck me as distinct and worth getting.

A good many of the Alliums are most appalling weeds. I regret to say I have been weak enough to admit several such into my garden, and I fear I shall never get rid of them again. They are harpies that can never be expelled. The best species that I know are *A. pedemontanum*, *A. Ostrowskianum*, and *A. kansuense*, of which last at present I have but a small plant. *Eremurus himalaicus* is one of the finest plants I have ever bloomed here. Last year it was ruined in bloom by late frosts, and this year the exigencies of garden alterations compelled me to move it. It has survived the moving, which I regret to say *E. Bungei* has not, but this, coupled perhaps with the terrible drought, has again prevented its flowering. *E. robustus nobilis*, now called *E. Elwesianus*, will not apparently accommodate itself

to the cold of my soil, or perhaps of Kentish winters.

I have not attempted *Calochorti* in the open, but some of the species at any rate are easily grown in pots and transferred in late spring to the borders. They are among the most beautiful of bulbous plants, and add a tone to the garden at a time when there are not many things of this class in bloom.

Some of the newer forms of Day Lily (*Hemerocallis*) are very well worth growing. The one which appears to do best here was sold to me as *H. Middendorffiana*, but I am not sure but what a still dwarfer form (*H. Dumortieri*) is not even better, though a 2½-inch pot plant of this flowered and died with me. *Wachendorfia thyrsoiflora*, though not quite hardy, is worth taking trouble about. J. C. L.

Commelina cœlestis.—This is an old-fashioned plant, having been introduced quite early in the present century, but it is rarely seen. It forms a small mass of tuberous roots, and though hardy in many districts where the soil is well drained, to be on the safe side it is better to lift them and treat the same as Dahlias, except that the tubers of this *Commelina* being much smaller they will not resist the same amount of drought as those of Dahlias will. The *Commelina* forms a stout branching plant that reaches a height of 18 inches to 2 feet, while the flowers are freely produced. They are protected by large sheathing bracts, and though the individual blooms last but a short time, they are produced in clusters, from whence a long succession is kept up. The flowers are composed of three petals of a beautiful azure-blue tint and are about an inch in diameter. There is a variety whose flowers are pure white, but it is not nearly so effective as the other, for a good deal of its attractiveness is owing to the uncommon tint of its blossoms. It may be readily raised from seed, which will flower the first season if sown early in the spring; but plants obtained in this way do not make so good a show as those from older tubers. So freely do they seed, that on light, warm soils after a mild winter young seedlings will frequently crop up in all directions.—H. P.

Begonia semperflorens Crimson Gem is a splendid plant for bedding either used by itself or with other kinds. A bed of it in full beauty in the Chiswick gardens is one of the brightest things to be seen there at present. Whilst the tuberous-rooted kinds are presenting a none too fine aspect in the majority of gardens, this kind is excellent. The plant is of strong, compact habit, the leaves dark in colour, in rich contrast to the crimson flowers.

Carnations from America by post.—Everyone will admit that we enjoy great advantages in the postal way in these days. Recently this was most forcibly brought to my notice from having had twenty Carnations of the Tree type sent me by a relative from Montreal through the parcels post. Although they were only packed in Moss (*Sphagnum*) in a cardboard box, they reached me in far better condition than I could have thought. There were ten kinds, and I am pleased to say I have not lost one of the kinds. I have now thirteen good strong plants out of the twenty growing away freely.—J. C. F.

Begonia semperflorens atro-purpurea in the flower garden.—This has proved a most useful plant in the flower garden, and at the present time (July 20) it is blooming freely. I have it arranged in a bed mixed with *Veronica Andersoni variegata*. One of its great merits is the free growth it makes. As soon as it is planted out it commences to make side shoots, which begin to show bloom when only an inch or so long. This *Begonia* is easily raised from seed. In the spring of 1892 I obtained a packet of seed and raised eight plants. Two of these were given away, but from the six left I worked up a stock of eighty plants in four months. This bed is one of the

brightest we have and is admired by everyone. The object of planting the *Veronica* with it is that when the *Begonia* is destroyed by frost, then the *Veronica* will keep the bed gay till severe frost sets in.—J. C., *Forde Abbey*.

Carnation Mrs. Reynolds Hole.—This I consider the most beautiful Carnation ever raised, as it is most vigorous in habit and never fails to give an abundance of grass for layering. The only fault it has hitherto supposed to have is pod-splitting. But this season it is remarkably free from this, as out of 200 or 300 plants faulty flowers from this cause have been very few indeed. To discard any Carnation merely because it may split a few pods occasionally is certainly not a very wise proceeding, as amongst these are some of the most beautiful flowers in cultivation. Unless the petals are very few, any Carnation is apt to split a few pods if the season should not exactly suit it. This of course is an ideal season for Carnations, and we must expect fewer split pods than usual, and a variety selected this season as free from this fault may certainly develop it another season. Unless a variety is an inveterate pod-splitter it should not be discarded.—A. YOUNG.

* * *Carolus Durand*, a Carnation with flowers of the same shade of colour, is, we think, much better than *Mrs. Reynolds Hole*.—ED.

A NURSERY OF CARNATIONS.

THE Carnations grown by Mr. Gifford at Montague Nurseries, Tottenham, N., are for the most part the best self-coloured kinds, and they are planted in rows, one variety to each row, to show the effect of decided colours. We have not seen in our visits to nurseries this year a finer break of border Carnations in the open, and thus planted they create a rich picture of strong and varied colours.

Many of the kinds are of Mr. Gifford's own raising, and we are pleased to see that he is growing well the best border varieties. The other sections are not forgotten, and the considerable space of ground planted was a few days ago a mass of bright colour. On this breezy hill-top, near Edmonton, but in quite country surroundings, the plants grow with marked vigour, protection being given only in winter. This would not be necessary if the nursery were placed in the country, at least further away from the metropolis. Heavy fog clouds envelop this neighbourhood in late autumn and winter, and to fog many losses in Carnations can be traced. Many of the varieties grown here are well-known good standard kinds. Mr. Gifford keeps this important, and we may say essential, point in view. A flower that splits badly is not thought much of. A very beautiful variety is named *Mrs. F. Gifford*, the flowers pure white, robust, full, and very useful for cutting, whilst they are not in the least split. A good self pink, the colour very rich and striking, is *Amy Herbert*, the flowers large, full, and in every way representing a fine type of Carnation. It is a variety that should be made good note of for effectiveness and clearness of tone. Both those well-known acquisitions, *Rose Celestial* and *Ruby*, were in full bloom; also a long line of *Ketton Rose*, that has been previously described in *THE GARDEN*. It is a full, striking flower and the plant is a sturdy grower. We do not care greatly for the yellow-coloured kinds, but Mr. Gifford has a few kinds that will be undoubtedly much grown in the future. *Leander*, one of his raising, is a very fine yellow Carnation and strong in growth—a most important point, as the great fault of this class is their weakly constitution. Even *Germania*, one of the best in its section, makes very little "grass," and the two kinds are grown near to each other, so that one may judge of their vigour. The flowers of *Leander* are large, full, and of refined yellow colour. Another of Mr. Gifford's seedlings is *Cantab*, which is a superb scarlet self and very fragrant, a rich clove scent. This, again, is a most important consideration. Too few of the new Carnations are strongly scented, and in aiming at rich fragrance in the flowers Mr. Gifford is

accomplishing a good work. We should think that this kind would become popular, the scarlet colouring being remarkably bright and the petals broad. Dazzle is a good scarlet, but the flowers are smaller.

Rose-coloured varieties are numerous in the list of good garden Carnations. Mr. Gifford's seedling *Dr. Parke* is a fine kind, the flowers of good size, full and rich self rose, a pleasing and charming shade, whilst the growth of the plant is free. Raisers hitherto, we think, have paid too little attention to the growth of the plant. A variety that is not robust and free is of little value. *Maggie Laurie*, blush-rose, is of great vigour, and a brilliant shade of rose-carmine is got in *Queen of Bedders*, which justifies its name as a bright, beautiful and effective border kind for planting in good masses. *Fiery Cross*, crimson-scarlet, a brilliant shade, is of note; also *The Moor*, one of the darkest of all Carnations. The flowers are of a deep clove colour, full, large, sweetly-scented, and produced freely. It is conspicuous in particular for its depth of shade, and grows with vigour. For contrast to other kinds it is valuable, but must not be used to excess. Three very beautiful white-flowered kinds are *Mrs. F. Watts*, which is too well known to describe, *Edith Brill* and *Empress*, the latter raised by Mr. Gifford.

A distinct break away somewhat in colour is *Duchess of York*, a new seedling raised by Mr. Gifford. The plant makes vigorous growth, and the flowers, large and of a charming flesh colour, appear early in the season, and are valuable for cutting. A bouquet of this type would be delightful. The growth is strong and the plant blooms with freedom. It is the deep coloured kinds that show up to the best advantage. Of this section Oxonian is noteworthy. The colour of the flowers is dark crimson, and, like the majority of the kinds in this collection, the flowers are borne with marked freedom on sturdy stems. *Bret Harte* is deep maroon, almost black, and a few plants make a change from those with lighter coloured flowers. *Herbert Railton*, carmine-rose, and *Comtesse de Paris* were in full beauty; also such familiar varieties as *Mrs. Reynolds Hole*.

There is a rich collection of yellow ground Carnations in this nursery, and they form a very interesting class when the varieties are of the finest character. The best of these have been described in *THE GARDEN* this year, so that further enumeration of names is unnecessary. Amongst other good things here we notice a variety named *Fair Rosamond*, which may be described as an improvement upon *Alice Ayres*. The flowers are larger than those of that popular kind, full, the ground white, striped with carmine. It is flowering exceptionally well, and is pleasing in form and colour. Mr. Gifford grows also bizarre and flaked Carnations remarkably well, and in the latter class we notice the variety *Lorna Doone*, a beautiful rose-pink, the flowers full and handsome. The plant grows vigorously.

We were charmed with the Carnations here, because grown in the open on a breezy exposed position, and in a way that we would recommend them to be arranged in private gardens, that is, in groups of several kinds, one variety in each group. The effect in colour is surprisingly rich, and we see the Carnation in its true light, that of a beautiful garden plant, strong, free, and of varied colours.

Lilium candidum.—Many complaints as to the failures of this beautiful Lily induce me to send a few notes as to how I treat my stock that has never yet failed to produce splendid spikes of bloom in quantity. The soil here is naturally a rather light loam resting on gravel, and as we are close to the seashore it is more or less mixed with shingly stones, and possibly to the perfect drainage a good deal of the success with this Lily may be due. Various opinions are held here, as elsewhere, as to the advisability of transplanting this Lily, but I find that the best crops of bloom are gathered from beds the second and third year after transplanting, and why the plants should not be benefited by fresh unexhausted soil I have yet to

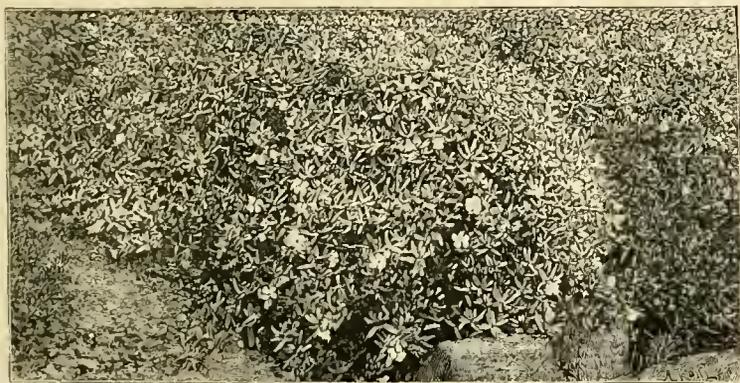

learn. I am well aware that clumps of this Lily do continue to bloom well for many years in cottage gardens here without transplanting. They are frequently mulched with road scrapings, yet they certainly do not produce such fine individual spikes as mine that have been transplanted do. I always transplant about the end of July, or very soon after the crop of bloom has been cut, when, having some fresh land deeply cultivated, I lift the Lilies with steel forks to get all the roots out intact, and proceed to plant at once in rows 2 feet apart and the bulbs 1½ feet, working in some sharp road grit with the bulbs. They require very little attention beyond keeping clean, and produce medium-sized spikes of bloom the next season, and a splendid full crop the second and third years. Few hardy flowers sell more freely or better repay the care bestowed on them.—J. GROOM, *Gospport*.

THE GROMWELLS.

(LITHOSPERMUM.)

THE Lithospermums are as choice and interesting as the Gentians and are more satisfactory in some respects, though some of the choicest of them will not stand our winters without protection. I have spent more trouble in trying to establish

L. GASTONI than any other plant in my collection. I have at last, I hope, successfully ac-

The Creeping Gromwell (*Lithospermum prostratum*). Engraved for THE GARDEN from a photograph sent by Mr. G. S. Symons, Chaddlewood, Plympton.

complished this feat, and though my present plant has not flowered, it has grown strongly all the summer, having come through the winter unharmed. This species wants watering during dry weather, and it is very liable to be attacked by Turnip-fly; indeed some fine pieces sent me some few years ago by Mr. Wolley Dod, and which were apparently doing well, were killed by this pest, though probably the soil beneath them was too dry.

L. OLEAFOLIUM I bought many years ago, and it lived (or rather did not die) on one or other of my rockeries for many winters, including that of 1890-91. I do not, however, suggest that it is hardy, for it did no good with me for years and never flowered. One day it occurred to me to dig it up when it was apparently *in articulo mortis*. This I did, potting the small piece of root that appeared to have any vitality after taking off the dead parts. This small plant grew vigorously all last autumn, and having been kept in a frame during the winter has flowered freely during the past season and is growing into a large plant. I do not mean to trust it out of a pot again. This is a choice and beautiful species, though less showy than some of the others, the colour being pale blue with a large admixture of the pink so characteristic of the Borage family.

L. PROSTRATUM is now doing well here in several positions. I have hitherto always failed with this, probably from planting it in positions where the roots could not find sufficient moisture. This, the commonest, is no doubt the most showy of all the

species in cultivation, while the exquisite little south Italian

L. GRAMINIFOLIUM is the most beautiful. I should have been inclined to give this species a good character for hardiness up to last Christmas, for it lived out on my rockery (with a flat bit of glass over it to throw off rain) for some years, and when I left home for ten days on the 28th of last December, I had a very fine plant. However, "when I came back the dog was dead." Dry as it had been kept, some very hard frost hit it too hard ever to recover.

L. PETREUM (Moltkia they want to call it now, I believe), one of the loveliest of rock shrubs, has flourished on one of my rockeries for ten years. It is quite hardy when planted high and dry, and will stand anything except the north-east blast, which injures the flowering shoots sometimes.

L. TINCTORIUM is a plant that I hope Messrs. Backhouse will be able to get us again. It is beautiful and very distinct. I had it on my rockery for one or two winters, protected like *Onosma*, for it is evergreen, and the leaves are rough and liable to rot in winter, but it succumbed to the cold of 1890-91.

L. CANESCENS I recently obtained from Mr. T. Smith, of Newry, to whose enterprise we owe the introduction and re-introduction of many rare and choice things. I have been asking about this plant and seeking it everywhere for the last ten or twelve years, but I could not get it, nor have I seen it in flower, nor have

I ever known anyone who has. Mr. Wolley Dod, indeed, to whose constant kindness I owe many of my best plants and very much of what I know about them, mentioned in a letter that he had a plant labelled under this name growing on one of his rockeries, and that it had never flowered (he has recently told me, by the way, that this same plant is dead), but I could get no other scrap of information on the subject. It seems, however, that as

Many a flower is born to blush unseen,
And waste its fragrance on the desert air,

so many a rare and choice plant is flourishing in English gardens whose owners are too modest or too indifferent to let an inquisitive public know of the plant. Last year, however (or it may have been two years ago), the Royal Horticultural Society promoted a sort of horticultural spelling-bee, in which we were all invited to name the best twenty or fifty or hundred plants of certain sorts and sizes. The answers or "votes" were tabulated and published in the society's journal, and from these I learned that the gardening public had agreed to place *Delphinium cardinale* (so well known for its perennial qualities!) at the head of the poll as "the most useful herbaceous perennial in cultivation over 4 feet high"; and that a sufficient number of cultivators of hardy plants had tried and succeeded with *L. canescens* as to place it thirty-third on the list of "the best perennial border plants under 9 inches," and above *Ranunculus pyrenaica*, "which came thirty-fourth"! What

have the nurserymen been about all this time? For myself, I cannot yet say whether I shall succeed in establishing this, though I shall give it all care, for if it is like its portrait—and it has been figured, if I recollect aright, both in the *Botanical Magazine* and by Paxton—it is worth all the pains that can be bestowed on it. The flowers are orange-yellow, and the habit appears to be something like that of *L. Gastoni*. The plant, which is North American, was known at one time as *Batschia canescens*.

L. ROSMARINIFOLIUM is not only not hardy, but one cannot even bury it in a pot on the rockery and induce one's friends to believe it is growing there, for if it happens to be alive at the time, it flowers in January. It has, in fact, no place or part among hardy flowers.

J. C. L.
Maidstone.

GROWING THE POT MARIGOLD.

ANYONE who has had trouble in the cultivation of our old and bold friend, the pot Marigold, may take courage from the following published in a contemporary:—

MARIGOLDS (*Calendula officinalis*).—The ash, &c., of these half-hardy annuals contain the following constituents:—

Iron oxide	0.92	Silica	2.10
Potash	39.26	Phosphoric acid	14.07
Soda	5.99	Sulphuric acid.....	4.68
Lime	20.82	Chlorine	2.16
Magnesia	9.63		
Albuminoids (N)			1.65 per cent.

They are benefited by being watered with a solution containing a quarter of an ounce each of kainit, iron sulphate, superphosphate of lime and nitrate of soda to two gallons of water. *This liquid manure must not be applied over the blooms!*

* * We suppose this must be called the "scientific horticulture!"—Ed.

Gaillardias at Tottenham.—When in Mr. Ware's nursery at Tottenham a few days ago we made note of a fine series of Gaillardias in full bloom. During recent years great improvement has been made in this charming class, and gradually the plants are getting into ordinary gardens. They will grow in only moderately good soil, stand unharmed English winters, if not unusually severe, and the gay-coloured flowers are useful for cutting, lasting when gathered several days in a fresh condition. With an advance as regards the colours of the flowers has also come a better habit of growth, the more recent kinds being dwarfer, more spreading and compact than the older type. For over three months they keep in bloom, and if a careful selection is made, some very distinct shades will be obtained. One of the most distinct Gaillardias raised is Vivian Grey, which we noticed at Tottenham and elsewhere. It has large flowers, self yellow in colour, and they are produced with great freedom. Maxima is conspicuous for the size of its blooms, but we do not think there is much gain in getting mere size. They are rich crimson in colour, with an edge of rich yellow. Aurora is of note for its quilled form, and we have now got flowers of various expression, quilled and so forth. Perfection is very dwarf in habit, and more suitable for beds than the taller kinds; its flowers are scarlet, edged with pale yellow. Surprise may be described as of a claret-red colour, the florets light yellow at the margin. We could name many other varieties, but a list of kinds merely is not very interesting. All the named varieties are valuable, and in all gardens this flower should be grown.

Varieties of *Begonia semperflorens*.—This *Begonia* is likely to play an important part in bedding arrangements of the future, and this year in more than one public park it is used. There are now several charming varieties, such as Princess Beatrice, Crimson Gem, Fairy Queen, Snowflake and Afterglow, which make a great show, the flowers being produced freely on the vigorous shoots. Some kinds, as Crimson Gem, have dark-

coloured leafage, which throws into bold relief the crimson flowers. The plants are not formal in growth and are very easily grown. When lifted and potted in late summer, before frosts have touched them, they will continue to bloom during the winter. We were reminded of their great usefulness by seeing a large collection of them in the Chiswick gardens, both in beds and in pots in one of the plant houses. When in pots they are of great beauty, and may be specially commended for cultivation in this way. The growth is longer naturally and the flowers paler in colour than in those in the open, but they are abundantly produced, a perfect mass of delicate bloom. We noticed the variety Princess Beatrice especially; it is a gem for pot culture. A charming kind is named Duke of Edinburgh; it is of strong growth, almost too robust, and the flowers are individually large, touched with rich rose, whilst one named alba is, under glass, practically pure white, although here and there touched with rose. It would be worth while for gardeners to take note of this section for decoration. The neat plants, crowded with flowers, are useful, not only in the greenhouse but in rooms, in which they keep in beauty for a considerable time. They are quite as worthy of culture as the more popular tuberous Begonias, and in time we shall no doubt get greater variety.

A NEW LILY.

A CONSIDERABLE amount of interest was excited by a very beautiful Lily to which a first-class certificate was awarded at the last meeting of the Royal Horticultural Society held at Chiswick on July 11. It was exhibited by Messrs. Veitch under the name of *L. Ukeyuri*, and by Messrs. Wallace, of Colchester, as *L. Alexandrae*. These names must only be regarded as provisional, and Mr. Baker will no doubt soon bestow upon it at all events a less awkward name than the Japanese title under which it was exhibited by Messrs. Veitch. This Lily is believed to be of hybrid origin, raised in Japan, and was spoken of by Mr. Wallace on page 348 of the last volume of THE GARDEN as a cross between *L. speciosum* and *L. longiflorum*, but the general opinion when the plants were exhibited was that it was a hybrid between *L. auratum* and *L. longiflorum*, with which opinion I perfectly agree, or rather I should give as one parent not the typical *L. auratum*, but its broader leaved and more massive flowered variety *platyphyllum*. Whether such is its origin or not, it is a really good Lily, and one destined, I should say, to hold its own under cultivation. The plants that have come under my observation have all been about 18 inches high and with a stout erect stem, clothed in an alternate manner with rather pale green foliage. The leaves are about 5 inches or 6 inches long and three-quarters of an inch or thereabouts in width, but they become wider just at the upper part. The pedicels in the strongest examples already show signs of branching, and as they get established this may become a permanent feature. The flowers are shorter than those of *L. longiflorum* and less shallow than in *L. auratum*, their colour being a pure unspotted white, with a shading of green towards the base of the tube both inside and outside of the flower. The segments of the flower reflex prettily, though less so than in the Japanese forms of *L. longiflorum*, while the anthers have no trace of the golden colour of this last, but are of a reddish brown, as in *L. auratum*. At the first glance the bulb might be taken for that of *L. longiflorum*, being of a yellowish white tint, but closer examination reveals the fact that it has certain points of resemblance to *L. auratum*. The plants that have come under my observation have been grown in pots and given the same treatment as the Golden-rayed Lily with very good results; in fact, it has proved far more satisfactory than *L. auratum*, which is this season in many cases a comparative failure. If it should, however, prove to be perfectly hardy, it will then form a good low-growing Lily for the open ground. I had almost omitted to mention that the flowers emit a very agreeable fragrance like that of the

longiflorum group. It will remove a probable opportunity for confusion when one authentic name is bestowed upon this Lily, for up to the present the case stands as follows: It was offered by one or two of our prominent Lily dealers during the dormant season as *L. Ukeyuri*, and as such some bulbs of it were disposed of at one of the London auction rooms early in the spring. Again, in THE GARDEN for April 29, Mr. Wallace speaks of it as a "new hybrid Japanese Lily, *Uke-uri*, which, anglicised, is Hookey's Lily, or *Lilium Hookeyi*"; and, lastly, we have the *Alexandrae* of the Chiswick show. H. P.

CLEMATISES IN FLOWER.

FROM the spring-time when the beautiful Himalayan *Clematis montana* with its profusion of pure flowers is at its best till autumn is upon us, we have a succession of *Clematis* flowers, and included among them are some of the showiest of all our outdoor climbers. While the bulk of those commonly met with consists of garden varieties, we have at the same time many of the original species or recognised varieties thereof that make a goodly show. *Clematis montana* mentioned above is one of these, and as a free-growing climber for a south wall there is little to equal it, at all events during the time of the year at which it flowers. A dozen years ago there was no *Clematis* that attracted so much attention as the Texan *C. coccinea*, which is now regarded only as a variety of *C. Viorna*. For a few years there was a great demand for it, and it was planted almost everywhere, in unsuitable as well as in suitable positions. The result was that many failed to grow and flower in a satisfactory manner, for it is really less vigorous than many of the others, and slugs are especially fond of the young shoots just as they are pushing through the soil. This, combined with the fact that some individuals are in the beauty of their blossoms a good deal inferior to others, no doubt caused this *Clematis* to be discarded by many. The peculiar shape and wax-like substance of the flower as well as its colour (for scarlet is with this exception unrepresented among hardy kinds) are points that are certain to attract attention. When first introduced there was a good deal of confusion between the scarlet *Clematis* and *C. Pitcheri*; in fact they were by some regarded as synonymous. *C. Pitcheri* is, however, compared with the other a poor plant, the flowers being of a dull purple hue. A thoroughly good *Clematis* not only for itself alone, but also for the numerous hybrid forms in whose production it has played a part, is the South European Vine Bower (*C. Viticella*), which is represented in our gardens by numerous varieties. A very richly coloured form was illustrated by a coloured plate in THE GARDEN, January 10, 1891. *C. Viticella* is especially noteworthy from having, in conjunction with *C. lanuginosa*, given us the beautiful *C. Jackmanni*, which, though raised about thirty years ago, is still grown to a greater extent than any other *Clematis*. *C. florida* and its variety *Sieboldi* are very distinct kinds, this latter being especially beautiful. The flowers of this are quite distinct in shape from those of any of the others, as they consist of six broad petals, which when fully expanded are creamy white. The most distinctive feature is, however, the centre of the flower, which is filled with narrow purplish petals, thus forming a double bloom. Not only do the individual blooms of *C. Sieboldi* remain in beauty for some time, but a thriving specimen will keep up a succession for months together. Our native Traveller's Joy (*C. Vitalba*) often forms a beautiful object in wood-

land scenery, while *C. flammula*, with its tangled mass of small, white, fragrant blossoms, is very pretty indeed towards the end of the summer and early in autumn. A very uncommon species is the pale yellow-flowered *C. graveolens*, that blooms much about the same time as the preceding. It is very noticeable from its distinct colour, though less showy than many of the others. The garden varieties, so much in evidence at the present season, are very numerous, but many of them closely resemble each other; in fact, the same may be said of most popular classes of plants, as a demand for any particular thing will at once cause so-called new varieties to be put on the market. Most of these summer-flowering hybrids have in the first place originated from *C. Viticella* and the large-flowered *C. lanuginosa*, while the progeny has been crossed and intercrossed with each other till the result has been the numerous and varied coloured forms now in cultivation. The largest flowered varieties owe this feature to *C. lanuginosa*, which was introduced from China over forty years ago. The varieties of this section are less robust than the others, while among them light-coloured flowers predominate. In most of them the blooms are white, blush or lavender, often with deeper stripes down the centre of each petal. The *Jackmanni* section, which includes several deep-coloured flowers, is admirably adapted for association with the lighter hues of the *lanuginosa* type. These different forms of *Clematis* may be used in various ways, as wall plants, for covering arches (for which they are often employed), or a beautiful effect may be produced by festooning stumps of trees with the stronger growing forms. *Clematises* are at times grown as pot specimens, and in this way are generally to be seen at some of the early summer shows in the neighbourhood of London. T.

Verbascum olympicum not the best.—

There is something so striking about this when in flower, that most of those who write about it are apt to over-estimate its importance as a garden plant, and I think "Delta" makes the same mistake on p. 47. It is not quite at home in the majority of shrubberies, and on a clay soil I find it of no use in the open. There is a *Mulleins* which is happy on all soils. It is *V. phlomoides*, the best of the family, and flowers for as many months as *V. olympicum* does weeks. I am very fond of the *Mulleins*, but I never grew *V. olympicum* really well except when planted at the foot of a wall. It is grand in leaf for a couple of seasons, for usually it does not flower till the third year. *V. phlomoides* is a true biennial, one of the best of this class of plants, and so easily grown, that if once introduced into the shrubbery it will generally perpetuate itself and come year after year from seed. It does not branch so freely and regularly as *V. olympicum*, but it is such a lasting thing, and that is the point that tells so much in its favour. The finest plant of it I ever saw I had last year. It sprang up early in the season previous in a border of deep light soil, and attained much strength. Last year its central flower-spike was over 8 feet high, and it had thirty-three lateral spikes, some of which were 4 feet.—A. H.

Forms of our native Water Lily.—Mr. Young does not say (p. 45) whether there is any difference in the size of the flowers of the two kinds of Water Lily he has. We have a very large kind that I should like to know more about. I have lately cut some flowers of it quite 6 inches across, and it makes a brave display. It is almost or quite as fine as the splendid hybrid of *M. Marliac's* named *Marliacea alba*. The sepals are of a bronzy green externally, and there is a slight tinge of pink internally at the base of the petals. In the excellent article from the pen of M. Vil-

morin on Water Lilies, which appeared in THE GARDEN of March 28, 1891, a large form is spoken of as having originated in Macedonia, but M. Vilmorin only knew it from description. Whether this that we have is the same I do not know, but it is a magnificent thing. Then the same writer speaks of another form named plenissima, which has a great number of petals altogether in excess of the number found in the flowers of the type and this fine variety. Does any reader of THE GARDEN know or grow it?—A. H.

Sea Hollies.—To see how large a number of varieties of *Elyngiums* there are in cultivation, it is needful to get into a hardy plant nursery, such as is at Long Ditton, although there have been introduced from time to time very many sorts that probably cannot now be found in commerce. In gardens even where hardy plants have been grown well and for a long time, the chief forms are the pretty blue amethystinum and the large silvery giganteum, but there are others equally, perhaps more attractive, amongst which the small-flowered and wonderfully free planum may be reckoned, and most valuable, especially for cutting. Very fine and blue in the stems is *Oliverianum*, but even bluer still is *Oliverianum superbum*, a variety that because of its very elegant form and intense blue colour should be universally grown. If to those named be added alpinum, I think the best possible half-dozen is found. It is interesting to find that although these Sea Hollies have been with us almost for centuries, yet they seem just now as if being raised from the dead. It is not at all a matter for surprise, they are so beautiful. I brought a handful of them home the other day and was frequently asked what they were, as no one seems to know them, whilst for filling vases they are most beautiful. It is unfortunate that these hardy plants cannot be propagated freely, but that seems to be impossible. All the best varieties increase slowly, and being in considerable demand, stocks are kept low.—A. D.

VARIETY IN SWEET PEAS.

I HAD an opportunity recently of seeing a large collection of Sweet Peas at Messrs. Veitch's trial grounds, Turnham Green. As is well known, to Mr. Eckford, of Wem, Salop, we are largely indebted for new colours, increase in size, and other improvements. Mr. Laxton is also working in the same field. There could scarcely be a worse season for these flowers, as, being forced into growth by the warmth during May, they produced early blooms and were over very quickly, the flowers being smaller than usual and quickly running to seed. I have also observed with these improved new Peas that unless given good culture they do not come up to the mark as regards size and substance. Sweet Peas are often sown much too thickly in private gardens; with less seed better results would be realised and a longer flowering season. The collection referred to had received no special treatment in the way of food or moisture. Many are very much alike, and many are flaked and striped. To the florist this diversity of marking is no doubt interesting, but my note is intended more for the amateur or gardener who requires a few with distinct markings, size, and long lasting when cut.

Mr. Eckford's seedlings stand out prominently despite the drought, one of the best being *Her Majesty*, a rosy pink self, large flowers. This is a valuable addition to the list; indeed, I prefer it to *Splendour*, a rose-pink of deeper shade. *Venus* is another variety of decided colour, a pale buff with shaded pink standards, and a beautiful flower when fully expanded. By some the colour may not be a favourite, but it is so distinct that it is a welcome addition. *Mrs. Gladstone* is worth room in every garden; this may be termed an improved *Princess Beatrice* and very much like the newer *Blushing Beauty*. *Mrs. Saukey* is another lovely flower, a pure white. This variety should be made a note of where a good white Sweet Pea is required. Another variety closely allied to these is named *Emily Henderson*. It is too much like the last two

varieties, but it is more robust in growth. This is of American origin. *Waverley* is of a distinct colour, a rose claret with shaded standards and pale blue wings. *Breatton*, dark brown, crimson wings and purple standards, is one of the darkest varieties and should be included in the list. *Monarch* is also a striking dark flower, a bronze-crimson with deep blue wings and a large bloom of good substance. Nearly allied in colour to the last named is *Purple Prince*. *Duke of Clarence* is a desirable introduction, a rosy claret self flower. *Dorothy Tennant*, a good mauve or fine violet; *Countess of Radnor*, deep lilac; and *Lemon Queen*, delicate blush tinted with lemon, are also good. *Delight* and *Primrose* are much alike in colour, a soft primrose shade. *Isa Eckford*, creamy white; *Empress of India*, rose-pink; *Apple Blossom*, somewhat like *Painted Lady*; *Splendour*, rose-pink; *Orange Prince*, a grand bloom, orange-red, are also distinct. *Cardinal*, shining crimson-scarlet, *Ignea*, *Firefly*, and the old *Invincible Scarlet* are the best in this colour. Among the blues, *Grand Blue* is fine; near to this is *Invincible Blue* and *Captain of the Blues*. I prefer the first named. *Indigo King* and *Purple King* are good. *Sylva* and *Rising Sun*, two of Mr. Laxton's seedlings, violet rose with lavender-blue edging, are good. *Mme. Carnot* is a fine dark purple; *Etna*, a dull purplish crimson, not a large flower, but a nice shade of colour; these last are some of Mr. Laxton's raising. A good selection may readily be made from the above.

G. WYTHES.

NOTES ON HARDY PLANTS.

Saxifraga virginicensis.—The true plant is a very distinct one in even its big family. It has two characteristics that are well marked—the roots are tuberous with persistent fibre, and the foliage evergreen, though in no way resembling either the mossy or encrusted sections. The leaves are in flat rosettes, after the form of small *Arabis* foliage, and rendered dull in colour by reason of the brown hairs or down. The flowers are equally distinct, but not at all showy, not even when you have allowed for their small size. They are carried on somewhat short-forked scapes or stems, and are but mere specks of white with brownish calyces. It is reasonable for us to doubt the hardness of *Virginian* flowers, but in this case I am pretty sure the plant is hardy enough. I have grown it quite twelve years, and it has had no protection whatever; neither is it fickle as to soil, though I give rather more black soil than I do to most European species.

Saxifraga odontophylla.—This is another distinct or even peculiar species. It has reniform, evenly-toothed leaves of a brittle and succulent character, and clothed with long, stiffish hairs. It is a little plant with a big wig of roots. The flowers are lovely, large, pure white, bell-shaped, and half filled with the anthers that are covered with pollen of a terra-cotta colour. The flowers last individually for a couple of weeks. This, too, is quite hardy, but it suffers from heavy thunder showers owing to its brittleness. Still my plants stand open to all sorts of weather.

Geum reptans.—I know no herbaceous creeper that can be claimed to be at once more suitable for and beautiful on a rockery. I think it does better in a little shade than otherwise, that is side shade and not top shade. Of the latter I think our rockeries would be better if quite free. The leaves, stems, flowers, and seeds of this plant are all distinct and beautiful. Several other plants sometimes go under the name in commerce, but once the true plant has been recognised there is little or no fear of mistaking it.

Gentiana septemfida.—This is a much more variable species than is generally supposed. The features of variation are colour of flowers, form of leaves, and general size of plants, especially stature. I have it in mature specimens with a stature of nearly 2 feet down to 8 inches or even less, and with leaves half the length of one's hand; some are lanceolate, others quite small and cor-

date, and these variations are repeated in several batches of seedlings, and I see grades of intermediate forms. As to flower-colour, there are dark indigo-blues, paling to nearly sky-blue. As this happens to be one of the best garden species—the freest to blossom and easiest to accommodate—the above facts may suggest the usefulness of seed-raising, provided quite fresh seed is obtainable. To try with old or doubtful seed is not profitable.

Clematis erecta fl.-pl.—When this can have the needful moist corner where its brittle stems will not be likely to be broken by the wind, it may be expected to make a charming and uncommon display in late summer. In the case of this *Clematis*, the double flowers are much superior to the typical ones in several ways, but the most valuable gain is the fact that the flowers are a better white and they last twice as long as single ones. With me the plant grows only about or scarcely 1 yard high, and, though wiry, is somewhat slender and better for some material to sustain it. Like all its family, the plant likes a free soil and plenty of moisture, and granted these, it soon forms a good-sized clump.

Erythræa diffusa.—This lovely *Gentian*-wort, with its bright rosy and sheeny flowers, is amongst the best and brightest of rock plants in mid-summer. Aptly it comes in the season of summer *Gentians*, and it is interesting to have a plant of this colour so nearly allied to the *Gentians*. It is a little evergreen creeper, and so nearly does it resemble the small *Veronica repens* in its foliage, that I have known some people pull it up under the impression that it was that weedy plant. It is, of course, totally different when in flower, the stems rising something like 4 inches or 6 inches high. If the plant has a moist place with plenty of sunshine, it will develop flowers in such masses as to cover itself, and there is no need to say how valuable such plants prove to be in July and August.

Cheiranthus Allioni.—It is a very common thing for a second crop of the dark flowers, of this desirable kind to appear in late summer, and this tendency may have been helped in the present forward summer. If the tops of the first crop are removed so as to prevent seed-bearing, a second crop of flowers will be secured. The loss of the seed may not imply much in this case, because you cannot trust seeds to produce the true form. On the other hand, when propagation is your object, by topping the plants as just stated, you not only get more flowers but fresh and earlier shoots from the base, which are the best of material for slipping off for young stock.

Veronica cupressoides.—I fear that sooner or later this is apt to go off in a sudden manner, especially in hot summers, not that I would like to say heat and drought are the cause, but so far as my experience goes, branches and even the whole plant have invariably gone off in the height of summer. There is not the least doubt as to the hardness of the plant against cold, and I am sure it is all the better for a deep root-run of light stuff with bigish stones near the surface.

Geranium balkanum.—So it seems this is only another instance of an old friend with a new name. For many years I had grown the *G. macrorrhizon*, with which, there is scarcely room for doubt, it is identical, until it got to the size of a door-mat, when, side by side with other *Geraniums*, I did not consider it worth culture as a garden flower. Such kinds as *cinereum*, *argenteum*, *subcaulescens*, *Endresii*, *ibericum*, *Wallichianum*, *Lambertianum*, and even the forms of *lancastriense* I thought were quite superior. When, as in this case, a plant is distributed with a provisional name, would it not be well to distinguish it by a query sign with the name? Two things this would at least serve to do: to put recipients on the alert as to identity, and give infinitely less trouble than correcting such errors as the present. When small roots of a supposed new plant are sent out they may for a year or two puzzle the best observer until the plants mature and flower, and the longer a plant has been carefully tended, the more keen

the disappointment when an old and discarded flower is identified. Had the untrustworthiness of the plant been indicated in some such way as above, growers might have pleased themselves as to whether they took the plant into their collections, and I certainly if they did elect to try it, annoyance might have been saved.

Oenothera marginata (syn. *eximia*).—The propagation of this glorious flower is easy or simple in the extreme if done now, but I suppose it is because the plant is now flowering so grandly that few care to mutilate it in any way at present. Sometimes you may take offsets from the running roots with a little fibre, and the big, pure white flowers of 3 inches to 4 inches across will in no way be hurt or hindered. Plants that are but one year in good fresh stuff of a light character produce this sort of material in greatest quantity. Older plants keep more compact, and then the flowering stems have to be taken as cuttings or slips. In doing this, do not fail to secure an inch or more of the brown portion at the base; such slips placed in a bed of sand and well watered, in full sunshine, will root freely in eight or twelve days, and may then be either potted or set in their permanent places. Young plants, even newly-made stock, are likely to stand a severe winter better than old plants. J. WOOD.

Woodville, Kirkstall.

PRUNING CLEMATISES.

I SHALL be glad to know when and how to prune the following Clematises, viz., *C. Jackmani*, *C. montana*, *C. Duchess of Edinburgh*, and *C. indivisa lobata*.—W. O'B.

* * * The pruning required by the different kinds of Clematis enumerated above will to a great extent depend upon the position in which they are growing, for if festooning any extensive support, such as neighbouring trees, or clothing an arbour, little if any pruning will be required, while, on the other hand, if trained to a wall where space is limited, pruning is absolutely necessary in order to keep the specimen within bounds.

Clematis montana flowers from the young shoots directly they push from the old wood, and consequently any severe pruning in winter will limit the display of blossoms. All that is needed is to remove any weak or exhausted wood that is not likely to flower, but be sure and retain the vigorous shoots, as they will yield the greatest wealth of blossoms. *Clematis Jackmani*, on the other hand, forms shoots of considerable length before they flower, so that they may during the winter or early spring be pruned back to good strong buds and any weak or exhausted shoots cut out. *Clematis Duchess of Edinburgh* will require little pruning, all that is needed being the thinning out of any weak growth during the winter when dormant. *Clematis indivisa lobata*, the evergreen species that requires the protection of a greenhouse, blooms early in the spring, and all the pruning needed must be done directly the blooming season is past. Where it is necessary, the vigorous shoots may be shortened back to good strong eyes and the weak ones thinned out, but in the case of this Clematis, as with the others, the less pruning that is indulged in unless in some exceptional cases the greater will be the display of blossoms, though such a free grower as *C. Jackmani* may sometimes form too dense a tangle unless pruned back somewhat during the winter before the buds push into growth.—T.

Campanula grandiflora Mariesi.—This is perhaps better known as *Platycodon*, and one of the finest perennials in bloom now. We noticed it in the Tottenham nursery of Mr. T. S. Ware. When in good soil it makes a handsome mass, the growth not rising more than a foot in height, compact, and leafy, whilst the flowers are large, produced freely, and of a pretty shade of blue. The best position for it is the rockery, and in pots it shows to advantage, owing to its dwarf, leafy habit and

free display of flowers. We should like to see this fine Bellflower more grown in borders. Also in bloom were the type, which is still uncommon in gardens, at least not so freely planted as it deserves to be, and the variety named *alba*, which has pure white flowers.

A note on tufted Pansies.—This class is beginning to wear a rather ragged aspect, but not all varieties. Many kinds are in full bloom in the Chiswick Gardens, and those that have maintained their character from spring we have made a note of. They are from Messrs. Dobbie and Co., and comprise the finest varieties in the collection. All are of good habit, compact, and the flowers make a mass of colour. William Niel is a good kind, the flowers of bold form and rich mauve-purple, a distinct hue. Queen of Scots is in fine bloom, the flowers whitish in colour, with a deep purple centre, and note should be taken of the variety Mrs. C. Turner, a rich purple self, very effective for its intense shade of colour. Pretty in its distinctive shade is Bridesmaid, which is of various tones of primrose, deepening in the centre to rich yellow. Ardwell Gem is a well-known kind, whilst a variety named Lord Elcho is also deep yellow, but relieved in the centre by stripes or streaks of purple. One of the boldest in the collection is Champion, the flowers large, produced freely and evenly, white with a small yellow eye and central radiating streaks of rich purple. Another kind worthy of mention is The Mearns, which has large flowers, the lower portion deep maroon, but passing to a lighter shade in the upper half, the eye yellow. Besides those of Messrs. Dobbie, Dr. Stuart, who has raised many good tufted Pansies, also has a collection. Two of the most noteworthy varieties are George Muirhead, the flowers large and primrose-yellow in colour, the lower portion of a deeper shade; whilst Sylvia is a good variety; the flowers, of bold shape, are white relieved by a small yellow centre.

SHORT NOTES.—FLOWER.

Delphinium nudicaule.—This must be accounted a good hot-weather plant. We have seen it very fine in many gardens and nurseries. It is a plant that must be grown in a mass to obtain a bold display.

Pentstemon barbatus Torreyi was one of the brightest plants in bloom in mid-July. It is a graceful form, a native of Colorado, and hardier than the species. The plant grows to a considerable height, the bright scarlet flowers appearing in tall, loose spikes. This fine *Pentstemon* when planted in a good mass in the border makes a fine show of colour, and continues gay for several weeks.

Eryngium alpinum.—I notice on p. 38 that *Eryngium alpinum* is said to be a weak grower. This certainly cannot be the case, or perhaps the plant alluded to was not *E. alpinum*. Both here and at several London nurseries and also in several private gardens I have always seen it, and found it to be the most robust of the family, though slower in forming a clump than the others.—M. PRICHARD, *Christchurch*.

Lilium Kramerii.—With regard to the notice of this Lily on p. 48, it may be pointed out that though now recognised as the *Lilium japonicum* of Thunberg, as stated in the article in question, yet a fact to bear in mind is that the specific name of *japonicum* is generally applied to *L. odorum*; indeed, this last mentioned Lily is more frequently sold as *L. japonicum Colchesteri* than by any other name. As a beautiful and distinct Lily *L. Kramerii* deserves all that can be said in its favour, but it is a bad traveller and, except in a few cases, a difficult Lily to grow.—H. P.

Eckford's Sweet Peas.—I purchased packets of the Sweet Peas sent out by Mr. Henry Eckford. They are (middle of June) at their best, and succession crops are coming forward strong and well. The rich and varied colours of the Peas are very beautiful and greatly valued for cutting. For first cutting I sowed the seed about the 1st of Feb-

ruary in boxes on rough leafy soil mixed with loam, covered the seed with soil sifted from refuse under the potting bench, and all I could desire has been realised.—M. TEMPLE, *Carron House, N.B.*

Some good summer flowers.—I send you specimens of *Michauxia campanuloides*, Sweet Sultan, fine *Coreopsis lanceolata*; also a spike of *Digitalis ferruginea*, although this is nearly over, and to be admired must be seen when the basal flowerets are open and the terminal ones in bud. I have had spikes 5 feet high and more, a cylindrical tapering truss, densely packed and set all round with no space between, of a quaint hue and chaste beauty, in cream and white, green and yellow, brown and purple tones.—J. H. REEVE, *North Walsham, Norfolk*.

GARDEN FLORA.

PLATE 920.

HARDY LINARIAS.

(WITH A COLOURED PLATE OF *L. DALMATICA*.)

IN a large genus like that of *Linaria* it is not a little surprising to see how few really useful species have found their way into general cultivation. Many of them are quite brilliant in their colours and markings. The annual species, chiefly confined to *L. reticulata* and its variety *aurea purpurea*, with occasionally *L. maroccana*, *spartea* and *tristis*, are far more popular than the perennial forms. The latter three, although by no means so showy as *L. reticulata*, will be found very useful, as well on account of variety as for their extremely free-flowering habit. There are numerous other species that might be added with considerable advantage; they may be cultivated in the flower borders with the greatest ease, little being required beyond sowing in late spring where they are intended to bloom, either in rows or patches, giving attention to thinning out the seedlings when they appear above ground. The perennial species, in addition to being less troublesome to manage, are as a whole more useful and varied in habit than the annuals. From the trailing *L. hepaticifolia* to the robust *L. dalmatica* of our coloured plate we have plants suitable for almost every conceivable position in the garden. The alpine *Toadflax* so brilliant and plentiful on the old moraines in the Swiss valleys, and so robust and beautiful on many rockeries, is nevertheless somewhat fastidious in many districts. In low-lying or damp gardens it is almost impossible to keep it alive, while in others the difficulty is to keep it from seeding and spoiling other weaker neighbours. Its trailing stems of glaucous leaves and numerous bluish violet flowers make it a worthy companion to the very best of our choice alpine.

L. DALMATICA, a coloured plate of which accompanies these notes, is a native of South-eastern Europe, and was introduced to this country about 1731. It is a very robust, vigorous-growing perennial, showy and useful alike for the border or the rock garden. It rarely exceeds 3½ feet in height, of a somewhat loose, straggling habit, but extremely free flowering, the flowers large and attractive. It may be increased readily from cuttings or from seed, which it ripens freely. *L. genistifolia*, a nearly allied species, is not so showy as *L. dalmatica*.

L. VULGARIS VAR. *PELORIA* is a very curious as well as a showy garden flower. It is by no means

* Drawn for THE GARDEN by Champion Jones, July 13, 1892, in the Royal Gardens, Kew. Lithographed and printed by Guillaume Severeys.

LINARIA DALMATICA

common in gardens, although a desirable plant, and at odd times found growing wild along with its parent. It differs from *L. vulgaris* and from most of the other *Linarias* in its having five spurs to each flower instead of only one. The flowers, indeed, have become quite regular. It seems, however, to be short-lived, and should be periodically propagated from the underground stems so freely produced when growing in light soil. The flowers, which are yellow, are produced in great abundance.

L. TRICORNITHORHA, one of the most beautiful species in cultivation, can hardly be classed as a hardy plant. It may, however, be wintered in a cold frame from cuttings struck in early autumn, or the old plants may be lifted and flowered during early winter in the greenhouse. The flowers are large, bright purple, and very showy.

L. origanifolia, *bipartita*, *crassifolia*, and some few others are worth growing and may occasionally be had in the trade. All the *Linarias* do best in light, rich soil, and may be increased either by cuttings or seeds. D. DEWAR.

Botanic Gardens, Glasgow.

THE WEEK'S WORK.

THE KITCHEN GARDEN.

WINTER GREENS.—Although the rains have not been exceptionally heavy so far at the time these notes are being written, yet they have been most beneficial in changing the aspect of all green and growing crops, especially those for winter and spring use. The soil being so warm, the growth of all such crops will now be very rapid. In some districts where watering has had to be exceptionally heavy to keep the crops anything like satisfactory, the soil around the plants will have become very firm. A good surface stirring will consequently be very desirable, working the hoe well up around the stems. Small plants left over in the seed-beds and which have now become stronger will, if now planted out, have ample time to become strong before winter. Coleworts, small-growing Savoys and Chou de Burghley will, if now planted, form most useful crops, and which, as far as flavour is concerned, are second to none. On light soils a dressing of soot strewn over the quarters where winter greens are growing will impart a healthy tone to the foliage and encourage a satisfactory growth.

TOMATOES IN HOUSES.—The change to duller and moister weather will bring about an attack of disease if care is not taken in both the heating and ventilation. Although up till now satisfactory crops have been secured, in some cases without the use of artificial heat, yet it is not now safe to dispense with it, as on account of the more moisture-laden atmosphere, the conditions are more favourable to the spread of disease. There need be but little fear of disease attacking the plants if a little warmth is kept in the pipes at night and on dull days, with also a free circulation of air. If any white fly is present, and which if allowed to gain headway quickly makes the fruit dirty, besides checking the progress of the plants, it may be effectually disposed of by syringing with soft water in which some carbolic soap has been dissolved. If before syringing the plants are cleared of all ripe and ripening fruit, the effects of the soap will pass away before other fruits ripen. The different fumigating cones and insecticides now being sold for the purpose may also be used, but the soap is most effectual, as if any dirt should be on either the fruit or foliage, this is removed by after syringings of soft water after it has been loosened by the decoction of soap and water.

ATTENTION TO THE PLANTS.—Plants which are growing in confined borders, pots or boxes will, on account of the earliness of the season, have grown more freely than usual, or rather have produced the crops earlier. If there is not space for further extension, these plants may be entirely rejuvenated by cutting in rather freely the old stems, and so

encouraging younger growth. If at the same time or as soon as the young growth commences to form a little of the old surface soil is removed, and this replaced with some fresh loam, wood-ashes, or burned refuse, with some pulverised horse manure and a little charcoal, healthy root-action will start, and the result will be a nice crop of late fruit. As the surface dressing becomes permeated with roots, assist the plants by giving liquid manure or some approved fertiliser. Plants which still have space must also be encouraged by rich top dressings, removing also some of the older foliage, and training in where there is space an extra branch. Any plants which, on account of being planted out in large and rich borders, are making a gross growth should have each leaf reduced by quite one half, also keeping the soil on the dry side. This may have the effect of causing the flowers to set more freely.

TOP-DRESSING CELERY.—This will be found to be a very needful operation in helping on the younger growth of Celery, as it provides a greater depth of suitable soil for the roots to ramify in. The later crops will not just yet require this addition, but the earliest supplies must receive attention at once. One advantage of top-dressing during the earliest stages of growth is that it prevents the outer leaves from spreading, and so causes more symmetrical heads to form. Top-dressing must not be confounded with earthing, this operation being best deferred until a strong plant is formed. Later crops will also be improved by stirring the soil about the plants.

YOUNG CARROTS FOR WINTER USE.—Unless the soil should be very suitable, this crop is the better for not being sown direct in the open, as thus the roots are apt to get eaten by grubs. The better system is to sow on an old hotbed, this being levelled and surfaced with about 6 inches of sandy soil. The lights, of course, will not be needed until inclement weather arrives, as the freer the exposure the better. If the depth between the surface of the bed and the top of the frame is considered too much, the space should be filled up with other material, which must be trodden in firmly before placing on the soil. The seeds should be sown thinly, and if the weather should prove dry, the soil must be kept freshened up with water through a fine rose. In gardens where Carrots may be sown in the open without fear of injury from grubs, select a sloping and sheltered border, providing a depth of suitable soil, as this latter is very essential for a winter crop. A free addition of old potting soil and burned refuse would suffice.

A. YOUNG.

FRUIT HOUSES.

VINERIES.—Latterly the weather has been even more trying to Grape growers than the remarkably hot weather previously experienced. Both ripe and ripening crops ought in dull wet weather to have fire-heat turned on, and a little front and top air left constantly on. Anything approaching stagnation in the atmosphere may lead to either cracking and wholesale decay of berries or the loss of bloom. Should there be a sudden burst of sunshine, even only lasting two or three minutes, this when there is no top air on is quickly followed by condensation of moisture on the berries, and if trickling down is not prevented, disfigurement and early decay are inevitable. Houses with top lap ventilators are the easiest to manage, as these can be opened in all weathers. In the case of those with running sashes it is better to leave these a little way open, even if the rain water does run down the walls, than to run risks of cracking of berries or scalding. During dull weather especially, all the ripe Grapes should be gone over daily, and every cracked berry taken out. Muscats as well as Madresfield Court and Foster's Seedling are liable to crack badly, especially when the roots are principally or solely outside. If the cracked berries are left till decay sets in, then every berry that adjoins will most probably have to be cut out and the bunch be greatly disfigured accordingly. Inside borders must be kept constantly moist, and this may mean at times too

much moisture in the atmosphere for either ripe or ripening Grapes. It is advisable, therefore, to heavily mulch with clean strawy litter, this conserving the moisture in the border and assisting in maintaining a drier atmosphere.

WASPS AND INSECT PESTS.—Wasps are unusually abundant, and have already made a fierce onslaught on ripe Grapes. Taking all the nests that can be found will not as a rule greatly relieve the Grape grower, and if the attempt is made to exclude wasps by means of muslin, wasp-netting, or cotton blinds fastened over all the ventilating openings, much harm may result by the exclusion of air. In dull, damp weather not nearly enough air finds its way through wasp-proof nettings, and a moist, stagnant atmosphere, as already shown, may easily do more harm than wasps. The same objection holds good with regard to the old plan of placing the bunches in muslin bags. All that is really needed is to place a few drops of Davis' wasp-killer in some of the berries that have been partly eaten, and this will clear the house of wasps in a surprisingly short time. What is equally satisfactory, fresh relays do not put in appearance, and an occasional renewal of the syrup will keep the Grapes quite free of wasps. The value of this very old, but not very well-known remedy cannot be over-estimated. Red spider, as might reasonably be anticipated, is very troublesome this season. While the bunches are hanging thickly on the Vines nothing in the way of syringing ought to be attempted, and sponging the leaves is of little avail at this late date. If the hot-water pipes are well coated with a paint made with flowers of sulphur and either milk or linseed oil and then made thoroughly hot for two or three nights in succession, the fumes will greatly check the spread of red spider, and probably destroy the greater portion of them. If the precaution is taken of opening the house before the sun strikes on it, no harm will result either to the bunches or foliage, both of which are now sufficiently well matured to stand the test. After the bunches are cut, clear water from the garden engine or syringe may be employed forcibly on the foliage, but the simplest and most effective plan of getting rid of red spider is to well coat both the upper and lower surfaces of the leaves with flowers of sulphur. First, slightly reduce the laterals, also cutting away superfluous sub-laterals, and then well syringe the Vines with water, to every three gallons of which a double handful of sulphur has been added. A second application may be needed in order to well coat the leaves, and the house being set wide open the ripening of wood and complete rest will be ensured. Thrips are rather more troublesome this season than usual, and these while the bunches are hanging can be best got rid of by frequent gentle fumigations with tobacco paper. There must be no flaring of the paper nor any heated fumes, or the foliage will suffer. A mat suspended immediately over where the apparatus is set would act as a safeguard against sudden over-heating, but the latter should be prevented as much as possible. There ought to be no fumigation in houses where the Grapes are nearly or quite ripe, as the flavour is likely to be badly affected by it, but the thrips should have no mercy shown them after the house is once cleared of fruit, tobacco water being the best remedy then. Mealy bug should be kept down by means of frequent hunts for them, all that are found being crushed where they are. Bunches can be cleared of this pest with a syringe, or, better still, by being placed under a tap with a good pressure of clear water.

FIGS.—Early started trees will produce a third crop if need be, but this is working the willing horse too hard. Directly the second crop is gathered a light thinning out of the wood may well take place, and some attention be paid to the foliage. If infested by red spider, it should have a thorough syringing every evening or the sulphur remedy, as advised in the case of early Vines, may be applied. The house having been kept rather dry during the ripening period, the chances are the borders are now too dry. These should have a good soaking at once, a second dose being given if

the first fails to well moisten the soil. Set the house wide open, and the trees thus well rested will most probably be in good condition for starting afresh next autumn or winter. Successional trees in both heated and unheated houses are now giving ripe fruit, those from the latter being extra fine. In both cases there ought to be a good second crop this season, and will be, too, if the wood is kept properly thinned out and thinly trained. Ripening Figs are liable to decay prematurely in a close, moist house, and the only preventive is the maintenance of a dry atmosphere, fire-heat in moderation assisting if only both front and top air is left on during the greater part of the day and all night long. Closing somewhat early and distributing moisture about the house will tend to swell the Figs to their full size, but air should be given again in the evening. Never gather Figs till they are fully ripe, as they will not improve after they are pulled.

PRACTICAL.

PLANT HOUSES.

EARLY BULBS.—Both by the advance slips of the usual autumnal bulb catalogues and by the advertising columns are we informed and reminded that the first arrivals of Roman Hyacinths and other useful bulbs are to hand, and may now be had for first early work without any further delay. Too much importance cannot, in my opinion, be attached to giving early orders in any case whether extra early flowers are needed or not. I much prefer to have my stock in hand rather than to have to wait for it; besides which too much exposure in a shop or warehouse is not, in my opinion desirable. By securing the requisite quantity in good time, the potting or boxing, as the case may be, can at once be proceeded with in smaller batches rather than by putting larger numbers in at once. This is a better mode of regulating the supply than by either having to force too much, or, on the other hand, to hold back as an opposite resource. Where large numbers are required as a cut supply and pots are short, boxes as used for Celery or small bedding plants may be used advantageously; in fact I prefer them as a means of saving labour as well. My practice with Roman Hyacinths is to put about fifty bulbs into one of these boxes, and then place one in a little more warmth every few days so as to have the flowers quite fresh for cutting. They will in fact flower very well in a close frame up to the end of October without any artificial heat at all. Potting or boxing is better done every fortnight than every month; by this means there is no difficulty in regulating the supply. It is not often, unless in special cases, that large numbers are wanted at one and the same time in private establishments; it is rather a succession so as to prevent a waste of good flower.

Having secured the stock, the same should be kept in a cool and dry place, a fruit room being a very good choice. Rather than let the bulbs lie in the bags in bulk it is much better to spread them out in one layer only. Our earliest will soon be in the soil with the object of having them in flower by the latter part of September. As soon as boxed they will be placed in a cool, moist place for about three weeks with a very light covering of cocoa fibre. If frame room is abundant it is a very good plan to use sash, but the covering will need to be kept moist by watering. These bulbs are not at all particular as to soil. For my own part I do not favour a rich compost; it has a tendency to force leaf growth at the expense of the flower-spikes. A good choice is that which has borne a crop of Melons to which only a little leaf soil or spent Mushroom manure need be added, the rougher portions forming the drainage in lieu of crocks if Moss be short. Crocking in the usual way is a waste of time, Moss being infinitely better, affording both food and moisture for the roots. The same soil will also answer for both Narcissi and Daffodils as well as the first early Tulips. Each of these should be got forward without any delay, so as to obtain a good root action in advance of any attempt at top growth. Where pots are

used the same remarks apply as regards drainage and soil. I prefer, however, to use 6-inch pots in preference to smaller ones; these will hold five or six bulbs of the Roman Hyacinths, and others in proportion to their size, thus making a better display than in the smaller size.

PLANTED-OUT STOCK.—In more than one case the plants will have suffered with other things through the long period of drought. It is needful, therefore, to look well to their condition in this respect, for if the roots do not obtain moisture close home, they will go in search of it farther away, and this will be all against the plants when lifted later on. Plenty of water should be applied close to the stems, so as to keep the root-action there in an active state. These remarks obtain in every case where this mode of culture is adopted, whilst at the same time assistance by frequent syringings should be given when showers do not prevail to give this encouragement to growth as well as to keep down all insect pests. Pinching the growths in nearly every case will be beneficial. Bouvardias, for instance, should be kept stopped at every second joint to secure dwarf bushy plants. No strong shoots should be allowed to run away with the vigour which ought to be better distributed. Red spider will have to be looked after upon Bouvardias after the hot weather of late. Solanums planted out should be stopped as soon as a full set of berries is secured, and all future strength thereafter concentrated in the swelling off in good time of the fruit. Early matured berries are far better than later ones, lasting quite as long as the latter are ever required to do. Red spider here again may give trouble, so also will green-fly in all probability. Salvias will rather stand in need of a check than of encouragement to make growth; this where needful can be effected by thrusting a fork under the plants and lightly lifting them, which will induce more roots to push forth nearer home. Hardly any insects will trouble these plants unless it be the white fly. Chrysanthemums want much the same treatment as the Salvias, the former being given two or three pinchings, and the latter more in proportion, a pyramidal outline being a good form to aim at. Carnations for winter flowering now planted out should be kept in good shape by a few sticks and ties—more of the latter than the former by all means. Callas should have every encouragement given them both by a plentiful supply of moisture and by occasional applications of manure, soot being an excellent medium for keeping worms and slugs at a respectable distance. If these have been planted upon the level ground rather than in trenches, it will be a capital plan to hollow out the ground slightly around the base so as to direct more water there. If in a dry position it will be better to top-dress with a little manure around the plants. Where the leaf growth is advancing some support may be needful.

J. HUDSON.

ORCHIDS.

WE cannot at present boast of a good display of bloom in any of the houses, and one can appreciate the beauty and pleasant perfume of the flowers of *Cattleya Gaskelliana*, which now adorn the stages in the *Cattleya* house. Soon these will be followed by the even more lovely *C. labiata*. At this season, too, we look for a fair proportion of flowers amongst the few *Aerides* which bloom at this season of the year. Years ago we were well content with *A. quinquevulnerum*, *A. suavisimum*, and perhaps *A. alline*. The first-named, as it used to be grown in the collection of Sigismund Rucker at Wandsworth, under the care of Mr. Pilcher, some twenty-five years ago, was at that time the most esteemed in this genus. Thanks to the energy of Orchid collectors, the autumn-flowering *Aerides* of those days have been greatly surpassed by such beautiful species as *A. Lawrenceæ*, the most splendid species in this genus. *A. Sanderianum* is by some considered a form of this species, its principal point of difference being in the ground colour of the flowers, which is a yellowish fawn,

while *A. Lawrenceæ* has a white ground. This class of *Aerides* succeeds best in the East India house. They seem to delight in heat and moisture, but much depends upon the details of the treatment as to whether the plants will grow healthily and flower well or struggle on in indifferent health, an eyesore rather than a delight to their owner. First as regards the material they are grown in. Clean drainage is best, with 2 inches or 3 inches of live Sphagnum Moss on the surface, and this should be intermingled plentifully with crocks and a small quantity of broken charcoal. Any decayed material seems to be obnoxious to the roots of *Aerides* and *Saccolabium*, so that it is not uncommon to find nearly all the roots that have run into the potting material in a dead or dying condition, the plant being supported by the air-roots only. This will show how important it is that the atmospheric conditions be attended to. Messrs. Veitch state in their "Manual of Orchidaceous Plants" that *A. Lawrenceæ* is found in its native habitat in the Philippine Islands associated with *Vanda Sanderiana* and *Phalænopsis Sanderiana*. These three splendid Orchids have been found growing together on the same tree. This gives us some idea of the treatment they require, and one would suppose that the treatment best adapted to one of them will answer for all three. A too close and over-moist atmosphere may be injurious, and is probably the reason why these Orchids are sometimes affected with blackish spots and blotches upon the leaves which sometimes sadly disfigure them. Greater care is necessary in winter, as damp at that time is more likely to be injurious. *Burlingtonia candida* is a very pretty Orchid which may flower at this season as well as in April or May. It is a charming Orchid; its pure white flowers, with the exception of a stain of yellow on the lip, are elegantly poised on gracefully drooping racemes, and are delightfully fragrant. The plants should be kept free from insect pests, and do not let them get very dry at the roots even during the resting period; when growing, water freely. In the warmest house many *Cypripediums* are in flower, and amongst them hybrid forms are conspicuous. The handsome *C. superbiens* (Veitchi) still holds its own as being one of the most distinct and beautiful of the section to which it belongs. Our plants of *C. Lawrenceanum* are now in flower; it is very late for this variety. *C. grande* is also well in flower, and is a very noble species. We value all the *Cypripediums* that flower in July, as the blooms are long lasting as a rule either in a cut state or left upon the plants.

I ought to add a word about the treatment at this season of two of the most distinct and beautiful of the *Cattleyas*, *C. Dowiana* and *C. superba*. The former has a tendency to start into growth almost as soon as it passes out of bloom, but this is not only injurious to the plant, but may be the cause of its failing to bloom next year. A cooler, dry place when the plants are in flower may prevent this. The handsome *C. superba* is a more easily managed species if it is once established upon the root part of a stump of Tree Fern. I find it succeeds best suspended near the roof glass in the lightest part of the warmest house and freely supplied with water when in growth. In winter when the plant is at rest a lower temperature is best. *C. Schofieldiana* must not be omitted; it has been introduced recently, and is flowering in some collections; it should be kept at the warm end of the *Cattleya* house. These long slender-stemmed *Cattleyas* require rather more attention to keep them in a healthy condition than the *C. labiata* group. Cleanliness is of much importance, and care should be taken not to give them too much water, nor should they be allowed to become over-dry at the roots even when at rest, for they take some time to recover again if the stems are allowed to shrink. During the hot dry weather we have had it was to be expected that insect pests and other parasites would attack the plants, and we have been busy exterminating them with a sponge and warm soft soapy water.

Several kinds of scale have got upon the leaves of *Cymbidiums*, *Cattleyas* and many of the *Cypripede-*

diums, and much injury is caused to the plants unless they are removed as soon as observed. All these parasites are most active when the plants are in an unhealthy atmosphere. If we could give all the occupants of the various houses exactly the treatment they require, it might not be so difficult to keep them quite clean; but it is scarcely possible that in a large household of Orchids each one of them will be supplied with all the essentials requisite to keep it in rude health.

J. DOUGLAS.

ROSE GARDEN.

NOTES ON ROSES.

PERHAPS we never had so peculiar a Rose season as the present. Many varieties have come quite different to their usual form both in colour and perfume. Take Prince C. de Rohan and Prince Arthur as examples among the deep-coloured section. Neither of these has shown the deep maroon and intense scarlet generally found, nor have others of the same shades been any better as regards intensity of colour. General Jacqueminot seems to have completely lost the deep shading in the cup of its petals, and has produced blooms much more like those of Thomas Mills. A recent experience of "Rosa" on page 59 is more or less the same as my own during the present season. What with the early season accompanied by not a few frosts quite late in the spring, followed by a long spell of dry weather and a scorching sun, it is little to be wondered at that many Roses were unable to produce good flowers. All through February and March the prospects of a good season were favourable, but after that time things went from bad to worse, at least as far as southern growers were concerned. Insect pests of all kinds attacked the plants earlier and far more persistently than usual, while we have already had more than one disease that is generally looked upon as being autumnal. Teas and light coloured Hybrid Perpetuals were infested with thrips, not the small brown variety found in the greenhouse upon Azaleas, &c., but a much larger kind, almost black in colour. This little pest was one of the chief causes of so many soiled blooms being exhibited at the Crystal Palace show. Feeding upon the Rose petals this variety of thrips produces a greater show of injury than does the kind which feeds upon the under part of any foliage; in short, the black thrips gives the blooms an appearance of having gone through rough weather. Mildew also set in very early. We seldom get this disease out of doors until the first crop of bloom is realised, but this season many of my plants were much affected by it.

Here, in mid-Sussex, we did not have a shower for almost three months, and as this was at the time of year when showery weather is most wanted, it is not very surprising that our Rose season should have proved so very inferior to what was anticipated early in the year. Another peculiarity that I have seldom noticed before was the baked-up appearance the majority of the bloom buds possessed. This was more especially marked among the Teas and Noisettes, and as these usually form their flower-buds earlier than the Hybrid Perpetuals, and as we had some very cold nights, followed by bright and scorching days, I can only attribute this to the extreme changes in the temperature.

Since writing the above notes we are being favoured with a few very welcome showers; these will put colour and life into the later

blooms. It is surprising what a difference there is in such varieties as Xavier Olibo, Abel Carrière and Prince C. de Rohan upon a dull morning after a shower compared to the same and similar varieties upon bright and dry mornings. Even such Teas as Ethel Brownlow and Madame Cusin would appear to be quite distinct from the same varieties under different conditions. Fortunately, the present showery weather is causing Roses to break out into clean growth for autumnal flowering, and if it continues for a few days we may have a good late season after all. When a Rose has not been able to expend its strength upon early summer blooms, the same plant will often afford a most agreeable crop during late autumn, and I have great hopes of this being the case with my own plants.

RIDGEWOOD.

POT ROSES.

WHERE these are grown it is generally with the object of securing early blooms to come in a little before those of the Maréchal Niel and Gloire de Dijon when turned out into borders under glass. In order to secure this, it is necessary to prepare your plants during August and September. Those which have flowered under forced treatment during the past winter, and which have been stood out of doors for some few weeks now, will need overhauling very shortly. Having made growth from January onwards, they have had quite long enough to form sufficient wood for our purpose, provided the plants were properly treated and not allowed to become dry or starved at the roots. My own plants have been standing out of doors since the end of June, and are now a little more than three parts ripened. I am alluding more especially to the Teas, this being the section more generally forced; Hybrid Perpetuals are far more easily ripened. In the case of Teas and Noisettes in pots, we can seldom get the whole of their wood into a state of maturity. Even in the open ground it requires quite a long spell of frost to stop their growth entirely; therefore, one need not feel afraid to repot any of these sections when about three parts ripened, as they would never quite leave off growing if provided with water and kept from a series of hard frosts.

When a plant has been growing in a pot for two or three seasons, it is well to knock it out and remove as much of the old soil as possible, even if it be placed in the same pot again. It does not much matter about a few of the roots being torn off, although, of course, it is much better to avoid this as far as possible. When Roses are lifted from the open and transplanted, it is absolutely unavoidable to injure many of their roots. A fair amount of healthy roots able to work into fresh soil is all that is necessary.

COMPOSITION AND DRAINAGE.—These demand far greater attention than many amateurs accord them. Take the compost first. It is by no means necessary that the yellow turfy loam so often recommended be used; indeed, if used alone it is not sufficiently lasting in nourishing powers for pot Roses. The plants will root into it freely and grow on well for a time, but it is soon exhausted, and unless we add some other constituents, repotting is necessary annually. This is my favourite compost: Good loam one third, thoroughly decayed vegetable refuse one third, road sweepings and manure making up the remainder. Add to this a few half-inch bones placed near the bottom of the pot, and you have a lasting compost that is capable of supporting your plants better and longer than if all maiden loam were used. It does not much matter what animal manure is used, but if stable manure be chosen, it should be well decayed, or it is apt to leave your compost too loose as time goes on. Pot firmly and pay particular attention to getting the soil well worked in among the roots. Nothing can be worse than having the roots cramped, or in a bunch towards one side of the pot. Always endeavour to get the plant a little deeper into the soil than it was before. Pot plants depend more

upon the sucker-like growths breaking from their crown than upon wood produced higher up, and these should be encouraged as much as possible. The drainage must be thorough, as when in full growth Roses require a lot of water, and the soil must never be allowed to become sodden.

After potting, stand the plants on the shady side of a hedge or wall, and do not neglect to afford them frequent sprinklings overhead two or three times a day during fine weather. This will guard against the wood shrivelling, and will also prevent the same from drawing all of the moisture from the roots for a short time.

At the end of September the roots should have made considerable progress in the fresh soil. The eyes upon the matured wood will have plumped up and be ready to break into new growth as soon as placed under cover. It is not a good plan to be too hasty in introducing the plants to heat, but they may be pruned now and stood in a close pit or frame for a time. Do not keep the pit shut up close and allow full autumnal suns to shine on it. This would cause a most injurious rise in the temperature. On the other hand, the plants should not be much shaded. Little pruning is necessary, simply cutting away weak growths and shortening back the stronger shoots to 1 foot or 2 feet according to the strength of each variety.

The above notes on the pot Roses are not intended to apply to such strong growers as Maréchal Niel, l'Idéal, and similar kinds. These need quite different treatment, and should never be disturbed at the roots after growth is completed, spring being the season for potting extra vigorous growers, and which bloom early upon the long rods made the previous summer. My notes are for such varieties as Catherine Mermet, The Bride, Dr. Grill, Mme. Falcot, Souvenir d'un Ami, &c.

P. U.

Tea Rose Narcisse is very charming this season. It has bloomed profusely from early summer and shows no signs of giving out, although many Teas are not in the best condition at present. The flowers are full and white, touched with pale yellow, not self yellow, as described in some catalogues, whilst there is a delicate fragrance. It is strong in growth and its freedom is a marked characteristic.

Rose Louis van Houtte.—In your "Notes for the Week" of July 15 (p. 44) I notice a statement concerning this fine Rose which quite took me by surprise, and for which I should need some further corroboration before I gave credence to it, viz., that it is a sport from Charles Lefebvre. I doubt it for the following reason, that the shape of the flower is quite distinct, whereas generally, if not always, in the case of sports the same form is maintained. The habit of the plant also is different, and I should therefore be extremely obliged if your correspondent would inform the readers of THE GARDEN what is the authority for this statement.—DELTA.

Tea Rose Princesse de Sagan.—This has been very beautiful lately, the flowers of a decided and striking colour, like a piece of rich crimson velvet. The plants are on a very clayey slope, and their satisfactory state shows that the constitution of the Rose is good. These red Teas seem to come very near the monthlies, but this kind is a precious and most desirable one.

Banksian Rose.—It is pleasant to read such interesting notes as that from Mr. J. B. M. Camm at p. 499 on a "Garden at Bournemouth." Mr. Camm remarked that the Banksian Rose and also the Clot of Gold refused to bloom in this garden. Probably Mr. Camm may be glad to hear that the former used to bloom most profusely many years ago on the south wall of a house known then under the name of The Firs in Christchurch Road. I well remember some twenty years ago seeing the south of The Firs covered with the blooms of this fine climbing Rose. It was planted on a terrace which ran along in front of the house, and had grown so freely that the stem was larger than a man's arm. No doubt the warm, dry, sunny situation

favoured its growth. An old plant of Cloth of Gold growing against a south wall in the gardens here blooms very freely.—JOHN CROOK, *Forde Abbey*.

THE ROCK GARDEN.

ACCESS TO ROCKS AND PLANTS.—I.

HOWEVER well a rock garden may be arranged, and however picturesque it may be, a great deal of the charm would be lost unless ready access can be had not only to the principal features of the work, but also to every plant used for the adornment of the rocks. The various means of approach to the different parts of the rock garden are—

- (1) Paths.
- (2) Steps.
- (3) Bridges.

(1) PATHS.

Without a path no garden could possibly be enjoyable, and least of all a rock garden, where we desire not only distant effects, but where some of the gems of the mountain flora used for adornment are so minute, that they would have to be inspected very closely to be appreciated. The necessity of such paths, however, does not imply that our rock garden should be dissected by a series of paths in the ordinary sense of the word, viz., more or less regular gravel walks. Such an arrangement would here be out of place even when the paths are not formal, but winding and irregular. There might be a broad, convenient main path either leading through or around that part of the grounds which contains the rock garden, but the paths required among the rocks should be of quite a different type. Here well-trimmed grass margins are not appropriate if the work is to represent the wild character of real rocks. But the margins might consist of a naturally short sward, such as we find on the moors, and be allowed to grow much as it pleases. All kinds of bulbs and alpine plants would grow in such a margin, and, if well selected and arranged, form a very attractive feature. This grassy margin should, of course, not be continuous, but be broken here and there by bolder masses of rocks and also single stones protruding from the surface. A pretty example of this kind is furnished by the accompanying engraving (No. 1), showing a path with irregular margins in the rock garden at Windermere.

Such a path need not be of even width throughout, and if it were made with stones and gravel, the latter need not be spread too evenly, but between the smooth parts intended for walking upon, rougher portions showing a more stony surface may be left here and there. These spots will be found an admirable home for many plants which it would otherwise be difficult to grow. *Linaria alpina*, *Erinus alpinus*, many of the neatest kinds of *Sedum*, *Sempervivum*, *Saxifragas*, and other lovers of stony soil would soon become established in such a place, and might easily be kept in such limits as not to be actually in the way, but enable us to use the path without treading on the plants. If plants of a particularly rare or beautiful kind have thus become established in a path, it may sometimes be advisable not to check their growth in any way, and in such a case it would be best to introduce a few flat stepping-stones here and there, which would admit of easy access without the danger of the plants being crushed by the feet of visitors to the rock garden.

A path like the one just described might branch off from a main walk leading to other parts of the garden, and by winding in and out

among the rocks would form an easy means of access to the main features of the work. But if the rock garden is of considerable extent this winding and irregular branch path itself might again be considered a kind of main path from which other bye-paths of an entirely different character branch off and admit a closer inspection of the various details of the work. Our means to effect this purpose are—

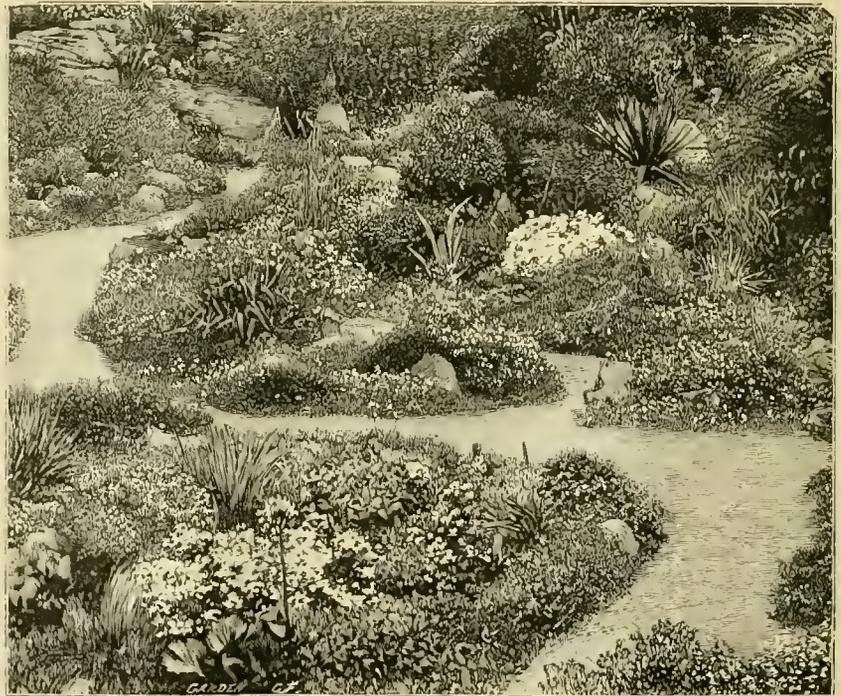

- (A) Rocky Paths.
- (B) Desiccated Streamlets.
- (C) Grass Paths.
- (D) Moss Paths.

In a rock garden on a large or small scale these various means of access can be so amalgamated that in going to any particular part of the work we should have to traverse three or four different kinds of paths without being aware that we are really walking on any path at all, and this combination should look accidental rather than intentional. It is this variety which gives a charm to the work, and will increase its

tion as the rock adjoining it, so as to appear as a continuance of the same block of rock. It may be desirable to introduce a step here and there to overcome the difficulty of varying levels, but this is an advantage rather than otherwise, and if well done will only increase the natural appearance. It goes without saying that such a rocky path should be bare only in the places actually required for walking upon, and might otherwise be planted in every fissure with plants of the same class as those clothing the main body of rock of which the rocky path is to appear as a part.

(B) THE DESICCATED STREAMLET.

As its name implies, this should resemble a dried-up streamlet, which is doing duty as a path. I have used this kind of path in many of my own works, but have never seen it elsewhere, though it forms an easy and effective means of variation. I form this supposed bed of a streamlet in precisely the same manner as

No. 1. Irregular path in rock garden at Windermere, the plants used as edgings allowed to grow naturally.

realistic appearance. As I have often introduced the kinds of path here enumerated with very successful results, I will here add a few words anent their construction.

(A) THE ROCKY PATH.

This, I think, should be an easy path to walk upon without having the appearance of any path at all, and if well constructed it should resemble natural rock fit to be walked upon without showing in any way that it was formed by artificial means. Covering the part intended for such a walk with flat stones, and then fixing the latter so as to be firm in the ground is an easy matter, but it is not so easy to make a path thus constructed harmonise with the rocks surrounding or adjoining it. In order to look perfectly natural, a rocky path must appear part of the rock itself. It need, therefore, never be of any great length, but might cross or continue paths of another kind, such as a Grass path on one side and a winding gravel path as described above on the other. If the rocks are constructed with stones of the stratified order, the rocky path should show precisely the same stratifica-

I have already described when speaking of streamlets for running water. But as this is not intended to hold water, the coating of concrete need not be so thick, neither need so much cement be used in proportion as in the construction of streamlets proper. All that is required is about 3 inches of concrete of sufficient strength to keep the stones and gravel with which this bed is to be covered in place. The stones used for this purpose should be waterwashed, i.e., rounded in shape, and if such river pebbles are not obtainable, pebbles and shingle from the seashore will do equally as well. The stones and gravel which are to form the bed must of course be put in place while the cement concrete is still wet, when a gentle pressure will be quite sufficient to ensure their being firmly secured as soon as the cement has become hard. Care must be taken not to have this operation performed in a slovenly manner, as otherwise the first shower of heavy rain would wash away the smaller particles of sand and gravel, with the result that hideous patches of bare cement would be

exposed to view. The larger stones are put at the sides and in the bends of the streamlet, just where in the natural course of events the water would have deposited them, leaving the middle comparatively smooth, forming a winding, but comfortable walk apparently formed by Nature. It might be so arranged that this water-bed can be utilised on rainy days as a convenient channel for draining off any superfluous surface water.

Such a path, if made with a little forethought and taste, will look perfectly natural, and will at the same time be found very convenient; but I think it most suitable for a rock garden on a large scale, where it might be joined by other grassy or mossy paths, which would enhance the realistic effect. The parts requiring most care in the construction are the beginning and the end of such a path. If the rock garden contains water, the best plan would be to make this dried-up streamlet appear like a former

fairly explain my meaning. Here an ordinary gravel walk traverses the rock garden, but the details of the work, such as the little bog bed in the bottom corner on the right, or the larger rock beds on the left side of the main path, can be closely inspected only by using the grass paths surrounding them. The combination of a grass path with a rocky path or with a desiccated streamlet, such as described above, is very effective and most natural in appearance when properly blended.

(b) THE MOSSY PATIL.

This kind of path is to be recommended for such parts of a rock garden as are densely shaded, perhaps, on the north side of massive rocks or by flowering shrubs, for only in a very shady situation can a mossy path be a success. The Moss has the advantage of looking fresh and green where little else would grow, forming at the same time a soft velvety carpet to walk

here in a sunny spot where the persistent sun of this year was on them till at least 7 p.m., yet they always closed up in their very complete fashion soon after mid-day. It is disappointing after seeing them very radiant to bring friends to survey some apparently withered stalks in the afternoon. I notice that if it should be cloudy about noon they do not shut so early or with the same uniformity.—W. D. R. D., *Castle Douglas*.

CHRYSANTHEMUMS.

SUMMER WORK AMONG CHRYSANTHEMUMS.

THE very hot and dry weather of the past few months is likely to be remembered by cultivators of this flower, more especially by those who grow the Chrysanthemum for the production of specimen blooms. As regards the growth and present look of the plants, there is little to be desired, the wood being firm and the leaves of leathery texture. But it is in the matter of flower-buds that our ordinary calculations have been upset. Buds that would not in most seasons come before well on in August appear a month earlier, and from my own observation growers are not a little puzzled as to what is best to do. There is an idea that the crown bud must be secured regardless of time and season. An idea prevails, too, that a plant grown on, unstopped only by Nature, produces but one crown bud during the season, and that on each of the three or more shoots selected on one plant. Now, a crown bud to me means a flower-bud which is surrounded by a cluster of little growth-shoots, not other smaller buds which accompany terminals later on. I find then a goodly list of well-known sorts that in a hot season like the present will give two and three distinct crown buds before the growth has finished. Vivian Morel, Wm. Tricker, Etoile de Lyon, Edwin Molyneux, Sunflower, G. C. Schwabe, Louis Behmer, are all fair examples. But the question is, which one is it safe to secure so that a perfect and well-developed bloom may result? A good rule is not to take a bud before August for November flowering. The earlier crown buds will, however, produce early blooms of extra size, but not shapely, and comparatively colourless. It is perfectly safe then to pick out the early buds and allow the plant to go on in its growth again in the case of those I named and by far the greater number of the Japanese kinds, but I will mention a few sorts that should have their flower-buds secured if they show even a week or two before August. The recently-introduced Charles Blick, G. W. Childs, Primrose League, Robert Owen, Robert Flowerday, Lord Brooke, Ruth Cleveland, and the better-known Mlle. Marie Hoste, M. Bernard, Alberic Lunden.

It is, however, the incurved varieties that are so unusually erratic this year. I saw at Reigate the other day in the collection of a large grower for exhibition such kinds as Lord Alcester and Empress of India producing flower-buds about every 6 inches of the shoots' growth. The cultivator was attempting to get the plants out of this habit by feeding them. The altered weather and genial showers of the past week or so will, I hope in his case as in my own, cause a free and healthy growth out of this budding state. Safe, though, it is to advise anyone not to allow flower-buds to remain on the plants of the sorts of which the above-named are types, for they seldom reward the owner with a good bloom taken before the middle of August. In fact, with any kind of incurved Chrysanthemum

No. 2. Ground plan showing irregular grass paths in rock garden branching off from main gravel walk.

tributary to a pond or streamlet; but if there is no real water, it might be made to vanish beneath some rock, giving the idea of having been continued underground. The beginning of such a path is perhaps best indicated by a cleft in the rock, the end of which cannot be seen (such as described in the last chapter on caves), and which would convey the idea of the "streamlet" having originated from a spring among the rocks.

(c) THE GRASS PATH.

This is best described as an irregular expanse of grass intervening between groups of rocks, and so arranged as to allow ready access to rocks and plants. Stones might project from the surface here and there at irregular intervals, but there should not be too many, as in order to form a convenient path the grass would have to be clipped frequently, and too many stones would seriously interfere with that operation. The second illustration (No. 2) will

upon and creating a pleasing variety in the rock garden. The mossy path might be further varied by being crossed by a rocky path here and there, or by being connected with a grass path or rocky steps leading to other parts of the work. About its construction little need be said, except that it should be as irregular as possible, and that in choosing Moss from the woods the short velvety kinds should be selected and carefully taken up in large thin pieces with earth attached. Somewhat heavy soil is best for a mossy path, and this should be loosened and well watered before the Moss is laid on and gently pressed down.

Exeter.

F. W. MEYER.

(To be continued.)

Commelina cœlestis has been flowering very abundantly this year, and is certainly of a very lovely blue. Its very "early closing" habits, however, are rather against it. There are several plants

I know this time is too early to secure its flower-buds; therefore, it is advisable to pinch them out if they appear. There is a point in connection with picking off superfluous shoots that needs attention this year on account of blind shoots being only too common. That is, if only one is wanted, allow two to grow an inch or so till it is certain a perfect point may be had to go onwards.

Insect pests have been with us in great number and variety, and I fancy earwigs are the cause of more blind shoots than are attributed to them. This pest is easily caught. An old plan is to place lengths of the stem of the Broad Bean among the leaves, and the enemy may be caught hiding in the hollow part. Pieces of paper squeezed in the hand and then placed among the leaves make capital traps if the above cannot be had. Examined each morning, hidden among the crevices many earwigs may be found. The insect most deadly to Chrysanthemums is what I take to be the spittle-bug in its small state. Its whereabouts may be noted by the tender tip of a shoot flagging when the sun is upon it, and if examined the same is flaccid and lifeless. A light green-winged fly with long legs will come from among the leaves, and either quickly run down the stem or fly away. It requires a very quick finger indeed to catch them. They curiously seem partial to certain kinds, for instance, varieties of the Queen family, Sunflower, Etoile de Lyon, Mlle. Marie Hoste, Lord Brooke, Edwin Molyneux, John Shrimpton, Anna Hartshorn. I should like to know if other growers are troubled with this. Certain I am that many attribute the work of this insect to thrips. Thrips is damaging, and it is advisable to dust the young flower-buds and shoots with tobacco powder occasionally when the weather is dry, for an atmosphere that is at all damp is unfavourable to this small pest. The leaf-mining fly has this season been less troublesome than usual, which is somewhat remarkable.

Feeding the plants with stimulants is a subject of some moment at this time of the year, being a thing that is much overdone. I cannot understand why the Chrysanthemum is a plant requiring in the eyes of so many persons such a vast quantity of the good things of plant life. An instance came to my notice a short time since. An amateur grower was with pride relating to me the size in inches of the leaves and stems of his plants, which certainly appeared remarkably large. On asking him if they had been assisted with manures he gave me quite a list of artificials he had used, besides employing 5 cwt. of bones in various forms to pot 300 plants, and this early in the month of July. Now I venture to say that a very great proportion of the blooms exhibited at our autumn shows come from growers who are very cautious indeed in the matter of feeding. Mr. Mease, of Leatherhead, whose flowers last season were the admiration of all who saw them, thinks that more failures in Chrysanthemum culture are due to over-feeding with manures than from any other cause. Carefully read the writings of another past-master, Mr. C. E. Shea, and note how comparatively little feeding with stimulants is recommended. Overfed Chrysanthemums are large in growth and leaf, but I should not be led away by them, as neither are solid. It is, however, perfectly safe to use soot water when the pots are well filled with roots. This gives to the leaves a healthy colour. It may also be syringed over the plants with the same result. Where top-dressing the plants is carried out it may now be done. I never favour the practice, because with the new soil on the

surface it is a most difficult matter to know if a plant is dry; the top may be moist and the harder soil below may become so parched as to cause damage to the roots. But sprinkling the surface of the soil with some fertiliser is a different matter, and is very beneficial when the flower-buds are swelling. As I have tried to point out, err on the side of weak quantities of these stimulants and depend more upon constant attention to watering and other daily details than upon any particular plant food to bring success in the autumn to a year's work.

H. SHOESMITH.

FEEDING CHRYSANTHEMUMS.

HAVING settled the time when Chrysanthemums require the addition of stimulating food to the ordinary soil in which they are growing, the next point is to consider what sort of food should be given and how to apply it with the greatest prospect of benefit to the plants. Every grower of experience has his particular feeding material, and no doubt in some instances with very good reasons. A judicious course of feeding the plants after they have exhausted the nutrient contained in the soil in which they are growing is a decided advantage, but there is another aspect to the affair that should not be forgotten, viz., that of overfeeding the plants. Some growers (inexperienced) think that if one dose of any particular form of manure given to the plants has a marked effect upon them, surely a double dose must have a beneficial influence on them also in the same proportion. Now this is a blunder which all ought to avoid, and I would specially caution beginners in this abuse of what might be the means of doing much good, but which is often turned into positive harm through the cultivator being over-zealous. Overfeeding is not only the direct means of causing much annoyance by the damping of the blooms, but it causes premature and abortive blooms, which only lead to disappointment. When plants are overfed, the roots are gorged beyond their powers of assimilation and ill health most assuredly follows.

The best kind of food to supply to the plants then is our next consideration. The cultivators of the present day have a much more extended list of kinds of manure to choose from than the growers of but a few years since, but whether the results obtained are in proportion is a point that I am not going to settle. If the various chemical manures now so largely employed are not infinitely superior to pure animal manures employed solely by former cultivators, they have the advantage of being so much more easily applied. Certainly artificial manures have the great advantage over animal manures that the plants can still be supplied with food even in continuous showery weather, even though they do not require water given to them artificially over a lengthened space of time. By sprinkling a small quantity on the soil when rain is falling it is gradually washed down to the roots, and the plants are benefited thereby. Even when animal manures are used largely a change to artificial cannot fail to be advantageous. While not pinning my faith to any one particular kind of food, I am positive that used with care there are a number that may be employed advantageously. The great point to observe is change of food; too much of any kind at one time is injurious to the plants in the same way that it is to individuals; they become so accustomed to it that it ceases to be of any value. A change of food is then most essential to obtain the greatest success.

Various kinds of liquid manure, such as the drainings from the cow houses and the stables, are excellent; I prefer the former, as being cooler. Where liquid manure cannot be had direct from tanks, a very good substitute may be had from a heap of manure by throwing clean water over it, allowing it to soak through the manure, and collecting it in a pit at the side of the heap. Sheep manure gathered fresh from the fields, the droppings from deer, and cow manure direct from the pens make excellent stimulants if managed properly. If water is added to any of these manures and used directly in a thick state, the sediment remaining on the top of the soil seals at once the passage way for future watering. Manures of this kind should be placed in a bag to prevent their dissolving and mixing with the water, thus rendering it thick. Place the bag in a tub or tank of water, allow it to soak for a few hours, when the water will be ready for use, and by moving the bag about in the water occasionally a regular supply may be maintained until the qualities of the manure are exhausted. Soot is almost indispensable to the growth of Chrysanthemums. Applied in a liquid form it soon produces a change in the colour of the foliage of pale-looking plants. Some place a quantity in a water-pot of water, stirring it to dissolve it, then pour it on to the soil in the pots; but this is wrong for the same reasons that using liquid manure in the same way is wrong.

The correct method of using soot in a liquid form is to place it in a bag. One bushel of soot in a bag will be ample for 100 gallons of water, and will last a long time along with other manures. It is much better to give soot weak and often than injure the roots of the plants by strong doses. I have seen plants denuded of their foliage half way up the stems through the misuse of soot.

It is not possible to define the quantities of manure to a given quantity of water. No one can make a mistake if the liquid made from animal manures is about the colour of brown brandy when diluted and fit to give to the plants. Night soil is undoubtedly an excellent stimulant; its smell is, however, objectionable in some instances. The best way to use this is to mix it with an equal quantity of dry, finely sifted soil, and apply it as a top-dressing. The roots quickly find their way into it, and show by their increase that it is appreciated. Bones supply phosphates to the plants which assist maturity of the wood, and without this latter all the time and cost incurred by the cultivator will be lost. Bones, however, in large size are not to be recommended as a direct stimulant, because they cannot give out their properties quickly enough, except when employed in dust form. Bones dissolved by the aid of sulphuric acid I find are best for plants growing in heavy and somewhat retentive soil. Those ground up finely to a powder and used without undergoing any chemical process at all I find are apt to give the foliage that pale hue which is not so pleasing to the eye as when densely green, especially if the weather throughout August is inclined to be showery. This is not mere supposition regarding the different action of the two forms of bones upon the plants, but is the result of practice over several years with them. The two kinds of stimulants that act the quickest of any on the leaves of Chrysanthemums are nitrate of soda and sulphate of ammonia, both very good aids when employed judiciously, but the reverse in careless hands. The former I dealt with in THE GARDEN of July 8; therefore it is not necessary to repeat what I there said, but simply to emphasise the method of its employment

and its beneficial effects in the purpose for which it was employed. The latter in careful hands provides the best of food for *Chrysanthemums*. The percentage of ammonia, however, contained in the different samples varies so much, that it is decidedly risky to use when obtained from various sources. The great point to observe in the employment of sulphate of ammonia is to be certain the plants are sufficiently well rooted. It is in neglecting this that so much danger is incurred. Some growers sprinkle the ammonia on the surface of the soil and water it in, but this is dangerous to the surface roots of the plants. I have seen the roots killed fully 2 inches down the pot through no other reason. The best way to apply sulphate of ammonia is in a liquid state. Commence by dissolving a quarter of an ounce in one gallon of liquid manure, increasing it gradually until half an ounce is reached, applying it once a week. The alteration in the colour of the leaves after its application can be quickly discerned if they were pale before. The main veins or arteries quickly assume a deep green, which rapidly spreads all over the leaf. The colour of the blooms is much improved also by the use of this manure.

Feeding the plants should continue until the blooms are three parts developed. It is while the petals are expanding and growing that the plants need assistance, although some persons assert that directly the colour of the blooms can be seen feeding should cease. Variety in food is what is required. Give a course of animal manure for, say, a fortnight, then a change to some approved form of chemical manure. Occasional doses of clear lime water will be of great benefit to the plants where lime is not naturally contained either in the soil or the water. It is a good plan to cease feeding for say a couple of days at a spell, supplying the roots with nothing beyond clear water with a view of purifying them, so to speak, and to enable them to more readily assimilate whatever food is given the plants through the roots. Some care is necessary in dealing with weakly growing sorts. They ought never to be subjected to such treatment as is accorded to strong-growing kinds like *Etoile de Lyon*, for example. Far better err on the side of weakness in the food. Seldom indeed do such varieties as *Mrs. Alpheus Hardy* benefit by the application of artificial food.

E. MOLYNEUX.

KITCHEN GARDEN.

WINTER SPINACH.

Not till young gardeners have known what it is to have a complete failure with winter Spinach, and also to have been once in a position to meet all demands for this winter vegetable, do they fully realise its value. Even then it is doubtful if proper steps are annually taken to guard against another partial or complete failure. Spinach is both a wholesome and a high class vegetable, added to which it is harder than most other kinds that are available during the winter. Broccoli, Savoys, Cabbage may be greatly injured or killed outright, and even Brussels Sprouts and Borecole badly crippled by frosts, and yet the Spinach survive apparently uninjured. Nor does it seem possible to grow too much for some establishments, and, all things considered, no crop gives better returns. Instead, therefore, of its being treated as of secondary importance, and its culture of a haphazard description accord-

ingly, the greatest pains should be taken with it. Since I have become fully alive to the value of this vegetable, a good breadth of ground has invariably been set apart for it early every summer.

It is immaterial which or what kind of crop it follows, but it is of importance that rather high or well-drained ground and a fairly open site be selected. This in my case is not out of the question, and as early in July as possible a liberal dressing of manure is wheeled on, spread and dug in. The ground being laid up roughly to the sunshine, it quickly becomes baked through, and directly a good soaking rain falls, what lumps there are are broken down and a surfacing of either soot or lime, which ever is most needed, forked in, a second fining down and forking over, though not deep enough in either case to reach the manure, being given should the opportunity occur. These proceedings are considered necessary both to purify the ground and for getting rid of grubs, and also because they admit of the seed being sown at the right time, let the weather be what it may. If those in charge of somewhat heavy land delay preparing this till near the time seed ought to be sown, it is scarcely possible to get it into condition, and a failure, either from too long delay in sowing or from the lumpy state of the ground, would most probably result. The manuring and purifying are also desirable in the case of lighter or free working soils. In the more northern or colder localities generally the end of July or first week in August is none too soon to make the first sowing, but in more favoured localities from August 10 to 14 is usually soon enough.

In any case a second sowing ought always to be made. There is just a possibility of the first sowing running to seed prematurely, or if it succeeds well, then the richness of the ground may promote a too luxuriant growth for hardiness to be certain. Ground is usually well manured for summer Cauliflowers and also Peas, and either of these crops would leave plenty behind to sustain Spinach. If, therefore, such ground is got into a free working condition, a light surfacing of lime not being wasted, and the seed sown about a fortnight later than the first sowing, or at any rate before August is past, there is every likelihood of a serviceable lot of Spinach being obtained. These late sowings would scarcely afford pickings during the winter, but the Spinach would grow strongly early in the spring and continue to do so till the spring sown rows were fully grown. On rich, well-prepared ground the seed should be sown in shallow drills drawn 15 inches apart, but if the ground is somewhat poor and, also when the seed is sown late, a distance of 12 inches apart is enough. If the seed is sown during dry weather, and it is unwise to wait for rain, then ought the drills to be watered prior to sowing the seed. Thin sowing is recommended, especially when the ground is in excellent condition for the crop, having to thin out severely greatly disturbing what plants are reserved. The seed not coming up very thickly, the first thinning-out may well be deferred till the thinnings are large enough to send to the kitchen, finally leaving the plants about 6 inches apart. All that is usually further necessary is to frequently stir the ground between the rows with a Dutch hoe, hand-weeding being also resorted to when weeds come up in the rows. The leaves required for use during the late autumn and winter months should be gathered carefully.

As already pointed out, I experience no difficulty in growing winter Spinach, but others that do, owing to the coldness of their garden, ought to resort to the good old plan of sowing

on raised beds. Some of the very best crops of winter Spinach I have ever seen were grown on raised beds in a garden where previous to the adoption of this plan failure always took place. A good open position was selected, and a space 6 feet wide and about 30 feet long pegged out. The best of the top soil was thrown out on both sides and a liberal dressing of manure forked into the trench thus made. Some nearly rotten manure, burnt soil and ashes from a garden smother, and any light fine soil available were then well mixed with the top soil as it was returned to its original position. Should there not be time for this bed of soil to settle considerably before the time arrived for seed-sowing, it was heavily trampled when in a dry state, the surface being re-loosened with the aid of a fork. Four rows of Spinach were found enough for these well-prepared beds. The Spinach alone repaid for all the trouble taken, but after it was cleared off a very little freshening up rendered the bed very suitable for Asparagus, which, I believe, was often planted by my friend in succession to the Spinach.

Old writers state that the prickly-seeded or winter Spinach is the hardest, and advise that this only be sown. Of late years, however, it has been repeatedly proved that the round-seeded or summer Spinach is quite as hardy as the foregoing, and is now quite as much sown. *Victoria* or *Monstrous Viroflay* is a decided improvement on either form, the leaves being considerably larger and more succulent, hardiness being about equal. During the winter before last, *Victoria* far surpassed the round-seeded, but curiously enough did not do so well last winter, being somewhat disappointing in fact. This points to the necessity of growing both forms, and is one more proof of the unwisdom of too hurriedly discarding well-tried old favourites. M. H.

Winter Lettuce.—In providing a supply of winter salading, it is very essential that Lettuce should have the foremost place. At this season of the year there is generally ground at disposal which might well be turned to account in providing a good supply of plants, and although in all cases it is not convenient to provide glass accommodation for the protection of the plants in case of severe frosts, yet more might be protected than there generally is with mats and oiled canvas covering. From the want of a little protection many a fine lot of plants has been completely spoiled, and which might with a little forethought have afforded good Lettuce for a month or two longer. This is more apt to occur with those which are planted over a considerable extent of ground. For this reason I much prefer to arrange the plants in beds, as with these there is but little trouble or material needed when the time comes for protection. Only growing sufficient plants for lifting and planting in frames is not a wise proceeding. Where movable frames are at disposal, the space these would occupy should be marked out before the plants are taken from the seed-bed, and into this space marked out set out the plants. When the time comes for protection, the frames are easily placed in position, and I find the plants so prepared keep much better than lifted plants. There are two or three well-tried old kinds that are particularly well adapted for winter. These are, amongst Cabbage forms, *All the Year Round*, *Stanstead Park* and *Hammersmith Hardy Green*. The *Cos* forms are *Hicks' Hardy White* and *Black-seeded Brown Cos*. From seeds sown now good plants should be forthcoming at the approach of winter or the latter end of autumn, suitable for removing into frames if so desired, or to be protected where grown. The young plants there should have ample room for development, as drawn plants, such as to be had from a crowded seed-bed, will not make good-hearted Lettuces. I have also noticed with these weakly, drawn-up Lettuce plants that

slugs and birds attack them sooner. A border well open to the sun should be chosen for the seed-bed, as the season is now past when Lettuces need to be raised on cooler sites. The soil must be well pulverised, and a little leaf soil and burned refuse will be found good material for dressing over the site if not in a good condition. The seeds should be sown in drills, arranging these 1 foot or 15 inches apart. By the time the little plants are ready, the weather will be quite genial enough for transplanting.—A. YOUNG.

Tomato Challenger cracking.—Mr. Young says with much truth that some varieties are more liable to cracking than others, and with favourable conditions in this respect Challenger, from the thinness of its skin, is certainly more addicted to it than many other varieties now in cultivation. I have had opportunities lately of inspecting some hundreds of plants of this variety in market establishments where no tendency to splitting of the fruits is known, and the variety certainly would not obtain such an extended patronage among market growers as it does were this failing common or unavoidable. There is no doubt whatever that the fault complained of is entirely caused by the treatment given, if not the fault of the cultivator. In the case of private growers the remedy is not always so fully under control, because the Tomatoes are treated so often as an accidental or catch crop, a few plants standing here and there wherever space can be found for them among, it may be, plants or fruit trees. The roof trellis of one of our houses is furnished with Cucumbers, Tomatoes occupying the back wall, at the foot of which is a narrow border very conveniently arranged for their accommodation. The Cucumbers as a matter of necessity claim the greater priority, the Tomatoes having to share the same treatment. Challenger, Perfection, and Early Ruby each occupy a portion of this wall, but the moist atmosphere constantly maintained, which is so essential for the healthy growth of the Cucumbers, causes the greater portion of the first-named sort to crack badly, the others not being affected scarcely at all in the matter of fruit cracking. In properly ventilated houses there is no reason for Tomatoes of any sort to crack, but in the moisture-laden atmosphere of fruit or plant houses where, in small places, they have of necessity to be grown this failing is common. A heavy watering following an over-dry state at the roots either in borders or confined in boxes or pots accounts for some fruit cracking, even should the atmosphere be dry and cool. Purposely avoiding extremes of moisture and drought will generally result in sound fruits, no matter what the sorts may be, but in warm and moist houses Challenger, according to my experience, is the most liable to crack.—W. STRUGNELL.

Peas and mildew.—Peas in these gardens grew with wonderful freedom during the spring, and indeed up to within a week prior to the time when the much-needed rain came. This was more particularly the case with the later summer and autumn Peas, but directly the rain and a cooler change of weather set in, mildew spread with alarming rapidity through almost every row. Calculation or "timing" of the various sowings this season is quite beyond the range of possibility. Those in our case intended for use in August are ready for gathering now and some are already gone. The crops at one time promised to be very heavy, but the long period of drought was too much for them, and now the chances of a continuous and late supply are almost beyond hope. I am afraid the mildew is so violent that there will be no chance, as is the case in some seasons, of obtaining a succession from rows having borne a premature crop. Last year I had quite as good a gathering from the second as from the first crop on some ranks which had been brought to a standstill from the dry state of the soil and the tropical heat, much the same as that which occurred this year, but with, of course, less severity, because of shorter duration. The best Peas both for vigour and productiveness in our case are those sown directly over the Celery trenches of last year simply filled

in and levelled down. No additional manure in any form was added either to the soil or as a mulching, and they evidently enjoyed the benefit of a deeply moved soil. These were the first victims to the disastrous influences of mildew, which was speedily transmitted to the whole of the adjoining rows of Duke of Albany, British Queen and other sorts intended for use during the whole of next month. Watering and mulching may have helped to carry them on more satisfactorily, but neither came within the chance of being carried into effect, for the simple reason that the material was unavailable for doing so. In some gardens mildew is always more prevalent than in others, and this garden seems peculiarly subject to it in a violent form. It is very disappointing, however, when the long-wished-for change of weather came, to find it should bring with it such direful consequences to the all-important vegetable.—Peas.—W. S., *Road Ashton.*

SOWING CABBAGE FOR SPRING USE.

IT may be considered a simple matter sowing seed for the supply through the early spring, but much depends upon the time of sowing, the state of the ground and the locality. So far the best Cabbage I have tried is Ellam's Early Dwarf. I am fully alive to the value of several kinds, but when one plants several thousands and finds one variety can be relied upon, it is well to grow that kind. I have named this variety in this note because by sowing an early or small variety one can make more than one sowing. Some may think it is not economical to do so, but it is especially if this sowing is practised and the planting done as soon as the plants are ready. In cold or late districts the seed should be sown the second week in July, and in a light warm position a week later. By sowing as advised, there will be plenty of plants for early planting and a good supply of Cabbage in the early spring. From the early sowing, that is in July, I select the largest plants and plant in rows 18 inches apart and half the distance from plant to plant. These occupy an open position, but sheltered from the east, and are large plants by winter. At times in severe weather they lose a few of their bottom leaves, but being moulded up well, they do not suffer much. These were ready the first week in April this year, coming in at a time choice vegetables were getting scarce. The smaller plants from the same sowing occupy an exposed position—that which has grown Onions, and the ground is also part planted with the second sowing, which takes place early in August, so that a succession is secured. One half the ground is heavily manured and the other merely cleaned, and in severe seasons there is scarcely any loss in the last-named, but the plants are later. With this vegetable earliness is everything, as at no season of the year is Cabbage more appreciated than in March or April. I have named March, as, given a mild winter, there is no difficulty in securing good Cabbage if Ellam's is sown as advised. When sowing the seed it is necessary to select ground in good condition and on the flat, so as to retain the moisture. I usually sow on a south border, but in such a season as this shall reverse matters somewhat and sow on a west one being cooler. It is also necessary to cover the soil with mats after sowing, having thoroughly watered previously, removing the covering as soon as the seeds have germinated. Only a small sowing is made this month, the larger one early in August, as this will give a large supply through May and June. By sowing twice and planting out the largest plants early there is a succession, as several plantings may be made later if desired in various positions. In gardens only requiring a limited supply two sowings are equally important, as should one run there is the other to fall back upon. In planting I prefer drills, as these retain the moisture. It is also important to plant early before the plants attain a large size and to plant firmly. It will be found advisable to prick out a good number of plants. When the planting is finished these may be placed

close together on a warm border or at the foot of a wall, and will come in useful early in the year to fill up the blanks in the beds, as in severe winters there will be some losses, especially among the late-planted lots. G. WYTHES.

VEGETABLE MARROWS.

SIXPENCE is the price asked by greengrocers for moderately sized Vegetable Marrows. It would be interesting to learn what is the original price obtained by the grower. The fact serves to show that our present method of disposing of vegetables to consumers is a cumbrous and costly one, and that for every penny paid for the article's production, a further penny has to be paid for its distribution. But it may be said that Vegetable Marrows should just now be realising a very good price, because as yet they are not plentiful, whilst Peas are pretty well over, though so early, and runner Beans are not yet much in evidence. It may seem odd that in a season when everything otherwise seems to be so unduly early these vegetables should not share in the general precocity, but both runner Beans and Marrows seem to have suffered from the drought, especially the former, for these made poor progress in their early stages of growth, except where watered, but that could only be done on a small scale, whilst the myriads of acres in the fields from which the markets are supplied could not be so favoured. Even in gardens where the Beans have been watered I have been surprised to find how comparatively late generally they are.

In the case of Marrows the chief reason perhaps, apart from the drought, why they are not, with so many other things fruiting early, is on account of the great risk to which the tender plants are subjected from late spring frosts. Few growers care to plant out large quantities earlier than the end of May or beginning of June; indeed, often the second week in June is reached before the plants are got out, and thus it is hardly possible for them to furnish fruits for cutting under six weeks. That there is no more profitable market period for Marrows than the month of July affords there can be no doubt, for whilst Peas are getting over and runners are not in, other vegetables are not abundant, whilst during August runner Beans are very cheap and plentiful, and in September there come in autumn Cauliflowers, and these are very formidable rivals to Vegetable Marrows. Thus it is that those few growers who got out plants early in May under hand-lights have exceptional opportunities to supply the July demand, and as the shelters, whether cloche, old-fashioned hand-light, or glass-roofed box, be materially enduring, they should doing some half-dozen years more than repay their original cost, especially that they may be used to protect Lettuces, Cauliflower plants, seeds, &c., during the winter months. It is very doubtful whether we make such complete use of protectors of this kind as they deserve, especially in the production of early Marrows, for whilst a good fruit may in July fetch from 3d. to 4d., perhaps more, in August smaller fruits may not realise more than from ½d. to 1d., and an entire van load comparatively a small sum. That is because everybody has Marrows in plenty, whilst only those who have cut early have made a profitable market. A. D.

SHORT NOTES.—KITCHEN.

Potatoes making a second growth.—A few days ago I went into a field where we grow Potatoes and examined them. I found that such late kinds as Magnum Bonum, Abundance, and others of this type had made shoots from the tuber 4 inches to 5 inches long, and in some instances they were forming a young tuber. This is not to be wondered at seeing how dry the soil had got previous to the rain.—J. Crook, *Forde Abbey.*

The best Cos autumn Lettuce.—No kind can, I think, equal Hicks' Hardy Cos. Now (July 20) is a good time to sow for autumn and early winter work.

Last year I sowed a patch at this season, and had good Lettuces up to nearly Christmas. It always plant some from this sowing early in September on a Vine border close to the front light on a raised ridge of soil which I put for them to grow in. Here they thrive grandly.—J. C. F.

SOCIETIES AND EXHIBITIONS.

ROYAL HORTICULTURAL SOCIETY.

The meeting in the Drill Hall, Westminster, on Tuesday last was much smaller than usual as regards the quantity of exhibits, but, as is often the case, novelties were plentiful.

Orchid Committee.

A first class certificate was given to each of the following—

CATLEYA CRISPA SUPERBA.—This is a well-named variety of *C. crispata*, a popular Brazilian Orchid, called also *Lælia crispata*. Two spikes were exhibited, one with eight flowers, which are large and beautifully coloured, the sepals narrow, and the broader petals wavy in character, of the purest white, with a much crested lip, deep purple, with a white margin, and in rich contrast to the other spotless portion of the flowers. It is a thoroughly useful Orchid, as much for its freedom as the exceptionally rich colouring of the flowers. From Mr. T. Statter, Stand Hall, Manchester.

MILTONIA VEXILLARIA DAISY HAYWOOD.—This is one of the most beautiful varieties that has appeared. It is a lovely acquisition to the many good forms of this Orchid already in cultivation. The plant shown bore a strong raceme of eight flowers, each of very large size, the lip measuring over 3 inches across and of the purest white, relieved only by a blotch of yellow at the base, whilst the smaller sepals and petals are slightly touched with rose. It is a superb *Miltonia*, the flowers, although of bold aspect and borne with great freedom, being quite free from any trace of coarseness. Exhibited by Mr. J. Salter, gardener to Mr. Haywood, Woodhatch Lodge, Reigate.

An award of merit went to each of the following—

CYPRIPEDIUM EDWARDI.—This is a beautiful hybrid, as one might expect with such parents as *C. Fairrieanum* and *C. Veitchi*. It was shown by Messrs. Pitcher and Manda, Hextable, Swanley, who have a thoroughly representative collection of *Cypripediums*. This hybrid combines the characteristic points of both parents, but shows, perhaps, a greater preponderance of *C. Veitchi*. The dorsal sepal is white, striped with deep crimson, the centre suffused with rich green, whilst the petals have the wavy character somewhat of those of *C. Fairrieanum*, the ground colour green, spotted with chocolate, whitish in the centre; the lip is light brown and green at the apex. Fortunately, the plant is of vigorous growth, the leaves marked in a similar way to those of *C. Veitchi*, but of a much deeper colour. It is a *Cypripedium* that, we should think, would get popular, and may rank amongst the finest forms of *C. Fairrieanum*.

CATLEYA HARDYANA (Tate's var.).—Everyone who cares for Orchids knows *C. Hardyana*, and this variety well deserves a distinct name. It is magnificent for colour, three flowers being exhibited. The sepals are rich rose-purple, the petals broad, wavy, and of a similar shade, but beautifully veined with white. The lip is far more intense in colour than that of the type, deep velvety crimson-purple, with a rich yellow eye-like blotch on either side of the entrance to the throat. It is nearly 3 inches across, wavy at the margin, and unrivalled for depth of colour. Shown by Mr. F. Billington, gardener to Mr. J. W. Lee, Audenshaw, near Manchester.

The groups of Orchids were not numerous, but well worthy of note. An interesting group, which comprised principally leading species and varie-

ties of *Cypripediums*, was exhibited by Messrs. B. S. Williams and Son, Upper Holloway. *C. Morganix* was finely represented. Also shown in splendid character were *Cypripedium Ashburtonix superbum*, *C. Swanium*, *C. Sedeni candidulum*, the large greyish green-flowered *C. tonsum*, *C. Harrisianum superbum*, and *C. cananthum*, which we think one of the most beautiful *Cypripediums* in cultivation. *Odontoglossum Harryanum* was remarkably well flowered; also *Pescatorea Dayana*, which has creamy white flowers, tipped with a rosy red colour. *Paphinia cristata grandis*, purple-crimson; *Trichocentrum tigrinum*, *Anguloa Ruckeri sanguinea*, *Cattleya gigas*, *C. Aclandix*, and *Platyclinis filiformis* were well flowered. A silver medal was awarded. A group of rare Orchids came from Messrs. Sander and Co., St. Albans. Included with this was a very fine batch of *Strobilanthes Dyerianus*, which has metallic-purple leaves, neat, and of great beauty. A seedling *Cypripedium* with pinkish flowers, and *C. Fausianum*, a hybrid between *C. Dauthieri* and *C. calophyllum superbum*, were of note; whilst another hybrid was shown named *C. nulus*, a cross between *C. hirsutum* and *C. Lawrenceanum*, the sepals of a light brownish colour, the petals rosy purple towards the apex. *C. Massaianum*, which was given an award of merit at the last meeting and described in THE GARDEN (p. 61), was shown in fine character. Very charming was *Zygopetalum (Promeneia) xanthinum*, the plant quite dwarf in growth and the flowers rich yellow, with spots of deep crimson at the base of the lip. *Mormodes pardinum* was exhibited in remarkably fine condition. The plant carried a raceme of twelve flowers, each of large size and rich yellow. *Aerides Saoderianum* with five spikes and *Miltonia vexillaria* in variety were included in this pleasing display. We must mention *Cypripedium hybridum Youngianum*, a very beautiful hybrid; *C. Venus*, light rose-pink; the scarlet flowered *Habenaria militaris*, *Miltonia Roezli alba*, pure white with yellow centre, and *Cattleya Gaskelliana* (silver medal). Messrs. Pitcher and Manda had *Sobralia macrantha var. Princess May*, the flowers of which are white tinted with rose, the lip of a deeper shade at the apex, and yellow within the throat. Mr. Statter had a number of interesting novelties, and was awarded a cultural commendation. *Lælia elegans* was represented by superb spikes. In the same collection was the beautiful *Lælia Amesiana*, which has bold flowers, sepals and petals touched with lilac, the lip crimson-purple, yellow at the entrance to the throat. *Cattleya Rex* (Stand Hall variety) is a good form, the sepals and petals primrose colour, the lip crimson purple, yellow in the throat, the outsides of the lobes apricot colour. Mr. McArthur, The London Nurseries, Maid Vale, had a pleasing group, in which we noticed *Oncidium prætextum*, a very good form of *Oncidium Jonesianum*, and such *Cypripediums* as *C. Seegerianum*, *C. Curtisii*, *C. volonteum*, and *C. Dayanum superbum*. Besides Orchids, the old but uncommon *Eucomis punctata* was shown in splendid condition (bronze medal). Mr. H. Dennison, Orchid grower to Mr. T. A. Gledstones, Manor House, Gunnersbury, received a cultural commendation for a well-grown plant of *Cattleya superba*. Messrs. W. L. Lewis and Co., Southgate, had *Cattleya gigas Turnbulliana*, the flowers of pleasing colour, petals soft rose-purple; the lip of a crimson-purple shade, very rich and handsome. *C. Dowiana var. Lewisiana* is noteworthy; the flowers are deep velvety purple as regards the lip and veined with gold.

Floral Committee.

A first-class certificate went to each of the following:—

CUPRESSUS MACROCARPA LUTEA.—This is a very distinct and vigorous growing form; the growth pale yellowish-green, a clear and pleasing shade of colour. It is, of course, difficult to judge of a plant in a pot, but this possesses evidently great merit; the variegation is distinct and not spotty. Shown by Messrs. Dickson, Chester.

CAMPANULA GRANDIFLORA MARIESI.—We can scarcely understand why such a plant should

receive a certificate. Of course, it is well worth the award, but then it has been in cultivation many years. It is compact in growth, dwarf, and a mass of large purple flowers at this season. To see this variety of *C. grandiflora*, better known, perhaps, as *Platycodon*, in perfection it must be left alone to develop into a broad mass. It is a pity that the plant is not more grown both on borders and rockeries. From Messrs. Paul and Son, Cheshunt.

SPIREEA ANTHONY WATERER.—We were pleased to see a first-class certificate awarded to this shrub. It is quite worthy of the award, as one does not often welcome such a strikingly handsome new shrub. We have described this sport from S. Bumalda on previous occasions, and a description is given of it in THE GARDEN (p. 44). We cannot add to anything there said, except to again remark that for the open and pot culture it is one of the most useful novelties that have appeared of recent years. The colour of the flowers is deep crimson, a superb shade. Exhibited by Mr. Anthony Waterer, Knaphill, near Woking.

CARNATION ESMERALDA.—This is a distinct and richly-coloured variety. The flowers, which are full and do not split, are yellow, striped with an ashy grey colour. We should like to see a plant of it, as much naturally depends upon the growth as regards its usefulness. Shown by Mr. F. Bull, Wormingford, Colchester.

SWEET PEA THE BELLE, with large blooms, well shaped, and of a pale rose shade, freckled, so to say, with a deeper tone. It is a bright and attractive kind. Mr. Eckford.

SWEET PEA ELIZA ECKFORD, which has very charming flowers, white, touched with rose-purple and a streak of the same colour down the centre of the large segment. Mr. Eckford.

CALADIUM LE NAIN ROUGE.—An acceptable addition to the kinds already in cultivation. It will form a good companion to *C. argyrites*, the growth of the plant dwarf and the leaves of a dark red colour. It is very free, and in every way a good variety. Shown by Messrs. J. Laing and Sons, Forest Hill.

BEGONIA (TUBEROUS) MRS BOURNE.—This is a tuberous-rooted variety, but we cannot understand why it should have been recognised. The flowers are large, yellow, single, with the outer whorl of segments running into leaf form. It is a curiosity, but such a variety, sportive and not fixed, cannot be regarded as a good garden plant. A botanical certificate would have been more appropriate. From Mrs. Darwin, The Grove, Huntingdon Road, Cambridge.

A botanical certificate was given to

DIDYMOCARPUS LACUNOSA.—This is a handsome kind, the flowers deep purple-maroon in colour, neat and pleasing. An interesting and noteworthy species. From Messrs. J. Veitch and Sons, Chelsea.

The exhibits before this committee were of much interest. One of the most important features consisted of a collection of Sweet Peas from Mr. Eckford. We have recently described the varieties raised by Mr. Eckford, but we made note of a few especially noteworthy, amongst them *Princess May*, rose and white, a delicately coloured flower; *Emily Eckford*, purple; *Excelsior*, brilliant crimson; *Mrs. Eckford*, pale yellow; *Ovid*, carmine-rose; *Mrs. Gladstone*, *Dorothy Tennant*, and *Lemon Queen*, besides several others, all of great merit. They show that this raiser is working on proper lines. Messrs. H. Canoeil and Sons, Swanley, had a group of tuberous *Begonias* raised from seed sown last February. The plants are remarkably compact in growth, and the flowers display considerable range of colour, comprising both double and single. As the varieties were not marked we cannot particularise, but the colours were extremely rich and pleasing. The variety *Octavie* was well represented, the plants literally bent down with the wealth of double white *Gardenia*-like flowers (silver medal). Messrs. J. Laing and Sons were also awarded a silver medal for a miscellaneous group in which the leading kinds of *Caladiums* were the chief feature, whilst the collection contained several superb tuberous *Begonias*, such as *Hero*, double crimson, and *Mrs. Ingram*, double

salmon. Messrs. E. D. Shuttleworth and Co., Peckham Rye, S.E., had a miscellaneous display of fire-foliaged and flowering plants; *Lilium auratum* and *Hydrangea paniculata grandiflora* were of merit. Carnations were not so largely shown as we anticipated. Mr. W. H. Divers, gardener to Mr. J. T. Hopwood, Ketton Hall, Stamford, had an interesting collection of many kinds and some very promising seedlings, but the finest exhibit comprised a large number of bunches of Ketton Rose, of which a coloured plate appeared in THE GARDEN January 16, 1892 (bronze medal). Messrs. J. Veitch and Sons had several interesting exhibits. *Retinospora squarrosa sulphurea* is a good kind, very compact, dense, and creamy yellow, and another excellent shrub is *Cupressus Lawsoniana versicolor*. *Lantana Drap d'Or* is worthy of note; the flowers are rich yellow, a deep glowing colour. *Carnation Celia*, rose, something like Ketton Rose, *Rhododendron Sylvia*, a large pale yellow-flowered greenhouse variety, very distinct and pleasing, were also shown. Other good plants shown were Marigold, single dwarf, the flowers rich yellow, crimson-purple at the base of the petals. The same firm had an interesting series of hardy Gladioli, of which one of the more distinct was Hugo de Vries, mauve-lilac, a very good type. Messrs. Paul and Son had a group of hardy flowers. They included *Linum flavum*, *Callirhoe involucrata* and hardy Gladioli in variety, *Campanula Parkeri*, white, violet at the base of the segments, and *Clematis Viticella kermesina*, rich claret. Mr. F. Bull, Warmingford, Colchester, had several good Carnations, and Mr. F. Roemer, Quedlinburg, *Humulus japonicus variegatus*, the leaves green, variegated with white. *Carnation La Villette*, the flowers yellow, striped with carmine, from Mr. E. Domaille, Guernsey, is a good kind of bright colour.

Fruit Committee.

There were some interesting exhibits before this committee. Choice fruit was staged in quantity. Apricots were shown by several exhibitors. Melons and Peaches were largely shown, and a very fine collection of Tomatoes was sent from the society's gardens.

An award of merit was given to a

SEEDLING MELON.—A large, white, thick-fleshed variety with a strong musk flavour. From Mr. Lee, The Gardens, Lynford Hall, Norfolk.

Messrs. Rivers, Sawbridgeworth, had a very fine collection of fruit grown in a cool orchard house, fourteen dishes being shown. These comprised *Bigarreau Noir de Guben*, Emperor Francis, and Geant de Hedelfinger Cherries, Lord Napier and Dryden Nectarines, Gros Pêche and Mexico Apricots, the latter no improvement on older kinds; *Souvenir de Congrès* and *Louise Bonne* of Jersey Pears, and some well finished Transparent Early and Late Gage Plums (silver Knightian medal). Messrs. Bunyard, Maidstone, staged a collection of Apples, chiefly early kinds, large, and well coloured. Some of the varieties were larger than is usually seen so early in the season. Red Astrachan, Irish Peach, Gladstone, Beauty of Bath, Early Joe, Tetofsky, a Russian variety rarely seen; Red Juneating, and Lady Stuffed being very good (silver Knightian medal). From Syon House Gardens, Brentford, Mr. Wythes sent six varieties of Apricots, Morello Cherries, and eighteen Melons. The Melons were medium-sized bright golden fruits, beautifully netted, the variety being the new seedling Beauty of Syon, which had a first-class certificate last year (bronze medal). From the R.H.S. gardens were sent nine varieties of Apricots, the varieties being Turkey, Hemskirk, Breda, Moorpark, Gros Pêche, Kaisha, St. Ambroise, Royal Orange and Early Shipley. This was an interesting exhibit, as it contained rare varieties. From the Royal Gardens, Frogmore, came four very fine dishes, these being Moorpark, Frogmore Early, Shipley's, and Powell's Late, a very desirable kind, large, of good flavour, and a vigorous grower in most soils. Mr. J. Smith, Mentmore Gardens, sent a valuable lot, having fine Moorpark, Hemskirk, Breda, Brown Turkey, Large Red (very good), and Frogmore Prolific. Messrs.

Bunyard, Maidstone, had Shipley's, Breda, Moorpark, Gros Pêche, Kaisha, and Hemskirk, not so ripe as some of the others. With these was also shown foliage of each kind. From Mr. Thomas also came a nice basket of Golden Hamburg Grapes and a very fine Smooth Cayenne Pine-apple weighing nearly 6 lbs. The plant which bore this had been rooted and grown from a sucker in ten months.

Mr. Divers, Ketton Hall, Stamford, had a fine box of Crimson Galande Peaches and Lord Napier Nectarines. Mr. Woodward, Barham Court Gardens, Maidstone, had a fine dish of Lord Napier Nectarines grown on standard trees in a cool house, and very good Alexander Peaches gathered from an east wall. Mr. Miller, Ruxley Lodge Gardens, Esher, staged good dishes of Grosse Mignonne, Alexandra Noblesse, and Royal George Peaches nicely finished. A dish of 1892 Apples was contributed by Mr. Jackson, Stroud, Gloucester, but of little value. A new seedling Apple was sent by Mr. Rich, Royal Nurseries, Bristol, but not sufficiently ripe to test its qualities. Mr. Smece, The Grange, Wallington, sent a dish of Early Joe Apples. A seedling Melon of no merit was staged by Mr. J. Rodbourn, Hailing Park Gardens, Croydon. A very fine collection of Tomatoes was sent from Chiswick, comprising thirty-four varieties, the best dishes being Trophy, Chemin, Ruby Queen, Perfection, Ridgway's Seedling, and Mikado. The best yellow varieties were Prince of Orange, Henderson's Golden Sunrise, Flying Dutchman, Golden Queen, Blenheim Orange, and Golden Jubilee. The Peach, the Cherry, and Plum Tomatoes were also sent. Mr. McDougall, Stirling, sent a seedling Tomato, but no improvement on present-day kinds. A very fine lot of Perfection Tomato was staged by Mr. May, Oakfield Gardens, Beckenham, Kent. These large fruits are not so much sought after as they were, those of medium size being now preferred.

In the course of his remarks on alpine plant houses, Mr. H. S. Leonard stated his notes would refer more to housing or sheltering tender alpine plants, as from considerable experience he had come to the conclusion that to grow these lovely subjects some protection is necessary in our damp climate. From close observation, he found protection essential not so much from cold as from damp. As previously explained, damp, if continuous, is fatal, also drip. Snow is a great protector, and shields the tender roots from extreme cold and prevents the severe frost from lifting the roots, which is a cause of failure in this country. There are various methods of protection, and he would describe the most suitable. In the first place hand glasses were a ready means of protecting a few plants, but this system was bad, inasmuch as the hand-light sheltered a few and killed the surrounding plants by the drip it threw on to those contiguous to the glass, so that he did not advise this mode of shelter. A strong sheet of glass supported at the sides was better, as this admitted air and light, so essential to the health of the plants. Though houses for alpine plants were now in their infancy, he predicted a wider field in the future, when alpine plant houses would be a regular feature in the rock or alpine garden. He had used for the less choice plants a well-glazed sash-light 6 feet by 4 feet placed against a sloping bank, the ends resting on four corner stones and the bottom against a walk, and found it answered admirably; but he now had his choice plants in a house on stages. He did not advise an expensive erection. Any ordinary workman could erect such a structure; the great points were good glazing and plenty of air. If the plants are on rockwork or planted out, the house cannot be utilised for other subjects, but such a house is always more or less gay with some choice plant, and, if located in the rock garden proper, is a welcome addition at all times of the year. He advised a low-pitched roof. When the plants were grown in pans there was considerable advantage, as during hot weather they could be removed and plunged in cocoa fibre

and the house employed for other plants. Many of the choicer Saxifrages are lovely, deserving of higher culture. There are other things, such as the choicer Bamboos, Primulas in variety, *Hostas*, &c. Near large towns it seems impossible to keep alpine in a healthy condition any length of time, as smoke and want of pure air soon cripple them in such places. A house is doubly valuable, as to a great extent fogs and smoke are defied and excessive moisture prevented. He thought many fought shy of this class of plants owing to the loss of choice varieties, but he felt sure these subjects deserved more care, and with care losses would be less frequent. He had such a house as described, and for the past few years he had lost very little.

Mr. G. Paul said his experience was that alpine, as a rule, got beautifully less and were difficult to manage. The house advised was necessary no doubt, but Mr. Leonard did not mention how one worked in these low-pitched places if the plants were close to the roof. The lecturer stated he would have the plants on stages and a walk down the centre. Sir W. Arbutnot thought frames equally valuable if properly used.

NATIONAL CHRYSANTHEMUM SOCIETY.

A MEETING of the committee of this society was held on the 21st inst. at the Royal Aquarium, Mr. R. Ballantine presiding. The secretary announced that four blooms of Chrysanthemums had been sent over from New South Wales frozen in blocks of ice for the opinion of the society. They had been despatched by a Mr. Faure, of Sydney, who stated that the grower was a Mr. R. Forsyth, of Sydney, and that the flowers formed part of the exhibit with which that grower won the silver cup at the Sydney show last April. The blooms were unnamed, but were large Japanese Chrysanthemums more or less incurved, and the colours appeared to be of a dull yellow or bronze in each case. A silver medal was awarded to Mr. Forsyth. Respecting the frozen flowers sent out by the National Society to Wellington, New Zealand, in return for those Mr. Earland sent last September, Mr. Harman Payne made the following communication. In a letter received from the secretary of the Wellington Horticultural Society he says, "All Chrysanthemum growers in this district are looking forward to the arrival of the frozen flowers. Unfortunately, they will not be here in time for our show, but the society intends to hold a supplementary show on their arrival." Another correspondent in a letter of later date writes to the following effect: "The frozen Chrysanthemums arrived in good condition, and a special show was held for them. A large number of people paid for admission. The English incurred were much admired on account of their perfect form; no flowers were ever exhibited in this city so perfect. With one or two exceptions the flowers retained their perfect colours. Altogether the exhibit proved very interesting both to growers and non-growers, and will no doubt be the cause of many taking a greater interest in Chrysanthemums." A newspaper report, speaking of the exhibit, mentions that only in one case did air bubbles interrupt the view, the freezing having been accomplished with so much skill. The writer adds: "Already the English blooms are being asked for by kindred societies all over the colonies, and they will be sent to Christchurch, Timaru, Dunedin, Auckland, and to Australia if possible, a requisition having been received from the Launceston Society to that effect."

Mr. Payne announced that the reports from Australia and New Zealand all referred to the bad weather during the recent Chrysanthemum season, and that the colonial exhibitions had suffered in consequence, as the growers there did not resort to protection in the way we did here.

The Wellington Society submitted for the decision of the National Chrysanthemum Society's committee a question as to the interpretation of one of their classes, viz., six pompons, distinct, in bunches or sprays, three flowers of each variety

with foliage, making eighteen blooms in all. One exhibitor so arranged his exhibit as to have three separate flowers of each variety, each flower being on a separate stem, the stems of each variety being tied together, while another exhibitor arranged his so as to have one spray of each variety, each spray having three flowers on one stem. It was resolved that the wording allowed the exhibitors to stage their blooms in either way.

From another New Zealand society at Cambridge the following interesting particulars were received: In the classes for Chrysanthemum cut blooms there were 1116 actually staged. The hall was much too small, for the tables left insufficient space for the public. In the class for children's bouquets, 381 were staged as follows: 116 table bouquets, 127 hand bouquets, and 141 bridal. Besides these, the children sent in thirty-six floral designs, such as wreaths, crosses, &c.

Twenty new members and two Fellows were elected, and the Cockermonth and North of England Society admitted in affiliation. Several members in the course of a discussion which subsequently ensued thought there was every prospect of the Chrysanthemum season being a late one this year.

EXHIBITION AT EARL'S COURT.

A SMALL, but charming show was held at the Gardening and Forestry Exhibition on Wednesday and Thursday last. Carnations were a leading feature, but there were many miscellaneous collections.

Carnations.

Considering the character of the summer, and that everything is practically a month in advance, the Carnations and Picotees were very fine, especially those from Manchester. The flowers were full, fresh, smooth and of fine colour, but unfortunately in the majority of classes shown with paper collars. We shall hope in time to see this barbarous and absurd system abolished. The best twenty-four Carnations came from Mr. E. Shaw, Morton, Manchester, but, unfortunately, the flowers were not named. We may point out that exhibitions would not be very interesting unless the various things were properly labelled. The exhibits of this grower were throughout of high character. Mr. J. Douglas, Great Gearies, Ilford, was second, his flowers including fine examples of Niobe p.p.h., Gregorius and Psyche, besides several others, which have been mentioned previously in THE GARDEN. There was good competition in the corresponding class for twenty-four yellow ground varieties, in which the first prize was taken by Mr. C. Turner, The Royal Nurseries, Slough. Most conspicuous were the blooms of Countess of Jersey, Agnes Chambers, Mrs. Henwood, Magnet, Mrs. A. Barnett, Annie Douglas, Janira and Nellie Bath, whilst the second prize went to Mr. J. Douglas, who had fine blooms of Horatius, Countess of Jersey and Aurora.

One of the most important classes was for twenty-four self and fancy varieties. The winner of the first prize was Mr. C. Turner, who had fine kinds for colour, such as King of Scarlets, a glowing shade, Salamander, Duchess of Sutherland, white, edged with pink, very charming; Germania, Nellie Bath, Mrs. A. Barnett, and Old Coin. A good second was Mr. G. Chaundy, New Marston, Oxford, he having Glaucus, bright scarlet, and Germania in excellent character. In the corresponding class for twelve, the premier award was made in favour of Mr. E. Shaw, whose flowers were again unnamed.

The Picotees were well shown, and again Mr. Shaw must be congratulated. His twenty-four flowers were of great merit, fresh, well coloured, full, and in true character; whilst those from Mr. C. Turner were also of merit, particularly Little Phil, Brunette, and several highly promising seedlings. Amongst the border kinds we must commend the six self-coloured varieties from Mr. Sage, gardener to the Earl of Dysart, Ham House, Twickenham. The scarlet-flowered Jim Smith, the

old Gloire de Nancy, Horace, Raby, Germania, and G. H. Sage were fine; the last is a distinct border variety, the flowers do not split, and they are full, compact, and bright salmon in colour. Messrs. Paul and Son, Cheshunt, had twelve good bunches of border kinds. One class was for any self-coloured Carnation, not less than twelve trusses, and the first prize went to Mr. Turner, who showed a very fine variety named Mrs. Apsley Smith, the flowers full, not in the least split, and brilliant scarlet in colour—a rich, effective kind. Mr. James Douglas was second with Crimson King, a richly coloured variety, the flowers compact, not split. This variety succeeds well out of doors. Mr. G. H. Sage came third with the variety named G. H. Sage.

Prizes were also offered for a basket or vase of Carnations for table decoration. A very charming arrangement was that from Miss C. B. Cole, Feltham. The variety used was Miss Joliffe, pleasingly set off with Fern; whilst Miss Nancy Cole was second, using the same kind, but the flowers were too much bunched together.

Several things were not for competition. Mr. G. Chaundy and Messrs. Paul and Son exhibited Carnations, and a large collection came from Mr. C. Turner, who had many sterling kinds.

Hardy Flowers.

These proved by no means the least interesting feature of the exhibition. The best twenty-four bunches, a fine exhibit, came from Messrs. Paul and Son, who had herbaceous Phlox Souvenir de Berryer, crimson; Gaillardias, Centaurea macrocephala, Helium pumilum, Scabiosa caucasica, Coreopsis lanceolata, Rudbeckia purpurea, and Potentilla Wm. Rollinson, orange, each kind represented by bold bunches. A good second was Mr. Sage, who edged his group in a charming way with Gypsophila paniculata, and had amongst other things Iceland Poppies, Liliun tigrinum, Eryngium Oliverianum, and E. planum. This class was open, but another, merely for twelve bunches, was confined to amateurs. In this Mr. Sage won the first prize, using to great advantage Gypsophila paniculata, and his other exhibits included a good bunch of his Carnation G. H. Sage, hardy Gladioli, and Helium pumilum. Mr. A. Newell, gardener to Sir E. Saunders, Fairlawn, Wimbledon, was second. The flowers were creditable, but we must remind this exhibitor that the nomenclature was at fault; Coreopsis lanceolata is not Corydalis lutea, nor is Helianthus rigidus, Asphodelus luteus. It is important to have the plants correctly named. Two classes were allotted to Sweet Peas; one was for twelve bunches, in which Mr. Eckford, Wem, Salop, was first, his varieties including such kinds as Black Beauty, Novelty, Countess of Radnor, Eliza Eckford, Mrs. Eckford, pale yellow, and Lady Penzance, rose. Mr. Newell was first for six excellent bunches.

The miscellaneous collections were very numerous. A silver-gilt medal was awarded to Messrs. John Laing and Sons, Forest Hill, for a splendid group of hardy flowers, one of the finest we have seen this season. Amongst noteworthy things were Chrysanthemum leucanthemum filiforme, the flower large, the petal divided at the apex, and of the purest white. Helium pumilum, Liliun longiflorum, herbaceous Phloxes in great variety, Lobelia cardinalis, Statice latifolia, Gladiolus brenchleyensis, Gaillardias, and Montbretias, besides many other fine things. Besides hardy flowers were flowers of their strain of single and double tuberous Begonias. Messrs. Barr and Son, Covent Garden, had a fine display, including large masses of Hyacinthus canticans, Liliun longiflorum giganteum, L. tigrinum sinense, Coreopsis lanceolata, Centaurea moschata in variety, and an excellent collection of double-flowered Balsams. An extra prize was awarded to Mr. Wythes, gardener to the Duke of Northumberland, Syon House, Isleworth, for a large and beautiful miscellaneous group in which Campanula pyramidalis and the white variety were leading features. C. carpatica was used also with excellent effect at the margin. Celosias blended well with foliage plants. A silver medal went to Mr. Eric Such,

Maidenhead, for a very fine collection of herbaceous Phloxes, representing distinctly coloured kinds boldly bunched. Mons. Thouret, rose, and Virgo Maria, white, were two of the most noticeable. The same exhibitor had a splendid show of Gaillardias. Roses were well shown by Messrs. Paul and Son, Cheshunt, who had a superb box of Augustine Gaiinoisseau, comprising the finest flowers we have seen of this variety this season. The varieties l'Idéal, Mrs. John Laing, Merveill de Lyon, and Polyantha Perle d'Or were largely represented. A silver-gilt medal was worthily given, and a similar award went to Messrs. F. Prior and Son, Myland Nurseries, Colchester, for several boxfuls of Hybrid Perpetuals and other varieties. Mr. Eckford received a bronze medal for his fine display of Sweet Peas, which we referred to in the R.H.S. report, and Mr. Anthony Waterer had flowers of his fine Spiraea Anthony Waterer.

Fruit.

A very good lot of fruit was staged, Black Grapes being specially fine. Melons were good, and Peaches remarkable for their size and finish. Fruit trees in pots were shown in good condition.

A first-class certificate was awarded to

MELON BEAUTY OF SYON.—This variety received a first-class certificate last October from the Royal Horticultural Society, and was now staged in fine condition. It is a medium-sized fruit with bright golden yellow skin nicely netted, flesh scarlet, of very fine flavour. From Mr. Wythes, Syon House.

Grapes were shown largely, especially in the class for three varieties. For three varieties, two bunches, Mr. T. Osman, Ottershaw Park, Chertsey, was first with two very fine bunches of Black Hamburg, Foster's Seedling fine bunches, and well finished Muscat of Alexandria. Mr. W. Tidy, Stanmore Hall Gardens, Gt. Stanmore, was a good second, staging very fine Gros Maroc grandly coloured, good Foster's, and Muscat of Alexandria. Third, Mr. W. Messenger, Woolverstone Park, Ipswich. In the class for three bunches of black Grapes nine lots were staged. This was a very fine class and the fruit well finished. Mr. J. Friend, gardener to Mr. P. C. Glyn, Rook's Nest, Godstone, was first with perfect bunches of Black Hamburg, good berries and well finished; second, Mr. Messenger, with bunches a little smaller, but well finished. In the class for white Grapes there was less competition and not so good bunches; Muscat of Alexandria was chiefly shown, but not well finished. Mr. W. H. Lees, Trent Park, New Barnet, secured the premier award with rather large, but loose bunches, but with good berries; second, Mr. Tidy, with smaller bunches of the same variety. There was a fair lot of Apricots staged in the single dish competition, Mr. W. H. Lees being first with good Moorpark; Mr. Messenger second with smaller fruit, same variety. Peaches were remarkably fine and well coloured, Mr. Maxim, Heckfield, Hampshire, being an easy first with a grand dish of Sea Eagle; second, Mr. T. Lees with finely coloured Grosse Mignonne. Plums were not numerous. Mr. Tidy was easily first with Jefferson; second, Mr. G. H. Sage, Ham House, Richmond. Dessert Apples were plentiful, but deceiving, the most showy being deficient in flavour. Mr. R. Grindrod, Whitfield Gardens, Hereford, staged the well-known Irish Peach and secured the leading award, Mr. Mundell, Moor Park, Rickmansworth, being second with Beauty of Bath. Pears were a poor lot, those staged in several dishes being hard and not fit for table. Mr. Friend was first for a nice dish of Jargonelle; second Mr. F. A. Hester with small fruits. Messrs. W. Paul and Son, Waltham Cross, staged two groups of fruit trees in pots. These were much admired, Peaches, Nectarines, Figs, Pears, Plums and Apples being shown. The best Nectarines were Elruge, Stanwick, Lord Napier, Humboldt, and Hunt's Tawny, with Royal George, Acton Scott, Early Silver and Stirling Castle Peaches (silver-gilt medal). Mr. G. Wythes, Syon House, Brentford, sent eighteen fruits of Melon Beauty of Syon and a collection of Apricots and Cherries (silver medal). Mr. R. Grindrod,

Whitfield, Hereford, had nice dishes of Warrington Gooseberries, Currants, and Apricots (bronze medal). Messrs. Canrell, Swanley, had a collection of Melons in variety. Mr. Tidy had two fine dishes of Tomatoes, one named Stanmore Hall Prolific being good. Mr. Laxton sent plants of his new Strawberry Royal Sovereign, lately certificated.

A full prize list is given in our advertising columns.

PUBLIC GARDENS.

Brockwell Park.—A large and influentially-signed petition in favour of the erection of entrance gates on the Brixton side of Brockwell Park was received and referred to the Parks Committee.

Parks and open spaces.—The addition of no less than 1000 acres to our parks and open spaces during the last four years has been of immense advantage to London. The committee and its sub-committees have held 176 meetings during the year. The Council possesses 14 parks, 30 open spaces, and 22 gardens, the annual cost of maintenance of which is £82,992, but there are few items of expenditure devolving upon the Council that receive more general approval than the money spent on London's open spaces.

St. Mary's Fields, Kilburn.—The Earl of Meath presided on Wednesday night at a meeting in St. Mary's Hall, Kilburn, in support of a movement for securing as a public recreation space the eight or ten acres remaining of what was once known as St. Mary's Fields, Kilburn, the other portion of which has been covered with houses. A resolution approving the object in view was carried unanimously, and it was also resolved to seek the assistance of the vestry of Hampstead, in which parish the land is situated, in bringing the matter before the London County Council.

Flowers at Ravenscourt Park.—It is a pleasure to see that hardy, even alpine plants are being more grown each year in the London parks. In the Ravenscourt Park at Hammersmith there is a raised bed near the free library in which various hardy plants are arranged with considerable taste amongst rockwork. The thing is not overdone, and the various kinds of Campanula, Hieracium, and other plants are in full beauty. The Fuchsias are very creditable also grouped on the turf, and the walls of the house referred to are clothed with creepers. This part was formerly a private garden and grounds, a fine avenue leading up to the residence, now a library for this district. Its better features have been preserved, and the arrangements of tufted Pansies and other flowers are highly commendable. A bed of Fuchsia with a groundwork of white tufted Pansy and edged with blue Lobelia is remarkably pleasing.

Paddington recreation grounds.—The executive committee, of which Mr. Joseph Guedalla is chairman, has now completed its labours extending over three years. The committee has collected altogether by private subscriptions and from public bodies the sum of £57,322, and the result has been to secure 25 acres for a public recreation ground within the four mile radius. No such public ground has hitherto existed in the metropolis, as whilst the ground will be devoted to athletic sports the public will have full and free access to it. A special feature of the ground is the outdoor gymnasium for children, which is crowded every summer evening. The ground will be handed over in September to the Paddington Vestry as trustees for the public. By arrangement with the executive committee that vestry has obtained an Act of Parliament this session enabling it to undertake the management and maintenance of the ground for the purpose of encouraging healthful outdoor games.

Lincoln's Inn Fields.—The Parliamentary Committee reported that they had considered the resolution of the council referring back to them

their report recommending the reintroduction of the Bill relating to Lincoln's Inn Fields, with instructions to consider whether the Bill should not be amended, in view of the decision of the Committee of the House of Lords to strike the clause relating to Lincoln's Inn Fields out of the Open Spaces Bill of the present session. They had consulted the solicitor and the parliamentary agent, and were advised that the way in which the council would be most likely to be successful in obtaining possession of Lincoln's Inn Fields as an open space for the public would be by seeking compulsory powers of acquisition under the terms and provisions of the Land Clauses Acts. They, therefore, recommended "that they be instructed to prepare a Bill for the compulsory acquisition of Lincoln's Inn Fields under the provisions of the Land Clauses Acts." The report was adopted.

THE NATIONAL ROSE SOCIETY'S CATALOGUE.

This is the usual jumble that Rose catalogues too often are. When the National Rose Society undertakes to form a catalogue we wonder the list does not partake of a simpler and more useful character. To begin with, there are irrational divisions of Roses into exhibition and garden kinds. If the whole world were made up of exhibitors it would even then be a poor way, but inasmuch as of all those who grow Roses not more than one in a thousand is an exhibitor, the Rose-growing public can hardly appreciate the wisdom of putting all the good Roses under the head of "exhibition Roses" and then repeating some of them elsewhere as "garden Roses." Such division is irrational to absurdity.

Then there are a number of needless minor divisions all tending to the general confusion of the whole. If classification is adopted at all, surely the so-called Hybrid Perpetuals should be succeeded by the Tea Roses, not the Hybrid Teas, a group of very slight importance as compared with the true Teas. The garden Rose classification begins with Provence and goes on to the Moss, Damask, China, Brier, and many other unimportant sections, the two of greatest importance coming at the end, and characterised by many absurdities and not a few omissions. Anyone taking these selected garden Rose lists as his guide will find them very imperfect and without some of the cream of the Tea Rose family. Hon. Edith Gifford is left out, and yet of all dwarf Tea Roses none can compare with it for fine effect and constant bloom. Where are Catherine Mermet, The Bride, and Narcisse, a lovely and free Rose? Are the two first named only grown by exhibitors? Then there are many lovely Roses that the exhibitor never gives a place to, as Mme. Joseph Schwartz and Marquise de Vivens, two representatives of many that are lovely, but never are seen at the shows. Among the single-flowered kinds, some of the very best are left out.

By far a better way than all this confusion and needless repetition would be to make an alphabetical catalogue of all good Roses, not only for the reason that it is the handiest way, but because it is often difficult to state the origin of many Roses. Taking them alphabetically, a description of each kind could be given once for all with the class it belongs to clearly marked at end of the description. At the end there should be a classification according to adaptability for exhibition or for any other use, and also according to origin.

As there would be no necessity to repeat the descriptions, there would be space to say all that was necessary about the kind in one concise paragraph. There is no known use for Roses that could not be dealt with in classifications at the end. It is not worth while bringing out a handsomely bound catalogue unless it is of some use to the Rose-loving public. At the end there should be a complete list of the known species. It would take up very little space and help the present taste for such Roses.

The weather in West Herts.—During the present month there have been as yet only five days which have been in any way unseasonably cool, but since the 8th the highest reading in shade has at no time exceeded 73°. The warmest night of the year as yet was that preceding the 20th, when the exposed thermometer never went lower than 59°. Rain has fallen on all but two days during the past week, and to the total depth of nearly 1½ inches, making this the heaviest fall in any one week since the end of February. My Roses are now for the first time beginning to make satisfactory growth, and especially is this the case with the Teas. The dwarf Brier stocks are also at last throwing out fresh shoots. Although frequently watered they have for weeks been at a standstill, and refused to make any progress until the recent rains came to their assistance.—E. M., Berkhamsted.

In my paper on page 83 the paragraph on *Anemone sylvestris* should read, "*Anemone sylvestris* . . . is quite at home in burnt earth and shade. *Anemone sulphurea* grows well," &c. It makes a great deal of difference, the latter being in full sun.—J. R. NEVE, Campden.

Pot Vines.—Kindly correct error in the R.H.S. Cliswick report, which states that I showed Grapes cut from a Vine in a 14-inch pot. It should be a 12-inch pot. The 14-inch pot holds about 50 per cent. more soil than the 12-inch.—J. HUNSON.

Araucarias bearing cones.—In answer to the query on the above (page 40), I have grown a number of plants from seed near Truro, and it is by no means rare for trees to produce fertile cones where the male and female are grown. The seeds are said to be good to eat when roasted.—WM. SANGWIN, Trelicick.

Names of plants.—R. C. Notcutt.—1, *Helianthus rigidus*; 2, *Gypsophila scorzonifolia*.—J. J. Simpson.—1, *Bromus sp.*; 2, *Nardus stricta*; 3, specimen too poor.—J. D. R. D.—*Lilium testaceum*.—G. Snell.—*Cynochos chlorochilon*.—D. Maurice.—1, *Dendrobium canaliculatum*; 2, *Cymbidium canaliculatum*.—Seeger and Tropp.—A very fine form of *Masdevallia Harryana*.—W. Richards.—It looks like *Desfontainia spinosa*, but cannot determine accurately from the leaves only.—A. B. C.—We cannot undertake to name florists' flowers.—G. Rorke.—1, *Polypodium vulgare*; 2, *Adiantum formosum*; 3, *Doryopteris palmata*; 4, *Lastrea decomposita*; 5, *Cyrtomium carolinianum*.—C. Rushmer.—1, *Cattleya gigas*; 2, *Cattleya Gaskelliana*, both very good forms.—W. Button.—1, *Auagallis arvensis*; 2, *Galinsoga parviflora*; 3, send again.—H. Cookson.—1, *Davallia Mooreana*; 2, *Lycopodium cernuum*; 3, *Microlepia birta cristata*.—G. Gloucester.—1, *Dendrochilum filiforme*; 2, *Acerides vireus*; 3, *Saccolabium bellinum*; 4, *Vanda alpina*.

"The Garden" Monthly Parts.—This journal is published in neatly bound Monthly Parts. In this form the coloured plates are best preserved, and it is most suitable for reference previous to the issue of the half-yearly volumes. Price 1s. 6d.; post free, 1s. 9d. Complete set of volumes of THE GARDEN from its commencement to end of 1892, forty-two vols., price, cloth, £30 12s.

"Gardening Illustrated" Monthly Parts.—This journal is published in neatly bound Monthly Parts, in which form it is most suitable for reference previous to the issue of the yearly volumes. Price 5d.; post free, 8d.

"Farm and Home" Monthly Parts.—This journal is published in neatly bound Monthly Parts, in which form it is most suitable for reference previous to the issue of the yearly volumes. Price 5d.; post free, 8d.

"Handy Flowers."—Giving descriptions of upwards of thirteen hundred of the most ornamental species, with directions for their arrangement, culture, &c. Fifth and Popular Edition, 1s.; post free, 1s. 3d.

"The Garden Annual" for 1893.—Contains Alphabetical Lists of all Branches of the Horticultural Trade. The Lists of Gardens and Country Seats (containing over 9000) have been very carefully and extensively revised, and are admitted to be the most complete ever published. Price 1s.; by post, 1s. 3d.

All of our readers who are interested in the improvement of cottage homes are invited to help us to make Cottage Gardening known. It is published at the very lowest price to meet the wants of those for whom it is intended, and copies will be sent for distribution free, by the publishers, Messrs. Cassell and Company, La Belle Sauvage, Ludgate Hill, E.C.

"This is an Art
Which does mend Nature: change it rather; but
THE ART ITSELF IS NATURE."—*Shakespeare*.

ORCHARD AND FRUIT GARDEN.

PEARS TOO EARLY.

CHOICE Pears are none too plentiful, though the crops are certainly considerably heavier than at one time thought possible. If, added to the comparative thinness of crops in places, the different varieties are much earlier in ripening than usual, it almost amounts to a certainty that Pears will be very scarce when most wanted. According to my experience, it is during November, December and January that really good Pears are most appreciated, this being when very many shooting and other parties are arranged in numerous country places. At such times a dozen or two Pears do not last long; in fact, three dozen per day are none too many in large establishments. If there are no Pears either to eat or even to look at on the dining-table, the dessert may be rightly said to be incomplete, but if present signs are any criterion, there will be a great many incomplete selections of dessert fruit next winter. Instead of its being necessary to ripen Jargonelles artificially in order to have presentable dishes by the second week in August, most of the fruit of this variety grown in the southern counties will be either rotten or eaten by birds and wasps long before these lines appear in print, Williams' Bon Chrétien and other successional varieties apparently being equally forward. It may be the change in the weather will have the effect of retarding the later varieties considerably, as it will otherwise benefit them. At present Marie Louise, Pitmaston Duchess, Doyenné du Comice, Conseiller de la Cour, Beurré Rance, Beurré Bachelier, Knight's Monarch, Duchesse d'Angoulême, and such like are swelling rapidly, and if it should happen that the fruits swell to a size more nearly approaching that of those grown in the Channel Islands without being unduly early, then we shall be the gainers. That Pears like more heat than they get during our average summers is evident enough, but unless the increased temperatures are accompanied by improved culture of the trees generally, the chances are premature ripening and in many cases a falling off in the quality of the fruit are inevitable. The trees ought to be prevented from becoming impoverished and dry at the roots, and the surroundings be further moistened by means of overhead syringings every evening after a clear hot day. This season the latter precaution has been most necessary not merely for adding moisture to the atmosphere, but also for the purpose of keeping red spider in check. On trees against warm walls which have received this attention fairly heavy crops of fine fruit are swelling off, though whether the latter will keep and ripen at their proper time remains to be seen. In very many instances enough rain has fallen to moisten the soil about fruit trees to a good depth, though not in all cases well up to the walls. It is at the latter point that the roots most often suffer from want of moisture. Being seldom, if ever, loosened, and perhaps long since rendered extremely poor, ordinary rainfall has but little

effect on the soil, the trees accordingly failing to derive all the benefit they ought to do from the rainfall. Those, therefore, who are anxious to have fine fruit and not out of season should attend at once to the borders. The surface being lightly loosened, a good soaking of water or weak liquid manure can then be given in an effective manner, that is, if such be still needed, and a mulching of strawy manure would complete the good work. August may yet prove to be a hot and dry month, and in this case I am of opinion that the overhead syringings every evening ought to recommence. Ripening of all kinds of fruits is hastened considerably by drying off at the roots and the maintenance of a dry atmosphere, and those, therefore, who are anxious to have Pears as late as possible ought to do all they can to check ripening. Premature ripening may likewise mean a falling off in size, and that is another good reason why plenty of moisture should be kept about the trees. Heavy cropping, again, is a mistake, especially if the trees are not in a healthy, free growing state, but there will be very many small Pears as well as extra finer ones this season owing to the faulty setting of the fruit. When the fruits have no seeds or pips in them nothing that can be done will cause them to swell to a large size.

GATHERING THE FRUIT.

What ought also to be taken into consideration is how far early or late gathering affects the keeping and ripening of the fruit. This point I hold to be well worthy of discussion in the pages of THE GARDEN, and those readers who are in a position to speak authoritatively in the matter, that is to say, can state positively that anything can be gained in the matter of gathering and storing somewhat differently to the orthodox methods, will confer a great favour by stating their practice. Will the fruit keep better after gathering if left on the trees till the pips are well browned and the dropping stage nearly or quite reached, or is it better to anticipate those symptoms? Again, should some varieties be treated differently to others, or are the same conditions to be observed in all cases? How does the time of gathering affect the quality of the fruit, and, finally, what can safely be done to retard ripening after the fruit is gathered? Every reader who is interested in Pear culture ought to be able to communicate something that is instructive about one or more varieties, and it is very certain, advice, brief or otherwise, would be fully appreciated just now. In order to set the ball a-rolling, I will give my own replies to the queries formulated, and if they do not agree with the generally expressed opinions, let those who can set me right do so. As a rule, Pears keep best by being gathered before the pips are browned or the fruit parts readily from the tree when raised out of its natural position. There is, however, the risk of being somewhat too hasty, shrivelling rather than ripening being the outcome. This season I shall start gathering when the seeds are just beginning to change colour, or if the fruits are too large or too few in number to be tested by cutting, some will be gathered directly this can be done without actually dragging them from the trees. About a week or ten days later another lot from the same trees will be stored, very few, if any, being left till they are ready to drop. It is impossible to give the exact time at which Pears should be gathered, so much depending upon the varieties and local circumstances. In all probability none will need to be left hanging till frosts put the finishing touch to them, Glou Morceau, Chaumontel, Ne Plus Meuris, Josephine de Malines, and other sorts usually late

in maturing being in a more forward condition than usual this season. Leaving early and second early varieties, including Jargonelle, Williams' Bon Chrétien and Beurré d'Amanlis, on the trees till they are yellow tends to spoil the quality, the fruit being more mealy than is the case with those gathered earlier and ripened off the trees. Much the same thing occurs if later varieties, including Easter Beurré, are left too long on the trees. When Pears are gathered a little in advance of the dropping period they may not be so well coloured, but this is amply atoned for in the superior lusciousness of the fruit. As before hinted, varieties differ considerably in their time of maturing on the trees, but the same rule should hold good as to the gathering tests throughout. That Pears should have somewhat warmer storage quarters than Apples there is no disputing, and a little extra warmth will sometimes both hasten ripening and improve the quality of the fruit. This season, however, it will be a great mistake to store them in very warm, dry rooms, as I feel certain the well-matured Pears will keep better than usual in lower temperatures. A dry room from which frosts are excluded, or where the temperature is seldom or ever below 40° and rarely above 55°, will best meet the case.

Somerset.

W. IGGULDEN.

STRAWBERRIES ON VARIOUS SOILS.

UNLIKE market growers, private gardeners have difficulties to surmount in the cultivation of Strawberries which the former are not likely to have, and that is in the nature of the soil. A grower for market on a fairly large scale will not attempt the cultivation of this fruit unless the soil should be suitable, whereas the private grower has to provide Strawberries whatever the soil may be. The methods of the private grower again are also often ridiculed, such, for instance, as the trouble taken in the preparation of the soil, and which the market grower may think quite unnecessary. The market grower, again, grows but one or two varieties, and such as are known to succeed well in the soil or district, but the private grower has to maintain a succession as long as possible; consequently varieties have to be grown which would not thrive well with the market grower under the rough-and-ready method of field culture. I am ready to admit that in many instances a lot of unnecessary trouble is undoubtedly taken in the matter of trenching; but if quite unnecessary in some instances it is not so in others, as I have met with cases where it was quite impossible to cultivate Strawberries successfully unless some form of trenching was adopted. The past season has been evidence of this, as in the majority of cases where the plants collapsed at the time when they should have been producing fruit it was on account of there not being a sufficient depth of worked and fertile soil. It is in such cases as this that an extra depth of soil must be provided, and this either by trenching if the soil will admit, or by bastard trenching if the sub-soil is not in a condition to enable it to be brought to the surface. The most successful instance I ever met with of Strawberry culture on a light and thin soil was at Loxford Hall, where Mr. Douglas produced some of the grandest crops I ever met with. His system was to plant annually. The soil in the first instance was well trenched, working in at the same time a good dressing of cow manure, healthy young plants which had been layered early in 3-inch pots being set

out in the latter part of July or during the early days of August. In no instance were the plants allowed to remain longer than one year—in fact, it was useless to allow them to remain longer, as if so, they would degenerate and do but little good. Now here was a very successful instance of good crops of Strawberries being produced annually, and this in soil in which it was thought it would be useless to attempt the cultivation of the Strawberry with any degree of success.

Trenching alone will not ensure success, as much depends upon the kind of plants and the manner of planting them. Those produced from yearling plants are much the best, as when runners are taken from older plants they are not nearly so satisfactory, as these, besides being small, are not in a condition to make a satisfactory growth. The planting may also seem a simple affair, but it requires to be done with care, in order that the plants may take quickly to the soil and soon become established. In the first place the surface should be made as firm as possible. When ready for planting a little fresh soil should also be at hand for placing around the balls. Not but that the plants will take to the soil without this fresh addition, but on poor or unkindly soils it gives them a start, and the results obtained well repay for the trouble taken. I use old potting soil with burned refuse, with an admixture of fresh soil if it can be spared. A spadeful is sufficient for each plant. This must be pressed well around the ball, leaving also a shallow depression around the plant as a receptacle for water. On heavy land trenching is not needed; in fact, I am sure the plants succeed better without it. These soils never have a hard subsoil, neither do the plants suffer to the same extent from want of water. A hard impervious clay, or such as has not been brought under cultivation, will of course require improving by the addition of road grit, burned soil, burned garden refuse, or anything of a like nature. But I refer to heavy land or such as has previously grown good vegetables. All that I find necessary to ensure the plants succeeding well is to fork over the soil to the full depth of the fork, working in a good dressing of manure and burned refuse. The system of planting is the same as on light or gravelly soils. Trenching such soils as these, besides being quite unnecessary, would, I am sure, not lead to successful results. Medium soils are the better for being bastard trenched.

Y. A. H.

STRAWBERRIES.

It may seem very like taking coals to Newcastle to attempt to supplement in any way the able and exhaustive instructions of Mr. W. Iggulden on these fruits (p. 77), yet may a few sentences of approval prove welcome and useful. I am pleased to find Mr. Iggulden an advocate of the bed system under certain conditions. I have noted for some years several tentative returns to the bed system, most of which have been more or less successful, and during the tremendous drought that we have now passed, the majority of these beds gave a good account of themselves. With deep cultivation and a sufficiency of manure such beds raised or on the flat are almost drought-proof. The abundant foliage wards off the heat so long as it remains green or nearly so. And if watering has to be resorted to, the grower of Strawberries in beds has the satisfaction of knowing that he utilises his water to the uttermost through his concentration of fruiting force, for three rows in a 4-foot bed, the rows running into a continuous mass, the second year will yield more fruit than

the usual system of growing in rows, unless the roots are crushed together as closely as from a foot to 15 inches apart, and from 6 inches to 12 inches from plant to plant in the rows. And when this is done the whole ground under Strawberries is converted into a huge bed under the name of row culture, and minus the 2-foot alleys between each bed of 3 feet or 4 feet wide which prove real solid conveniences for gathering and culture. Permit me also to emphasise the importance that Mr. Iggulden attributes to a hard bed for Strawberries. Many of the failures, partial or complete, one is constantly meeting with arise from this cause. The plants cannot readily bite soft, spongy earth, and if they do and manage to feed on it or the manure buried, the result is weakly or divided crowns and little or nothing but leaves and lanky stems. Such types of plants are almost sure to reproduce their leaf-like characters through successive crops of runners. On the other hand, solidity of soil favours the production of broad, thick, short-stemmed leaves and fat crowns, the progenitors of stout flower stems and full crops of luscious fruit of the highest quality. Fortunately for growers, these superb qualities are also handed down to us in their runners. The importance of partial shade for late Strawberries is another point of very great importance adverted to by Mr. Iggulden. Since the general adoption of the culture of Strawberries in open rows in gardens and fields, the influence of shade on this peculiarly sensitive fruit has been too little attended to, and yet few cultivators can have overlooked the fact that most of the flavour has been burned out of the fruit. This has been especially so this year. Many Strawberries have lacked size, while nearly all of those grown in the open unless on shady borders have been deficient in flavour. Hence most of us have grown our latest crops on shady borders. Years ago I remember trying the Elton, which was a great favourite, in the open fully exposed to the sun. It was scarcely worth eating. I have also grown latest of All in dense shade and in glaring sunshine, and the difference in flavour of the fruit in the shade was very marked. Of course, the shade of a north or east border makes the late Strawberries later. There is often the difference of three weeks between the same Strawberry in sunshine and shade. But the point here and now of most moment to enforce is that many Strawberries are better also grown in partial shade. The finest Garibaldi, Keens' Seedling, President and others grown by me have been from east or north borders, or sites with several points of these cool quarters in them.

Many years ago I threw up some borders running partly across the garden from east to west. The two fronts of the borders were thus thrown up back to back to a ridge in the middle. Both the south and north borders were planted with Strawberries, part of them with the same varieties and part with different varieties. As was to be expected, those on the south side were nearly a month earlier than those on the north. But it turned out that the unexpected also occurred—those on the north side yielded the most and the finest fruit. Both banks were alike in an open part of the garden fully open to light and air. The bank as well as the bed system of Strawberry culture may be worth trying, for shade as well as other reasons, if there is any chance of a succession of dry seasons. D. T. F.

Morello Cherries as bush trees.—Although the Morello thrives best when grown against north walls, yet as a bush tree in the open it also does well.

My method of treatment is to allow a freer growth than usually recommended, the branches being thinned out where necessary if at all likely to be crowded. I planted some trees seven years ago and they have not missed a crop since the second year. In fact, as regards the Morello's cropping qualities generally it has no equal, as this is generally of annual occurrence whatever the season.—A. YOUNG.

NOTES OF THE WEEK.

Chrysanthemum maximum filiforme.—I send you a bunch of above. It is by far the finest of all white Marguerites. It was raised here, and flowered for the first time last year.—T. SMITH, *Newry*.

** A charming and distinct plant.—ED.

A good herbaceous Phlox is named Amazon. The plant is remarkably compact and of vigorous habit, quite bushy, and the flowers, which are produced in dense heads, are pure white. Each specimen is a dense mass of bloom. A group of it would look remarkably fine, especially if in the front of dark-leaved shrubs.

Pavia macrostachya is one of the few shrubs that bloom late, and a large specimen was recently in full beauty in the Coombe Wood nursery of Messrs. J. Veitch and Sons. When in full bloom it is a fine picture, the flowers being produced with great freedom and in dense plummy spikes. The growth is spreading and the foliage abundant, in rich contrast to the wealth of bloom. It is a native of North America, and should be given ample space to spread out in its own characteristic way, whilst it will succeed in quite ordinary soil.

—Messrs. Dickson send us this beautiful dwarf-flowering Chestnut. Among many other flowering shrubs it is certainly the most beautiful and hardy. No pleasure ground should be without groups of this important low-flowering tree, which is as fragrant as it is fine in form of leaf and flower.

Strawberry Royal Sovereign.—By same post we beg to send you a coloured plate of the new Royal Sovereign Strawberry. The flavour of this variety is excellent (equal to British Queen) and as early as Noble, large, of better colour, a good grower and cropper.—LAXTON BROTHERS.

The Agapanthus is very charming when seen on the Grass of those riverside residences whose lawns dip down into the Thames. We noticed the other day the fine effect of the large tubs filled with Agapanthus in the garden of Sir Whittaker Ellis at Richmond. In such positions the flowers are more striking than in the usual run of gardens.

Hydrangea paniculata grandiflora is one of the best shrubs in flower in the Royal Gardens, Kew. A bed of it on the turf, with a groundwork of purple tufted Pansy, is very charming and a happy contrast of colour. This Hydrangea is one of the finest things one can have in the later months of the year, especially when boldly grouped in this way.

Carnations from Rothesay.—We have had some very good blooms of self Carnations from Messrs. Dobbie, of Rothesay, and are pleased to see that fine kinds of that class are being more attended to in the north, where evidently they thrive. We presume that the plants have been out all the winter, as they certainly should be where they are well grown.

The Montbretias are splendid plants for giving colour to a light sunny border. They were a fine picture a few days ago in the narrow border skirting the Orchid house at Kew, and it is in this position that the Belladonna Lily besides many other none too hardy things flower to perfection. M. Pottsi, M. crocosmifera, and M. rosea, a very pleasing variety that is not seen often in gardens, will succeed remarkably well under such conditions, creating a bright show of colour. It is a pity that

the *Montbretia* is not used more freely in this bold picturesque way, because there is no want of suitable positions in the southern counties for making such a feature.

Lilium japonicum Alexandræ.—We send you by parcel post a spike of *Lilium japonicum* var. *Alexandræ* bearing two flowers. As you will observe, the flowers are of great size and substance, quite 8 inches across, the petals over 2 inches in width. From all appearance it promises to be a grand acquisition, the flowers being so large and the plant lasts in flower for many days.—WALLACE AND CO., Colchester.

The Apricot in London.—As an evidence that this is an extraordinary season I may mention that in the middle of my garden stands an Apricot tree loaded with fine ripe fruit. The tree was brought from France about seventeen years ago, and (with the exception of a very little blossom one year) has never before shown any indication of fruiting.—B. G. JENKINS, 43, *Chatsworth Road, West Dulwich, S.E.*

A fine contrast of colour we noticed recently was composed of yellow *Calceolarias* and *Lobelia cardinalis*. We do not care greatly for the *Calceolaria*; it is far too gaudy and garish, but used with the *Lobelia* is not aggressive. This type of *Lobelia* requires to be used judiciously in the garden, but its splendid chocolate leafage and crimson flowers tell well in beds; whilst the plants are in perfection at a season when many things are rapidly going past their best.

Lachenalia glaucium is a curious species. Several plants of it are in full bloom in the Cape house at Kew. The leaves are boldly blotched with deep chocolate on a rich green ground, and the scapes are marked in a similar way, whilst the flowers are crowded together, the colouring very distinct. It may be described as of a bluish shade touched with red, a singular, though not very charming association of colour. The plant is exceptionally free, and a specimen or two of it is interesting in the greenhouse.

Picotee Lottie Kirlow.—I send you flowers of Picotee Lottie Kirlow for your inspection, thinking that perhaps the last did not reach you fresh. The variety is exceptionally vigorous for a yellow ground, growing 2½ feet high and flowering abundantly. I enclose you a photo of a bouquet of it and also one of a large bed.—GEO. HOLMES, *Harby Road, York.*

* * Mr. Holmes sends us vigorous specimens of this yellow ground Carnation, and clearly he does it well. The variety merits trial even in face of the great advantages in effect of the self-coloured kinds—always the most vigorous in habit—on stiff or poor soils.—ED.

Two interesting Orchids in bloom in the Orchard house at Kew are *Satyrium militare* and *Rodriguesia* (*Burlingtonia*) *pubescens*. The *Satyrium* is the more noteworthy of the two, and a healthy mass of it is in bloom. The stems are sturdy, and the leaves clasp it to the summit, the distinctly coloured flowers which appear in the upper portion standing out in bold contrast. They are not particularly showy—white marked with crimson-brown, but this characteristic marking is in bold contrast to the pale green of the leaves. The *Burlingtonia* is a charming species, bearing a raceme of white flowers relieved by a yellow base at the lip.

Crinum Mcorei is a lovely flower, and, although well known by name, it is not often one sees it in such beauty as in the greenhouse at Kew, where there is a large group of it. The flowers are so bold in aspect and pleasing in colour—a soft rosy pink—that they are sure to attract attention. A succession is maintained, as several are borne on the same scape and they open one after the other. This *Crinum* need not be treated entirely as a house plant. After the flowering season is over it may be transferred to the garden until autumn, and without the slightest fear of injury. It may be compared as regards treatment to the *Agapanthus*, and will succeed with just protection enough

in winter to keep it safe from frost. Rains spoil the heavy flowers in the open, and they are, when several specimens are seen together, much finer and purer in colour under glass.

Mr. Alfred Parsons' pictures.—All who have the opportunity should see these pictures and sketches made in Japan, where Mr. Parsons has lately spent more than a year. We have not for many years seen any collection in which the flower world comes into the picture with so much interest. Many of them are extremely delicate in colour and teeming with beautiful life, interesting to all garden lovers. Few, if any, artists have the knowledge of flowers that Mr. Parsons possesses, which knowledge led him to take the trouble to find out in Japan the most beautiful things and beautiful localities for flowers—points that would have escaped the attention of the ordinary traveller, or even painter. They are at the gallery of the Fine Art Society in New Bond Street, W.

Apple Devonshire Quarrenden.—With this I send you a branch of this early dessert Apple to illustrate its free-bearing capabilities when grown on what is known as the extension system of training. The branch measures 3 feet long, and upon it there are 115 fruits, rather smaller than is customary with this variety, but accounted for by the excessive drought experienced here this season. As a market Apple Devonshire Quarrenden is by far the most valuable during the month of July, good fruit fetching 8s. per bushel. No Apple that I know succeeds better on the extension system of pruning, especially where the soil is of a loamy character. Here in this garden, which mainly consists of a strong adhesive class of soil, this variety is liable to canker, and requires a good deal of attention in getting the roots near to the surface, and keeping them there by frequent mulchings of half decayed manure.—E. MOLYNEUX.

Clethra alnifolia.—Owing, it may be, to the abundant sunshine this summer, our plants of *Clethra alnifolia* are flowering more profusely than usual, and at this season of the year when hardy shrubs in flower are by no means plentiful, they prove especially welcome. The plants are from 3 feet to 4 feet high, bearing toothed, obovate leaves of a bright deep green, which together with the neat rounded habit makes an admirable setting for the flowers. The racemes are terminal, erect, 4 inches or more long, the flowers dull white, and possessing a delightful fragrance, which suggests at once Wallflowers and Hawthorn. This plant is one of our oldest American plants, having been introduced, so says London, in 1731. It is found in the Eastern United States from New England southwards. It belongs to the *Erica* family, but, unlike its European fellow species *C. arborea*, is deciduous. It likes a lightish soil, and a proportion of peat is advisable.—B.

Antirrhinums.—I send for your inspection a strain of Antirrhinums raised from seed sown early in the year, the plants of which are now coming into full bloom. The strain is dwarf in habit and compact in growth, throwing up a number of side shoots that go on producing flowers until quite late in the season. You will observe that some of the varieties are spotted or mottled upon a yellow ground rather than striped, and that the colours of the splashes are singularly bright. Among them are a number of rich crimson and scarlet selfs. The flowers are large, stout, and of fine form. These Antirrhinums make a charming bed, or they can be isolated in the mixed borders. In a cut state the flowers show up well by gas or lamplight, and they are much admired by all who see them. The plants which are now flowering will, if they survive the winter, make large specimens by the early part of next summer.—R. DEAN.

Echinacea purpurea and Rudbeckia purpurea.—We had shared the impression (which we believe to be general) that these two plants were the same. Unless there is still another species of which we know nothing, the two specimens sent with this seemingly show that there is a vast difference between the plants both in flower, foliage and size. Can you oblige us by naming

them? We seem to have had them both as *Echinacea*. Our stocks are growing side by side under identical conditions, so there is no question that the vastly greater size and fineness of the one are not the result of any special culture. We think you will agree that it is a superb hardy plant. *Rudbeckia maxima* hard by makes a noble contrast.—H. S. LEONARD.

* * It is *Rudbeckia purpurea*, and the plants sent are two very different forms of the same species. The specimen sent is very handsome and well grown. *Rudbeckia purpurea* was figured and the genus described by Mr. Dewar in *THE GARDEN* of April 29, 1893.—ED.

Cannas at Chiswick.—A most interesting collection of Cannas is in bloom in the Royal Horticultural Gardens at Chiswick, comprising many of the newer varieties. We made note of several fine kinds, and they comprised Alphonse Bouvier, the flowers deep crimson, wavy at the edge, the leaves of a fine dark green. Ulrich Brunner is one of the best of these French Cannas, the flowers large and of a deep self crimson, whilst also meritorious are Doyen Jean Sisley, orange-scarlet, deep chocolate leaves; P. Marquant, which produces a dense spike of brick-red flowers; C. Turner, a seedling, the flowers large and rich yellow, barred with crimson; Lohengrin, dwarf and compact in habit, deep green leaves, and orange-scarlet flowers; and such fine kinds as Francisque Morel and Francois Crozy. One of the best is *Premices de Nice*, which has self light sulphur flowers, a very distinct and attractive variety; Gloire d'Empal, has carmine flowers, in rich contrast to the chocolate leaves. Wilhelm Pfitzer, light crimson; Jules Chrétien, Felix Crousse, Admiral Conrabet, Avenir, orange-scarlet, Duchesse de Mortemarte, yellow, heavily spotted and barred with crimson, and Prof. David, reddish buff, edged with yellow, were also good.

Lilium Henryi is superb in the Royal Gardens, Kew, and the more one sees of this fine species, so much the more its usefulness becomes apparent. We have never seen it finer than this year, and it should be made careful note of. It is one of the Lilies of the future, and attains over 8 feet in height, the stem bearing several blooms of great richness. During the past few years we have received several fine plants from Western China, and this is especially noteworthy. *L. Henryi*, it may be interesting to mention, flowered at Kew for the first time in 1890. At first the stems did not attain more than 4 feet in height, but with increased vigour they, as mentioned, much exceed those dimensions. The leaves are deep green, pointed, and the flowers are similar to those of *L. speciosum*; in truth, its popular name of the yellow-flowered *L. speciosum* is not inappropriate, except that the flowers are scarcely yellow—rather of a rich apricot colour, marked with numerous brownish red spots. They are large, showy, and when backed by deep green-leaved shrubs very rich in tone. In *THE GARDEN* of August 29, 1891 (p. 195), it mentions that Dr. Henry, after whom it is named, found this beautiful Lily in only two places, and in each case near to Ichang. It grows from 200 feet to 2000 feet elevation and on grassy slopes.

A glut of Mushrooms.—There has been an extraordinary lot of Mushrooms collected lately. So very plentiful were they, that they could scarcely be sold at 1d. per lb. Last year some of the heaviest crops of Mushrooms ever seen were produced in the neighbourhood of Stourton, Wilts, quite a harvest being reaped by the poor people who had the privilege of gathering and selling them. One old lady of a business-like turn of mind bought up all that she could get at 2d. per lb., packed them in baskets, and forwarded the lot to Birmingham and elsewhere. After paying expenses the returns were 1d. per lb., and as the woman in question paid away £100, her profits on the transaction were just 100 per cent. This July the same fields were equally as productive as last year, and the farmers determined to reserve the right of collecting the Mushrooms, preferring to do it themselves by way of compensation for loss of hay crop.

Instead, however, of being well repaid for their trouble, several of them actually lost money in the matter, the markets being glutted with Mushrooms, large quantities being spoilt accordingly. In one instance a greengrocer invested so extensively in Mushrooms, under the impression that the midland towns would be badly supplied, that he was a loser to the extent of £20, and I heard of another man who lost £12. The glut was soon over, however, Mushrooms being scarcer now than might reasonably have been anticipated.—I.

Lily of the Valley Tree (*Clethra arborea*).—For more than a century has this shrub been grown in English gardens, having been introduced to Kew by Masson in 1784. Whilst it is one of the best known of greenhouse subjects—every old garden and most new ones possessing specimens of it—it has never been much grown so far as numbers go. The reason of this is that it does not as a rule flower until of almost tree-like dimensions except after unusually bright seasons. In the year 1888 I had a small plant in an 8-inch pot with about a dozen shoots on it and not more than 18 inches high, yet, owing, I surmise, to the excess of sunshine in 1887, every shoot carried a large and beautiful spike of the white flowers, whose shape and pose have suggested the name of Lily of the Valley Tree. But neither before nor since have I noticed so small a plant in full bloom. When 5 feet to 6 feet high plants may be had in flower regularly every season by growing them in pots and standing them out of doors during summer. Planted permanently indoors they often do not flower so freely, running rather to leaf-growth. In the latter case I have found that root-pruning is useful for checking over-luxuriance of growth and inducing flowering. But it is only in lofty houses and in shady positions that such treatment is needed. They should be planted in a light position and if possible near the glass. Pot plants should be grown in rich loam and be given abundance of manure water when stood outside. The best means of obtaining an abundance of flowers is to keep the plants somewhat pot-bound, yet feeding them well at the same time.—B.

Notes from Chester.—Roses are yet about in profusion. Sunflowers, Clematises, and Lilies everywhere abundant, and no scarcity of flowers in the shrubberies. *Ligustrum japonicum* is exceptionally fine, as you will see by the spray sent, as also is *Olearia laaasti*. There is a pretty little *Pavia* just now in full flower, with its dainty jaunty air; its flowers, bearing long filaments carrying the anthers, give it this look, and when the rest of the *Pavias* have fallen back upon foliage effects for charm, *Pavia macrostachya* is in perfection. The Clematises are grand; from pure white to richest depths of purple festoons flank the walks and crowd the pillars with riches. We send you two sprays of the scented varieties. *Clematis cœrulea odorata* is very free flowering, and as you pass the column round which it is entwined the scent is very pronounced and acceptable. *Clematis flammula rubra marginata* is also very fine. The *Bignonia grandiflora* is bold and beautiful. The spray we send will give some idea of its effectiveness in its natural growth on the walls, in which position it is perfectly hardy. There are other creepers and climbers in the nurseries here equally worth special consideration, and it is hard to make choice where so many claim attention. Amongst the flowering shrubs *Leycesteria formosa* is most attractive. Its heavy pendulous racemes of curious flowers are showy, but the plant itself has a glaucous greenness peculiarly its own. *Potentilla fruticosa* is a mass of golden blossom, and *Rubus odoratus*, with its conspicuous foliage and its simple inflorescence, commends itself to the notice it deserves. We send some sprays of *Colutea* (the Bladder Senna), a curious and always welcome shrub. One spike we send, too, of the beautiful *Yucca flaccida*, a stately column of silver bells, very effective, and a fitting subject with which to close the list. The sprays sent have all been cut from the open.—DICKSONS.

Epidendrum vitellinum majus.—Mr. Appleton sends us a spike of 11 om of this plant

upwards of 1 foot long, and bearing fifteen flowers of great size, exquisite in colour, and of good substance. He says, "This is from a plant grown quite cold and damp. At first I grew it hot, and I used to get two or three miserable flowers only, but now you see what I get. Last year I had a small plant in a 5-inch pan with seven spikes." The spike sent is about the strongest that has come under our notice.

MICROBES AND VEGETATION.

THERE are certain very minute organisms which of recent years have been brought into great notoriety on account of the number of diseases which are attributed to their agency. I allude to germs, bacteria, bacilli, microbes, micro-organisms, or by whatever names these microscopic fungi, which are now proved to be the immediate cause of so many diseases, are known by. This family, in consequence of the habits of many of its members, has a very evil reputation, but, like most other families, all the members do not deserve this general condemnation, for many are of very great service to mankind—for instance, yeast and the other microbes connected with the fermentation of alcoholic liquids. But those which are the most useful, perhaps, are those which affect the fertility of the soil. The practice of adding various substances to the soil to render it more prolific is of great antiquity, and it has long been known that it is the amount of nitrogenous matter in manure that gives it its greatest value, and it is for this reason that decaying animal and vegetable substances are of such value as manure. In fact, so essential is nitrogen in some form to plant life, that the soil without it would be positively barren, however suitable it might be in other ways for the growth of plants. The nitrates in the soil are absorbed by plants and converted by them into the albuminous matter required by the animals which feed on them. When animals or plants die and decompose, this decomposition, or resolution of the complex material of which they are formed into more simple substances, is effected by various kinds of bacteria, some of which attack albuminous matter and change it into other nitrogenous forms, ammonia among the number. Others, again, convert the ammonia into nitrous acid, which is altered by yet another kind into nitric acid, the form of nitrogenous compounds most easily assimilated by plants. Nitrate of soda, which is so much used as manure, and of which there are such enormous deposits in Chili and Peru, is now supposed to owe its origin to certain bacteria, which probably had much greater powers of nitrification than those with which we are at present acquainted. It is evident then that bacteria which have this nitrifying power are of the greatest service to mankind. Agricultural chemists have discovered that while the amount of nitrogen in most crops can easily be accounted for by the quantity they can derive from the soil, certain leguminous plants, Peas, Beans, Tares, &c., contain an amount which cannot be accounted for in this way, and it has been a point of much uncertainty from whence these plants derived this unusual amount of nitrogen. It has recently been discovered by Prof. Hellriegel and Dr. Wilfarth that the plants absorb the free nitrogen in the soil (which has been derived from the air), and that their power to absorb it depends entirely on the presence of certain bacteria which live in the soil, and also in the roots of the plants in question; their infestation of the roots causes certain small swellings or nodules

to form on them. This nitrifying power of these microbes has been proved to exist by sowing the seeds of leguminous plants in soil which had been freed from bacteria and in soil which contained them. The plants where there were no bacteria made a comparatively poor growth and did not contain an unusual amount of nitrogen, whilst the others grew in a perfectly natural manner and absorbed the usual excess of nitrogen. Prof. Nobbe has further proved that in many cases a different kind of microbe is required for each different sort of plant. For example, a Pea plant grown in soil entirely freed from bacteria, but inoculated with those from the nodules on the roots of a Lupine, did not grow with anything like the same vigour of other Pea plants which were grown in the same soil, but impregnated with microbes from a Pea plant. It is clear, therefore, that these microbes play no unimportant part in the fertility of our gardens and fields. Besides these bacteria which are so beneficial to plant life, there are others which cause disease in plants, just as some kinds cause disease in the human species. This subject has not been much worked at, and I quite imagine that some diseases of plants, the cause of which is at present unknown, will eventually be found to be the result of the plants being attacked by these minute organisms. In America this subject has received a certain amount of attention, and a Dr. Russell has published a paper in the reports of the John Hopkins Hospital at Baltimore of various experiments and observations which have been made to elucidate these obscure diseases. He has found that usually a healthy plant with its outer membranes unbroken is free from bacteria within its tissues, but when the tissues of a plant have been wounded, bacteria are often found in them. He mentions several different kinds of these micro-organisms which infest plants; among the most common are the Pear blight, or fire blight (*Bacillus amylovorus*). This species is almost entirely confined to plants of the same nature as Apples and Pears. It usually attacks the "more succulent parts of the tree, and may be recognised by the blackened or burnt appearance of the parts affected." *Bacillus oleæ-tuberculosis* attacks the Peach, Plum, Apricot, Vine, Fig, Pear, Apple, various conifers, &c. It causes destruction of the tissues and the formation of spaces in them. This induces a secondary local growth, and causes an internal hypertrophy in the bark, which gradually produces the local death of the tissue. Another nearly allied species causes excrescences on the shoots, &c. Many of these minute micro-organisms are easily carried about by the wind, and many of the commoner kinds are no doubt ever present in the air around us at any ordinary altitude. Experiments which have been made for this purpose show that the air in towns will contain (the numbers vary very much according to circumstances) seventy micro-organisms in every two gallons of air. In the country the number is much less, particularly upon high ground. The decomposition of dead organic matter is entirely caused by these microbes, and it is obvious that such matter quickly begins to decay, particularly in warm, moist weather, which is favourable to the growth of these germs. Under these circumstances milk, soup, and beer will turn sour and meat become tainted and unfit for food in the course of a few hours. These minute micro-organisms, therefore, play a very important part in the economy of Nature, though their very existence was unknown comparatively a few years ago.

G. S. S.

COTEHELE—ANOTHER VIEW.

HAVING lately given some account of Cotehele, of which we this week publish another view, we need say no more of the place generally. The picturesque freedom of the planting and surroundings is delightful, especially to those who see so many stiff, trim gardens both in England and France. In France lately we were staying in a very pretty house with a beautiful brown-tiled roof—a really solid example of a house a couple of centuries old. There was not a flower on it, or a spray of creeper, or any living thing. A suggestion that it would be none the worse for a few tall Tea Roses was met with a shake of the head.

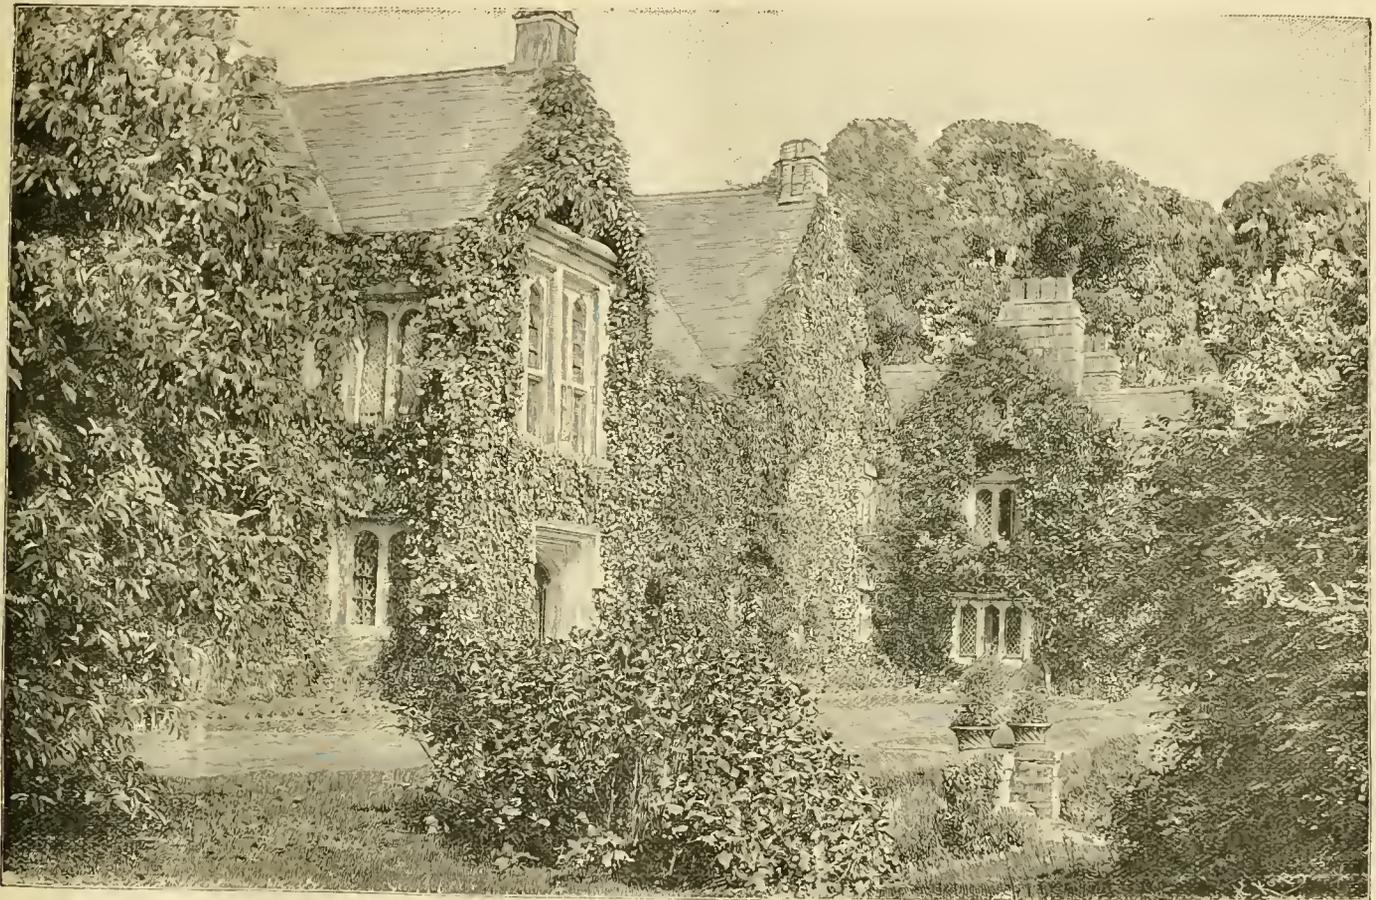

ROSE GARDEN.

THE LATE DROUGHT AND THE BUDDING OF ROSES.

“RIDGEWOOD” makes reference to this in his seasonable and useful article on budding in a recent issue of THE GARDEN. But in not a few gardens and districts the winter frosts and spring and summer droughts have wrought such havoc among Rose stocks and Roses, that but little budding can be done this year, and what little may be possible cannot be done just yet, for neither stocks nor buds are ready. True, the Rose blooms may have been a month or more in advance of their normal season, though both stocks and buds may be quite as

of suitable buds to transfer and a sufficiency of stocks with rising bark and flowing sap.

True, as a rule July is perhaps the best month in the twelve for the budding of Roses. But it must never be forgotten by those who would achieve the largest measure of success in this delightful art that condition, and not the calendar, must determine the time. The unprecedented drought has knocked our Roses out of condition, and we must wait for their recovery alike in bud and stock before we can attain to success. Recent rains and the cooler temperature alike favour the growth of Rose stocks and Rose buds. It may possibly be too late to pull up either to normal size. Neither is this necessary to command success. But a certain plumpness and semi-maturity are essential in the buds with a readiness to flit into new

Cotehele House—another view. Engraved for THE GARDEN from a photograph by Mr. Hayman, Launceston.

Certain architects have the pretension of keeping flowers off their walls, and we suppose they enlist a sanitarian here and there to their views. Happily, this fashion does not obtain at Cotehele, which, as will be seen, is delightfully covered. Whatever people may think of the influence of Ivy on walls—and we should not put it on the walls of a very beautiful house except in a limited degree—there are a certain number of plants to which no objection can apply, such as the more delicate Clematises and the superb Roses we now have, such as Bouquet d’Or, Lamarque, and many others. If it is a question of attaching them to the walls, it is quite easily got over by an Oak trellis framework and various other ways.

much behind time. Perhaps no form of vegetation suffered more from the drought than Rose stocks. Early planted stocks on good soil have stood the drought wonderfully well, but poor stocks on poor soils planted late have perished by hundreds, and the survivors are mostly very weak at the best. Many of them have their growth yet to make or to grow into workable size for budding. Rose buds, too, of some sorts are almost as scarce and as unfit as the stocks. The short shoots have been forced into bloom to the sacrifice of anything like plumpness or fatness in the wood-buds, and even those that have attained to the necessary fulness or semi-maturity seem disposed to remain where they are rather than to facilitate their transfer to foster-mother stocks and roots. Now it is a mere truism to assert that we cannot bud Roses unless we have abundance

quarters under the gentlest possible manipulation or pressure of the budder. The stock must also prove suitable in every way. Given such conditions, budding may be successfully prosecuted all the year round, and in such seasons as this, when the great drought has driven Roses and Rose-buds wholly out of time, we may bud as the Roses grow into condition from July till November. The latter month is named, that none, however late their Briers, may despair, though it is hoped that most of the readers of THE GARDEN will be able to complete their budding in July, August, September, or October at the latest. While the bark will rise and the buds can be transferred freely to their foster stocks, budding will prove successful. So far as hardiness is concerned, late buds are hardier than early ones. Dormant buds winter safest and as a rule

do best the following season. I am well aware that there are dormant buds and dormant buds, and that neither need of necessity be abnormally late buds so far as the mere act of insertion goes. Buds may also be forced into dormancy through late insertion, and such late buds winter safely. But the treatment of the stocks will also keep early-inserted buds dormant, and all dormant buds from whatever cause are safer than excited buds or those started into growth the current year. But the great comfort for those whose stocks and buds have been dried or baked so out of condition as to render present budding impossible lies in the fact that there are yet several months before them, in which they may yet hope to be able to bud with pleasure and success. Thousands of bark-bound Brier and other Rose stocks that refused to yield an inch to the budding knife while the drought lasted have begun to yield on the heels of the rain. A little more of this latter or a liberal artificial watering will cause most of them to follow. By selecting small buds in fit condition, small stocks, that could not have been worked at all had we waited for average size either of buds or stocks, may be budded quite successfully. This is an important consideration, as Roses are likely to be abnormally scarce and dear in 1894. D. T. F.

Rose Bardou Job, introduced by Nabonnand in 1887, is one of the best garden Hybrid Teas we have. It is almost single, very large and distinct, and a first-rate grower. I considered it the finest of all the garden Roses exhibited at the National Rose Society's Crystal Palace show. The colour is an intense glowing crimson with a dash of purplish maroon pervading the centre of the petals.—R.

Rose Lady Henry Grosvenor is another grand Hybrid Tea, and one which I should be inclined to class with those styled exhibition varieties. In shape it is perfect. While not a vigorous grower, it is very free-flowering and constant. Of good imbricated form, creamy white in colour, with soft peach shadings, Lady H. Grosvenor is certainly one of the most distinct and beautiful Hybrid Teas we have. I have not yet given it a fair trial as a pot Rose, but have little doubt it will prove admirably adapted for this purpose; if so, it will become almost invaluable.—P.

Rose Horace Vernet, introduced by J. B. Guillot fils in 1866, would seem to be the Rose of the season. At the Crystal Palace show this uncertain Rose was well shown in many collections, far more numerous than for many years past. It gained the medal as being the best Hybrid Perpetual in the nurserymen's classes both at the Crystal Palace and at Worksop. It would seem that the district of Bedale, in Yorkshire, suits this Rose, as the Messrs. Harkness carried off the medal in both instances. In the majority of gardens Horace Vernet is a most disappointing Rose, seldom thriving except as a maiden upon the seedling or cutting Brier, and it can scarcely be recommended to any but growers for exhibition. No doubt a large number will be purchased on the strength of the Crystal Palace and Worksop flowers, but many who plant it will be doomed to serious disappointment.—R.

Rose Bouquet d'Or.—"D. T. F.'s" latest communication on this Rose (see p. 67) would seem to imply that by going to the Noisettes for Bouquet d'Or I was going to a class that could not be compared with the Teas. The mysteries of Rose classification are such, that who can tell why Gloire de Dijon and Mme. Berard are Tea Roses and Bouquet d'Or a Noisette? The truth is that through Bouquet d'Or being placed in this list it remained in comparative obscurity till later years. Has "D. T. F." ever tried it fairly? I imagine not, or he would hardly have needed to hint at non-forthcoming

evidence of its requiring a wall or a sheltered spot to encourage it to open freely. "D. T. F." has often pleaded for Roses in the garden landscape growing into huge bushes smothering themselves in blossom. No Rose is finer for the purpose than this, and certainly there is no wall too high for it to climb in common with others of its kind.—A. H.

Tea Rose Marquise de Vivens.—This is a lovely Rose, but unfortunately one only meets with it here and there in gardens. The flowers are only semi-double, but so profusely borne that one does not notice how short a time they last. In its wonderful colour there is nothing like it, with a pale creamy pink suffused exterior, and the rich flush of bright rosy pink in the centre of the flower. When half opened the flower affords a delightful colour study, and is altogether attractive. The charm of the Rose in three states is truthfully shown in the plate of it that appeared in THE GARDEN of February 16, 1889.

Rose Duke of Edinburgh.—This Rose is unusually late with me this year in spite of the early season. My plants are very healthy and are sending up strong flowering shoots, but I had no blooms till the end of July. The Duke of Edinburgh has not met with its wonted success at the late shows, and I have seen but few examples this year at all approaching to the usual form. In its season this Rose is almost unrivalled for its glorious colour, a dazzling fiery scarlet. A mass of this variety in full bloom, with the evening sun glancing on the handsome foliage and lighting up the scarlet blooms, is a sight not to be forgotten. This Rose should find a place in every collection, as in it are embodied all the good qualities that mark a perfect Rose—vigorous growth, freedom of bloom, handsome foliage, perfect form, fragrance, and a dazzling brightness such as few kinds can rival.—R. A. JENKINS, *Highgate*.

PREVENTING THE DEARTH OF ROSE PLANTS NEXT YEAR.

To prevent a dearth of Roses next year a good plan will be to put in available cuttings now. The summer pruning of Roses has long been more or less practised. Its object has mainly been to obtain a fuller and a better autumn bloom. By limiting space and thus concentrating force, finer blooms and freer growths are obtained. But in seasons like this, with most of our Roses more or less weakened through the protracted growth, and many stocks and plants even killed through the same cause, we wisely and well summer-prune for purposes of propagation, as well as for the improvement of existing plants and their blooms. Perhaps the very best conditioned Rose for this purpose is slightly over three-quarters ripe. At that stage, cuttings of any convenient or procurable length firmly inserted in good sandy loam on a partially shaded border in the open air will be almost sure to root, the rooting becoming more certain if a heel, however short, of older wood is attached to each cutting. This may be called the rough-and-ready plan of rooting Rose cuttings in the open air in summer, and there are many modifications of it, from the protection of a hand-light, bell-glass, cold frame to the rooting of cuttings or buds in semi-tropical temperatures or semi-saturated atmospheres. Under some of the many forms of the summer propagation of the Rose, almost every surplus shoot or bud may be converted into a separate plant.

During ordinary conditions of seasons, with those ready facilities for the propagation of Roses by stem-budding or root-grafting, this and other methods of propagating Roses by cuttings are but little practised. But this year all such methods deserve a trial to prevent a famine of plants or their rise to famine prices. All Roses will not root alike readily from cuttings of the growing wood in summer, and generally Teas and Chinas root more freely than Hybrid Perpetuals or most others.

The length of the shoots is far less important than their condition; a length of from 6 inches to 9 inches

proves convenient. But one bud in the earth and one in the air should suffice could such short cuttings be kept sufficiently firm to prevent disturbance or shifting before rooting. Hence it is safe practice to place a third or a fourth of the length of the cutting under ground. If the cutting is heeled off it needs no further making, unless its head is too long, when it should be cut off to an average of 6 inches or so. All the leaves may also be left intact; the bottom ones are mostly removed for convenience. But some hold they are better left on, their slight action exciting the emission of roots. This rough-and-ready mode of making and rooting Roses produces suckers as well as roots. So much the better, one is almost tempted to add; the more suckers on own-root Roses the better, inasmuch as every sucker is also a Rose in its own right. Such plan's soon spread into stools of Roses, and if anyone feels disposed to say or to feel that stools of the finest Tea or other Roses are too much of a good thing, he has the remedy in his own hands by dividing the stools into units and keeping every unit to a single-stemmed Rose ever afterwards. D. T. F.

AUTUMN PROSPECTS.

HAVING recently been favoured with some most welcome showers, the autumn prospects of Roses in the south of England have been considerably increased; indeed, I may say they were never so good as at present. Both the Hybrid Perpetuals and Bourbons, as well as the Teas and Noisettes, promise a good show of autumn bloom. The two latter classes are always good autumnal bloomers, but this season they promise to be much better than usual. All of my plants seem to have started afresh since the rain, and, being particularly free from mildew, I have great hopes of a good late crop, which will, as "I. M. H." remarks on page 67, be a considerable compensation for the few good blooms already secured. Dwarfs especially are making grand shoots from the base, and unless the dreaded mildew should attack them, we are certain to realise good blooms from these growths. As an inducement towards more new growth, I would advise the removal of all full-blown flowers and seed-pods, as these absorb much more of the plant's strength than many imagine. "I. M. H." advocates the shortening back of strong growths of this season where they are matured. This is a very good plan if carried out judiciously and not too rigorously. I do not think there is much risk attached to it, but it must only be practised upon the ordinary growers, like General Jacqueminot, Duke of Edinburgh, &c. The climbing Roses must not be treated in this manner, or they will only produce more lateral growths—of little service—instead of blooms. This warning would seem necessary because "I. M. H." does not mention the class of Rose, and some few readers might perchance use the knife upon Maréchal Niel, Gloire de Dijon, and kindred varieties.

Last year about this time I sent a note upon the summer pruning of strong growers. I would again call attention to the importance of this. Unless we can secure a healthy, vigorous, and thoroughly matured growth upon this valuable class of Roses, we are not likely to be favoured with such a grand display of bloom early in the summer as this section is capable of providing. By removing some of the side or lateral growths, we throw more vigour into the remainder, and also allow the free access of air. This is one of the most essential factors towards well-matured wood; without this, the extra strong climbers are of little service. If the hints I gave in another article are followed, viz., the planting of

strong bush growers alternately with the climbers, we shall have a good summer and autumnal display upon the lower parts of walls and fences. This system of summer pruning is equally applicable to the same varieties when grown as pillar Roses, and should also be practised in the case of pegged-down plants.

The extreme earliness of the present season will probably result in some of the more forward shoots producing a full crop of flowers late in the autumn. W. Allen Richardson, Celine Forestier, l'Idéal, and others do occasionally afford us a grand autumnal display, lasting up to the middle of November during a mild autumn. Where a well-ripened shoot shows a tendency to break into side growths, I would certainly remove about a foot or so of it and encourage an autumn crop. If the shoot breaks into growth from beneath each leaf and does not produce a bloom this season, such shoot will be of very little service next spring.

RIDGEWOOD.

Sweet Briers.—I share with "A. H." the regret of the over-naming of the hybrid Sweet Briers if such exists, and especially the making of mere colour the basis of names, as this is specially evanescent, and, as "A. H." truly remarks, varies much among the common Briers according to soil, locality, &c. We have also several varieties of Sweet Brier already, though little known or grown, covering the whole field of colour, from flaming scarlet or fiery red to white, the latter and the double scarlet and white being the more rare. All these and the varieties known as Celestial and Splendens will probably play important parts in the production of future hybrids. Two prominent points will not be lost sight of—the fixing of the exquisite order of the Sweet Brier on the leaves of our Teas or other Roses, and the enlarging and doubling of the flowers of the new Briers. The latter is perhaps of the least importance, for I agree with "A. H." that we have few singles among Roses to equal masses of Sweet Brier in full flower or covered with their coral haps, and the effects would at least prove more distinct, if not more pleasing, were we more careful to use and grow in quantity all the old varieties and variations of the common Sweet Brier we already possess. Instead of this the run on big Roses has almost uprooted the common and other Sweet Briers from many gardens.—D. T. F.

SHORT NOTES.—ROSES.

Rose Narcisse.—My chief fault with this charming Rose is its weakly growth. The flowers are as good as you say (p. 68), but it is difficult to get enough of them on many soils and in most places.—D. T. F.

Rose Marie van Houtte.—Seldom or never has this Rose been finer than this year. It seems to have enjoyed rather than endured the heat, and produced an unusually fine crop of its richly coloured, well-formed flowers. Either on a wall or as a bush or in a group there are few more attractive Roses than this. Experienced rosarians are constantly finding fresh charms in Marie van Houtte, and novices who know little about Roses are won to the pleasures of a new pursuit through the same medium.—D. T. F.

Rose Princess of Wales.—It was pleasing to find such a flattering notice of this fine Rose (p. 66). I have long thought it one of the most beautiful Roses raised and sent out by the late Mr. Bennett. Unfortunately, it is not a vigorous grower under the same conditions as suits most Tea Roses. It also appears to be more tender and suffers more severely from frosts. But well done, as by Mr. Prince, of Oxford, and others, there is hardly a Rose to equal the Princess of Wales in chasteness of form and refinement of colouring.—D. T. F.

STOVE AND GREENHOUSE.

SHOW AND REGAL PELARGONIUMS.

I WAS very pleased to see a few varieties spoken highly of by A. Young in THE GARDEN (page 42), as I have at different times recommended them, especially Empress of India and Duchess of Fife. They were both originally distributed by Messrs. Hayes, of Edmonton, who have done so much to render this class of Pelargoniums popular. Empress of India is, I should say, a seedling from Gold Mine, also raised by Messrs. Hayes about a dozen years ago, and still a very desirable variety. Duchess of Fife, on the other hand, is doubtless a sport from Madame Thibaut. It is a popular Pelargonium name, for previous to the distribution of the Regal variety bearing that title there was a Madame Thibaut belonging to the double-flowered zonal class, and about nine years ago one of the Ivy-leaved section of that name became very popular. The Regal Madame Thibaut was, when first sent out, totally distinct in foliage and habit from any other variety, but there are now several others bearing much the same characteristics. Among the varieties that have originated as sports from Madame Thibaut may be mentioned Prince Henry, sent out by Messrs. Perkins, of Leamington, a much deeper and brighter coloured flower than the original; Duchess of Teck, white, with the exception of a slight feathering in the upper petals. This is a coarse-growing variety with irregularly disposed petals. Duchess of Fife is of a robust, but neat, sturdy habit, and remarkably free blooming, the flowers being of a rich carmine tint, with a white centre and narrow white edge to the petals. This season we have another of this class from the same source, viz., Lady Duff, the flowers of which are somewhat more crimped at the edges, and perhaps a little brighter, but the difference between it and the preceding is not great. Of varieties with white flowers, or at all events with the colour limited to a slight feathering which is scarcely noticeable, we have a great many, but a particular favourite of mine and one that Messrs. Hayes speak very highly of is Fimbriatum album, a close, compact-growing form, with large globular trusses composed of a number of prettily crimped blossoms of the purest satiny white. Some blooms are slightly marked in the upper petals, while others are quite pure. The pretty crimped edges of the petals are very noticeable in this variety. One that I recently noted belonging to this class is Duke of York, a very beautiful and distinct flower. The blooms of this are semi-double, and in the arrangement of the petals and their unusual substance they remind one of some of the oldest of the Regal class, such as Queen Victoria. The colour of Duke of York is a bright scarlet lake, with a broad margin of white and a centre of the same tint. In some flowers the colour of the petals runs into the broad white margin in the shape of a bright-coloured netting. This is a remarkably showy Pelargonium, but not of such sturdy growth as the sports from Madame Thibaut. H. P.

Gloriosa superba.—What a grand deciduous stove climbing plant this is! Although now more plentiful, it is not nearly grown so much as it deserves. Its culture is of the simplest, and it is never troubled with insects. All the culture needed is to dry it off in the autumn as the foliage changes, keeping the soil afterwards perfectly dry until the time comes for starting it again in the spring. The soil must be both open and fairly rich. I use the same as for our deciduous Calanthes, the tubers being potted at the same time. The Gloriosa takes a plentiful supply of water whilst in full growth.—A. YOUNG.

Begonia semperflorens seedlings.—Either by a course of selection or by intercrossing with some allied kind there are now a great many forms of B. semperflorens in cultivation, stock of which is readily kept up by cuttings. Still, some of them at least come true from seed, and plants raised by

this means in the spring form very effective specimens for the greenhouse at this season. The variety atro-purpurea, with deep coloured blossoms and leaves that acquire a reddish tinge when fully exposed to the sun, is very distinct and telling, while the pure white Snowflake is the farthest removed from it, and is really a beautiful form. They need to be treated much as the tuberous varieties, that is, the seed should be sown in a gentle heat early in the year, pricking off the seedlings as they require it, and afterwards potting on when necessary. Those with bright coloured flowers have that feature a good deal intensified when grown fully exposed to the sun. Owing to the popularity of the tuberous forms, the fibrous rooted Begonias scarcely attain the position that they deserve, but B. semperflorens and its varieties show signs of coming to the front.—H. P.

Tropæolum tricolor (W. O'B.)—This, which will now be in a state of complete rest, should be potted about September, using for the purpose a compost consisting of about equal parts of loam and well-decayed leaf-mould or peat, with a liberal amount of sand. Clean pots and thorough drainage are essential, and in potting, the upper part of the tuber should be on a level with the soil. A very limited supply of water should be given till the plants are in active growth—in fact, at all times over-watering must be especially guarded against. A light position in the greenhouse will just suit this Tropæolum. Directly the young slender shoots make their appearance the support or trellis that is destined for them should be placed in position, as the shoots quickly get in a tangle, and it is then a difficult matter to separate them. In purchasing tubers of this Tropæolum the mistake is often made of obtaining them too late in the season, as if kept dry after an endeavour to start into growth the young shoot perishes, and if potted and placed under favourable conditions no further growth will take place. The tuber, however, will remain plump and firm, and with proper treatment will start away the following season as if it had experienced no check. After the flowering season water should be gradually withheld, and when the bulb is quite dormant it should be discontinued altogether.—T.

Cassia corymbosa.—This is rarely met with in gardens now-a-days, but it is well worthy of extended culture. It is now in full beauty, the long corymbs of yellow flowers having a charming effect. I have a plant against a back wall in a cool corridor. During the winter it is headed back to a stump, and in the spring fresh and vigorous shoots burst forth and grow ahead until surmounted with flowers. Blooming as it does at this season it demands more attention, as about now such flowering shrubs are not very plentiful.—A. YOUNG.

PITCHER PLANTS.

(NEPENTHES.)

I SHALL be glad if you will give in THE GARDEN instructions for the culture of Nepenthes. I have one, and although it grows fairly well the leaves do not produce pitchers, only a spur at the end.—ROBERT F. PARKINSON, Barbadoes.

** From the above statement I am inclined to think the plant has got upon a stem, and in this state pitchers are not freely produced until the plants become climbers. The pitchers produced upon the short shoots about the base and on the lateral shoots are very beautiful, and totally distinct from those borne on the scandent stems. N. Hookeriana, N. Rafflesiana, and N. Chelsoni are amongst the handsomest of their race. It will always be advisable to keep a number of shoots round the base and some shoots cut back near the base to produce laterals, as upon these the largest and best-shaped pitchers will be borne. Nepenthes make very handsome ornaments kept in a thoroughly moist atmosphere which never falls below about 70° or 75° in the summer, and never lower than 65° in the winter or cool season. They are surface rooters, and spread with great rapidity

They naturally grow in boggy soil, but I have found them to do well in peat fibre and Sphagnum Moss in about equal parts. Nepenthes should be well drained, when they may have an abundance of water both to their roots and overhead from the syringe. They also make excellent basket plants, hung up in the hottest stove, and in this state one seldom allows them to get large enough to develop the peculiar pitchers of the stem leaves, because they are kept cut back every year, and these stems will serve to perpetuate the species by being made into cuttings.

WM. HUGH GOWER.

The Oleander.—Occasionally in some old-fashioned garden a few large plants of Oleander may be met with, and beautifully they will flower throughout the summer months, but their merits in this respect are very generally overlooked, and there is, I am assured, really no demand for them in nurseries. They are very apt to run up tall and naked, but to obviate this as far as possible the plants should when young be freely stopped. A few large specimens in pots or tubs form a very noticeable feature at the present time. They need the protection of a greenhouse or conservatory, and flower best if stood out of doors in a sheltered sunny nook as soon as all danger from frosts is over. As the blooms expand the plants may if needed be removed under glass, or they can be allowed to remain out of doors, where the flowers will open beautifully. The propagation of the Oleander is a simple matter, as cuttings will strike root readily if inserted in either soil or water. There are numerous varieties, all of which are of continental origin, for the Oleander is more popular there than it is in this country.—H. P.

Tecoma jasminoides.—Occasionally this plant is met with in old conservatories and orangeries, where at this season of the year its panicles of white flowers are very effective. It requires to be grown in a light and airy part of the greenhouse or conservatory so as to ensure its blooming, and I also notice it flowers the more freely as it gains age.—A. YOUNG.

Coutarea Scherffiana (G. J. B.).—The specimen you send asking if this is the plant known as *Gardenia globosa* belongs to this genus. It has much larger flowers, which are pure white, and it makes a very handsome plant. I think this was put into commerce by M. Linden, of Brussels, some few years ago. I believe it comes from Guiana.—W.

Batatas paniculata.—A Hindon sends a specimen of this which he says is the plant which yields the cotton in South Africa. The above is its name. It is a strong climbing plant with large palmate leaves and pretty purple flowers. It is somewhat difficult to say where it is a native of, for it would appear to be scattered over a large portion of the tropical world. In the western part of Africa it is cultivated largely, its large tuberous roots being used for food, but in the southern part of the same continent the white settlers get a material from its seeds which is known by the name of Natal cotton. In this country it forms a handsome stove climber, and requires to be potted in loam and leaf mould made fairly sandy. The pots should be well drained and the plants kept rather dry in the winter. The plant I believe originally came from India.

Layering Souvenir de la Malmaison Carnations.—I have no doubt that "Southron" obtains good plants by his method of layering, but in the south of England at any rate I fail to see that one need shelter the plants in frames during the rooting process. I always layer mine in the open ground, choosing a sheltered, but very sunny position. In six weeks from layering they are well rooted and ready for potting. When layering them I invariably turn them out of the pots, as new roots are at once pushed into the fresh soil, and this not only helps the layers to root quickly, but also puts strength into them. This is a good way with all Carnations grown in pots. If a plant is at all sickly, weak, or the

roots have come into a bad condition, turning it out of the pot into fresh, well-sweetened ground acts magically, the foliage assumes a healthy green, and the layers begin to push forth new leaves. I am certain that 40 per cent. of strength is thereby put into them. I must confess to some surprise at seeing shading advocated. I have always thought that the layers can hardly get too much sun in our climate. It has seemed to me that my plants were better rooted after a hot July and August than when these months happen to be more or less cool and moist. Layering is not like putting in cuttings, as the young shoots get the benefit of the flow of sap from the old wood till they make roots. A warm condition of the ground, of course, encourages root-formation, all that one has to do being to supply the requisite amount of moisture. When potted up, I think a little shade for a time from hot sun is very helpful.—J. C. B.

Crinum Powellii.—This is, as stated on page 87, just the subject to plant out in a cool house, but where it cannot be treated in this way, it may, nevertheless, be grown and flowered well in pots. In the case of single bulbs a good sized one will require a pot 9 inches or more in diameter, and if three are grown together there should be a corresponding increase in the size of the pot employed. In any case there must be a sufficient depth of soil to bury the base of the large club-shaped bulb at least 6 inches below the surface. Even then there will be a good deal of the bulb above the ground. When in pots, the plants may be wintered in a cool greenhouse or in a frame protected from frost, and in the spring when all danger from late spring frosts is over they can be plunged outside; if in the full sun, say at the foot of a south wall, so much the better for the future display of bloom.—H. P.

Cotyledon mamillaris.—G. Fischer asks for a name for this plant; here it is, and a very pretty species it is. One seldom sees these plants in gardens now, but at one time they were largely grown. The plant in question is singularly beautiful, having cylindrical succulent leaves, which are very glaucous green, and terminal pendulous spikes, which are of a deep brown. The flowers are arranged in alternate bunches of three, the tube being of a reddish brown, the limb being more of a dark chestnut brown. Altogether it is a very pleasing plant, but certainly not new, as it was known to Linnæus the younger. It comes from Namaqualand and other parts of the western parts of Cape Colony.—W.

Higginsia refulgens (H. Weller).—This is the name of your plant. These plants two or three decades ago were held in high estimation by everyone having a stove for their accommodation, and I think the species we then had in cultivation were principally due to the exertions of M. Linden, of Brussels. Beautiful plants these were, but now-a-days one never sees these dwarf, pretty, ornamental-leaved plants with their dark bronzy leaves. *H. discolor* was, I believe, the first one of these introduced about 1850, under the name of *Campylobotrys discolor*, then amongst others came *pyrophylla*, *smaragdina*, *regalis*, *argyroneura*, *refulgens* and *Ghiesbreghtii*, all of them very beautiful and dwarf, saving the last named, which was a tall-growing ungainly plant. They should be potted in a mixture of peat and leaf mould, to which may be added a little loam and some sharp sand; drain the pots well, water freely both at the roots and overhead, and shade them from the direct rays of the sun.—W. H. G.

New Fuchsias.—Many of the newer Fuchsias, more especially those from the Continent, are remarkable only for the production of large ungainly blossoms, and the habit of the plant and shape of the flower seem to be completely ignored. Most of the newer varieties that have come under my notice lately have been those with double blossoms, with in the majority of cases a large and ugly corolla, while the sepals are reduced to very small proportions, thus totally destroying the symmetrical shape of the flower. Again, in many old varieties the sepals recurve in a very elegant manner, while new forms are frequently met with in which they

are disposed horizontally or nearly so. The truth of the matter appears to be that there is among Fuchsias really no very wide range in form or colour, and many that may happen to slightly differ from the older kinds, whether an improvement thereon or otherwise, are sent out as new. It is true these remarks will apply with equal force to other subjects, more especially to Pelargoniums, and above all to Chrysanthemums. Of good shaped varieties of Fuchsias may be mentioned most of those with white tube and sepals, especially one of the oldest of all—Guiding Star; many of the single dark varieties, such as Try-me-o, Lord Falmouth, Wave of Life, Lord Elche, and others; while of double varieties some of the best are Molesworth, Duchess of Edinburgh, Beauty of Exeter, Sir Garnet Wolseley, La France, and Avalanche.—H. P.

GARDEN FLORA.

PLATE 921.

PLEROMA MACRANTHUM.

(WITH A COLOURED PLATE.*)

THIS is the best of the many species of *Pleroma* which have been introduced and tried as garden plants in England. There are over a hundred species known, but only a small fraction of these, say about ten or a dozen, are large flowered and handsome enough to deserve the notice of gardeners. The genus is not as a rule happy under cultivation; for instance, the beautiful *P. elegans* cannot be grown by the majority of gardeners. I have seen a few good specimens of it at exhibitions years ago, and it was, and may be still, one of the specialities of Messrs. Backhouse and Sons, York. But I think most gardeners will agree with me that it combines with exceptional beauty of flower exceptional "miffiness" under cultivation. *Pleroma macranthum* is, on the contrary, as easy to manage as it is beautiful. Anyone with an ordinary greenhouse can grow it, and it is equally happy whether grown in pots and trained as a small bush or treated as a climber, training its shoots along rafters or against pillars in a sunny position in the greenhouse. It is grown in both ways at Kew, where its flowers are an attraction in the greenhouse in autumn, winter, and spring. Some cultivators recommend training it on a balloon trellis; others pinch its shoots frequently so as to make it self-supporting. It likes a turfy soil, preferably equal parts of loam and peat with plenty of silver sand; it also likes plenty of water and a sunny position. Pot plants should be placed outside for the summer, the exposure to air and sunshine keeping the growth sturdy and inducing a good set of flower-buds.

P. macranthum has been in cultivation about thirty years. It was first described by Dr. Seemann from a specimen discovered by M. Libon in the province of St. Katherine, Brazil, under the name of *Lasiandra macrantha*, by which name it is still known to some cultivators. Plants were introduced and flowered by M. Linden in his nursery at

* Drawn for THE GARDEN in the Royal Gardens, Kew, by Gertrude Hamilton, October 5, 1892. Lithographed and printed by Guillaume Severeyns.

PLEPOMIA MACBAINII CHINN

Brussels in 1864. Mr. Bull also obtained it and distributed it in England. I have seen flowers fully 5 inches in diameter. When they first expand they are almost pure ultramarine blue, fading to deep purple—the colour of *Clematis Jackmani*—with age. The leaves vary in length from 3 inches to 5 inches. Cuttings of this plant strike root freely. I have seen healthy, large, well-flowered specimens grown in a stove from which they were never removed.

P. elegans is a native of the Organ Mountains, in Brazil, where it was discovered by Gardiner, and afterwards introduced by Mr. W. Lobb, who sent it to Messrs. Veitch and Sons, with whom it flowered in June, 1846. It was then described as “a plant of great beauty, with copious, glossy, strongly nerved foliage and flowers of a large size and peculiarly splendid colour, to the rich velvety purple of whose hue no pencil can do justice.” It forms a compact shrub 3 feet to 6 feet high, with short semi-erect branches tinged with red, and clothed with opposite pairs of ovate leaves 2 inches long. The flowers are borne singly on the ends of the branches, each being over 2 inches across and coloured deep blue with a purplish hue. It thrives under greenhouse treatment, and when well grown it is one of the most beautiful of all melastomaceous shrubs.

The genus *Tibouchina*, several species of which were figured and described a few years ago by M. Linden in *l'illustration Horticole*, and of which, I believe, plants are in cultivation in the Brussels nursery, is, according to Bentham and Hooker, nothing more than *Pleroma* under a new name. If the flowers are as beautiful as they are figured and described, and if the plants are as easily managed as that here represented, they will be most valuable additions to the garden representatives of the large order Melastomaceæ.

W. W.

THE WEEK'S WORK.

HARDY FRUITS.

APRICOTS.—These have carried extraordinary crops, and this, coupled with the long spell of dry, hot weather, has left the trees in a much enfeebled state. Soaking rains have done much towards freshening them up. Unless, however, the rains are supplemented by a free use of the syringe or engine in all cases where red spider is plentiful, and a good soaking of liquid manure when the trees have been many years established in the same position, the chances are there will be a great falling off in the crops next season. If the flower-buds are feeble or few in number, it is quite useless to expect a full crop, and the remedy should be applied in anticipation. Apricots ripen fairly well after being gathered in quite a hard state, and if wasps or birds cannot be kept from late fruit, gather it and store thinly in a dry fruit room. The colour is improved if the sound fruits only just changing to yellow are wrapped separately in a square of tissue paper and packed in a box of soft sweet hay.

PEACHES AND NECTARINES.—The change of weather has considerably checked the ripening of these, but all will yet be very much earlier than usual. Continue the overhead syringing in the case of all the trees other than those carrying

nearly or quite ripe fruit, red spider being kept in check by this means, the fruit also swelling to a larger size. The colouring will be perfect if only the leaves are kept from shading the fruit. Some of the varieties, notably those of American origin, change or ripen very quickly, and the trees ought to be gone over once and sometimes twice in a day in order to prevent any fruit falling. Wasps, woodlice and birds are all fond of Peaches and Nectarines, and are responsible for many losses. Taking their nests, trapping many in suspended bottles half-filled with beer, water and sugar in mixture are sometimes sufficient remedies for wasps, and if these fail the effect of a few drops of Davis's wasp-killer on some of the partially eaten fruit should be tried. Many still adhere to the good old custom of enclosing each fruit when nearly ripe in a muslin bag, and if the latter is secured to the branch it will prevent any over-ripe fruit from falling. If these bags are used they must be gone over frequently, as they are favourite resorts for woodlice. The latter should be hunted out of all dry corners and clusters of dead leaves and crushed, their hiding places at the foot of walls being also found. A free use of the syringe and watering-pot, however, is the best remedy, dryness rather than moisture most favouring the increase and congregating of these pests. If birds are troublesome, hang fish nets loosely over the trees.

PEARS.—Tomtits are leaving the Peas and turning their attention to Pears, to which they promise to do much harm. They do not make a clean sweep of the fruit they start on, but are content to peck a small hole near the footstalk, every Pear on a tree being sometimes thus served. This greatly impairs the value or keeping properties of the fruit, and should, therefore, be prevented as much as possible. These small birds are not easily scared by the report of a gun, and are very difficult to either shoot or trap. The most that can be done to check their destructive habits is to double fish nets, and hang these loosely over the wall trees, small pyramids, bushes and horizontally trained trees being also similarly treated if the crops are worth taking so much trouble with. The fine netting is the best for the purpose. Black-birds soon discover the softest fruit, and if these cannot be kept off by means of fish nets the gun ought to be freely used against them.

PLUMS.—These are most favoured by wasps, and if no other preventive measures are of any avail, some of the best of the trees might for a few days or weeks be closely covered with blinds or other cotton material used for protecting the trees in the spring, serim canvas and muslin also answering for the purpose. If the fruit is to be kept for any particular day, it should be gathered before it is dead ripe, and only the soundest be saved. Cover with wasp-proof netting of some kind, or place in a cool, dry safe. In some positions the trees are badly overrun by red spider, and already present a somewhat naked appearance. Up till the time the fruit is nearly ripe, over-head syringing should be persevered with, every morning and evening being none too often, and after it is gathered recommence the syringing as before. Coating the leaves with flowers of sulphur, and leaving this on them for about a week, would destroy most of the red spider, and this should be done if the syringe is not sufficiently effective. If not already done, mulch the ground about the trees with strawy litter, this conserving the moisture and preventing cracking. These need this little attention after carrying such heavy crops.

MORELLO CHERRIES.—Late in August and during September there is every likelihood of fruit for pies other than Apples being somewhat scarce. Morello Cherries are remarkably plentiful and good, and though early in ripening might yet hang well if protected from wasps and much wet. At present the wasp-killer is equal to keeping away wasps, but should it eventually fail or not be available, then ought some of the trees to be closely covered with wasp netting. This will keep out insects, ward off some of the rainfall, and let in a fair amount of air. About once a week trees thus covered ought to be examined and any decaying

fruit cut away. Left entirely to the tender mercies of wasps, there will soon be nothing but stems and stones left.

GOOSEBERRIES AND CURRANTS.—There has been too much rain lately for the former, the larger varieties cracking badly and the quality of all suffering. Birds are best kept from them by means of a wire net-covered structure, but the wasps have also to be reckoned with, and those who wish to preserve the fruit from these cannot do better than neatly enclose several bushes with one large square of wasp-proof netting. Any way the fruit will not hang nearly so late as usual. Damp is frequently very fatal to Red and White Currants, especially when these hang in great clusters. If not already done, lightly thin out the clusters and shorten back all side shoots and leaders to a length of about 5 inches. Then mat over neatly, so as to shut out wasps. Uncover occasionally with a view to removing decaying bunches.

W. IGGULDEN.

THE KITCHEN GARDEN.

HARVESTING AUTUMN-SOWN ONIONS.—Where these were planted out on firm and well-manured soil I find they are not much earlier in changing colour than in ordinary seasons. If through late planting the tops are not changing, they had better be bent over, this checking growth and hastening on the ripening. It is most important that these should be harvested well, as in those gardens where the Onion grub has been prevalent too much care cannot be taken with those autumn-sown. If allowed to remain fixed to the ground after being fit for pulling, a spell of wet would either cause the base of the bulbs to decay or else they would split and commence growing again. As they are being pulled lay the base of the bulbs to the sun, taking care that the tops of the one lot do not overlap those of the other. They might remain on the ground if the weather should be dry for a few days, but the ripening is more satisfactory if the bulbs can be removed under cover, where they can be freely exposed to sun and air and be protected from rains. After they have become well ripened it is a good plan to rope them, hanging them afterwards in a cool, dry, and airy shed, where they will remain sound for a long time.

SOWING ONION SEED.—For young Onions to weather the winter well it is essential that they are not too forward, as if at all over-grown the chances are they will receive such injury from frosts if a severe period should follow, that they will be of little use for the purpose intended. For this reason, in late districts seed should be sown in the first week in August or up to the 12th of the month, and from this latter date up to the 21st for the earlier districts. The soil must not be too highly manured, neither must it be loose, as it is most important that the root-run should be firm. Ground manured early in the season for Potatoes or any other crop which is now cleared off will be quite rich enough. A dressing of burned garden refuse and soot should be given, this being worked into the surface with a rake before the ground is trodden over. Select an open and sunny site, as then the growth is more satisfactory in every respect. The drills should be drawn a foot apart, these after the seeds are sown being lightly trodden over. The larger Tripoli varieties are those generally selected for sowing during this month, but the White Spanish and Danver's Yellow may also be sown. Early White Naples is a good variety for drawing during the winter for salad.

CHERVIL.—This being generally in much request for flavouring and also as a substitute for Parsley for garnishing during the winter months, seeds must be sown now. As it is not on all soils that it will thrive satisfactorily, a dressing of old lime rubbish broken up finely and strewed over the surface should be given, as Chervil is essentially a lime-loving subject. Failing lime rubbish, apply a dressing of freshly slaked lime. The site should be sloping and also open to the sun. The drills must be drawn shallow, as oftentimes Chervil fails

to germinate on account of the seeds being sown too deeply.

CORN SALAD.—At a time when material for the salad bowl is generally scarce, anything which will assist in making up this deficiency is invaluable. For this purpose the Corn Salad should be sown, as during the early spring months when fresh growth is taking place it is very palatable when mixed with other subjects. The seeds should now be sown. It is best sown on a border in the open in drills 6 inches or 8 inches apart, the seedlings being thinned out if at all crowded.

WINTER RADISHES.—These are also acceptable for mixing with winter salads. For this purpose the Black Spanish and China Rose should be sown. These are sown in drills 6 inches or 8 inches apart, and taken up in the early part of November or before frost arrives, and stored in sand in a cool shed. Sowings of the ordinary summer forms should also be kept up as long as possible. The French Breakfast is the best Radish to grow either for summer or late supplies.

WATERING LATE PEAS.—The rains have not been sufficient to reach the roots of the latest Peas, and if these are to be of any value, weekly soakings of water must be applied, as mildew at this season quickly attacks them if at all dry at the roots. Dryness at the roots and damp foliage predispose the haulm to this fungus, and as in very many gardens the main-crop Peas have been very scanty, means should certainly be taken so that the latest sowings should afford some acceptable gatherings.

WINTER LETTUCE.—As this is an indispensable crop, sowings must be made at once for providing a sufficiency of plants to meet all demands. It is a good plan to not only raise sufficient plants for lifting and planting in frames, but also to provide a quantity which can be quickly protected in case of early frosts coming on. I raise the Lettuces on a south border recently cleared of Potatoes, and here the plants grow well, the site being both fertile and in a well pulverised condition. Hick's Hardy White Cos, Black-seeded Brown Cos, All the Year Round, and Stanstead Park are not to be beaten for winter work.

A. YOUNG.

ORCHIDS.

Now that we are in the month of August the attention of the cultivator must be given to the ripening of the bulbs, so that the plants may pass well through the winter. Many species require a very high temperature when they are making their growth, and that must be continued until the growth is complete, when the plants should be gradually inured to less heat. At this season all the Dendrobiums require careful attention, for some of them have a tendency to start again as soon as growth is completed, and this can only be prevented by taking the plants out of the high temperature and moist atmosphere and keeping them very much drier and cooler. This has been alluded to in a previous number, but the plants are so easily injured by inattention, that I must urge the importance of attending to them without a moment's delay. All the earliest flowering plants are now in their resting place, and a note must be taken of those that flowered earliest, for they must be the plants to be first placed in the forcing house. *Dendrobium nobile* by good management may easily be had in bloom from Christmas to midsummer and the more beautiful *D. Wardianum* for almost as long. Other hybrids and specific forms may be had with them, but it is necessary to see to the ripening of the growths at the right time. But even this will fail to produce good flowering plants unless they are also well rested in the late autumn and winter months. Many of them have already been at rest for some time, and will be kept apart from those which will complete and mature their growths later. A few plants that succeed best in the house where the Dendrobiums make

their growth are the *Vanda teres* and *V. Hookeri*, the latter not at all so easily managed as the former; it is more slender in growth, and does not seem to take well to any system of culture which I have tried. On the other hand, there is no difficulty in growing *V. teres* year after year; it will make growths from a foot to 18 inches in length in one season, and when grown in a light position with plenty of heat and moisture the plants generally flower well. Anderson's variety is rather freer in producing its flowers than the ordinary form. *Oncidium ampliatum majus* has been introduced in large numbers recently, and the plants do admirably grown in the Dendrobium house, and when I say Dendrobium house, I do not mean a house set apart for Dendrobiums and nothing else, for ours is merely a Melon house of very simple construction and with no special ventilating arrangements. All the plants needing repotting or rebasketing are seen to before they are placed into the house. The usual compost of equal parts fibrous peat and Sphagnum is used for the Dendrobiums and *Oncidiums*, but the *Vandas* are planted in Sphagnum Moss merely without any addition except broken pots and charcoal, and no great depth of material is needed, as by far the larger portion of the *Vanda* roots are made outside the pots; they cling firmly to teak rods which are tied together with copper wire.

In the East India house there has been much work done during the past week; several species and garden varieties of *Cypripediums* required repotting. Small seedlings which had not grown so well as we expected had to be taken out of their pots where they had not made many roots and repotted into the same sized flower-pots in which they had been growing previously. Larger plants had quite filled their flower-pots with roots, and some of them of the *Cypripedium Sedeni* type were almost pushing up out of the pots, the roots being so numerous. Scale gets upon some of the *Cypripediums*, and should be removed on its first appearance, for it is not so easily removed when once it has obtained a good foothold without materially injuring the plants. Repotting *Miltonia Roezli* was also concluded. In gardens where Orchids are not the first consideration it is not easy to find time to do all the work exactly when we want to do it, and some plants have to wait longer than they ought to do, but if time cannot be spared both to clean the plants from scale and other insect pests, and also to repot them, I would rather let the repotting stand over and see that they are cleaned. Small seedlings require careful looking to, as the plants in very small pots soon suffer from lack of water, and they get a serious check, which may cause them to get into a bad way and retard their flowering not by months merely, but by years. In the Cattleya house, now that all the repotting of the summer and spring flowering *Cattleyas* has been seen to, there is not a great deal to do except to keep the plants clean. There is no excuse for thrips being upon these plants and upon the *Lelias*, for they will stand fumigating, but in some instances other plants have to be grown in the house besides *Cattleyas*, and these may not be able to stand the fumigating so well as the *Cattleyas*. *Miltonia vexillaria*, for instance, is so easily injured by tobacco smoke, that it is never safe to fumigate a house with plants of this in it, but for the present they are in the cool house, where they seem to do very well with *Masdevallias*. It is well to fumigate as a preventive when the *Miltonias* are not in the house. These plants must be cleaned by dipping them in diluted tobacco water. I find that *Cattleya Skinneri* and *Laelia elegans* are the most liable to be injured by thrips, and these plants should be carefully watched, for if they are kept clean by fumigating all the others will be safe. The weather has been more changeable recently, and more attention is needed to keep the houses right, but the weather has been better for the cool house, as hitherto, besides the excessive dryness of the atmosphere by day, there has been no dew at night; now that so much rain has fallen the night dews have been heavy. The temperatures are still kept up about the maximum point as advised in previous numbers.

J. DOUGLAS.

PLANT HOUSES.

STOVES.—LATE POTTING.—It is not advisable unless in extreme cases to pot large or specimen plants later than this, and then only can it be recommended when a good command of heat is at disposal. In such instances as unhealthy plants, where it is palpably evident that a further decline in vigour will ensue unless potting be resorted to, it is far better to attend to it. This more often than not will have been brought about by over-potting on previous occasions, although in some cases it will be the natural result, more particularly where the soil has not been of the best description. There is time yet with a brisk temperature to obtain a good root-action before winter sets in, but particular care through that season must be given to watering and other details. Plants of rapid growth are those which will more readily re-establish themselves, but rather than expend too much time and labour upon these it is far better to depend upon younger stock.

It is rather in the case of young and vigorous plants that late potting will be of the greatest benefit, and then it must not be carried too far. Only just a shift in any instance should be given; this will be ample for the remainder of the growing season. Young plants of *Dracenas*, of *Crotons*, of *Pandanads*, of *Palms*, or other decorative stock upon which a dependence is being placed for the late autumn and winter come under this category. When it is seen that any of these cannot well continue to thrive without another shift, then let them have it, but bear in mind that by feeding them often with liquid or artificial manures and by watering at all times with a free hand, many of these will remain in the best of health in quite small pots. More often than not failure to grow these plants in a satisfactory manner in small pots results from not watering freely enough; to allow such to suffer a few times means ultimate ruin or at least a sickly appearance. In potting now, more dependence should be placed upon good soil rather than upon mere quantity. Such plants as are now potted should not be again used for any purpose out of the stove until thoroughly re-established. After potting a little more shade and atmospheric moisture, too, will be necessary for a week or two, and if bottom-heat is available, this might be applied for a short time, but not continued.

INSECT PESTS.—It is just possible that where other work has been pressing from one cause or another, the plants have not had the needful amount of attention in respect to insects. If this be the case, then no time should be lost in cleansing them. To allow any to remain in this condition longer than can possibly be avoided is discredit, and indicates want of energy as well as lax ideas of cultivation. Scale often gives a lot of annoyance and trouble, and also causes a deal of filth at this time of the year, to say nothing as to mealy bug. Between syringing and sponging, or by the two in combination, a different appearance can soon be made in any case, and hence onwards a determined stand should be made against these pests. Both thrips and red spider are concurrent with hot and dry weather; these too must be kept in abeyance, otherwise the foliage will be sooner and more permanently injured even than in the case of the two first-named insects. By a free use of the syringe in a thorough manner, however, there should not be much need of fear from this source. When the syringing is only half done, the tops of the plants being the only portion that is wetted thereby, it must not cause any surprise if both thrips and spider in their varied forms do give trouble.

WATERING.—As before indicated, this should receive all due attention. To treat all plants alike in this respect shows a want of their particular requirements. *Palms* and *Crotons* among fine-foliaged plants, and *Allamandas*, *Rondeletias* and *Vincas* of flowering subjects all take a liberal supply, and it is easy to detect instances where they have not had it. *Dracenas*, *Pandanads* and *Anthuriums* hardly require so much, nor do *Clerodendrons*, *Bougainvilleas* or *Ixoras*. With such weather as we have been having, and may yet have a repetition of,

it is quite needful to give close attention to watering. In any case where further assistance is needed to sustain the plants, as, for instance, those now flowering freely, as well as those already indicated, resort should be had to manures in one form or another, using a discrimination between plants of permanent character in their present pots and soil and those which are annually shaken out and repotted. Where climbers or other plants are growing in open borders, do not be led away with the idea that they are sufficiently moist at the roots just because they are so upon the surface. This may be the case easily enough; see to it, therefore, that it does not occur. The roots may have wandered away where restriction has not been given in any form, and they will continue to travel still further if they are not liberally treated.

TEMPERATURE, &c.—A night temperature of 70° or 72° will be sufficient for any purpose. When above this to any appreciable extent, a little top air may be advantageously given at nightfall. When very sultry and if more than usually hot during the day, let the plants rest without any fire-heat at all. It is not now advisable to close quite so early, otherwise the temperature will remain too high with no corresponding advantage. Of course, with little heat in the pipes there is not so much need of late damping down as earlier in the year; otherwise the moisture will be in excess in the morning. J. HUDSON.

FLOWER GARDEN.

HEUCHERA SANGUINEA.

THE correspondence in your columns about the cultivation of *Heuchera sanguinea* seems to me to be very curious. It is a striking instance of the different conclusions to which we may be driven by our different circumstances. Still, there must be some explanation of it all and some clue by which we may thread our way through the varying representations. I venture to think that the reason why Mr. Tallack fails is just because his plants are grown at the foot of a sunny wall; they are too much dried up there, and they do nothing accordingly. It is the large proportion of sharp sand and leaf-mould to which Mr. R. W. Hosier is beholden for blossom, and "M. A. R.," of Liphook, is very much on the same lines, I should fancy, because the *Heucheras* and *Rhododendrons* seem to fare alike in his hands, and no *Rhododendron* will ever endure to be dried up. But what does rather puzzle me is to read the announcement of Mr. Wood—who has so often taught me so much—that he can have "a mass of verdant foliage without flowers." Verdant foliage! Why I should consider that to be a certain precursor of blossom, and if I can only keep the foliage of *Heuchera sanguinea* bright and green, I esteem the whole thing to be done. I owe this positive, perhaps too positive, opinion to the remark of one of your correspondents some time ago. Just now I am away from home, and I cannot, therefore, hunt up his words in some old number of *THE GARDEN*, and I do not remember who he was, but I know that the drift of his remarks about *Heuchera sanguinea* came to this: You must take care of the foliage and then the blossom will take care of itself. As that seemed to me to be a very sensible piece of advice, I acted on it without any delay, and I take this opportunity of acknowledging my indebtedness to the writer for the success I have had. Following a rule which I invariably observe about a difficult plant, I divided my stock of *Heuchera sanguinea* into two separate portions. The one I left where it had been and as it had been for a long time before, and the result has been a prolongation

of barrenness; the other I took in hand with a view to the well-being of the foliage, and a very large crop of blossom has come of it. I suppose it would be dangerous to say without counting the withered stalks that I have had hundreds of flowers, and I cannot do this while I am away from home, but I am quite certain that I have had scores of them, and the deep red colour (! have said red, and I do not use a specific term for safety's sake) attracted the attention of every visitor who came within my garden gates and saw this glorious flower, which was in all respects quite as happy as though it were living under the sky of Mexico and had chosen for itself what it wanted to have. To my mind, *Heuchera sanguinea* is the finest of all recent introductions of hardy plants, except Irises, if it be taken for granted that it prospers and does well. A clump of rather dry leaves which have a tendency to become brown does not call for any rapturous admiration. But let the plant have a fair chance, and what look like little bells of coral dance over the pleasant-looking cushions beneath them; and I know of nothing prettier during the happy month of May, when so many of the best things are at their best and all is glad around. My good friend Canon Ellacombe, in one of his interesting papers to the pages of your contemporary—I am referring to a non-horticultural paper—gave it as his opinion quite recently that *Dielytra spectabilis* is the best new hardy plant that we have had for fifty years, and when I read his words I felt almost inclined to say there may be two opinions about that; and though he is not the person from whom to differ without much consideration, I am bold to aver that if I were obliged to part with either *Dielytra spectabilis* or *Heuchera sanguinea*, I would let the former go. Mexico, and not China, would win the day in my eyes, and the loss of *Dielytra spectabilis* would now occasion a much less void in my garden than if *Heuchera sanguinea* were taken away from it. But reverting to the matter of culture, I would only add that I made a sort of compost of good loam, a great deal of peat and some old decayed cow manure and sand, and in this the plants have done excellently well. They have been planted in full sun, and I do not think it matters one jot whether they be on the level or on a slope. I imagine that the foliage must never be allowed to get into an unhappy condition, and I think that if that be attended to, all will come right. I have a fancy that the clumps must be pulled to pieces from time to time, and I quite agree with Mr. Wood when he writes that liberal mulchings do them great good. If very large specimens are left to themselves for a long time, the crowns become crowded together, and the soil gets to be impoverished, and the flowers entirely fail. At one end of my rockery this summer in an equally good situation with the other facing south, *Heuchera sanguinea*, when it was left to its own devices, did nothing at all; at another end it was most noticeable both for gracefulness and colour which could not be exceeded. I never by any chance give it any protection, and it does not seem to me to require it.—HENRY EWBANK.

— Another word about this not flowering. I see nothing in the several notes of correspondents (page 84) to oppose my theory submitted on page 85, whilst Mr. Hosier, who is successful with it, describes conditions that would be likely to save the plant from the form of injury I mentioned. Anyhow, any grower may satisfy himself on this fact by examining his plants even yet, that where the plants have failed to flower the last year's points or somewhat bulkier crowns have gone

black and blind; had these pushed there would have been flowers. I think I may add, for a certainty for years both at home and in other gardens, I have been in the habit of watching this plant, and where I have seen the previous year's bulky buds in a black and dead state I have asked, "Do you get flowers?" and invariably the answer has been, "No," or "Very few." I take it that the cause of these flower crowns dying is winter wet. I think so because plants left quite exposed are uncertain to flower, and those sheltered from wet by a sheet of glass open at all sides never fail provided they have made free and healthy foliage the previous summer. Mr. Hosier's plants (page 84), in "very narrow deep crevices of the rocks," which do so well, get, I suppose, the shelter in some degree that I recommend for general trial. I may also be allowed here, and fittingly, to say a word about shelter for other plants from winter wet. I have tried it on plants that I consider needed it, and also on such as I knew could survive any sort of a winter without it, and in all cases the results have been a most marked improvement of the plant in leaf and flower. Some of the mossy and silvery Saxifrages are changed almost beyond recognition for the better. Let me be clear. Do not shelter your plants, as I know many have done, by taking your plants to the cover, but bring the cover to the plants, otherwise you defeat your own ends, for to move or disturb a plant in the teeth of winter debilitates or possibly gives it its death stroke. Simply fix a piece of glass over the plant without touching it and leave all around quite open, then you get what you want and nothing more, *i.e.*, you do not get drawn growth, but dry tops and crowns. I have seen sheets of glass laid on plants; this is deadly, and far worse than no cover at all, for where there is contact condensed moisture will be held and rot must result; if not, it will be more from accident than anything else.—J. WOOD.

Funkia Sieboldi.—This fine Plantain Lily does extremely well here at Highgate. A small plant obtained from Holland three years ago has developed into a magnificent specimen with nearly forty crowns. This *Funkia* would be well worth growing for its noble foliage alone, but its beauty is greatly enhanced by the long spikes of pretty lilac flowers which it throws up so freely during the summer months. It is not at all hard to grow and flower well. Given abundance of moisture in the hot weather it will flourish in almost any position. *F. grandiflora* is not so accommodating. It is impossible to make this variety flower unless given a sheltered and sunny position, but under glass its white, sweet-scented blooms are freely produced. Its leaves are of a much brighter green than those of *F. Sieboldi*, and it blooms in late summer.—R. A. JENKINS, *Highgate*.

Hollyhocks from seed.—It is curious to note what a clean sweep the little red fungus has made of the Hollyhock in many gardens. It is worth while considering whether a different way of cultivation would not lead to good results with so favourite a plant. It is no longer necessary to increase the plants from cuttings, and thereby give the fungus a chance of keeping the plants company, as the different colours are to be had from seed; and, as they come fairly true in this way—say 80 per cent., if the seed be good—it is easy to have fine plants in this way by raising plants every year to bloom the following. The plants from seed are just as susceptible to the attack of the puccinia as those from cuttings; but from seed we have the advantage of a clean start, and if the ground where we put out our seedlings is free from the pest, the plants will escape and give a fine bloom. Plants so grown are often very beautiful, and the colours soft and true. The Hollyhock, like the Carnation, comes into bloom when many of the summer flowers are over, and for this, among other reasons, it is a welcome aid in many gardens. There is another advantage in the plan, that we are absolved from the need of buying named plants more or less expensive to get and keep. The seedlings may be raised in frames, or

when the ground is warm in early summer, and, when well up, the little plants should be pricked out where they are to bloom in good rich soil.—*Field.*

FLOWER GARDEN NOTES.

THE mention of *Prunus Pissardi* in a recent number in connection with summer bedding reminds one of the many hardy plants that can be similarly employed to great advantage, plants, too, varying altogether in character and very opposite as to height and general appearance, as far apart as, for instance, the stately *Ailanthus glandulosa* and the small trailing *Campanula* or the common, but beautiful double *Camomile*. It strikes one rather forcibly that there is an element of stiffness about that particular bed quoted on page 86, beautiful in a certain way and well arranged as it may be, and that a groundwork of *Calceolaria* and rings of *Viola* do not fit in altogether well with tree-like Plums and Maples. I think this fine-leaved *Prunus* would be seen to better advantage if planted thinly in a groundwork of white *Marguerites* or, say, alternate clumps of *Gautonia* with the *Prunus*, and the beds filled in with *Aster Amellus bessarabicus*. This *Starwort*, by the way, and *Aster acris*, another very free rather early flowering variety, make very fine beds associated with bold clumps of *Fuchsia gracilis*. As an instance of what may be done with the *Ailanthus glandulosa* above mentioned, I noticed the other day what otherwise would have been a very formal border, a ribbon border in fact facing a wall, wonderfully relieved by plants of the *Tree of Heaven* some 6 feet high in very fine foliage at intervals of 12 feet. In somewhat similar circumstances, viz., ribbon bordering, how admirably occasional good plants of *Nicotiana affinis* come in, especially if in the list of plants used in the bordering dark shades of colour predominate. This *Tobacco* did not this year bear out its character for hardiness; none made their appearance in the spring, except in one case where they had been close against a south wall. *Carnation* layering is now in active progress, and the grass must be pronounced abundant and excellent in quality, especially when the exceptional season is taken into consideration. This is especially the case with all members of the *Clove* family, which have seldom been in better form. With early layering well-done grand plants are likely to be ready to hand by the end of September. It seems somewhat strange the plants should have weathered the long spell of drought so remarkably well. I fancy it is partly owing to a liberal use of horse droppings at planting time, which, besides acting as a wholesome stimulant, held and retained the heavy rains of February.

Beds having been prepared for *Viola* cuttings, we shall get these in as quickly as possible. I have generally put them on an open border under a north wall, but with the idea of getting them out earlier than usual in the spring of 1894, I have this season prepared a bed in one of our home-made frames, where the plants can be covered with old lights and cloths to shelter them during the worst of the weather. In addition to our standard colours in white, yellow, dark purple, represented respectively by *White Swan*, *Bullion*, *Archie Grant*, with *Countess of Kintore*, I have this year selected from among the newer varieties for propagation *Annie King*, *Duchess of Sutherland* and *William Niel* as likely to supply some pleasing shades of colour hitherto wanting. Plenty of cuttings are available from young plants, but old stuff (spring-divided) has made little headway. An inspection of the herbaceous borders last week, to note anything of special value that must be increased in the coming autumn, has brought *Gypsophila paniculata* into prominent notice. It is difficult to have too much of this beautiful herbaceous plant. It is a veritable gem for cutting, and is yearly increasing in favour. In one of the best decorated dinner tables I have seen this year—simple, but

wonderfully attractive—this *Gypsophila*, with *Splendour* and *Princess Beatrice Sweet Peas* was used. Those who want plenty of cut flowers should also note *Statiche latifolia* and *Statiche Gmelioi*, both very light, graceful and pretty. Whilst on the subject of cut flowers, let me put in a good word for *Tamarix gallica*, a deciduous shrub of very elegant growth that furnishes an abundant supply of foliage all through the summer months. This can be readily propagated from cuttings, as indeed can the *Gypsophila*, although a stock of the latter will be more expeditiously obtained by division.

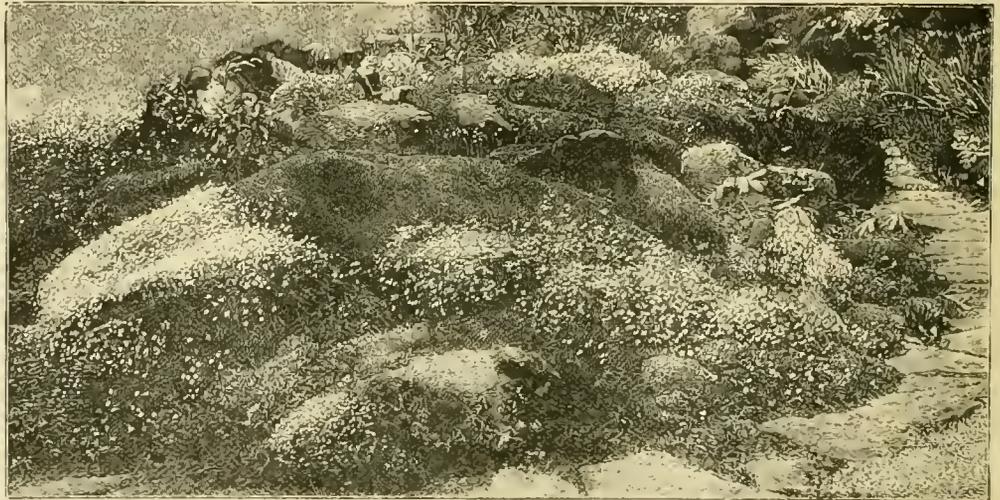

Not much time must be lost after the beginning of August in deciding as to the flower garden arrangements for another season, that some fairly accurate idea may be formed as to the number of cuttings required of different varieties.

Claremont.

E. BURRELL.

A ROCKY MOUND.

A ROCKY MOUND similar to the one here illustrated can be constructed in any garden, however small. It was my first attempt at rock

Part of the rock garden at Brookfield, Hathersage, Sheffield. Engraved for THE GARDEN from a photograph sent by Mr. G. H. Cammell.

gardening, and additions have been made from time to time. It is a mound of heath soil, among which rocks are embedded, and is planted with many varieties of *Saxifrage*, *Sun Roses*, *Maiden Pink*, *Soapworts*, *alpine Linaria*, *alpine Aster*, *Veronica rupestris*, *Erinus alpinus*, *Silene alpestris* and other free-growing alpinas. After a time all the ground has been covered and each variety holds its own successfully, determined not to give way to its neighbour. *Podophyllum peltatum* appears here and there in unlooked-for places, and the ground *Laurel* and *American Bird's-foot Violet* find a place on the shady side. The result is pleasing not only when the plants are flowering, but throughout the year.

G. H. C.

Nemesia strumosa.—I look upon this as the most valuable addition to our list of half-hardy annuals that we have had for some years, and I am surprised that some people find fault with it. I sowed my packet of seed early in February, and when the plants were large enough pricked off some six or eight into a $4\frac{1}{2}$ -inch pot. The plants grew vigorously, and in due time showed flowering stems in abundance. Later on I transferred the plants bodily into a 9 $\frac{1}{2}$ -inch pot, and they have now been in full flower for nearly three months, and I think if I cut down the flowering stems I shall

have a crop of young shoots which will keep on the blooming season for a while longer. The colour of the flowers is a pleasing bright orange, reminding one of a plant we used to see long ago—*Thunbergia alata*. Those which were planted in the ground—have had, like all annuals this year, a hard time of it, but they are now coming into flower, and in ordinary seasons I have no doubt they would have been in flower long ago. Some of the seed was sown out of doors, and will come into flower later on—DELTA.

CUT FLOWERS IN HOT WEATHER.

It is not often that spring and early summer flowers have been so short-lived as during this year, and none have proved more disappointing than *Roses*. The latter, both against walls and in the open, commenced expanding fully a month earlier than usual. No fault could be found with the quantity of blooms on healthy trees, and the size was also satisfactory, but as regards durability not much that is favourable can be said. It was even worse with the *Hybrid Perpetuals*, these opening in the morning and being past their best before the day was over. At this time of year large

quantities of cut flowers have to be sent from the country to London, and where owners of gardens are not away from home, these just now delight in sending boxes of *Roses* and other flowers to their friends. The question is, of what good are many of these flowers by the time they reach their destination? Even when properly selected and skilfully packed, they cannot be of much service after they are received; while those consigned to friends by novices must prove very disappointing. During hot and dry weather *Roses* should be cut while yet cool and, it may be, laden with dew, the preference being given to half-open buds, blooms nearly or quite fully expanded being worthless for packing. Supposing postal or train arrangements do not admit of the *Roses* being packed and sent away in time for the flowers to reach their destination the same day, then ought all of them to be set upright with their ends in pans of water in a cool darkened room, in readiness for packing towards evening. Even then some of them may be found too advanced for packing, but the rest will have absorbed a portion of the water, and being also perfectly cool, they may be packed closely together without fear of their heating badly during the journey. Where so many amateur packers err is in handling and arranging the blooms too carelessly. If they are loose in the box when started, they will be in a bad plight by the time their destination is reached, not a few of them being shaken all to pieces. What are wanted

are light yet strong wooden boxes of sufficient depth to hold about two layers of Roses. Line these with paper, place a layer of common Fern fronds or other greenery in the bottom, and on this closely and flatly pack a layer of the heavier Roses. On the latter place more Fern fronds or else a covering of paper, and then add another layer of Roses closely and flatly as before; cover with more soft greenery and paper on this, and if the lid does not close down tightly, so as to prevent the contents of the box from shifting, place a layer of either soft Moss, wood wool, or cotton wool over the paper.

Flimsy cardboard boxes, cotton wool, and a too free use of damp Moss, or moisture in any way, are causes of very many failures of flowers to travel satisfactorily. If the boxes are not strong enough to bear the pressure of other packages being placed on them, either use boxes strong enough to bear a little rough usage, or else do not disappoint by sending those not capable of saving their contents intact. Over-anxious packers seem to think cotton wool must be used about the flowers if these are to travel well, but, though serviceable in some respects, it is responsible for very many failures. The flowers must not come into actual contact with it, or, otherwise, instead of arriving at their destination perfectly fresh, they will be flagging badly, owing to the packing material having absorbed the moisture from them. If used either above or below flowers, it should always be divided from them by means of a sheet of tissue paper, and then they will most probably travel satisfactorily. Damp Moss, if only a few flowers are sent, will certainly keep them fresh, and to a certain extent prevent bruising. In this case lay the flowers flatly and closely on the Moss, cover them with tissue paper, and use enough light Moss or cotton wool to fill the box, the lid fitting down rather tightly on the packing material. When large boxes of either Roses or mixed flowers are sent a considerable distance in hot weather, a free use of damp Moss may ruin the lot, as it is liable to heat badly, the flowers, more especially Roses, falling directly they are unpacked. As it happens, there is no need for the use of any moist packing material, a mass of flowers and greenery preserving one another perfectly fresh, especially if they were cut when in a cool state and generally treated as advised in the case of Roses. Certain flowers, or those of a flimsy character, will not travel or often even keep well under any circumstances. Among these must, unfortunately, be included Poppies. These, if cut when quite young, will last for two days in a cool room, and might be sent to the town house for a dinner party, the Iceland forms being perhaps the best for this purpose. Light boxes should be wholly and closely filled with such flowers as these, nothing but very light packing material coming between them and the lid of the box. Not many other single flowers, if we except Sweet Peas, travel well, but semi-double zonal Pelargoniums, semi-double Ivy-leaved Pelargoniums, if gummed, Stocks, Asters, Zinnias, double Dahlias, Sun-flowers, Mignonette, and Carnations all travel and last well after they are received. The last-named are among the most serviceable and generally acceptable flowers that could be sent or given to anyone, and ought to be largely grown wherever cut flowers are in great demand.

In packing mixed boxes, line the boxes as advised in the case of those for Roses, and lay the heaviest, including any Roses there may be, in the bottom, and the lighter or more flimsy flowers on the top, finishing off with Fern fronds face downwards. Once more let me point out the great necessity for arranging them closely and flatly together, and also for closing the lid down tightly on the paper-covered top layer. Flowers ought to be unpacked in a cool, but not airy room, and there be at once arranged in either vases or temporarily in bowls of water.—*Field*.

Sweet Peas.—The complaint that there are too many of these is very just, but the cause is more likely to be extended than reduced. Raisers will go on putting into commerce sorts so-called that

differ in an infinitesimal degree from others sent out. That we have far too many Sweet Peas is due to the fact that three-fourths of those in commerce are of washy, slaty, or dirty tints, or else one of those mixed, striped or bizarre hues that cannot in any way be described as pleasing. It is a pity that seedsmen do not refuse to catalogue any but such as have very decided and taking colours and ignore all others. That course would soon stop this sending out of so much rubbish. The most useful and pleasing tints in Sweet Peas are pure white, pink, bright red, blue, and a good maroon-purple. Given these colours under whatever names found, we have the best. The pink or flesh varieties are particularly pleasing and in high favour for table decoration. Almost everywhere Sweet Peas have had a short season, but those who made sowings early in June if they induced the seeds to germinate, should now be reaping a reward in rows that will bloom well late into the autumn.—A. D.

—The admirers of Sweet Peas were lately afforded a good opportunity at Earl's Court of verifying the assertion in a recent number of THE GARDEN (p. 87), that there are far too many names; indeed, the principal point of difference to be detected, as least in some cases, is the name itself. Striped flowers and those whose colouring is dull and undecided have nothing to recommend them, yet a number of varieties of this class are to be found in the long lists that are issued at the present day. Princess Beatrice is, as stated in the above-mentioned article, a good brightly coloured variety, and so is Orange Prince, one of those shown on a coloured plate issued with THE GARDEN, March 12, 1892. The grower of these flowers for sale finds, however, that unless there are exceptional circumstances, a good pure white-flowered variety will meet with a readier sale than any other.—H. P.

NOTES ON HERBACEOUS PHLOXES.

THE present year has not proved favourable to the herbaceous Phlox or plants of that class, the severe drought until recently stunting the growth and promoting early flowering. But the large and interesting collection in the Chiswick Gardens is worthy of note. The plants are not so free and striking as in more favourable seasons, but they are flowering with freedom, many of the varieties being decided and distinct in colour.

This type of Phlox has during the past few years got popular in gardens, and the reason is obvious. Much improved kinds have been raised, a large number by French growers, and the habit is usually both compact and dwarf. Although perhaps this may not be thought an important matter, much depends upon this point as to the usefulness of the variety. Some are tall, straggling, and untidy, but the majority of those in bloom at Chiswick are bushy, compact, and vigorous, each plant crowned with heavy masses of finely coloured flowers, the individual blooms of bold size and form. Not a few of the colours, crimson, purple, carmine, and so forth, are remarkably bright, making a rich and decided display. With a judicious selection the garden may be kept gay with Phloxes from early summer until late autumn if the finer varieties of the Phlox suffruticosa section are chosen, and also of the later-blooming Phlox decussata forms. There is a great wealth of colour in both races, and it is important not to get too many purple, magenta, or carmine tones. These abound, and in a large collection one sees how many varieties occur with flowers that differ only slightly from each other in colour. At Chiswick the major portion of the collection is of the latter type, but owing to the dryness of the season the plants are in bloom much earlier than usual. The suffruticosa section is not so rich in good kinds as the other, and one of the finest is the variety Miss Mima, which has white flowers with a delicate pink centre. The plants have been received from many growers who are well known as having taken much interest in this flower.

Mons. Lemoine's name is of frequent occurrence, and in his nursery at Nancy, France, he has done good work in hybridising to get better and more diversified colours. Mr. Forbes, Hawick, N.B., Messrs. Dicksons, of Chester, and Messrs. Paul and Son, Chesham, contribute liberally from their rich stores.

The collection, at present in full bloom, is somewhat bewildering, many varieties approaching one another closely in the colour and expression of the flowers. A severe sifting-out is essential, and the rejection of dingy and weak mauve-coloured kinds that have a poor, unsatisfactory effect. Bright, decided colours are not wanting, and the plants for the most part are dwarf and bushy in habit, naturally so, not merely the outcome of an abnormally dry year. For the guidance of those readers of THE GARDEN who are searching for a few very distinct and pleasing forms, we have carefully gone through the Chiswick collection and selected the brightest and most refined shades of colour, carefully eliminating all dull and washed-out tones. The Phloxes are of the greatest use in the garden when well grouped together to get the richest possible effect from the flowers. Such a beautiful variety as Independence would look well, being of dense spreading habit, each sturdy stem surmounted by a large mass of pure white flowers. This is quite one of the best of the white-flowered kinds in the collection. The Queen and Delicata are also white-flowered varieties, compact in habit, the latter enriched with a rose-coloured centre. It is interesting to notice the great difference that the centre makes to the flower, and in the case of the variety Aphrodite it is lemon-yellow—a delicate contrast. Any of these white kinds may be chosen, but, of course, there is much similarity between them; for instance, Countess of Aberdeen, with rose-purple eye, Queen Mary and Mons. Rafarin are practically the same. Varieties with white flowers and purplish centres are comparatively common. Henri Murger is distinct; the flower is large, white, with a bold rosy purple centre. Perle and Purété are two very charming acquisitions. The former of the two is distinct, each flower of large size and white, touched with rose, the trusses compact and produced freely above a wealth of deep green foliage. This is one of the most beautiful kinds in the collection; whilst Purété is white, as its name suggests, and the plant is dwarf and exceptionally compact.

Many creditable varieties will be passed over in these notes. It is impossible in the majority of gardens to grow many Phloxes, even if it were desirable. The great thing is to get the more telling and beautiful colours, which are not too numerous. General Chaver is a fine kind, the individual flowers exceptionally large, and the brilliant salmon-red colour is remarkably effective. A good mass of this would make a great display. George Goodall is another fine variety, free, vigorous, and of delightful colour, which is bright carmine-rose. One of the best in the collection is John Forbes, which bears a very large rosy purple flower with a deeper coloured centre; and worthy of note is the variety Graham W. Culloch, an ugly name for a flower. Why are not simpler names given than such effusions as this? This is one of the deepest in the collection, the flowers brilliant self crimson, a penetrating shade, being conspicuous even amongst the large number of other kinds. A superb variety in every way is one named Adonis, which should be found in the smallest selection. The individual flower is of very large size well shaped, and clear salmon in colour, the base of the petals white and the eye purple. A large mass of this would create a pleasing feature in the garden. We do not care for flowers of a magenta shade as a rule, and, unfortunately, there are many varieties of mauve, purplish and allied tints which must be carefully avoided. We are surprised that so many of this type get into good catalogues. Too long lists are confusing. Of the magenta-coloured forms, a very good type is Pont Briquet, which has flowers of peculiar brilliancy, not a dead, but a bright and decided shade. Matador is a variety of fine colour, salmon-red with deep maroon centre, and the bold heavy truss is

supported by strong stems. In this group, so to say, may be included the variety *Etna*, a vivid salmon-scarlet colour, each flower of large size, broad and showy. A kind that we should select perhaps as soon as any is *Eugène Danzavilliers*, a French variety, but of splendid habit, spreading, yet bushy, strong and exceptionally free. The flowers are scarcely sufficiently strong in colour, but their mauve tint, the centre white, is beautiful in a mass. Another gem is *Boule de Feu*, the colour brilliant orange-scarlet with deep maroon eye, and we may also mention as of note, *Mrs. Kinghorn*, rich salmon-rose, the trusses very large; *B. S. Williams*, brilliant crimson, exceptionally bold and vigorous spikes; *Aurore Bereale*, bright orange-scarlet; *Princess of Wales*, white with purple eye; and *Baronne d'Arche*, rich rose. This selection is not too large, and each colour is as far as possible included if sufficiently worthy.

In planting this type of Phlox, remember to get a few of the *suffruticosa* section, which should be planted in the border with those that bloom later to get a succession of flowers. A gay effect may be maintained for several weeks with a judicious selection, although this year the recent long-continued drought has proved trying, the bloom quickly going past its best. We need not make reference to the cultivation of this fine perennial. It is necessary to thin out the shoots if too thick in spring, and enrich the soil at that season if the plants have been in the same position for some time.

CHRYSANTHEMUMS.

BUD FORMATION.

If there is one phase in cultivating Chrysanthemums for the production of large blooms of more importance than another it is that of making a proper selection of buds. Even in an ordinary season this is a troublesome detail, but what must it be in such a peculiar season as the present, when, owing to so much drought, the plants have developed breaks and buds in an unaccountable manner? Many of the varieties, the Queen family, for instance, have formed flower-buds at least three times already, which is sufficient to upset any calculation that may be made as to the probable date of either the crown or the terminal bud forming. No doubt the extremely dry state of the atmosphere during the months of May and June predisposed to so much irregularity of growth and bud-formation in the plants. We can supply moisture to the roots as required, but we cannot altogether prevent the arid state of the atmosphere. Chrysanthemums are moisture-loving plants, not only about their roots, but amongst and around the foliage also. We never see such luxuriance of wood and foliage during a dry season as is to be found in one that is less dry. Too much heat and too little atmospheric moisture tend to contract the sap vessels, and thus check free growth. Experienced cultivators of Chrysanthemums for large blooms, whether for exhibition or home decoration, know quite well it is useless to expect high-class blooms if the right bud is not selected. If the buds set too early, instead of perfect globe-like flowers in the incurved section being produced, huge coarse-looking examples, the petals of which reflex instead of incurve, will be the result. Not only will the time required to cultivate the plants be wasted, but grave disappointment is certain to follow. The blooms resulting from too early bud-selection will possibly be large in diameter, but they will lack the two essential points which go to make a perfect flower, viz., depth and solidity. This is the point wherein so many beginners fail.

They are not able to discriminate between the right date and the requirements of each variety owing to a lack of experience. As a rule, many varieties in all sections produce the finest flowers from what are known as crown buds. Why this particular bud is known as a crown it is difficult to determine, because several other buds are formed in exactly the same way. In fact, all buds are alike except in the case of the terminal, which is surrounded by other buds, but in the case of crowns the bud is encircled with growth-shoots. For this latter reason it probably takes the definition of crown, being the centre or prominent part. There is nothing distinct about the bud, which usually forms in August and is selected to give the finest bloom, from that which is the product and cause of the first break—multiplication of shoots—sometimes occurring in April and at other times during May, according to circumstances, such as early or late propagation, manner in which the plants have been treated, and so on. The naming of this bud has become a matter of following a fashion set by the earlier growers of some thirty years ago, or more perhaps.

Not only have the plants this season exhibited this peculiarity of bud-formation here, but from many letters received and observations of other growers' plants, I am led to the belief that it is general. Many beginners, in cultivating the plants for large blooms, are in a fix, owing to so much premature growth and bud-forming, that they are uncertain how to act to obtain the greatest measure of success. Having learnt that crown buds as known to the fraternity produce the finest blooms, they are afraid to risk the loss of these said buds by removing them and retaining the shoots awaiting the formation of other buds. I lately saw a collection of Chrysanthemums grown with a view to producing large blooms in which most of the buds were "taken"; in fact, many were the size of Peas. I am afraid this said cultivator has a disappointment in store for him. Instead of the plants developing blooms when most required, November perhaps, the bulk will be in flower fully by the middle of October, many earlier than that date, and some of the plants will never be satisfactory. Where the buds are formed so early, the petals burst from the calyx long before the plants ought to be housed; the consequence is the florets are rotted by night dews and rains, the petals being very often deformed and unable to unfold into a good bloom.

Those persons who wish to have the bulk of their plants in flower during November, with some few towards the end of October, should now pay special attention to the plants that are forming their buds. With the exception of a few Japanese kinds, such as *Boule d'Or*, *Mrs. Alpheus Hardy*, *Pelican*, and *Mrs. Falconer Jameson*, that were not topped, but allowed to grow uninterruptedly until the natural breaks in the plants were made, all should have any buds that formed before the last week of July promptly removed. By the third week in August other buds will have formed; these will give the most satisfactory flowers. They may not measure quite so many inches in diameter, but they will have greater depth of petal, solidity, and be decidedly of a richer colour, and last fresh much longer. Take, for example, the pure white Japanese variety *Avalanche*. Plants of this are now (July 20) forming buds at the end of the second break. If these were allowed to remain, as in many instances through want of knowledge on the part of the cultivator, they will develop blooms early in October, and for any purpose of exhibi-

tion they will be utterly useless. The blooms would be of large size, but the florets would be narrow as compared with those from buds formed a month hence, and they would only tend to increase the anxiety of the intended exhibitor and add to his chagrin when he saw the petals around the base of the bloom commence to fade fully three weeks before the date of the exhibition. By removing the bud promptly and taking up one single shoot as before on the same branch, buds that will form from the middle to the end of August would certainly prove satisfactory. E. MOLYNEUX.

EARLY FLOWERING CHRYSANTHEMUMS.

MANY excellent kinds have been recently added to this useful class of Chrysanthemums, and they should help to make even more popular a group which precedes those that have given to this plant the name of Autumn Queen. *Lady Fitzwigram* cannot be too highly praised because of its being a white flower, and those growers whose business it is to provide cut bloom in quantity will find this variety a gem for early autumn work. As a decorative plant for the greenhouse it will make one of the most useful, its dwarf character and wonderful freedom of bloom commending it to all. It was raised from seed in this country. *Ryecroft Glory* appears likely to form a deep yellow companion to the last-named, as it possesses a similar habit and is equally free-flowering. Both varieties give large, well-formed blooms if disbudded to about half a dozen flowers to a plant. The soft pink and white *M. Gustave Grunerwald*, which last season was with me so very promising, has this year been good as a bush plant, but I have experienced a difficulty in getting it to produce large flowers on account of a tendency to give bloom-buds instead of leaves. Nevertheless, it is a first-rate kind, and should be excellent for planting in a mixed border out of doors. For this purpose the old stools of the early-flowering Chrysanthemums may be profitably kept in a frame through the winter and planted out about April. Not only will a larger bush than from young struck plants be the result, but they may be expected to flower a fortnight earlier. *Amy Russell* is a pale pink sport from *Mme. Desgrange*, and on that account cannot fail to be esteemed. The *Desgranges* are quite a class in themselves, for from the white type we have *Mrs. Burrell*, pale yellow; *G. Wermig*, a few shades deeper; and *Mrs. Hawkins*, deeper yellow still. I find the last rather more tender than the others; indeed, all of the *Desgranges* are fine-rooted and require delicate treatment in the young stages. They strike best in a little warmth, and may have a greenhouse shelf near the glass till the end of March, at which time they receive the usual cold frame culture. *Mme. Desgrange* and its sports should not be potted in a compost so rich in manure as that used for the bulk of Chrysanthemums, and, like all of the weakly growers, they do not require manure water in a strong state when growing. Returning to the newer kinds, *General Hawkes* attracted some attention last year on account of its rich deep crimson colour. It is a prettily formed Japanese flower of large size when grown for that object, but cultivated for quantity of flower it makes a capital display in a collection. It is not, however, among the earliest, the month of October being really its proper time. Another novelty flowering midway between the forwardest and those which bloom at the ordinary season (November) is *Gloire de Mezin*. This is a Japanese form, loose and graceful, and of a beautiful light amber shade. The growth of the plant is good, and the leaves a remarkably dark green. *Coral Queen*, as its name denotes, is a very distinct shade, the flower of twisted form. It should become a favourite for cut flowers during early autumn. *Mme. Zephir Lionnet* was much admired when exhibited last year. It is deep yellow, rather small, but exceedingly free-flowering. Among older varieties *La Vierge* deservedly holds its own as one of the very best whites. It makes a

pretty pot plant and blooms well out of doors. *Souvenir de M. Menier* is still a favourite with me. It makes a noble bloom when disbudded to three on a plant. *Sydenham White* must give place to the first named in these notes. Some of the pompon or small-flowered varieties are pretty planted in mixed borders, and are also welcome for cutting purposes. *Piercy's* seedling, bronzy yellow, makes a nice bush plant for pot work as well. The same may be said of *L'Ami Conderchet*, creamy white. Its growth is bushy and loaded with flowers. *Mrs. Cullingford*, bluish white outside and pure under glass, is a most useful kind, and *Mignon*, yellow, makes a capital bedder. *Little Bob*, crimson, is similarly adapted. *Lyon* is a well-known rosy purple flower; its shaded red sport, *Alice Butcher*, should be equally so. *Blushing Bride* must not be left out, being an excellent sort for early flowering.

After the August and September bloomers come those which continue the wealth of *Chrysanthemum* flowers until the bulk come in during the dullest months of the year. *William Holmes* is a brilliant crimson bloom margined old gold. This has been a favourite for some years past, and is still in its way the best. *Mlle. Lacroix*, creamy white, is the perfection of Japanese form and essentially an October kind. It has two sports, the first being *Annie Clibran*, pink, and *Mr. Charles E. Shea*, light yellow, the three forming one of the most useful trios for bush plants, cut flowers, or such purposes yet raised. *Elaine* may still be considered the purest white *Chrysanthemum* known, and for that reason alone cannot be discarded. *Felix Cassagneau* has flowers of nice drooping form of a light buff colour. The growth of the plant is slender, but free, and altogether it is a decided acquisition. *Miss Anna Hartshorn*, although often seen in November, is really an early kind and one of the best. It has loosely incurved flowers, tinted white, with a peculiar wax-like look. *Bouquet de Dame* is a flower not quite so pure as *Elaine*, but more massive and the plant is of dwarf growth. *Lady Selborne* is another good white. *Cesare Costa* may be named as one of the richest crimson coloured *Chrysanthemums* we have. It must be grown without much feeding with manures, as it is liable to produce wood hollow in the centre, which causes the blooms to damp and decay. A sweetly pretty shade of colour has *Margot*, rose-chamois. It is of easy culture, too, and much esteemed for cutting. *Miss Gorton*, creamy pink, is another kind likely to keep in our lists for some time to come. *W. Tricker*, one of the leading exhibition sorts, notwithstanding its earliness, is also a splendid decorative variety of a delicate pink colour. A few of the incurved *Chrysanthemums* cultivated for early blooming are *Mrs. Geo. Rundle*, pure white; *Mr. Geo. Glenny*, primrose; and *Golden Geo. Glenny*, a deeper colour. These three are very beautiful if grown for a quantity of bloom, and persons who generally object to the incurved class are found to value them.

H. S.

ORCHIDS.

STANHOPEAS.

THIS is a genus of South American and Mexican epiphytal Orchids, containing many beautiful species and varieties, the majority of them highly perfumed. They are closely allied to the *Coryanthes*, but they are somewhat less complicated in their structure; moreover they differ considerably in their habits, for I have been told by those who have collected them that whilst the *Coryanthes* grow upon the tops of the highest branches quite exposed to the fullest sun, *Stanhopeas* grow in the shade. *Stanhopeas* used to be largely grown, but of late years they have been discarded, first, on account of the unsuitableness of the flowers for cutting, and next, because of their perfume,

for with two or three blooms open together their aromatic odour was quite overpowering. Some species, however, are not pleasantly scented, and amongst these may be mentioned *S. graveolens*. This species I have never grown, although I have seen it on several occasions in collections in German gardens. Such is not the case with a remarkable and fine flower of *S. tigrina* which recently came to hand from Messrs. W. and G. Drover, nurserymen, of Fareham. The plant, they say, has two spikes, one bearing two flowers, and the other three. The specimen sent measures fully 6 inches across and is very agreeably scented. When I used to grow *Stanhopeas* extensively I have had plants of the species sent with three and four spikes upon them, but, unfortunately, the flowers do not remain long in beauty, two or three days being the longest they live. The flower-spikes of these plants are always pendent, and therefore pot culture is not suitable for them. They prefer open teak wood baskets, so that the spike can readily find an opening to push its way out. This should be well drained, and I like to use pieces of charcoal for this purpose in preference to broken pots. For soil use good brown peat fibre, *Sphagnum Moss* in about equal parts, and during the growing season give the plants an abundant supply of water both at their roots and overhead. At this season the heat of the *Cattleya* house will be found ample, but in the winter-time, when the plants are resting, remove them to the *Odontoglossum* house, and at this time very little water will be requisite, only enough being given to keep the bulbs from shrivelling. In the summer time water on the foliage is absolutely necessary in order to counteract the spread of red spider and other insects. The following are a few of the very best of the kinds which are now to be found in cultivation:—

S. TIGRINA is the species sent by Messrs. Drover for a name. It is a very large flower, measuring fully 6 inches across, with an unusually large and massive lip; the sepals are much broader than the petals, the ground colour of which is yellow, heavily blotched and spotted with deep purple; the large lip is orange-yellow on the margins, where it is spotted with purple, and it has a large eye-like spot of blackish brown on each side of the upper edge, while inside it is wholly of a deep purple; the middle portion of the lip is in the form of two bent horns, and is thick and waxy in texture, ivory white, profusely spotted and dotted with crimson. The front portion is of the same ivory white, spotted throughout with crimson, the long column broadly winged, flaked and freckled. This plant was introduced to this country nearly sixty years ago by Mr. Hugh Low, of Clapton, the grandfather of the present head of the firm, and the founder of that establishment. It was collected at a considerable elevation, so that it will be found to thrive in a lower temperature than is usually accorded it.

S. PLATYCERAS is another large and handsome species, which I have only seen in the Burford Lodge collection. It was figured in *THE GARDEN* a few years ago (Vol. XXXIII., t. 652). The plant was introduced to our gardens about twenty years ago by Mr. Stuart Low, of the Clapton nurseries, but he never disclosed its native country, and it still remains a rare plant. The sepals and petals are of a creamy yellow, freely spotted with purple. The long column is winged in the upper half, white, dotted and spotted of a purplish hue. It is a most desirable plant.

S. SHUTTLEWORTH, a fine kind of more recent introduction, is named after its introducer. The ground colour is of an apricot-yellow, spotted and blotched with a reddish purple. It is a rare plant at present and yields a delicious odour.

S. EBURNEA.—This is an old species, cultivated in our gardens nearly seventy years ago, but it

still remains a rare plant; the whole of the flower is ivory white, saving a few spots on the lip. I have to correct two errors connected with this species which I have made upon former occasions when writing of this plant. Brazil is not its native country, but the coast-line of Venezuela and other parts of South America; and again I made a mistake in separating this species from *grandiflora*; they are synonymous.

There are many other fine *Stanhopeas*; amongst them may be noted *S. Devonensis*, *S. Wardi*, *S. oculata*, *S. Martiana*, *S. bucephalus*, *S. oculata*, *S. ornaticissima*, *S. insignis*, and others, besides a great number of handsome varieties, which I should again like to see become popular.

WM. HUGH GOWER.

Oncidium Gardneri.—A spike of a very fine variety of this species comes from Mr. Appleton, of Weston super-Mare. It is paniculate, bearing many flowers. The ground colour is bright rich yellow, much suffused with bright chestnut, lip large, fan-shaped, rich golden-yellow, having a broad band of bright chestnut brown near the margin, the crest a fleshy mass, studded with numerous waxy knobs. The flowers are very fragrant. This plant comes near to many others, but this now before me is certainly the typical plant named by Lindley, and which first was grown in this country by the Messrs. Rollisson in their nursery at Tooting.—W. H. G.

Oncidium nubigenum comes from Mr. Appleton for a name. It grows at an altitude of from 11,000 feet to 13,000 feet. The flowers sent represent a very good variety, the sepals and petals being of a soft creamy-rose colour, lip three-lobed, white suffused with a rosy tinge, and bearing a violet spot immediately in front of the bright yellow crest. This very charming species, which I certainly consider it, appears to me distinct from *O. cucullatum* or *O. Phalenopsis*. It is a pretty, delicate flower, and I have had great difficulty in keeping the plant in a healthy condition during such weather as we have been experiencing this season, but I have always found it do best in the *Odontoglossum* house, treated to plenty of air especially at night, always keeping a good moist atmosphere.—W. H. G.

Phalenopsis grandiflora.—This plant does not frequently come to hand. Mr. Appleton says in his letter to me, "It is a pity to cut the spike, but it has been out some time, and I do not want to spoil the plant, which has another smaller spike as well." I think it was quite right to cut it. By cutting off the spike the health of the plant is not endangered. This spike bearing a dozen blooms is from a somewhat small specimen, but the flowers are large and very good in shape.—W.

Phalenopsis Stuartiana (*C. Jocelyn*).—The leaves of this have the white or grey blotches peculiar to those of *P. Schilleriana*. The blooms are white, the lower half of the lateral sepals profusely spotted with deep cinnamon on a yellow ground, lip having the same fluke-like appendages in front which are so prominent in *P. Schilleriana*, the basal part densely spotted with rich crimson, crest yellow. The flowers sent, I am told, are from a panicle bearing thirty flowers, which have been open since the beginning of June. The flowers have been on the plant quite long enough and they should be cut. I am in favour of your proposed plan of putting seaweed under the plants, but do not put it too thick or it will rot too soon.—W.

Bulbophyllum barbigerum.—A flowering plant of this remarkable little Orchid in the warm house at Kew attracts just now a good deal of attention from visitors. Like most of the *Bulbophyllums*, it has no pretensions to beauty, but possesses in an ample degree that curious floral structure which is characteristic more or less throughout the genus, and which makes it so interesting to naturalists. The flower-spike springs from the base of the small one-leaved pseudo-bulb, and carries about half a score flowers. These are chiefly of a dull reddish brown, the lip

being furnished with a conspicuous tuft of long purplish hairs. The lip, as is the case with all *Bulbophyllums*, is lightly balanced on a hinge, so that every movement of the air, however slight, sets up a curious dancing motion. This apparently spontaneous movement of the flower is a source of great wonderment to the uninitiated visitor, and counteracts to some extent the disappointment of learning that every Orchid does not bear a striking resemblance to some insect or other form of animal life, which is still a not uncommon delusion.—B.

Lælia elegans alba (*C. Jocelyn*).—This is the name of the variety of *Lælia* which you send, and a very nice form it is. These light-flowered forms of *L. elegans* are more frequently seen in the spring months than in the autumn. The sepals and petals are pure white, and the lip a rich crimson-purple in front, this colour also lining the margin of the side lobes; throat pale yellow. This is a first-rate companion for the dark varieties which I see are beginning to come in now.—W.

Sobralia xantholeuca.—Several new species and varieties have been added to cultivated *Sobralias* in recent years, but none possess greater attractiveness than *S. xantholeuca*. It is a native of Central America, whence it was first introduced in quantity by Messrs. Sander and Co., of St. Albans, although it had for some time previously been known from a single specimen—probably imported with *S. macrantha*. It has the usual reed-like growth which distinguishes this genus from any other in general cultivation, the stems being 3 feet high and carrying broad, striated, deep green leaves. The flower is $\frac{1}{2}$ inches in width, slightly more in depth. It is entirely yellow, but whilst the sepals and petals are of a pale sulphur shade, the beautiful convolute lip is in the centre of a much deeper yellow and the frilled margin is almost white. Besides possessing such a distinct charm in colour, this species is superior as a garden plant to *S. macrantha* from the fact that the flowers individually last about three days instead of only one, as in the case of the older species. One flower only is open on a stem at once, but a quick succession is maintained, which keeps the plant continually in bloom when once the flowering season has commenced. It should be potted in fibrous loam kept open by a little peat, broken charcoal or potsherds and silver sand. It may be grown in the *Cattleya* house and, like all the *Sobralias*, likes a plentiful supply of water when in growth.—B.

Lælia monophylla.—Quite distinct from any other *Lælia* in cultivation is this charming little species from the mountains of Jamaica. It has never been very common in cultivation, but appears to be becoming better known than it was a few years ago, although its restricted geographical limits and comparative rarity in a wild state will probably always make it uncommon in gardens. Its thin erect pseudo-bulbs—not much thicker than a knitting needle—are usually about 5 inches or 6 inches high, bearing a single narrow leaf $2\frac{1}{2}$ inches long; occasionally, however, two leaves may be seen on one stem. The flower is solitary and measures nearly 2 inches across, the colour being a vivid orange-red. The comparatively unfrequent occurrence of this colour in Orchids, combined with the exceptionally dainty appearance of the whole plant, gives this species a great charm, and it is certainly one which all Orchid lovers will admire. It first became known to European botanists fifty years ago, but its cultivation dates from 1881, when it was re-discovered by Mr. Morris, then director of public gardens in Jamaica. It grows on St. Andrew's Mountains at an elevation of 4500 feet.—B.

The weather in West Herta.—July was the sixth unseasonably warm, and the fifth unseasonably dry month that we have had in succession. Since February only about $4\frac{1}{2}$ inches of rain have fallen, or less than half the average amount for the same period. During the thirty-eight years over

which the Berkhamsted rainfall records extend, there has been no previous instance of so scanty a fall in any consecutive five months. Although rain fell on no fewer than twenty days in July, the total measurement fell short of the average for the month by about half an inch. The soil in my garden still remains very dry at a short distance below the surface.—E. M., *Berkhamsted*.

PUBLIC GARDENS.

The Tower Walk.—It is through the exertions of Mr. Samuel Montagu, member for Whitechapel, that the Tower Walk has been thrown open to the public daily until October. Little doubt is entertained that the concession will be made perpetual. The Walk is an enjoyable promenade twice the size of the terrace of the Houses of Parliament.

Churchyards as open spaces.—On the recommendation of the Parks Committee it was agreed to continue to maintain Carlton Square Garden, Mile End; Holy Trinity churchyard, Bow; Limehouse churchyard; Rotherhithe (St. Paul's) churchyard; Russell Court playground, Strand; Shadwell (St. Paul's) churchyard; Spa Fields playground, Clerkenwell; St. Bartholomew's churchyard, Bethnal Green; Stepney churchyard, and Winthrop Street playground for one year, until October 31, 1894, and that previously to that date the Council do further consider the question.

Recreation ground for Lee.—The Earl of Northbrook and Lord Buring have consented to pay one-half of the cost of the purchase of a piece of ground, eight acres in extent, in Manor Lane, Lee, for the purposes of a recreation ground. The price of the piece of land is £6400, and, deducting the one-half referred to and a further sum of £2000 which the Parks Committee are prepared to recommend the London County Council to contribute, the amount required to be raised in the locality is only £1200. This it is thought can be obtained without much difficulty, and if not subscribed by the residents will probably be paid out of the rates, forming a charge of only a farthing in the pound for thirty years.

Another open space.—One of the historic parts of the New River, between Canonbury Tower and the Old Thatched House, has been recently covered in and laid with turf, and the Earl of Meath and the Public Gardens Association have offered to lay out the space as a public recreation ground if the Islington Vestry will thenceforward maintain it. The spot in question is picturesquely situated, and the Old Thatched House portion is remembered as a pleasure space a score of years ago. As a recreation ground it will be peculiarly acceptable inasmuch as it is surrounded by poor property. It is understood that the New River Water Company are agreeable to the proposal, and as the Islington Vestry have accepted the suggestion of Lord Meath, this boon to Lower Islington may be looked upon as settled.

National Rose Society.—As inquiries have reached us as to the character of the circular recently issued by Mr. C. J. Grahame, owing to the circular and envelope being headed "National Rose Society," we think it should be clearly understood by our members (1) that Mr. Grahame has resigned his position as a member of the committee; (2) that the document in question has no official sanction whatever.—H. HONEYWOOD D'OMBRAIN, EDWARD MAWLEY, *Hon. Secretaries*.

Royal Horticultural Society.—The next meeting of the Royal Horticultural Society will be held on Tuesday, August 8, at the Drill Hall, James Street, Victoria Street. Mr. J. G. Baker, of the

Royal Herbarium, Kew, has promised to deliver a lecture on Cannas at 3 o'clock, and the council will feel obliged to exhibitors who will endeavour to make a special feature of these plants on that day. There will not be another meeting in the Drill Hall until Sept. 12, owing to the intervention of the four days' show at the Royal Agricultural Hall, Islington, from Aug. 29 to Sept. 1.

Gardeners' Orphan Fund.—The monthly meeting of the committee took place on the 28th ult. at the Horticultural Club, Hotel Windsor, William Marshall in the chair. In the course of the evening several matters of interest connected with the administration of the fund were discussed and reserved for further consideration. The following special receipts were announced: From Mr. J. Lyne, The Gardens, Foxbury, Chislehurst (local secretary), £16 ls.; Mr. G. W. Cummins, The Gardens, The Grange, Wallington (local secretary), sale of flowers at Croydon show, £8; collected at the Wimbledon flower show, £4 2s. 6d.; and box per Mr. T. Kneller, The Gardens, Studley Royal, Ripon, '9s. After the transaction of some routine business, the committee adjourned until the last Friday in October.

Death of Mr. William Thomson, Jun.—We regret to have to record the death from pleurisy on Sunday, July 30, at the age of 44, of Mr. William Thomson, Jun., eldest son of Mr. William Thomson, of the Tweed Vineyard. About a year ago he had a severe attack of influenza, from which he never completely recovered. Previous to going to Clovenfords, he was for many years in the National Bank of Scotland in Edinburgh. He leaves a wife and four young children. His remains were buried on Wednesday in the little churchyard at Clovenfords on the banks of the Gala water.

Names of plants.—*F. B.*—*Rudbeckia* Newmanni; 2, 3, 4, the Golden Rod (*Solidago virgaurea*).—*L. C. Bobtink*.—Maiden's Wreath (*Fruanea ramosa*).—*F. P. B.*—*Lilium testaceum*.—*J. E. S.*—We cannot name from leaves only.—*W. & G. Draver*.—*Stanhopea tigrina*.—*F. Wheatly*.—1, *Oncidium Gardnerianum*; 2, *Cattleya gigas*, a somewhat small flower, but of good colour.—*G. T.*—*Epidendrum vitellinum majus*.—*F. Sharp*.—1, *Phegopteris trichodes*; 2, *Loxogramma lanceolata*; 3, *Cycloplexis semioedrata*; 4, *Davallia leptophylla*; 5, *Microlepia cristata*; 6, *Odontosoria tenuifolia*.—*H. B.*—1, a form of *Vanda Roxburghi*, nothing at all like *Saccolabium curvifolium*; 2, *Oncidium divaricatum*.—*G. Fischer*.—*Cotyledon mamillaris*.—*H. Weller*.—*Higginsia refulgens*.—*E. Semper*.—*Buphthalmum speciosum*.—*T. W.*—*Epacris paludosa*.—*J. Waters*.—1, *Epidendrum Wallisi*; 2, *Cattleya granulosa*; 3, *Oncidium bifolium*.—*G. Green*.—*Maxillaria nigrescens*.

"The Garden" Monthly Parts.—This journal is published in neatly bound Monthly Parts. In this form the coloured plates are best preserved, and it is most suitable for reference previous to the issue of the half-yearly volumes. Price 1s. 6d.; post free, 1s. 9d. Complete set of volumes of THE GARDEN from its commencement to end of 1892, forty-two vols., price, cloth, £30 12s.

"Gardening Illustrated" Monthly Parts.—This journal is published in neatly bound Monthly Parts, in which form it is most suitable for reference previous to the issue of the yearly volumes. Price 5d.; post free, 8d.

"Farm and Home" Monthly Parts.—This journal is published in neatly bound Monthly Parts, in which form it is most suitable for reference previous to the issue of the yearly volumes. Price 5d.; post free, 8d.

"Hardy Flowers."—Giving descriptions of upwards of thirteen hundred of the most ornamental species, with directions for their arrangement, culture, &c. Fifth and Popular Edition 1s.; post free, 1s. 3d.

"The Garden Annual" for 1893.—Contains Alphabetical Lists of all Branches of the Horticultural Trade. The Lists of Gardens and Country Seats (containing over 9000) have been very carefully and extensively revised, and are admitted to be the most complete ever published. Price 1s.; by post, 1s. 3d.

All our readers who are interested in the improvement of cottage homes are invited to help us to make **Cottage Gardening** known. It is published at the very lowest price to meet the wants of those for whom it is intended, and copies will be sent for distribution free, by the publishers, Messrs. Cassell and Company, La Belle Sauvage, Ludgate Hill, E.C.

No. 1154. SATURDAY, August 12, 1883. Vol. XLIV.

"This is an Art
Which does mend Nature: change it rather; but
THE ART ITSELF IS NATURE."—Shakespeare.

ORCHARD AND FRUIT GARDEN.

A BIG CROP OF APPLES.

RECENTLY on riding through a fertile valley in Wiltshire I was agreeably surprised to see how well the Apple trees were furnished with fruit. Those on quite low ground were carrying better crops than I expected to see, while all on slopes or rising ground were literally smothered with Apples. What about the quality will be the first inquiry? and here again I must express surprise at what is to be seen. Large the fruit are not by any means, but, considering the weight of the crops, not much fault can be found. Those trees on low ground, not being so heavily laden and not feeling the drought so much, might have been expected to produce finer fruit than those in more elevated positions, but such apparently is not the case. In all probability the best flowers were killed and the rest crippled somewhat by spring frosts, this accounting in several instances that I have inquired into for the smallness of the fruit. From various other counties, including Dorset, Devon, Worcester, and Herefordshire, I hear much the same report, Apples being very abundant, but wanting in size. In the two first-mentioned districts I saw the trees when in full bloom, and on the majority of old standards there appeared to be more bunches of flower than healthy leaves, and the great drought following upon this stunted growth looked at one time like spoiling everything. Luckily the change came in time to save the Apple crops, and now that these promise to be worth gathering the question arises, What is to be done with the surplus produce?

As far as producers are concerned, extra heavy crops generally are not desirable. They take a lot out of the trees, and the market returns scarcely compensate the grower for the trouble of gathering and marketing even. Previous experience ought to make the owners of orchards more chary of sending anything and everything to the markets, but instead of adopting more sensible methods not a few of them give up in despair. Either they sell all the fruit as it hangs on the trees to the highest bidder or else convert the bulk into cider. It is true immense quantities of Apples, grown more especially in the south-western counties, are of no value other than for the latter purpose, but there are very many that might be more profitably turned to account if only the owners went the right way to work in the matter. At present farmers or those who only send fruit to the markets casually have a bad reputation among salesmen. They cannot be trusted to pack and send Apples either sensibly or honestly, and as a consequence their consignments never realise good prices. In the first place there ought to be no general mixing of varieties. When early and late, dessert and cooking varieties are all jumbled up together the consignment is fit for nothing but the pigs, and this season those who still follow this absurd practice will find their returns scarcely cover the cost of carriage. Unfortunately, very many of the varieties still largely grown in old orchards are unrecognis-

able by experts, local names being all that can be given them, and that by local people. It ought, however, to have long since been determined whether they will keep or not, and for what purpose they are best adapted. Instead of rushing all indiscriminately into the nearest markets, there ought to be some system of selection and storing adopted. Let those that are fit for use early be marketed direct from the trees, the midseason varieties being stored in heaps under the trees and roughly protected, and the rest or all that will keep late be placed in cool, dry rooms or sheds. All being properly placed on market according to their season, remunerative, if not exactly the best, prices will be obtained for the lot.

Directly the great glut of Plums is exhausted there will be a better demand both for dessert and cooking Apples. Many of what are known as August Apples are already over or nearly so. Margaret, Early Harvest, Irish Peach, Devonshire Quarrenden and Beauty of Bath are all over with me, and to all appearances the earliest cooking Apples will not keep long. In any case it is advisable to at once lighten the crops of Keswick Codlin, Lord Sutherland, Stirling Castle, Jolly Beggar, and such-like early soft varieties, and fairly good prices will most probably be given. What, however, salesmen prefer are showy Apples of the stamp of Worcester Pearmain, Duchess of Oldenburg, Cox's Pomona, Emperor Alexander, Hoary Morning, Manks Codlin, and that very attractive-looking west-country variety Tom Putt. These can be sold readily in quantity for either cooking or dessert, and obtain the best prices accordingly. Few now-a-days need be told that good samples of Blenheim Orange will always realise good prices, this being one of the sorts that ought to be stored for early winter use or sales. Cox's Orange Pippin is not often found in the older orchards, but what there are of it on the younger trees ought certainly to be taken good care of. Of Sturmer Pippin I have seen several fine trees, the value of which their owners were surprised to learn. It should be remembered that this is probably the very best late dessert Apple we have, and pays well for storing till the spring. D'Arcy Spice has not as yet spread far beyond a district in Essex where it originated, but all who, fortunately for themselves, have good trees of this excellent late dessert Apple should take good care of the produce.

Very much more might be added as to the value of different varieties, but my object is to serve the owners of old orchards rather than those in charge of a few named garden trees, and will therefore conclude with a few more general remarks. In addition to keeping the sorts separated as much as possible, more pains ought to be taken with the gathering than farmers, as a rule, think necessary. Instead of either shaking off or thrashing down the fruit, the best of it, at any rate, ought to be gathered and brought down from the trees in bags slung across the men's shoulders. There can be no excuse this season as to scarcity of labour, there being only too many able men who would be glad of a job of any kind. A responsible person, and not careless labourers should attend to the sorting over and packing. All under-sized or unsound fruit ought to be thrown on one side, none but sound, good-sized Apples meeting with a ready sale at remunerative prices in years of plenty. There should be no topping up, that is to say, no putting a lot of much mixed fruit at the bottom and finishing off with only the very best, as this is a very stale and long since "played-out" trick. Sieves and

hampers can usually be had from leading market salesmen in provincial, as well as metropolitan markets, and if the first consignment is found to give satisfaction, the next will receive better attention accordingly, and *vice versa*. Senders by rail who prefer to pay carriage on their produce should also insist upon their hampers going at what is known as traders' rates, this making a very material difference to the prospects of the venture. Sell all the windfalls and mixed samples generally locally, as it is very certain it will not pay to send these to a distance this season. I. M.

A LONG SUCCESSION OF STRAWBERRIES.

THIS fruit this season was soon over. I gathered good fruit for a period of nearly five weeks from the open ground, so I cannot complain much as regards a short season, and when I write of gathering for that time, I do not mean a few stray fruits, but daily supplies. As regards size, there was little to complain of in the early lots, but as the season advanced, daily gatherings were imperative if the fruit was required to be sent any distance, as owing to the excessive drought and heat it was soon spoilt if allowed to remain when ripe. When fine ripe fruit of Noble grown in the open, merely protecting the bloom, can be shown early in May, as was done by Mr. Iggulden at a meeting of the Royal Horticultural Society on the 9th, it shows what can be done by growing various kinds and thus securing a long succession. Though Mr. Iggulden was ahead of me considerably, as I did not gather the same variety till the 16th, still the latter date shows the earliness of the season, as I did not protect in any way, the plants being grown at the foot of a wall on a south border. Years ago, before Noble was introduced, I used to adopt the three years' system of culture, but seeing others get such excellent results from young plants, I adopted the plan of only taking one crop. I admit this plan is not practicable in all gardens or with all varieties. Want of space and deficiency of labour to prepare runners must be taken into consideration when the fruit is cultivated for size and in a given time, as it is useless to plant out weak runners at the end of the autumn and expect good results the next summer. Indeed, one cannot plant too early, and you cannot get vigorous runners in July if you have taken a crop of fruit; hence the necessity of getting them from maiden plants. This is not always practicable in a small garden and it is not always possible to buy. To get a long succession of fruit, the planting or preparation is the chief point in the production. I admit we have made rapid progress in the way of variety, earliness being the chief point; but we must not lose sight of another equally important one in private gardens—that is flavour.

John Ruskin was a little later than Noble, and a Strawberry not so much grown as its merits deserve, viz., Pauline, was only three days behind John Ruskin and King of Earlies. Pauline, I admit, is not a handsome fruit, but it is of good flavour. As will be seen, there is a lack of early fruiting kinds. Vicomtesse Héricart de Thury follows these early varieties very closely, and is still one of the best Strawberries grown. In this note it is scarcely necessary to travel over ground often traversed and give the qualities of the mid-season kinds, such as La Grosse Sucrée, President, Keens' Seedling if true, British Queen, and the Pine section, of which Elton is a good type. I would now point out the value of the late varieties. Waterloo with me this season has done badly, being very much infested with red spider, and, strange to say, I find it does worse on a north border than an east, and it does not produce runners very freely. Where it does well it is late, and prolongs the season. Jubilee should be included in all collections where late fruits are desired. It is a grand dry weather Strawberry. This variety I had in quantity four weeks after the others had been in, and another point in its favour, it does equally well a second year. This variety

I grow in two lots, getting one a few days in advance of the other. Latest of All on a north border is our last one in fruit, and I cannot praise it too highly. This is a seedling from British Queen and Helena Gloede, bearing large wedge-shaped fruit of grand flavour, almost equal to that of British Queen. It is not so vigorous in growth as Jubilee, but it is very valuable, as it forms a succession to it and thus ekes out the season. I have named the above as forming a long succession, and by planting these late kinds in various positions there will be no difficulty in securing a long fruiting season. G. WYTHES.

STRAWBERRIES IN THE OPEN GROUND.

THE past season was a short one for this crop in most districts. This was especially so in districts where the cultivator had to depend on old plantations, for these, owing to the lack of moisture in the early part of the season, were not able to develop their flower-spikes properly. As a consequence the fruit was small and imperfect. If the same pains were taken to secure strong plants for the open ground as are evinced in procuring those for forcing, fewer complaints would be heard concerning poor crops and small fruit. I invariably prepare a sufficient number of plants each season to replace those taken up, so that about the same number may be in full bearing annually.

ESTABLISHING THE PLANTS.—The soil used for this purpose consists of about a half of well-decayed manure and half loam taken from an old Cucumber bed. This is passed through a half-inch sieve to mix it thoroughly and render it fine enough for use in small pots. In such a mixture the plants soon take root and become established. For layering, 3-inch pots are used, and these being filled with the above mixture (no crocks are used) and taken to the beds where plants are growing are plunged up to the rim. The best and strongest runners are then selected, one being pegged down in the centre of each pot and stopped at the first joint. These soon root, and by the end of July or beginning of August have filled the pots and are ready for planting.

PREPARING THE GROUND.—Strawberries delight in a rich fertile soil, and for this reason special preparation is necessary, where the soil has become at all exhausted, to encourage growth as much as possible. If it is intended to plant on a piece of ground lately occupied by another crop, a liberal dressing of manure should be given, and the soil afterwards dug as deeply as its depth will allow, care being taken not to turn up any of the poor subsoil. In doing this all clods on heavy ground should be broken to pieces, so as to render the soil as fine as possible. Rows should then be marked out, in which operation the cultivator must be guided by the quality of his ground. If it be strong and in good condition he should allow a distance of 2 feet 6 inches between the rows, but if, on the contrary, the soil be shallow and light, then 2 feet will be found sufficient.

PLANTING.—This may seem a simple process to some, but on it the well-being of the plants depends to a great extent. No one would think of simply putting a plant into a pot and then filling the latter with soil; on the contrary, the mould is rammed firmly round the ball till all is as hard and firm as if the plant had been growing there for years. Yet how little pains is bestowed on plants in the open. They are often just stuck into the soil and left to grow haphazard, and if by chance the weather is dry at planting they may get a little water, but as often as not they have to do without it, for planting is too often delayed till it is too late in the season for the plants to make any progress. When planting, make a hole in the centre of the fresh soil that was brought, and turning the plant out of the pot put it in so deep, that the base is about an inch below the level of the surrounding ground. Then with a blunt stick ram the soil round till all is quite firm; it will then be seen that each plant is in a shallow basin. Planting

should never be done if the soil is too moist to admit of its being made quite firm, for unless the roots can take a strong hold of the soil growth will be unsatisfactory. The foliage will be soft and flabby, and the crowns will not ripen thoroughly.

WATERING.—Plants in pots that are prepared for forcing have every attention paid to them in this respect; then why should not those in the open ground be similarly treated? As before remarked, there is a hollow or basin round each plant, and if the weather prove hot and dry, watering will be needed three or four times a week. Such weather often occurs in August and September, and when this is so, special care is required if the plants are to make steady progress. They will not only require watering regularly, but will benefit by the application of weak doses of liquid manure. If this cannot be had, sprinkle the surface of the soil round the plants with artificial manure once a week after the plants have become established, which will be in about a fortnight after planting. Assuming this to be done the first week in August, the plants would grow up to the middle of October or even later during a mild season.

SUBSEQUENT TREATMENT.—All runners should be removed as they show themselves. Weeds must be kept down so as to admit all the light possible, and by the time the plants have done growing, large, plump, well-ripened crowns will be the result. Should the winter be severe, it will be well to cover the crowns with Bracken or other litter during hard frost, but this should be removed when a thaw sets in, or the plants will suffer from damp. Plants so treated will produce good crops of fine fruit the first season, and though the crop may not be so heavy as on two-year-old plants, the fruit will be larger and in every way superior. P. H.

Caterpillar destroying Grapes.—For the past few weeks my Grapes have dropped off. This, I thought, was caused by a mouse, but this morning I found the enclosed grub that I feel sure has caused the mischief. I have sent a few Grapes so that you can see how they have been damaged.—J. C.

* * In reply to the above from "J. C.," the caterpillar which you sent, and which had injured your Grapes, had begun its transformation into a chrysalis before it reached me, so that I am unable to name it more definitely than to say that it was the caterpillar of a small moth belonging to the family Tortricidæ. I do not know of any satisfactory plan of destroying caterpillars which attack Grapes but carefully examining each bunch and picking off the pests. Any insecticide which you might apply would injure the fruit, unless it was very young, by giving it an unpleasant flavour and spoiling its appearance. The moths will probably emerge from the chrysalides in the course of the next month. It is always a good precaution to kill any small moths you may find in a vinery or other glass house, as their caterpillars are sure to do harm. Out of doors it is difficult, as any mischief they may do is not so much noticed. They are exposed to many natural enemies, and some caterpillars are really useful in destroying weeds.—G. S. S.

Fire heat for Grapes in hot weather.—I have not the least doubt that the recent hot weather will have led many people to dispense with the use of fire heat in their vineries, thinking that the continuing of it, besides being quite unnecessary, would be also injurious to the well-being of the Vines. Economy is often put forward as the reason of this proceeding, but I am certain that it is quite the opposite. The Grapes apparently may be going on satisfactorily as to colouring, but this will be only fleeting, as I am certain if fire heat is wholly withdrawn, at the close of the season there will be an outcry as to the shrivelled state of the berries and their not keeping well. Various reasons will no doubt be given as to the cause of this unsatisfactory state of things, but the proper one, the want of fire heat during the growing season, will very likely not be

thought of. If good Grapes worthy of the name are to be produced, fire heat should not be dispensed with for a single night, let the weather be ever so bright. That late Grapes will be coloured much earlier than usual there can be no denying, but this is no reason why fire heat should wholly be dispensed with. Not much is required certainly, but the pipes should certainly be luke-warm not later than 7 p.m., and on dull days the whole time. Where fire heat is not used, the temperature may apparently feel comfortable at night and also very likely at 6 a.m. in the morning, but between these times there will be a cold clamminess that anyone would little dream of who has not entered vineries during the early hours of the morning. On account of the Grapes and foliage being colder than the surrounding atmosphere, moisture will quickly condense upon them, and, as I have pointed out in a previous note on "Bloom on Grapes," this is also in danger of being spoiled. To think of producing good Muscat Grapes without fire heat at night-time during even the warmest weather is an impossibility.—A. YOUNG.

CROPPING YOUNG VINES.

I FEEL convinced that if Vines were not allowed to carry a single bunch during the first two years of their life a much greater weight of fruit could be taken from them in after years. The bearing powers of many Vines are undoubtedly wonderfully lowered by overcropping in the earlier stages of their existence. There is a natural desire to get a crop of fruit as soon as possible after planting, but it would be better if the first thought was given to securing strength and permanent fertility in the Vines. It would be interesting to note the difference of girth of stem in two sets of Vines, one of which had been cropped in the ordinary way from the first year after planting, the other not having been allowed to fruit during the first two seasons. The disparity would, I feel sure, be considerable. It requires, however, more self-denial to wait until the third year from planting than most Vine growers are possessed of. Growers for profit are naturally anxious for a quick return on the outlay incurred in building and planting, the modern system being to crop heavily and feed liberally from the time the Vines come into bearing. Very few would care to wait a couple of years before taking a bunch of fruit from their Vines however great the advantages might be in the long run. Cropping very lightly for the first two years is, however, very different from taxing the capacity of the Vine to its full extent. Four years ago I planted a couple of Alicante Vines at the end of a lean-to house. The first year I stopped them when they had made about 6 feet of growth, and then they ran up to the full extent of the rafters, which are 14 feet in length. The following winter they were cut back to where I had stopped them the previous summer. They showed well for fruit, but I allowed each Vine to bear two bunches only. The following year they carried four bunches each. Last year I took from them 41 lbs. of Grapes, every bunch finishing off well, the berries being black as Sloes and with perfect bloom on them. As the stems only touch the rafters at about 18 inches from the front plate, and I allow 18 inches at top for extension after the berries set, there were but about 11 feet of bearing wood to each Vine. From Vines of that age I doubt if it would be possible to finish off a greater weight of fruit. Had these two Vines been cropped to their full capacity from the time they came into bearing condition, it would not have been possible to take that weight of well-coloured Grapes from them without lowering their vitality. When Vines are cropped rather beyond their powers during the first two or three years, they do not seem to be able to do themselves justice in after years. J. C. B.

Preserving Grapes from wasps.—I would advise "J. W." to get some "toiletting," which is a kind of very coarse muslin, and have some made into bags for preserving Grapes from wasps. If

the bags are put on carefully and made large enough to hang loosely, no bloom will be rubbed off. This is a cheap and effective remedy, and the bags last for years with care.—A. LONG.

Fruit in Surrey.—Since I sent you a few notes respecting fruit in one part of Surrey I have been very much about Farnham and Banstead, having had ample opportunities to see the condition of the hardy fruit crops in essentially rural districts. About the former district, and especially in the Rowledge area, the crops of Apples, Pears, and Plums are truly wonderful. I must have seen literally thousands of bushels of fruit in the course of a moderate ride, the trees forming grand pictures just now, the Apples especially putting on much colour. Even Lord Suffield there colours appreciably on the base as the fruits hang on the boughs. Red Quarrenden, Barchard's Seedling, and Duchess of Oldenburg are grandly coloured. Many varieties it is difficult to name without close inspection, but there are good size generally and a wondrous crop. Williams', Calbasse, Louise Bonne, and some other well-known Pears are in immense profusion, and of Plums, Green Gage, Gisborne, Washington, Victoria, Orleans, and others are very heavy. The general estimate is that the hardy fruit crop is one of the finest ever known, and I think, so far as I have seen elsewhere, the county of Surrey is entitled to take very high rank for its fruit production. That is doubtless due largely to its sand and chalk substrata, which are usually cool and sweet. The inference is that it is a county which may well receive greater attention for fruit culture. Some of the best crops are found on the high districts, showing that an ample circulation of air is conducive to fertility of the bloom, whilst in such cases colour always forms a most prominent feature. We may expect to have all hardy autumn fruits exceptionally cheap for a time presently.—A. D.

Hale's Early Peach.—I do not think this variety is grown in the open as much as it deserves. It is a very good variety, and comes in useful just as the fruit indoors is getting scarce. This season I gathered good fruit from a south wall the third week in July. I do not care for some of the American varieties of Peaches, as some are very deficient in flavour, but Hale's Early, besides being very early, is also of good flavour. This variety is not fastidious as to soil, as it will do well in light or thin soil, and with me rarely fails to crop freely. I have also seen it do well on an east aspect; indeed, on the latter it produces finer fruit and of such good quality, that one could have imagined it to have been grown in a case or cool house. I do not grow it under glass, as I prefer Amsden June, being larger, but for a late or unheated Peach house Hale's Early may be planted with confidence as to its setting and free-cropping qualities.—G. WYTHES.

Ripening Peach wood and pruning.—Both Peach and Nectarine trees are making a free growth where they have been liberally treated. I would point out the necessity of thinning or pruning as soon as possible in the early autumn, this admitting light and air and allowing the shoots required for next season's fruit and furnishing of the trees to get fully matured. If due attention is now paid to the ripening of the wood, there will be less canker and gumming. I would advise going over the trees frequently during the summer months, removing useless wood, so as to do away with excessive pruning at one time. Of course, where summer pinching is duly attended to, there will be less need of severe cutting; but it often happens through press of work that this cannot be attended to, and recourse must be had to thinning at this date, and the earlier it is done the better. I have seen many failures with this crop through the branches being grown too thickly and then cutting them away all at once. Peach and Nectarine trees can be lifted successfully in the autumn before the leaves fall, and I refer to this to point out that I do not advise excessive pruning, but would prefer lifting to check gross wood, especially in young trees. There is often far too much wood left at the winter pruning, and, of

course, without careful dishudding, overcrowding cannot be avoided. Some varieties grow more vigorously than others and should get more room. For instance, Royal George—one of the best-flavoured Peaches grown—suffers badly from mildew if the branches are at all crowded. It is useless to lay in a lot of wood and then have to remove a large portion of it early next year. Giving a little time to Peach and Nectarine trees now is time saved, as there is less to do in the spring and the trees present a neater appearance. Unnailing in the winter is an easy matter, and though an old-fashioned plan, I still adhere to it. The trees, too, are more easily cleaned when the wood is thin.—G. WYTHES.

NOTES OF THE WEEK.

Verbena venosa.—We do not see much of this fine old plant in gardens. It is very handsome, the purple-violet flowers being produced very freely, and they last long in beauty. In Mr. Morse's nursery at Epsom this Verbena is pleasing. It is excellent for massing.

The Water Lily house at Kew is in perfection now, the Water Lilies being in full bloom. They are in beauty about 10 o'clock, and all the leading species and varieties are in the collection. We noticed *Nymphaea Laydekeri rosea* in bloom—a rare and beautiful kind, recently described in THE GARDEN.

Tropæolum Vesuvius is a fine variety for bedding. It is used largely at Kew and the plants are very bright. They are compact, bushy, and the bluish glaucous leaves are almost hidden by the brilliant scarlet flowers. It does not run to leaf and comes very true. This exceptionally dry summer has just suited the Tropæolums.

Castilleja indivisa is in full bloom on the Kew rockery. It is a comparatively rare plant, but deserves to be more known, as at this season it is very bright, especially when grown in a large clump. It is a half-hardy annual and amenable to the same treatment as the majority of its class. The flowers are not showy, as it is the bright orange-scarlet bracts that form the great feature of the plant.

Rubus odoratus.—This is a lovely summer-flowering shrub when seen growing in its own way, as in the Wisley garden of Mr. G. F. Wilson, where there is a superb mass of it. It is only when permitted to spread that its true beauty is revealed. If cramped for space it is utterly spoilt. The growth is very robust and the leaves large, whilst the rich rosy purple flowers are produced in profusion, making a fine contrast to the foliage.

Lilium Leichtlini.—This charming Lily is one of the prettiest of the family in bloom at this season. A coloured plate was given of it in THE GARDEN, April 8, 1882, and doubtless if it were more easily grown it would be amongst the most popular kinds in cultivation. The flowers are delicate yellow, almost primrose in colour, and freely spotted; whilst the segments reflex somewhat in the style of those of the Tiger Lilies. It is not, however, a Lily for every garden.

Agapanthus Mooreanus is a charming form of *A. umbellatus*. One gets a little tired of the latter, as it is used so much in gardens, but *A. Mooreanus* is a change. It requires similar treatment, and in a few favoured spots in the more southern counties it will live out of doors, but as a rule it is not sufficiently hardy to trust entirely in the open. The whole plant is much smaller than the type, but does not lose in beauty. There is a certain delicacy of aspect in the slender scapes of blue flowers.

The French varieties of Canna are more often seen this year than heretofore, but they have not been altogether satisfactory owing to the severe drought. It is not wise to use them too freely, as they cannot in England attain such splendour

as in the South European gardens. We have, however, seen lately several very good beds with a fair display of bloom. The great thing is to get varieties of rich, decided colour, not too many of the striped, blotched, or spotted kinds, which are more attractive under glass.

Fruit growing in California.—We hear so much about the advantages of California for fruit, &c., that the note below is surprising.

The country banks in California are so pressed for coin that they refuse to make the customary advances either on wheat or fruit, and the result is that grain in many places is going to waste because the ranchmen have not money to pay for harvesting; the case is still worse with growers of fruit, because there is no market for it in the orchard. The canneries are all idle since the banks have failed to make the usual advances, so that only a small part of the fruit crop is being dried by women and children.

Hardy Fuchsias are in full beauty, and we noticed in a warm border skirting the temperate house at Kew several kinds in bloom. *F. Riccartoni*, *F. virgata*, and *F. gracilis* were noteworthy, each a little bush and smothered with rich crimson flowers. There is a charming grace about the hardy Fuchsia, and we think it might be much more planted even near large towns if a spot not too cold or exposed be found for it. We remember the fine effect produced by splendid bushes of *F. Riccartoni* in the gardens at Tan-y-bwlch, North Wales, where it succeeds well used in association with Hydrangeas.

Lilium tigrinum at Kew.—This splendid Lily is in perfection just now in the Royal Gardens, Kew, and we have never in any garden seen such a mass of one kind. The variety is splendens, which is the finest of the tigrinum section, the flowers borne with great freedom, whilst individually they are large, and brilliant orange-scarlet freely spotted with chocolate or a similar colour. The Lilies are most freely planted near the Palm house, and this variety is represented by large masses not only amongst shrubs, but also near the group of Aracarias. The effect of the brilliant flowers against the dark green of the Aracaria is remarkably striking.

The Watsonias.—We were pleased to see a few days ago in the Royal Gardens, Kew, plants of *W. marginata* in full bloom. Not sufficient use is made of this interesting class, and although scarcely so easy to grow as some things, no great difficulties have to be overcome. *W. marginata* is a delightful kind. The flowers, produced on a slender stem, are borne close together, which makes the soft rose-purple colour the more effective. A good mass of them is charming, and we hope that these handsome Cape bulbs will be more grown in the future. There are not a great many kinds, and the position for them must be sunny, not too exposed, and the soil light.

Fuchsia fulgens.—One seldom sees this fine Fuchsia used for bedding, and we are pleased to see that there is a single bed of it in the Royal Horticultural Society's gardens at Chiswick near the old council room. *F. fulgens* is such a bold, handsome plant, both in leaf and flower, that it should be more planted in gardens and parks. The leaves are large, abundant, and of a distinct glaucous tint, which is well contrasted with the free display of long tubular scarlet flowers. A single specimen of it would make a good feature; at any rate, such a fine old-fashioned plant is worth taking care of. It is a pleasure to see that in the London parks more attention is being paid to the older types of Fuchsias, which make splendid beds.

Carnation blooms.—We have much pleasure in sending you a box of Carnation blooms cut from the open from layers planted outside last autumn. Carnations are with us the leading feature, and we grow all the sections extensively, in which appear not only the older standard favourites, but also the newer introductions. One of the finest things yet brought out, and admitted so by the best authorities, is one we are distributing this autumn for the first time, named Lady Nina Balfour, a full description of which we herewith

enclose. As evidence of its merit we may mention that it has been ordered for the Royal Gardens at Windsor, Sandringham, Laeken (Belgium), and quite a number of the leading garden establishments in all parts of the country.

Roscoea purpurea.—It is not very often one sees this fine old plant in gardens, and any position will not suit it. In the warm sheltered border of light soil skirting the Orchid house at Kew it succeeds well, and for several weeks past the healthy clumps have been in full bloom, the flowers opening in succession. They are not very showy, but produced freely, purple in colour, as suggested by the specific name, and very pleasing peeping out from the wealth of pale green leafage. It is not troublesome to grow under such conditions, and a border like this will accommodate many charming plants that it is impossible to grow in full exposure. This species of *Roscoea* was introduced from Nepal in 1820, and has therefore been long in English gardens.

The Cyrtanthuses.—Usually these are grown in a greenhouse, and properly so, but in a favourable position they can be trusted in the open, where in a warm, sheltered spot they will bloom throughout the summer. This note is prompted through seeing a bed of them at Kew, where several kinds are blooming freely near the Orchid house. Here in a sheltered spot and light soil, raised considerably above the surface to throw off damp, these Cape bulbs are at home. We should not recommend them to be grown in this way in every garden, but where means are at command such a bed is a change from the various other arrangements that tire one through their monotonous aspect. The two chief kinds used are *C. Mackeni*, which has creamy white flowers, and the yellow-flowered *C. lutescens*.

New Water Lilies from M. Latour-Marliac.—We have had some charming flowers of new Lilies from this distinguished raiser, who has given us some quite new and charming aspects of hardy plant beauty. A new kind of flower garden is to come soon, and that is the garden of water flowers. There are many garden waters which might be full of lovely things that one hardly ever sees with a plant. For instance, the lake in front of the Palm house at Kew might be a garden picture of beautiful water flowers instead of being devoted to the unclean water-fowl that are now its only "ornament." I have seen this year pictures of our own Water Lilies alone. How much more may we do with the noble Water Lilies of all colours, for which flower lovers must be for ever grateful to to M. Latour-Marliac.—W. R.

Crinum Powellii.—The flower of the week is this hardy *Crinum*. It has not failed us now for some years, but probably was never before quite so good as now, having revelled in the great heat, whilst there has been an absence of wind storms which usually tear and in some degree injure its fine leafage. Now, however, the leaves stand out, some of them over 6 feet in length, and from each mass of leafage stands boldly up a stout spike 4 feet high crowned with about a dozen buds and blooms. The buds are quite crimson, but they open into a lovely soft pink flower. Happily, all do not come at once, but in succession for several weeks. This is the most important *Crinum*, and at the foot of a wall it would be happy in hundreds of gardens. Its lovely colour and form are admirably shown in the coloured plate which appeared in THE GARDEN of January 25, 1890.—A. H.

Hyacinthus candicans.—This is, perhaps, better known as *Galtonia candicans*, but both names are freely used. There are few handsomer Cape bulbs in cultivation than this and few so easily grown, whilst from seed it flowers in about four years. This season the spikes are dwarf, owing to the long drought, and the plant thus loses in beauty. One does not care for it much unless boldly grouped with other things, its sturdy spikes needing some relief in the way of shrubs. This is gained by grouping it amongst evergreen shrubs, and it is especially striking when associated

with the crimson-flowered *Fuchsia Riccartoni*. At Tan-y-bwlch, in the Festiniog valley, North Wales, Mr. Roberts (the gardener) makes good use of the *Galtonia*, and, we may remark, of hardy flowers in general, grouping them in a bold and picturesque way. It is in perfection, fortunately, at a time of year when we look for a change and the flowers of early summer are practically over.

Everlasting Peas.—Much is said now-a-days about Sweet Peas, and justly so, but I doubt if the Everlasting Peas are not equally valuable from an ornamental point of view. It is astonishing the length of time Everlasting Peas will continue in bloom when in good soil, especially if they are given a good watering with manure water when in full growth. I have some large patches of *Lathyrus latifolius* and its white form growing near to my cottage. I place some long Fir branches around them every spring from 8 feet to 10 feet high, and they have grown above these some 2 feet or 3 feet this summer. They are grown in this way to hide a brick wall and serve another purpose, viz., to cut from for filling vases. Few things are more charming than a handful of the white kind placed in a vase mixed with *Mignonette*. I find them most useful for filling small glasses for placing on the dinner table, and when thus used they are much appreciated. Our plants have been in bloom for over two months, and now (August 4) they look as if they would continue for many weeks to come.—J. Crook.

The herbaceous Lobelia is one of the finest plants in bloom now. We have seen it well used in many of the London parks, and in the bedding arrangements at the Zoological Gardens it is always a fine feature. It is only within comparatively recent times that *L. fulgens* and such forms as *Firefly* and *Queen Victoria* have been thus boldly planted, but they are very effective, especially when used in contrast with such things as *Calceolarias*, *Ageratums*, and other colours in harmony with the deep chocolate-toned leafage. We greatly admire a single bed of it with a suitable edging, and in the autumn it provides a fine picture, a welcome relief to the bedding plants usually seen. The contrast between the intense crimson flowers and dark foliage is remarkably striking. In the majority of places it is wise to lift the clumps when frost comes and plant out in a cold frame, where they will be safe through the winter months. Damp is a great enemy to this class of *Lobelia*. It requires rather a sheltered position and a moderately moist soil. Under these conditions a very fine leaf growth results with a proportionate display of bloom.

Hypericum oblongifolium is one of the most beautiful shrubs in bloom now. It is very charming in the Wisley garden of Mr. G. F. Wilson, and in the Royal Gardens, Kew, good use is made of it as a shrub for massing boldly. A coloured plate of it is given in THE GARDEN, September 4, 1886. This species is a native of the Himalayas, whence it was introduced about the year 1856 by Messrs. J. Veitch and Sons. It is found in Sikkim and the Khasia Mountains at varying altitudes from 4000 feet to 12,000 feet above the sea. Unfortunately, it is not so hardy as one could wish, but if not too much exposed it will withstand hard frost without injury. The habit of the shrub is compact, the leaves evergreen, and the branches of a reddish tint, which serves to enhance the beauty of the large, rich golden yellow flowers, which are produced in profusion and make a fine display of colour, having a very graceful aspect, especially conspicuous when the shrub stands out singly. *H. patulum*, we may remark, is planted largely at Kew. It is not so tall and graceful in growth as *H. oblongifolium*, and the flowers are smaller and paler in colour.

Oncidium dasystyle.—In the large and somewhat bewildering genus of *Oncidium* there are many beautiful and many curious species, but I do not know one which combines these two characteristics so markedly as does *O. dasystyle*. It is a native of Brazil, coming from the celebrated region of the Organ Mountains, whence it was first imported by Messrs. B. S. Williams, of Holo-

way. It has green, elliptical pseudo-bulbs 1½ inches high, bearing at the top a pair of linear, lanceolate, deep green leaves from 5 inches to 10 inches long, according to the strength of the plant. The length of the scape and the number of flowers it carries vary also from the same cause. I have seen over twenty flowers on the scape, but, as a rule, it is less than half that number. The flower is nearly 2 inches in vertical diameter, but is not so much across, the sepals and petals being pale yellow, freely dotted with brownish purple. The lip is proportionately large, the front portion being broad and spreading and of a soft, unspotted yellow. It is the crest of the lip which gives the flower its peculiar character; this part is shaped like a small beetle, and the resemblance is rendered still more striking by its having the same black metallic lustre. On strong plants the flower-spikes will sometimes branch and continue producing blooms for three months, viz., July, August and September. It is advisable to sometimes remove the scape before it has spent itself, as the species is apt to become exhausted by over-flowering. It should be grown in the cool house in pots, using a compost of peat fibre and Sphagnum.—B.

Phaius maculatus.—This Orchid was first brought to England in 1823, but it has never been so extensively cultivated as its various attractions would lead one to expect. At the present time it is one of the least known of the Phaiuses. It is an evergreen plant, and occupies a high place amongst the comparatively small number of Orchids which have a claim to rank as ornamental-foliaged plants, the leaves in this instance being deep green, conspicuously marked with round yellow spots; they measure from 1½ feet to 2 feet in length, are plaited, and taper to a long fine point. The scape is quite erect, somewhat shorter than the leaves, and bears from 10 to 15 flowers. The flowers are each from 2 inches to 3 inches across, and for the main part of a clear soft yellow. A fine contrast is, however, obtained by the frilled margin of the lip being a rich reddish brown. Besides the typical spotted-leaved form, there is another in all respects identical except that the leaves are uniformly green. This is flowering now at Kew. The species is a native of Northern India, and its first introduction to cultivation is due to Dr. Wallich. Like the other Phaiuses from the same region, it should be treated as a terrestrial plant, using a proportion of one-half fibrous loam in the compost, the remainder chopped Moss, peat, and silver sand. It may be grown in the Cattleya house.

Tufted Pansies from Chirnside.—With a very lovely crowd of his pure and delicate tufted Pansies, Dr. Stuart writes us on August 7 from Chirnside: "I send you a box by this afternoon's post containing some blooms of the newer ones, which are great improvements in some respects. *Violetta* and *Sylvia* still hold their own, and I see them in fine condition in many places. *Sylvia* blooms profusely when the frost stops in spring. *Violetta* in my garden does not flower freely till the end of May. The early part of this summer was disastrous to seedling beds and to plants not well established. I should have lost hundreds had I not replanted. I have some lovely breaks this year, pale blues with yellow centres and rayless eyes. There are none of these in the lot sent, but at some other time when the plants are in flower I shall send you a few blooms. I have been crossing the *Trolliuses* this year—*T. europeus* × *americanus* or *aurantiacus*. Some grand forms have resulted, many deep orange in colour. At this time some seedlings are in bloom for the first time, but I must defer sending you them till spring, when they bloom naturally. *T. europeus* is a good seed-bearer, the sepals folding over the apex of the flower, so that when the anthers are cut out and the pollen well distributed on the pistil, as a rule insects do not readily find admittance to work mischief. I have a fine bed of new sorts, some unflowered."

The English Flower Garden.—Design, Views and Plants. Third edition, revised, with many new illustrations. London: J. Murray, and through all booksellers.

TREES AND SHRUBS.

RHODODENDRON FALCONERI AT DORKING.

THE plant a truss of bloom of which is here figured flowered when it was, I suppose, 3 feet or 4 feet high. I happened to be invited to dine with the late A. Barclay, of Bury Hill, and knew that Dr. Hooker (as he then was) was there, so I took a truss with me. Dr. Hooker's observation to me was, "I do not know what English pruning may do, but in its native woods it is a very ugly tree." The reason is obvious. When left to itself,

to prune them, and so they grow lanky and straggling. D. D. HEATH.

Killlands, Dorking.

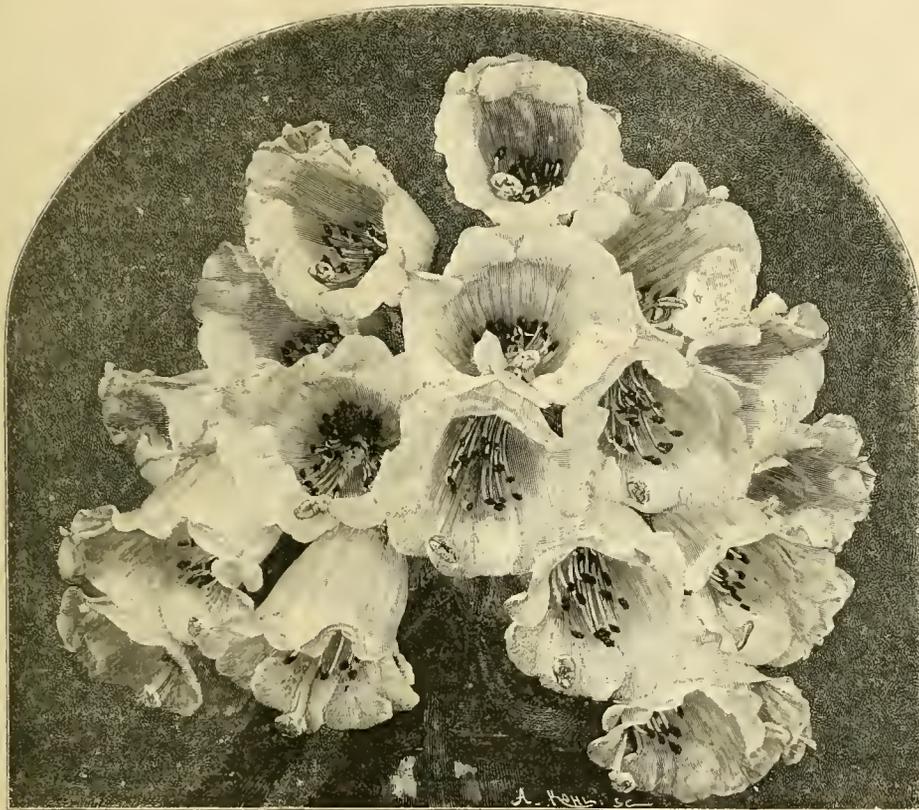

Catalpa bignonioides.—A very fine specimen of this is in full bloom in Ravenscourt Park, Hammer-smith. It is not often one finds a noble example of this Catalpa in a public park, and when in full flower, as at present, it has a noteworthy aspect. The Catalpa is very striking either when small or large, the leaves rich green in colour set off by a profusion of large Horse Chestnut-like spotted flowers.

Hibiscus syriacus—If any further proof of the abnormal season was needed it may be found in the fact that some of the earliest blossoms of a form of this Hibiscus were expanded before July had left us, certainly very much earlier than is

all it might be worth while trying such things as the Cherry Plum for fences, but it is not worth while in our country. The Cherry Plum (*Pyrus Myrobalana*) is not likely to have any value for us save as an ornamental tree worth a place among those that flower early. *Prunus Pissardi*, a tree of recent introduction to our gardens, is simply a purple-leaved variety of the Cherry Plum, and bears the same kind of fruit.—*The Field*.

Euonymus radicans—This little *Euonymus* is a capital thing for edging walks and flower-beds on the Grass. The beds on the lawn at St. George's Hill, Byfleet, are edged with it, and very nice they look when the zonal Pelargoniums and other tender bedding plants are in bloom. These edgings were planted nearly twenty years ago, and have been kept clipped just as is the case with Box edging. It is not only at this time of year that they have a nice appearance, they are equally pleasing in winter, the variegation of the *Euonymus* forming a nice contrast to the green Grass.—J. C. B.

Variegated Elms.—Where these do well they are but little inferior to the variegated *Acer*. This summer seems to have agreed well with them, the variegation being very clear. The yellow-leaved Elm seems to be rather rare. I have a nice tree of it which this season has coloured finely. All the variegated Elms are slow of growth, requiring ten years from planting to render them really effective. They look best standing in the near proximity of dark-leaved Evergreens, or in isolated positions on the grass.—J. C. B.

Truss of *Rhododendron Falconeri*. Engraved for THE GARDEN from a photograph sent by Mr. D. D. Heath, Killlands, Dorking.

CONIFERS AND THE DROUGHT.

IN most districts we are, without doubt, congratulating ourselves upon the refreshing rainfall of the past two or three weeks. This fact, however, must not be allowed to lead those astray who, through being situated in districts that have suffered the most, have still need of a further downfall, and that probably more than they are actually aware of at the present time. It is surprising how soon Conifers and other shrubs revive after a good shower or two, but if this be not maintained they will soon suffer again. In many instances a thorough good soaking will be found most desirable. Half-and-half measures will not do, for the work has to be gone over again in quick time. Some growers, I imagine, are under the impression that Conifers do not need that amount of attention in this direction that other things do, just because they do not show symptoms of distress in such a plain fashion. Let them continue to suffer, however, and the result will be dead or dying branches, with the risk also of two seasons' foliage being shed in one season and the plants or trees thus made barer than they should be. Beyond these evils they may die outright, not only freshly-planted ones, but even where two or three years have elapsed since this work was done. Where and when, may I ask, do we find Conifers thriving the best? Those who have taken note of this will have observed that it is where water abounds the most or when the rainfall is quite up to the average. This being so, it is quite needful to turn our observations to account to preserve any from succumbing or in any way suffering. In some cases it may be found needful to prick up the surface or to make a ring with other soil at a good distance from the stems to prevent the water from running away rather than penetrating where most needed. Besides this, in very bad cases the garden engine will be of good service, it being plied daily for a time. In the case of the Fir tree family there is another attendant evil, this being the risk of fungoid development at the roots when after an excessive drought, moisture is again absorbed. There is a disposition in most of the Coniferæ to cast

and if it meets with no accident, all the side buds of each year perish, and the tree will consist of long bare spokes with just one whorl of leaves, and a flower or leaf-bud at the end. I can see the process going on on the higher branches, which I cannot easily reach.

The winter of 1890-1 was a very severe one, and almost all the buds on the tree were killed. I expected the tree to follow. But instead of this, it soon appeared that it had just pruned itself all over. The little green pimples below each dead bud, which usually die off, expanded vigorously, and now it is in better condition than ever it was. It now over-tops the wall by several feet without any appearance of missing the shelter; only I cannot well get at the leading shoots

usually the case. The variety in question, *cœlestis*, is generally the first to unfold its blossoms, but that is probably owing to the position occupied by the plant, as I have not noticed any difference elsewhere. It is one of the best of the numerous forms of this Hibiscus, the flowers being single and of a decided bluish tinge. In planting the Hibiscus in question, it should be borne in mind that it suffers considerably during the summer if in a dry position, and to be seen at its best it needs a sunny spot where there is a cool moist soil; if of a loamy nature and fairly deep, so much the better.—T.

The Cherry Plum in fruit, and as a hedge plant.—We do not know who was the first to advise the planting of this tree in fences, and we doubt its value much. We have lately noticed trees in France laden with fruit, which is of poor flavour and probably useless. The tree gets open and weak in its old age—quite the opposite of our excellent native Thorn, surely the best of fence plants and almost the only necessary one. In countries where this Thorn grows badly or not at

off the rainfall beyond the branches rather than to direct it towards the stem and around it. Taking this into consideration, all due allowance should be made, more particularly where the trees are planted upon slopes. If the Coniferæ continue to suffer from drought, what is not accomplished thereby will be further added to when cold and easterly winds again prevail. It takes years to raise many a specimen to good dimensions, but it is only a question of a few months effecting their ruin in times of excessive drought.

PINUS.

Wood wasps at Earl's Court.—A singular and probably unprecedented event has occurred within the past few days at the Gardening and Forestry Exhibition in the development and maturity of a number of specimens of the wood wasp (*Sirex juvenis*). A small slab of wood cut from a diseased Pine tree in Windsor Forest had been sent by permission of the Ranger, Prince Christian, to the exhibition as an illustration of the mischief wrought by insects. It was observed to be riddled by holes, but it was not imagined that any larvae were hidden in the wood. Early in the week, however, a ticking, scraping noise was heard, and presently the head of a wood wasp made its appearance, the creature having eaten away that portion of wood which intervened between his retreat and the outer world. Others subsequently made their appearance, the total number being sixteen females and two males. They are somewhat formidable-looking insects, being quite an inch in length, with long, broad wings. The female is slightly larger than the male and has a steel-blue body, while that of the male is orange-red. It is the custom for the female to pierce a hole in the bark and deposit her eggs, and the larvae eat their way into the sap-wood, where they remain for nearly two years before they attain the perfect state. It is evident from the presence of so many wasps in such a comparatively small plank—about 3 feet in length—that their ravages are liable to cause great destruction in a Pine wood.

KITCHEN GARDEN.

WINTER CUCUMBERS.

IN some establishments there is almost a constant demand for Cucumbers, and in very many more they would be appreciated at all times if available. Naturally, the supply during the winter is very limited, not, however, because they are particularly difficult to grow, but rather owing to house room of a suitable character not being forthcoming. In gardens where Melons are extensively grown in houses these are often followed at this time of year with Cucumbers. Supposing a few plants of the latter are already well up to the roof, another batch would soon be ready to plant, and to succeed these a third and most probably a last lot of plants would be raised early in August. No attempt is made to keep the plants in a bearing state after one good exhausting crop has been taken from them, the method of culture adopted being somewhat similar to that which answers well in the case of Melons. Very high temperatures are not necessary for late autumn and winter Cucumbers. What suits the majority of stove plants agrees equally well with Cucumbers, and it is no uncommon thing for two or three plants of the latter to be successfully grown at one end of a plant stove. During the winter a night temperature of about 65° will meet the case, an occasional drop to 60° doing no harm. In the daytime an increase of 5° more or less according to the weather experienced should take

place, a fairly moist atmosphere rather than much overhead syringing being desirable.

In any case, or whether the Cucumbers are to have a forcing house or houses to themselves, or are to take their chance with a variety of other heat-loving plants, the start ought to be made with clean healthy plants. Starvelings, or any kept in small pots long enough for the stems to become hard and the leaves yellow, are very slow in recovering from such a check, while if either thrips, green-fly, or red spider have taken possession of the foliage, this also militates greatly against progress. If the seeds are sown separately in 2½-inch or slightly larger pots and kept in a frame over a slight hotbed quite clear of other insect-infested plants, there is every likelihood of their germinating strongly, the plants being clean and healthy when wanted for the house. Cleanliness is of so much importance in Cucumber culture, that there should be no half-hearted steps taken in cleansing the houses that are to grow them. Old soil and hot-bed material should be cleared out, wood-work and glass well washed, and the walls receive a dressing of hot lime water. Whether the plants shall have the benefit of a hotbed or not should depend upon circumstances, and it is open to the cultivator to grow them either in fairly large pots or in mounds of soil. If there are pits with hot-water pipes in the bottom, either fill up with well-prepared heating material or else bridge over with strips of wood and slates. The use of heating material saves fire-heat during dull or cold weather in August and the early part of September, but I have been most successful when this kind of bottom-heat was dispensed with, slate-covered benches along the fronts of stoves and forcing houses suiting Cucumbers remarkably well. The decaying heating material is scarcely a suitable rooting medium for winter Cucumbers, the roots thriving best when principally confined to 12 inch or slightly larger pots. Pots are not needed when a staging is devoted to the plants, but may well be used if they have to share the space with a variety of other pot plants. Much depends upon the kind of compost used, anything of a close, heavy nature being objectionable. What does suit them well is a mixture consisting of three parts of roughly broken up light fibrous loam, the finer particles being rejected, to one made up of mortar rubbish and burnt soil. The pots used should be about three parts filled with soil, while if mounds are formed in preference, let these be about 3 feet apart and each consist of about one peck of compost. It is not a great heap of soil that Cucumbers want or should have at one time, frequent additions better suiting them. Planting in a great mass of soil has been the cause of an early breakdown of plants during the summer, and proves even more quickly fatal during the autumn and winter months. No matter how well the plants may be attended to, if the root action is defective it is not much of a crop that will be produced.

Healthy growing plants being duly put out in the mounds or pots as the case may be, these must be kept growing strongly, and which will not happen if the soil about the roots is allowed to become very dry. Carefully support with stakes, remove side shoots up to the roof trellis, but do not pinch out the point either before or after the trellis is reached unless it is caught or scalded by strong sunshine, in which case another lower shoot must take its place. Continue the leading shoot straight up the trellis till the limit is reached or exhaustion takes place, and lay in a sufficiency of the side shoots right and left to thinly clothe the roof. If successional plants are coming

on, fruit the earliest to their utmost capacity at once and throw them away directly they break down. The laterals never fail to show fruit, and by stopping these at the second or third joint and allowing them to bear all the way up the roof, it is surprising what a great number of good Cucumbers a plant will quickly produce. If it is desirable that the plants remain as long as possible in a productive state, then the cropping must be light at the outset, or there will be a failure before December. Better be content with three or four good fruits on a plant at one time than attempt to grow double that number imperfectly with the certainty of an early collapse owing to over-cropping. If the plants continue in a healthy growing state after having produced a dozen or more fruit, thin out the young shoots, train those reserved thinly on the trellis and stop beyond the second fruiting joint. If red spider starts on the older leaves, dredge these at once with flowers of sulphur. Thrips, green and black fly should be kept down by means of diluted tobacco water. It is a mistake to be constantly applying liquid manure, especially if this is of a nature that will clog the soil. All that is really needed to keep the plants growing strongly and bearing well is to top-dress every week or ten days with a mixture of equal parts of roughly broken up fibrous loam and good flaky horse stable manure. A heap of this should be either kept in the house or ready mixed in a shed, warming it in the latter case prior to using it in November and December. As fast as the white roots show on the surface cover them with the loam and manure, piling it up round the stems and heaping it gradually several inches above the pots when these are used. Enough clear water should be used to keep the soil uniformly moist, and this, coupled with a moist atmosphere and fairly brisk heat, will sustain the plants surprisingly well.

Telegraph is one of, if not the very best variety for late autumn and winter culture, and ought certainly to be selected when Cucumbers are required for cooking and serving as a vegetable or *entrée*. For the latter purpose the fruit should be left hanging long enough on the plants to become extra "fat," though not long enough to become old and yellowish in colour. Cardiff Castle is also admirably adapted for winter culture, as this variety is of few productive growth, the fruit being rather short, but excellent in quality. GROWER.

Peas mildew.—Many, no doubt, have had the same experience as "W. S." with regard to late Peas being attacked with mildew so soon after the long-wished for rain had come. The only variety which I have here that has resisted the attack of mildew is *Ne Plus Ultra*. This is quite free from it and just in flower. Other sorts close by, such as *Champion of England* and *Veitch's Perfection*, are much mildew. —A. J. LONG, *Wyfold Court Gardens, near Reading*.

Cauliflowers—Now that the weather has become cooler with frequent showers, it is possible to regard Cauliflowers with greater respect. During the summer so far the heat and drought had developed aphid and caterpillar so abundantly, that Cauliflowers presented anything but an appetising form. Now they have greatly improved, but still leave much to be desired, as aphid is hard to displace even with the aid of the heaviest showers, and caterpillars need much watching. It is now the late summer and autumn varieties that need most attention, and if these be occasionally examined so as to remove caterpillars, very much indeed may be done to bring the heads into a cleaner condition. Those who have now early planted *Magnum Bonum* Cauliflower should find

heads turning in shortly. This is a very fine white early selection from the well-known Autumn Giant. This latter succeeds it early in the autumn, and then comes Veitch's Self-protecting to keep the stock plentiful until Christmas. Thus with the Snowball type, under whatever name grown, to heart in early in June, Cauliflowers furnish a long season and a most important garden crop. The dry spring and early summer are responsible for very many blanks, but still these are not so marked as might well have been expected. What is now of the greatest importance is clearing the plants of their insect pests ere they have become too plentiful, and only by very close attention can such cleansing be accomplished. When our tender summer crops have been killed, perhaps by an early frost, then specially will the value of Cauliflowers be realised.—A. D.

RUNNER BEANS.

THERE is no late summer vegetable that seems to be doing better, if so well, as are runner Beans. Even in cottage gardens and allotments runners are universally good. One reason for this is no doubt because, growing so tall, the plants get above surrounding crops and have plenty of light and air; then being sown singly in rows they are usually more thinly planted than is the case with dwarf Beans, for instance, for these are often sown two or three rows together, and the plants being so close and crowded, the product is poor and the plants of short duration. There seems also to be a general knowledge that to have runner Beans in good form it is needful to give to the soil some special preparation. When only one line or row is concerned, that is not a difficult matter, and the opening of a trench, burying into it an extra dressing of manure and giving also occasional soakings of water, all conduce to good results. It is doubtful whether, viewed from a pecuniary aspect, there is any other vegetable that gives so profitable a return from a single row occupying, perhaps, a width of 3 feet of soil as does a well-staked row of these climbers. The earlier showers which broke the long spell of drought came at an excellent time to fertilise and save the first flowers. Not that the rain assists to pollenise, because the process has to be done before the flowers are fully expanded, as is the case with Peas, but drought at the roots and in the air, combined with strong sun-beat, is found to be very harmful in that respect, and unless the conditions are changed by showers or frequent syringings and waterings, almost entire loss of bloom results. I found also in numerous small gardens and allotments that some of the finer forms of Beans now in commerce are being largely grown. It is not at all difficult to discern from the length of the pods that the new Ne Plus Ultra strain is getting abundant. There are several fine selections under other titles in commerce, all the product of special selection, and although some seem now to be so good that improvement is very difficult, yet efforts are not lacking to secure any form of improvement that may present itself. The large or giant-podded forms have little merit, but the narrow, long pods are both handsome and of delicious quality. The flowers of some of these finer varieties also have greater size and richer colour, so that, apart from the utilitarian aspect of a well-grown and trained row of runner Beans, there is also very much of rich colour and beauty. A.

RENOVATING CROPS.

IF rain has fallen in other districts in the same degree that it has fallen at Kingston, then will a most marked improvement be visible very quickly in all descriptions of garden crops. Not that one shower suffices to moisten soil, literally baked dry, to any depth, but a continuation of showers with a material cessation of heat in time brings the soil into a fertile state, and being so warm, the effect is marvellous. We have now to dread too much rain, for a wet autumn will in

turn be just as harmful as the drought of early summer has been. However, the showers should encourage sowing and planting in all directions, so as to enable the autumn to be prolific, as the summer so far has been rather barren. We can yet sow some of the earlier maturing Peas, and especially the dwarf ones. A couple of sowings of any of these may in the cooler, moister weather give capital crops in September and October. We may yet make a couple of sowings of dwarf Beans of such as Ne Plus Ultra and the Negro, as these soon fruit. New sowings can be made of Nantes Carrot on well-prepared soil to give produce through the autumn and early winter, and if a sowing be made at once of the Queen Onion, it will be possible to obtain if small at least very useful bulbs that may materially help out the very shortened crops at present growing, whilst there is ample time for Onion bulbs to swell. Sowings for standing the winter are best made in August. Where Beetroots are very thin it may not be too late to sow seed of the Turnip-rooted variety, as this turns in early, and very good roots may result before the close of the winter. Sowings of two or three varieties of Cabbages may well be made now for planting out in August, especially of such as Atkins' Matchless, Ellam's Early, Early York; also sowings yet of dwarf green Coleworts, as plants put out in August will give nice if small heads. Then it is worth while making sowings of Snowball or Early Forcing Cauliflower in boxes so as to have plants that will head in during the late autumn. These will be found most useful where the Autumn Giant Cauliflower has clubbed or otherwise done badly because of the drought. Peas that show a poor crop, because dryness at the roots has caused the flowers to be infertile may be pulled off at once, and room be made for Celery trenches. Then sowings may be made of prickly Spinach, certainly the best for summer use, and of Round Flanders Spinach twice in August to give early and late winter pickings. Then both Lettuce and Endive seeds may be sown, as these are quick growing. Radish seed will if sown now give several yieldings. There are so many things, Turnips especially, which there is ample time to sow, and where early Potatoes, Peas, Beans, are got off early, the ground may, now that rain has come, be recropped with great rapidity, and the autumn be made to compensate in a large degree for the comparative scarcity of the early summer.

A. D.

THE GREAT DROUGHT OF 1893.

THE drought of 1893 will unquestionably take its place among the recorded events of history, if regard be had to its intensity, the length of time during which it has lasted, and the wide extent of the earth's surface it has overspread. Treating the British Islands as a whole, the drought may be considered as embracing by much the greater part of the country for the fifteen weeks beginning with March 5. But while copious rains have fallen during the past few weeks in many places, it may be regarded as continued to near the present time in many of the more important agricultural districts in the south.

The drought was most severely felt in the southern division of England, and least in the north of Scotland. Over Scotland, England, and Ireland it increased in intensity, with pretty uniform regularity, from north to south. Thus the deficiency in percentages from the average rainfall of that portion of the year was 30 at Lairg and 59 in Berwickshire; 59 at Penrith, and 90 at Dungeness and Falmouth, and 38 at Londonderry and 67 at Waterford. The least deficiency at any of the stations of the *Weekly Weather Report* was 1 at Glencarrou, in Ross-shire, and the greatest at Dungeness and Falmouth, as stated above. At Glencarrou the amount of the rainfall was 16.91 inches; whereas it was only 0.60 inch at Dungeness, 0.77 inch in London, 0.92 inch in Scilly, and 0.91 inch at Falmouth. At places south of a line drawn from Cambridge to Scilly less than a fourth part of the average rainfall of these fifteen weeks was collected, and consequently over this large

district the effects of the drought have been most disastrous to agriculture and horticulture, the hay crop, for example, being in many places a complete failure. It was altogether a unique experience, in travelling in June from London to Scotland, to mark the great and steady improvement in the condition of the crops in the northward journey.

During the period the type of weather prevailing was eminently anticyclonic, with the appearance, ever and anon, in localities more or less restricted, of small satellite cyclones with their attendant thunderstorms and rains. Hence the remarkably sporadic character of much of the rainfall, of which the most remarkable instance was a rainfall of 1.19 inch at Parsonstown on June 10 and no rain whatever at any other of the telegraph stations of the meteorological office in this country. Heavy local rains of this type, with downpours of an inch or upwards, were recorded on May 17, 18, 20 and 21, and June 10. It is also to be noted that many thunderstorms occurred during the period unaccompanied with rain, just as happened generally in the east of Scotland in June, 1887, on the day of the Queen's jubilee; and frequently large drops of rain fell, quite insufficient even to wet the ground, and scattered over narrow paths of inconsiderable length. Very heavy rains occurred over the eastern districts of Scotland, practically terminating the drought there, on June 22 and 23, when on these two days 4.20 inches fell at the North Esk reservoir on the Pentland Hills, 3.32 inches at Roslin, 2.21 inches at Aberdeen, 2.06 inches at Logie Coldstone, near Ballater, and nearly 2 inches at many places, whilst generally in the west little and at many places no rain fell at all.

Temperature was phenomenally and almost continuously high in March, April, May, and June, specially as regards the first three of these months. Thus, for London the mean of the three months was 4°.3 above the mean of the previous 130 years; and in Edinburgh 3°.3. The only springs since 1763 with a mean temperature exceeding that of 1893 were for London, 1811 and 1791, which were respectively 5°.2 and 4°.3 above the average; and for Edinburgh, 1779 and 1781, which exceeded the mean by 4° 0 and 3° 8. It is highly interesting to note that large as these figures are, the Ben Nevis figures far exceed them, the mean temperature at this high-level observatory for March, April, and May last being 6° 6 above the mean of these months, a result due to the prevailing anticyclones, which so frequently are attended there with abnormally high temperatures.

The drought has also extended over nearly the whole of Europe, large portions of Canada, the United States, and other parts of the globe. In the north of Italy no living person recollects to have seen the Italian Lakes so low, and the Southern Alps so greatly denuded of their snow covering. It is estimated that over the wheat growing countries of the world this valuable crop will be to no inconsiderable extent under the average. On the other hand, in other parts of the world the rainfall has been exceptionally heavy, and followed with widespread disastrous floods, as in the cotton districts of the United States and in Queensland.

In London, the total amount of rain that fell during the 110 days from March 4 to June 22 was 0.77 inch. Mr. Symons, our best authority on the question of droughts, enumerates eight droughts which have been recorded during the present century. Of these the longest continued was 105 days, from March 11 to June 23, 1844; and thus the drought of the present year is the greatest in the British Islands authenticated by meteorological records.—*Nature*.

Paraffin as an insecticide.—"Y. A. II." may well say that extreme caution is necessary in the employment of paraffin. I know of an instance where a lot of nice young fruit trees has been completely ruined by enveloping the stems with cloths steeped in paraffin to keep them free from the winter moth. The trees, which had just come into good bearing condition, were killed outright. Everyone who uses paraffin for the destruction of

insect pests, whether on fruit trees or plants, should first, by careful experiment, find out how much of it any particular plant will bear without injury. Not long since I saw some large plants of *Stephanotis* which had been syringed for mealy bug. It had the desired effect as regards the destruction of the bug, but killed almost every flower-bud. Had the owner used a weaker mixture he might have killed the insects and not injured the plants. One difficulty connected with the use of insecticides is caused by the varying condition of the foliage. After bright weather the leaves will bear a much stronger dose than when growth has been made in a sunless time.—J. C. B.

FERNS.

FLOWERING FERNS.

(ANEMIAS.)

THIS is a family of Ferns possessing great attractions for the majority of Fern growers, and they may be so grown as to become extremely useful for indoor decoration. Some of these plants make charming objects for decorating the Fern case, but I would advise that the plants be put in these structures in their pots when in flower, because I think they grow far better in the Fern house. These plants are all of dwarf habit of growth and have a somewhat similar aspect, yet they do differ essentially, and where a collection is grown this becomes very evident. *Anemias* all come from tropical countries, and consequently require stove heat to grow them to perfection. They should be potted in turfy loam, fibrous peat and sand well mixed. The plants should be liberally treated to water at all seasons, but do not use the syringe for sprinkling them overhead. Pots of too large a size must not be used. I give below a few of the best kinds, and some very pretty ones have not yet been introduced in a living state.

A. ADIANTIFOLIA is a handsome Fern, sending its fronds up from a creeping rhizome. The fronds are each from 9 inches to 1 foot in height and from 6 inches to 8 inches broad, triangular in shape and of a rich shining green; the fertile segments (in pairs) spring from the base of the leafy portion of the frond; the spore cases turn to a rich brown and thus represent a flowering raceme. In the variety named *asplenifolia* the sterile frond is less divided, whilst another more finely-cut form is called *A. curvifolia*.

A. CHEILANTHOIDES.—In this plant we have one of the most beautiful species, but at the same time it is one of the most delicate and tender, requiring to be kept constantly in stove heat. The fronds are each from 6 inches to 12 inches high, three times divided and finely cut, slightly pubescent and somewhat light green in colour; the fertile segments are some 6 inches or 8 inches high and of a light brown. This makes a charming little specimen and is well deserving of special attention.

A. CAUDATA.—A specially distinct and handsome species, which is rare in cultivation. It used to be grown in Mr. Williams' nursery, he having imported it from Brazil some years ago. It makes pinnate sterile fronds, which bear some two or three dozen pairs of pinnae of a dark green. It is a very handsome plant, which is sometimes called *A. radicans*.

A. COLLINA is another extremely handsome kind, having the stem clothed with ferruginous hairs. The sterile pinnae are large, rich green, and the fertile segments are very handsome. This species may be used for table decoration.

A. DREGIANA.—This plant is remarkable in that it is found in South Africa, while nearly all the other kinds are American. It is very handsome, and the fertile segments are large, the sterile pinnae being coriaceous in texture and deep green.

A. HIRSUTA, a plant which I once obtained from the Botanic Gardens in Berlin, well bore out the name, the fronds being quite shaggy, far more so

than in the same species growing at home with me at the same time. It is a very elegant plant; the sterile pinnae are more or less again divided, and soft green in colour. The fertile segments are less developed than in many of the kinds; it makes an elegant specimen for the stove.

A. MANDIOCCANA.—This plant is said not to differ from *A. collina* by some, but when growing side by side with it it presents a very different aspect, the pinnae being quite different in shape and colour and more closely set. The rachis is clothed with deep reddish brown hairs, the fertile fronds are also more dense. This plant makes an exceedingly pretty ornament in the sitting room.

A. TOMENTOSA (here figured) is a variable species, and recorded from the East Indies as well as from Peru and the West Indian Islands. Beddome calls it *A. Wightiana*. The fronds are from 6 inches to a foot long, more or less clothed with a downy

Anemidictyon phyllitidis.

pubescence, the fertile segments being dense. This plant has always been rare in cultivation as far as I am aware.

There is also another genus of plants which greatly resembles the above; indeed, only differing in having the veins netted or reticulated; it is called *Anemidictyon*, and the species which I refer to in this place is a stronger grower than either of the above-named plants, and makes a splendid ornament for indoor decoration, being free in growth, the fertile fronds very dense and beautiful. It is called

A. PHYLLITIDIS.—This (see illustration) makes fronds from 1 foot to 2 feet or more high; the sterile ones are pinnate, the long pinnae being bright rich green, the fertile ones erect, and rich brown. A very distinct form of this plant is called *fraxinifolium*.

W. H. GOWER.

Maiden-hair Ferns in cool houses.—I can quite bear out the observations of "Grower" in

last week's GARDEN as to the desirability of growing Maiden-hair Ferns under cool treatment. I have a few hundred plants, from small ones in 5-inch pots to larger ones 3 feet or more over. The best of them are growing in a cool conservatory where they have been for the past five or six years. I never saw plants so healthy or more vigorous. The roof of the structure is of rough plate glass. The plants are potted in alternate years, and some of them not so often. Last year they were all potted, and this season not at all. I am certain that to annually repot Maiden-hair Ferns is a mistake. To keep up their vigour, a dressing of some fertiliser is given at least once a week.—A. YOUNG.

FERNS IN FORECOURT GARDENS.

THE practice of planting forecourt gardens on a northern aspect, and indeed odd places where little else will grow, with common hardy Ferns is extending, and, I think, with the best results. Take, for instance, a suburban road, lined with small villa residences on either side running east to west. It is usual to give forecourt gardens to such, and on the north side the sun shines all day, or nearly so, but on the south side only at early morn and at the close of the day, and that mainly during the height of the summer. On one side pretty patches of flowering plants can be had if only a little attention be given them, but on the opposite side flowers fail to do well from lack of sunshine, especially so when Limes, Laburnums, Sycamores, and such forecourt trees are planted. In such cases the Virginian Creeper can be used to cover the walls of the mansion, and a hardy fernery can be formed by way of filling up the foreground. I have seen several such, and they are always more satisfactory than anything in the way of summer flower gardening.

In early spring before the new fronds of the Ferns develop, I have seen early Crocuses, Snowdrops, Scillas, and Daffodils peeping through the soil and unfolding their blossoms, with Primroses, Hepaticas, and a few early bloomers among perennials lending their aid. With summer comes a vigorous growth of the Ferns, and there is during the season something decidedly refreshing to feast the eye upon. Ferns are general favourites, and there need be no surprise at this. Nearly all Ferns have a delicacy and grace of outline, a softness of form, a beauty of colour that commend them to all genuine lovers of Nature, and though it is sometimes said that the liking for Ferns is but a caprice of passing fashion, I think they have held their own in public estimation long enough to leave their use unaffected by changing fashion. The most successful Fern plantations I have seen in small forecourt gardens are those in which the Fern bed was raised above the level of the ground. Roots or stones can be employed with which to form the bed, and provision should be made for a deep root-run by providing a bed formed of good fibry loam, some well-decomposed manure, leaf soil and peat. Ferns of the more robust hardy character are not so particular about soil as is generally supposed

so long as it is free and good, for they may be found in fair condition in almost any soils, from loam stiffening into clay and peat running into simply sand. Give them vegetable *debris* and fibry loam, and they will succeed if looked after in the matter of moisture. As a matter of course, in laying the foundation of a small Fern bed, care should be taken that the soil at the commencement after planting be not washed down into the path. In a short time the roots of the Ferns finding their way among the soil will bind it together; till then care is necessary.

In a small space there is little opportunity for growing some of the choice kinds of hardy Ferns, the aim being rather to have a bold mass of green foliage as soon as possible. To this end the best kinds to plant are the Lady Fern (*Athyrium Filix-femina*), the Male Fern (*Lastræa Filix-mas*), *Scopolendrium* (Hart's-tongue) and the common prickly Shield Fern (*Polystichum aculeatum*). In advocating the employment of the stronger-growing hardy Ferns in forecourt gardens, I have no intention of expecting such a garden to become a representative hardy fernery. More can, of course, be done in a large space than in a contracted one, and it is possible that he who commences in a small way may be led on to attempt greater things, and with correspondingly encouraging results. So far the simple aim is to encourage the planting of forecourt gardens in cool and shaded aspects with Ferns. Recently I was engaged in awarding prizes to forecourt gardens, and it was found those open to the south or south-west were the most effective by reason of their being better suited to the growth of flowers; but here and there I came upon a pleasant Fern garden good enough to be recognised. There are many neglected forecourts which might be beautified by the introduction of Ferns, and I should like to see the practice of planting them in this way extended. R. D.

Wasps—I can fully endorse "Practical's" remarks as to the efficacy of Davis' wasp destroyer (p. 101), as it has more than once saved our Grapes from their ravages. This remedy is somewhat of a puzzle to me, as it is apparently so harmless and very few dead wasps are ever seen in or about the houses where it is used, but it certainly drives them away, and few or none ever return to molest the Grapes if it is used according to directions. A very little of the mixture goes a long way. I have never tried it for use out of doors, but shall do so this year. I notice in the same issue of your paper (July 29) another correspondent says, in answer to a query about wasps attacking Grapes, that "there is no remedy that he can use in the house that would do any good." Surely "J. C." cannot have tried the above-mentioned remedy, or he would not have committed himself to such a statement. It appears likely that we shall have a veritable plague of wasps this year. The country round seems all alive with them already, and in a lane less than a mile long I counted last week forty-three nests. We have destroyed thirty-seven nests here within the garden boundaries, and there must be still more to destroy. This seems strange, as very few queens were seen during spring. Hornets, too, are very plentiful, and several nests have been

destroyed. I find nothing equal to gas tar where it can be easily procured for this purpose, a 3½-gallon can holding enough tar to destroy about eight nests; but, of course, this is of no use unless the holes run downwards, and nests by the water-side (a favourite spot) can rarely be destroyed by this or by similar means, as the holes generally run upwards from the bank side.—J. C. TALLACK.

ORCHIDS.

PHAJUS.

This genus has long been grown in our stoves and hothouses, one kind (*P. bicolor*) having been introduced considerably over a century

Anemia tomentosa.

ago. This species was introduced to the island of Jamaica over 100 years ago also, and there it has become a thoroughly wild plant. This plant is not indigenous to the Western Hemisphere at all, but its real home is in various parts of Cochin China and in Northern India. Some handsome new species have been recently introduced and some beautiful hybrids have been raised at home. I have a spray of a Phajus from "W. H. R." asking for its name, which I am unable to give him with that amount of confidence I like to feel when giving the name of a plant sent to me for that purpose, as the flowers have all faded to a dull yellowish buff. The flowers, however, remind me of those of the plant raised by Mr. Cookson a few years ago between Phajus Wallichii and *P. tuberculatus*, and named *P. Cooksoni* in his honour by Rolfe. "W. H. R." may see by the description given below if it resembles his plant or not.

The Phajuscs have ample plaited deep green leaves, which spring from a short thick bud. These are persistent for several years. The flower-spike is erect, bearing many flowers, which last long in beauty. Most of them are terrestrial plants and are easily grown, doing well with a mixed collection of ornamental-leaved stove plants, saving the kinds from Madagascar, which hitherto have been found less amenable to cultivation. The majority of the kinds thrive potted in a mixture of good turfy loam and fibrous peat. The pots must be well drained, and during the summer or growing season the plants require a great deal of water both to the roots and overhead. Many persons keep the plants in the shade, and in such a position the leaves are of a deeper green, but I like to give them a fair amount of sun and light, shading, of course, during the hottest part of the day. They require strong heat when growing with a moist atmosphere, but during the winter months, when at rest, they may be kept in a temperature ranging from about 50° to 55°. The following kinds are all worthy of cultivation:—

P. GRANDIFOLIUS.—This plant makes large ovate bulbs, from which spring the plicate leaves, which are each some 3 feet long and rich deep green. The spike is erect, rising up to 3 feet or 4 feet and bearing many flowers, which, although not highly coloured, are always welcome, opening, as they do, during February and the beginning of March. The sepals and petals are china white on the outside, of a tawny brown within, and the helmet-shaped lip is of a lighter colour than the petals and flushed with rosy purple. It varies, however, in the depth and richness of its colouring a great deal.

P. MACULATUS is less robust than the preceding. The leaves are pale glaucous green, irregularly spotted with pale yellow; the scape is erect and many-flowered, the flowers some 3 inches across and of a pale clear yellow, the lip being crisp in front and of a dark reddish brown. It is usual for Orchid fanciers to look down upon this plant and say it is not worth growing, but my readers who do not know the species will be delighted with its blooms when they expand.

P. WALLICHI is a much larger and more robust growing kind than *P. grandifolius*, but it has the same habit of growth, with strongly plicate leaves of a deep green; the spike is stout, erect and many-flowered, the individual blooms being some 5 inches across; the sepals and petals are china white on the outside, tawny yellow in front, flushed with brown, the large lip being deep orange at the base, suffused with pale purple. The form called *P. Manni* appears to be a very superior variety, the flower being larger and more fully expanded.

P. COOKSONI.—This was raised by Mr. Cookson, of Wylam-on-Tyne, and it is the only known hybrid Phajus as far as I know, and it is the plant, I think, which "W. H. R." sends for a name. The sepals and petals are yellowish white on the outside, yellowish brown within; the tube of the lip and the spur yellow, the front portion being rosy carmine, which changes with age to a buff.

The following two species have been introduced in great numbers during the past few years, by Mr. Sander, from the interior of Madagascar, and they have both been rather difficult to grow; at any rate, they thrive best with those who have an East Indian Orchid house in which to accommodate them, with a nice moist atmosphere.

P. HUMBLIOTI is a very handsome and distinct kind, having somewhat small bulbs and broad plicate leaves which are rich green; the scape is erect, bearing a raceme of about ten or twelve flowers, each 2 inches or more across, sepals and petals thick in texture, white suffused with rose. The lip is somewhat fiddle-shaped, the side lobes brownish crimson, the front lobe having a white centre, which bears a pair of yellow teeth, the margin being of a lovely rosy purple. This plant I

have seen growing freely and well. The most difficult plant that I know in the genus or in the whole Orchid family to grow well and freely is

P. TUBERCULOSUS. This is more of an epiphytal kind, and although it has been now in our gardens for about thirteen years it has not yet been successfully grown. I have seen this plant thriving in the freest manner with Mr. Sandor at St. Albans, where it is grown in baskets filled with peat fibre and Sphagnum Moss, and exceptionally well drained. The baskets are suspended over the water in the house used to grow the Water Lilies in. In this position the plants can have any amount of water, and they are never subjected to a lower temperature than 65°, whilst in the summer-time it runs up to nearly 90°. So great a temperature is not necessary to its well-being, for I have seen it growing and doing well with other people in a shady part of the house used for the *Aerides*, *Vandas* and *Saccolabiums*. It has fusiform bulbs bearing oblong lanceolate leaves, which are about 1 foot in length and deep green; the erect spike is somewhat longer, bearing several flowers, each of which is nearly 3 inches across and waxy in texture, the sepals and petals white, the lip three-lobed with large side lobes, with a ground colour of rich orange, dotted all over with reddish purple; middle lobe white, suffused with rose, and bearing on the disc three raised deep yellow-toothed lines. It is one of the most beautiful and striking Orchids that I know. W. HUGH GOWER.

Burlingtonia venusta (*Hugh Innes*).—I think this is the species you send for a name, but really this and the *Brassavola* were dried up past recognition. *Burlingtonia venusta* has rather stiff dark green leaves, the spike pendulous, and the flowers pure white stained with yellow in the lip, and quite destitute of any perfume.—W. H. G.

Oncidium zebrinum (*T. Hudson*).—It is by no means surprising that you call this an *Odontoglossum*, for the flowers are very much like those of this plant. *Oncidium zebrinum* flowered with Mr. W. Bull, of Chelsea, for the first time in Europe, about twenty-one years ago, but like most things it is a little early this year on account of the weather. The flowers are borne upon a long branching spike, the branches short and but few flowered. The sepals and petals are much undulated, white, transversely streaked with reddish brown, lip small, white with red dots and a yellow crest. It grows well in the cool house with the *Odontoglossums*. It comes from the mountains in Venezuela.—W. H. G.

Bifrenaria vitellina.—C. Poynder sends this old species for the correct name, which, I think, is given above. It was introduced many years ago from Brazil; the flowers are orange-yellow, having a splot of black at the base of the lip. It is by no means a showy plant, and it is not much grown; in fact it is only to be found in botanic gardens and such places.—W. H. G.

Oncidium pulvinatum (*T. Green*).—Flowers of this plant come for a name. This species was introduced by Mr. Harrison, of Liverpool, some fifty five years ago, and I think it has been grown in our gardens ever since. It produces long slender flower-spikes. The flowers before me are each an inch across, the outer segments yellow at the tip, passing into reddish brown at the base. The lip pale yellow with red spots. It is a very pretty species, and one that succeeds well in the stove or intermediate house.—W. H. G.

Sobralia from Cheshire.—These plants, I am glad to see, are becoming more popular. I some time ago noted a lovely new form from the Messrs. Pitcher and Manda, of Hextable, called Princess May, having pure white sepals and petals, the front lobe of the lip being suffused with delicate heliotrope, and now I have some beautiful forms from Mr. Hardy, Pickering Lodge, Timperley. One is very fine, resembling the flower of *Cattleya Schroderæ*. The sepals are white, flushed with pale rose, the petals broader, of a more decided rose colour, lip large, the whole throat of a rich golden yellow, the disc deep orange, the outer por-

tion deep rose, continued all round the side lobes. The next is also a remarkable flower and very handsome, having pure white sepals and petals and a lemon-yellow lip, with a somewhat triangular patch of white on the front lobe. The next is a beautifully coloured form of *S. xantholeuca*, the whole flower being of a rich yellow, which becomes orange in the throat, the front lobe being prettily frilled and undulated. These plants require somewhat large pots, which must be well drained. Use for soil turfy loam and peat, and do not elevate the plants above the pot's rim; water freely when growing, keeping them in good heat. They may be rested cool and not allowed to suffer from want of water.—W.

CATTELEYA ELDORADO.

I AM in receipt of various forms of this very handsome kind from different persons, some asking for my opinion and some for a name. Amongst the latter are "D. M.," Mr. Appleton, "G. B.," and W. A. Gunner, who sends me a white form, which is called *Wallisi* in some gardens, but which was named and figured upon its first flowering by M. Linden, of Brussels, *Cattleya virginalis*. The form sent by Mr. Appleton is a light one and a poor variety; the others are fairly coloured forms, but a flower which has come from T. Grossmith is a grand form of the kind known as *splendens*. This plant was imported from the banks of the Rio Negro by M. Linden about twenty-seven years ago, and the first time I saw it in flower was in Brussels just before it left for the Paris exhibition, the year after its introduction. This *Cattleya* is decidedly a grand acquisition, and although it varies in the colour of its flowers, yet the peculiar stout leaves and pseudo-bulbs render it very distinct. In Mr. Grossmith's flower the sepals and petals are soft clear rose, the petals much broader than the sepals, the centre being pure ivory white and the outer part flushed with a deeper rose or rosy lilac; the lip is large, the throat rich deep orange, outside of which is a zone of pure white, beyond which is the deepest and richest violet-purple I have ever seen, while the margin is prettily undulated and toothed. The typical plant is less brightly coloured, but it is marked in a similar manner; whilst the variety *virginalis* is somewhat smaller and pure white, saving the orange throat. A variety called *crocata* has the sepals and petals of a soft rose colour, and the lip rich orange in the throat. Another known by the name of *ornata* has the sepals and petals of a deep rose colour, the petals tipped with rosy purple and the lip of the typical form. All these varieties are very desirable plants, and they should be grown in a somewhat different way to the great majority of the labiata section of these plants, that is to say, they require to be kept hotter, and during the resting season the plants may be kept drier. I had some newly-imported plants when with the Messrs. Rollisson and Sons, and they grew and flowered annually and in great perfection, producing many varieties. Upon one occasion we had a consignment all of which were *virginalis*. WILLIAM HUGH GOWER.

Cattleya aurea.—Flowers of this plant come to hand from Mr. Hamilton Leigh for C. Dowiana, which he says is a very free flowering plant. This seems to be its character. I think the plant which Mr. Leigh promises me a flower of later on, and which he says has the petals flaked with crimson, is the true *C. Dowiana*. The flowers sent are those of the variety *aurea*. I am glad Mr. Leigh is so successful with *Cattleyas*, but cannot understand why *gigas* proves so unmanageable. Try

growing it in baskets hung up near the roof glass with full exposure to the sun, shading only during the hottest part of the day to preserve from burning.—W. H. G.

Miltonia Regnelli.—Mr. Innes sends me from Glenville, Waterford, flowers of this species. I am always glad to see this plant, because I was the first to flower it in this country. A plant given to me by Herr Schiller when visiting his garden flowered soon after its arrival home. It was a far nobler form than the one sent. The flowers on a good variety are nearly 3 inches across, the sepals and petals white, the lip rose, streaked with rosy purple. The variety known as Mr. Rucker's, called *superba*, is the finest I have seen, having rosy purple sepals and petals and a large lip, which is wholly dark purplish magenta. Mr. Innes' variety is not this one, but I should like to see it again another season.—W.

Lælia monophylla.—Flowers of this very interesting species come to me from Hugh Innes, gardener to Mr. Goff, of Waterford. This little plant is a native of Jamaica, where it was rediscovered some twelve years ago by Mr. D. Morris, now assistant-director of the Botanic Gardens at Kew, growing upon the lower branches of trees on St. Andrew's Mountains at some 4000 ft. or 5000 ft. elevation. Mr. J. O'Brien has been the principal agent in bringing this plant before the growers of this country, and I have seen it growing freely in several places. It bears but a single flower, which varies in size on a strong and robust plant. The flower measures about 2 inches across, the colour being of a rich bright orange-scarlet. This plant is the only representative of the genus in the island, and it is not to be found, or has not been found, in any other spot. It is figured in the *Botanical Magazine*, t. 6683.—W. H. G.

Cattleya Loddigesii.—G. Eastnor sends a very fine variety of this species, which he says is much liked by his employer. It flowers freely, the blooms being thick and waxy, of a nice size for sprays, &c., the colour being a delicate shade of soft rosy lilac. This plant was the first *Cattleya* grown in the country, but in the early days it was called *Epidendrum*, to which genus indeed Reichenbach reduced all the *Cattleyas* before he died. It grows freely with the labiata section of the genus, and requires potting in a similar manner.—W. H. G.

CHRYSANTHEMUMS.

CHRYSANTHEMUMS AT RYECROFT NURSERY.

A VISIT to the Chrysanthemum nursery of Mr. H. J. Jones at Lewisham cannot fail to be of immense value to all who are interested in this branch of horticulture. Here may be seen 6000 Chrysanthemum plants growing in pots, and without exception all are in superb health. Mr. Jones does not cultivate those kinds now so well known, such as the Queen family for instance, for the production of blooms, but devotes his time and space to the growth of new sorts. The plan Mr. Jones adopts with seedlings is to raise a big batch yearly from seed obtained from various sources, such as from America, France, and Japan, as well as from his own saving. The very best varieties are chosen for hybridising. Habit of growth is the first consideration. In the matter of colour those of decided tints are chosen as seed-bearers. Rich crimsons like Edwin Molyneux, which combines excellence of habit as well, is a favourite for this purpose.

As giving an idea of how thoroughly seedling Chrysanthemums are tested, Mr. Jones has 1000 plants raised from seed sown early this year. All are so far advanced at the present time as to be in a state to produce blooms this year. The most promising are marked and set aside for future trial. A period of two years is required before a variety can be thoroughly tested, as the flowers of many that turn out really good have the first year

but a single row of florets; 500 of these second-year trial sorts are now being finally tested. What strikes one most of all is the remarkably sturdy habit of growth the most of them possess. The present year's seedlings are now making their first break, many of them not being higher than 1 foot. The year-old plants retain that style of growth; the tallest plant was not more than 3 feet 6 inches at the time of my visit. Crown buds were fast appearing in the points of the shoots, which is an indication that the best blooms will be seen upon them. The date for bud-formation is evidently about the right time for testing purposes, especially when we consider that the bulk of the seedling plants belongs to the Japanese section. Varieties of the hairy kinds, of which Mrs. A. Hardy was the forerunner, are being largely tested. No less than thirty sorts from M. Sautel are being grown.

Mr. Jones evidently thinks that there is a future before this race, so peculiar and quaint are many of them with their hirsute appendage. New varieties like Charles Davis are being largely grown. Mr. Jones thinks highly of this latest addition to the Japanese section. Its parent, Viviani Morel, is now acknowledged to be the finest variety in existence, and its sport is said to be a fac-simile in style of bloom, but of a lovely yellow in point of colour. In growth it is promising, not exhibiting such a tendency to premature bud-formation as its parent. No less than 200 plants of Spaulding's new sorts are on trial also. M. Calvat's varieties are also receiving considerable attention. From the blooms shown in England by this raiser, they appeared to please the British connoisseurs. Princess May, Beauty of Exmouth, Robert Owen, Countess of Hambleton, and Ruth Cleveland are names that occur to me of sterling varieties that are likely in the future to be in demand.

It must not be assumed that the older sorts are altogether pushed on one side to make room for the newer introductions. Mr. Jones retains stocks of all that are worth a place. These are grown in small pots and plunged out of doors in one long bed, allowed to grow with but one shoot, and being struck late and not receiving artificial aid in the way of manure, as though they were cultivated for bloom, a splendid lot of cuttings is available when required. It might be thought that Chrysanthemum propagation is confined to so many months in the year. This is not so. Evidently it appears to go on all the year round to meet the demands of the trade. Summer propagation is done in shallow boxes of sandy soil stood in a frame with the lights taken off. Mr. Jones has a splendid batch of pompons of leading kinds, very bushy and dwarf.

E. MOLYNEUX.

SEASONABLE NOTES.

THE plants for all purposes are now making extremely rapid growth and need much attention in securing the points of the shoots to their supports to avoid being broken by strong winds or heavy rains. Some varieties are so short-jointed, that in low-lying, damp districts some cultivators are beginning to fear such plants will not ripen their wood sufficiently if we get a continuance of moist, dull weather. My advice to such persons is to thin the leaves judiciously, so as to admit a greater amount of sun, air and wind to the stems and branches. I do not mean to make the plants quite clean of their main leaves the whole length of their stem, but to remove an odd leaf here and there where they overlap each other. In districts similar to those already noted it is at times a difficult matter to get such varieties as the Princess Teck family forward enough to give satisfactory blooms by the middle of November, much less during the early part of that month. Where such a thing exists as a spare wall with a southern exposure, it is a good plan to stand the pots at the base of the wall and train the shoots on the wall so that they receive the benefit of warmth from the wall. This enables them to mature their growth and form the desired bud earlier than they would, by at least a fortnight in the ordinary way.

It is not necessary that a high wall only should be utilised for this purpose. A low wall, provided it has the proper aspect, will suffice equally well. The shoots can be trained crosswise over each other, but in such a manner that the leaves of one plant do not exclude the light too much from those of the other. The extra warmth derived by the plants from the wall must hasten on their growth and also the maturation of the wood. Varieties belonging to this family, and even the original as well, never produce shapely blooms from what are known as crown buds; therefore recourse must be had to buds formed a stage later and which of necessity throw the forming of this bud several weeks later. No variety that I am acquainted with exhibits so marked a difference between the blooms obtained from strictly crown buds and from others. In the former the blooms are flat; what few petals there are reflex instead of incurve, while the colour is several shades paler than it ought to be. The proper form of blooms in the Teck family is of the best incurved type; the depth very often exceeds the diameter, while the petals are very fleshy, thoroughly incurving, and possessing unrivalled colouring. The blush tint in Princess Teck is unrivalled, and so is the flesh-pink or rosy blush of Hero of Stoke Newington, a sport from the former. Some of the finest blooms ever seen belonging to this family were obtained by the aid of a wall in the manner described.

E. M.

NEW EARLY-FLOWERING CHRYSANTHEMUMS OF 1893.

So far as I have been able to learn at present, the early-flowering Japanese Chrysanthemums, of which we have recently received so many varieties, have not been so satisfactory as one might have expected. A large importer and grower of this class of Chrysanthemum informs me that he has nothing yet in flower that would justify a visit to his nursery.

The contributions to the lists have hitherto been received from continental growers, the American climate, on account of its heat and dryness, not being favourable to the growth of this section of Chrysanthemums. It is noticeable, however, in the American catalogues that a few early-flowered varieties are now being put into commerce, and no doubt if American growers can succeed in seeding these flowers which stand their summer the best, a new and useful race of early Chrysanthemums may thus be obtained.

M. Délaux, as usual, sends out a considerable number, and M. Boucharlat also contributes to the lists for the first time for many years. He tells us that the twelve varieties distributed by him are in every way distinct from existing sorts, each variety having been examined in comparison with those already in cultivation. It may be excusable to mention that it was from his nursery nearly twenty years ago that a set comprising the well-known Mme. Desgrange was sent out, and that if those now announced are of the same standard of excellence as that variety, there will be a ready acceptance of them by those cultivators in this country who pay special attention to early-blooming Chrysanthemums.

The forthcoming exhibition at the Aquarium in September seems to offer but little encouragement for the introduction of novelties, which is a costly and, it is to be feared, unremunerative business to those concerned. Many of the new sorts which are stated by the raisers to be in full bloom by a given date fail to respond to the description given of them. The difference between the climate of the south of France and ours may, of course, make all the difference, and it seems to me that the open border and not the show board is the place for which these early Chrysanthemums are more properly fitted.

- Alfred Sabatier (Délaux).—Violet-rose, striped white, golden centre, dwarf.
- Autocrat (Henderson).—Deep yellow.
- B. Boissonnat (Boucharlat).—Japanese; purple-violet, good habit, dwarf.

- Billecart Charles (Délaux).—Japanese; fine petals, dark carmine-yellow, shaded dark red in centre, reverse silvery.
- Boule d'Or (Boucharlat).—Japanese; broad petals, light chrome-yellow, dwarf.
- Candeur (Lacroix).—Japanese; long petals, pure white.
- Capitaine Fournier (Délaux).—Japanese; violet-rose on white ground, striped and tipped white, centre golden.
- Cassini (Lacroix).—Japanese; slightly incurved, bright orange-red, reverse old gold, dwarf.
- Charles Gérard (Délaux).—Japanese; broad petals, lilac-rose, striped white, centre golden.
- Creole (May).—Japanese incurved; deep claret, reverse garnet.
- Duning (Délaux).—Japanese; long petals, violet, striped white, golden centre.
- Edmond Besserat (Délaux).—Incurved; rose, glazed white.
- Edmond Duval (Délaux).—Japanese; pure white.
- Ernest Irroy (Délaux).—Japanese; salmon, nankeen and gold, striped rose, centre dark yellow.
- Fadette (Délaux).—Silvery lilac, centre golden, fibriate.
- Fulstaff (May).—Deep pink, base rose.
- Gaspard Boucharlat (Boucharlat).—Japanese; brick-red, dwarf.
- Georges Gayon (Délaux).—Japanese; twisted petals, creamy white centre darker.
- Haré d'Olphore (Délaux).—Japanese; violet rose, speckled white, tubulated petals of silvery white.
- Henri Clicquot (Délaux).—Broad petals, silver-lilac, shaded azure, dwarf.
- J. Lermont (Boucharlat).—Japanese; dark chrome-yellow, streaked red at base of petals.
- John White (Pitcher and Manda).—Fine pearl white.
- Jules Fournier (Délaux).—Japanese; long drooping petals, silvery light lilac-rose, centre darker.
- Jules Mumm (Délaux).—Carmine-amaranth, reverse silvery white, old gold centre.
- Krug Paul (Délaux).—Japanese; long petals, golden yellow, edged and striped crimson.
- Lady Florence (Pitcher and Manda).—Rich yellow, early.
- La France (Pitcher and Manda).—Pink, early.
- La Fontaine (Boucharlat).—Japanese; creamy white, good habit, fairly dwarf.
- L'Été (Délaux).—Japanese; similar to Fremy, but colour rather darker.
- Le Fidame de Moiraex (Délaux).—Canary-yellow, glazed silvery white, orange centre.
- Lumière d'Argent (Délaux).—Anemone; guard florets silvery white with lilac reverse, centre golden.
- Mme. Bérard (Délaux).—Japanese; broad petals, golden red, shaded salmon and violet-rose tipped gold, centre same colour.
- Mme. Cavalier (Boucharlat).—Japanese; bright rose, tipped sulphur-yellow.
- Mme. Cavé (Délaux).—Japanese; dull white, edged rose.
- Mme. Chapuis (Boucharlat).—Japanese; white petals, edged purple-rose, dwarf.
- Mme. Dangeville-Guerard (Délaux).—Japanese; long petals, wax-like white, shaded violet-rose.
- Mme. de Chossat (Boucharlat).—Japanese; pure white.
- Mme. Henri Corbin (Délaux).—Lilac-rose, glazed silvery white.
- Mme. Henri Corbin (Délaux).—Japanese; long petals, silvery white, shaded rose.
- Mme. Jules Moquet (Délaux).—Japanese; bright dark yellow, lightened red, centre silvery rose.
- Mme. Marchand (Délaux).—Japanese; soft rose and silvery white, golden centre.
- Mme. Paul Pujol (Délaux).—Japanese; light yellow.
- Mme. René Larriev (Délaux).—Japanese; broad petals, waxy white, lightened rose, golden centre.
- Mlle. Marie Gourre (Délaux).—White, striped rose, centre gold.
- Mlle. Madeleine Fabre (Délaux).—Rose, glazed silver, golden centre.
- Mlle. Pujol (Délaux).—Japanese; white, centre cream, dwarf.
- Mlle. Suzanne Couvreur (Délaux).—Japanese; fine petals, dull white, shaded rose.
- Messidorine Fauvel (Délaux).—Japanese; long drooping petals, silvery lilac-rose, reverse old gold.
- Molière (Boucharlat).—Japanese; light salmon-rose, golden reverse.
- M. Augremy (Délaux).—Japanese; silver and purple-amaranth.
- M. Et. Prouverelle (Lacroix).—Japanese; long petals, flesh-white, streaked light lilac.

M. Emile Rosette (Délaux).—Darker in colour than Edouard Audignier.

M. Henri Lorquin (Délaux).—Golden red, tipped velvety crimson.

M. Henri Corbin fils (Délaux).—Fiery dark crimson, darker than Culling'ordi.

M. le Dr. Jules Fabre (Délaux).—Japanese; dark gold, striped dark crimson-red.

M. Pierre Carayon (Délaux).—Japanese; broad petals, flesh-white shaded rose.

Mrs. Howard Hinkle (Hill).—Japanese reflexed; rose terra-cotta.

Mrs. W. C. van Horn (Pitcher and Manda).—deep buff, shaded carmine.

Mrs. J. T. Anthony (Pitcher and Manda).—Japanese reflexed; dark pink changing to blush-white.

Mrs. Katherine B. Lewis (Pitcher and Manda).—Japanese; long petals, canary-yellow.

Mr. James T. Closson (Pitcher and Manda).—In-curved; lemon-yellow.

N. Farre (D'aux).—Japanese; long petals, canary-yellow.

Paul Valade (Délaux).—Salmon-red, golden centre, silvery reverse.

Perrier-Jouet (Délaux).—Broad petals, dark crimson-amaranth, edged white, centre gold.

P. J. Stahl (Boucharlat).—Japanese; crimson-red, shaded purple.

President Edouard Barre (Délaux).—Dark blood-red-crimson, golden centre.

President Leon Simon (Délaux).—Dark carmine top, shaded and striped white, golden centre.

Professeur Maxime Cornu (Délaux).—Japanese; broad petals, pure white.

René Deutz (Délaux).—Japanese; long petals, purple-garnet-red, speckled white.

Saint Marceau (Délaux).—Japanese; long outer petals, cream, passing to white, centre dark cream.

Sigurd (Lacroix).—Japanese; broad petals, dark carmine, reverse ashy white.

Sr. de Jules Pourbair (Délaux).—Japanese; long petals, bright salmon, shaded golden violet, silvery reverse, tipped old gold.

Sr. de M. Courreux (Délaux).—Bright fiery-red, dark golden yellow centre.

Tolstoi (Boucharlat).—Japanese; brick-red on golden ground.

Vne. Louis Pommeroy (Délaux).—Pure white, edged dark carmine-rose, golden centre, dwarf.

W. Clibran (Boucharlat).—Japanese; broad petals, light garnet-red.

C. HARMAN PAYNE.

GARDEN FLORA.

PLATE 922.

DIPLADENIAS.

(WITH A COLOURED PLATE. *)

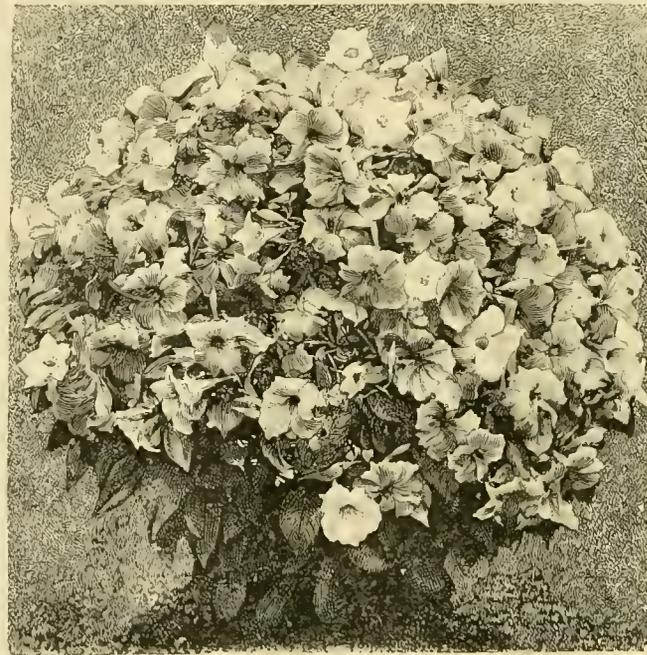

The Dipladenias are amongst the finest of all our stove flowering climbers; in fact, I consider them unsurpassed when proper attention is given to their culture. More care and attention are required to attain to the best results than are needed with Bougainvilleas or Allamandas, whilst where the mealy bug is found pretty general it will be a marvel if the Dipladenias escape its ravages. Hence, no doubt, they are not cultivated so extensively as they would otherwise be, whilst in addition, from want of better knowledge as to their treatment at the root, many plants are ruined through excess of water. These allusions are not by any means made to deter cultivators from giving them further trials, but rather to point out where failure will occur and thus safeguard the plants. When these essentials to success are duly taken note of, the future of the plants is pretty sure to be of the most satisfactory character. Give them the same amount of care as one would bestow upon Cape Heaths or New Holland plants and they will grow freely enough. The

amount of water, for instance, which an Allamanda will absorb is vastly in excess of that required for a Dipladenia; in fact, the latter would come much nearer to the succulent plants as represented by Epiphyllums and other Cacti in this respect, although it does not, I know, come under the same classification. Starting with cuttings or young plants is better than taking to larger examples. Young plants can be purchased cheaply enough now-a-days. The presence, therefore, of the Dipladenias in our stoves should be far more general than it is. It is not surely too much trouble to give them the attention requisite to ensure their thriving well! As before stated, the mealy bug has no doubt ruined a good number of plants. Where this has been the case, then at once decide to exterminate the bug and make a clean start. It is to me rather astonishing that the burden of such a plant pest should be borne with so much equanimity, as it is, as if it were one of the deterrents to plant culture which has to be endured without any hope of

additions when the peat is not of the best; so also is yellow turfy loam. Firm potting I consider thoroughly essential, for it has to be of a more permanent character than in the case of such plants as Allamandas and Clerodendrons, which every spring may be reduced considerably at the roots. Not so with Dipladenias, however, unless one wishes to run a risk that has no compensating advantage even if it is escaped. The roots of the Dipladenias are so different, being much finer in the tissues, but not nearly so rapid in growth. They have a good store house in their tubers (somewhat after that of the Dahlia); these have not been provided by Nature without a "reason why." I take it that in case of drought to any excess these tubers supply both the top growth and the fibrous roots also. By overwatering and soddening the soil there is the danger of decay of the tubers setting in, hence the whole fabric suffers. But little room should be allowed for watering; this is a very good way of guarding against too much being given them. I have

known the plants when in the best of health and flowering freely to go for weeks together without being watered at all. In this way it is next to impossible to sour the soil, whilst the plants will continue for several seasons without more than a shift or two when they have once attained to a fair size.

In potting these larger plants, I once used some fertilising Moss to a moderate amount with very good results; the plants were then some twelve years or so old, yet they flowered more freely than ever after the use of the Moss. In younger plants it would probably have forced wood growth in a corresponding degree, but it is doubtful if the advantage would be permanent in such a case. A little of this Moss makes a good top dressing with peat when potting is not really required. As to training, I much prefer to grow the plants on wires near to the glass, either hori-

Dipladenia Brearleyana.

zontally or up the roof as the case may be. Never tie down the shoots as they grow when trellises are provided for each plant, but rather take up each shoot towards the glass by means of a piece of fine string as a support. When showing colour the flower trusses can then be arranged as desired upon the trellis. Considering the tender nature of the foliage, care has to be taken not to injure it when looking after insect pests. A camel's-hair brush is about the best thing to employ; if its use with a well-tried insecticide be followed up there will not be any cause to complain of insects doing any harm. The points of the shoots should always be carefully preserved from injury when doing any work, for the loss of a point, unless very early in the season, means the loss also of one or more flower trusses, except in the case of such like kinds as *D. boliviensis*, which mainly flowers upon the lateral shoots. As to pruning, but little is required; it is rather a matter of thinning out the weakly wood to give place to the stronger. This should be done as soon as the plants go to rest in the autumn. Shading should be sparingly used at all times.

* DRAWN FOR THE GARDEN by Gertrude Hamilton in the gardens at Gunnersbury House. Lithographed and printed by Guillaume Serevyns.

DEPARTMENT OF AGRICULTURE
WASHINGTON, D. C.

Bottom-heat I do not care to recommend; at the best there is in its use a likelihood of too much moisture remaining about the roots, thus acting prejudicially thereto, whilst the soil itself will not be improved in any case. The only time in which bottom-heat might be an advantage would be in the case of quite young plants or cuttings. These latter strike freely enough, but take a little longer time in making a decided start than those of most plants; short growths with a heel are the best cuttings. The flowers of any kind are extremely useful in a cut state, lasting well when in water and being seen to best advantage in shallow glasses, resting on a carpeting of Fern or other suitable foliage.

VARIETIES.

There are, with the addition of the splendid hybrids now cultivated, a few, at least, of the species which are worthy of every attention. Of these latter I would particularly draw attention to the subject of this week's coloured plate—

DIPLODENDIA BOLIVIENSIS.—This being a white variety adds greatly to its value in many ways when cut, whilst upon the plant the free-flowering character it possesses adds further to its value. Month after month from early summer to late autumn it will continue to flower without any intermission. The trusses are not so large or of such a continuous nature as in most other kinds, but they are produced much more freely. Being a smooth-leaved kind it is not so difficult to keep clean, nor is it so liable to insects as the other and somewhat downy-leaved varieties. It was awarded the first prize as the finest new plant in flower at the R.H.S. exhibition on June 16, 1893. Messrs. Veitch and Sons, who introduced and exhibited it, say in their new plant catalogue of 1870: "This distinct stove plant may be best described as a very free flowering white Dipladenia. In habit it is very compact, producing an abundance of flowers in a much smaller state than almost any other species. The foliage is medium in size and of a light glossy green colour. The flowers are somewhat smaller than those of *D. crassanoda*, pure white, with a distinct yellow centre, and will be accepted as a pleasing addition to the already popular class of Dipladenias." These remarks hold good now as then. The only surprising thing about it is that such an exceedingly useful plant should even now be so little grown when cut flowers are more in request than ever.

D. SPLENDENS is another lovely species from the Organ Mountains. It is a vigorous grower, more so probably than any other kind. When seen in first-class condition it is a variety of surprising beauty, both the trusses and the flowers being large. The colour of the flowers when aged is nearly white, with a faint trace only of soft pink, the latter colour predominating in the younger stages. This species is one of the most continuous in producing flowers upon the same spike. As a parent, its characteristics are easily seen in *D. amabilis* and other kinds.

D. CRASSANODA is a species from Rio Janeiro. It is now seldom seen in good condition, being somewhat of a shy grower unless under the very best culture. It flowers freely enough after a good growth has been obtained. The colour of its flowers is a deep rose.

D. AMABILIS is one of the best known hybrids (*D. crassanoda* × *D. splendens*), being a most profuse flowering and free-growing plant. It is without doubt far superior to *D. crassanoda*. Its flowers are of the same shade, of the two darker, perhaps, whilst it has the continuity of flowering as in *D. splendens*. As a specimen for exhibition it is one of the very best. As such it was shown by Mr. Thos. Baines many years ago in splendid form.

D. BREARLEYANA is another grand hybrid, probably from the same parentage as the former. Its flowers are larger in size and possess of the two more substance than those of *D. amabilis*, whilst the

colour is several shades darker (an intensely dark crimson). It is not, however, so frequently seen shown as a specimen.

D. INSIGNIS has much of the same character as *D. Brearleyana*; the flowers are of a rich deep rosy carmine, as deep on the outer as on the inner side of the corolla, with the base of the tube white. It is a vigorous grower and also a free-flowering variety when under the best conditions. It was raised in Yorkshire from *D. amabilis*.

D. AMONA is another excellent hybrid, with flowers resembling those of *D. splendens*, which is no doubt one of its parents; the blooms are somewhat smaller, but with the same characteristics as that species. It should be grown as a companion plant to *D. amabilis*, being quite a contrast to it in colour.

D. WILLIAMSII is of the same shade of colour as *D. splendens*, with smaller foliage and greater freedom of flowering. Where it is already grown *D. amona* is hardly needed.

These form about the best selection now in commerce.

D. ATROPURPUREA, first introduced from Brazil in 1814, is now seldom seen, having apparently nearly dropped out of cultivation. It has flowers of a deep purplish or chocolate shade with a dark orangthroat—not a striking combination of colour; in freedom of flowering and style of growth it is more after *D. boliviensis*, but cannot be compared in any sense with it. It was shown in good condition by Messrs. Sander and Co. at the last Temple show of the R.H.S. J. H.

THE WEEK'S WORK.

THE KITCHEN GARDEN.

RUNNER BEANS.—Although runner Beans have bloomed most profusely this season, yet so far pods have not formed very freely, the parched state of the atmosphere being the cause of this. Now that the weather is cooler this will no doubt be changed, but if not, the best course is to syringe the plants lightly overhead just as the sun is going off them. This, coupled with the soil being kept well moistened, will lead to satisfactory results. Owing to the plants not having been overburdened with pods, there is every probability of even the first sowings keeping in bearing until cut off by frost. Even if the supply at any time is above the demand, it must be remembered that by salting down the surplus in earthenware jars a good winter vegetable is obtained. The pods should not be allowed to remain on the plants, as this will impoverish them as much as even dryness at the roots. In reserving pods for seed, it is better to give up a row for this purpose, selecting the best shaped pods.

TURNIPS FOR SPRING GREENS.—It is certainly late for sowing Turnips for coming to any size suitable for storing, but not for affording roots to produce a supply of spring greens, not but that the roots sometimes grow to a presentable size if the autumn should keep open and mild. Ground recently cleared of Potatoes will be in good condition for this crop without much preparation except forking over the soil. If at all loose the surface should be equally trodden over and the seeds sown thinly in drills. This latter is a necessity, as the seeds germinate readily at this season and a crowded growth is very undesirable. Where the opportunity was taken at the middle of July of making the main winter sowings, the beneficial showers generally experienced at this time caused a quick and even germination, the seedlings being very healthy. Do not upon any account neglect thinning them out, first going over with a hoe, leaving the seedlings in small bunches at equal distances apart, and a few days afterwards single them out, a surface hoeing afterwards settling the soil about them and so encouraging a free growth.

LIFTING POTATOES.—There will not be any need to leave any Potatoes, except the latest, in the ground much after this, indeed if at all. In those cases where the winter greens have been set out between the rows, the removal of the Potatoes will enable these to make a much more satisfactory growth. In lifting the tubers the better course is to take them away to a cool shed, and if possible place in a layer of about a foot in thickness, taking care to totally exclude light, or the tubers will quickly become green. If the shed will allow of light being excluded by darkening windows, this should be done in preference to covering up the tubers. Storing the tubers in large heaps is not to be commended, this causing them to become heated. The quality of more Potatoes is spoiled through over-heating after being dry than many people are aware of.

WINTER SPINACH.—This being a most important crop for the winter and spring months, it is necessary that preparation for sowing should now commence. If the soil has already been prepared, all that will be necessary to do is to strew a dressing of soot over the ground, also burnt refuse if at hand, this being knocked into the surface with a heavy rake, afterwards lightly treading the surface evenly over if at all loose. In cases where the ground has not been prepared, manuring will be necessary if at all poor; but as this crop follows well after Potatoes, and as the nature of the season has been such that this crop has not extracted much nutriment from the soil, a forking over will generally suffice, well breaking the soil in the turning. The drills should be drawn 15 inches or 18 inches apart, the seeds being sown thinly. As soon as the seedlings appear, another dressing of soot should be given, this making the soil all the more distasteful to grubs, which in some seasons play sad havoc with this crop. This and timely and frequent hoeing are what are needed to cause the plants to make a free growth. In the more favourable localities the 20th of the month is a good time for sowing, but a few days one way or the other will not make much difference.

A. YOUNG.

FRUIT HOUSES.

MELONS.—Of late there has been very little sunshine, the weather being all in favour of cracking of fruit and canker at the stems. It is when the fruit is near the ripening stage that both the cracking and canker are most liable to take place. The remedy for the former is the maintenance of a drier atmosphere with the aid of more fire-heat and a little top air. Keeping the roots also a little on the dry side is a safe and good practice after colouring of the fruit has commenced, but it must not be carried out much in advance of the ripening period, or otherwise the fruit will be small in size and poor in flavour. If a space about the stems 9 inches in diameter is kept perfectly dry it is not often that canker will take place, but should it be discovered at the collar, scrape the affected part clean at once and dry the wound thoroughly with newly slaked lime, or failing the latter Portland cement. If this remedy is persevered with as often as need be, not a plant will be lost. Swelling fruit ought not to be much confined by supports of any kind. Secure the haulm at the footstalk to the trellis with a strong piece of raffia, and merely string up the fruit when it is seen they are nearing the ripening period.

LATE MELONS.—There will be a scarcity of Plums, Peaches, and Cherries this autumn, all having ripened or are ripening very much earlier than usual or desirable in many cases. This being so, there is all the more reason why Melons should be kept going as late in the year as possible in order to add a little variety to the dessert. Plants that are now swelling off their first crops should be kept in good health with a view to taking a second lot of fruit from them. Red spider ought to be kept down by means of sulphur in the syringing water, and thrips, green and black fly with the aid of tobacco water. Do not stop hard, but allow a few shoots to grow freely, then pinch out the

points, the second crop being produced by the side shoots that result. Much depends upon the state of the roots. Unless these can be kept in an active state, the first crop will not be of the best quality, and the second of still less value. In addition to keeping the soil uniformly moist add enough strong loamy soil on each side of the ridge to bring it up to a level, making it quite firm and also top-dress with more of the same, with a sprinkling of a quick-acting artificial manure added. If pulverised right soil is available, nothing will suit Melons better than this applied mixed with loam as a top-dressing. There should be no drying-off at the roots while the first crop is ripening, this whether more fruit has been set or not. In dull, cold weather during August and constantly afterwards fire-heat must be turned on, a brisk heat accompanied by a moist atmosphere being needed to swell the fruit to a good size. It is somewhat late to sow seed now, but if there are any small, healthy plants on the place, these might well be fruited in the autumn. Pot culture is to be preferred at this late date to planting out in ridges. Use pots 14 inches or rather more in diameter and a compost consisting principally of strong loam, to which a sprinkling of mortar rubbish, or lime, soot and bone-meal are added. Drain the pots well and pot firmly, taking care to keep the collar of the plants just above the level of the soil. Melons, unlike Cucumbers, will not stand having soil heaped up about the stems; therefore fill up the pots to the rims at once. A fairly brisk bottom-heat, generated by well-prepared stable manure, and later on with this and leaves, favours a strong clean growth, especially seeing that it obviates the necessity for applying much fire-heat for some time to come. Heating material, though desirable, is not, however, absolutely necessary. Either stand or plunge the pots nearly close together, pot Melons not requiring much room. Carefully train till the roof trellis is reached, side shoots being pinched out directly they show, leaving them till they need cutting out with a knife being a very risky proceeding. Train the leading growths straight up the roof to a length of about 3 feet and then take out the points. Laterals that do not show fruit should be early stopped at the second leaf, and those that have perfect female flowers should be stopped one joint beyond these. Up to the flowering period overhead syringing may be resorted to when the house is closed on clear days, but it should be discontinued directly the flowers are opening. Two fruits are quite as many as each plant will swell to a good size, and in order to be certain of these, two or three flowers ought to be fertilised at about the same time, or directly the pollen is dry. Once the Melons are swelling freely they must be kept going, liquid manure and a renewal or increase of bottom-heat being beneficial.

MELONS IN FRAMES.—It is the fruit nearing the ripening stage that gives the most trouble this season, these cracking and cankering badly. The fruits, as a rule, are of good size, solid and well-netted, but since the change in the weather many complaints are heard of Melons failing to ripen satisfactorily. While the fruits are swelling fast, and till such time as colouring commences, there should be no actual drying off at the roots, but novices are warned against over-doing either the watering or over-head sprinkling. It is the latter that is apt to cause cracking and should not be done in dull weather, nor at any time after the fruits are well netted. Lay them up on inverted pots among, but not wholly clear of the leaves, lightly thin out superfluous shoots, ventilate rather freely on warm days, and in particular give a chink of air at the back of the frame or pit before the sun has gained much power. A renewal of the linings or an increase of bottom-heat would greatly assist in the swelling off of late fruit, but care must be taken not to confine the vapour that may find its way inside. It is the coarse netted varieties that are most liable to canker, especially if syringed or sprinkled often. Some have been spoilt owing to drip reaching them, and drip ought, therefore, to be guarded against. Directly any of the coarse lines of netting open

unduly or give signs of canker, scrape the affected part with a knife and dress with newly-slaked lime. Unless this is done in good time the fruit may be spoilt in a few hours. When the fruits are cracked all round the foot-stalk cut them, but do not send them to the table till they are softer to the touch. Both Blenheim Orange and Hero of Lockinge are improved by being kept in a warm dry room for about a week after being cut.

PRACTICAL.

PLANT HOUSES.

GREENHOUSE PLANTS.—**SHOW AND FANCY PELARGONIUMS.**—All of these should by now be cut back after having been well ripened off and rested for a short time. The most exposed and sunny position out of doors will be the best for them. At the time of pruning, cuttings can be taken to keep up the stock; these are struck much the easiest by being inserted in sandy soil upon an open border out of doors. These cuttings will make nice plants to winter in 3-inch or 4-inch pots, being potted up towards the end of September. The whole of the stock should now be gone through, or at the latest as soon as the buds commence to swell up and burst. To leave this work any later will cause a check to root action, it being of the utmost importance to have the pots again well filled with roots by the time winter sets in. Reducing the old ball should always be practised. If the plants be vigorous ones and naturally of strong growth, a moderate reduction will suffice, so that they can at least go back into the same sized pot again. Others of weaker growth, as the fancies, should be reduced sufficiently to go into a smaller sized pot than that out of which they have been shaken. In these they will winter more securely with less tendency to make a sappy growth, which at that season is particularly to be avoided. After potting, stand again in the open air and keep them all as hardy as possible. For this autumn potting the soil should consist chiefly of good loam with sand and a small amount of manure from an old Mushroom bed, this latter being worked through a sieve, so that it may be well incorporated with the other soil. No rank manure or anything to excite growth should be thought of for reasons already given. In the event of a heavy rainfall, protection in a cold frame will be advisable to prevent the soil becoming soddened.

ZONAL PELARGONIUMS.—If any of the winter-flowering plants are not yet in their blooming pots no time should be lost in seeing to this work, but only just a shift should be given them now, using good soil with some manure, as advised above. These should not be allowed to flower yet, whilst if any shoots are growing away too freely, another and last stopping may be given them. Avoid keeping these plants in a damp place; the more sun and air they are exposed to the better will it be for their future welfare. I would much rather see the foliage hard and sturdy, perhaps rather pale-looking, with short foot-stalks and of medium size than larger and of a deeper green and sappy. The former will stand all the better. Earlier plants intended for autumn flowering should now be allowed to push up their flower-spikes; these will then come in useful in September and October. For the present these also should remain outside, only being taken in when the first trusses expand.

SCENTED-LEAVED PELARGONIUMS.—These are often despised and considered as being out of date or old-fashioned, but they are, nevertheless, very useful both as plants and for cutting. There are many things grown for the cool house that do not pay for their culture nearly so well. Varieties can be chosen either for cutting more particularly or for use as plants. For the former purpose I advise *radula* (balsam-scented), *capitatum* (rose-scented), and *fragrans* (nutmeg-scented), and to these for pot plants should be added *denticulatum majus*, *silicifolium odoratum*, *quercifolium*, *radula majus*, *Fair Helen* and *Lady Plymouth*. Now is a good time to take cuttings for striking in the open border or pots; these will make useful plants

another spring. Those who already grow them should keep their plants fully exposed to light and air, and should any stock have been cut hard or be otherwise out of health, a fresh shift may be given them, reducing the old ball or not, according to circumstances.

CINERARIAS AND CALCEOLARIAS, &C.—Do not let these escape notice; if the stock of either be short, another sowing should be made at once. The best of the latter that I ever had were only pricked into 2½-inch pots in October, whilst the former will also have plenty of time to grow in the spring for late blooming. *Cinerarias* now in 3-inch pots should receive a shift, the best plants going into 6-inch ones; others, perhaps, still in seed-pans should be potted off at once before they become drawn. Full exposure is by far the better treatment, to grow them rank and sappy is quite a mistake, as it also is to sow the seed too early and be thus compelled to pot on to save them. The plan of growing the *Cinerarias* in a frame under a north wall is not in my opinion ever advisable, unless it be for the sake of taking cuttings rather than depending upon seedlings. If the *Calceolarias* from earlier sowings be not yet pricked off, no time should be lost in doing this work; if forwarder, they will probably be fit for small pots. These plants I would keep in the shade for a few weeks longer; they require to be kept cool and moist, whilst there is not much fear of too free a growth yet. Do not in the case of either of the foregoing plants use a rich soil; good loam and leaf-mould will answer well, and for the first potting this should be worked through a sieve. *Primulas*, like *Cinerarias*, should be grown hard, not being kept in the shade. If the plants are of good size, the lights can be left off night and day in fine weather. Do not defer potting where it is needed, but bear in mind that large pots are not advisable if they are not well filled with roots in another month. A late sowing made now will give an extremely useful stock of plants for late spring flowering or for the special purpose of seed-saving, these being better than larger ones.

JAMES HUDSON.

ORCHIDS.

I HAVE urged the importance of being very careful to maintain a healthy state of the atmosphere and also to keep the plants free from all parasites. It is like putting water into a sieve to try to grow Orchids if they are not free from insect pests. The gardener's time, when he is not busy repotting his plants, cannot be better employed than by looking over them again and again for thrips, scale and green-fly, or a species of aphid of a distinctly yellow colour, with which I was too well acquainted a few years ago, but which I have managed to get rid of for good, I hope. Whenever the plant was touched the insects marched rapidly to the roots of the Orchid, where they would remain secure amongst the *Sphagnum Moss* until all signs of danger were over. By the frequent use of soft soapy water and tobacco liquor we at length quite destroyed them. They used to do much damage to the drooping spikes of *Dendrobium Farmeri* and the fair white blossoms of *Calanthe veratrifolia*. This plant has not long passed out of bloom, and now is a good time to repot it. I find fibrous yellow loam is the best material. This should be torn up by hand and be mixed with a fair proportion of decayed manure and leaf-mould. As far as my experience goes, I have concluded that peat is better left out altogether, but as the plants require a liberal supply of water when growing, and as at no time must the soil be allowed to become dry, the potting material becomes sour unless the loam is good and the pots are well drained. They do not form an immense mass of roots like *Cymbidium Lowianum* for instance, and during repotting care must be taken not to allow the roots to be injured. Our largest plants are in 12-inch pots, and these must be filled to about a third of their depth with clean drainage, large pieces at the bottom, smaller at the top; with over the

drainage some very tough fibrous loam from which all or nearly all the clay particles have been shaken out. Some coarse sand should be mixed with the compost. I use Bedfordshire sand, the particles of which are like small pebbles; some broken potsherds and pieces of charcoal are also mixed with it, as it is necessary that it should be in a condition to remain porous for a period of from one to two years. In repotting all the *Calanthes*, the compost should not be raised in a mound in the same way as for *Cattleyas*, *Lælias* and such plants as need peat and *Sphagnum*. All the *Calanthes* are treated more like ordinary hothouse plants than *Orchids*. Even now, with all the increased facilities of obtaining knowledge of *Orchid* culture, one sees *Orchids* that grow naturally in loam, and are ditch plants in their native country, still found treated in the same way as *Vandas* or *Cattleyas* that are found high upon trees, and live by sending their long thong-like roots into the air. Besides the pure white *Calanthe veratrifolia*, there is *C. masuca* and the fine garden variety raised from it, *C. Dominii*. This last variety, by the way, is not at all common now. Our stock of plants got into bad condition, and although all attention was given to them, they gradually became worse, and I had reluctantly to throw them out. The best grown plant I ever saw, or perhaps anyone ever saw, was in the collection of Sir Trevor Lawrence, Bart., at Burford Lodge. About half the material it was growing in seemed to be lumps of charcoal, but I do not know whether it still retains its vigorous condition; perhaps not, but it would be easy to raise seedlings from the same parents. The deciduous species and garden varieties of *Calanthes* now require to be freely supplied with water at the roots, and to be kept in the warmest house near the glass roof, and frequent applications of weak manure water will give great vigour to the plants.

All *Orchids* growing in the warm house if in the midseason of their growth should be freely watered, and any *Cypripediums* which have passed out of bloom and are starting to grow should be repotted if they require it. Many of these do better in loam than they do in peat of any kind, and *Sphagnum* mixed with it. The very distinct *C. Spicerianum* succeeds well in loam, and it is feasible to suppose the hybrids raised from it in gardens will also succeed in loam. I have proved that some of them do. *C. Leeannum*, for instance, still one of the best of them, does admirably in loam, and is even more vigorous than the parent. *C. niveum* seems to do well with limestone in the compost, and the allied species and varieties, such as *C. bellatulum*, *C. Godefroyæ*, and probably *C. concolor*, would do well with similar treatment. So far as our knowledge extends at present, *C. bellatulum* seems to take best to artificial treatment. None of them like to get quite dry at the roots, but when not in growth they are better kept on the dry side. When repotting these small-growing *Cypripediums* it is better to err on the side of under rather than over-potting them; whereas, such species and varieties, of which *C. grande* may be taken as the type, can have a good shift almost at any time. We may expect the nights soon to be rather cold, and it will not do to be caught with no heat on now. The watchful cultivator studies his temperatures at 10 p.m., and by long experience of studying the weather at that time can tell what it is likely to be by the next morning, and will bank up his fires accordingly. There is not so much danger of the weather suddenly changing now as there is in the spring, but the temperatures in all the divisions should be well up to the highest point allowed at night when banking up at ten. The cool house ranges between 50° and 55°, with scarcely any help from artificial heat, and with rather more help from the heating apparatus the *Cattleya* house is about 60°, less or more, while it is better not to allow the East Indian house to fall below 65°, but it will more often be at 70° at ten at night. See that all the houses are well ventilated, but it is an error to allow a constant draught of dry air to circulate through the houses. When the

wind blows dry from the east, shut the side ventilators against it, especially in the cool house.

J. DOUGLAS.

FLOWER GARDEN.

HARDY FLOWERS.

IRISES AND IRIDEÆ.

I AGREE with my friend Mr. Ewbank that the *Oncocyclus*, or, as Mr. Baker proposes to call them, the Cushion Irises are what may well be the *ne plus ultra* of the gardener's ambition. There are few things that equal them in beauty and nothing in the whole range of hardy plants that even approaches them in interest. Mr. Ewbank is himself, I hope, on the track of what may some day prove, if not a royal, at any rate a decent road to success, and when he has found it or made it, I will invest in a load of the Maidstone paving-stones and again try to grow the Cushion Irises. In the meantime, and *en attendant*, I intend to harden my heart, avert my eyes from their names in the autumn catalogues, and let them rigidly alone, for the game is at once too expensive and too disappointing to be played continuously. Apart, however, from this particular section, the very Faubourg St. Germain of the family, whose exclusiveness I admit for the present to be unassailable, there is a fuller and more prolonged interest and pleasure to be obtained by the cultivation of the Iris than from any other race of plants, and the interest is botanical as well as horticultural. From the former point of view, the Beardless or *Apogon* section are a host in themselves; while by occasional mild excursions into *Evansia* and by crediting some of the broad-leaved bearded Irises with specific honours, the same interest may be enhanced and extended. The whole range of bulbous Iris is yours into the bargain.

For a small garden I have a fair number of Iris species here, but last winter I invested in Mr. Baker's "Irideæ," and my knowledge of botany being, I regret to admit, hazy, not to say limited, a perusal of this book has robbed me of "all my peace of mind," like the "May Queen" at another floral festival, and has induced a general scepticism in the matter of my labels, which has destroyed my self-satisfaction as a collector and may possibly militate against the complete accuracy of what I may have to say about my plants. The scheme of these remarks is to notice only botanical species and only those that are more or less new to myself; consequently, I shall not mention many of the broad-leaved or Flag Irises; but while on this subject I may remark that I think it is a pity some effort is not made to reform the nomenclature of these by finally discarding Latin names for varieties which the best authorities agree are not true specific ones. There are at present seven Latin adjectives under which names the nurserymen sell these so-called German Irises. These are *germanica*, *pallida*, *amœna*, *aphylla*, *neglecta*, *squalens* and *variegata*. It is true that these names represent distinct "types," which, for the purpose of identification and sale, require names; but Professor Foster has shown conclusively that the sorts that pass under the third, fourth and fifth of these names have never been found wild and are clearly of garden origin. It seems to me, therefore, to be in the interest both of garden-

ing and of science to get rid of them in these cases. There could be no difficulty in finding substitutes. We have already got *Juno* in this connection, so we might stick to the classics and have *Venus*, *Minerva* and *Ariadne*, the latter, of course, taking the place of *neglecta*—that silliest of all Latin adjectives of the botanist in trouble for a word; or, on the other hand, we might enlarge the compliment already paid to "gallant little Wales," and add *Griffithia*, *Owensia*, &c., to *Evansia*, *be-latinising*, as far as necessary, the whole range of Welsh patronymics. This, however, is a question for the botanical hierarchy.

I observe, by the way, that Mr. Baker assigns to *I. aphylla* (a name—and not a very apposite one in this connection—given by Linnaeus) a habitat in Eastern Europe, but the *I. aphylla* of Linnaeus has evidently no affinity to the *Mme. Chereau* sort of thing of our gardens, but as far as I can make out (for there are many synonyms) is the same thing as what is generally sold by nurserymen as *I. nudicaulis*.

One of the finest of all Irises is the Asiatic variety of the common *I. germanica*, the flowers being of great size. Mr. Ewbank, to whom I am indebted for many good things of the kind, gave it to me, and I was obliged to get him to send me a second piece, for my first plant died away somewhat unaccountably. This is a species that requires some little care to thoroughly establish. The variety is usually known and sold as *I. asiatica*, but it appears to be ignored by Mr. Baker, who assigns the name to some variety of *I. pallida*. The rich purple variety of the German Iris and the somewhat dwarfer and equally rich coloured *I. Kochii* are both well worth possessing, the latter apparently flowering some fortnight or more later than the former variety, and a good contrast to the former, as flowering contemporaneously, is the white or almost white Sicilian form of *I. lutescens* known as *I. statellæ*. The whitest of the Flag Irises known as *I. albicans* does not appear to be as reliable or as floriferous as the more common *I. florentina*. Having regard to Professor Foster's admirable lecture on the subject and to my own confession of general ignorance at the commencement of these notes, it would be absurd for me to attempt to speak of any of the dwarf Irises (known in gardens as *I. pumila*) under specific names. I have here a dwarf species, distinct altogether from the common dwarf purple Iris of gardens, having very rich red-purple flowers, given me some years ago by Mr. Ewbank. I asked him last year to send me another supply of *I. balkana* (having failed to establish this the year before), and I duly received a piece, which also showed some disinclination to accommodate itself to my soil last autumn and winter; however, I coaxed it into good temper in a pot, and it has since grown well and flowered in the open. It is certainly not *I. balkana*, but I think it not unlikely that it may be one of Professor Foster's hybrids, of which that species is one of the parents. The general tone of the flower is light yellowish white, with blue blotches and markings, something like, though far dwarfer and less pronounced than a hybrid variety I saw at Kew the other day labelled *I. Baleng*, the parentage of which is not a very difficult conundrum to guess. *I. arenaria* is easy to grow, but it is not hardy in the open, and I have failed for some reason or other to keep it through last winter in a pot in a frame. I regret this, as it is a good deal the best of the yellow dwarf Irises. *I. flavissima* var. *Bloudowi* grows freely on a raised rockery and is quite hardy, but has not yet flowered here.

I. cristata grown on a raised tuffet of stones and peat grows freely and flowers well. I have taken some time to establish this, and have lost several plants. Here at any rate on my cold soil it must have peat, and I put a piece of glass over it in winter, which I daresay is unnecessary. The flowers are among the loveliest of this family and among the most fugacious. This is, I believe, the only species of the *Evansia* class that I now possess, *I. stylosa* being of no use in my soil and climate, even when planted in next to nothing between stones, though I have occasionally had flowers on it which proved toothsome to the winter slug.

I. lacustris I do not possess and have never seen. It sounds interesting and should be good, but I imagine it is at present rare in gardens. *I. verna* grows slowly, and has not yet bloomed with me. This latter, by the way, is classed in a sub-genus (*Pardanthopsis*), of which there appear to be few known species.

Among the more tractable and easily grown species of

BEARDLESS IRIS (APOGON),

I. tridentata is in my opinion the prince. I believe (though I humbly confess I am not certain) I am speaking of *I. tridentata* (Pursh.), and not of an Iris of which the proper name, by right of primogeniture, appears to be *I. Hookeri*. It is a beautiful bright lilac and very free blooming. I had the ill-luck to visit Mr. Ewbank's garden in May, 1889, being the year after one of the wettest and coldest summers of recent record, and this was one of the few Irises blooming well where many had failed to flower. I have had it in my garden ever since, and it has never failed until the present year, from which I infer that it is one of the sorts that do best in moist soil, and that an entire absence of moisture such as we have suffered from during the present year is fatal to its flowering. Another good Iris that has failed this year apparently from the same cause is *I. setosa*, a much richer and redder purple than the plant usually sold as *I. virginica* (properly *I. versicolor* var. *virginica*), which has also done poorly from the same cause. One of the most beautiful Irises of this class is *I. missouriensis* (syn., *I. Tolmeana*), with graceful pale green ribbed foliage and bright lilac drooping petals. This is one of the earliest to bloom. I have no doubt this name is correct, though some years ago I got a plant under this name from Ware's nursery with pale blue flowers, very much of the same form, and generally with the habit of *I. Kämpferi*, the difference being that my plant flowered freely in common dry soil, which *I. Kämpferi*, as all the world knows, does not. *I. prismatica* is a rich-coloured Iris, though I can see little difference between this and the fine form of *I. sibirica* commonly sold as *I. orientalis*, a name which is, it seems, properly attached to the tall white Iris named by Linnæus and usually called *I. ochroleuca*. Another good Iris of the same style is *I. longipetala*. All these, except *setosa*, are N. American. I have strong plants labelled respectively *I. humilis* and *I. graminea*, but I cannot see much difference in them. The flowers in both cases are produced on short stalks, much shorter than the foliage, which is dark green and Grass-like. Another Iris with the same bad habit of flowering below the leaves is what THE GARDEN has named for me *I. ensata*, and which I bought at York as *I. Alberti*. This has narrow, rather dull lilac flowers, and, though vigorous, is not a valuable garden plant. *I. ruthenica*, which would be better called by Pallas' name, *I. cæspitosa* (for it has a range from N. China to

Transylvania, and is by no means exclusively Russian), grows very vigorously on a raised rockery, but the flowers, though pretty, are sparsely produced. It probably suffers from the unfavourable climatic conditions which affect so many other Asiatic species in this country.

Some years ago I grew and flowered here a very remarkable Iris with yellowish white falls and netted at the base with claret-purple veins. This, which was sold to me as *I. Douglasi*, must, I think, be the "Santa Cruz" variety of that species. I have managed to get it again once or twice, but have not yet succeeded in establishing it again. I have failed, too, with one or two plants sent me by Mr. Ewbank of a much stronger and taller species under the same name. Mr. Ewbank's plant, I have little doubt, is the right thing, and it also has yellowish white flowers. This species is very distinct, and well worth any trouble to establish and grow. I at any rate do not mean to rest till I have got it doing well. *I. hexagona* is a beautiful species from the Southern States, and is not quite hardy in the open in such a garden as mine. *I. tenax*, a most remarkable and altogether lovely Iris, I have never seen anywhere except in Mr. Ware's nursery, or rather in his greenhouse. I doubt whether this has ever been established in the open in England, though it seems to occur as far north as British Columbia. If any of your readers has got this growing satisfactorily, I should be interested to hear about it. A year or two ago I bought *I. bracteata*, but after careful nursing the plant has flowered, and has produced blooms which the nurseman who sold it me informs me are those of *I. pumila* var. *macrocarpa*. The latter name (which is, I fancy, quite new, original and entirely unauthorised and absurd) is perhaps meant to console me for my disappointment. I am disappointed, for it is said to be one of the finest of the yellow species; but after all what more beautiful yellow can there be than our own Water Flag (*I. pseudacorus*)? *I. aurea* is a magnificent species that somewhat resents moving. Its ally, *I. Mennieri*, has failed to grow, perhaps from the prolonged drought. *I. ochroleuca* (or are we to call it *I. orientalis*?) is said, I believe, to like moisture. I do not dispute this, but it has hardly ever flowered here until the present year, when it has bloomed freely, and the best plants I have ever seen of this were in a town garden on top of a dry bank. *I. cuprea*, a very remarkable plant, of which the flower is unique in colour, has bloomed here for the first time for many years. There is something very capricious about this species.

I have not been very successful with the early flowering bulbous Irises. *I. reticulata* grows with great freedom, but the varieties of this and such congeners as *I. Histrio* die away the second year. *I. Bakeriana* flowered here in Jan., 1892, in the open, but then one does not want this in the open at such a time, so I potted it and it failed to bloom this year, as did the pretty little *I. Danfordiæ* and one or two others of this tribe.

Orthosanthus multiflorus, which I saw in the rockery at Kew some years ago, is not hardy, but is worth taking a little trouble about, and I should like to grow it if procurable. It is an Australian plant. Many other of the *Sisyrinchiums*, such as the dwarf *S. bermudianum*, are also well worth growing. I have never interested myself much in *Crocus* species, though I do not mean to imply that they are not interesting. The autumn species (to people

who are at home in autumn) are the best. The winter-flowering species are mere frame or greenhouse things. Most of the spring sorts (except perhaps *C. Imperati*) are out-paced and out-faced by the Dutch varieties.

J. C. L.

Sibthorpia europæa variegata.—This variegated form of the Money-wort is wonderfully pretty when grown in a suspended pot, pan, or basket, or clothing what might be otherwise a bare spot with its neat, dense and prettily variegated leaves. It needs a fairly close, dampish atmosphere, as where exposed to draughts or to a direct current of air in any way the foliage soon becomes browned. The variegation, which consists of a comparatively broad white margin to the leaf, is very regular and constant. It was the subject of one of the first, if not the very first coloured plate issued with THE GARDEN. This was on January 23, 1875.—11. P.

Zonal Pelargonium Mons. Porrier.—This is a very distinct zonal *Pelargonium* of vigorous, yet compact habit and with strongly marked zonal leaves, very free blooming, and producing large, bold trusses of deep magenta-rose flowers. A bed of it in the gardens of the Royal Horticultural Society at Chiswick shows it off to the best advantage; the colour is distinct and striking. It would, I think, make an excellent market variety.—R. D.

Verbaacum olympicum and *V. phlomoides*.—"A. H." does well to call the attention of your readers to the value of that grand old plant *V. phlomoides*. Here we have a plant of magnificent port and colour, whose only fault seems to be that it is easily and quickly grown. What other plant among biennials can surpass this both in colour and size? *V. olympicum*, though classed as a biennial, cannot be depended on to flower the year after sowing, even when it has the aid of a sunny wall. I have plants now in such a position that were sent to me three years ago and they have not flowered. One plant flowered this year, and has been very fine indeed, and one cannot help admiring it. Two others flowered last year, but we shall have to wait for the rest at least another year. With *V. phlomoides* planted in the same positions or in any open position in the garden, we could have had an annual display of colour far surpassing what we have had from the other kind. While writing of the *Verbascums*, I should like to caution anyone who may be intending to grow the varieties of *V. phœniceum* against planting them where the mid-day sun will shine on them, or the flowers will look half-dead during the daytime.—J. C. TALLACK, *Livermere Park*.

Maurandya Barclayana.—Treated as a tender annual this will flower freely if planted outside during the summer months, and it is really both pretty and distinct. It is a slender, yet free growing climber, with leaves more or less heart-shaped, while the flowers are tubular with spreading lobes after the manner of some *gesneraceous* plants. Their colour is a kind of violet-purple, though individuals vary somewhat in hue. It is quite an old plant in gardens, having been introduced from Mexico in 1825, and seeds of it are readily obtainable at a cheap rate. They should be sown early in the spring in a gentle heat so as to have good plants when the time arrives to place them in the open ground. They may be treated in various ways, but a very pleasing effect is produced by allowing them to ramble over a few sticks.—T.

Carnation Mrs. Reynolds Hole.—Mr. Young must be exceptionally fortunate to be able to grow this *Carnation* so well, and also in being able to call this "an ideal season for Carnations." Here I have great difficulty in keeping up a stock of the *Carnation* in question, and this year it is much worse than usual; in fact it is the worst kind I have out of at least fifty varieties. There can be no doubt about its being a most lovely thing when in good form, but my experience would not lead me to plant it in quantity for colour effect. *Carolus Durand*, on the other hand, may be absolutely

depended on to grow well and to give a wealth of lovely flowers which, if not exactly of the same shade of colour, come very near it, being rather deeper coloured than usual this year, and surpassing it in form, substance and vigour, the grass alone of this variety being a pleasure to behold. Of course, no one would be induced to throw away an otherwise good variety simply because a few of the earliest flowers split their pods; at the same time a variety which did this to any great extent should be discarded as soon as it can be replaced by another vigorous kind in the same colour not having this bad trait. I hope we may yet see the day in which we shall have a race of good garden Carnations, non-splitters and with good constitution in a variety of colour sufficient for all purposes of garden effect, while to this should be added that charm of charms among Carnations, a delicious scent.—J. C. TALLACK.

Cannas.—Some good examples of the large flowering race of Cannas form a very pleasing feature in Hyde Park. They are in the shape of large masses grown in pots and plunged in the turf at a sufficient distance from each other to allow for the full development of the handsome foliage. Many of them are flowering freely, and their brightly coloured blossoms serve to lighten up the mass of noble foliage. There are a great many flower-spikes in various stages of development, so that the display of bloom bids fair to continue till frost comes. One advantage of growing these large-flowered Cannas in pots is that as the season advances they can be lifted without any check, and may then be taken under glass, where their flowers will continue to develop for some time. The fact that they are very accommodating during the depth of winter is also another point in their favour.—T.

The white Virgin's Bower.—We were charmed lately with this plant as grown in Mr. Hugh Smith's garden at Roehampton. It was trained over a balloon-like trellis in the flower garden, and was covered with white flowers and creamy buds, forming a beautiful bower. The plant is quite hardy. This is another proof of what we have often said—that the greatest beauty of the Clematis is not in the large purple, metallic-looking kinds so common now, but in the smaller and infinitely more graceful wild sorts, of which there are many in cultivation, and some as yet not grown in gardens. Among them, however, it will not be easy to find any more beautiful than the various forms of Clematis Viticella—a white variety of which is the plant we saw at Roehampton.—*The Field.*

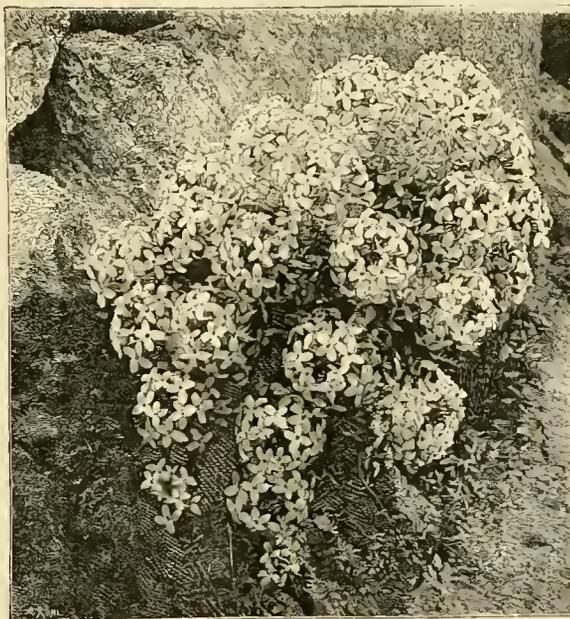

CARNATIONS—NEW SELFS.

AMONG the kinds on trial this year are some good ones that came to us from Mr. Weguelin, of Teignmouth. Lady Maud Hastings is very pretty and distinct, with a full, perfectly fringed flower that does not burst. In colour it is a distinct shade of salmon-pink. It has a drooping habit, but flowers freely. Mrs. Howard Paul, pink, is worthy of note, soft in colour and perfect in shape. Howard Paul, a scarlet kind, is bright and free, but the flowers all lack substance and are not full enough. There are much better red selfs in cultivation. Two more brilliant scarlets from the same source are good examples of what not to send out for garden decoration if they always behave as they have done with us. They are Lord Wolseley and Napoleon, two strong growers, sturdy and showy, but every bloom bursts. They were tolerable in the drought, but since the rain has come, every flower has burst. This is really a grave defect, sufficient to disqualify any new kind for garden decoration. It would be well if our raisers would regard it in this light, for it is satisfactory to notice that most of the fine new kinds do not burst. Others from Mr. Weguelin that do not offend in this respect, but are good in colour and constitution, are Mont Blanc, white; Rosalind, a bright pink, very good; and Aunty Rose, rosy pink. Baron Jules Evain, a French kind, appears free and good, profuse and distinct, its flowers being of a deep dark maroon. Mr. F.

Gifford sent several apparent acquisitions, especially Leander, a yellow self. Alfred Ash, from the same source, is fine, the flowers very large and full, but not bursting, the colour a rich deep pink. Cantab, deep red, and Montague, of a brighter shade of red, have been fine. Mlle. Hochard is a splendid white self from the noted French raiser, broad in petal and perfect in form. It has the appearance of being a white Countess of Paris, the expression of the flower and slight fringing of the petals being similar, but another season's trial with strong plants put out early must take place before it is proved to be a white Countess, flowering long and freely as that sterling kind invariably does. A. H.

TCHICHATSCHIEFFIA ISATIDEA.

This most beautiful alpine is a native of Asia Minor, and has been named by Boissier in honour of the celebrated Russian naturalist. It is perfectly hardy, and not particular as to soil or situation, but prefers growing among rocks. From a tuft of spatulate oblong leaves which

Tchichatschiffia isatidea. Engraved for THE GARDEN from a photograph sent by Max Leichtlin.

is formed in the first year, appear the flowers in the second season; the leaves are dark green, thickly beset with shining silky hairs, from amongst which, in the second year, rises the thumb-thick flower-stalk showing a combined thyrus of Syringa-like bright rosy lilac flowers, which are fragrant like vanilla. The bunch is over a foot across, and is in great beauty from the end of April to the end of May. It belongs to the Crucifere. Its striking beauty and uncommon appearance stamp it as a first-class plant.

Baden-Baden.

MAX LEICHTLIN.

Verbena Melindres.—Very often our so-called improvement of plants means the desertion of a noble wild type for a mixture of "new and choice" varieties which individually may have charms of their own, but in effect are poor. This is the case with the Verbena, the fine old red Melindres being a most effective plant, a brilliant red. The kinds raised from it are many and of all sorts of colours, but a mass of them is as nothing to a like mass of the old Melindres, as we have lately had an opportunity of observing by growing the two masses near and under the same conditions. In both cases the

plants were raised from seed in spring—a much better way than that of increasing named kinds by cuttings. The cuttings, even when carried safe through the winter, usually carry the germs of insect and other pests, too ready to eat up and destroy the young growth; by raising the plants from seed we have a clean start, and if the frames, pits, or houses in which they are grown are quite free from vermin, the chances are we may have a perfectly healthy stock to put in the beds. There is much to be said in favour of raising half-hardy plants from seed—plants that at no distant day were always increased by cuttings. We depend on the seedsman's enterprise to fix the colours for us, and offer beautiful things like Verbenas and many other plants in distinct and definite colours. This they are now doing successfully, and every year will see an extension of the practice.—*The Field.*

NOTES ON HARDY PLANTS.

Primula Reidi.—This plant is certainly a perennial. I have grown it four or five years and I have still a portion of the original root. I say a portion because I have propagated it by division, which, in part at least, is another proof that the root is of perennial duration. Seed-raising for this is doubtless the best means of propagation. It may be useful to point out the extreme irregularity of the growth of the seeds. I have a pan of seed that has been yielding for nearly two years. Further, I have two sowings of this year's seeds sown in June, and some have already vegetated.

Helianthemum Fumana.

—This is a very distinct Sun Rose, foliage evergreen, of dark hue, stout, and narrow, in the way almost of Phloxes of the setacea class. The flowers are not large, but in umbels, and bright lemon-yellow. It assumes somewhat the tree habit—on one stem, though but 6 inches or 9 inches high. It is a characteristic little shrub and flowers late, which is rather a recommendation. I find it likes a gritty soil and full sunshine.

Spiraea palmata.—We often see this in a shrivelled state both as to leaves and flowers. The cause is drought, and if the plants receive a check from this they show it clearly to the end of the season. Deep tilth and plenty of moisture they must have. Moreover, the crimson flowers are of a richer hue when the plant is well grown. I consider this one of our best herbaceous plants where it can be accommodated.

Spiraea palmata alba.—This in bold groups is especially useful just now, when white flowers are getting scarcer and the general effect in the garden is growing more rank and sere. Against this state nothing helps like masses of white, and this plant should be noted for the purpose. Indeed, any white flowers that come after the middle of July should be so planted as to show up in considerable quantity. This has been tried side by side with the typical crimson, and though in a measure they are contemporaneous and the effect proportionately striking, the crimson is rather too early for the white, and so the rich contrast that might otherwise have been got from flowers noted for their long duration is lost. Yet I have seen almost a full measure of success brought about by setting back the crimson in a double sense of the term, that is, causing the date of bloom to be a little later by setting back the plants in a little tree shade, but keeping the white fully exposed. It is not needful to say how much better these Spiræas do when in the close vicinity of water or boggy places.

Lychnis Sieboldi.—We should do well to plant this more; in fact, one rarely sees it even in

gardens where the largest and finest selections of hardy flowers are grown. It is something more, something better than a white variety of Haageana. The plant has a neat habit, a stature of a foot, and large flowers of snowy whiteness. The flowers remind one of the big white single blooms of *Primula sinensis*. Why a plant of this description is not largely planted it is hard to say. It lasts a long time in blossom and never looks shabby, like the taller *Lychnis*s, and it is perfectly hardy and otherwise reliable in ordinary garden soil.

Lychnis fulgens is another good thing with dazzling red flowers, and with a bolder style than Haageana of the deepest varieties. It does not, however, last as long, but being of but a few inches stature it does not take much room or ever become untidy, and therefore it might be worth a place in good company. What it really requires is to be grown in good sized specimens or planted in groups.

Papaver glaucum.—I think I saw it stated somewhere that this was a perennial. It will not prove so, but it is a charming novelty, dwarf, neat, and bearing abundance of brilliant cupped flowers.

Reseda glauca is a beautiful plant quite worth growing for its neat glaucous tufts of pretty foliage, especially as it is a perennial. It is also an alpine species, and if not too closely examined resembles the alpine Pinks for foliar habit. Then it is rather a happy thought that we can now have the favourite Mignonette family represented among our alpine flowers by a neat little perennial like the present.

Silene quadridentata.—The very small true form, the one that often passes current as *S. quadrifida*, is one of those gems that all the summer long delights us with its snowy little flowers in masses, so that it often makes a more telling patch than many bigger flowers. I find that this is really a scarce plant in private collections, and even more so under what I believe to be its right name. The plant I grow is without doubt DeCandolle's plant, tufted, with erect and slender stems freely brachied; leaves small, narrow, and pilose; flowers small, paniculated, with a clavate and campanulate calyx, and petals four-toothed. It begins to flower in May at a stature of 1 inch, and goes on till September, reaching a stature of 3 inches to 4 inches. It is a variable species, being the parent of *S. pusilla* (Waldst.). I find it a very easily grown alpine, and it likes nothing better than root-division once or twice in summer, when it neither flags nor stops flowering. In winter it goes back to quite a surface or Moss-like habit. If you disturb it then you may lose it.

Dianthus Atkinsoni.—I propagate this by very short cuttings with a heel of the older stems. It is true there is not an atom of grass to be seen even after its long season (quite eight weeks) of flowers. I get material for cuttings this way: I remove the many branched and top-heavy flower-stems somewhat before the flowers are over. The advantages are: you gain your object much sooner with ample time to root the cuttings before cold weather sets in; you save some of the vigour of the plants by removing the seed pods, which form in about 25 per cent. of the flowers, but which, though they fill fairly well, have never yet proved fertile with me; and you also probably catch all the grubs that eat the leaves hollow in the upper parts that are removed, and so save the stems from being bored. Anyhow, the sooner you cut the plants over, the more safety in this respect, but you should not omit to examine the old stools and stubbed parts, in order to make as sure as possible of freedom from grubs. Usually in three weeks after heading over grass is ready to take. I put the cuttings in a pan of sand and water for a day so that they almost float. There should not be so much water as to stand separate, only just to be level with the sand. After a day remove the bit of clay from the outer bottom of the hole of pan, when cuttings and sand will settle solid. The advantages of this plan are: the cuttings never flag, and they may be set in the open sunshine at once, when the rooting process goes on

more quickly than in shady places or closed frames, to say nothing of the more sturdy character of the little plants, which I usually have rooted and in their little pots in three weeks or a month according to weather. The more sunshine, the more attention and the more progress.

Silene Argoa.—This may be a scarce or even rare plant, as it is reputed to be, but I do not see why it should, only by the rule of seldom seen and seldom appreciated. Still there is a pleasing if peculiar feature about the plant when in flower. It grows 9 inches high with a dense habit both as regards top and underground stems, which are many branched. The flowers come in early summer and last but a short time individually, but some weeks in succession. They are 1 inch across, and of a dull salmon or nearly crushed strawberry colour. The whole plant is hoary, and when getting sere, almost hispid.

Epilobium Billardierianum.—Of all the species I know of this large genus, this is the most useful and pretty for the rockery. It is a perennial here, and reproduces itself moderately from seed as well. The genus is not a favourite one with gardeners, but this proves very attractive in a good patch; at a first glance few would take it for one of the Willow Herbs. It is a small species with big flowers that expand well and keep open, and they are of a soft flesh tint, but the more showy feature is in the foliage, borne on stems 2 inches to 5 inches high. The leaves, strap-shaped and half an inch to 1 inch long, are of thick almost leathery texture and glisten like wet glass; for most of the summer, if grown in full sunshine, as the plant should be, the leaves reflex, almost curl, and assume a lovely russetty red tint, and the stems being almost black they have a rich effect. Besides, the flowers, which appear about the same time and are half an inch in diameter, touch off by their flesh tint the heavier colours; the contrast is still more sharp by reason of the long seed-pods being of almost ebony blackness and bulky proportions for so small a plant. The plant is more or less in evidence the year round. I give no special care, indeed none, to it. It springs up in the hard walks and sunny places from seed, and is exceedingly pretty on top of a wall kept moist.

Hypericum nummularium.—Why this does not faster come to the front among choice alpine I do not know, but in time I think it must do so. It is one of the comparatively few things that has all points good and not a single fault—dwarf, procumbent, neat, a pretty and distinct setting of foliage, large flowers of thick substance, that last a long time, sufficiently verdant in winter to be seen, and yet not more so than to practically reclothe itself with new verdure annually. It spreads but slowly, so that it is not like many of the smaller St. John's Worts that become pests. For clothing the sharp edges of moist rocks as with a living fringe, or for gilding narrow crevices in late summer with its numerous golden blossoms, nothing could be in better taste, and at the same time more novel. If once you see a plant of it well grown and in full blossom, it will need no further commendation. It likes light and moist black soil with plenty of sand. I lost many plants in stiff soil, and success only came under the changed conditions.

Dryas lanata.—My liking for this grows more and more. Of the kinds I grow, *D. octopetala*, *D. o. minor*, *D. tenella*, and *D. Drummondii*, I consider it the best. It is the latest to flower and is in now. In many ways it closely resembles *octopetala*, and for a time I saw little or no difference, for its specific name points to a property wanting in the British type. It is when the plants get vigorous that they assert themselves as distinct in their flowers, which are larger and more imbricated; the foliage also is rather broader and more woolly.

Woodville, Kirkstall.

J. WOOD.

Some tender biennials.—Whilst Pentstemons are, when they can be induced to stand the winter safely, always very fine the following season, still

the somewhat tender nature of the plant renders it needful to bestow some care upon it. I have often raised plants from seed sown in March under glass, got them out into the open ground about the middle of May, had them flowering profusely all the autumn, and then have had every plant killed in the winter should that season happen to be severe. The very same thing has frequently happened to Snapdragons, for both these and Pentstemons, if they can be induced to withstand the ensuing winter, always then give the finest spikes of bloom. Unfortunately, such good fortune as saving the plants seldom happened. Even in such case ample reward had been found in the beautiful autumn blooming. Both of these charming biennials can easily be propagated by means of cuttings, but that means trouble, and few want to be so bothered. The best course on the whole to take is to sow seed now, and from the seedlings to plant out about the end of September the strongest, for small hard plants will often live where old ones will die, preserving the smaller seedlings in shallow boxes or dibbled up thinly into frames near the glass. These will make fine well-rooted plants to go out towards the end of April, and will bloom profusely through the summer. It is best to give some protection where possible, as in such case plants are assured, whilst they may otherwise be killed. The fine Brompton Stocks often get killed wholesale out-doors. Now and then in specially sheltered places they escape, but it must be where the soil is naturally dry and the atmosphere is active. It is indeed a pity that we cannot have Brompton Stocks as we used to do, for they are among the most beautiful of biennials. Those who, having sown seed about the end of May, can now put some plants into $\frac{1}{2}$ -inch pots and get them well rooted, and later have them shifted into 6-inch pots to stand the winter in a frame, turning them out into the open ground early in April, would in that way preserve their plants from harm and secure very respectable spikes of bloom. The richly perfumed branching Queen Stock needs somewhat similar care, for this, though said to be hardy, I have seen destroyed wholesale when planted even beneath overhanging trees. The various forms of the Sweet Scabious, very beautiful indeed, and flowering finely when kept through the winter, again need some protection during hard weather. It is a good plan to have these sown early in September in a frame and so wintered.—A. D.

GRASSES, &c, FOR USE DURING WINTER.

MOST Grasses and wild plants that are suitable for drying for decoration during the months of the year when flowers are difficult to obtain are now ripe enough for cutting, and most of us will be thinking of replacing our last year's stock. The Cat's-tails (*Typha latifolia*) are perhaps the most useful of aquatics, and are very effective. If cut in time, and just now they are about right, they will last from one season to another, but if left too late they will burst. A very suitable plant to use in conjunction with the *Typha* is *Arundo conspicua*, one of the most beautiful of our tall, reed-like Grasses. Its graceful silky plumes mixed with the brown tail like spikes of the *Typha* look very handsome. It should be used in preference to the Pampas Grass, except for high wall decoration, being much lighter. The Aquatic Grass (*Poa sp.*) must not be forgotten, for it is light and strong, and dries well. The feathery tufts of the Cotton Grass (*Eriophorum vaginatum*) may also be used with good effect. A very valuable addition to our collection is the *Eryngium*. There are many varieties to choose from. They last almost any length of time, but gradually lose their colour. While uncut they should be well tied up to prevent the stems from growing in fantastic curves, which may be awkward in decorating. Another large and ornamental genus of plants is the *Echinops*, or Globe Thistle. The blue or white florets look very pretty among Grasses, &c. All the above-named flowers and Grasses may be effectively combined in a terra-cotta vase about 18 inches in

height. The Cat's-tails and the Arundo can hardly be cut with too long stems. An arrangement of this kind is a charming finish to a corner of a drawing-room. If colour be desired, nothing is so showy as the large seed-pods of the Gladwyn (*Iris fetidissima*), showing the large orange-red berries. The common Teazel (*Dipsacus sylvestris*) would also give a touch of light colour when the flowers are freshly cut.

For smaller vases and for mixing with fresh flowers, the ornamental flowering Grasses are invaluable. *Agrostis nebulosa* and *A. pulchella*, the Quaking Grasses (*Briza*), Turk's-head (*Lagurus ovatus*), and *Eragrostis elegans* are the best. These are all annuals, and may easily be raised from seed. They should not be gathered until they are fully open, or they will shrivel and curl up. *Typha minor*, also the bright crisp flowers of the Everlastings (*Helichrysum*) and the lighter *Rhodanthes* are very useful to give solidity to arrangements of the finer Grasses. The *Helichrysums* and the *Rhodanthes* should be gathered when but partly opened and hung head downwards in a cool place till the stems are dry. None of the above should be put into water at all when they are cut for drying. L. H.

A pleasing contrast of colour.—One of the most pleasing arrangements of flowers we have seen this season was made up of a bold group of *Gladiolus brenchleyensis* and *Honesty*, the contrast being delightful.

Gaultheria tricophyllea.—I am very glad to learn from Mr. Wood's note in THE GARDEN of July 22 the name of this charming little *Gaultheria*, which Mr. Wood kindly sent me three years ago, labelled "*Gaultheria sp.* from the Himalayas at an altitude of 14,000 feet." Planted in pure peat and sand, it has spread some feet over the rockery. It is a deep rooter, and makes its way under the stones, appearing among the surrounding plants. The blue berries are wonderfully brilliant.—ROBERT BIRKBECK, *Loch Hourn Heath, Inverness-shire.*

Carnation Mrs. Reynolds Hole.—With all due respect to your editorial remarks in another paragraph headed "Carnation Mrs. Reynolds Hole," *Carolus Durand* is not by many shades as deep an orange as Mrs. Reynolds Hole, being more of a buff-yellow. I have grown this variety together with most of the best French Carnations for several years; it is a better flower and a more perfect bloom, but nothing that I have yet seen approaches the richness of colouring of this Carnation, except it be my own seedling Mrs. Frank Bibby, of which I have as yet only a few plants, and none for disposal.—H. W. WEGUELIN, *Sheldon, Teignmouth.*

Carnation Leander.—I must beg to differ with "A. H." in his statement in your number of July 29, that yellows as a class are "scarce, weak, and disappointing." I do not know what they may be in Sussex, from which county I believe he writes, but here in Devonshire I never wish to see finer and stronger plants than I have grown in yellows and yellow grounds this season. *Leander* did very well with me, and formed one of a box of eighteen blooms with which I took first prize at our local show. It was much admired, but I do not call it a thoroughly satisfactory yellow, being, although large, somewhat ragged, and cannot be depended upon not to split. However, when a good bloom is found it is very good, but not to be compared to such flowers, for instance, as *Simonite's Countess of Salisbury*. This is certainly the finest yellow I ever saw, being far larger than *Germania*, but at the same time retaining the form and beauty of colour of this now well-known variety. And then there are *Sybil*, *Exquisite*, *Duchess of Portland*, *Ovid*, and a number of others by the same raiser that grow as strongly out of doors as any Carnation can. And then how lovely are *Douglas' yellow grounds*, of which that splendid *Picotee Robert Sydenham* is perhaps the best. I had upwards of a hundred plants of this variety all in bloom at once the other day, and they were a splendid sight. *Almeira* has also done well with

me this year, and had the left-hand corner place in the box above alluded to. All these yellows and yellow grounds are planted out in October, are out all winter in all weathers without any protection, and flower strongly and well, giving good sturdy grass for layering in July.—H. W. WEGUELIN.

Poisoning by *Primula obconica*.—About eighteen months ago I was consulted by a lady for repeated attacks of an intensely irritable papular eruption on both hands. The eruption lasted three or four days, and then the skin desquamated. On one occasion the chin was affected. My patient was an enthusiastic gardener and had a considerable knowledge of plants. She suspected the *Primula obconica* from having read of its peculiar properties; and, in order to put her suspicions to the test, bared her arm and lightly passed a bunch of its leaves round the middle of the forearm. Nothing happened until the next day, more than twelve hours after the experiment, when a broad band of small papules appeared on a raised base giving rise to almost intolerable itching. She found that it was not necessary for the juice of the leaves to be applied to the skin, and also that if the fingers, after handling the plant, touched the face, the eruption was produced there as well. A strange feature was the fact that there was no effect until after the lapse of so many hours. The flowers alone had no evil influence. For several months before the cause of the trouble was discovered this patient's life was almost unendurable from the terrible irritation. After getting rid of all of this particular kind of *Primula* there was no further attack.—C. KINGSLEY ACKLAND, L.R.C.P., Lond., *Bideford, July 22, in Lancet.*

THE FRUIT CROPS.

THE FRUIT CROPS.

FRUIT growers and all interested in the production of hardy fruit generally will have had good reasons for remembering the year 1893. Our troubles, commencing with the flowering period, have increased as the season wore on, and they are not over yet by any means. The trees of all kinds were in an unusually promising state at the outset, the flower-buds being both abundant and stout. Apricots were the first to expand, and a very rough time they had of it. Severe frosts were experienced while the trees were in full bloom, and again after the fruit was about the size of Cherries, this being late in March. Strange to relate, a very little protection saved them, the crops being heavier than they have been for many years past. Plums, again, were in full flower exceptionally early, those against sunny walls being very gay about March 25. Frosts did not injure these either before or after the fruit was set, though at one time it did not seem possible for any to survive, 12° of frost being rather trying to tiny green fruit. The warm dry walls must have saved the fruit, and the crops are remarkably heavy. As far as standard and pyramid Plums are concerned, the crops with me are a complete failure. Pears against moderately warm walls were in flower at the end of March and promised well, but the newly-set fruit and late expanded flowers were not proof against the severe frosts experienced on and about April 13. Large quantities of newly-set fruit dropped off wholesale, and the crops are very variable accordingly. Where the sun struck full on the trees while yet in a frosted state very few fruits are now to be seen, but the trees against walls with a southern and south-west aspect are fairly well furnished with fruit. In some gardens in this district standards and pyramids are carrying quite heavy crops, in others they are very lightly cropped. Cherries in variety flowered

profusely and escaped injury from frosts. Better crops of fine fruit I never saw. Much the same remarks apply to Peaches and Nectarines. Many flowers were certainly blackened by frosts, but abundance was left behind, thinning out being necessarily severe. Apples in sheltered positions were the greatest sufferers from the frost. It did not actually destroy the flowers outright in all cases, but was responsible, I believe, for the great numbers of small malformed fruits there are this season. Trees more fully exposed to all weathers flowered later than April 13, and as a rule are heavily laden with fruit, too much so in many cases. Frosts did not injure Gooseberries and Currants as much as anticipated, but the early buds and flowers on Strawberries were all blackened.

It will thus be seen that a good start was made in spite of the frosts, the latter doing so little harm comparatively, owing to the dryness of the atmosphere. Had they followed upon hail or rain, or if there had been an average amount of humidity in the atmosphere, the delicate flowers and newly-set fruit would nearly all have been destroyed. But if a dry though cold air saved the crops, a long continuance of the same was not good for the leaf growth of the trees. It checked healthy progress and favoured the increase of all kinds of insect pests. Aphides, caterpillars, red spider, and diseases of a fungoid nature have all proved serious troubles, the long-sustained drought greatly aggravating the evil. This has been a fine season for vendors of insecticides and for the trial of all sorts of concoctions, but in every case it has been uphill work exterminating insects. We wanted drenching rains and more moisture in the atmosphere badly, and to all appearances very many fruit trees have sustained injuries from which they will not very quickly recover.

The very welcome change in the weather may have taken place in time to greatly benefit several kinds of fruit, but our troubles are far from being over. Early ripening has been the order of the day, but being able to gather various kinds of fruit fully a month earlier than usual is, in my opinion, a very doubtful advantage. In the first place it throws everything, so to speak, out of gear. Being able to gather Strawberries on May 5 was something to boast of certainly, but what about the hundreds of pot plants grown to waste, or what amounted to the same? That would, however, be a trifling matter, affecting the "many" but little, not having abundance of fruit during the tropical weather felt towards the end of June being the greatest drawback. A great heat so early in the summer is not good for the class of fruit we grow, especially if drought also prevails, Strawberries being among the first to indicate they do not like it. They coloured only too readily, but there was a want of sweetness and richness in the flavour not often observable. Other small fruits were very early and not nearly so sweet as desirable. Apricots, notably the *Large Early* and *Early Moorpark*, were fit to gather about June 20, but the fruit ripening then and since has not been so fine as usual and not juicy enough. Peaches, on the other hand, are greatly improved by the heat, the quality being nearly or quite equal to what has been grown under glass. I gathered the first ripe fruit of *Early Alexander* on June 18, *Hale's Early* being fully three weeks later instead of ten days or a fortnight, as of old, owing probably to the change in the weather. In any case, this should be one of the best seasons for Peaches on record, Nectarines also promising well. Of Plums the first to ripen was *Rivers' Prolific*, but *Morocco* is nearly as early

and a much better fruit. De Montfort on a south-east wall was perfectly ripe on July 10, and when slightly shrivelled is even more richly flavoured. Oullin's Golden was only two or three days later, and the tree is carrying a grand crop of fruit. Early Transparent, Green Gage, McLaughlin's Gage, The Czar, Victoria, Kirke's and Coe's Golden Drop are all equally well laden with fine fruit, but there will not be many left by the end of August or when they are often most wanted. Doyenné d'Été is the earliest Pear we have, and we commenced gathering ripe fruit on July 3, Citron des Carnes being nine days later. On July 16 the first ripe Jargonelle was gathered, and if all other varieties are correspondingly early in ripening, there will be fewer Pears left at midwinter than is the case in years of scarcity. We do not want Marie Louise and Doyenné du Comice ripe early in October, but it is only too likely that such will be the case. Apples promise to be both fine and early in ripening on young trees, and early as well as very small and abundant on old trees. The latter were the greatest sufferers from caterpillars and aphides, and the bulk of the fruit on those in old orchards is miserably small. Many thousands of the trees planted during the past ten years ought this season to give proof of the superiority of young trees over old ones, the Blenheim Orange excepted, and modern selections over those which gained favour in older times. If properly placed on the markets, home-grown Apples ought this season to more than hold their own against importations generally. As previously hinted, we are not out of our troubles when the ripening period is reached. Birds have been even more troublesome than usual, but these are more than rivalled by wasps. Nothing comes amiss to the latter, even unripe Pears and Apples being attacked by them. A tree of Jargonelle Pear was wholly cleared of fruit, nothing but skins being left, before we could destroy many nests; but a free use of gas tar among the nests and Davis' wasp-killer on the different kinds of fruit being attacked has done wonders, and I am in hopes the best portion of the fruit will have a chance to ripen properly. Nuts are fairly plentiful, or I ought to say were, for the squirrels were more numerous than of late years and were not killed in time to save the Filberts. Yet the kernels were not half formed when eaten.

W. IGGULDEN.

Marston Gardens, Frome, Somerset.

SOUTHERN.

Claremont, Esher.—A diary of outdoor gardening operations for May and June of the present season, so far as the kitchen and hardy fruit gardens are concerned, consists mainly of a record of watering, mulching, and battles against insect pests. Where water is laid on and there has been an abundant supply—where the hose in fact has literally been going day and night—crops have done well, for here it is nothing less than an Egyptian temperature following a flood of water. But such places are an exception, and in the majority of cases, despite an immense amount of labour, failures and disappointments have to be chronicled. Good surface mulching has proved of wonderful service on our rather light soil for both fruit and vegetables, and without it the amount of water we have been able to give in individual cases would never have benefited the recipients in the slightest degree. Every wall tree is mulched, as well as cordon Gooseberries and Currants, also half the vegetable crops, and very many flowers. Insect enemies have been very troublesome, red spider especially covering every kind of foliage at all susceptible to its attacks. We have managed

to keep it fairly in check except in the case of a portion of the Peach and Nectarine wall adjoining a Strawberry border. Runners of the latter fruit were late in coming this season. There was no opportunity for cleaning and less for soaking the Strawberry bed. It became simply alive with spider, and the trees on the wall had a bad time. Concerning the operation that brought them round and settled the red spider, I may have something more to say in a future note. It may be sufficient to record for the present that sulphur was thoroughly tried and found wanting. Aphides, green, black and grey, have been plentiful. Cherries and Plums especially have wanted constant attention. In the kitchen garden black fly has crippled two crops of Broad, and red spider very much checked French Beans. Thrips also has played sad havoc with the Peas. Wasps are plentiful, as may be imagined from the fact that fifty nests have already been destroyed within a radius of half a mile from where these notes are penned. As a set off against the wasps whilst on the subject of insects, bees have done well; a good take of honey is already (July 17) in hand, and given a favourable time for another six weeks, over 100 lbs. of honey will be taken off two hives, and yet plenty left to carry them well through the winter without artificial feeding. Earwigs are getting troublesome, and Bean traps on walls and small pots on Dahlia stakes are already strongly in evidence. The fruit crops, on the whole, are below the average in quantity, and very much below in size and quality. Peaches and Nectarines were numerically strong, but despite heavy thinning will be much smaller than usual. Apricots are very abundant, but these also are small; indeed, the latter remark applies so emphatically to every kind of fruit that it is useless to particularise individual cases. Cherries, both dessert and Morello, were and are very fair, but in the case of the first named the quality is not up to the average. Plums promised a grand crop and set well, but three parts of the fruit, all, in fact, not protected by the foliage, were blackened by a late frost; there is now only a fair sprinkling. Outdoor Grapes will be plentiful and good, berries already the size of small marbles. Apples and Pears are both very thin; so far as I have been able to gather they are a very partial crop this year, plenty in some gardens, but fruit a lot below average in size; in other gardens the worst crop known for years. In the matter of small fruits Strawberries were a thin crop and quickly over; Gooseberries also thin. Raspberries and all the Currants have been good; these are all grown in those parts of the garden least likely to be affected by the prolonged drought.

Vegetables, considering the season, have done fairly well; mulching has been largely practised in the kitchen garden as well as in the fruit garden, and watering as much as possible. Such vegetables as Spinach and the early and mid-season Cauliflowers have been in and over with lightning-like rapidity. Lettuce has been very scarce; the best to stand is Marvel, rather peculiar in colour, but a very valuable sort in a season like the present. Beans, runner and French, sown respectively in well-soaked trenches and deep drills and well mulched, are doing well. Such things as Celery, the Kales, and mid-season and late Broccoli are later than usual, but are making good headway since the rain. Peas (it has been impossible to water these) have been poor; late sowings, however, of William Hurst are looking well. Potatoes are small, but a clean, handsome sample and quite free from disease.—E. BURRELL.

Swanmore Park, Bishop's Waltham.—In spite of the remarkably dry season experienced here this year, the hardy fruit crop is by far the best I have seen for the last fifteen years. Some kinds of fruit are perhaps a trifle smaller than usual, owing to lack of moisture, but taken altogether it is a good season. The soil here is heavy and retentive for at least 3 feet deep, which is in its favour considering the extreme drought passed through. Apples are a heavy crop, especially such varieties as Cox's Orange Pippin, King of the Pippins, Devonshire Quarrenden, Irish

Peach, Worcester Pearmain, Blenheim Orange, Pine-apple Russet, Benoni, Red Astrachan, and Ashmead's Kernel Improved amongst dessert kinds; of kitchen varieties, Lord Grosvenor, Lord Sufield, Keswick Codlin, Warner's King, Ecklinville, Mère de Ménage, New Hawthornden, Yorkshire Greening, Tower of Glamis, Harvey's Wiltshire Defiance, Stirling Castle, Bramley's Seedling, Golden Spire, Lane's Prince Albert, Pott's Seedling, Bismarck, Councillor, Cardinal, Hollandbury and Grenadier. The foliage suffered somewhat in the early part of the season from the attack of aphid and a little later from red spider, which checked the growth of the trees, but by liberally washing the trees with tobacco water and so't soap dissolved these pests were kept under somewhat. The copious rains now falling will assist the swelling of the fruit considerably. Pears are by far the best crops we have had here both on the walls and in the open. Unfortunately, but few sorts will succeed in this soil when planted in the open; the soil being heavy and cold during winter, the growth of the previous season dies back very much, rendering the trees unfruitful. We have, however, good crops of Doyenné du Comice, Duchesse d'Angoulême, Comte de Lamy, Beurré d'Amanlis, and Catillac. On walls we have Jargonelle, Marie Louise, Pitmaston Duchess, Louise Bonne of Jersey, Thompson's, Napoleon, Ne Plus Meuris, Williams' Bon Chrétien, Winter Nelis and Passe Colmar carrying good crops of fruit. Plums are an exceedingly heavy crop both on walls and in the open; the trees are healthy and the fruit promises to be of good quality. The most prolific kinds (they never fail here) are Coe's Golden Drop, Orleans, Victoria, White Magnum Bonum, Washington, Jefferson, Kirke's, Green Gage, Bryanston Gage, Diamond and Mitchellson's. Cherries bear full crops annually; indeed, the trees are yearly too heavily laden; some of them exhibit signs of exhaustion owing to the heavy crops of fruit they bear. Governor Wood is the best early sort; May Duke, White Heart, Bigarreau Napoleon, and Elton are all good. Morell's succeed capitally against a north wall. The fruit of this sort is finer than hitherto. Peaches and Nectarines are regarded here as the most certain of hardy fruit. The crop of all kinds is exceptionally heavy this season. We have them growing on various aspects, south, east and west; in all cases they succeed well. Alexander, Waterloo, Early Louise, Hale's Early, Bellegarde, Gros-e Mignonne, Royal George, Walburton Admirable, Dymond, and Princess of Wales are the Peaches grown. Elnage is the only Nectarine cultivated that crops freely. Much labour was necessary to keep the trees free from insect pests by daily syringing with clear water and an occasional washing of the leaves with an insecticide, copious supplies of water to the roots being also given. Where labour for this work could be expended, the trees enjoyed the fierce sun-heat. Strawberries in this garden were not a great success. The plants suffered from the severe frost of last winter and again from the drought of this spring, but in the neighbourhood where the soil is more inclined to sand or loam good crops have been secured. Several hundreds of acres of this fruit are cultivated in the neighbourhood for the London and other markets, and good prices have been realised. The fruit has ripened well, the flavour good, and the flesh firm. The number of varieties grown is few, Sir Joseph Paxton being the sheet-anchor of the market man. A few cultivators grow Noble, but not to a large extent. It is not found to ripen earlier than Sir J. Paxton, while in point of flavour and cropping it is a long way behind. Alice Maud, Lucas, Eleanor and Princess Frederick William are favoured by a limited few. Taken as a whole, small fruits have done very well. Gooseberries suffered a little from cold winds in the spring and also from red spider; in spite of this the crop of fruit was a heavy one. Black Currants ripened very quickly; in consequence of this the fruit was small. Red Currants were a full crop. Nuts are an average crop.

Vegetable crops have suffered severely where water and mulching material were limited, Peas

in some gardens being quite a failure owing to drought. By the aid of heavy mulchings of manure and copious supplies of water we were enabled to keep up a supply. Well-tried varieties, like Duke of Albany, Fortyfold, Sharpe's Victor and English Wonder, have again done good service. Potatoes, though small, are good in quality where the laud was deeply moved. All the members of the Brassica tribe have been much interfered with by caterpillars. Taking all things into consideration, the crops on the whole look remarkably well.—E. MOLYNEUX.

Grenehurst, Capel, Dorking.—Here we have a very abundant fruit crop this year. Bush trees of all kinds are very heavily laden. Gooseberries are very small, although so numerous, and the bushes have suffered very much from the ravages of the caterpillar. Strawberries were very poor owing to the long spell of dry weather, the late ones doing better than the earlier sorts. Raspberries were poor, but the autumn fruiting ones are promising to bear well. Peaches and Nectarines outdoors are a very heavy crop, and since the recent rains are swelling very fast. Plums, both on walls and standard trees, are carrying good crops of fruit. Had the rain not come as it did a fortnight ago I am afraid that orchard fruits would not have been worth gathering.

Vegetables are now promising well for the autumn, but during the long spell of hot weather we had great difficulty in getting enough to keep the kitchen supplied. Flowers have been almost a failure this season outdoors, and many Roses have died. Our soil is a very heavy, poor clay, but retains moisture for a longer period than soils of a very light nature. Wasps are very numerous in this neighbourhood, and unless the nests are destroyed either by heavy rains or by some of the many means now employed for taking them, I fear all the fruit will be destroyed.—W. SHEPHERD.

Woolmer Gardens, Liphook.—In this district all fruits have been and are plentiful, rather smaller than usual, and about a month earlier. Cherry and Plum trees were infested with fly, Gooseberry trees with red spider. Pears, Apricots, and outdoor Peaches have done better this year than for many years, and have been remarkably early. Waterloo Peach was ripe by June 20, and Apricots by June 25, Doyenné d'Été Pear by the 30th. Filberts and hedge Nuts abundant.

Vegetables have been poor, especially in gardens where water was scarce. Carrots, spring planted Cabbage, and early Brussels Sprouts were dying off wholesale with grubs at the roots. The recent rains have checked them somewhat now. The Onion maggot has been very prevalent. Potatoes in places have died away before a crop has matured. Peas have done fairly well, and the hot weather has suited Cos Lettuce to perfection. Nearly all vegetables are about three weeks earlier than usual.—J. TAVENER.

Royal Gardens, Windsor.—Considering the fine display of bloom in this district, the present state and prospects of fruit crops are very disappointing. The late spring frosts thinned the bloom considerably, and Pears on April 10, when 10° of frost was registered, fell off the trees in quantities. The early flowers on Strawberries also were killed; nevertheless, there would have been good crops, even better than of late years, had the season, as regards rainfall, been anything like normal, but the long and probably unprecedented drought had a most disastrous effect on the fruit crop. February was a wet month (rainfall 3.90 in.). During March, April, May, and June the total rainfall was only 1.71 in., and for six months ending June 30, 6.02 in., the average here being 12.00 in. It need scarcely be said that under such conditions fruits are small, and all crops, including vegetables, below the mark as regards quality. Watering has been persevered with daily, and was absolutely necessary in many cases, more with a view of keeping trees alive than saving the crop of fruit, but, I fear, with only partial success, and that many trees, especially wall trees and newly-

planted ones, are more or less permanently injured. After looking through the fruit gardens I may briefly summarise my observations as follows: Apples about half a crop and very small. Pears much under average. Apricots plentiful. Plums very few. Cherries abundant crop, but small. Peaches and Nectarines good crops. Strawberries good crops and very early. Bush fruits and Nuts medium crops. As usual, in a dry summer, insect pests are very troublesome, blackfly and caterpillars on fruit trees, and maggot made sad havoc among Onions.

Vegetables have all suffered from drought. Peas were early (first gathered May 16), and a fairly good supply has been maintained, but only by copious drenchings with the hose. Potatoes are very small and crop light. Late crops are looking fairly well, though mildew and fly infest the haulm, and no case of disease has up to date come under my notice.—OWEN THOMAS.

Knebworth, Herts.—The state of the fruit crops in these gardens and in the district is, speaking generally, very good. In some few low-lying positions and in others where exposed to the north-east winds, the frost on the night of April 13 did a deal of damage to Apple and Pear blossom, and as a consequence the crops are somewhat variable and below the average in those places. In all the higher positions, however, which I have visited, full crops of Apples, and Pears are the rule. All the stone and bush fruits are everywhere heavy crops. Strawberries and Raspberries are the two crops among fruits that have suffered the most from the long drought and excessive heat, more especially on light soils. Strawberries suffered more, in my opinion, from the tropical heat and want of moisture in the air to swell them than from want of water at the roots. This was certainly the cause in our case, for our plantations of plants had several delugings of water. There was more than a full crop of fruit set, but only the first-set fruits swelled off, the later set fruits failing to swell at all, and having the appearance of being cooked on the plants. We failed to get more than a first picking of fruit from the plantations, thus making the Strawberry season a very short one. Evidently the weather was too tropical for this temperate zone fruit. Raspberries, where growing on heavier soils resting on cool bottoms, are, as with us, good crops, Semper Fidelis being the heaviest cropper and the finest fruit. Speaking more particularly of the fruit crops in these gardens, only once before in a quarter of a century have we had so uniformly good crops of fruit throughout. Apricots, Peaches, Plums, and Cherries on walls are heavy crops, and have given a lot of trouble to thin out. The same may be said of some varieties of Pears, the crop of which fruit is perhaps the lightest of all, yet fully an average. Gooseberries and Currants are excessive crops. Crops under glass have benefited much from the fine sunny weather. Peaches, Nectarines and Grapes are extra good both in size and quality, but to carry them on they have required double the usual quantity of water at the roots and also damping down of the houses to keep the air from getting too dry and parched. It has also been necessary to cover the glass over the Vines with a thick coat of whitewash to preserve the leaves from scorching, and help to ward off red spider, which is very prevalent this season. Tomatoes are also heavy crops under glass, of excellent colour and fine flavour. Orchard standards of both Apples and Pears are heavily laden with fruit. Some varieties of the former, such as Wellington, Hawthornden, Ecklinville, Irish Peach, Fearn's Pippin, King and several others, are heavily cropped. The rains which have fallen since the 8th ult., and more copiously the last few days, have come in the nick of time, as many of the old-established trees were just beginning to show the effects of the long drought and were hanging out signals of distress. There is a chance now for the trees to swell the fruit off to a fair size, otherwise the fruit would have been small and poor. One very noticeable feature in all

the Apples and Pears without exception that have come under my notice this season is, they are free from skin blemishes, the fruit being clear and smooth and already putting on good colour—a result evidently to be credited to the long spell of fine, dry sunny weather, which has been inimical to the spreading of the fungoid pests, which attack the fruit in moister seasons.

It is among vegetable crops that the long drought and excessive heat have been most severely felt and had to be battled with, and, save where abundant supplies of water could be had ready to hand and where the soil was good, deeply tilled, and full of plant food, the crops have been very light, and in most instances of very poor quality. In this latter respect Potatoes are, however, an exception, as they are almost everywhere of excellent quality, samples very clean, though undersized. First earlies with us are about one-third of a crop as compared with last year, but second earlies now being lifted are turning out far better than we anticipated, crop about two-thirds in weight and the tubers of good usable size and of super-excellent quality. They have been growing on a piece of deeply worked ground full of manure, and this enabled them to go on growing and the haulm to be sustained in a fresh state, holding out against the drought much longer than it could or would have done had the ground been in a different condition. But this much can be said for all other crops growing on deeply tilled and enriched ground, and is one of the valuable lessons to be learnt from this trying season of drought. Late Potatoes in the fields were got in in a very dry soil, which remained in that state for fully ten weeks. The growth was very irregular, a great proportion of the sets failing to sprout at all, and altogether the crops looked very miserable up to the 8th ult., but the rains since then have revived them and they are now looking well, and as there is plenty of time yet for them to mature, fairly good crops, I think, may be looked forward to. Early and second early crops of Peas have been very fitful in the supplies, the pods filling badly. This arose not so much through being dry at the root, for ours were kept constantly watered, as from the excessive heat which, like the Strawberries, they could not stand against, the succession flowers and even the newly-formed slats being scorched and shrivelled up, and giving the plants such a check they could not get over it. The consequence was where we ought to have had several successional gatherings from rows we had to be content with only one. The later sown lots are now looking well and podding freely, and we shall have good supplies through August and September. Cauliflowers, Spinach, French Beans, and all kinds of salading have had to be constantly watered to keep the supplies up at all. The main crops of Carrots, Onions, Beet, and Brussels Sprouts which were got in early and growing on rich, deeply worked ground have held their own against the drought with very little water being given them, and are now looking well and promise good crops. They show no appearance of having passed through a long season of dry weather. Asparagus is the only vegetable which seems to have enjoyed the great heat and drought without having any water given it. The season of 1893 will be long remembered for many things. Among these may be named its abnormal earliness of most crops. We gathered our first dish of Peas (Exonian) on May 20, more than a fortnight earlier than on any previous year. On the same date we gathered the first dish of Strawberries (La Grosse Sucrée) three weeks in advance of any previous date. Most insect plagues have been more than usually rife, and a constant war has had to be carried on against them to keep them under. On the other hand, the garden slug was never so absent as this season. I have not seen a single slug. A valuable lesson will have been taught most cultivators of the value and necessity for deeply working and enriching the ground with sufficient and proper plant foods as against poorly worked and impoverished soil for sustaining crops through a long season of drought.—J. KIPLING.

SOCIETIES AND EXHIBITIONS.

ROYAL HORTICULTURAL SOCIETY.

AUGUST 8, 1893.

THE Drill Hall was very well filled with exhibits at this meeting, more almost than one could expect considering the nearness of the larger exhibition at the Agricultural Hall, Islington. Orchids were not present in large numbers, but a few good things were shown. The entries for examination before the floral committee, however, were more numerous than at any meeting since the Temple show in May last. These were of a representative character of things in season, earlier than usual in some instances, Gladioli in particular being remarkably fine for the early part of August. Cannas, upon which the lecture on this occasion was delivered, were represented chiefly by the best of the flowering varieties. A fine lot of spikes of Hollyhocks was sent from Scotland. Hardy flowers from other sources were likewise good. Amongst fruit there were several Melons of promise, better than at any previous show this year. Numbers of dishes of Plums and Apples were also staged; also Peaches and Nectarines, denoting in many instances the earliness of the season.

Orchid Committee.

First-class certificates were awarded to

MILTONIA JOICEYANA, which is nothing more than a fine form of *Miltonia Clowesi* major, decidedly not a distinct species in any sense; the flowers have all the characteristics of *M. Clowesi*, but are larger, the peculiarity with which the lip with age assumes a dull yellow tint, being exactly the same; the flowers were large and well coloured. From Major Joicey, Sunningdale Park.

LÆLIA TENEBROSA (Walton Grange variety).—A distinctly coloured form of the type, with yellowish green sepals and petals, and a faint tracing only of the distinctly coppery shading of *L. tenebrosa*; the lip was tipped with pale rose, but in other respects similar to the type; a cut specimen, two flowers, being shown. From Mr. W. J. Thomson, Walton Grange, Stone, Staffs.

Awards of merit were made to—

LÆLIA NOVELTY (*L. elegans* × *L. Dayana*), the flowers of which are of the size of those of *L. Dayana*, the sepals and petals paler than in that species, but the lip darker, being of a rich velvety crimson, the growth rather taller than in the species just named. From Messrs. J. Veitch and Sons, Royal Exotic Nursery, Chelsea.

CYPRIPEDIUM THAYERIANUM (*C. Lawrenceanum* × *C. Boxalli atratum*).—This has much of the character of the latter parent, but with much deeper coloured flowers, the flowers being a rich vinous-purple. From Messrs. Sander and Co., St. Albans.

CYPRIPEDIUM ÆNA-SUPERBIENS (*C. granthamii* × *superbiens*).—In this hybrid the form and style of flower were those of *C. superbiens*, but it was larger in all its parts, a bronzy purple pervading the same; a very fine and distinct hybrid, the dorsal sepal large and the petals broad. From Sir Trevor Lawrence, Burford Lodge, Dorking.

Botanical certificates were awarded to—

AGANISIA IONOPTERA.—A species with small, but pretty flowers, with violet shading on a light ground. From Sir Trevor Lawrence.

EARINA SUAVEOLENS.—A small botanical curiosity. From the Royal Botanic Gardens, Glasnevin.

A cultural commendation was most deservedly awarded to a finely cultivated example of *Vanda Sanderiana* bearing flowers of unusual size, the spike having eleven blooms fully developed. From Major Joicey. Sir Trevor Lawrence had a few choice Orchids, amongst which were several spikes (cut) of *Acerides Lawrenceae* (Sander's var.); these spikes were extra vigorous and bore large massive flowers, richly coloured, *Schomburgkia Lyonsi*, a very pretty species, with purple and white flowers; *Cy-*

ripedium Har-froyæ (*C. Harrisianum* × *C. Gode-froyæ*), a large and fine hybrid, with rather pale-coloured flowers of superior form; *Cattleya Blesensis*, after *L. Dayana*, but paler; *Lælia elegans Turneri* Purple Prince, a splendid dark form, and *L. Philbrickiana*, not one of the prettiest of hybrids, were also shown (silver Banksian medal). Messrs. Sander and Co. sent several very meritorious plants, among which were *Vanda Sanderiana* in good form, *Cypripedium Yonngianum* bearing three flowers to the spike, all fresh and good, with distinct drooping petals; *Cypripedium Macfarlanei* with green and white flowers after *C. Spicerianum*; *Acerides Ballantineanum aureum*, with distinct yellow lip; *Acerides Sanderianum* with fine spikes, with rich crimson markings on the flowers; *Grammatophyllum Fenzlianum*, with green and pale brown blossoms on a long spike; *Cypripedium Maynardi* and *Calanthe Sanderiana* (silver Banksian medal). Mr. Measures, Cambridge Lodge, Camberwell, showed *Cypripedium Numa superbum*, a distinct and showy form, also *C. Yonngianum* previously alluded to. Mr. Owen Thomas sent from the Royal Gardens, Windsor, a healthy plant of *Saccolabium Blumei majus* bearing one fine spike of flowers.

Floral Committee.

First-class certificates were awarded to—

GREVILLEA BANKSI, a distinct species introduced as far back as 1868, but which has apparently escaped notice to some extent. The style of growth is that of *G. robusta*, but the leaves are not so much sub-divided; it is a very promising kind for use in a small state. From Messrs. John Laing and Sons, Forest Hill, S.E.

LIATRIS PYCNOSTACHYA, with long spikes closely set with small flowers of a pale purple colour. It was first introduced in 1732, and is a fine and distinct hardy border plant. From Messrs. Paul and Son.

MONTBRETIA CROCOSMILEFLORA FLORE-PLENO.—Best described as a double form of this fine species; the growth is also vigorous. From Sir Trevor Lawrence.

Awards of merit were given to

CANNA DUCHESS OF YORK.—A yellow variety with a profusion of orange-coloured spots, the growth free and the spikes of good size. From Messrs. Kelway and Son, Langport.

CANNA KONINGEN CHARLOTTE, of which plants were shown, a more commendable method than cut flowers. The growth in this case was extremely dwarf, the colouring after the style of *Mme. Crozy*, but lighter—a rare variety. From Mr. W. Pfützer, Stuttgart.

CANNA MICHELET.—A very fine bright orange-scarlet, with extra large flowers and spikes. From Sir Trevor Lawrence.

CANNA CAPITAIN DE LUZZONI.—A large pale yellow variety, spotted with pale orange, the petals broad and massive. From M. Lemoine, Nancy.

CANNA GLOIRE DE L'EMPIRE.—A fine crimson variety, with large, broad-petalled flowers and fine spikes. MM. Vilmorin et Cie.

CANNA LOHENGRIIN.—A pale orange hybrid, self-coloured, and very distinct, the trusses large. MM. Vilmorin et Cie.

CANNA PRESIDENT CARNOT.—Cinnabar-red in colour, lightly spotted carmine, foliage rich purple, a distinct and handsome variety. From MM. Vilmorin et Cie.

GLADIOLUS DUKE OF YORK.—Spike extra large, also the flowers, in colour a rich carmine, with white feathering. From Messrs. Kelway and Son.

GLADIOLUS ALFRED HENDERSON.—Colour dark cerise, with purplish feathering; the flowers large, also the spike. Messrs. Kelway and Son.

GLADIOLUS GROVER CLEVELAND.—A dark cherry red, very fine and distinct, nearly self-coloured. Messrs. Kelway and Son.

GLADIOLUS JOHN WARREN.—Rich salmon-coloured flowers and dark featherings; another distinct kind. Messrs. Kelway and Son.

HOLLYHOCK AMARANTH.—A fine and very double seedling, with flowers of a decided amarant-pink, extra large. From Messrs. Webb and Brand, Saffron Walden.

BEGONIA SEMPERFLORENS VERNON.—Extra dwarf habit, the foliage of a bronzy red shade; the flowers salmon-red, very profusely produced. The plant had evidently been grown out of doors, showing it to be a useful bedding plant. From Messrs. J. Laing and Sons.

CALADIUM PRESIDENT DE LA DEVANSAYE, with reddish foliage, almost self coloured, a narrow edging of olive green running round each leaf. Messrs. J. Laing and Son, and Mr. Bause, Norwood.

TRITOMA OISIRIS—A very distinct addition to this genus. The flowers and buds were of a pale yellow, without any trace of orange or scarlet, the growth apparently rather tall. Messrs. Paul and Son, Cheshunt.

PHLOX ETNA.—A very bright salmon coloured variety with dense spikes and a dwarf habit. Messrs. Paul and Son.

HEDERA HELIX VAR. TESSELLATA.—A distinctly marked form of the common Ivy, with veinings after the manner of the variegated Japanese Honeysuckle, but not so distinct. From Miss Browning, Algiers.

CROTON MADAME ERNEST BERGMAN.—A promising addition to an already large family; the growth medium, the foliage broad, the colour rich golden orange, with dark olive green. Mr. Bause.

DRACÆNA ALEXANDER LAING.—Best described as a much improved form of *D. superba*, being more graceful in habit and slightly more robust, the growth free. From Mr. Bause.

Mr. Jas. Hudson, Gunnedbury House, Acton (Messrs. de Rothschild's), sent a large group of *Campanula pyramidalis* (silver-gilt Flora medal). Messrs. Kelway and Son sent a magnificent group of Gladioli in great variety, the spikes finely developed and in the best possible condition. Besides those certificated the following should be noted: *Marengo*, a rich scarlet; *Hemon*, a shade of buff; *Lord Hawke*, extra large, light salmon-pink; *Leonard Kelway*, an extra dark velvety crimson; and *Duchess of York*, with yellow spots. Besides the foregoing there were several fine varieties of *Gaillardias*, amongst which *Topaz* was very distinct, a pale or lemon-yellow self, and *James Kelway*, a dark red, with golden eye. *Belladonna Lilies* (*Amaryllis belladonna*) were shown well; also the best sorts of hardy herbaceous flowers in season (silver-gilt medal). Messrs. J. Laing and Sons had a group of plants, in which were included *Chironia exifera* with pretty pink flowers, narrow leaves, and dwarf growth; *Strobilanthes Dyerianus*, *Stenandrium Lindenii*, *Sonerila le petit Leon*, *Bertolonia Comte de Kerchove* and other varieties, *Croton Mortii*, and small Palms with other things (silver-gilt medal). Messrs. Dobbie and Co. had a large display of Carnations in bunches, which were feeling the effects of the heat somewhat. The best were *White Dame*, pure in colour; *Mary Morris*, still one of the best pinks; and *King of Scarlets*. Sweet Peas were finely shown by the same firm. The best of these were *Queen of England*, *Splendour*, *Monarch*, *Princess Beatrice*, *Orange Prince*, *Mr. Eckford*, *Marchioness of Bute*, *Her Majesty*, *Miss Blanche Terry*, *Emily Henderson*, and *Violet Queen*. Both Carnations and Sweet Peas were shown, as they should be, in bunches (silver Flora medal).

A silver Flora medal was awarded to Mr. John Forbes, Hawick, N.B., for a magnificent exhibit of Hollyhocks, the best seen in London for some years. The spikes were of extra length, not so dense as usual, and bore fine flowers, the finest being *Alba superba*, *J. M. Lindsay*, *James McDonald*, *Miss Dawson*, *Mrs. Edgar*, *Conquest*, and *Golden Drop*. *Pentstemons* and *Antirrhinums* were included. Messrs. Cannell and Sons, Swanley, received the same award (silver Flora medal) for a group of their splendid strain of tuberous *Begonias*, plants and cut blooms, *Octavie*, a beautiful pure white double, being one of the best plants; the singles were also excellent. Very fine *Antirrhinums*, cut and shown in bunches, came from the same source, showing great diversity of rich colour

and compact growth. Messrs. W. Paul and Son also received a silver Flora medal for a very fine display of hardy cut flowers and Roses, the effects of the past drought not having had any ill effects thereon; the best Roses to hold out were La France, Charles Lefebvre, Malmaison, Mme. Pernet Ducher, Mme. Charles Testout, Mme. Berard, and Mlle. Prosper Lugnier. Other hardy flowers embraced *Zauschneria californica*, not often seen, good *Lilium tigrinum superbum*, as well as *Montbretias* in beautiful variety. Cannas were also included.

A silver Banksian medal was voted to Sir Trevor Lawrence for Cannas (a fine exhibit) and *Gladiolus Childsi* (?). Messrs. Cheal and Son, Crawley, and Messrs. Shuttleworth also received silver Banksian medals for cut hardy flowers.

Fruit Committee.

There were some very fine collections of fruit staged, Apples, Pears, Plums and Peaches being largely shown. Melons were also shown in large numbers, and better than usual, no less than three awards being given.

Awards of merit were given to—

MELON HERO OF ISLEWORTH, a very finely netted fruit, green flesh, medium size, and of fine flavour. The fruits staged were scarcely ripe. This will undoubtedly prove a valuable addition to the somewhat limited number of varieties possessing green flesh. From Mr. Wythes, Syon House.

MELON COUNTY COUNCILLOR, a scarlet flesh, a cross between Triumph and Blenheim Orange, slightly netted and of good flavour. From Mr. W. Palmer, Cobden Villas, Andover.

MELON ROYAL PRINCE.—Very much like the above-named, but with white flesh, very sweet, the rind thin. Mr. W. Palmer.

Melons were also shown by Mr. Thomas, The Royal Gardens, Frogmore; Mr. Webster, Springfield Gardens, Great Marlow; Mr. A. J. Reed, Farnham Chase, Farnham Royal; and Mr. Sanson, Widsworthy Court, Houston, Devon. A very fine collection of fruit was staged by Messrs. Veitch, Royal Exotic Nurseries, Chelsea; over seventy dishes were put up. The Plums were remarkable for their large size and finish. These were grown in the open, the best being Washington, McLaughlin's, a very fine Gage and of splendid flavour; Belle de Louvain, Early Golden Drop, Early Transparent Gage, Angelina Burdett, Lawson's Golden Gage, and Kirke's. There were also some fine dishes of Apples, the best being Kerry Pippin, Lady Sudeley, Worcester Pearmain, very highly coloured, Seaton House, very fine, and Early Strawberry. Some good dishes of early Pears, Morello Cherries, Damsons, Raspberries and Crabs, and half a dozen Peach and Nectarine trees in pots in full bearing were also shown (silver-gilt Knightian medal). Messrs. Cheal, Crawley, Sussex, also had a very good collection of hardy fruits, some seventy dishes, including good Jefferson, Belgian Purple, Archduke and Golden Gage Plums, nice Irish Peach, Emperor Napoleon, Mr. Gladstone and Lady Sudeley Apples, and some fine dishes of Crabs and Pears (silver Banksian medal). Mr. Thomas, The Royal Gardens, Frogmore, contributed some very fine Peaches and Nectarines, having thirteen dishes of Peaches and eight of Nectarines, and several dishes of Pears. The best Peaches were Dr. Hogg, Violette Hative, Premier, Stirling Castle, Goshawk, and Grosse Mignonne, and the best Nectarines, Lord Napier, Elruge, Pine-apple, and Hardwicke Seedling (silver Banksian medal). Very fine smooth Cayenne Pine-apples, averaging seven to nine pounds in weight, came from Mr. R. Nicholas, Castle Hill Gardens, South Moulton, Devon (silver Banksian medal). Mr. Bunyard sent a very fine dish of Lady Sudeley Apple and three dishes of early Pears, the varieties being Benrre Giffard, a very good early fruit on the Quince, and Petite Marguerite and Précoce de Trevouf. Grapes were sent from Mr. Allis, Old Warden Park Gardens, Biggleswade, Beds, the variety being a good form of Hamburgh. A seedling Apple named Monmouth, a cooking variety, came from Mr. T. Godfrey, Edmonds Nursery, Hillingdon. A seedling Tomato came from Mr.

Freer, New Brompton, but it too closely resembled Perfection to merit a special award. A new ridge Cucumber named Baker's Triumph came from Messrs. Jarman, Chard. A very good collection of ornamental Gourds was sent by Messrs. Cheal, Crawley. A new seedling Potato named George Dickson, and one with considerable merit, came from Mr. Mackereth, Silverston. This was requested to be sent to Chiswick. Some Grapes affected with a new kind of mildew were referred to the scientific committee.

Mr. Baker, of the Royal Gardens, Kew, gave a lecture on Cannas. He also illustrated his notes with diagrams, and went at great length into the species and dates of raising various hybrids. He stated there were two types of the Canna, which is closely allied to the Ginger plant and Banana in its structure. He found that most of the hybrids came from two species, *C. iridiflora* and *C. glauca*, and by hybridising with the Warscewicz type there was a distinct gain, as this gave much larger blooms of a brilliant scarlet colour with dwarfier growth. The Canna was now used extensively for sub-tropical effect in the flower garden. On the Continent much greater strides had been made in the hybridising of these plants. Near Paris there were extensive establishments where these plants had been made a speciality of. The lecturer went into the merits of the earlier raisers, such as Miller, Roscoe, and others, and of the advantages of plates over dried specimens, as these latter could not be relied upon, the colours soon changing. During the last twenty years raisers had done much in improving the habit and size of foliage. One great advantage of these plants is that they fertilise readily. The new hybrids are of easy culture. Owing to this ready method of culture the original forms are largely going out of cultivation, but this should not be, as they are valuable for hybridising and as a means of reference. Mr. Geo. Paul stated he had considerable experience with Cannas, and found there was a lot of seedlings from hybrids not of great value, being too much alike.

GARDENING AND FORESTRY EXHIBITION, EARL'S COURT.

AUGUST 9.

ONE of the best shows of the season was that held at Earl's Court on Wednesday last. Hardy flowers in particular were a feature, and the groups of high merit. The tent was uncomfortably filled, and it would have been better if the groups had had a larger space devoted to them.

A fine group of flowering and fine-foliaged plants came from Messrs. J. Laing and Sons, Forest Hill. It was a remarkably effective arrangement, bold, not too crowded, and well deserved the first prize. A variety of things was shown, and especially good were the tuberous Begonias, one kind named Sir Blundell Maple being a single variety with large orange-scarlet flowers. Other plants of note were *Campanula pyramidalis*, *Lilium speciosum Krætzleri*, or album, *Disa grandiflora*, *Odontoglossum Harryanum*, *Dracæna Lord Wolsley*, deep bronzy green, margined with crimson; *Gloxinias* and the pretty *Chironia exifolia*, the flowers rose in colour. We must also praise the group of *Lilium speciosum* from Mr. Charles Turner, The Royal Nurseries, Slough, which gained the premier award. The type and variety *Krætzleri* were both finely represented. An excellent group of *Crotons* and *Dracænas* came from Mr. W. Howe, gardener to Mr. H. Tate, Park Hill, Streatham Common, which was accorded first prize. The plants were well grown and of good colour. An interesting feature was the class for a collection of hardy flowers, and the first place was taken by Messrs. Paul and Son, Old Nurseries, Cheshunt, who had an exceptionally massive group. *Lilium tigrinum splendens* was splendid; also the various kinds of perennial Sunflowers, *Phloxes* (especially

the variety *Le Nain Blanche*, pure white), *Rudbeckia purpurea*, one of the finest hardy plants in bloom now; *Tropeolum speciosum*, *Pyrethrums*, and *Gaillardias*. An excellent second was Mr. Such, Mal'tenhead, who had a choice selection of kinds, *Gaillardias*, *Phloxes*, *Coreopsis lanceolata*, perennial Sunflowers, and a few other choice things. An extra prize went to Messrs. J. Laing and Sons for a very creditable display. Another important class was for an arrangement of flowering and fine-foliaged plants, and here Mr. G. Wythes, gardener to the Duke of Northumberland, Syon House, Isleworth, was first, showing *Fraxeos*, *Campanula pyramidalis*, and other well-known plants.

The bunches of hardy flowers formed a very beautiful feature. They were as a rule a little too crowded, and thereby lost in effect. The class for twenty-four was well filled, and Messrs. Paul and Son were first. They showed large masses of each kind represented, and therefore the effect was rich. *Gaillardias* in variety were noteworthy, particularly that good yellow-flowered kind named Vivian Grey; also *Phloxes*, *Liatris pycnostachya*, *Montbretias*, *Rudbeckia Newmanni*, and *Echinops ruthenicus*. We may also mention that a good second was Mr. Cuthbertson, Rothesay, N.B., who had a fine selection of plants. In another class for hardy flowers the winner of the first prize was Mr. G. Wythes, who had a choice assortment of kinds; a close second was Mr. G. H. Sage, gardener to the Earl of Dysart, Ham House, Twickenham. For nine bunches the premier award went to Mr. Newell, gardener to Sir Edwin Saunders, Fairlawn, Wimbledon; Mr. Sage second, he having a fine mass of *Inula glandulosa*. We noticed in the various collections of hardy flowers that *Eryogium planum* was almost without exception exhibited well. We are pleased to see that this beautiful Sea Holly is popular.

As is often the case, the miscellaneous department was remarkably strong. Mr. Forbes, Hawick, N.B., showed a large bank of the East Lothian Stocks, white and crimson, representing a splendid strain, whilst the same exhibitor had the finest group of Hollyhock spikes we have seen of recent years. The varieties were not all new, and we noticed many of Chater's kinds, thus showing that a large number of the old varieties escaped destruction by disease. A silver-gilt medal went to this fine display. A large and remarkably well-grown group of *Campanula pyramidalis*, the typical and white variety, came from Mr. Hudson, The Gardens, Gunnersbury House, Acton (silver-gilt medal). A similar award was made to Messrs. Kelway and Son, Langport, Somerset, for a superb collection of *Gladioli*, *Gaillardias* and Cannas. Of the *Gladioli*, very fine were Countess Craven, rose; Marengo, scarlet; Duchess of York, light lilac; and John Warren, scarlet; whilst the *Gaillardias*, a yellow variety, with raised crimson centre, named Topaz, was of note. The collection also comprised such hardy flowers as *Amaryllis Belladonna* and *Eryngium planum*. A silver medal went to each of the following exhibits: Messrs. Barr and Son, Covent Garden, had a large group of hardy flowers, in which Sweet Peas were well represented. Pentstemons, perennial Sunflowers, Tiger Lilies in variety, Dahlias, Iceland Poppies and other things were staged in handsome bunches. Roses were not very freely shown, but Messrs. Paul and Son had a fine collection. Such kinds as *Augustine Guinoiseau*, *l'Idéal*, W. A. Richardson, *Souvenir de la Malmaison*, *Alphonse Soupert* and *Belle Lyonnaise* were excellent. Lilies of the Valley, splendid for this season of the year, were shown by Mr. T. Jancock, Dersingham, Norfolk. Show Dahlias were exhibited in great variety by Mr. J. Walker, Thame, Oxon; the varieties Mrs. W. Slack, Bendigo, Harry Keith, John Walker, Harrison Weir, Colonist and F. J. Saltmarsh were worthy of mention. The flowers from Messrs. J. Cheal and Son, Crawley, comprised Cactus, decorative, pompon and show Dahlias, Sweet Peas and other things in bloom now—a bright and attractive group. Hardy flowers, such as *Phloxes* and *Gladioli*, were shown well and in quantity by Mr. Cuthbertson.

A charming feature of the show consisted of the various floral arrangements from Miss Lilian Hudson, Acton, a hall vase of Bulrushes and Grasses being exceedingly pretty, because arranged with rare taste. It was a creditable display, and deserved well the silver-gilt medal awarded. We do not want Chrysanthemums now. They are peculiarly out of season on a hot August day, but we must mention that a group of pot plants and flowers as fine as those often seen in November came from Mr. McMillan, Trinity Cottage, Edinburgh. The varieties Mlle. Lacroix, Edwin Molyreux, Annie Clibran, C. Wagstaff, and the single-flowered Mary Anderson were remarkably fine (silver medal). Messrs. J. Laing and Sons exhibited *Begonia semperflorens* (Vernon's variety) well, and a new Carnation named Stanstead Beauty. It has large fringed flowers, rosy pink in colour, and sweetly scented.

Fruit.

For six dishes hardy fruit, Mr. G. Wythes, Syon House Gardens, Brentford, was first, having very good Royal George Peaches, Pine-apple Nectarines, excellent Williams' Bon Chrétien Pears, Jefferson Plums, Morello Cherries, and Worcester Pearmain Apples—a nice even lot. Second, Mr. G. Sage, Ham House Gardens, Twickenham, with very fine Jefferson, Kirke's, and Green Gage Plums, Mulberries, Yellow Ingestre Apple and Pears. Mr. B. Nicholas, Castle Hill Gardens, South Moulton, staged the fine group of Pines he had the previous day at the R.H.S.; these were awarded a silver medal. Messrs. Cheal, Crawley, staged the very fine collection of Apples exhibited the previous day, also the collection of Gourds (silver medal). Mr. A. H. Rickwood, Fulwell Park Gardens, Twickenham, staged a nice collection of fruit, consisting of good Hiale's Early, Barrington, Grosse Mignonne, Early Louise, Prince of Wales, and Early Louise Peaches, Lord Napier Nectarines, Melons and Plums, Kirke's and Jefferson being the best dishes of the last (silver medal). Mr. T. A. Hester, Plumstead, had a great number of Plums consisting of the best known kinds, Apples, Cherries, Apricots, and Tomatoes (silver medal). Mr. Pocock, Cranford Gardens, put up some dishes of huge Peaches, pale coloured fruits of an American variety (bronze medal). Mr. Beasley, Ealing, had some dishes of very fine Lord Suffield Apples. Mr. McDougall, Stirling, staged his new seedling Tomato named Ravenna; this is much like Perfection. Mr. Eames, Twickenham, sent Cucumbers of nice shape and a dark green colour. Messrs. Spooner, Hounslow, had a collection of hardy fruit nicely arranged in baskets.

A full prize list will be found in our advertisement columns.

The weather in West Herts.—During the past week the weather has been on the whole unseasonably warm. On Tuesday the highest reading in shade reached 81° and on Wednesday 82°. On the other hand, during Saturday night a thermometer exposed on the surface of the lawn fell to within 7° of the freezing-point. The temperature of the ground at 1 foot deep now stands at 68°, and at 2 feet deep at 64°, or respectively 5° and 2° warmer than on the same day last year. On Thursday, the 3rd inst., about half an inch of rain fell, but since then no rain worth mentioning has fallen. Since the beginning of the month nearly half an inch of rain water has passed through my heavy soil percolation gauge, but less than one-tenth through the light soil gauge.—E. M., *Berkhamsted*.

Fruit culture.—The Board of Agriculture have been requested to draw the attention of fruit growers to an international exhibition, to be held by the Russian Society of Fruit Culture, under the patronage of the Czar, at St. Petersburg, in the autumn of 1894, with the object of showing the present condition of the cultivation of fruit and vegetables, of viticulture, of the cultivation of various special plants, and the manufacture of their products. A congress of pomologists will be convened simultaneously with the exhibition. The exhibition will comprise the following sections:

1, fresh fruit; 2, fresh vegetables; 3, dried fruit and vegetables, preserved or treated by other processes; 4, wine, cider, perry, and other fruit beverages; 5, hops and medical herbs; 6, seeds; 7, fruit trees and bushes; 8, horticultural implements and appliances, and technicality of production; 9, literary, scientific, and educational accessories, collections, plans, &c. Detailed regulations of the exhibition and programmes of the various competitions will be published and distributed towards the end of the year 1893. Persons interested in the progress of horticulture and pomology, both in Russia and other countries, are invited by the Russian Government to take part in this international exhibition and congress. Applications for further information should be addressed to the offices of the International Exhibition of Fruit Culture, 1894, Imperial Agricultural Museum, Fontanka 10, St. Petersburg.

NATIONAL ROSE SOCIETY.

As a very unnecessary circular from the secretaries of the N.R.S. appeared in your issue of the 5th inst., I now enclose that circular:—

NATIONAL ROSE SOCIETY.

*Coombe Road, Croydon,
July, 1893.*

SIR,

In order to obtain the views of as many members as possible on certain subjects which have been under discussion for some time past in regard to our society's arrangements, and which affect all of us who are exhibitors, I have had the questions which are annexed drawn up. I hope you will favour me with an early reply, for which I enclose a stamped envelope.

CHARLES J. GRAHAME.

1. Do you think the annual Tea Rose show at the London Scottish Drill Hall, Westminster, advantageous or otherwise to the society and its exhibitors, and would you maintain or abolish it?
2. (a) About what date do you consider best for our annual metropolitan show?
(b) Do you think Saturday the best day on which to hold that meeting, or do you think the exact day of the week immaterial?
3. About what date do you consider best for the provincial show, bearing in view that this meeting should be fixed chiefly to suit growers in late districts?
4. (a) Do you think two metropolitan shows of equal importance would be preferable to the present arrangement of a metropolitan and provincial show?
(b) Or if the arrangements for the two shows be left as they now are, would you divide the prize money more equally?
5. Do you think it would be desirable that candidates for membership in our society should go through a form of election?

No one unless intensely stupid could think the circular was official, and as to any necessity for such sanction, I repudiate such an inference. As the secretaries have thought proper to notice in public print the fact, without explanation, that I have resigned my membership of the committee of the society, I beg to say I did so early in June, and also the local secretaryship at Croydon, as I found it worse than useless to belong in any way officially to a society in which stolid opposition is offered at committees to all suggestions and propositions made in the society's best future interests by the younger members of it. It may be within your readers' recollection that in 1891, partly with the valuable assistance of your journal, I carried an important reform in the working of the society; then, as now, the most strenuous opposition was offered to my proposals, notably by the secretaries who have now addressed you. Do the secretaries think that reform could now be undone? I have no hesitation in stating that this year, as before, any reforms which the members desire will be carried at the annual meeting, and that also notwithstanding all opposition which may be generated from either a

spirit of jealousy or of red-tapeism.—CHARLES J. GRAHAME, *Hunning Hall, Briststone, I.W.*

* * We insert this at Mr. Grahame's request, but sincerely wish that exhibitors would think more of Roses and less of their shows and little personalities.—ED.

Death of Mr. Thomas Laxton.—We regret to have to announce the death of a very distinguished raiser of plants, Mr. Laxton, of Bedford, who died on last Sunday afternoon, after an illness of some eight weeks' duration, in his sixty-third year. He was well known to many of the interesting results of crossing plants whereby many notable additions to our gardens have been made, including Strawberries, Apples, Peas, runner Beans, and Sweet Peas. Among Strawberries Royal Sovereign he considered the best he had ever raised. We understand that the business will be continued by his sons under the style of Laxton Brothers.

Kainit (J. Sallier).—Kainit is a potash manure obtained from large beds of crude potash salts worked in Germany. It is a white crystalline mixture of salt, &c., and may be bought guaranteed to contain 25 per cent. of sulphate of potash. In 1 cwt. of such a sample there will be 15½ lbs. of potash—as much as there is in a ton of really good farmyard manure.

Moss-covered walks.—We have had here this season a perfect plague of the greenish olive coloured Ulva, which covers all the walks. For some years past we have had it more or less on the white limestone gravel walks, but since the rains following the great drought and heat, it covers also the blue limestone gravel in the kitchen garden. The fact that it springs up freely in one night on the limestone which has been watered with weed-killer some time previously seems to corroborate the popular notion that it comes in the thunderstorm. Can it be that the spores are carried in the thunderclouds? Does it appear on granite gravel in the abundance in which we have it? I have seen it in ferruginous sand gravel. With us it never appears on the turf, and scarcely if at all on the borders.—R. MILNE-REDHEAD, *Holden Clough, Clitheroe.*

Water bouquet (Constant Reader).—See THE GARDEN numbers of Sept. 14, 1889, p. 235; Sept. 21, 1889, p. 259, and Oct. 12, 1889, p. 340.

Names of plants.—S. H. B.—Please send better specimens; that sent was quite rotten.—H. R. J.—1 and 2, send better specimens; 3, looks like *Eulalia zelandica*; 4, *Viburnum Lantana* (the Wayfaring Tree).—T. A. J.—*Cattleya Schilleriana*, middling form.—W. Thompson.—We do not name florists' flowers.

"The Garden" Monthly Parts.—This journal is published in neatly bound Monthly Parts. In this form the coloured plates are best preserved, and it is most suitable for reference previous to the issue of the half-yearly volumes. Price 1s. 6d.; post free, 1s. 9d. Complete set of volumes of THE GARDEN from its commencement to end of 1892, forty-two vols., price, cloth, £30 12s.

"Gardening Illustrated" Monthly Parts.—This journal is published in neatly bound Monthly Parts, in which form it is most suitable for reference previous to the issue of the yearly volumes. Price 5d.; post free, 8d.

"Farm and Home" Monthly Parts.—This journal is published in neatly bound Monthly Parts, in which form it is most suitable for reference previous to the issue of the yearly volumes. Price 5d.; post free, 8d.

"Hardy Flowers."—Giving descriptions of upwards of thirteen hundred of the most ornamental species, with directions for their arrangement, culture, &c. Fifth and Popular Edition, 1s.; post free, 1s. 2d.

"The Garden Annual" for 1893.—Contains Alphabetical Lists of all Branches of the Horticultural Trade. The Lists of Gardens and Country Seats (containing over 9000) have been very carefully and extensively revised, and are admitted to be the most complete ever published. Price 1s.; by post, 1s. 2d.

All of our readers who are interested in the improvement of cottage homes are invited to help us to make **Cottage Gardening** known. It is published at the very lowest price to meet the wants of those for whom it is intended, and copies will be sent for distribution, free, by the publishers, Messrs. Cassell and Company, 1a, Belle Lane, Ludgate Hill, E.C.

No. 1135. SATURDAY, August 19, 1893. Vol. XLIV.

"This is an Art
Which does mend Nature: change it rather; but
THE ART ITSELF IS NATURE."—Shakespeare.

FLOWER GARDEN.

HARDY WATER LILIES.

It is well-nigh impossible to say too much in favour of these exquisite flowers when seen doing well. I can corroborate all that "A. H." (p. 86) says of *M. Latour-Marliac's* new seedling *Nymphaea Laydekeri rosea*, which is a gem in its way and neat in habit as compared with other kinds. It is, perhaps, the finest in colour of all the pigmy *Nymphaeas*, although *N. pygmaea helvola*, with soft yellow and orange stars amongst its red foliage, runs it pretty hard. As growing here in a cold water pond, both have flowered freely for many weeks past along with the typical white *N. pygmaea* from China, and all have passed the two recent winters entirely unscathed.

Perhaps the freest and most luxuriant of all is the sulphur-flowered *N. Marliacea Chromatella*, presumably a hybrid between *N. flava* (or *N. mexicana*) and the Bohemian *N. candida*. This has leaves of a stout olive-green tint marbled with purple or red-brown, and its flowers are soft sulphur-yellow tinted with orange in the centre. As cut from the plant and gently opened with the fingers, and then floated in a big bowl along with two or three of its own leaves, nothing could well be more lovely in the way of a flower. I have been cutting flowers of this for over two months, and still there is a new and ample supply forthcoming. The same may be said of two or three other kinds sent me by *M. Marliac*, viz., *N. Marliacea carnea* (deep rose) and *N. M. albida* (rose shading to white). These are also very luxuriant and free blooming, both leaves and flowers being very large and effective in form and colour. The true rosy Water Lily of Sweden, *N. alba rosea* (*N. Casparyi*), has not as yet bloomed here, but it is growing well, as also is the Cape Cod rosy variety of *N. odorata*, a charming and shapely sweet-scented flower. Of white varieties there are three or four at least all good and free, and none more beautiful than our native kind, which, however, varies enormously in form, size, colour and habit. In the old herbals a larger and a smaller form of *N. alba* are often mentioned and sometimes illustrated, and in a recent number of THE GARDEN mention was made of a rosy English form having been seen, as also a greenish white one, while some forms are of a creamy white, even approaching a sulphur hue. A friend who was admiring our Water Lily pond the other day assured me that he had seen a pale rosy form amongst some common white ones on the lake or tarn that is sometimes passed in

ascending Snowdon from Llanberris, but it was not of the clear deep rose of Caspary's plant from Nerike, nor even that of the dainty *N. odorata rosea* of America. *N. candida*, the glossy-leaved Water Lily of Bohemia, and *N. tuberosa* (from North America) are alike white forms, well worth a place where space is ample for their accommodation; but the finest of all the whites, perhaps, is the giant form of *N. alba* (or is it of *N. candida*?) long ago famous in the classical old gardens at Hampton Court. I saw established plants of this variety (see Thompson's "Gardener's Assistant," second edition, page 720) in Co. Wicklow the other day, and the flowers fairly astonished a Water Lily-loving friend by their size and shape. The foliage was also most remarkable, and, if memory serves me rightly, I believe this variety is grown at Oxford under the name of *N. candidissima*. Can the name be a mistake for *N. candida*? I ask this because it is a name quite common in gardens, as at Oxford and Cambridge and elsewhere, but it is not to be found in books or dictionaries. I hope all travellers who are fond of aquatic plants, and of *Nymphaeas* in particular, will observe any kinds they may come across very closely, since forms varying in size and in tint are not uncommon, and some varieties are earlier, later, or more free-flowering than are others. The only drawback to Water Lilies is their slowness in establishing themselves unless on a deep rich bottom. They are much benefited by a rich mulching of river or pond mud and cow manure, and even by the addition of liquid manure to the tank or pool in which they grow. The rosy varieties especially never show their best form and deepest colouring until thoroughly at home in the mud below, say the second or third year after planting. The present season has been a most favourable one for these and most other aquatics, and if we could look forward to other years as sunny and as warm, we should not despair of establishing some of the sub-tropical *Nymphaeas*, such as *N. thermalis* and *N. coerulea*, even if not the hardier Japanese and American varieties of the princely genus *Nelumbium*.

A pond is not always an absolute necessity for the enjoyment of these lovely flowers. At Easton Lodge I lately saw several large pots full of *N. alba* plunged in a little cement tank only 18 inches or so in depth, and they were flowering freely. The late Rev. J. Ellacombe used to grow a collection of *Nymphaeas* and other aquatics in tubs in an enclosure near to a pump that supplied the water. There are three kinds at least, viz., *N. pygmaea* (white), *N. pygmaea helvola* (yellow), and *N. Laydekeri rosea* (rose-pink) that could be grown in any tub or large bowl in a foot of water and 6 inches of rich mud and sand.

The enemies of Water Lilies are water rats or voles, and swans and other aquatic birds often pull them to pieces, but the plants can be protected with wire netting. Wherever there are pools or lakes and ponds near the house the careful introduction of Water Lilies and other aquatics will yield a charm

not easily attainable in other ways, and once well planted they will increase in beauty and interest from year to year. F. W. B.

INTERMEDIATE STOCKS.

THESE are extremely useful and showy plants, but, as far as the south of England is concerned, not so much employed for the decoration of the flower garden as I think they deserve to be. The general plan is to have intermediate Stocks in pots for house decoration, and while extremely useful in that way, it appears to limit their capacities for floral decoration, as when a good strain is employed they make charming fragrant beds in May and June and remain in bloom for a considerable period. They have been termed "spring Stocks," and the designation is an appropriate one.

We have very fine strains of white and scarlet intermediate Stocks, the former especially, in cultivation at the present day; the purple is also to be met with in good character, but it is not so plentiful as the other two. When employed for house and window decoration, one method of raising plants is to sow in August or early in September, using a fine and rather light rich soil, placing four or five seeds in a pot and plunging them up to their rims in ashes in a cold frame with a glass covering; then when large enough the plants are thinned out to three, or the pots can contain more or less according to their size. Some sow in boxes, and when the plants are large enough they are potted singly into small pots. Shifted into $\frac{4\frac{1}{2}}$ -inch pots and bloomed in them, when well managed and in good soil fine heads of flower are obtained.

Some plant their intermediate Stocks out in beds. They are very gay while they last, and in the case of a good double strain the bloom continues for some time, and they can then be succeeded by dwarf Asters in bud, as the last-named come into bloom quickly and take up the floral succession at once and carry it on until the autumn. Or the Stocks may be planted with some coloured *Viola* which will contrast well with them, and when the Stocks have done blooming, they can be removed and the *Viola* will fill the bed.

The most valuable section of bedding Stock is that known as the East Lothian Intermediate. By sowing early in March under glass, such as a cold frame, and taking care to sprinkle the seeds thinly over the surface so as to avoid much thinning, the plants may remain in the seed-beds until they are planted out to bloom in autumn, care being taken meanwhile to keep them as stocky and robust as possible. Care should be taken to transplant them with good balls of soil, and if properly planted in the beds, they will flower in August, September and October, and, given a mild autumn, up to November. This is the method usually adopted in the north, and I have seen lines of the East Lothian Stocks in grand bloom at the end of August. In the south, where they will stand better than in the north, they can be sown a little later, and, duly planted out, in a favourable season they will bloom in autumn and again in spring if they survive the winter, and they seem to be of a hardier character than the Bromptons. The colours of the East Lothian are crimson, scarlet, white and purple. A strain of the latter distributed by Mr. John Forbes, Buccleuch Nurseries, Hawick, is very fine indeed, as could have been seen at the Chiswick gardens of the Royal Horticultural Society this summer.

Stocks must have good soil; the richer the soil the more finely do they bloom and the more brilliant are their colours. The ground should be deeply dug and well manured. The roots of Stocks travel for a considerable distance downwards; hence the advantage of having the soil deeply stirred. R. D.

Zonal Pelargoniums at Chiswick.—One of the more interesting features in the Chiswick gardens this year is a collection of zonal Pelargoniums,

each variety planted side by side in rows, thus affording opportunity to make comparisons. It is not often one gets such a "trial" of this peculiar bedder, but such a representation of the zonal Pelargonium is worthy of note. The double varieties are of small account for the open, and against the singles make a conspicuously poor display. This class has received many fine additions of recent years, the individual flowers of perfect shape, and borne in large, heavy trusses. It is not easy to describe the colours of the flowers in the blaze of varied hues presented to the eye. A few of the finest in the collection we carefully selected, some well known, others comparatively scarce. W. B. Miller may be described as vivid crimson, a peculiarly brilliant shade, the flowers individually of large size. One sees a number of kinds of the Henry Jacoby class, such as General Outram and Dr. Orton. A brilliant kind is Ayesha, the flowers bright rose-crimson, and held well up. An exceptionally fine type is Gen. Quinot, pure self salmon, a clear shade and bright. A fine crimson is Col. Seeley, with a white eye that adds to its lustre. One of the best in this large collection is Charles Mason, which produces a neat bold truss of scarlet flowers set off by a small white central eye. Rev. F. Hay produces a splendid truss, the flowers individually pure scarlet, and another fine scarlet kind is Fournaise, very rich and striking. That fine Pelargonium Souvenir de St. Amand is well represented, and both in pots and in the open this variety shows to advantage. It is one of the most distinct in the whole collection. Ouida, brilliant scarlet, is also good. Also worthy of cultivation are Mrs. Miller, pink; Armand de Pontmartin, lilac; La Lorraine, rosy lilac; Amy Amphlett, white; Mrs. Pearson, orange-scarlet; and Col. Colville, purplish crimson. The majority of the plants, except the doubles, which require pot culture to develop their true beauty, are in full bloom, and those interested in zonal Pelargoniums would find a rich assortment of the best kinds at present in cultivation.

Tufted Pansy Bluebell.—It is very interesting to find that at Hampton Court this fine old Viola is still more largely grown and used than any other. Whether mixed with silver variegated Pelargoniums, with which the blue flowers so pleasingly harmonise, or whether associated as an edging with that pretty silver Grass, *Dactylis glomerata variegata*, Viola Bluebell is beautiful, blooming most profusely, and could not in effect be excelled by any other even ever so new. It speaks volumes for the old variety that it should be grown far more than any other almost universally, for I see it constantly in cottage and villa gardens; indeed, it crops up everywhere. For growth, freedom, and size of flowers it is still one of the very best of tufted Pansies, and will long be grown.—A.

Begonias as bedders.—Whilst closely planted masses of these popular flowers almost invariably fail to produce a very pleasing effect, yet when the plants are put out thinly on to some suitable carpet they are charming. A large bed at Hampton Court edged with Mrs. Pollock Pelargonium and Iresine Herbsti intermixed has the centre of large crimson-flowered Begonias, all specially selected to match in colour, intermixed, but thinly, with white-flowered Fuchsias, each plant standing separate from the other, and on a carpet of *Koniga variegata* and mauve Viola Mrs. Turner. This is so far from being a stiff, formal bed that it excites much admiration. Large white Begonias intermixed with creamy Zinnias and mauve Violas are also very pleasing.—A. D.

Lilies in the north of England.—After reading the interesting article by "J. C. L." in THE GARDEN, July 29, it occurred to me that a few notes on Lilies as grown in the north of England might be acceptable. This garden slopes to the south-east, nearly 800 feet above the sea level, stiff loam full of stones, an ideal soil for Roses, which flourish better than the Lilies. *Lilium candidum* does only fairly. White and common Martagons well; the white likes a little shade. *L. chalcedonicum*, *croceum*, *davuricum*, and the old-fashioned yellow

Turk's-cap flourish and increase fast. One bulb of *pardalinum* is now a large clump and flowers well. *Pomponium verum* has increased in the same way, and has more flowers. The Tigers do well both in the border and in a made peat bed, where I have also in a flourishing condition double *Thunbergianum*, pink and white *speciosum*, *canadense*, and *Szovitzianum*. One bulb of *L. testaceum* planted eight or nine years ago in loam is now a clump with eleven stems. Last year they stood 6 feet high; this summer the drought (the greatest in the memory of the oldest inhabitant) has kept them shorter. *L. superbum* is now (August 1) bearing two great heads of bloom on stems over 5 feet high. Now for the failures. *L. Humboldtii*, *Batemanna*, and *auratum* are dead, but I mean to try them again. *Krameri* has come up two years in the peat bed, but only to a height of 6 inches. *Browni* is the same this year; last summer it was the glory of the garden with a large head of flowers. I may add that no Lily here has ever been protected (and the last three winters have been arctic), except that the shrubs in the peat bed are some small protection to the young shoots in spring.—M. P. F., *Ullswater*.

DURATION OF LILY BLOOMS.

OWING to the hot and dry weather the individual blooms of the different Lilies did not remain long in beauty unless exceptionally situated, but whether exposed to the full sunshine or protected from it, some species retain their freshness for a very much longer period than others. The bulk of the earliest Lilies in the open ground consists of those with erect blossoms, corresponding with the sub-genus *Isolirion* of Mr. Baker, and as a rule they do not remain long in beauty. This feature is especially noticeable in *L. davuricum* or *L. umbellatum*, as it is often called, different forms of which are commonly to be met with. They are very bright and effective when first expanded, but soon become dull, though the petals do not drop for some little time after the change in colour takes place. The dwarf *L. elegans* or *Thunbergianum* is very prolific in varieties, and some of the red ones, notably *bilugulatum* and *sanguineum*, change as quickly as the forms of *L. umbellatum*. The richly tinted *Van Houttei*, illustrated in THE GARDEN, November 8, 1890, retains the brightness of its colouring much longer than those above-mentioned, while the yellow varieties, such as *alutaceum*, *Prince of Orange*, and *Alice Wilson*, change but very little before they drop. Two species of this section stand out as especially noteworthy by reason of the length of time that the flowers remain in perfection. They are *L. bulbiferum*, that flowers much about the same time as *L. davuricum*, but the blooms are brighter and remain in beauty for a very much longer period, and above all the old *Orange Lily* (*Lilium croceum*), a clump of which with me has been in flower from the middle of June to the end of July. Not only has a succession of bloom been maintained, but each flower retains its beauty for such a long time. This is certainly one of the best ordinary garden Lilies that we possess, as apart from its other features the blossoms are of a very bright and effective tint. Some of the members of the Martagon or Turk's-cap group have petals of unusual substance, and they all remain in good condition for a longer period than most Lilies. The yellow-flowered *L. Hansoni*, the Black Martagon (*dalmaticum*), and especially *L. chalcedonicum*, which is commonly known as the Scarlet Martagon, are all good lasting Lilies. *L. chalcedonicum* is, however, the best of them all in this respect, for the blooms remain in beauty a very long time, and that, too, during what is generally the hottest period of the year, for its usual period of blooming is during the month of July. The small, but prettily reflexed and brightly coloured blossoms of this Lily are very beautiful, and it should certainly be more generally planted than it is. In common with many others, it will seldom flower much the first season after planting. *L. Leichtlini*, a pretty pale

yellow flower, plentifully dotted with brownish red, remains fresh for a considerable time, while there are several of about an average duration. Under this head must be included such kinds as *L. auratum*, *L. longiflorum*, *L. tigrinum*, *L. testaceum*, *L. Batemannia*, *L. Browni*, *L. canadense*, *L. Szovitzianum*, *L. pardalinum*, *L. Krameri*, *L. Humboldtii*, and others. The most conspicuous of all the varieties of *L. auratum* is the red-banded *rubro-vittatum* or *cruentum*, which when the blossoms are first expanded is wonderfully bright and effective, but the coloured portion soon changes to more of a dull brownish hue, and it is then not nearly so attractive as at first. From the fact that they do not flower till the summer's heat is as a rule a good deal abated, all the varieties of *L. speciosum* remain in beauty longer than many of those that bloom earlier in the season, for towards the end of August or in September and even October they remain fresh for a very long time. The new *L. Henryi* has much the same substance as *L. speciosum*, and lasts about as long as that does. The stately *L. sulphureum* (the once *L. Wallichianum superbum*) is one of the later blooming Lilies and a good lasting one, but the most noticeable in this respect of all the tube-flowered group is the *Neilgherry Lily* (*L. neilgherrense*), whose long, tube-shaped flowers are of a thick, wax-like substance. This is particularly noticeable for its large massive flowers, often borne on comparatively short stems, the late season at which it blooms, that is, the three last months of the year. The short flower-stems frequently met with in this Lily are caused by the fact that in some individuals the stem, after leaving the crown of the bulb, proceeds in a horizontal or even downward direction for some little distance before it appears above ground, and when it does so the flower-stem is sure to be short. In pots the stem will often go to quite the bottom of the pot and come up on the side directly opposite to that where it went down. In speaking of Lily blooms, one curious fact may be noted with regard to some forms of *L. Washingtonianum*, and that is when first opened the flowers are white or nearly so, but they quickly change to a purplish hue. H. P.

CARNATIONS IN PAPER COLLARS.

THE methods adopted by exhibitors of Carnations of showing the flowers they grow so well are mostly very poor and formal, tending to detract from the beauty of the flower, but the most ridiculous of all is that of showing Carnations with paper collars round their necks. The only wonder is that a storm of ridicule and abuse does not arise and put a stop to the whole thing, for a small body of florists would hardly continue the practice if those who provided the main support of their society made a strong protest against it. We visited the recent Carnation show, and found quite half of the flowers set up in this way. A society that permits, in fact encourages, this does nothing to benefit Carnation growers at large. In its full force of colour in the garden, the Carnation is ahead of the Rose if one grows the fine self kinds in bold masses, but no one would dream of this or form the slightest idea of its value as a garden flower from visiting the London Carnation show. One of a flower's charms is its individuality, but the florist allows none of this. He has a fixed ideal in his own mind to which the flower must conform, and whether he is showing twelve or twenty-four or any number of kinds, he puts each one in a paper collar, and with his tweezers proceeds to manipulate the flower, laying out the petals one by one till he has made the flower come as near as possible to his self-created standard of supposed perfection. There is no secrecy nor attempt to disguise the fact, for one has only to go to the show during the early morning hours to see the thing performed. It is all a part of the wretched tenets that bind the florist to his narrow ways. He tries to justify the practice by claiming that it sets forth the flower and better displays the marking on the petals of the flaked and bizarre kinds. It is wrong, however, to give these undue

prominence, as the important kinds are the selfs. These, too, though they have no stripes, whatever their colour, whether red, rose, white or purple, all are enclosed in the inevitable white collar and set out on green boards without a scrap of foliage of their own. If flowers are shown, the least we may ask is to see them as they grow, and then we can judge them truly on their merits. No flower is worse treated than the Carnation, and the whole proceeding is so simple and childish as to be unworthy of notice but for the serious attention that many give to it. If no actual harm is done, it misleads the general public and shows them a fine flower in a false and stupid way.

FLOWER GARDEN NOTES.

CARPET BEDDING.—Although it would seem that this particular style is gradually dying out, yet the fact that both in public and private gardens occasional beds are still met with testifies to a slight demand, "just," I have heard it remarked, "for the sake of variety." If anything of the kind is attempted, it should be thoroughly well done, and as beds will now be about at their best, notes may be taken of specially good points and of errors in judgment, for it must be remembered that good carpet bedding does not simply mean that these particular beds should be well filled and nicely kept, but that sound taste must prevail in the original construction of the bed, the aim being to avoid on the one hand splitting it up into too many lines and patterns, and on the other too great a preponderance of any given colour. In this latter matter one sees, for instance, tiny patterns that are utterly worthless for producing any effect dotted very sparingly on a heavy groundwork of green or yellow. Again, it seems a pity now that the rigid adherence to a perfectly flat surface is at an end, and we have a free and welcome use of dot plants to insist on the prompt and entire removal of all flowers from succulents, where at any rate these are employed on or towards the centre of beds. As a slight instance, let us imagine a large bed in which two large stars on a groundwork are the main idea. The centres of these stars might consist of *Echeveria glauca* in flower, and the points of *Iresine Wallisi*, whilst if the variegated *Mesembryanthemum* was employed for the groundwork of the bed, any bright patterns of say *Alternanthera amena* in the same might also have flowering *Echeverias* as centres. They are also very pretty and effective on a groundwork of *Herniaria glabra*. As a set off against this I should like to draw attention to a few beds just now in good trim that are making a grand show at a minimum of expense. A 5s. packet of seed has given us three large beds of Margaret Carnations; planted at a foot apart they have furnished the ground well, and are throwing up a fine lot of flowers in many shades of colour. This new race is a great boon to all who have not the time to spare or object to the initial expense of choice named border varieties, and although they cannot hold their own in the way of individual beauty with such choice things as Countess of Paris, Ketton Rose and the best of the Cloves, some excellent flowers are produced from each packet of seed, and the plants are invariably free and vigorous in habit.

I suppose of all bedding plants *Violas* make the finest show at the least possible cost. Their employment together with suitable herbaceous plants for large beds has been previously recommended. Let me just give an instance or two of their effectiveness when so employed. Four large beds were thinly planted (at intervals of 4 feet) last autumn with nice little clumps of the variegated *Spiræa Ulmaria*, with *Statice latifolia*, *Zauschneria californica* and *Lobelia cardinalis*, and in the early spring were filled in respectively with *Violas Archie Grant*, *Ardwell Gem* (a lovely pale yellow), *William Niel* and *Countess of Kintore*. The perennials have not shown quite their true form in this exceptionally dry season, but the four beds are bad to beat, and are likely to bear testimony

to the fine and long-sustained summer display that can be secured with the aid of such materials. I thought of trying next season in a similar manner the white *Antirrhinum* with *Illuminator Viola*. Writing of *Antirrhinums* reminds one that this as well as many other perennials may be sown at the present time if there is a desire to increase existing stock in this manner. It is not necessary to do this every year, as some very good things are obtained from a packet of seed, and these can the next year be increased by cuttings or division as the nature of the plants requires. All hardy plants can be sown if necessary on the open border, but it is just as well to give them the benefit of a frame if there is one to spare; any trouble with birds is thereby avoided, and the soil can always be kept in just about the right condition for the quick germination of the seed and consequent development of the plant. If the Snapdragons are wanted for purely bedding purposes—that is, to form lines or patterns, the Tom Thumb varieties of *A. majus* will be found most serviceable. If *Myosotis* and *Silene* are likely to be required for any special spring display, they can be sown thinly on a shady border. Both these annuals, however, are now more generally used in outlying parts of the pleasure grounds, bulbs, *Polyanthus* in variety, the choicer strains of Wallflowers and *Violas* having taken their place in the immediate neighbourhood of the mansion. A good batch of Sweet William is always acceptable. If seedlings are ready and the ground not yet prepared for their reception, they can also be pricked out on some shady border ready to be transferred to their permanent quarters. It may be as well to remind those who are likely to want a good supply of cut flowers early in the year that good *Daiffodils* seem likely to be obtainable at low prices, and there are few things more easily grown or more appreciated. At the expenditure of one guinea or something like it, 100 each of those useful varieties, *obvallaris*, *princeps*, and *Stella*, can be secured sufficient to furnish a goodly supply of successional bloom for cutting.

E. BURRELL.

Claremont.

The Purple Coneflower (*Echinacea purpurea*).—This is subject to such an amount of variation when raised from seed, that an erroneous impression might be formed concerning it. The variations are not merely of a slight character. I remember seeing a batch of seedlings in flower in Mr. Thompson's nursery at Ipswich, and there was a variety of forms even to an extreme degree, some quite inferior with narrow petals which reflexed, and others having long, broad petals spread out into a bold, showy flower. I had a similar experience when raising the plant from seed. The only way to increase it in its finest form is by division.—A. H.

A new Lily.—Since writing the note under the above title on page 98 I have had an opportunity of seeing numerous examples of this Lily in the hands of different cultivators, and also of perusing Mr. Baker's article thereon in the *Gardener's Chronicle*. It is by Mr. Baker regarded as a variety of *L. japonicum* of Thunberg under the varietal name of *Alexandria*, and its supposed hybrid origin is passed over. Still, I cannot agree with Mr. Baker where in speaking of *L. japonicum* he says *L. Krameri* and *L. Barriannum* are forms of the species with pale red flowers. I know nothing whatever of *L. Barriannum*, but between this new Lily and *L. Krameri* there are very few points in common except that they both belong to the same section of the genus. Neither in bulb, foliage nor flower do they resemble each other in the least. After an examination of the numerous examples that have come under my notice I am still further convinced of the hybrid origin of this Lily, as there is a considerable amount of variation to be found among different individuals, some showing a greater leaning towards *L. longiflorum* and others to *L. auratum*. Not only do the leaves vary in size and disposition on the stem, but the flowers differ a great deal from each other. In

some the tube is short and the flower widely expanded, while in others it is longer and narrower and altogether more of the *longiflorum* shape. While in most cases the anthers are brown, examples occur in which they are of a deep yellow tint, not very much removed from some forms of *L. longiflorum*. In some the greenish shade extends much farther over the flower than in others, while occasionally a flower with a pinkish tinge on the exterior may be found.—H. P.

MARKET GARDEN NOTES.

RUNNER BEANS.—When these make 14s. per bushel in the last week of July, it is a sure sign that the yield generally is very deficient. As a fact I have never seen the field crops which furnish the London markets look so bad. Even where the ground is subjected to high culture the plants are stunted and incapable of giving any quantity of Beans. Should we get copious rain during this month and frosts keep off in September, there will undoubtedly be abundant supplies during the early autumn, otherwise Runner Beans will remain dear. Even at a very moderate price this esculent pays well in a favourable season, as the plants yield for a period of three months, and a large amount of Beans can be taken from an acre where the ground is well cultivated. This season, however, in spite of the much higher prices obtainable, the yield is so light, that the extra money will not compensate for loss of bulk. It is curious, too, that whilst vegetables generally have been this season earlier than usual, Runner Beans are rather later.

ONIONS.—These on our light Surrey lards are a failure. Here and there one may see a very moderate crop, but in a general way there will not be enough taken from the ground to pay expenses. From twenty acres of land one grower will not get more than twenty bushels of Onions. The weather being so parching, the young plants could not get into free growth and were eaten up by maggots. When June happens to be very dry we rarely get good Onion crops, and this year the heat and drought during that month were phenomenal. From the time the seed was sown up to the end of July we did not get enough rain to moisten the soil more than an inch in depth. Even where the grub has not been so destructive the Onions are small in comparison to what they would have been with more moisture in the ground. In localities specially favourable to Onions where the maggot is not destructive, the bulk of produce taken from the ground will be much under average, and prices for Onions this coming winter will undoubtedly be considerably higher than usual.

WINTER GREENS.—The few showers we have had during the last fortnight have been very welcome, rendering the planting out of large breadths of Coleworts and other winter greens easier and more satisfactory than has hitherto been the case. With the ground in a dust-dry condition and no means of watering, the plants were quite as well, or even better, in the seed beds until the rain came. *Brussels Sprouts* put out for early gathering a month or more ago will be almost as late as those planted since the change of weather. Some that were put out in the beginning of July looked a week afterwards quite shrivelled up; they seemed to have hardly a vestige of green leaf left to them. The Cabbage tribe has wonderful powers of recuperation, but such a severe check at planting must have an influence on the crop, retarding progress and lessening its value.

CUT FLOWERS.—The intense heat has brought on hardy flowers employed for cutting so rapidly, that the London markets must be poorly supplied during September and October. Many things that are relied on for giving a lot of bloom during the coming month will be over by that time; herbaceous *Phloxes* will soon be over, and even *Michaelmas Daisies* and some of the perennial *Sunflowers* are being brought into market at the present time. Early flowering *Chrysanthemums* are a month

before their time, and will be past just when in ordinary seasons they are in full bloom. If September frosts keep off there will be plenty of Dahlias, but if they should be cut off early in the month, there will be little in the way of cut blooms in the open to take to market. Up to the present this has been a fine season for those who make a speciality of Dahlias. The plants came into flower some weeks earlier than usual, and where they were put out in good time and well cared for, a large quantity of bloom has been taken from them. One of the very best things for cutting is the Gaillardia. Plants raised from seed give some little range of colour, and the more they are cut from the more they bloom. The newer varieties have been much in request this summer. Iceland Poppies are also greatly in favour, and both these and Gaillardias have stood the heat and drought very well. When sent to market, however, the former must be cut just before the blooms are quite expanded or they shatter. J. C. B.

ORCHIDS.

TWO COOL HOUSE VANDAS.

(V. AMESIANA AND V. KIMBALLIANA.)

I AM much interested in these two plants, having seen the former when it first flowered. Afterwards I saw V. Kimballiana when it first bloomed in Mr. Low's nursery at Clapton. Mr. Boxall, who collected these plants, says he got them in the Shan States, on the north-eastern boundary of Burmah. They grow mostly on rocky prominences, and also on trees at some 4000 feet to 5000 feet elevation. Consequently the plants grow far better under cool treatment, but not so cool, I think, as some of my friends try to persuade me. Mr. Boxall informed me that the ground is frequently covered with hoar frosts in the early morning, but I do not urge my friend Mr. Gibson to try to imitate such a condition of things with these plants under cultivation. We know that many plants thrive with us under very different conditions to what they are subjected to in a state of Nature. I saw in Mr. Low's nursery V. Kimballiana in very fine condition and flowering most profusely, whilst at the same time of year I saw in a gentleman's garden some plants out of the same batch, and some of the best pieces too, that had been treated as East Indian Vandas. The latter plants apparently had not recovered from their journey, and had but a poor spike or two of bloom; whilst those plants left with Mr. Low and treated as Odontoglossums were perfect pictures of health, bearing many spikes, and some of these carrying twelve flowers. I advise both these plants to be grown in the warm end of the Odontoglossum house, giving them an abundance of water during the summer season, but reducing the quantity considerably in the cooler weather. Drain the pots well, filling up with clean and sweet Sphagnum Moss, and do not let the plants suffer from want of moisture in the resting season.

V. KIMBALLIANA, of which a coloured figure appeared in THE GARDEN of April 9, 1890, is a beautiful plant. It was dried to such an extent upon its arrival, that many took it for a plant having terete leaves. The peduncles are axillary, and bear from six to twelve flowers, which in the sepals and petals are pure white; the lateral sepals are a great deal the larger and sickle-shaped. The lip is large, the side lobes small, yellow, spotted with reddish brown, the middle lobe large and flat, of a bright rich amethyst-purple, having a long incurved purple spur.

V. AMESIANA.—The Messrs. Low had but a single plant of this species when it first flowered in their nursery, and it was figured in the "Orchid Album," t. 296. Curiously enough, when next it came to them with V. Kimballiana the plants appeared more robust and fuller of roots. Although the flowers vary considerably in colour, I have never seen any so richly marked as those of the plant that found its way to Mr. Ames' collection in America. It, like the above, makes leaves that are deeply channelled on the upper side, rounded below, and pale green. The spikes are erect, bearing many flowers, which are very fragrant, the sepals and petals white-rose or rosy purple, the lip being rose. In some varieties this colour is quite absent, and this form gets the name of alba in gardens, and a form with the lip stained with rosy mauve I have seen called lilacina. WM. HUGH GOWER.

Cattleya citrina aurantiaca.—This is a new variety of the well-known old Mexican species, having quite a novel appearance. In addition to being so distinct in colour, the sepals and petals are spreading, less fleshy or waxy than usual, nearly equal, and pale lemon-yellow in colour. The side lobes of the lip and basal part are deep lemon-yellow, and have several raised lines from the disc to the front, of a very deep orange-yellow, the front of the lip being of the same hue. The plant, I am told, is quite undistinguishable in its growth from the type, but the flowers are quite different; so much so, that I failed to recognise them at first. It was sent to me from The Woodlands collection at Streatham.—W. H. G.

Cattleya Dowiana aurea Statteriana.—This beautiful form first flowered in the grand collection brought together by Mr. J. Statter, of Whitefield, Manchester. It is a superb and showy variety of the typical plant, having sepals and petals of a soft creamy white, the large three-lobed lip being soft crimson-magenta on the front lobe, streaked with distinct lines of rich gold.—*Orchid Album*, t. 468.

Lælia Schilleriana.—"W." sends a flower with a question asking if it is not *Lælia elegans* Schræderæ? I am totally unacquainted with such a variety. The flower sent is none other than a very good form of the kind named above. I am somewhat surprised at seeing it at this season of the year, for it generally flowers during the late spring or early summer months; the sepals and petals are light, and the lip is similar to that of the typical form of *L. elegans*, of which it is generally considered a variety, but from which I distinguish it at once by its middle lobe not being clawed, as in *L. elegans*.—W.

Aerides Sanderianum.—This very gorgeous plant is now flowering very freely in the nurseries at St. Albans. It is quite as vigorous as the noble *Aerides Lawrenceæ*, of which it is but a colour variety. It varies in nothing but the ground colour of the flowers, which in the variety now under consideration is of a soft shade of yellow, whilst in *Lawrenceæ* the ground colour is waxy white. The flowers of both plants are very fragrant. We are told that these two plants often grow together with *Phalenopsis Sanderiana* and *Vanda Sanderiana* in the island of Mindanao.—W.

Cymbidium eburneum.—This plant, figured in the "Orchid Album," t. 467, has deliciously fragrant flowers. It first flowered in English gardens in 1847, and it remained rare and expensive until 1875, when Mr. Williams imported some in very good order. He also received word from his collector of the conditions under which the plant existed in a state of Nature, and from that time the plant has grown well and flowered profusely.

Cattleya Gaskelliana.—I have before me sundry flowers from readers of THE GARDEN, and it really is quite astonishing to note how much the flowers vary, some of them being quite worthless. G. Hubbard sends a very good variety which reminds me much of the form which I used to know by the name of *labiata pallida* in years gone by. The

flowers are nearly 7 inches across, the sepals and petals broad and full and deep rosy lilac in colour, lip large, prettily undulated round the edge, and margined with rose, ground colour of the front lobe creamy white, with a large broad apical blotch of rich magenta, and a citron-yellow throat, which makes up a flower of great beauty. C. James sends three flowers of as many varieties that do not require special comment, they being all fair ordinary forms, and Mr. Broome, from Llandudno, sends a very handsome flower, but nearly destitute of colour in the lip, which I cannot call a good variety. H. Johnstone sends me the pure white, known as *C. Gaskelliana alba*, the flower of which is wholly pure white saving the throat, which is clear soft yellow.—G.

Sobralia Sanderæ.—This in growth somewhat resembles *S. macrantha*, but I am told it is from a quite different region. The flowers are large, having a full spreading lip, and, like the spreading sepals and petals, are of the purest white; the white lip is prettily frilled, and the throat is a rich yellow. The plant is quite different from the variety which I noted from Mr. Hardy's collection at Timperley, Cheshire.—W. H. G.

Aerides Warneri (G. B.).—This is a rare old plant now seldom seen. I do not know from what district it was brought. It is quite distinct from *crispum* by its ascending leaves and by its slender stem. The flowers, however, very much resemble those of *A. crispum*. "G. B." may send me as many flowers as he likes, but I do not wish him to wait until he can send a whole spike intact, as in the present case. I should very much like to see the *Aerides* and *Saccolabiums* again become popular, as these plants are extremely showy, pleasing and ornamental, yielding also a delicious perfume.—W.

SHORT NOTES.—ORCHIDS.

Lælia elegans leucotata.—This is a sterling novelty, which I recently saw at Mr. Measures', The Woodlands, Streatham. In growth there is little or nothing to distinguish it from the typical *L. elegans*, but the flower, as its name implies, is of the purest white.—G.

Cypripedium callosum Sanderæ.—This is a very beautiful variety. It has the depressed petals of the typical plant, but the whole flower is of the purest white, saving the green veins, which in the dorsal sepals are very conspicuous. It is a flower possessing much grace and elegance.

Cattleya Trianae Regina.—This is at once a neat and showy kind. The variety originated at Holloway, but is now in the collection of the Hon. F. L. Ames, of Boston. It is one of the most chaste varieties of *C. Trianae*, the whole flower being pure paper-white, saving the large stam of purplish magenta and pale yellow in the throat.—*Orchid Album*, t. 466.

Cattleya Sanderiana.—Two remarkable flowers of this variety come to hand from Mr. Wilkinson. They are not remarkable for their size, but this will doubtless improve, for the sender says the plant was divided last year. The colours are exquisite, the whole lip being intensely deep coloured. I should like to see this variety next season and in fresher condition. I have never observed so deep a colour before.—W.

Odontoglossum Edwardi.—This (figured in the "Orchid Album," t. 465) is a very distinct and handsome species. It was discovered by Edward Klaboch, a nephew of the world-renowned Roehl. The plant flowered for the first time in this country in 1880 under the care of Mr. Osborne, when he had charge of the very fine collection brought together during the life of the late Mr. H. J. Buchan, of Southampton.

Cattleya Schofieldiana.—"W." sends me a very good variety of this plant, which some authorities reduce to a variety of *granulosa*. It is a grand plant, having large flowers, which have a ground colour of tawny yellow in the sepals and petals, flushed with greenish purple and profusely spotted with crimson, side lobe of the lip white, the large front lobe clawed, of a bright magenta-purple, thickly set with little papulae. It is a beautiful and showy flower.—W.

SYDENHAM, NORTH DEVON.

SYDENHAM is situated about seven miles north-west from Tavistock and eight miles east from Launceston, and is, therefore, close to the borders of North Cornwall. The drive from Coryton (the nearest railway station) is a delightful one, leading through woodlands and pleasant meadows, fringed with wooded slopes. An ideal wayside cottage is passed on the road, such as would delight the artist in search of a picturesque subject. The porch is smothered with fragrant Honeysuckle (just now in full bloom), while Roses and Ivy almost cover the rest of the building, which is made still more attractive and cheerful by bright-coloured Gladioli, Phloxes and other flowers close to the drive. A shady wood is passed next, and through openings are obtained every now and then delightful glimpses of scenery, with fertile

Sydenham has an interesting history. The oldest portion of the building is so old that no record of its construction can be traced, but the greater portion was restored and partly rebuilt in the Elizabethan style about the year 1600 by Sir Thomas Wise, who died in 1629. In the accompanying engraving the oldest part of the house is that seen on the left. The enormous old window lights up a grand old staircase, with balustrading of carved Oak. Adjoining is the spacious dining-room, being probably the oldest room in the house. The walls are panelled with carved Oak, blackened by age and decorated by inlaid work of unique design. The magnificent fire-place in the hall was added in the year 1656 by Sir Edward Wise. During the civil war the mansion was garrisoned for the king, but was taken in 1645. It is probably after that date that the more modern smaller windows in the right

bourhood. The walls on this side are covered with several kinds of creepers, some of them of considerable size, viz., Cluster Roses, Magnolia grandiflora, Forsythia viridissima, yellow Jessamine, and Ivy.

The opposite side of the house, i.e., the south-west front, is depicted in the engraving. The climbing plants covering the walls are Crataegus Pyracantha, Kerria japonica, Clematis Jackmanni, Virginian Creeper, Roses of several kinds, notably Gloire de Dijon and white Cluster. Over the door in the centre are festoons of white Jessamine, and the receding wall to the right is clothed by a huge Wistaria sinensis, Everlasting Pea, Pyrus japonica, Clematis, Escallonia and others, all combining to form a delightful picture. Hardy Fuchsias and Yuccas are planted on each side of the steps leading from the central door to the formal garden.

Sydenham House, Devon. Engraved for THE GARDEN from a photograph by Mr. Hayman, Launceston.

meadows traversed by the river Lid on one side of the road and steep hills covered with stately Oak and other timber on the other side. Here and there an Abies Douglasi, Silver Fir or Copper Beech stands out prominently among the Oak and Beech composing the main body of the wood, and an undergrowth of Hollies, Ferns, Hazel and Rhododendron is kept just sufficiently light to admit of a charming peep between the trees at frequent intervals. Near the corner of a branch road is the quaint little gardener's cottage nestling among the trees. The building is covered with Ivy, Jessamine and Cluster Roses reaching up to the thatched overhanging roof. The small garden in front is bright with standard Roses, Dahlias, &c. A little further on an avenue of stately Elms, the age of which must be several centuries, leads up to Sydenham House.

The owner kindly conducted me over the most interesting parts of the house and grounds.

wing of the house (as seen on the illustration) were constructed. The Tremayne family came into possession some time after the death of Sir Edward Wise in 1675. In 1736 the iron gates of the main entrance were erected. They are immediately opposite the avenue of Elm trees referred to above, and from here a broad gravel path some 40 yards in length leads in a straight line through a square lawn and over granite steps to the front door on the north-west side of the mansion. The ground plan of the house is in the form of the letter E, and two beds of Begonias on each side of the steps are of the same pattern; four other flower beds on this small lawn are also of angular shape, but in the form of the letter I, edged with Box and planted with Verbenas in distinct colours. The portico, which bears the family crest, is built of granite from the tors of Dartmoor, but the main building was erected with stone of a slaty nature found in the neigh-

The south-east wall of the mansion is covered by two huge horizontally trained Pear trees, viz., Swan's Egg and Duc d'Orange. On one of these trees (which is seen on the illustration) I counted over forty pairs of horizontal main branches which had evidently been trained with faultless regularity.

The formal garden, from the centre of which the view here depicted was taken, is surrounded by a wall about 7 feet to 8 feet high, and forms a square about $1\frac{1}{2}$ acres in extent. Unlike many so-called formal gardens of the modern type, this does not contain a single feature which is not strictly in harmony with its ancient surroundings. Here no modern flower beds of the wall paper pattern have been allowed to mar the beauty of the velvety lawn, and there are no pieces of statuary or crockery to spoil the dignity of the time-honoured mansion, but all is simplicity itself, and, therefore, a sense of complete harmony pervades the whole. The

broad gravel walk in front of the house is perfectly straight. Between this and the house is an old-fashioned border for hardy perennials, and the wide part in front of the receding portion of the mansion has been turned into a flower garden. The flower beds are angular, and of the same L shape as those on the north-east side. They are edged with Box and planted with dwarf Roses, the ground between the Roses being covered by a carpet of Heliotrope—a happy combination. The terrace slope is not abrupt, but gently undulating, with a straight streamlet of water about 18 inches wide running parallel with the main walk. Those walls of the formal garden which run at right angles with the house are covered with fruit trees of all kinds, which just now (August 1) are mostly heavily laden with an abundant crop. At the foot of these walls is a narrow line of Lily of the Valley, and a herbaceous border edged with Box running parallel with the walls is separated from the lawn by a straight, broad gravel path. These borders are filled with Peonies, Irises, Phloxes, Anemones, Enocheras, Dahlias, fine plants of the bright yellow *Centaurea macrocephala*, Austrian Briers, Aconites 7 feet high, Gladioli, Campanulas in many varieties, Golden Rod, Red Valerian, and many others intermixed with Sunflowers and dwarf kinds of annuals. A sloping lawn 12 yards wide studded with handsome shrubs borders the Ivy-covered wall running parallel with the house. The square piece of lawn, which is completely surrounded by the broad gravel walks, measures about 100 yards each way, and contains in the centre a rectangular pond about 90 yards in length and 10 yards in width, the straight line being broken by semi-circular recesses in the middle and by plants of graceful outline, notably several *Arundo Donax* and *Glycerium argenteum*, as seen in the foreground of the picture here engraved. Here I also noticed eight handsome specimens of the Royal Fern (*Osmunda regalis*), which I was told were planted nearly fifty years ago, and measure now quite 12 feet in diameter.

The formal garden is bounded on the south-west side by park-like meadows traversed by a tributary to the river Lid, and on the south-east side by the well-stocked kitchen garden, about $1\frac{1}{2}$ acres in extent. The glass is confined to a greenhouse and frames employed chiefly in the production of the plants required for the flower garden and borders.

Close to the main entrance on the north-east side is a piece of pleasure ground of about $2\frac{1}{2}$ acres, which is separated from the other parts of the gardens by a public road, and has been called the "Turtle Grove." This was formerly an orchard, but has been transformed by the present owner, who pointed out to me among other interesting features a Cedar of Lebanon about 40 feet high, which had been planted in 1847, and was raised from seed which Mr. Tremayne himself had gathered on Mount Lebanon. All the walks in this pleasure ground are straight, so as to correspond with those near the mansion. There are also angular beds of Azaleas, Rhododendrons, and other flowering shrubs intermixed with hardy perennials and annuals. Among the larger trees I noticed good specimens of *Abies Douglasi*, Red Cedar, Hemlock Spruce, Scarlet Oak, Sycamore, Copper Beech, and Scotch Fir. Many walks are so arranged as to lead from one tree to another with square spots of gravel for seats beneath the trees.

Mr. Tremayne also owns the charming estate of "Helliggan," near St. Austell, Cornwall, famous for its fine avenue of *Benthamia fragifera*, the first introduced into this country and

raised from seed imported by the father of the present owner.

F. W. MEYER.

Exeter.

KITCHEN GARDEN.

FRENCH BEANS.

WITH me so far the present season has been one of the best that I can remember for the growth of this crop. The seed of the dwarf kinds sown early in the season made rapid progress, owing to the hot weather, and yielded a very early supply from the open ground. Runners, too, that were sown in April had made good growth by the beginning of May. These, however, had to be protected, as the garden lies very low, and so is subject to late spring frosts. This season was an exception, no frost being registered after April 27. The early rows of dwarfs have long since been over, but the first row of runners is now in full bearing, and with care and attention will continue to be so for a month or more. Beans require good ground and plenty of room to grow if satisfactory results are to be obtained. I adopt the plan of sowing in rows 8 feet apart, usually on ground that was occupied with winter Spinach. Trenches are taken out 2 feet wide and about 15 inches deep, and these being about three-fourths filled with decayed manure, the remainder is filled to within 2 inches or 3 inches of the surrounding ground with the soil which was taken out. The seed is sown in two lines 9 inches apart, the seeds being 6 inches from each other in the row. When growth has been made to the extent of a few inches, stakes are put to the plants. I use 12-foot hop poles, which are thrust into holes made in the ground with an iron bar. The holes are made a foot apart along each side of the row and about 6 inches from the plants. The poles are put up obliquely, leaning over the open space between the rows, so that they will be about as far from each other at the upper ends as they are from those of the next row. The bine from two plants is taken to each pole and secured with a green rush, this process being repeated from time to time as it is found necessary till the plants have reached the tops of the poles. Owing to there being so much bine, it is evident there must be a corresponding amount of produce, for when runner Beans are grown in this manner, the foliage and flowers are exposed to all the light and air possible.

To keep the plants in a healthy flourishing condition, it is clear that a large amount of food will be requisite for their support. If we consider the amount of moisture absorbed by such a crop, it will at once be apparent that more nourishment must be supplied to keep the plants fruiting than even the liberal supply of manure afforded in the first instance. Nitrogen plays an important part in the growth of Beans, especially when the pods are swelling, so that this element must be supplied occasionally in small quantities as it is required. Such manures should be rendered very fine, so that when sprinkled along the sides of the rows they may be more easily dissolved by rain or watering. Potash is also very beneficial, and should be supplied in a similar manner to nitrogen, but the cultivator must be guided somewhat by the weather and other circumstances if he would make the most of the different materials used. In showery weather plants do not require so much feeding, for the rain liberates the various acids and gases of the soil, so that the roots can take

them up. It would, however, take a great quantity of rain to thoroughly moisten the soil at the foot of a row of tall Beans when in full growth, for the quantity of moisture extracted therefrom is enormous. Anyone can easily satisfy himself of this, for if a row of Beans be given a soaking in hot weather, it will be found on examining the soil a couple of days afterwards that scarcely a particle of moisture is left in it, so that unless artificial manures are dissolved the roots cannot imbibe them. For this reason when water is given do not fail to give sufficient to carry the various compounds down to the lowest roots, so that all may do their fair share of work. Nor is this all. The thoughtful grower will not fail to see that all pods are gathered when large enough for use. It is not so much that the pods rob the plant of its nourishment as the seeds which are being formed in them. Therefore, if we would have the greatest amount of suitable pods for food we must not attempt to save seed, but rather leave them to those who grow exclusively for that purpose. If, however, some special variety is required, then select some of the longest and straightest pods and mark them by tying a piece of matting or string round the stem, so that they may not be plucked while gathering for the kitchen. It is a good plan to go over the crop every other day and take off all pods that are fit for use, as this will greatly benefit those that are swelling. The pods thus picked off may be put down in brine for winter use, but they must be covered and not too many kept together, or the flavour will be spoilt. About the middle of August is a good time to sow seed of a dwarf kind for succession. The seed should be sown on a warm border or a raised bed in the Melon ground, where the plants can have the assistance of a cold frame temporarily after the middle of September, for the nights get cold and slight frosts often occur. Heavy rains, too, are very prevalent towards the end of the month, which prevent the flowers from getting fertilised. The lights should, however, be removed on all favourable occasions, or the plants will become tender.

H. C. P.

TOMATOES ALL THE YEAR ROUND.

AT this date Tomatoes are abundant, the tropical summer having just suited them. Even the outdoor plants are showing heavy crops, fruit having been gathered earlier than ever was known from plants grown in the open. Owing to the favourable Tomato season the earlier or summer plants will become exhausted sooner than usual, but there will be no difficulty in securing a succession if plants are grown for the purpose. No doubt late in the year and early next year Tomatoes will command a good price. I have in previous notes pointed out the value of early Tomatoes. A good lot of late fruit is equally valuable, and with such a favourable early season there will be more demand for late fruits, as I do not think green vegetables will be any too plentiful unless we get a very favourable autumn, as so far most of the Brassica crops do not look promising.

To get a late batch of fruiting plants I sow in April and May. These plants are grown as sturdily as possible, plunging them in ashes in the open during the early summer months, giving the final shift into 12-inch pots at the end of July, and by the end of August they are studded with fruit, when they are removed to a low pit, tied up to the roof, plunging part of the pots and feeding. These plants give fruit well up to the end of the year. Having been grown in the open, they are very dwarf. They are given no heat till we get frost or fogs in the autumn, and then only sufficient to keep the atmosphere buoyant and prevent damping. It is surprising what a quantity of fruit two

dozen plants will produce. With care good fruit may be had through January and February. I would point out the importance of growing these autumn plants as sturdily as possible, as if kept too warm they will collapse with a change of weather; also the value of a good set before introduction to their winter quarters. I am writing these notes from a private grower's point of view. No doubt large growers would not be content with a small quantity and would adopt other methods. Those who have a few plants left over from a late sowing would find them serviceable if they grew them on for late fruit, and from several years' experience I can testify to their usefulness. I now come to the supply through March or April or earlier, and here there is greater difficulty. As everyone knows, these fruits are difficult to set in the last and first months of the year.

I am now raising (the end of July) the plants for late work. The seedlings are grown as sturdily as possible and potted into 6 inch pots as soon as ready, again potting into 8-inch. By the end of September or early in October these plants are placed on shelves in fruit houses. They are then showing fruit freely, but this must not be forced. The plants must be kept moving by giving a little weak manure water. By giving abundance of air in fine weather the plants set a few blooms in October if carefully watered. Early in the year they are removed to the house just cleared of the late autumn fruiters, tied up to the trellis, and the pots plunged over the rims in rich compost into which the top roots soon find their way. The house should be kept at from 55° to 60° according to the weather. With more warmth the fruits commence to swell, are ripe early in March, and may be had in abundance in April, and by extension of side branches the plant will fruit all the summer. Some may object to plunging the pots, but it is necessary to restrict root action. If planted out, a new growth would take place, and the fruit set would be at a standstill. I would also point out the necessity of airing freely in mild weather. In potting Tomatoes for winter no manures of any kind should be used. Attention must also be paid to varieties for winter work, and so far as my experience goes, the smooth, even-fruited varieties are bad. Last year I grew a few Conference, but prefer the Old Red, as I find it sets best, and though not handsome, it is of good flavour and useful. Good winter fruit may also be secured from cuttings, but it is necessary to strike early. I formerly adopted this plan to get early crops, but find I get the best results from plants sown and grown as hardy as possible.

G. WYTHES.

Sandwich Island Mammoth Salsafy.—This is far superior to the old form, and will, I feel sure, be more largely cultivated, as it gives much better and larger roots, being longer and more fleshy. I am aware there are various objections to Salsafy, the chief one being its tendency to run or bolt in the late summer months; but the above variety is much superior in that respect, as it does not run so badly and is of excellent quality when cooked. Another objection is trouble in cooking, but this is soon overcome, as the roots being larger, they are more readily prepared. If this variety is sown early in May in ground not freshly manured, there will be few complaints as to running or forking, as in the older kind. This variety is valuable in the spring when there is a lack of other vegetables, as it keeps well till that date if stored in a cool cellar or root store. I prefer it to Scorzonera, as it is grown more readily and with very little trouble. Both these vegetables have not been extensively cultivated, owing to the reasons given above, but they are often sown much too early and in heavily manured land.—G. WYTHES.

Cabbage caterpillars.—As breadths of Cabbages have been terribly infested and much injured this summer both by attacks of caterpillars and aphids, it may be interesting to learn that through the simple use of fine salt sprinkled lightly over Cabbages once a week, not only were both classes of insects entirely destroyed, but the fertile pro-

porties of the salt assisted to make the dressed Cabbages into first-class samples. That salt has undoubted manurial properties we all know, but, all the same, we too seldom recognise the fact by employing it. The recent very dry weather presented a most desirable opportunity for testing the value of salt, not only as manure, but also in the production of moisture. Had dressings of salt been thus applied, it seems very probable that many crops, otherwise dried up, might have thriven and been profitable. The person who told me the result of this Cabbage salting experiment said that a mild form of pickle might perhaps be as efficacious, or more so. It is very interesting to learn that the salt exercised no harmful influence on the Cabbages, but, of course, the leafage is of a hard leathery texture and not likely to suffer from moderate dressings. It is not at all too late for the effects of either dry salt or of salt water to be tested upon autumn Cauliflowers, for many of these are infested with insects; so also are many Cabbages, Savoys and Brussels Sprouts.—A. D.

THE POTATO CROP.

HOWEVER injurious the past dry weather may have been to vegetable crops as a whole, this has been an ideal season for the Potato. Failures, no doubt, there are, but where the soil has been well worked and properly manured, the crops, as far as my observation has gone, are better than they have been for some years past. As yet not a trace of disease has been seen or even heard of hereabouts, and it is to be hoped that this is general. Even varieties which in the ordinary run of seasons generally get tainted with disease are this year perfectly free, so we may well look forward to some fine crops being stored. The season being so favourable, the second-rate later varieties will be much better in quality, so it behoves growers to see that the tubers are stored in a manner to ensure the quality being improved. So much depends upon the storing, that however perfect may have been the growth, the quality, if the tubers are not well stored, deteriorates. The tubers are certainly rather smaller than usual (as might be expected), but instead of this being a defect, it should enhance their value. Of course, it must not be inferred that I refer to very small tubers from poor soil, but Potatoes grown under a proper system of cultivation.

As regards manuring, it would be interesting to know how the crops have fared where only artificial manures have been used, as on account of the dry state of the soil, this season has not been favourable for their free action. Of course, no one can tell how the season is going to turn out, or we might work accordingly. Evidently this has been a season where stable or farmyard manure has been of decided benefit, this retaining moisture and giving it off for the benefit of the crop. This year I used well-decayed manure with a free use of burnt refuse, this latter being scattered in the drills, and in the case of the earlier crops old Mushroom-bed manure as well, this also being scattered along the drills. The Potatoes have made full use of it, as when the tubers were being lifted, they were in a cluster about the manure. I never had Potatoes clearer in the skin.

The first early Potatoes will have been lifted ere this, as well as second early. It is strange how some people will persist in leaving their Potatoes in the soil after they have stopped growing and the haulm fallen over, or until every vestige of green has died away. This is what I may call inviting the disease and spoiling the quality as well. With late Potatoes it is certainly advisable to let the haulm change

colour before lifting them, as it has been proved again and again how much superior late Potatoes are in quality when lifted as the haulm changes colour. On account of the season being so early, the lifting of the latest crops even will be fully three weeks earlier than usual, but this is an advantage, as it will enable their being dug in good weather. The quality the tubers will ultimately attain depends so much upon the storing, that too much care cannot be taken in what may appear a very simple process. Stored in large heaps, sweating takes place, and when this is the case the Potatoes become what is termed "soapy" in texture. The same also happens if the tubers are kept closely covered up after being dug, the moisture not being able to escape. If possible the tubers should be laid out in a layer of about a foot or 18 inches in thickness, but be totally excluded from light either by darkening the windows or covering over lightly with a thin layer of straw or old mats, this allowing the moisture to escape and so enabling them to become perfectly dry. Low and damp cellars are the worst possible places for storing Potatoes; therefore for this reason select as dry a shed as possible if there should not be a proper Potato store.

Abberley Hall, Stourport.

A. Y.

TOMATO CULTURE.

THE Tomato seems to be a wonderfully ductile plant in the matter of methods of culture, and the varying results obtained, all more or less good, show how very difficult it is to lay down any hard and fast line for its cultivation. A few days since I saw plants being grown in gigantic pots big as washing-tubs. That they were enormously overdone with root room was very evident, and yet they cropped fairly well. At Teddington more recently I saw a row of plants on either side of a span house, the centre stage full of double Begonias. These were fruiting finely in 8-inch pots, and if the fruits were not large, they were very handsome and solid. The grower believed that under such root restriction he obtained the best flavour and greatest solidity. That is a matter well worthy of consideration. In another garden a splendid crop of Hepper's Goliath was being got from a bed about 15 inches wide and 6 inches deep, the plants being about 14 inches apart. And elsewhere grand crops of several fine varieties, such as Challenger, Conqueror, &c., were being got from a similar bed of soil, but the plants were only 12 inches apart. When we remember what a capital crop Mr. Hindson obtained last year at Gunnersbury from plants growing in ashes only, we must conclude that an excess of soil is a great mistake, that it is needless, and that the product is somewhat coarse fruits, rather soft and watery, and by no means of the best flavour.

The tendency of fruits to crack on the upper or stem side is generally due to too much root-moisture and too much atmospheric humidity. Plants that are allowed to become dry then are deluged with water, especially when they are carrying ripening fruits, of necessity suffer from the great changes in sap-production resulting from this varied wet and dry treatment. Even where the roots are kept fairly moist equably, and they never should be allowed to become wet, they yet often suffer from the alternations of atmosphere. Practically, Tomatoes cannot have too much air provided they have warmth, whilst always the drier the air is the better. On the other hand, excessive heat is rather conducive to barrenness, just as a low temperature is conducive to the same end, and when the sun is exceptionally strong, and the temperature, even with all possible air given, yet ranges high, it is a question whether a little temporary shading may not be useful. It has been asserted that at such times gentle syringings are helpful in setting the bloom. That may be, but

certainly they should be given early ere the sun attained too much power. One of the oddest things about Tomatoes is the exceedingly varied nature of the recommendations given to both old and new sorts by various growers. The chief gain, so far as I can discover, that is found in some new sorts is that we are getting greater weight in a smaller area, and a larger percentage of pretty, and hence more saleable, fruits. I greatly prefer the deep or Apple-shaped varieties, such as A 1 and Challenger, to the large flat Tropies or allied varieties, and if these fruits be set up in a small pile on a dish as Apples are, judges would all the more readily discern their merits. They seldom crack, are very solid, are never too big, and are of the best flavour, especially when grown in a limited root area. A. D.

AUTUMN-RAISED CAULIFLOWERS.

LIKE the sowing of Peas in November, so the raising of Cauliflowers in the autumn is looked upon by many people as old-fashioned. Taking the ordinary run of seasons, I never remember to have seen so few notices in the gardening press as to one variety of Cauliflower being better than another. This, of course, is on account of the almost general failure of the crop. My impression is that where the plants were raised in the autumn and well cared for during the winter and early spring, they have proved better able to withstand the trying ordeal than others raised in the spring. Good Cauliflowers can be grown by being raised in the autumn if the details attending their growth are well attended to. Amongst the causes of failure there are two or three which I will now draw attention to as being the most general. The first is sowing the seeds too early, the second not providing suitable soil for the young plants to root into after being pricked off, and, lastly, coddling them up too much. In pricking out any class of vegetable, too much reliance is placed on old potting soil. Old potting soil is useful material, all gardeners will admit, but for pricking out Cauliflowers into it is perfectly useless. It is not holding enough, and, instead of being able to lift the plants with a good ball, the soil falls away from the roots, and when this takes place with spring-planted Cauliflowers they rarely recover from the check. The evil is pretty much the same if the roots go down deeply, as on account of this taking place it is impossible to take up the plants with a compact ball. If no soil is at hand suitable for the purpose of pricking out, then the best course to adopt is to pot the plants.

I consider the first week in September quite early enough to sow the seeds. Considering that only two or three square yards are needed, it is an easy matter to add a little finer and fresh soil, and if at all dry, well moisten the seed drills before sowing. As mildew is apt to attack the young seedlings if the site of the seed-bed is not favourably situated, see that this has a full southern exposure. By sowing at the time stated the plants have time to become large enough for pricking off before an inclement time arrives. The frame must be placed in an open position and also on a hard surface of cinder ashes, this preventing the roots striking down deeply. Pricking out the seedlings on to exhausted hotbeds is not at all a good practice, as by this process the plants will surely become too large before it is safe to plant them out, and besides the check received in the removal from such rich rooting quarters will again end in failure. The frame having been placed in position, over the bottom should be laid a thickness of 2 inches or 3 inches of

rotten manure, which should be beaten down rather firmly. Over this should be spread another like thickness of good holding soil, say three parts loam to one of pulverised horse droppings, with a little leaf soil also added. The young seedlings should be pricked out 4 inches apart. Although frame protection is now given, the plants must not in any way be coddled by keeping the lights over them when not needed, or they will surely become much too large to transplant safely; in fact, the lights must be kept off except during cold rains. In severe frost the plants require to be efficiently protected either with mats or straw over the lights; the sides of the frames also should be protected, as if the weather should be severe, frost quickly penetrates through the sides. The plants would also be further benefited by having the surface soil stirred occasionally.

In growing the plants in pots the same treatment is needed as regards protection and so forth. Five-inch pots, or what are termed 48's, are the best to use, as when smaller ones are used the roots become cramped; consequently the plants are apt to receive a check. The soil for pot plants should be made as holding as possible. After being potted off, the better plan to ensure their wintering well is to plunge the pots in the frames, keeping them as close to the glass as possible. Where there are sufficient hand-lights for the purpose at disposal, the young plants may be even pricked out into these, placing the lights on the border where it is intended for them to remain until they come to maturity. In fact, by this method the earliest heads obtainable are cut, unless of course actually forced. The soil in the first place must be well worked and manured, and into each light prick out nine plants, these being further reduced to four or five plants in the spring. The best varieties to sow in the autumn are, I consider, Early Dwarf Erfurt, Early London, Walcheren and Large Asiatic. A. YOUNG.

Thinning Seakale crowns and feeding.—

Thinning the crowns of Seakale was scarcely ever practised when old roots were grown year after year; indeed it was not so necessary, as the plant was split up into several crowns spread over a larger surface, but with single roots it is more important, as if these small side growths are left the root is much weakened, and the leading shoot or crown does not make a thick growth so desirable with roots for forcing. When the young sets are planted in lines there is more necessity for this thinning, as the growths soon become crowded and much weakened, but if each shoot is restricted to the strongest growth, there will be more room for the plants, and early ripening is facilitated. Feeding is also equally important, as if a strong growth has resulted from planting in rich soil the roots will have absorbed and used up the food placed in the soil, so that a dressing on the surface of a good fertiliser after the removal of such shoots or useless growths will be of great value. I am induced to send this note on feeding, seeing the excellent results obtained by flooding with sewage. I have never seen such Kale as that grown on a sewage farm, thus showing that food is required in addition to that placed in the soil. I am well aware that only a few can give the above stimulant, but many can utilise liquid manure from the stables or cow yard, and even without such manures Seakale of the best quality may be grown by dressing between the rows with fish manure; this may then be washed down. I have found fish manure a valuable help for Seakale and Asparagus, while Celery is also greatly benefited.—G. WYTHES.

Celeriac as a winter vegetable.—This, though not grown nearly so much as it deserves, is an excellent vegetable on account of its good keeping qualities. It is described as Turnip-rooted Celery and used for soups. This latter is a poor

description, as if well grown its use for soups alone will not bring it into favour. I have seen some very poor examples in our greengrocers' windows in this country indeed only fit for soup, but there is no need to have such poor roots, as if the same attention as is bestowed on Celery were given to it, there would be no reason to complain of it. Celeriac is not so difficult to grow as Celery, and is not so readily affected by severe weather. Those who have a stock and are desirous of securing strong roots by winter, would do well to bestow a little attention in the way of feeding and moisture. I would also point out the value of the root for use in the garden where vegetables are required in variety, especially where stewed Celery is liked. If sown at the same time as Celery, pricked out similarly, and then planted in rich ground 18 inches to 2 feet apart in rows, there will be nice roots by winter. Celeriac is often starved. I would advise copious supplies of liquid manure now and whilst in active growth, and during hot or dry weather there is no better plan than mulching between the rows with decayed or spent Mushroom manure. I also prefer to plant in drills, so that the plants at the start do not suffer from want of moisture. Salt or, what is better, fish manure sprinkled between the rows in showery weather is a grand fertiliser. I have also used guano, but I prefer fish manure. It is necessary during growth to go over the plants and restrict the growth to one crown. There are only a few varieties of this vegetable. The Early Erfurt and the large smooth Prague are the best. I prefer the latter.—S. H. B.

THE ROCK GARDEN.

ACCESS TO ROCKS AND PLANTS.—II.

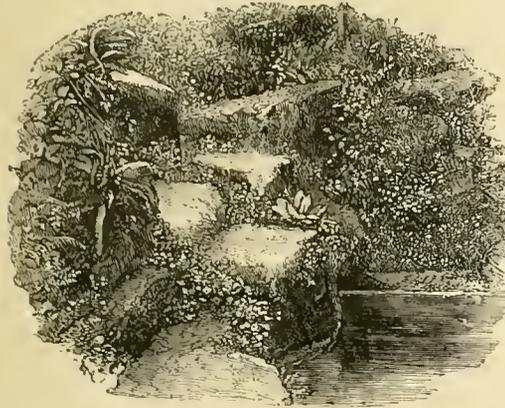

(2) STEPS.

STEPS in the rock garden are quite as important as the paths referred to in the last chapter, but their use is naturally confined to the boldest and most irregular part of the work, where, in spite of more or less sudden elevations or depressions, access to rocks and plants would be desirable. It has been previously pointed out that sunk rock gardens possess many advantages for growing choice and rare alpine, and such excavated ground will often require steps in various places even if the work is only of moderate extent. Deep rocky slopes without steps would be inaccessible, and plants growing in such positions could not be attended to as easily as would be desirable. Here a path would not be practical, as it would be too steep for comfortable walking, and would, moreover, be partly destroyed after every heavy shower. For such steep places then steps would be the most convenient and practical mode of access, forming not only an easy approach, but enabling us to grow many of the floral gems delighting in the chinks and fissures offered by such a situation. Among the rocks themselves I think only one kind of steps suitable, viz.,

IRREGULAR STEPS.

Nothing could be more calculated to mar the harmony and beauty of a picturesque rocky scene than the introduction of a regular staircase among the rocks that should resemble Nature's work. Steps may be a necessity, but this should never be evident. The passage through the rocks might resemble a natural winding ravine, the steps appearing like a continuance of the rocky ledges adjoining them, being in one part close together, in another farther apart; here turning to the right, there to the left, and though forming on the whole a very easy means of ascent or descent, looking in reality as different as possible from steps proper. Nor is this all; the realistic effect will be enhanced by not confining the

rocky steps to the main passage or ravine alone, winding and irregular as this may be, but by introducing branch passages connected with other rocky ledges, grass paths, or rocky paths, so that if design were apparent at all, it would be difficult to point out to what particular object or in what particular direction the rocky passage is leading. In a rock garden thus arranged visitors might traverse any number of steps without being aware of it, owing to the complete absence of anything in the least suggestive of a staircase or steps in the ordinary

No. 1.—Irregular steps through steep part of rock garden.

sense of the word, and owing also to the proper blending of the rocky ledges which serve as steps with the adjacent rocks.

The illustrations are good examples of work of this kind. In No. 1 ("Irregular steps through steep part of rock garden") the flat portions of the rocks which serve as steps do not lead to any particular place, but are arranged with careless irregularity, while the chinks and fissures between the stones are receptacles for plants of all kinds. The second engraving (No. 2)—"Steps on gently sloping ground in rock garden"—shows a variation of such steps suitable for the less abruptly sloping parts of a rocky passage. Here the stony ledges or steps are kept farther apart, with here and there a space of coarse rocky *débris* intervening and fringed on both sides with luxuriant vegetation of alpine plants.

The construction of steps such as those depicted above is not difficult, but requires careful planning at the beginning of the work. My own practice is as follows: When entrusted with the construction of a rock garden, I invariably prepare a rough ground plan of the work, showing its relative position to other parts of the garden, and especially showing the most desirable and practical approaches. The position of paths, steps, and rocky passages is then marked out on the ground and furnishes a basis for arranging and distributing the chief features of the work. I consider it a great mistake to erect the bolder masses of rocks first and not to provide proper facility for access until the principal work has been almost completed. From experience I find it much more difficult to build steps which shall blend harmoniously with rocks already constructed than to build rocks which partake of the same character with regard to form, stratification, &c., as the rocky steps which have been constructed first and serve as a sort of foundation for the other work. Cement I never use for securing such rocky steps, but the stones are embedded firmly in soil which is rammed with a stick, while a person stands on the stone to ensure its being so fixed that no footsteps can ever shake it. Where two or more stones are required to form one step,

they are let into the ground so as to leave a narrow crevice between them, which is afterwards filled with soil suitable to the plants to be grown. When constructing steps of this kind, I begin, of course, at the bottom, laying after each stepping-stone the foundation-stones for the adjacent rocks at the sides, which latter often receive in this manner additional support through resting on the stepping-stones. By this procedure the adjoining rocks are made from the outset to correspond with the steps, and a proper blending is easily effected. The rise from step to step should vary continually, but should never be more than 6 inches or 7 inches, as a greater rise would make walking uncomfortable, especially to ladies. But the width of the steps might vary from a foot or two to a yard or two. The more variation the better. The intervals between the steps, too, should vary considerably, being, of course, closer together in the steepest parts, but broken here and there by portions of rocky or other paths, according to the more or less slanting nature of the ground, and with a view of enabling us to arrange the adjacent parts so as to be the most effective and at the same time easily reached.

REGULAR STEPS IN THE ROCK GARDEN.

I have just stated that regular steps of any kind should be strictly avoided among rocks, and that where steps are necessary they should be of such a form as to suggest the idea of their having been formed by Nature. As frequently pointed out, however, a rock garden should never consist of rocks alone. If the work is of any extent at all, there would probably be one or more grassy slopes or shrubby banks forming a kind of connecting link between the rock garden proper and other parts of the garden, and here steps of a more regular pattern would be not only suitable, but often preferable. In such a position not even the most fastidious critic could object to rustic steps of some kind, however regular they may be, provided they are not arranged in a straight line, but in a suitable curve and form. But steps which, in my opinion, are the most objectionable are those which can be called neither regular nor irregular, and have consequently an appearance too clumsy to suggest the skilful handiwork of man and too formal to look like Nature's work. If we must have steps, let them be either regular or quite irregular, but never a mixture of both.

This does not imply that regular steps in a position like that above indicated should consist of costly masonry, hewn stones and the like. On the contrary, the simpler the better, but the work might be at least neatly done, and though having quite a "rustic" appearance, it need not look clumsy and awkward.

RUSTIC STEPS OF WOOD OR STONES.

WOOD STEPS.—A very simple method of making rustic steps consists in the employment of wood for that purpose. The great disadvantage is that sooner or later the wood will decay and require renewal, but where timber is plentiful this may be of little consequence. Larch poles say 6 inches to 8 inches

thick are a good material for this purpose. The poles are sawn in halves lengthways, and are then cut into equal pieces 3½ feet to 4 feet long, according to the desired width of the steps. For sharp curves the pieces should be a little longer, as they would have to be placed in a more diagonal direction than steps approximately parallel. The bark is preserved by the driving in of a few nails with flat heads, and if thus secured will last at least for several years. Two Oak posts are next driven firmly into the ground, so that the top end is about an inch below the level intended for the first step, and against these posts a piece of Larch is nailed or screwed securely. The next step is kept on a level about 6 inches higher and secured in the same way as the first, and when all is completed the space between each two steps is filled with stones and gravel as for an ordinary path. As the posts were kept an inch below the level of the step, they will be covered by the gravel and completely hidden from view. The wood used for steps need not necessarily be Larch, but any kind with a rough surface will do as well. Pieces of gnarled and knotty Oak are best used without the bark, and are very suitable for the purpose.

STONE STEPS.—For stability, steps made of stone should undoubtedly have the preference. If the stones procurable are not of the required shape, a skilled mason will soon overcome the difficulty. Several stones may be used to form one step, but they must be firmly embedded in the ground, and, like the irregular steps described above, these rustic steps may have the fissures intervening between the stones filled with suitable vegetation. But steps made of wood cannot well be adorned in the same way, as plants would naturally tend to hasten the decay of that material.

RAILINGS.—Rustic railings made of crooked Oak or other wood are sometimes fixed to steps of this kind, and, it cannot be denied, look often very pretty for a time, especially if intertwined with Clematis and other suitable climbing plants. But, unfortunately, the duration of the wood-work is seldom more than three or four years even if painted with boiled oil and other preservatives. Of late years rustic wood—as, for instance, the bark of Silver Birch and other kinds—has been very successfully imitated

No. 2.—Steps on gently sloping ground in rock garden.

in iron. When really well done, this has a light and graceful effect combined with the very desirable quality of being practically indestructible.

F. W. MEYER.

Esoter.

(To be continued.)

STOVE AND GREENHOUSE.

THE CHIMNEY BELLFLOWER.

(CAMPANULA PYRAMIDALIS.)

This variety is probably one of the oldest of the genus under cultivation, having been under culture in one way or another for nearly 400 years, being at the same time a native of Europe and hardy in favourable localities in this country. Around London it has been known to stand outside uninjured through the winter, but it is scarcely advisable to risk the stock in this fashion. What has most to be feared during the winter is excess of moisture rather than extreme cold in outside culture, whilst in frames a close atmosphere is equally prejudicial, more particularly if the crowns of the plants be dense ones with lateral shoots and foliage in proportion. The prevalence of fogs around the metropolis and other busy centres also militates against this plant, and these not being pure fogs further aggravate the mischief when outside entirely. In any cold frame, however, with an average amount of care it is easy to keep the plants in safety. The best way is to plunge the pots in coal ashes up to the rim, or over it, at the same time keeping them as near as possible to the glass. From the end of October until well in March no watering should be thought of, and any signs of decay in the leaves at the same time be attended to and removed. If in extremely cold weather it is considered desirable to use protecting material, it is a better plan to leave on a chink of air than close down for days, together perhaps quite closely. When room cannot be found under glass, the next best way is to stack the plants, as Strawberries are sometimes done, on their sides, so as to keep the roots on the dry side. In the case of frame-grown plants, no protection at all is needed after March; they may then stand outside entirely, but be plunged, if possible, so as to protect the roots in some measure.

CULTURE AND PROPAGATION.

Considerably more plants are now raised from seed than by any other means, but they may be increased by root cuttings in a similar way to Seakale. This latter plan is a capital one when a superior form is detected amongst a batch of seedlings so as to secure its increase without future variation. They do vary, and that in an unmistakable manner both in colour and habit. The deep blue and the pure white are possibly the two best shades; whilst in the habit there is a considerable difference in the density of the spikes as well as in the height of the plants, which varies from 2½ feet to 8 feet. The taller plants are in many ways the most ornamental when with dense spikes 4 feet and 5 feet in length. This shows the necessity of either careful selection of the seed or propagation by root cuttings. The seed should be sown from March to May. The earlier sowing will often yield plants of fairly good size that will flower in about sixteen or seventeen months from the sowing of the seed. These may be useful, but they are not so ornamental or imposing as plants nearly a year older. If sown

in May, pricked off as soon as fit to handle, and afterwards potted and wintered either in 3 inch or 4-inch pots, they have all the next season in which to grow. Thus they make grand plants for the following season in 10-inch or 12-inch pots. After being wintered in small pots they may be potted about April into 6-inch pots, or larger ones if the plants be extra strong. Another shift will be needed later in the season. This time the most promising may be potted into their blooming pots if there be room enough to winter them thus, otherwise into about 9-inch pots, one further shift being given the following April or early in May, at any rate before the spikes begin to push up. The soil best suited to them is good turfy loam with some silver sand or road scrapings; to this a little leaf-mould may be added in preference to any rotten manure, the latter having a tendency to create too vigorous or sappy a growth. In potting after the seedling stage has been passed the soil should be made as firm as in pot Strawberries, or firmer if possible, the crowns of the plants being kept slightly elevated each time of potting, as in the case of hard-wooded Cape Heaths.

WATERING AND OTHER TREATMENT.

The water-pot must not at any time be used too freely, otherwise the plants will decay at the base of the stem, or run a risk of doing so. Anyone can note for himself in the breaking off of a fresh leaf what an amount of sap is stored in its vessels; this points to a careful course of watering. When the plants are well rooted, weak liquid manure is decidedly beneficial, more particularly during the flowering season. That made from cow manure with some soot added thereto is suitable. No plunging should be practised when the plants are potted into their flowering pots, otherwise there will be a tendency towards too much moisture.

USES, &c.

As soon as the first flowers unfold, the plants should be placed in a light and airy greenhouse where they will make a fine display for about a month or longer. When more fully expanded, a light shading is beneficial. Flowering as they do from the middle of July to the end of August, they are of essential value in conservatory decoration, supplying colours and form not seen in anything else. Considering their easy culture (and inexpensive too), *C. pyramidalis* should be more grown than it is. It is equally at home in the conservatory of the rich as in the more modest structure of the amateur. As a market plant, however, it would not probably pay to grow it, but this is no real criterion of value and utility.

BLUE BELL.

Allamandas.—The two most popular varieties still of Allamanda for growing as specimen plants are without doubt *A. Hendersoni* and *A. nobilis*. They are both splendid kinds and quite distinct from each other in colour, both being free growers and as free bloomers under good cultivation. *A. Hendersoni* is sometimes met with still under the pseudonym of *A. Wardleaca*, which may as well be dropped once for all, the origin of the latter name and supposed variation being well known to most old plant growers of twenty-five years back. These two species (*A. Hendersoni* and *A. nobilis*) must rank as two of the finest. To these should at least be added *A. grandiflora*, which when well grown, the plants being grafted one upon as free-growing stock, are no mean rivals for either of the fore-

going. This species succeeds admirably planted out, and for many purposes in a cut state is preferable to other sorts. This family of plants has in the past suffered in reputation more than once through being grown in the shade. None should be given them; rather let them act as a shade to other plants. The blossoms will then be more profuse and of greater substance.—H.

Clerodendron fallax.—These who possess good flowering plants of this variety may turn them to good account in other than their stove houses at this season of the year. In the stove the flowers do not last so long, while at the same time there is frequently a disposition to damp off, thus injuring others. In a cooler house these drawbacks are avoided in a large measure, whilst the plants are perfectly safe for at least six weeks to come.—H.

Dipladenia boliviensis as a specimen plant.—Considering the time this species has been in cultivation in this country, it is surprising that it has escaped notice to such an extent as it has done for growing into a specimen plant. At the last show at Newcastle-on-Tyne two grand plants of it were exhibited in profuse flower, whilst as regards healthy, vigorous growth nothing better could be desired. These two plants were shown respectively by Mr. Letts and Mr. Nicholas, the former gardener at Aske, and the latter at Up-leatham, two of the Marquis of Zetland's seats in Yorkshire. These two plants were patterns of what specimens should be; they were trained upon globular trellises and in flower all round, not being got up to such a face as is frequently seen. This same species is grown splendidly by Mr. Gibson at Halstead, near Sevenoaks, in a similar way. Being a variety that continues in flower for such a lengthened period, more attention should undoubtedly be given to it. Given a healthy young plant, it does not take long to grow the same into a good specimen, besides which there is nothing at all like it among stove climbers.—H.

Heliotropes.—Numerous fine examples of President Garfield, one of the best of the dark-flowered varieties, are just now in unusually good condition in Hyde Park. Many of them are pyramid shaped, or nearly so, and 4 feet or 5 feet in height, each bearing a great profusion of richly coloured fragrant blossoms, though, as regards this latter feature, the dark varieties are not so fragrant as the lighter ones. In the deep-tinted forms, too, the clusters of flowers are more compact than in the others. A group of a dozen or so good specimen plants plunged in the grass has a very pretty effect, while Heliotrope is such a general favourite, that it attracts a considerable share of attention. Good examples are also to be seen hawked in the streets of London grown in the regulation market pot. Again, where cut flowers are in demand Heliotrope at all seasons is very useful, and trained up the wall or pillars of a warm house a plant will often bloom throughout the winter.—H. P.

Telfairia occidentalis (The Oil Nut of Western Africa) (*G. Cameron*).—This is the name of the flowers you send, which you say you received from Old Calabar under the English name given above. It forms a very ornamental climber in our stoves, its pure white flowers, which have a purple eye, being prettily fringed round the eye. The flowers are succeeded by large handsome yellowish green fruits, which have a number of wings, and which contain a quantity of large seeds, which are cooked and eaten by the natives.—W. G.

Tecoma jasminoides.—The finest flowered example of this beautiful greenhouse climber (alluded to on p. 120) that has ever come under my observation was a dozen years ago or thereabouts in the gardens at Hillfield, Reigate, where during the lifetime of the late Mr. Wilson Saunders a remarkable collection of plants was brought together. It was after the dispersal of the collection there that I saw this particular specimen, which was planted out in a greenhouse and had taken possession of a good part of the

roof. Some of the lights were removed during the summer, so that the plant received plenty of sun and air, and as it had not been pruned or tied in any way, the long flexible shoots hung about in wild confusion. Under such treatment it was profusely laden with its beautiful blossoms, the bright coloured throat of which contrasted markedly with the pure white of the rest of the flower. I also know several large specimens of this climber that are subjected to periodical pruning and tying, the result being a total absence of bloom. We should doubtless see a far greater amount of bloom on many roof climbers if they were allowed more freedom of growth, for under the treatment usually accorded them the wood does not get sufficiently ripened for the production of blossoms. That this ripening is very essential to their flowering is well shown in the case of a near ally of the above, *Tecoma capensis*, that rarely produces blossoms when growing in a partially shaded greenhouse, but if the strongest shoots are taken as cuttings in the spring and, after being grown on, are exposed outdoors to the hottest of the summer's sun, they will flower freely.—H. P.

SHORT NOTES.—STOVE AND GREENHOUSE.

Cuscuta chiliensis.—"H. B. P." sends a piece of this plant for a name. He says it has been remarkably pretty, but is now fading. This is a species rarely seen. It has drooping flowers like Lily of the Valley, and is very beautiful; you should save seeds of it.—W. H. G.

Abelia floribunda (*T. Hughes*).—This is a fine free-flowering plant, of which a plate was given in THE GARDEN some few years back. It requires a cool greenhouse to grow in your district, and you should plant it in loam and peat made sandy. The flowers are tubular, rich rosy purple and pendent. It is a native of Mexico.—W. H. G.

Fuchsia Improved Rose of Castile.—It is always a dangerous practice to give any new variety an old appellation with the prefix Improved. Especially is it so in this case, as the old Rose of Castile is one of the freest and prettiest Fuchsias ever introduced. Yet the new one is an improvement, as anyone growing it will find, flowers larger, growth more robust, and wonderfully free to flower.—D.

ROSE GARDEN.

THE SELECTION OF ROSE BUDS.

PERHAPS it had been better to have incorporated these few notes in my article upon budding Roses given a week or two back, but as much progress will not have been made yet, I am in hopes it may still be of some little service. The selection of Rose buds is of far greater importance than many realise. The general plan is to cut off any wood which bears plump and ripe buds, irrespective of whether the plant be a good one of its type and variety, or whether the shoot used for budding be weakly or not. It stands to reason that a bud obtained from a strong and healthy plant will be more likely to produce its like than if a bud be selected from a plant of weak or indifferent growth. Taking *La France* as a type of medium growth, we find that buds obtained from a plant which produces stout wood make much better plants than those obtained from a weaker plant, even if the shoot used for budding be fairly strong. Roses like *Horace Vernet*, *Xavier Olibo*, &c., are improved or not year by year through a judicious selection of buds. We have many proofs of this. For instance, when a new Rose of sterling merit is brought out—take *A. K. Williams* and *The Bride* for examples—a great strain is put upon it by both professional and

amateur growers in endeavouring to procure a good stock of plants as soon as possible. In order to do this every available eye is worked, both by budding and grafting, and as a consequence we get a more or less number of plants that are far from strong and healthy in growth. These being used as parents of others, the variety gradually deteriorates. As time goes on and a sufficient stock is secured without working every available eye, and a selection of the most suitable buds is made, we find the variety improving and coming back to its proper standard. Both of the Roses I have cited as examples have proved this theory most conclusively, and instead of being looked upon as indifferent growers are now among the most generally useful varieties we have. But if it is necessary to select buds of these medium growers, it is even more so in the case of climbers and extra strong Hybrid Perpetuals. Take the latter first, *Mme. Gabriel Luizet* as an example. This variety makes some extra strong growths after flowering, and if buds be taken from these we shall find the resulting growth produce blooms early the first season; in fact, exactly the same as if the eyes were still upon the parent plant. In the ordinary course of things, such strong shoots would be pegged down and would produce blooms more or less from every eye. The germ of the bloom is stored in the eye or bud during the process of ripening, and it matters little whether it be transferred to a stock or left upon the original shoot. For this reason I would always choose buds of these strong growers from the longest shoots. We then get a flower early and plenty of time is left for the long rods to be made afterwards. If buds be chosen from beneath a bloom, in the majority of cases there will be no flowers the first year, but only vigorous growth for blooming next season.

Turning to the climbing Teas and Noisettes, we find that *Maréchal Niel* and *William Allen Richardson* will produce much better plants when the buds are selected from beneath a flower, it really being upon the same principle as the strong-growing Hybrid Perpetuals. My own observations have proved that it is much better to get a healthy young plant of these as soon as possible; therefore I select buds from below a flower. This is again noticed in the case of grafted plants. If wood from the long rods of the previous season be used as scions, almost always a weakly shoot is produced at first and sometimes a puny bud developed. Later on a strong rod may be pushed up, but I consider it best to use scions bearing what I will style growing instead of flowering eyes. Generally only one or at most two eyes are used on a scion, and if these are going to send out a puny shoot, we have to depend upon the minor eyes at the base of this for the production of strong rod-like growth, so valuable among the climbing Teas and Noisettes. The buds beneath a flower are also generally better matured than those upon a long rod still in full growth. Much depends upon having a strong and healthy start in the case of the two varieties last named, for if they once hang about, as it were, they seldom produce satisfactory plants. R.

Rose Triomphe de Rennes as an autumn bloomer.—"Ridgewood" names several well known and beautiful Roses, such as *l'Idéal*, *Celine Forestier*, and *Wm. Allen Richardson* as likely to bloom more freely than usual this autumn. Some of the finest examples of autumnal blooming I have ever had were produced from strong standard plants of *Triomphe de Rennes*. This Rose is one of the more tender, and is apt to get crippled or

killed back in a severe winter or harsh spring. Otherwise it is one of the most beautiful and useful soft golden Roses we have. *Celine Forestier* is a little the hardier of the two. But both may be relied upon for a good show of bloom right through the autumn months if of sufficient size and maturity. Even *Maréchal Niel* may be grown and pruned into late blooming in the open air, though this king of all golden Roses is more coy in the matter of autumn blooming than either of the others named.—D. T. F.

Rose Bouquet d'Or.—I quite agree with "A. H.'s" last note as to the more or less capricious divisions among Roses, such as *Teas*, *Noisettes*, &c., and rather than vindicate or define such, I will almost accept the *Bouquet d'Or* at his high estimate. I confess that I have less experience with it than with *Gloire de Dijon*, and for this good reason, that finding the latter so full of beauty and merit I could never get too much of it. With a slight qualification, however, I am pleased to agree with "A. H.'s" closing sentence, that few Roses are finer than *Bouquet d'Or* for forming huge bushes, which flower freely in soil that suits them.—D. T. F.

Tea Rose Narcisse.—I do not find this lovely little Rose at all weak in growth when established. It is not of course so vigorous as *Dr. Grill*, but the plant throws out sturdy, strong shoots, and it has a singular horizontal spreading habit. The immense trusses that terminate these shoots suggested to me *Lamarque* in miniature as truly describing the profusion of the kind. A group of small plants has lately been flowering freely.—A. H.

—Some four years ago when I first took charge of this garden I drew attention to this fine useful Rose, and I have noted many others have praised it since. It blooms with me more profusely than any other Rose, although I grow many kinds. It is growing on a sheltered corner of a south wall. I have cut blooms from this plant in April and high on till Christmas.—J. C., *Forde Abbey*.

ROSES AND WASPS.

TO THE EDITOR OF THE GARDEN.

SIR,—Numerous as the insect enemies of the Rose are, it seems we are yet to be troubled with an additional pest that has never before come under my notice. In my case it cannot be because the wasps have no other food close, for there are many gallons of Plums and Apples within a few yards. Although they are eating this fruit to an exasperating extent, they have also pitched upon my Roses. The buds seem to be most fancied, but even when partly open, the wasps have eaten portions out of several.

Two days ago they were first noticed, and my idea was that they were after some insect. Upon closer observation I found no trace of aphid or other insect, and was soon obliged to come to the unwelcome conclusion that wasps had commenced feeding upon Roses. At first there were but one or two wasps, but in the course of the day quite a number were engaged upon the same plant. I may remark here that probably these facts would not have come so closely under my notice had it not been that the plant was close to a greenhouse door very frequently used. Two days ago this plant of *Marie van Houtte* carried some four or five dozen healthy buds. Now it has been a hard matter to find half-a-dozen not entirely eaten away. Several of the buds have been closely watched in order to see if any of the gummy matter often noticed upon Rose buds when injured by insects existed. This, by the way, is sweet, and attracts ants among other pests, while several winged insects will return to it again and again upon being disturbed.

But I could discover absolutely nothing to attract the wasps except healthy Rose buds.

I enclose you some buds that you may be able to see the immense damage wasps are likely to do to our favourite flowers should they extend operations and become a recognised Rose pest. It would be very interesting if other rosarians would kindly notice whether wasps are upon their plants or not and report the result.

THE HYBRID TEAS.

BEING now recognised as a distinct class by the National Rose Society and a descriptive list of them given in the official catalogue, a few comments upon this section may be welcome. In the first place we will define what is styled a Hybrid Tea. It is the result of a cross between a Tea-scented and a Hybrid Perpetual Rose. This section has been much increased of late, and the late Mr. Henry Bennett perhaps devoted more attention to this branch than to any other. He raised Her Majesty, Lady Henry Grosvenor, Lady Mary Fitzwilliam, Viscountess Folkestone and Grace Darling among others. All of these are first-class. Her Majesty is still classed as a Hybrid Perpetual, but this seems to me to be wrong, as it was the result of a cross between Mabel Morrison and Canari; therefore it is equally as much a Hybrid Tea as Lady Mary Fitzwilliam, a cross between Devoniensis and Vic'or Verdier. The foliage of Her Majesty has much of the high colouring found among the Teas. A list now in front of me enumerates between sixty and seventy varieties of Hybrid Teas, and although many of them are of little merit, there are some (notably those already named) which must rank as our very best Roses. La France and its many sports and seedlings also come under this heading, while not the least valuable variety is Captain Christy, a cross between Victor Verdier and Safrano.

In the National Rose Society's catalogue of 1884 we do not find many Hybrid Teas, and these were incorporated with the larger class of Hybrid Perpetuals. The new catalogue of 1893 contains no less than twenty varieties, exactly half of which are considered fit for exhibition. With one or two exceptions, the chief characteristics of this class are its freedom in flowering and midway position held by it between the two great classes. So closely do some of them resemble one or the other, that it is difficult to decide to which they belong. Old varieties like La France, whose pedigree is lost, are placed with the Hybrid Teas because its growth and habit point to the infusion of much Tea or China blood in its constitution. The shorter-growing varieties are grand when grown as pot plants, and all will do much better when cultivated upon the seedling or cutting Brier than upon the Manetti. Although the class is small at present, it contains both short and tall growers. Lady Mary Fitzwilliam and Kaiserin Friedrich may well represent the two extremes.

R.

Rose Princess of Wales.—I can fully confirm all that "D. T. F." says of this Rose. True, it is a very delicate and oftentimes disappointing grower, but when once the plant breaks away it will produce a fair quantity of most charming blooms. Comtesse de Nadailac and Princess of Wales possess a charming combination of colours found in no other Rose.—R.

Dark Roses and the drought.—The unexpected has happened in regard to these during the year 1893. Dark Roses as a class have been at their best through the baking drought; hence, one of the greatest pleasures and surprises of rosarians. Dark Roses, new and old, but especially old, were very much in evidence alike at shows and in gardens. Seldom or never, perhaps, have such fine old brilliant Roses as General Jacqueminot, Marie Rady, Marie Blumann, Duke of Edinburgh,

Charles Lefebvre, Prince Camille de Rohan, Reynolds Hole, Maurice Bernardin, and John Bright been better and more perfect. Among other dark Roses the following have also been conspicuous through the brilliancy of their colour in spite of, or in consequence of, the heat and the drought: Beauty of Waltham, Duchess of Bedford, Alfred Colomb, Duke of Wellington, Fisher Holmes, Le Havre, Ferdinand de Lesseps, Senateur Vaise, Harrison Weir, Star of Waltham, Horace Vernet, Jean Soupert, Mrs. Harry Turner, and Prince Arthur. Of this last brilliant Rose, almost the only one added to our list by one of the most successful growers, Mr. Benjamin Cant, of Colchester, it may truly be said that it has excelled itself amid the glitter and glare of the three months' drought.—D. T. F.

Rose Kaiserin Friedrich.—This grand climber is now in full beauty, it is equally as hardy and free flowering as the old Gloire de Dijon, and was, in fact, a seedling from that old favourite crossed with Perle des Jardins. Although it does not partake so much of the last-named variety as its raisers claimed for it, Kaiserin Friedrich is undoubtedly one of our more distinct and valuable climbers. Towards the autumn the flowers are very highly coloured, oftentimes tinged and flushed with the same sweet rosy shade found in Marie van Houtte; even the palest blooms, growing in shade, are like the very bright blooms of a Gloire de Dijon.—P. U.

Rose Duchesse de Caylus, a Rose bracketed as synonymous with Penelope Mayo, is one of the older varieties that have come particularly good with me this year. I do not remember it ever being so good before. Delicious in scent, bright, full and lasting, it is by no means to be despised, although it has been surpassed in size. Now and again one of the older and almost forgotten varieties crops up again in all its glory, and is very welcome.—R.

Wild Roses of Western America.—In the far West one of the most common and beautiful of the wild Roses is the Cinnamon Rose (*Rosa cinnamomea*), with its close ally, the *Rosa nutkensis*. The peculiar light rosy tint is possessed by few other species. In the Rocky Mountain region, *Rosa blanda* and its close ally, *Rosa arkansana*, take its place.—*Meehan's Monthly*.

Rose Mme. Hoste has won a position in the first rank of Teas, and is generally acknowledged as one of the very best pale yellows; indeed I cannot think of one I could conscientiously place in front of it. As a proof of its great perfection, we find it figuring as the medal Rose for the best bloom both in the trade and the amateur divisions at the Worksop Rose show. In habit, size, and shape it much resembles Anna Ollivier, but I think it produces a greater proportion of large flowers, while the plant is equally as free blooming.—U. S.

GARDEN FLORA.

PLATE 923.

WATSONIAS.

(WITH A COLOURED PLATE OF *W. ANGUSTA*.)

The genus *Watsonia* is very closely related to *Gladiolus*, the main differences between them being that the segments of the flowers of *Gladiolus* are irregular, whilst in *Watsonia* they are regular, and in the stamens of *Gladiolus* being attached to the base of the corolla tube, whereas in *Watsonia* they are attached to the middle of the tube; there is also a difference in the anthers and stigma. All these differences, however, are not of a character to count for much with cultivators. It is remarkable that

* Drawn for THE GARDEN by Champion Jones in the Royal Gardens, Kew, August 5, 1892. Lithographed and printed by Guillaume Severeys.

whilst the genus *Gladiolus* has for many years enjoyed great popularity with cultivators, who have crossed the different species with each other with most wonderful results, only very little attention has been paid to the *Watsonias*, and were it not that some of the species are still grown at Kew and a few similar establishments, it is probable that the genus would go out of cultivation altogether. There is no lack of either beauty or interest in *Watsonias* as compared with *Gladioli*, and so far as my experience goes the behaviour of both genera under cultivation is very similar. The genus *Watsonia* was named by Philip Miller in compliment to Dr. William Watson, F.R.S., an eminent electrician and botanist, who was knighted just previous to his death, which occurred about a century ago. The species, of which fifteen have been described, are all natives of South Africa, where they occur in great numbers in the open plains along with *Gladioli*, *Ixias*, and similar bulbous plants. They have corms exactly the same as *Gladioli*, and they spring into growth and flower at the same period. They are all about as hardy as *Gladioli*, requiring to be lifted and wintered in a shed in England, although in a sheltered border they may be left outside permanently if covered with litter or mats in very cold weather. We prefer to lift them annually, clean and dry them, and keep them in small boxes in a dry shed till March, when we replant them in the borders exactly as we do the Cape species of *Gladioli*. They flower in July, August, and September, and they are most decorative both in the flower-bed and when cut and arranged in vases. The small species, such as *W. aletroides*, *W. humilis*, *W. marginata*, and *W. punctata* we grow in pots in a frame, placing them in a cold greenhouse when in flower.

W. ANGUSTA.—Although the plant figured is grown at Kew under this name, it is not exactly that species as described by Mr. Baker in his "Handbook of Iridæ." It was sent to Kew by Mr. Butters, the curator of the Botanic Garden at Port Elizabeth, in 1891 as "a scarlet-flowered *Watsonia*, probably new." It flowered from June to November last year planted out in a sunny frame, and its peculiar colour won for it much attention from visitors. It is by far the brightest of all the *Watsonias* of the same section, the colour being a brilliant flame red. Its spikes were 3 feet or more high, the lower leaves 18 inches long by three-quarters of an inch broad, leathery and rigid. There were twenty-five flowers and buds on the longest spikes, and they developed in slow succession. There were about fifty plants in a group all flowering together, and they were most effective. According to Mr. Baker, *W. angusta* has been called *fulgida*, *atro-sanguinea*, and *iridifolia fulgens*, names which would appear to indicate that the bright colour of the flowers attracted the special notice of the sponsors. Gardeners will be disposed to wish the name *fulgida* had been retained for this plant. Mr. Baker said, when he saw it in flower, it was a scarlet-flowered variety of *W. Meriana*, but he did not give it a distinctive name. It might with equal propriety be called a form of *W. coccinea*.

W. MERIANA.—This is the commonest species in South Africa and the best known in gardens here. It has been called the scarlet Tuberose and various other names. In the *Botanical Magazine* it is called an *Antholyza*, and Jacquin figured it as a *Gladiolus*. Except in the colour of the flowers and in the usually branching spikes of *W. Meriana*, I see no difference between this and the plant here figured as *W. angusta*. The flowers of the former are rose-red or scarlet, and if we accept Mr. Baker's classification, there are white varieties also. For garden purposes, however, I think we may venture to retain the name *iridifolia* for the white-flowered *Watsonia* introduced a year or two ago by Mr. O'Brien. *W. Meriana* was cultivated by Philip Miller, and it has never quite gone out

fine old brilliant roses as General Jacquemont, the Royal Gardens, Kew, August 6, 1852. Litographed by Philip Miller, and it has never quite gone out
Marie Rady, Marie Blumann, Duke of Edinburgh, and printed by Guillaume Severeys.

of cultivation since. I have collected quantities of it in South Africa, its tall scapes being a common feature of hillsides and even along railway cuttings. It is a good garden plant, with a sturdy constitution and a free-flowering disposition.

W. IRIDIFOLIA.—A figure of the white variety of this was published in THE GARDEN in March last, p. 229, where it is called *W. alba*, apparently on the authority of Mr. Arderne, of Cape Town, who claims to have first found the plant "in the Worcester Valley, about eighty miles from Cape Town, in a peaty boggy marsh amongst thousands of the common pink variety." Others have also claimed the credit of this discovery, and it is therefore probable that it has been found by more than one person. Mr. J. O'Brien introduced it and flowered it in 1889, when it was named and described by Mr. N. E. Brown as *W. iridifolia* var. *O'Brieni*. A short time after this bulbs of it were sent from South Africa to Kew under the name of *W. iridifolia alba*, and I have also seen it called *W. Meriana alba*. Whatever name we give it—a simple way out of the difficulty would be to call it the white *Watsonia* and let Latin specifications alone—there can be only one opinion as to its purity and beauty of flower. In the summer of 1891 a group of it in a bed on a lawn at Kew was a picture, the tallest spikes being 4 feet high with five or six branches and numerous long-tubed, broad mouthed flowers each fully 2 inches across and pure white. Each branch bore from twelve to twenty flowers on a spike, arranged distichously and close together. They were without spot or shade of any kind and fragrant.

W. COCCINEA.—This may be described as a dwarf form of *W. angusta*, the plant growing to about a foot in height, with six or eight loosely arranged tubular bright crimson flowers on a spike, the flowers resembling in size and form those shown in the plate. We were at first inclined to call the plant figured *W. coccinea*, but it does not agree at all with the figure of this species in the *Botanical Magazine*, t. 1194.

W. DENSIFLORA is an erect growing species with ensiform leaves 2 feet long and spikes of the same length bearing wheat-ear-like heads of rose-red flowers, as many as fifty blooms being borne in a single head. The closely imbricating spathe-valves or sheaths from which the flowers spring are remarkably like a large ear of wheat, especially when in bud. The type was introduced by Messrs. Veitch and Sons in 1878, and is figured in the *Botanical Magazine*, t. 6400. It has flowered several times since then at Kew. In 1889 Mr. Medley Wood, of Natal, sent to Kew seeds of a white-flowered variety of it, and the plants raised from them flowered in a bed outside in September

of 1891. The leaves of this variety were 2 feet long, an inch broad, very rigid, with a yellow margin and a stiff, almost spiny tip. The scape was over 2 feet in height, and it bore a dense head of tubular white flowers an inch long and broad. Mr. W. Wood writing about this plant in 1882 stated that it is always found in company with the type, but is more plentiful in some seasons than in others. It is noteworthy that all the Kew plants, which were raised from seed, were white-flowered.

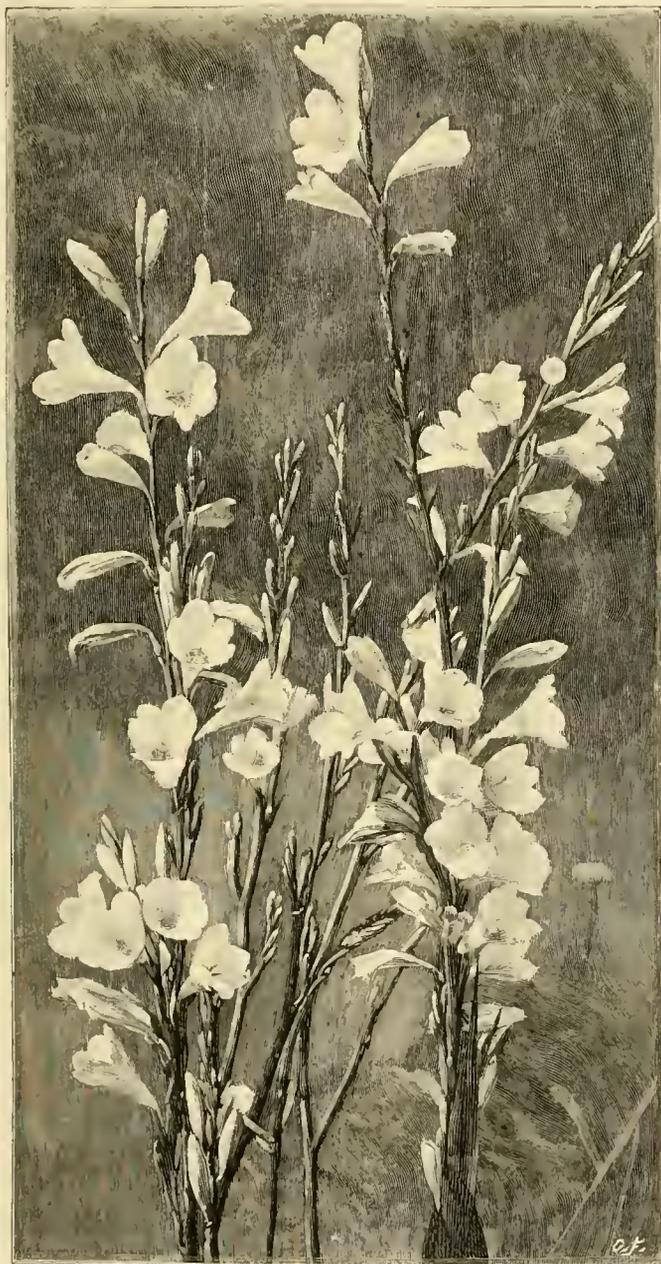

W. ROSEA.—This is a large flowered handsome

scape bearing numerous *Ixia*-like flowers an inch across and coloured mauve-pink. I first made the acquaintance of this plant in 1882, when it flowered in the Cape house at Kew in June. As already stated, it may be seen in flower at Kew now. Its resemblance to an *Ixia*—in flower only, the leaf being broad and *Gladiolus*-like—is seen in the fact that Aiton named it *Ixia marginata*.

W. ALETROIDES.—Several masses of this have been flowering freely this summer in the Cape house at Kew. In my opinion it is one of the prettiest of Cape bulbs, the leaves being ensiform, a foot long and dark green, the scapes from 1 foot to 2 feet long, sometimes branched, curved and clothed with nodding tubular flowers, not unlike those of *Lachenalia* in shape, but larger and coloured bright scarlet, with a tinge of orange about the mouth of the tube. The segments are small and scarcely reflexed. This species is worth a place in every greenhouse. It occurs sometimes in cultivation. It flowered freely in a border at Kew in 1886. A plant which used to be called

W. PLANTAGINEA, and is now placed in the genus *Micranthus* by Mr. Baker, has been in cultivation some years at Kew, where it flowers in July. Its spikes are a foot high, and it may be called a miniature *W. densiflora*, the flowers being arranged closely together in an erect spicate head. It has been called *W. triticea*, or the Wheat-like *Watsonia*. The flowers are small and purplish.

There are several named garden varieties of *Watsonia* about which I know little, except that they are probably only forms of *W. Meriana*. There is ample and sufficiently varied material in *Watsonias* to make it worth while for some grower and breeder of bulbs to systematically work at them with a view to evolving a race of first-class varieties, as has been done with *Gladiolus*.
W. W.

Watsonia iridifolia alba.

species with spikes 3 feet or 4 feet high, branched near the top, and bearing numerous bright rose-red flowers in August. It flowered freely at Kew in 1887, and it may be seen in flower there now near the T range in company with *W. marginata*, the two occupying a bed on a lawn near the Orchid house. It is an old introduction, and is sometimes catalogued by the Continental bulb growers. The leaves are rigid, about 18 inches long, and dark green with a brown-yellow margin. The flowers are each 2 inches long and *Crocus*-like in shape.

W. MARGINATA is a tall species, with a branched

THE WEEK'S WORK.

THE KITCHEN GARDEN.

SPRING SOWN ONIONS—There will be little need to leave these long on the ground this season, as they promise to ripen off quickly. The bulbs, if not so large as usual, promise to be of very good shape, there being but few thick-necked ones amongst them. Before pulling the bulbs the whole bed should be gone over and the tops of the Onions laid all one way, so as to expose the bulbs to the full influence of the sun, this also assisting in that thorough ripening so essential for Onions to keep well. In the course of a few days the bulbs should be drawn, laying them in rows with the base facing the sun. If the weather should remain hot and dry, they may remain in the open until thoroughly ripened; but if not, lay them under cover, but where they may receive an abundance of air and also have the benefit of full sunshine. Pickling Onions, if not already drawn, should be attended to at once, as the silver-skinned varieties will start into growth again very quickly if a heavy rain should follow, when, of course, they would be spoilt, it being very needful that these be very sound for the purpose.

CABBAGE FOR SUCCESSION.—The past year or two has shown how needful it is to have a good plot of Cabbage for spring cutting. The varieties which prove suitable for this purpose are Enfield Market, Battersea and Nonpareil. These, if sown earlier, are in danger of bolting; therefore the present date is the most suitable. Do not crowd the plants into small beds, but allow plenty of space by sowing in drills in an open part of the garden. To assist germination, take care that the drills are well moistened before sowing, that is if the weather should be dry. This is also the most suitable date to sow seed of the pickling Cabbages.

PREPARING GROUND FOR PLANTING.—Generally in those gardens where very close cropping has to be practised the plot set apart for planting the main batch of Cabbage follows on after Onions. To secure Cabbage of good quality

the ground must be in good heart, and if more attention was paid to this there would not be complaints as to Cabbage being only a second-rate crop. The site having been well manured the soil should be dug with forks. By being dug thus early there will be time for the ground to become consolidated by the time the plants are fit for planting.

PARSLEY FOR WINTER.—A few weeks since I drew attention to the necessity of providing a good supply of Parsley for winter use either by sowing or transplanting, but up till now this has not been a good season for this latter operation, the weather having been much too dry. It is not yet too late to transplant, if a sufficient quantity is not growing freely, either into low frames prepared for the purpose, or anywhere where protection may be afforded when necessity arises. In either case a firm rooting medium must be afforded, and the roots having been fixed firmly at planting, watering must be followed up and also shading until the roots have taken to the soil. Where no such provision for affording winter supplies is being made, the better course will be to cut over a portion of the plants from the spring sowing, clearing away all rubbish, when the after growth will be of such a nature as will enable it to withstand frost. Where the Parsley is transplanted into deep frames it will be advisable to fill up with some open material before filling in the soil, so that the tops of the plants can be as near the glass as possible.

A. YOUNG.

HARDY FRUITS.

THE FRUIT ROOM.—If not already done, no time should be lost in putting the fruit rooms into thorough order for what is to be stored in them. Several varieties of Apples and Pears have already ripened, and a considerable quantity has been stored in the more forward localities. Unless the surroundings are quite clean and free of smells, the flavour of Apples is quickly tainted, and Pears, though not so susceptible, may yet be practically spoiled owing to contact with or confinement in something that is strong-smelling. Let the roofs and walls have a dressing of lime wash and the shelves a good scrub down, everything being done to make the fruit store fresh and sweet. On no account ought Apples to come into contact with either straw or hay. At first these substances may be perfectly sweet, but they soon become damp when fruit rests upon them, and a disagreeable, musty smell is given off, the Apples in particular soon tasting strongly of it. This warning about the use of hay and straw is frequently given, but, judging from the Apples that are tasted at the autumn shows, very few fruit growers profit by it. Pears keep best closely packed stalk uppermost in single layers, the latticed shelves in the orthodox fruit room answering well. Some prefer to line these shelves with clean kitchen paper, and it is very advisable to do this when there is much air passing through the room at times. Seeing that low temperatures are also undesirable, lining the shelves and covering the layers of fruit with more of the same paper whenever frosts are imminent will serve to protect considerably. Pears also keep well and ripen admirably in drawers, but somewhat cool, dry shelves are most to be desired this forward season. If Apples are abundant and storage room limited in extent, the floors of the fruit room as well as a spare or disused bed-room and other cool dry places may be utilised. Where there is a chance of cold air drawing up through crevices in the floor, cover with paper and then store none but sound fruit in great heaps. Apples will stand low temperatures well, but are not frost-proof. They ought therefore to be stored where it is possible to cover them with paper, mats, and such-like whenever severe frosts are expected. If either boxes or hampers are plentiful, these also could be filled with fruit and stored one above another if need be. Neither Pears nor Apples, however, will keep well if gathered and handled carelessly. All that are bruised or damaged in any way ought

to be separated from those which are sound and be the first used. Neglect this precaution, and the chances are a very few unsound fruit will early commence decaying and spoil a great many that come into contact with them.

OTHER METHODS OF STORING APPLES.—There is such an abundance of Apples this season, that many of them will very probably be spoiled or sacrificed for want of storage room. Supposing the small supplies of choicer varieties are given what are considered the best places, that is to say, all the spare shelves in the fruit-room, the floors also being utilised, other storage quarters ought also to be devised. Sometimes the fruit keeps better in these make-shift places than it does in the regular fruit rooms. A dark, cool, not very dry and well-sweetened shed, with either a thatched roof and walls, or ceiled roof and mat-lined walls, suits Apples admirably, nothing answering better than a disused Mushroom house. In this case shelves should be constructed so as to admit of storing not more than two or three layers deep, and the fruit can then be looked over, any that is decaying removed, without the necessity for any undue handling of or turning over that which is sound. With so many to select from, it need hardly be pointed out that there is no sense in saving and storing small or scrubby fruit. It sometimes happens that Apples are so very plentiful, that their owners fail to find sufficient room for all under cover of a shed or room of any kind, but that is no reason why a quantity of fairly long-keeping varieties should be left in the orchards to spoil. In all such instances the plan of storing Apples somewhat similarly to Potatoes should be tried. Select a well-drained sheltered spot, cover the ground either with boards or fresh wheat straw, and then form a long mound of sound, hand-gathered fruit. They should be left uncovered when it is dry during the next ten days or fortnight, and then be covered with clean wheat straw, or fresh leaves and mats over these, strips of timber being used to keep everything in its place. It is the varieties that ripen in November and December that ought principally to be thus stored, though it sometimes happens that they keep better in these open-air ridges than they do in rooms.

W. IGGULDEN.

ORCHIDS.

THE climatic differences of our seasons are very remarkable, and the effects of those conditions upon the plants are much greater than people would think. No one can complain of the lack of sunshine or of heat during the present season, and the probabilities are that although there is not much difference in the appearance of the plants, they are likely to flower better next season. Owing to the greater evaporation from sun-heat and an unusually dry state of the atmosphere about midsummer, the houses required more damping down than usual. This is one of the details of Orchid culture which gardeners fail to master; they either overdo it or underdo it, and most of them go through the performance of it without considering either the weather or the condition of the plants. I have seen the young growths of Dendrobiums damp off, owing to too much moisture in the atmosphere combined with insufficiency of fresh air. Some growers also syringe their Dendrobiums regularly when in growth, and this certainly adds greatly to the risk of the growths damping off. I think a thorough good syringing does some Orchids good occasionally, but the indiscriminate use of the syringe may produce disastrous results, or at least do harm instead of good. The state of the weather and the condition of the plants must always be studied. Watering, syringing, damping the house, and ventilating must be learned by practice to a large extent.

This is perhaps the worst time of the year to obtain a display of Orchid blooms; the houses present a very dull appearance for those who only care for Orchids when they are in flower, but the Orchid fancier takes a

delight in the plants at all seasons, and looks forward to the time when the flowers will repay him for many months of care. There are yet some species and varieties of great beauty which flower now and enliven the houses with their gay colours. One of the handsomest is *Vanda Sanderiana*, one of the most difficult of the genus to establish or to keep in good condition after it is established. Flowering at the same time are the finest of all the *Aerides*, viz., *A. Lawrenceæ* and the distinct *Sander's* variety. They were both exhibited by various cultivators at the R.H.S. meeting in the Drill Hall the other day, and as so many good cultivators are growing them, each successful effort will add to our knowledge of the best cultural conditions to command success. Heat and moisture when growing and not too much dryness when at rest seem, as far as we know at present, to suit them best. They have both been found on the same tree with the lovely *Phalenopsis Sanderiana*, growing on the south-east coast of the island of Mindanao, and it has been stated that they grow so near the coast line, that "the long trailing roots of the *Vanda* are often within reach of the salt spray." A distinct and handsome Orchid now in flower is *Cattleya granulosa Schofieldiana*. The tawny yellow flowers spotted with reddish brown and borne on tall stems have a striking effect; varieties of *Laelia elegans* are even more chaste and beautiful. I noted the striking contrast the other day between two well flowered examples of *L. elegans* Schilleriana and Turner's variety, the sepals and petals of the former white, faintly tinged or flushed with pale rose, and the rich amethyst-purple and reddish maroon of the latter. Other varieties of *L. elegans* and *C. granulosa* may be found in collections at this season, and are justly prized. *Vanda suavis* and *V. tricolor* in variety also give occasional spikes of their handsomely marked and richly spotted flowers, and a contrast to all of them are the long-branched spikes of *Oncidium incurvum*. I was looking over a collection of *Cypripediums* this week and found about a score of very fine species and varieties in flower, but of the dwarfier growing type, *C. superbiens* was certainly the most beautiful, and of the taller *C. longifolium* type, the garden variety *C. Sedeni candidulum* was the most chaste and elegant in flower and growth. The pretty little *C. niveum* was amongst them, and has a delicate transparent beauty all its own. I remarked last week that this group of *Cypripediums* liked limestone in the soil. A good cultivator who tried to grow the *C. niveum* group in different kinds of soil and various composts advised abundance of water all the year round, and the compost in which they thrive best was two-thirds yellow loam, one-sixth nodules of chalk, and one-sixth of coarse leaf-mould, the plants being grown in the East India house near the glass roof. This group of *Cypripediums* may be reported now as well as at any other time, and many other species and varieties of them may be reported with advantage. The large vigorous specimens may have a good shift. It is a great mistake to allow such garden varieties as *C. grande*, *C. Dominicanum*, *C. Sedeni*, and varieties of this type to become pot-bound; they are often injured thereby. One point I might allude to with advantage, and that is the cleaning of some varieties of *Cypripedium* with short brittle leaves like *C. concolor*. An inexperienced cultivator might snatch hold of a leaf and bend it up to get the sponge at the under side of it, but this must be done very carefully, else the leaves snap off and the plants suffer loss in consequence.

In alluding to the treatment of the deciduous section of Dendrobiums two weeks ago, those of the nigro-hirsute section which are not deciduous were not mentioned. They do not require the same system of resting, and might be injured by too much exposure to the sun. The queen of the section, *D. formosum giganteum* should now be showing its flowers, and must on that account be freely supplied with water to develop them to their fullest size. Where *D. formosum* grows there is rain during the greater part of the year, so that naturally it has no resting period, and ever-dryness

may be the cause of its not doing so well with us. It succeeds best with basket culture near the roof glass of the warmest house when growing. *D. formosum* is found near the sea-coast, and has been found in positions where the plants may sometimes be covered with the spray. *D. infundibulum*, *D. eburneum* and *D. Jamesianum* are found in the higher, more inland districts, and are probably geographical forms of the same species, but they require rather different treatment. *D. Jamesianum* is doing well in the cool house. *D. macrophyllum*, the pretty, strongly-scented *D. Bensonæ* and *D. Dalhousianum* should now be in the warmest house; as they are yet in full growth, see that they do not suffer a check from want of water. All the three of them will flower well next year if they can be encouraged to make good growths now. The weather has been very sultry again, not much artificial heat being needed to keep up the temperature to the highest summer point.

J. DOUGLAS.

PLANT HOUSES.

FREESIAS.—No time should be lost in getting the main stock of these potted up, whilst none should be left out of the soil longer than the end of the month. Later than this will weaken the bulbs, causing them to shrivel. Large pots are undesirable, anything beyond 6 inches diameter being needless. A dozen good bulbs can be easily got into a pot of the size named. For early flowering there is no doubt that imported stock is far better than home-grown, having the advantage as regards thorough ripening. These bulbs are worth taking pains with; therefore, good soil should be chosen for them—fibrous loam and leaf-mould with some spent Mushroom bed manure and road scrapings being as good as can be chosen. When potted, one good watering should be given and the pots stood in a cold frame; a light surface covering not more than an inch in thickness should then be given. The object of this is to keep the moisture in the soil, it being thus retained in a more equable manner. When the growth is seen to be pushing through the fibre, this latter should be lightly shaken off, but from that time onwards the lights should be kept on to prevent too much draught about them. Watering for a time until there is plenty of roots must be done cautiously.

EARLY HYACINTHS, &c.—The earliest Roman Hyacinths should now be rooting, a fresh batch being put into soil every ten days or a fortnight. The earliest of the other kinds should also be ordered without delay; these may be advantageously confined to one of a colour. Grand Vedette as a single white, Norma as a pink, Robert Steiger as a red, and Grand Vedette, azure-blue, with William I. as a dark blue, are reliable kinds for first early work. To these should be added the early French straw-coloured, to which allusion has previously been made, but which bears repeating. Where this variety has thus far escaped notice, it should no longer do so as a succession to the earliest Roman Hyacinths, but associated with them when not extra early. In its colour alone it is essentially good and distinct. For flowering about Christmas-time without hard forcing it is excellent. In either of these sorts alluded to it is useless to expect the best results if forcing be attempted in the slightest degree before a good number of roots has been made. Pot early, therefore, and retard rather than force hard.

EARLY NARCISSI, &c.—The early double Roman and the Snowflake form of the Early Paper-white are the best. These should now be potted or boxed to suit the demand. If it be as plants, then pots are the best; if for a cut flower supply, then boxes will answer well. For first early work the Duc van Thol Tulips are the best of the family. If these be in demand before or at Christmas, it will not be advisable to delay starting into growth much longer. To follow these there is nothing better than the double Tournesol and Vermilion Brilliant (single). These should be treated like the Roman Hyacinths. *Lilium Harrisii* or the so-

called Bermuda Lily for the first early work should be obtained and potted without any further delay. This Lily for the time and until a good stock of roots has been made should be treated like the Freesias. Note should be made particularly that large pots are undesirable; 6-inch pots are large enough in any case for the largest of bulbs, whilst oftentimes this size will hold two or even three comfortably.

LACHENALIAS.—These ought now to have attention for re-sorting and potting up, otherwise growth will take place, and if this be the case, a check is given that might have been avoided. I prefer for my own part to use a soil with rather more leaf-mould and manure in it than is usually chosen for Hyacinths, &c., whilst at the same time it may very suitably be worked through a rather coarse meshed sieve, the rougher parts being afterwards placed as drainage over the crocks. Where there is a large stock it is just as well to let a part stand over the second year. I have known them thus do remarkably well; all that is then needed is a fresh surface-dressing. The fact should not be lost sight of that *Lachenalias*, more particularly *L. tricolor* and *L. pendula*, are very suitable subjects for basket culture. This will be an excellent way of using up any spare stock, but it should be composed of the largest bulbs. What is needed is a supply of good Moss to line the baskets; the bulbs can then be worked all over the bottom and sides, so as to present an even appearance through the baskets when the growth is well developed. The tops of the baskets must have provision made for a plentiful supply of water. *L. Nelsoni* should have attention turned to it, also *L. aurea*; these yellow kinds are very distinct and handsome, but, unfortunately, rather dear as yet.

TUBEROSES.—The earliest of these, the African bulbs, will be ready early in September, and probably by the end of this month. With these no time should be lost if required for winter flowering. When potted, a good place will be a pit just emptied of Melons, or anywhere near the glass with warmth, but not too much of it until growth appears. At first the supply of water should be limited, a surface-dressing with cocoa fibre being a saving in this respect. By growing these early Tuberoses the need of extra early forcing of the *Gardenia* may be avoided; whilst as regards treatment, the two may be accommodated together very well indeed. For this early flowering, it is just as well to put three bulbs together, and for this mode of culture an 8-inch pot is ample, or even one of a less size; by this means room and labour are saved.

JAMES HUDSON.

ORCHARD AND FRUIT GARDEN.

GATHERING PEARS.

PEARS will, no doubt, be early this season, and, according to my observations, many of the varieties will require closely looking after, or the quality will be sadly wanting. Having this in view, I quite agree with Mr. Jggulden that much useful advice might be communicated if readers who are in the position to do so would only state their practice in gathering any variety or varieties so that they reach the greatest perfection. The quality that Pears will ultimately have depends so much upon the gathering, that too much care cannot be taken in this operation. That many varieties of Pears are left too long on the trees there cannot be any doubt, and frequently I have come across fruits at exhibitions that only too plainly showed that this had been the case. Sound to all outward appearance they may be, but the practised eye can tell at a glance that they are but poor apologies for the variety when in perfection. This state of things has been the result of not gathering early enough, and I am very

much of the opinion that if ordinary precautions are not taken, "mealy" Pears will be very much in evidence this season. Not that the season itself will affect the quality, but on account of this being early there may be a tendency to leave the fruits on the trees up to the usual time of gathering in ordinary seasons. It will also be interesting to watch the behaviour of those varieties of Pears which are termed "gritty," or which seldom come to perfection in this country, except in favourable soils and districts. The early season might certainly improve these, and my advice in the case of these would be to leave them on the trees as long as possible. I am also of the opinion that the majority of other good winter Pears should be allowed to remain on as long as possible, or until they part readily from the tree when lifted up in the hand.

Before commenting further upon the gathering of these late Pears I will refer to the varieties generally in season throughout September and October. Amongst these are Williams' Bon Chrétien, Beurré d'Amanlis, Beurré Superfin, Mme. Treuve, Louise Bonne of Jersey, Fondante d'Automne, Doyenné Boussoch, and Beurré Hardy. To all appearance these are all much before their time, or quite fully three weeks earlier. Leaving these varieties on the trees until just on the point of dropping before gathering them will lessen their quality considerably. Keep they may do, but the flesh will not be nearly so melting as if they had been gathered earlier—in fact, decidedly rough, and they will go off at the core when to all outward appearance they appear sound. A limit might be allowed to Beurré Superfin and Beurré Hardy so as to prolong their season, but the earlier gathered will be of much the better quality. Gathered at the right period, Fondante d'Automne is really a delicious Pear, and to prolong the season of this variety it is sometimes recommended that gatherings should take place at intervals. From the first two gatherings where a week is allowed between, the quality is really first-rate, but after this the fruits seldom, if ever, come up to the standard of the earlier gathered. The flesh even now is remarkably sweet, and it would not be at all unsafe now to make the first gathering. It is certainly unfortunate if our October Pears should be in and over a month before their usual season of ripening, but unless I am very much mistaken this is what they will be, as it is certainly in the later season that Pears are the most appreciated.

Seeing that these Pears, which are usually in season throughout October, are much earlier, and that leaving them on the trees as long as they will hang depreciates their quality, we must consider the best means by which the later kinds can be retarded. Marie Louise, Thompson's, Doyenné du Comice, and also Pitmaston Duchess are amongst the best November Pears, which will ripen up thoroughly if allowed to hang as long as they can, and I should think this would be the best mode of retarding them, as if they were gathered earlier they would most surely ripen up. Conseiller de la Cour should also be allowed to hang, as then the quality comes up very well indeed. To think of retarding the main winter kinds by also gathering earlier will not, I think, assist this end. As a rule our climate is not sufficiently favourable for the thorough ripening of late Pears, except, of course, in favoured soils and districts, so altogether the lengthened season may be in their favour. It may certainly not be necessary to allow them to hang till frosts put the finishing touch to them, as this, although the best under

the circumstances in late seasons, is not the best mode of maturing. Such varieties as Glou Morceau, Ne Plus Meuris, Emile d'Heyst, Beurré d'Aremberg, Passe Colmar, Winter Nelis, Beurré de Jonghe, Josephine de Malines, Marie Benoist, Beurré Sterckmans, Passe Crassane, Bergamote d'Esperen, Olivier de Serres, and Doyenné d'Alen on should certainly be allowed to hang until they will part readily from the tree. No doubt in those gardens where a good water supply is laid on and this can be applied without much difficulty, good fruits should certainly be forthcoming, as was the case in the Jubilee year, some of those kinds enumerated above swelling up to an exceptional size, the quality also being superb. Y. A. H.

Two good pot Figs for forcing.—This season I had every opportunity of testing the merits of several varieties of Figs for early fruiting in pots. Of the newer kinds the heaviest croppers were St. John's and Pingo de Mel. These varieties do not shed their first crop like many other kinds and swell up quickly. Those who have not yet grown either of the above varieties for early forcing would do well to give them a trial. St. John's is a large white-fleshed fruit, sweet and juicy. This variety I gathered the end of March from plants in 12-inch pots. Pingo de Mel has a yellowish flesh and the tree is equally fruitful. St. John's is of erect habit, while the other is spreading. Both varieties have heavy first crops, but do not bear so freely a second time, like Brown Turkey and other older kinds. Out of twelve varieties the two varieties named were the best. They were grown in a low house started early in December, and came in far in advance of older kinds. I have now grown St. John's three seasons as a pot plant, and am more pleased with it this season than ever on account of its free-bearing and easy forcing qualities. It is wonderful the quantity of fruit these plants will produce even from trees in small pots if due attention is paid to feeding, stopping, and moisture.—G. WYTHES.

Size and flavour in fruit.—It is clear that a hot dry season like the present reveals some new features to fruit growers. In my garden all kinds of fruit are far better in flavour and larger in size this year than they have been during the last few years. Peaches are fine in flavour. Royal George is most delicious when taken off the tree just a day before it is sent to table. Noblesse is equally good. I doubt if these two kinds are surpassed from a flavour point of view. The flavour of Jargonelle Pears was also better than in any previous year; to have this at its best it must remain till almost ripe on the trees. Strawberries were very fine as regards size and flavour. A neighbour remarked to me recently that he never had Sir J. Paxton so highly flavoured and fine before. During the last few days I have been gathering many kinds of Plums from walls. Such kinds as Jefferson and the finer kinds of Gages are simply delicious.—J. C. F.

Grapes shanking (P. B.).—This may arise from more than one cause. The roots may be in a bad state through working in an unsuitable soil, or, as this season has been exceptionally dry, the border may be too dry for healthy root-action. In the latter case a good soaking with liquid manure will be beneficial. If the fault arises from the roots being in a cold, deep, undrained border, the only remedy will be root-lifting and a new border.

Preserving Grapes from wasps.—I am surprised that anyone should advise the use of muslin bags for the preservation of Grapes from wasps' attacks when by simply touching the partially eaten berries with a small drop of Scott's or Davis' wasp destroyer from a pointed stick their clearance from the house is speedily effected. Mr. A. Long (page 130) surely has not yet found the value of these frequently advertised remedies, or he would not recommend the use of the old-

fashioned muslin bag. If he has not done so, he should lose no time in proving their intrinsic value, and I am persuaded that their trial will have the effect of rendering the muslin bag no longer necessary in the vinery or any other house.—W. S.

Caterpillars destroying Grapes (W. M. S.).—Your Vine is attacked by the caterpillar of a small moth, one of the Tortricidæ, but I cannot say to what species it belongs. The use of any insecticide would injure the fruit and do more harm than good, so that there is little else to be done but examine the bunches and pick out the caterpillars. Some might be induced to fall by shaking or jarring the bunches. Any small moths found inside a vinery should be killed, as their presence can do no good and may do harm.—G. S. S.

MILDEW ON VINES.

I THINK that more mildew is caused in vineries by the admission of front air at the time when the Vines are in bloom than from all other causes put together. I see instances of this yearly. Mildew on Vines is very often found in the amateur's vinery and greenhouse combined, simply because the front ventilators are opened freely for the benefit of the plants growing along with the Vines. Hot sun, accompanied with cold easterly winds, is most productive of mildew in vineries where they are at all exposed to draught. Some writers attempt to account for the presence of mildew on not only Vines, but Peaches and other plants, by reason of the uncongenial state of the roots; but I hardly know what line of argument such persons would take up when badly infested vineries, Peach houses and Rose houses are thoroughly cleansed of this fungus without molesting the roots in the slightest. I am satisfied that draughts of cold air admitted through opening the ventilators in opposite directions, like those at the top and bottom of any house, will produce a full crop of mildew.

I have a good example illustrating the defective system of air-giving and its baneful results. I have two plants of *Maréchal Niel* Rose growing in a temporary border in a small span-roofed house very much exposed to the east wind. One plant is at the entrance and facing the opening door, where it, of necessity, is subject to cold draughts on opening the door. This plant is annually mildewed more or less, while the other at the opposite end of the house does not show the slightest trace of the fungus. The same treatment is accorded to both plants in other respects. In a rather lofty Peach house mildew was for a couple of years very troublesome on the trees growing over the front trellis. The ventilators being pivot-hung, they admitted a quantity of air when opened. No matter how hot the sun was, if the wind was blowing from the east mildew was certain to attack the trees when the front ventilators were opened. Now they are never opened in the spring, except for a short time during the hottest part of the day, and then but a little. Under this treatment mildew is not known in that particular house.

I had the misfortune some years since to have all the Vines in the late house badly attacked with mildew, the result of trying an experiment. The vineries here, three in number, are lofty, wide, lean-to in shape, with 4-foot high lights at the back. That devoted to late varieties is 30 feet long and 18 feet wide, and arranged at the east end, which is exposed to cutting winds. When the Vines were in bloom during the month of April we had very hot sun. One day I, being advised to admit front

air rather freely to the Vines, incautiously did so. When the berries were the size of peas the mildew was plainly visible. It spread very rapidly indeed not only to nearly all the bunches, but to the leaves and young wood also. In order to check it the border was kept perfectly dry on the surface—in fact it was covered with flowers of sulphur. The pipes were made hot, and afterwards coated with sulphur made into the consistency of paint. In addition to this the bunches as well as the affected leaves were dusted over with the sulphur. The main rods were likewise painted their whole length with the same sulphur mixture, this being repeated at the end of a month. The hot-water pipes were kept continually hot, air being admitted in moderate quantity through the top ventilators only. The following winter the rods were again coated with sulphur, with the result that mildew was present the following year in but small quantity. By early removing affected berries and dusting the leaves with sulphur where affected the fungus was stamped out entirely. Until the berries commence to colour the front ventilators are not opened, neither have the roots been interfered with beyond an annual top-dressing. E. MOLYNEUX.

Peaches dropping.—Two years ago I had a nice small Peach house erected, and planted four Peach trees, the roots of three of them being inside, but those of one outside. Three of them were young trees, the other a tree some eight or ten years old that I had growing against a wall, but removed to the house. They were all planted in fine new loam from a pasture field, but without any manure. They have all grown splendidly, and appear to be in good robust health and covered with leaves. They were all covered with blossom, and all appeared to set fruit freely, but since then it has all dropped from the finest looking tree. Three fruits only remain on the next finest tree. There is a fair crop on the tree that grew best, and the old tree has some two dozen fruit on it. Can you tell me how it is that the two finest trees have cast all their fruit, and how should I treat them for next season? The tree that has its roots outside is the one that has not a single fruit on it.—J. S.

* * * If "J. S." had mentioned the size of the fruit when it dropped off there would have been a better chance of arriving at a correct conclusion as to the cause of the failure to swell properly. Seeing that the trees are in good health, the wholesale falling off can scarcely be attributed to dryness at the roots, as it is very certain if watering had been neglected this season red spider would have been in the ascendant. The symptoms point to exuberance of growth being the cause of the fruit dropping prematurely. When the trees are first planted in a good, not necessarily rich border, and for two or three seasons after, they are liable to grow very vigorously, though bud-dropping is more often than not the outcome of this grossness. In this instance either the set was faulty or else the fruit was disturbed by the rapid expansion of the wood. The fact of the least vigorous tree being the most fruitful fully bears out this conclusion. All that I can suggest as to the treatment that is most likely to correct the unfortunate habit of dropping the fruit is a very light use of the knife, and in particular the retention of the smaller wood or spray when the winter pruning is done. It sometimes happens that the spray will carry fruit when the strong wood fails. Let the trees have the full benefit of all the sunshine going and as much air as possible. If the wood is still very green and comparatively soft, a little fire-heat during dull showery weather in addition to the free circulation of air will do good. Not till the trees promise to swell a good crop of fruit to its full size should any feeding at the roots be attempted.—W. I.

TREES AND SHRUBS.

ARALIA SIEBOLDI IN CORNWALL.

THE Aralia, part of which is here figured, is growing in the grounds here. Its height is 8 feet 6 inches, the greatest width of the plant being 15 feet 6 inches. From the collar there rise six main stems, the largest being at 1 foot from the ground 12 inches in circumference. It was planted out about fourteen years ago, being then a small plant in a 5-inch or 6-inch pot. It is growing about 15 feet from a wall facing north-east, partially under a Beech tree, and is fairly sheltered from all winds. The soil is light and well drained, the subsoil being clay slate. It has never had any manure of any sort, and has never had any care taken of it be-

Aralia Sieboldi in the garden at Mount Charles, Truro. Engraved for THE GARDEN from a photograph sent by Mr. A. P. Nix.

yond removing other things to give it room. The engraving only gives less than half of the Aralia. A *Chamaerops Fortunei* has rather spoilt one side of it, but that has been moved this spring. What appears to be the stem of the Aralia is the *Chamaerops* mentioned above. The Aralia has suffered a good deal from the drought, many leaves having fallen, but it has much recovered since the rain, and the new growths are coming on well. The *Chamaerops* has not suffered much from the removal, and I have little doubt as to its survival, although it was moved in the middle of the drought. I have a Siberian Crab tree that is a perfect picture; the branches are bent nearly to the ground with the weight of the fruit. In ordinary times I can walk under them. *Rhododendrons*,

which should have bloomed in May, are now coming out, their vitality being renewed by the rain.

ARTHUR P. NIX.

Mount Charles, Truro.

Stephandra flexuosa.—Apart from the small whitish flowers, which are not particularly showy, this is a very pretty shrub, which to be seen at its best must not be crowded up, as a great deal of its beauty consists in the graceful manner in which its branches are arranged. It is nearly related to the *Spireas*, and bears a certain amount of resemblance to some of them. As a shrub from 4 ft. to 6 ft. in height this *Stephandra* displays itself to the best advantage. The principal shoots are erect, the upper portion as well as the branches gracefully arching, while the entire bark is bright red. The leaves, which are disposed alternately in a very regular manner along the slender shoots, are trilobate, very deeply cut, and about a couple of inches in length. They are of rather a pale shade of green. This *Stephandra* is a native of

white or pink. They are very sweetly scented. Besides its value for its own sake as a beautiful flowering shrub, this *Azalea* will in all probability render the hybridist good service in the production of a race that will extend the flowering season of the *Azalea*, and at the same time combine the brighter colours of some of the earlier flowering hybrids with the late blooming qualities of *A. viscosa*.—T.

Leycesteria formosa.—We are pleased to see that a group of this fine shrub has been planted in the Bamboo garden at Kew. It is a native of the Himalayas, from whence it was introduced in 1824, and is of charming grace, whilst no fear need be entertained as to its hardiness. When in suitable soil and position it will grow fully 6 feet in height, the branches gracefully bent and very leafy, the purplish white flowers and bracts in appropriate contrast. Then we get the rich purple berries in autumn, and in especially sheltered spots the branches retain their leafy character throughout the winter, but usually it is deciduous. Ordinary soil will suffice; in fact, it is in a sense everybody's shrub.

Amorpha canescens.—Although this plant was first introduced, according to Loudon, in 1812, it does not at any subsequent period appear to have been common; now, at any rate, it is very rarely seen. The name occurs in the sale lists of some Continental nurserymen, but we have not yet been able to get the true canescent species; the plant which figures under the name appears to be a form of *A. fruticosa*. It is, however, very different from and superior to that species, making slender shoots each year 1½ feet to 2 feet long, which (in the open, at any rate) are killed back annually. The most striking character peculiar to this species is the hoary appearance of the stems and leaves, imparted by a covering of short grey hairs. The flowers, borne on a compact raceme at the end of each shoot, are of a bright bluish purple. In most years it flowers during August, but is this year somewhat earlier than usual. It is a native of the Southern United States and is described as growing on the banks of the rivers Missouri and Mississippi.—B.

Lespedeza Sieboldi.—This is the name applied at Kew to the plant commonly known as *Desmodium penduliflorum*, whose profusion of rosy purple pea-shaped blossoms form such a pleasing feature in early autumn. Between this plant and *Lespedeza bicolor* there has been for many years and in various publications, including the "Dictionary of Gardening," a good deal of confusion, for these two plants are regarded as synonymous with each other, though they are really perfectly distinct. The plant hitherto regarded as *Desmodium penduliflorum* is of a half-shrubby character, that after flowering dies nearly to the ground and pushes up the following season's shoots from a few large buds near the base of the plant. The shoots are long and slender, the tallest reaching a height of 6 feet or even more. They are rather thinly clothed, especially towards the base, with trifoliate leaves and terminated by crowded racemes of rosy purple pea-shaped blossoms. The flowering season is usually from the middle of September onwards, though this year the flowers will in all probability be earlier than that. *Lespedeza bicolor* commences to bloom early in August and is usually over before the *Desmodium* begins. It (the *Lespedeza*) is an upright-growing plant from 3 feet to 4 feet in height, with far rounder leaflets than the other and the flowers are not nearly so showy. It is pleasing to record the fact that the distinctness of these two plants is now recognised by our botanical authorities, and on this point it should be borne in mind that *Lespedeza Sieboldi* is as a garden plant much superior to *L. bicolor*, though in many gardens a place may well be found for both of them, especially when it is remembered that, in common with many of the Leguminosæ, they resist drought better than several other classes of plants.—T.

Japan, from whence it was introduced a little over twenty years ago, but Messrs. Veitch were, I believe, the first to put it into commerce about ten years later. As a graceful shrub of a pleasing and distinct appearance, and one at the same time that is not very particular as to soil or situation, this *Stephandra* has much to recommend it.—T.

Azalea viscosa.—By the early part of August (especially during such a season as the present when many autumn-flowering subjects are already past their best) this *Azalea* with only a few of its blooms still in an unexpanded state is sure to be noticed, as this beautiful class of hardy flowering shrubs is chiefly identified with the spring months, and the fact that there are some species that bloom much later on is apt to be generally overlooked. After *A. rhombica* and *A. mollis* come the bulk of the hybrid varieties, known collectively as Ghent *Azaleas*, while the season is continued by the Californian *A. occidentalis*, and lastly, by the subject of this note—*A. viscosa*. The individual blooms of the last are rather small, and in colour

Hypericums in bloom.—As the summer advances and but few flowering shrubs are left us, many of the *Hypericums* are very gay with their

wealth of golden blossoms, which colour is but little represented among shrubs at this season, though numerous enough in the case of herbaceous subjects, notably some of the larger Composite. The Hypericums are natives of a considerable tract of country in Europe, Asia and North America, and of them the Indian and Japanese species are remarkably showy, but not always of sufficient hardness to resist our more severe winters. Three of these eastern species have already been illustrated by means of coloured plates in THE GARDEN, viz., *H. patulum*, Vol. XII., *H. triflorum*, Vol. XXIII., and *H. oblongifolium*, Vol. XXX, while a hybrid form from one of these is now among the most popular of all Hypericums. This is *H. Moserianum*, which was obtained by intercrossing the Japanese *H. patulum* with the common Rose of Sharon (*H. calycinum*). This last is certainly one of the best of the dwarf St. John's Worts, but is far too common to need anything further said with regard to it. *Hypericum olympicum*, figured in THE GARDEN, April 2, 1887, is another low-growing species, but quite distinct from the preceding. The foliage of this is very glaucous, while the flowers are large, but more starry than in the eastern species. The first two kinds mentioned by London are *H. elatum*, which forms a somewhat erect, freely branching bush, that reaches a height of 3 feet or 4 feet. The flowers of this are small, but of a rich yellow, and borne in great profusion, while in the case of *H. hircinum* which grows about a yard high, they are of a paler yellow, while the stamens are so long that they project somewhat further than the petals. Of these two, *H. elatum* is a native of North America, and *H. hircinum* of Spain.—T.

THE FRUIT CROPS.

SOUTHERN.

Heckfield Place, Winchfield.—With such an exceptional season it is gratifying to be able to report the fruit crops as quite up to the average, and although on such gravelly soils as ours where the drought has been felt most severely, a falling off in size is the only noticeable feature to complain of. Apples, probably the most important crop of all, are quite up to the average, fruit on old orchard trees being decidedly smaller, whilst trees in the kitchen garden where water has been available are good. Cellini Pippin, Lord Burghley, King of the Pippins, Pott's Seedling, Bienheim, and Deux Ans are fairly well laden with good fruit. Pears are also good, those favoured with a goodly supply of water carrying good crops of fine fruit. Those worthy of note are Brockworth Park, Beurré Hardy, Durandean, Marie Louise, Glou Morceau, and Knight's Monarch, the last in my opinion being one of the very best of the winter Pears, although very apt to lose a great many of its fruit prematurely. Of the many varieties grown here I know of no more juicy and delicious Pear than Knight's Monarch after Christmas. Apricots set an enormous crop, heavy thinning having to be done at an early period and again at intervals to reduce the crop, which has been extra fine where water has been applied freely. Early Cherries were destroyed by a late frost, but Morellos are plentiful and good. Peaches are also good, and trees exceptionally clean and healthy, frequent washing down with the garden hose keeping spider and black-fly in subjection. Strawberries have been bad, the fruit small and poor in flavour, and the season very short. The same remarks apply to other bush fruits. Gooseberries were badly infested with red spider, many trees dying outright.

Kitchen garden crops have wonderfully improved since the rain, but I should hardly think a gardener's energy was ever more severely taxed than it has been this season in this department, especially where labour is short and the demand great. Peas have refused to grow. Carrots have in many places gone off altogether, and Onions

have fared but little better. A mild and genial autumn may, however, mend matters in this department.—A. MAXIM.

Nuneham Park, Abingdon.—The prospects generally, considering the exceptional season we have just passed through, are very cheering. Apples are a full crop and good; our best are Blenheim Orange, Cox's Orange, King, Kerry, and Gooseberry Pippins, Beauty of Kent, Kentish Filba-ket, Cellini, Cox's Pomona, Hawthornden, Hollandbury, Lord Suffield, Stirling Castle, and Wellington. Pears are an average crop, the best being Beurré Bachelier, Beurré Diel, Conseiller de la Cour, Duchesse d'Angoulême, Easter Beurré, and Marie Louise. Apricots have been a very heavy crop, fruit large, and, owing to the tropical weather, beautifully ripened, but fully a month in advance of their usual season. Cherries of sweet varieties were plentiful and good. Morellos abundant. Plums are a very heavy crop; indeed it would be hard to particularise any variety this season. Of Peaches and Nectarines I am not able to speak, as we grow none outside. Of small fruits, Black, Red, and White Currants, Raspberries, and Gooseberries are abundant. Strawberries with us (and I may say this neighbourhood generally) were about half a crop, owing to the long-continued drought, and fully three weeks earlier than usual. Fortunately, I mulched early in the season, otherwise the crop would have been light. Noble with us withstood the drought as well as any variety. Figs and Quinces are an average crop. Medlars light. Filberts plentiful. Walnuts scarcely any.

Potatoes are looking well, although the crop of early varieties has so far been light, but at the same time of excellent quality, and so far no trace of disease.—ARTHUR GEORGE NICHOLS.

Kingston-on-Thames.—Exceptional opportunities for seeing the general condition of the fruit crops in many parts of Surrey and West Middlesex enable me to say that in spite of the long drought the crops have been and are generally very good indeed, and in some places wonderfully so. On the whole, the Surrey sand and irregular ground formation seem to give some of the best imaginable products. Apples are not so abundant or so fine as usual on dwarf trees on the Paradise stock, except where kept well watered and mulched. Where left to take care of themselves, and especially thickly planted, the effect on the fruit crop has been harmful. Still there has been, if less wood growth, very much of stout bud-formation that should on dwarf trees produce a heavy crop next year. In the case of standard trees, especially on old ones, there are heavy crops, but these are chiefly of the old orchard varieties. Standard trees seem to have felt the effect of the drought but slightly, and where the fruit is small it is perhaps more due to heat or dryness of the atmosphere and excessive cropping than of drought at the roots. In many districts the Pear crop is a wonderful one; Williams' Bon Chrétien, Louise Bonne, Beurré d'Amansil, Marie Louise, &c., are often found crowded with fruit. At Hook, just beyond Surbiton, Williams Pear trees many years old are carrying wonderful crops, many trees having from ten to twelve bushels on each, perhaps even more, and a fine sample. Dwarf trees on the Quince have not done very well, but are making fruit-buds freely. Wall Pears are generally good everywhere, and now that such fine rains have fallen the samples should be excellent, as in all similar cases the fruits have materially swollen. Plums have been a partial crop, only here and there heavy. These and Damsons not only have suffered at the roots from the drought, but the hot, dry atmosphere generated aphids and spider to an unusual extent. Out of these troubles the trees are now growing. The best crops seem to be on Rivers' Early Prolific, Victoria and Czar, and in some cases Green Gages are abundant. All allowance being made, however, Plums will be plentiful in the markets. All descriptions of Cherries have been heavy crops, although the fruit may not have been so fine as usual. Still there has been no cracking. Morellos have fruited wonderfully on bush, standard, and wall trees. Still Cherries have been much troubled

with aphids; so, too, have been Black Currants, the crop having been but a moderate one, as the bloom, doubtless owing to sharp frosts in April, was then greatly thinned. Red and White Currants have been abundant and fairly good. Perhaps Gooseberries suffered most from the drought, as spider was so general. Rarely have the bushes been worse attacked. Still there has been plenty of Gooseberries. The effect of the spider attack on the bushes may be more apparent next year. Of the bush fruits, Raspberries suffered most, as in many cases the berries almost withered up instead of swelling. However, new canes are making good growth now. Strawberries, because shallow rooted, also very materially felt the drought, and whilst fruits were for a short time abundant and cheap, the season was soon over. Plants now are rapidly recovering. Walnuts and small Nuts are fine, clean, and very abundant. Wall stone fruits have been and still are wonderfully plentiful—indeed, it is a great Peach season.

VEGETABLE CROPS.—The most remarkable thing in relation to nearly all vegetables is the wonderful recovery shown all round since the rains have fallen. Early Potatoes were small, but good; later ones should give a splendid crop. Peas have been seriously affected both by root-dryness and flower-blindness, so that crops have been light and of short duration. Broad Beans poor and much blighted. Runner Beans are everywhere good, and will now give abundant crops. Dwarf Beans have been much affected with spider, but on good ground are cropping fairly well. Cauliflowers have been indifferent and much blighted; so also have been Cabbages. All kinds of winter greens and especially Brussels Sprouts will be good and plentiful. They are making remarkable progress since the rain. Onions are thin from spring sowings, but autumn sowings have capital results. Carrots are very good; so also are Parsnips. Beet has come very irregularly, but there will be plenty. White Turnips are now growing rapidly. Marrows are fruiting fast, and Tomatoes outdoors are excellent. The vegetable promise for the winter is of the best.—A. DEAN.

Wycombe Abbey, High Wycombe.—Notwithstanding a season of almost unparalleled dryness, the fruit crops, as a whole, are unquestionably very satisfactory, and with the exception of Pears, most other kinds will be above an ordinary average crop. As might naturally be expected under the conditions, the insect pests are numerous and troublesome, so much so that in some places the damage done by the green and black fly and by that terrible enemy, the red spider, will assuredly do the trees harm and in all probability affect the quality of the fruit this year. I never remember in my experience to have seen the Apple trees so badly affected by the red spider. Peaches, Nectarines and Plums are likewise smothered with these insects in many places. Apples are good and plentiful. Pears rather scarce. Plums and Gages abundant. Cherries of all kinds have been a splendid crop, and the conditions most suitable for finishing them in fine order. Peaches and Nectarines full crops of fruit, which apparently will be below the usual size. Apricots a full crop, but smaller in size than usual. Bush fruits, as Currants, Gooseberries and Raspberries, very good. Strawberries, if anything, under the average and not so large as usual. This fruit has doubtless suffered more through the prolonged drought than any other, and where a good supply of water could not be obtained the crop was quickly over.

VEGETABLES.—The effect of the prolonged drought this season is plainly visible in this department, and never in the course of my experience have I seen the kitchen garden crops altogether in such an unsatisfactory state as they were at midsummer this year. The crops of early Potatoes had made but little growth and the tubers were fit for lifting to be stored away. This we did and found them to yield only a light crop of medium-sized tubers. The later crops showed unmistakable signs of the need of water by a restricted growth in the haulm, which under the sun's powerful influence flagged freely, and doubtless this crop will not turn out to be very good as regards quan-

tity. The root crops, as Onions, Carrots, Turnips, Beet, &c., which were not watered show unmistakable signs of having a struggling existence. The Brassica tribe likewise in some measure shared the same fate—Cabbages in particular; instead of being fresh and green, the leaves in some places were almost as blue as a whetstone, but since rain came all the subjects have improved, and with more of it we shall find our autumn crops will turn out to be as good as they are generally. In this locality hills and valleys abound, and Potatoes, of course, are considerably grown in both situations, and I may here observe from the present appearance of the crops, combined with the almost unprecedented character of the season, a lesson may be drawn, which evidently shows the advantage the early-planted crops possess over those which are later, and is conclusive that early planting is to be recommended for such hilly positions where the air generally is dry and the plants are less liable to injury from late frosts. And why? Because at the time of early planting the soil naturally is moist and growth at the roots will proceed and the plants become established firmly in the soil before our usual dry period commences. In the valleys, where rich soil abounds and moisture likewise, the planting should be done later because under these conditions growth is rapid and vigorous; consequently the haulm is tender and therefore much more liable to be injured by late frosts.

—GEO. THOS. MILES.

Warren House Gardens, Kingston, Surrey.—Considering the exceptionally dry weather, I do not think that the various crops have suffered quite so much as one might have anticipated. Bush fruits have been heavy. Currants small. Raspberries very small and poor. Apples good crops on most trees, but on a few trees the fruit will be small. Pears a medium crop, Williams' Bon Chrétien excepted. Standard Plums medium, but on walls a good crop. Peaches, Nectarines and Apricots good crops, but small. Cherries good, both on standards and walls. Strawberries have been a failure generally in this district. The earlier varieties, such as Noble, Keens' Seedling and Captain, had very fair crops. Of the midseason varieties, President, Sir C. Napier, James Veitch, British Queen and Sir J. Paxton were poor; Waterloo very poor; but of Laxton's Latest of All a good crop of large, cockscomb-shaped fruit, rather pale in colour and of a capital flavour, was picked.

Vegetable crops have no doubt suffered very much this season on account of the exceptional dryness of the season. The first batch of Peas was ready to pick fully a fortnight earlier than usual, the second sowing being ready at the end of May. All other varieties have been poor except Huntingdonian, growing only to about half the height which they attain in ordinary seasons, thereby producing less than half of the usual crop. Huntingdonian, although an old friend, I still find one of the best midseason varieties, especially on this poor, light gravelly soil. It has given a good crop of well-filled pods and of good flavour this year, which has been very acceptable, considering the partial failure of the other varieties. Broad Beans have suffered very much this season from the black fly; the early sorts escaped it fairly well, but the late sowings were completely smothered by the fly as soon as they were out of the ground. The Onion crop in some gardens has been entirely destroyed by the Onion maggot; in other gardens adjoining no trace of it has been seen. This is the first season that I have known the maggot to attack Leeks, although it did not attack them until it had cleared the Onion bed. Potatoes are turning out well, although small, and free at present from disease. Parsnips, I think, will turn out a fair crop. Carrots and Beet will be small; the seed of the two last lay in the ground for fully a month before germinating.—G. WOODGATE.

Maiden Erleigh, Reading.—For fruit of all kinds the present is the best season we have had for many years. Apples are an average crop, and since the welcome rains we had in the second week in the month, viz., nearly 1½ inches, they are now growing apace. Pears also are an average crop and the fruit very clean. This applies to such

kinds as Glou Morceau, Bergamote d'Esperen, Winter Nelis, Jean de Witte, Josephine de Malines, and other late kinds which seldom come free from cracks and spots, thus proving that in an ordinary season we do not get sun enough for Pears. Plums also are plentiful both on walls and in the open, and we have not had the trees so free from aphid for many years. By the way, I may add that all our fruit trees have received copious supplies of water. Apricots, which we have been gathering in quantity since the end of June, are an enormous crop. The following are the kinds already gathered and which ripened in the order named: Sardinian, New Large Early, Oullin's Early, New Early (very fine), Frogmore Early, Royal and Roman; and the following are yet to ripen: D'Alsace, Kaisha, Moorpark, Turkey and Shipley's. Peaches and Nectarines are good crops, and the trees, which were much infested with black aphid early in the season, are now clean and healthy. Cherries, both sweet and Morello, have been heavy crops; the former, owing to the dry weather and heat, were smaller than usual, but the Morellos on north walls and bushes are very fine. Of bush fruits, Gooseberries were a very heavy crop, and although the bushes have not made so much growth as usual, there has been little difference in the size of the fruit. Warrington does not promise to keep so long as usual. Both Red and Black Currants have been good. Raspberries also a full crop. Strawberries grown on south, east and north borders, as well as on open quarters, gave us a long season considering the great heat, and it is some years since we were able to gather so many for preserving. President and Sir Joseph Paxton on north borders were the most satisfactory, but Sir Joseph was also splendid on open quarters, thus proving it to be a really dry-weather kind. Walnuts, Cobs, and Filberts are enormous crops and very fine.

POTATOES.—On good or deeply trenched ground the Potato crop is all that can be desired and the quality superb. On shallow soils the crop is very light indeed, the tubers being exceedingly small. This, I regret to say, is the general condition of the crop in cottage and allotment gardens, and the outlook for the winter is gloomy indeed. Disease has also appeared within the last few days. After the spring Cabbage was cut, vegetables were exceedingly scarce till French Beans came in. On shallow as also on light soils, Peas were only kept going by much labour spent in watering them, whilst on good holding ground they have been fairly satisfactory without water. Roots, viz., Carrots and Beet, where sown before the month of May, are very uneven; but where sown after then and not thinned till July they are looking well. Partial loss of the Onion crop by maggot is general in the district.—T. TURTON.

Dropmore.—Throughout this district the fruit crops generally are up to the average. Of course, everything has been more or less affected by the exceptionally dry season, and our district being also a dry one we have probably suffered more than other favoured localities. Nevertheless, we have a good supply of fruit, although Apples and Pears are not a full crop. All trees of the former both in orchard and garden cropped very heavily last year; consequently a crop rather under the average quite answers to our expectations this year. Of pyramids on the Paradise stock, Pott's Seedling, Ecklinville Seedling, Lane's Prince Albert, Lord Grosvenor, Bismarck, Winter Hawthornden, Grenadier, Cox's Orange Pippin, and Worcester Pearmain are bearing good crops; as also of orchard trees are Devonshire Quarrenden, Cox's Orange Pippin, King of the Pippins, and Blenheim Orange. Pears suffered somewhat from frosts while in bloom, and are mostly thin crops, the best being on trees of Seckel, Williams' Bon Chrétien, Louise Bonne of Jersey, Pitmaston Duchess, Beurré Diel, Mme. Trévey, Glou Morceau, and Doyenné du Comice. Peaches, Nectarines, and Apricots on walls are full crops, all having to be considerably thinned. Apricots are the heaviest crop we have had for some years, and notwithstanding the dry weather have attained a fair size and ripened well. Peaches and Nectarines also

promise to be equally good; the trees are healthy and fairly free from insect pests. Waterloo Peach ripened in June, and now (July 24) Grosse Mignonne is ripe outdoors. Our orchard Plum trees had all fruit-buds destroyed by bullfinches, but generally the Plum crop is unusually heavy, and all wall trees are heavily cropped. Cherries were plentiful, but rather small. Bush fruits very abundant, especially Gooseberries. Strawberries fairly good, smaller than usual. We gathered the first outside on May 9, and have just finished off with Elton Pine and Oxonian.

Vegetables have suffered from the continued drought, but the supply has been fairly good. Peas are rather more than half their usual height, but we have as yet since the commencement of the season gathered a daily supply, our standard kinds now being Autocrat and Ne Plus Ultra. Cabbage and other green stuff are badly infested with fly and a kind of white aphid. Potatoes are good in quality and no disease yet; the tubers are smaller than usual.—CHAS. HERRIN.

Digswell, Welwyn.—Peaches medium. Nectarines very poor, especially the clingstone varieties, such as Pine-apple and Sir C. Napier. Apricots very good. Plums extra good all round here. Cherries below the average with the exception of Morellos. Pears vary; in some gardens they are abundant, while in others there are very few. Apples a good crop all round. The trees, especially Plum trees, have suffered very much owing to the long drought. Bush fruit plentiful, but very inferior in size and flavour. Strawberries very poor. With reference to inside fruits they have been exceptionally fine, especially early houses, considering the long drought we have passed through. The principal gardens around here are looking surprisingly well, as I find my neighbours have done the same as myself—devoted a greater part of the labour to watering.

With vegetables the long drought has made sad havoc, more especially in gardens where there is lack of water. Peas very good, also dwarf Beans. Runners are now doing well. Broad Beans very poor. Cauliflowers fairly good, but, speaking generally, the Brassica tribe has suffered very much. Root crops are below the average, taking Digswell gardens as an average; we have had to sow two or three times to get a medium crop of Parsnips, Beets, Carrots, Turnips, &c. Onions medium crop. Potatoes (early) very small; Main-crops are now showing a tendency to grow again. Celery since rain is looking very promising (generally).—W. L. BASTIN.

Eridge Castle.—The fruit crops in the county of Sussex have been, and are most abundant, but owing to the great heat and absence of rain, they were but very short lived, and did not swell out to half the size. Orchard fruits are very fine. Pears, Apples and Plums have been much benefited by the recent rains, and will now swell out to their full size; the only difference is that they will all be ripe a month before their time owing to the great heat, for nearly three months in some cases it was 92° in the shade. I cannot let the opportunity pass without strongly urging all interested in fruit culture to keep bees in their gardens; they set the blossoms in the spring and are the means of us growing our own honey.

Vegetables have suffered severely from the want of rain, the Peas most of all. Potatoes have been so far excellent, and in many cases were planted and grew without a single shower, the moisture in the earth being sufficient to bring the crops to maturity. Wasps are a great plague, the northern wasps, which build their nests suspended in trees and bushes, being very numerous. Taking the year as a whole the weather has been the most remarkable during the memory of man, for we had 100 days with only an inch of rainfall.—J. RUST.

Ottershaw Park, Chertsey.—Apples are under average with the exception of a few sorts. Keswick Codlin, Irish Peach, Stirling Castle, and Fletcher's Seedling have a good crop. A good few fruit dropped before we had the much-needed rain, but since then the fruit is swelling fast. Pears are under average, but Marie Louise, Wil-

liams' Bon Chrétien, and Beurré Clairgeau on walls have a good crop. Damsons are a good average crop; the trees looked very bad and blighted early in the season, but since the rain they are looking well. Plums a good average; trees are now looking well. Cherries considerably under average (except the Morello); the trees and blooms alike were much damaged with frost. Nuts are a very good average. Peaches and Nectarines are a good crop, and where the trees have been attended to are now looking well. Apricots average. Small fruits are very good. Strawberries good average, but the late sorts were soon over on account of the dry weather.

All the early Potatoes have turned out well, but small; the best are Ashleaf and Sutton's Ring-leader. The late ones on good ground are looking well. Early Peas and Beans turned out well, and the late ones are looking well. The mid-season Turnips and Cauliflowers are a failure.—THOMAS OSMAN.

The Durdans, Epsom.—Apples, Pears, and Plums are an average crop in this locality. Cherries under average. Apricots a heavy crop. Raspberries, Currants, and Gooseberries good. Strawberries we commenced gathering on May 15 from John Ruskin and Noble both on the same date (a good crop); all the other sorts were a short crop and soon over.—J. BARCLAY.

Brambletye, Sussex.—The fruit crops in this neighbourhood are very good, notwithstanding the four months of hot, dry weather that we have passed through; but the welcome deluge of rain that we had on July 12 seems to have reached the roots of all sorts of vegetation and given everything (from the Grass on the lawns to Apple trees) new life. The Apple crop is a very heavy one, but on some trees the fruit will be smaller than usual. The following varieties are all heavily laden with fruit: Alfriston, Bismarck, Blenheim Orange, Bramley's Seedling and Wiltshire Defiance (both very fine), D. T. Fish, Flower of Kent, Hawthornden, The Queen, Hanwell Souring, Lord Suffield, Oslin, Worcester Pearmain, Cox's Orange Pippin, Warner's King, Lord Grosvenor, Lady Henniker, Hoary Morning, King of the Pippins, Rosemary Russet, Pott's Seedling, Mannington's Pearmain, Cellini, Dumelow's Seedling, Ecklinville, Golden Noble, Tower of Glamis, and many others. Pears on most trees are but a thin crop. Plums of all kinds (excepting Damsons) are a splendid crop, the standards requiring the branches to be propped up all round the trees. Peaches and Nectarines are a good crop. Dessert Cherries were fairly plentiful, but the trees suffered very much from black fly. Morellos are a good average crop, as they always are here. Black, Red and White Currants were an exceptionally heavy crop. The Gooseberry crop is all that could be desired, but the bushes have been very much infested with the caterpillar, which has given us much trouble. Raspberries were plentiful, but small, and had a very short season owing to the hot weather that we have had. Strawberries were a good crop, but the fruit was rather smaller than usual. Cobs, Filberts and Walnuts are most abundant.

Early Potatoes have been good in quantity and quality, but the tubers are smaller than they have been in former years. The later varieties are looking well. I have seen no signs of disease as yet. The vegetable crops are all looking well now, but we have passed through a most trying season, the Pea and Bean crop having been all but a failure.—GEORGE F. GLEN.

Harrow Weald Park, Stanmore, N.—Apples with us are a good crop, also Pears and Plums. Peaches and Nectarines outside are a good crop. Gooseberries were plentiful, but very small on account of the drought. Currants, Black and Red, a good crop, and not affected by the drought. Raspberries a light crop. Strawberries were plentiful, but dried up and flavour bad.

With regard to vegetables, Peas were a failure after the early sowings were gathered, four long rows of Main-crop Peas yielding only half a peck. Onions, which generally do well, are almost a failure, yet in the neighbourhood they have done

well in some cases. Carrots have come up very thin. Beet has not suffered so much, coming up very well. I see in looking over the crops since the recent rains that some of the seed is just coming through. The rains have come too late for the Potatoes, as I see the tubers are all growing out. Except in the case of early varieties, they seem to be a good crop.—J. MARTIN.

Condover House, Alresford, Hants.—Ours is a particularly dry and sandy soil with a subsoil of chalk, at an average depth of 15 inches to 18 inches. We have had less rain in the district than in adjoining neighbourhoods, as measured by the rain gauge; consequently all small seeds have required constant and plentiful waterings to obtain a medium crop. Peas and Beans have, although watered well, grown only to a medium height, and have borne much under the average crop. The early growth of all the crops was very good. The wireworm and white maggot have been very destructive to the green crops. Potatoes of the early kinds grew well at first, but have now ripened off. Late varieties have sprouts several inches long. Disease has not shown itself as yet.

Strawberries suffered through the drought, although they blossomed remarkably well. The great heat shrivelled up the late blossoms. Raspberries are a magnificent crop and much above the average. Currants, Red and Black, are over the average in quantity and quality, with a good flavour. Gooseberries are a heavy crop and decidedly above the average. Plums and Damsons have only a sprinkling of fruit, although they blossomed well. Late frosts were injurious to them. Cherries, too, bore remarkably well considering the season. The best crop of the garden, however, is the Apples. The fruit is fine without exception, and trees both young and old are bearing heavy crops, which in many cases require support. In fourteen years' residence here I have not known the Apple crop better. All kinds are bearing equally well. Gooseberry, Currant and Apple trees that have not borne for some years have done so this year. Pears are much under the average in quantity; the frost damaged the blossom.—ANDREW OLIVER.

Wray Park, Reigate.—The fruit crop in this district I think very good. Here with me Strawberries have been a good crop, but the season short owing to the drought. Gooseberries, Currants, and Raspberries abundant. Apples and Pears abundant. Plums not quite the average. Vegetables have been very good considering the season.—J. HOAD.

Bassett Wood, Southampton.—Strawberries a fair crop, but small in size. Small fruits, such as Raspberries, &c., very good. Plum trees heavily laden, but fruit small. Cherries not so good as usual. Peaches and Nectarines good. Apples plentiful. Pears a good crop and fruit fine. In fact, the only fruit that really seemed to suffer from the dry season was Strawberries.—F. BONEY.

Bookham Lodge, Cobham.—Apples, Pears, and Plums under average, very small in places. Cherries average. Peaches and Nectarines good. Apricots good. Small fruits full crop. Strawberries very poor. Nuts good. The long-continued drought experienced in this part of Surrey will not soon be forgotten by those gardeners who have had to battle against it, especially those who like myself found their water supply fail just when most wanted. Small seeds lay dormant for weeks till sufficient moisture fell to cause germination to take place; consequently several successive sowings came up at the same time, making a regular supply quite an impossibility. I found it so at least after having worked the same garden for eighteen years. The effects of good deep cultivation with plenty of good farmyard manure trenched in in autumn and early winter never in my experience showed to more advantage than this summer. We have been favoured with sufficient showers to make the meadows become green and the crops in the garden to start, but where crops have been growing and the ground become firm it is as dry as ever 2 inches below the

surface. In my case water is still scarce and must be used with care. Insects have been very numerous, causing much labour to be spent on wall trees. Red and White Currants are very dirty from the same cause; in many instances very little growth has been made.—A. J. SANDERS.

Bearwood, Wokingham.—The fruit crops here and in this district are not so good as last year. Apples and Pears are under average. Plums the same. Wall fruits, Peaches, Nectarines, Apricots and Cherries are a good average crop. Bush fruits the same, only badly infested with insects. Strawberries promised well, but suffered very severely from the great drought. In many places the plants were completely burnt up. This season will be long remembered as the most trying one to gardeners ever known. All kinds of fruits are small owing to want of moisture, and a great many Apples and Pears have fallen through the great drought.

Potatoes are promising. Our early crops have turned out well, later ones the same, and free from disease.—JAMES TEGG.

Broomfield Hall, Sunningdale.—The fruit crops are very good on the whole. Apples are a good crop both on standard and pyramidal trees, but in all cases the fruit is small on those trees we have not found time to water. Of Pears, a few kinds are carrying good crops both on the walls and on the trees in the open. The following kinds have good crops: Marie Louise, Louise Bonne, Easter Beurré, Doyenné d'Été, Doyenné du Comice, and Williams' Bon Chrétien. On others the crop is thin. Apricots are continually dying with us, trees of all ages going off in the same mysterious way, sometimes a branch, sometimes half a tree, and occasionally a whole tree dying in one season. Those trees we have left are carrying good crops of fair fruit, but they were protected when in bloom. Having a large unbeated orchard house, we have only three Peach trees on the open wall. They were protected in the spring and bore good crops. Fruit of Alexander was ripe the first week in July; they were small, but the flavour was very good. Early Beatrice was ten days later; the fruit was much larger than that of the former, and although the flavour did not equal that of Alexander, I think we never had it quite so good. Plum trees on walls, where protected when in bloom, are bearing good crops, but those not covered, both on south and west walls, have no fruit. The pyramids, although not protected in any way, are laden with fruit. Morello Cherries and the Florence on the walls have good crops, though not protected in the spring, while the bloom of May Duke and Ashton was all destroyed by the frost. Pyramidal trees gave us good crops, both May Duke and the Bigarreau tribe, and as we had no damp weather to cause the fruit to crack, we had a supply from them for a longer time than in any previous year. We gave them copious waterings at the roots at intervals. This seems to prove that it is moisture in the atmosphere and not in the soil which is the cause of cracking in this useful fruit. Strawberries bore a very good crop, and, thanks to a good supply of water in their near vicinity, the size and flavour were good, but after Noble and Pioneer, all the other kinds both late and early were ripe at the same time, so that the season was very short. Gooseberries and Red Currants have borne good crops. Raspberries suffered very much from the want of rain, and the Black Currants were almost a failure from the same cause.—G. BURT.

Old Warden Park, Biggleswade.—Apples are a good average crop; the fruit of many kinds is rather smaller than usual, but now the rain has come they are swelling fast. The Codlin type, such as Lord Suffield, is better than I have ever seen it. Pears are about half a crop, but rather small on bush trees, better results on walls. Beurré Clairgeau, Louise Bonne of Jersey, Marie Louise, and Williams' Bon Chrétien are the best. Plums are a good average crop. Apricots half a crop. Peaches and Nectarines on unprotected walls are carrying full crops, and are ripening a month or five weeks earlier this season. The trees

generally are healthier and better than they have been for some years; the fruit is of good size, quality, and colour. We began to gather the first week in July, but they have been assisted with liberal waterings. Strawberries showed abundance of bloom, but owing to the late spring frosts, the long drought, and excessive heat we have only had about half a crop, and this was only secured by heavy watering. Laxton's Scarlet Queen was the pioneer this season, beating John Ruskin and Noble by a few days. Laxton's Latest of All has proved itself a good variety of the British Queen type, of excellent flavour, doing well on light sandy soils where British Queen will not succeed. Oxonian was the latest, with finely coloured fruit. Gooseberries full crop. Other kinds of small fruits about half a crop, but very small and ripening irregularly. Owing to the long drought it has cost a good deal in labour and nets to protect the fruit from the ravages of the birds, which are very numerous here. As soon as the fruit shows signs of colouring it is attacked and devoured. The little blue-tits are very troublesome; they set nets of ordinary sized mesh at defiance.

Most kinds of vegetables have suffered from the drought; it has only been from highly cultivated and deeply dug soil that the best results have been had. Under these conditions Peas, Cauliflowers, and other spring crops were excellent up to mid-summer. Insects have been troublesome more or less, but the foliage on most kinds of fruit and forest trees is of a fine dark green colour. Owing to the welcome rain we had during July (over 3½ inches) vegetation is making rapid strides.—G. R. ALLIS.

BOOKS.

LES ORCHIDEES RUSTIQUES.*

This is a neatly-printed, paper-covered volume of 242 pages and thirty-nine engravings, and is devoted to the description and culture of Orchids that are hardy at Paris and Geneva. It treats of their botanical characteristics, fertilisation, classification and culture in a popular manner, and is a desirable book for all who are fond of growing the numerous hardy members of this enormous family. We have very often felt the want of a handy little work of this kind, one which can be referred to in a few minutes as to anything connected with these "gems of earth" and their culture in the garden. So far as our native British Orchids are concerned, Mr. A. D. Webster long ago gave us a reliable book full of notes and suggestions, but M. Correvon takes us further afield, and tells us what the hardy Orchids of Europe really are and how we are to successfully treat them.

The chapters on the fecundation and classification appeal, it may possibly be, only to the more educated of amateur cultivators. As a handbook for continental growers of terrestrial Orchids it is as perfect as such a book can be expected to be, and the price places it well within the reach of all who care for its subject-matter.

It is high time we had a revival of hardy Orchid culture. Since H.R.H. the Comte de Paris left Twickenham some years ago these plants have been but rarely seen at our London flower shows. I shall never forget the delight I felt at seeing some of Mr. Needle's exhibits at S. Kensington, which contained the most luxuriant pots of Orchis and Ophrys, Cypripedes, Bletia, Listera, Platanthera and Nigritella, all in full flower as the seasons sped round. Some pots of Ophrys speculum in yellow loam and nodules of limestone will never fade from my

* "Les Orchidées Rustiques," par Henri Correvon. Geneva and Paris, 1893, pp. 242, with engravings, &c.

memory. So also in another garden have I seen luxuriant pots of Calopogon pulchellus, Cypripedes of many kinds, and pans of the exquisite Ophrys dedicated respectfully, let us hope, to the bee, and the spider, and the silly little fly! Then we remember the great masses of the purple Orchis of Madeira and the Canary Islands, *O. foliosa*, as it luxuriates at Edge Hall, in the rich soil of Cheshire. Even here in the old University garden at Dublin one of the first things I noted when I first saw the place, now some fifteen years ago, was pots of the great Orchis latifolia of Algeria with spikes 9 inches in length on scapes 2 feet in height. The bulbs had been collected by Dr. E. P. Wright, M.D., and had been thus splendidly grown in sound Wicklow loam by my friend and predecessor, Mr. F. W. Moore. Even the Japanese Bletia hyacinthina is hardy here in sandy peaty earth near to water, and the stock came from a fair garden in Devon, from which a friend dug me a patch with a spade, as he told me, because it was smothering up some choice alpiners in the same rich peaty border. Happy alpiners, happy Bletia! it could not have been more healthy nor more vigorous had it been dug up in its native Eastern woods and jungles. Those who succeed with Kämpfer's Iris in peat near to water levels should try this Bletia, Orchis foliosa, *O. latifolia*, Cypripedium spectabile, *C. macranthum*, *C. parviflorum*, and *C. acule* under the same conditions, for if they do so I feel sure they will never regret the experiment, bold as it may appear to some to be. It is not at all easy, even from the neat little black and white figures of M. Correvon, to realise a tithe of the beauty and grace of form and colouring as really shown by this insect-loving race of flowers.

In order to get a glimpse of the beauty and variety of these flowers, one must glance over the exquisite coloured plates as published by Barla in his "Flore Illustrée de Nice et des Alpes-Maritimes" (Iconographie des Orchidées), also at Moggridge's "Contribution to the Flora of Mentone," at the hardy Orchids figured in Reichenbach's great "Flora Germanica," and lastly, but by no means least, at those illustrated by Sowerby in our own noble "English Botany" (second edition by J. Syme Boswell). Even if you do this much in any good library, you will not have seen half the portraits of the hardy Orchids now known, and if we have a fault to find with our talented author, it is that he has kept to the high road and the shady lanes, so to speak, of his subject, and has not ventured out of the beaten track to tell us of the hardy Orchids known to exist on the cold mountains of both hemispheres. Even the "Flower of the Gods" (*Disa grandiflora*) is hardy and has flowered in the open air in Ireland at least twice within recent memory, viz., once at Glasnevin in the late respected Dr. David Moore's time, and more recently Mr. H. Hart has flowered it in his open-air garden in Co. Donegal. My friend Mr. C. L. Mann, of Milwaukee, U.S.A., quite lately sent me splendid plants per post (from Florida, I believe) of *Epidendrum conopseum*, one of the, even if not the most northern of all true epiphytal or tree-growing Orchids, and in all seriousness he advised me to try it on the Magnolia trees in our college garden. I did not like to venture this much, but it has thriven apace on a log in a cool and airy porch, and I really do intend to try a plant or two on the large-leaved evergreen Magnolias by the walls next May or June. Another good notion of Mr. Mann's was that by hybridising this *E. conopseum* with other species of *Epidendrum* in our cool houses, we might add size and colour to its undoubted

hardiness and perfume, and so inaugurate a new race of hardy or half-hardy epiphytal Orchids in our gardens. On glancing over the Orchid figures in our "English Botany," the wonder is that we have done so little to cultivate the best forms of the Orchids that grow so splendidly in our fields and on our limestone clays in Kent, in Sussex, in Hampshire, and elsewhere. What can be finer in April or May than the great crimson-purple spikes of the Kilmarnock Orchis as seen at Glasnevin, where Dr. D. Moore introduced it a wilding years ago, or as it can be seen at Straffan in a border amongst other choice native flowers discovered by the Hon. Mrs. Burton, to whom we are all indebted for first bringing us bulbs of Bernard's Narcissus from the Pyrenees? With this elegant little book in their hands, we sincerely hope that all tourists who are fond of their gardens will keep a sharp outlook not only on the European and North African continents, but also at home here in England, Ireland and Scotland, for any well-marked varieties of these exquisite flowers. In gathering roots for ourselves so much is learned or gained in addition to the flower itself. We gain a hundred cultural hints unknown to those who simply order or purchase their flowers at the nearest or most convenient nursery. We not only collect our flowers beautiful, but we reap also a rich harvest of cultural experience, and the flowers become to us the happiest and most lovely of mementoes of meadow or mountain, or of sedgy mere. Even had we no other beautiful hardy plant than Cypripedium spectabile, Orchis foliosa, *O. latifolia* and Bletia hyacinthina, M. Correvon's book would be amply justified. Of course all of us cannot well scour Europe, North Africa, and Madeira, or the Canary Islands to collect our own flowers, yet those who are debarred from travel can be supplied by both English and Continental nurserymen.

In conclusion, I may be allowed to allude to that rarest perhaps of all the European Orchids, viz., *Spiranthes Romanzoffiana*, which has quite recently been discovered in two new Irish localities, viz., in the Co. Armagh, and happily in considerable quantity, and in Londonderry, so that there is now no fear of its vanishing from Irish soil. The figure of this rare plant given by our author at p. 191 of his book was from a sketch supplied to Dr. M. T. Masters, F.R.S., of the *Gardeners' Chronicle* ten or twelve years ago. M. Correvon may be right in saying his figure is "après Webster," but Mr. Webster obtained the block or electrotype from the *Chronicle*. This is only one of the few little slips and errors observable in this volume, but as a foreigner M. Correvon has been singularly fortunate in escaping pitfalls of this kind.

M. Correvon rightly laments that Cypripedium Calceolus has been ruthlessly uprooted in Switzerland, but we are glad to know on pretty good authority that it exists to-day in at least three of our northern counties in England, viz., Lancashire, Yorkshire, and Durham, and I got three fine plants from a wild habitat in Northumberland only a year or two ago, and have reason to believe it is still luxuriant in a wood in that country. In Siberia this plant abounds along with the great purple *C. macranthum*, and in America it is abundantly represented by *C. parviflorum* and *C. pubescens*, both merely geographical forms of our European species.

I can conscientiously recommend M. Correvon's neat little work to all interested, and regret that pressing business prevented my alluding to its appearance some few months ago.

F. W. BURBIDGE.

NOTES OF THE WEEK.

Dahlia Pearl.—There are so many good Dahlias, that the trouble is to select the best for making distinct beds. This variety is planted in a single bed at Kew, and justifies a note. It is dwarf, compact, and the large pure white flowers appear above the wealth of leafage.

Apricots in London.—Herewith specimen of Apricots mentioned in your paper August 5. There were upwards of 600 on the tree.—B. G. JENKINS, *Dulwich, S. E.*

* * Flavour excellent; far better than that of the ordinary imported market fruit.—ED.

Gourds at Kew.—The Gourds in the herbaraceous ground at Kew are again an interesting feature this year. They have a quaint aspect climbing up rustic poles, and the collection is representative. It can be seen how greatly the fruits vary in shape, size, and colour. Of course, this kind of planting may be overdone, but a little of it is welcome as a change.

Tufted Pansies at Wemyss Castle.—Mr. J. Clark, gardener at Wemyss Castle, sends us several photographs, showing masses of these as grown there. They include such varieties as Bessie Clark, Blue Bell, and Wemyss Gold. They are used there as bedding plants with fine effect, but we think they are more precious as carpet plants to taller flowers, such as Tea Roses, and also as border plants, edgings, &c.

Begonia Octavie, which is well represented in Messrs. Cannell and Sons' nursery at Swanley, is one of the most beautiful double-flowered Begonias ever raised. This is high praise, but the flowers are exquisite, quite double, and pure white, showing a tinge of green when first expanded. This fades off with age. The plant is compact, free and almost hidden with the wealth of bloom.

Crocoemia aurea imperialis is a splendid flower. A mass of it is in bloom at Kew in the warm border skirting the economic house. The flowers are borne freely on the stems, and individually are very large, rich orange-yellow on the outside, but within more of a self apricot tint. It is a fine thing to form a group of if the position is warm and the soil light. It was raised by Max Leichtlin from seed sown in 1883.

Citrus trifoliata in fruit.—This species is fruiting in the nursery of Mr. Morse at Epsom. This, we believe, is unusual. Some time since a note appeared in THE GARDEN stating a plant of it fruited freely quite in the south of England. *C. trifoliata* is an interesting shrub, the flowers very fragrant and the branches armed with formidable spines. The fruit is small, crinkled, and like that of the common Orange in miniature.

Polygonum cuspidatum compactum.—The common Japanese Knotweed (*P. cuspidatum*) is one of the most familiar plants in our gardens. It is very beautiful, but, unfortunately, a thorough weed. The variety *compactum*, however, is not so rampant and the growth is remarkably compact, hence its name, yet not so much so as to deprive the plant of elegance. One sees very little of it in gardens, but it is well worth growing, the wrinkled leaves being of the deepest green colour. An isolated specimen on the turf is handsome.

Clematis Stanleyi is flowering in a warm, sunny border in the Royal Gardens, Kew. This species is disappointing, the flowers being too pale in colour, whilst the plants are not hardy enough to stand an English winter. A coloured plate was given of it in THE GARDEN, Jan. 24, 1891. This species is a native of South Africa, and was first discovered by the collector Burke about fifty years ago. It is interesting to note that it was introduced through Kew in April, 1889, Mr. E. Galpin, of Barberton, having sent seeds. With the protection of a cool greenhouse it is more satisfactory, but, unfortunately, the plant loses in value when a greenhouse temperature is necessary for its cul-

tivation. There is a marked difference in both leaves and flowers, the latter varying greatly in colour. Some are pure white, whilst others are shaded with rose.

Aristolochia gigas Sturtevanti.—Mr. R. Willis, Cluny Gardens, Edinburgh, in sending us two photographs of a flower of this which has just opened in the Botanic Gardens, Edinburgh, says: "A flower of this has just opened in the Edinburgh Botanic Gardens. It is said to be one of the largest known, measuring 1 foot 3 inches, by 1 foot, and having a tail of 3 feet. Its colour is a pale yellow, with a throat of deep purple, while the long tail exhibits a delicate purple veining. Its odour is, however, unpleasant. It is commonly called the Duck or Pelican Flower on account of the shape of the blossom presenting a certain resemblance to those birds."

Gladiolus brencleyensis, which has played a large part in the history of many fine hybrids, is one of the principal flowers of the week. Even against the numberless hybrids in cultivation at the present day this *Gladiolus* has held its own, and when boldly grouped there is no more brilliant August flower. Its bright scarlet colour, noble spike, easy culture, and lateness entitle it to consideration. We have lately seen it used to advantage, especially in one case, in which the groundwork of the bed was *Gypsophila paniculata*. *G. brencleyensis* is not so expensive as some *Gladioli*, and may therefore be used with greater freedom in the garden.

Annuals in masses.—The finest annuals that we have seen in this notoriously poor year for them are immediately in front of the Palm house at Kew. The beds are made upon what was once a stretch of gravel without anything to relieve its monotony. We are pleased to see that every available opportunity is taken at Kew to cover the ground with flowers. The annuals are in large masses of one distinct kind, and comprise *Verbenas*, *Brachycome iberidiflora*, *Zinnias*, *Chrysanthemum bicolor*, dwarf French Marigolds, *Asters*, *Linum grandiflorum coccineum*, *Dianthus Heddegi*, *Convolvulus minor*, *Viscaria oculata*, and the lilac flowered *Leptosiphon densiflorus*.

Seedling Verbenas.—We are pleased to see that seedling *Verbenas* are grown in many gardens. We have made note recently of several fine beds, and the plants are healthier than named kinds, although amongst these are many splendid colours, as may be seen in the Swanley nursery. The seed is, however, sold in distinct colours, and there is no trouble with the plants during the winter, when those of named kinds have to be protected from mildew and other ailments. A bed of seedlings is full of interest, and many very beautiful colours occur—rich sapphire-blue, rose, crimson and pure white. Beds of both *Verbenas* and varieties of *Phlox Drummondii* should be in every garden.

Amaryllis belladonna blanda.—This is sometimes labelled *Coburgia blanda*. It is a pale rose variety of the *Belladonna Lily*, and large clumps of it are in full beauty in the narrow border skirting the Orchid house at Kew. It was introduced from Cape Colony in 1754, and a figure is given of it in the *Botanical Magazine*, t. 1450. The type was introduced earlier. Although the *Belladonna Lily* is well known by name, one does not often see large masses of it in gardens, although such a position as that at Kew will suit the bulbs to perfection. There is much beauty in the bold flowers, which gain in contrast with the chocolate coloured scapes. The position must be sheltered, sunny, and the soil light. A border skirting a plant house will suit the *Belladonna Lily* well.

Crinum Moorei album is flowering in the Epsom nursery. We should like to see both this and the type more grown in English gardens. They may be planted out of doors in mild districts and sheltered positions without fear of injury from frost if the crowns are protected with a covering of leaf-mould or coal ashes, but preferably the former. A group of them in the greenhouse is

also very beautiful. We may mention that a coloured plate of *C. Moorei* was given in THE GARDEN for March 5, 1881. Seeds of this species were sent to the late Mr. Moore, of Glasnevin, from South Africa by Mr. Webb. The plants were grown at first, like so many other things, in the stove, but were afterwards tried in the open with success. A good clump of this *Crinum* in a suitable spot is a charming picture.

Carnation blooms from Kelao.—We have much pleasure in sending you a box of *Carnation* blooms cut from the open from layers planted outside last autumn. *Carnations* are with us the leading feature, and we grow all the sections extensively, in which appear not only the older standard favourites, but also the newer introductions. One of the finest things yet brought out, and admitted so by the best authorities, is one we are distributing this autumn for the first time, named *Lady Nina Balfour*.—LAING AND MATHER.

* * * *Duchess of Fife*, a rose, seems a very promising flower, but it is impossible to tell the true value unless new varieties are tried side by side with others of the same colour. *Lady Nina Balfour* looks very distinct and good, and is very sweetly scented.—ED.

Gentiana asclepiadea.—This is a remarkably handsome *Gentian*, popularly known as the *Willow Gentian*. Two very fine clumps of it are at present in full bloom on the Kew rockery. They are a mass of foliage, the branches almost covered with deep blue flowers—the typical colour—but those of the variety *alba*, with which it is associated, are, as suggested by the name, pure white. This species is the more valuable because it blooms at this season, when the rock garden begins to lose in freshness and beauty. The position for this species should be sheltered and moist, whilst the plant is deciduous, so is not unsightly during winter. It will grow when well placed fully 2 feet high, flowering the whole length of the stem. Seed is not difficult to raise, and seedlings bloom better than divided pieces.

PUBLIC GARDENS.

NOTES FROM THE PARKS.

ONE of the prettiest open spaces in London is Battersea Park, and we are pleased to see that the arrangements this season are tasteful, and many plants used that were formerly considered fit only for a herbaceous border. Near the Albert Bridge entrance are fine borders of hardy flowers, embracing *Hollyhocks*, perennial *Sunflowers*, and similar things, well grouped together, whilst on the turf *Statice latifolia* is planted in clumps. This bold style of using hardy plants is to be commended, and their beauty in mid-August is a rebuke to those who say that with the departure of July they have lost their beauty. It is simply a matter of careful selection. One sees with pleasure the great use that is now made of perennials in the parks of England. *Dulwich*, *Brockwell*, *Regent's*, *Victoria*, *Hyde*, and other parks are beautified by them, and there is a gay show from quite late spring until the *Chrysanthemums* bloom in November.

It is interesting to know that the French varieties of *Canna* are liberally planted, and we recently noticed that old kind named *Premices de Nice*, which is dwarf, and bears an abundance of rich yellow flowers, fully equal in effectiveness to those of any of the more modern acquisitions. We often think that modern things are inferior to old varieties, but the craze for novelties so-called is responsible for the introduction of much rubbish which would have been despised twenty years ago. Opposite this border of perennials in Battersea Park are seven

raised rectangular beds, which, unlike previous years, are not planted so freely with zonal Pelargoniums. A charming use is made of pretty things. Thus two of the beds are filled with tufted Pansies—a mass of bloom—in one case being associated with variegated zonal Pelargoniums. Two of the other beds were composed respectively of crimson and white Antirrhinums. We are pleased to see such a free use made of this flower. It blooms over a long season, and if planted sufficiently close together makes a fine mass of colour. Another year a change would be made by keeping the colours apart, the white or crimson by itself making a brave show. Another perennial planted largely in this park is the herbaceous Phlox, and the two principal varieties are the crimson and white. Close to the Battersea Park Station entrance is a very large bed of Phloxes of these two colours mixed with Gladioli. The Phloxes are very fine, loading the air with their rich fragrance, and the white kind in particular is beautiful. The plants are compact in habit, sturdy, and bear large heads of pure white bloom. Amongst the Phloxes are many colours, but none are richer than crimson and pure white. Reject the purplish and magenta shades, which are not pleasing when perfectly fresh, and far less so when dried or faded by the sun. They soon lose their beauty. One bed in the sub-tropical garden was composed simply of the white-flowered Phlox associated with variegated Abutilon, the margin Funkia. The white flowers are thrown into relief by a background of dark-leaved shrubs. One of the boldest arrangements is that of the Coral Plant (*Erythrina crista-galli*) and the Thorn Apple (*Brugmansia Knightii*). The *Brugmansia* is bearing a free display of its large pendent fragrant white flowers. We have seldom seen finer specimens, and the contrast with the scarlet flowers of the *Erythrina* is distinct and effective. Even the more common things may be, and are planted in a way to create bright colour. A bed of double crimson and purple Stocks is very handsome, the flowers of *Lilium longiflorum* in contrast. Not many years ago such a bold arrangement would scarcely have been thought of. As in most places this year, the tuberous *Begonia* is scarcely happy. It is not blooming with its usual freedom by reason of the long-continued and excessive drought. The season has proved far too hot for it, and it is getting too late to expect great things. We may point out that the plants are used with great taste. In one bed the surface of the soil is covered with Stonecrop, the *Begonias* breaking this flat groundwork; whilst in another arrangement they are planted with the variegated *Dactylis*. *Begonias* go with the *Dactylis* as well as any plant, and in many gardens pretty pictures have resulted from this happy association. A great point is to cover the bare ground with flowers at every opportunity. Margins of the Virginian Stock to borders filled with shrubs give a desirable break of colour. At a point of vantage is boldly grouped the herbaceous *Lobelia*, a mass of rich and striking colour. It is a glorious flower in late summer for its richness and striking aspect. An effective arrangement is composed chiefly of *Eucalyptus globulus*, always well planted in this park; whilst the groundwork is made up of *Petunias*, *Lilium longiflorum* and variegated *Abutilon*. At various places one sees *Plumbago capensis* in bloom, a dark-leaved shrub usually throwing into bold relief the delicate blue flowers. Every available spot is utilised either with flowering or foliage plants. The Palms in cool and shady positions afford grate-

ful relief to the masses of flowers, and succulents are planted largely, sometimes as single specimens on the turf or in beds. A good bed of succulents only is not without beauty, but they must not be overdone.

Much is made of the Lily, but it is not a first-class town flower. *L. croceum* is perhaps the best, but praiseworthy attempts are made to grow Lilies in the shrubby borders as a relief to the heavy and monotonous green leafage. Such borders are, however, riddled with roots. *L. lancifolium* is blooming well.

Battersea Park is interesting for its trees, and a few days ago *Hibiscus syriacus* in many varieties was blooming with great freedom. There are several good specimens of it in this park, although it is a tree neglected in the majority of English gardens. We care little for the purplish tinted flowers, as they have a very dead effect, so to speak, quickly losing their fresh colouring, nor is the double kind very handsome. The single varieties are far more effective. This *Hibiscus* is a good town tree, and the finest growth is seen where the position is moderately shady with the soil both deep and moist. A wet, boggy soil is not suitable, nor, on the other hand, is a dry one. Usually one sees a dearth of the best edging plants in parks, excepting Regent's Park, in which many pretty things are used to advantage. A very fine border or margin at Battersea is composed of the yellow-flowered *Gazania splendens*, which is strikingly handsome, its flowers large and rich orange in colour. A great danger, happily not pronounced at Battersea, is relying too much on one flower for effect, say the *Fuchsia*. But there is ample choice without producing weariness through constant repetition of the same subject.

All the parks are now in beauty. Hyde Park is conspicuous for *Fuchsias* and *Plumbagos*, besides other things on the Grass by Park Lane, and Regent's Park is worth visiting for its charming variety of flowers disposed with great taste.

MR. T. LAXTON.

A FRIEND of the late Mr. Laxton, to whose death we referred in our last issue, sends us the following:—

Mr. Laxton had a great taste for horticulture from his birth, and commenced his experiments in hybridisation as an amusement about the year 1865. In 1868 (July 7) he obtained a first-class certificate from the R.H.S. for Pea Supreme, raised by crossing the old Sugar Pea with *Ne Plus Ultra*, *Alpa* being his next certificated Pea, R.H.S., Aug. 2, 1869. He also took up zonal Pelargoniums at this time, raising *Jewel*, August 2, 1871. Then followed *Emily Laxton*, one of the first semi-double scarlets, and the first double white, named after the late Jean Sisley, with whom he had a good deal of correspondence about this time. Then followed in quick succession *Peas William I.*, *Dr. Hogg*, *Omega*, *Fillbasket*, and *G. F. Wilson*. He also turned his attention to *Roses*, his first being *Chas. Darwin*, followed by *Annie Laxton*, *Emily Laxton*, *Dr. Hogg*, *Mrs. Laxton*, *Princess Louise*, *Duchess of Bedford*, and *Mrs. Harry Turner*. Apples also claimed attention, and it was through him *Peasgood's Nonsuch* was introduced. This was raised from a pip sown by a cottager in an old flower-pot at Stamford. He still continued his experiments with *Peas*, and corresponded with the late *Chas. Darwin* as to the cross-fertilisation of this genus. *Strawberries* were also taken in hand, the old and still well-known *Traveller* being one of his first, followed by *Dr. Roden*. Owing to serious reverses at Stamford, he moved to Bedford in Jan., 1878, and took trial and experimental grounds at Girtford, Sandy, devoting now his whole life and strength

to the work he always had so much at heart. The first certificate he gained was for *Pea Minimum*, a dwarf, only 6 inches high; then followed *John Bull*, *William Hurst*, *Evolution*, *Charmer*. He also at this time gave his attention to *Potatoes*, raising by cross-fertilisation *Reward*, *Bouncer*, *Beds Here*, and selected the valuable white variety from the original pink *Beauty of Hebron*, and which is now so extensively, and in fact almost exclusively, grown by market gardeners as well as many others. He did not forget *Sweet Peas*, *Invincible Carmine* (still the brightest scarlet) being his first. This was followed by *Invincible Blue*, the nearest approach then and probably now to a blue *Sweet Pea*. Time, however, would not allow of his continuing this work, which he relinquished in favour of *Strawberries*. He first raised at Girtford, *King of the Earlies*, still much grown for its high flavour and earliness, followed by *Captain* and *Noble*, which, unlike all his other seedlings, was not an artificial hybrid, but a natural one—*Forman's Excelsior* probably crossed with the strong-growing American variety *Kerr's Prolific*, which was in the next row. *Tomatoes* also were treated by him, *Laxton's Open Air*, a dwarf selection from the old *Conqueror*, being still considered one of the best. *Apple Schoolmaster* he raised from a chance pip sown at random. Then followed *Strawberries Latest of All*, *A. F. Barron*, *Commander*, *Jubilee*, *White Knight*. *Potatoes* still had a share of his labours—the *Early Laxton* (*Sharpe's Victor* × *Ashleaf*), earlier and an improvement on both, and likely to be very largely grown for market. *Peas* still were cared for. *Walton Hero*, *Earliest of All*, *Early William* (the early selection from *William I.*), *Alderman*, *Oracle*, then the fine *Gradus*, which he considered his greatest achievement (*Earliest of All* × *Duke of Albany*), producing a pod as early as *Earliest of All*, with the size of *Duke of Albany*. This *Pea*, he believed, had a great future before it. The *Brassica* tribe did not claim much attention, owing to their liability to natural cross-fertilisation, and therefore deterioration of stock; but *Chou de Bedford* was raised from the old *Couve Tronchuda* × *Chou de Burghley*.

Unfortunately, he died when his work was gaining for him some pecuniary recompense for the years of ceaseless toil almost at an actual loss, for the time and money expended to produce his novelties were astonishing. His great aim was to produce something better than, distinct from and in every way superior to existing varieties, and not to flood the market with useless products. Nearly everything raised was the result of careful selection and trial after artificial cross-fertilisation; not, as in so many instances, the new selection from some well-known variety. He always believed that careful selection and seeding from the best and strongest must produce better results than from immature and impoverished blooms, and in all his work this point he kept steadily in view, never hybridising two weakly growing varieties. He also firmly believed in seed-saving from the earliest seed to produce an earlier strain, and in this he was particularly successful, as, for instance, in the selection from *Pea William I.*, which gave him a strain nearly a fortnight in advance of the type. *Runner Beans The Czar* (still the largest white-flowered runner), *Girtford Giant* (a cross between the *Czar* and the old scarlet), and the new *Titan* (*Czar* × *Girtford Giant*), and *Cucumber Laxton's Open Air* (the outdoor *Ridge* × *Telegraph*), producing in a good season very handsome smooth fruit in the open, are evidences of his labours. Unfortunately, he left much work unfinished, and, as he often remarked, a man in his position ought to have three lifetimes to see his work thoroughly finished. He has left many seedlings still untried, his last new *Strawberry*, *Royal Sovereign* (*King of Earlies* × *Noble*), and which he considered the best he had yet introduced, being only distributed this season, 1893.

He was for many years a Fellow of the R.H.S., and for several years served on the fruit committee of the R.H.S. He was also formerly a Fellow of the Linnean Society. He corresponded and wrote articles for many horticultural journals

both at home and America, but of latter years time and strength would not admit of much in this respect. Thirty years of incessant work at his life hobby left him enfeebled both in body and pocket, and he leaves a widow, three daughters (none too well provided for), and four sons, by two of whom (William and Edward) the business will be continued.

NOTES FROM DIDCOT.

TO THE EDITOR OF THE GARDEN.

SIR,—As you like to have notes from various gardens, I send you one or two which may be interesting. Many years ago I planted a *Maréchal Niel* Rose on the south-west wall of my house. After some years the grafted scion had become so much greater than the stock upon which it was grafted, that it died out. I then determined to grow the *Maréchal Niel* on its own roots. This may be some twelve years ago. It flourished marvellously. About 6 inches from the soil there sprang two great branches which reached some 16 feet or 18 feet in height. It blooms abundantly, but it is evident that the aspect does not thoroughly suit the colour of the flower, as it only attains its great beauty when cut for the table. About the end of April last one of the two limbs (if I may so call them) died out, and I cut it down to the part from whence it sprang. This seemed to throw the vigour into the other limb, and immediately two shoots appeared, which have now reached 15 feet in height. The limb from which they spring is at 1 foot from the ground, $6\frac{1}{2}$ inches in circumference, and 6 inches in circumference at 6 feet from the ground. I think for vigour of growth this exceeds any plant I have seen. The leaves are from the young shoots of *Maréchal Niel*, not four months old and yet 15 feet in length. Many years ago an old nurseryman gave me a plant of *Salvia argentea*. The leaves are broad, like those of *Saxifraga crassifolia*, only covered with a silvery down. My poor old friend called it (as nurserymen do) "a good thing," but I do not know much about that. It is too straggling in its flowering habit. His son and successor tells me he has long lost it. I wish you could see my scarlet Siberian Crab in front of my library windows. It is a picture, and was grand when it was in flower. Why do not people plant this tree more upon their lawns? The season has been short with us for flowers. *Gladiolus Colvillei* The Bride was a failure from the excessive drought. I am afraid the later sorts will suffer from the same cause. Our fruit crops have been fine, Green Gages beating the record. Apples a heavy crop, but small in size. A Quince tree which I had from Normandy thirty years ago, and which always flowers abundantly, making a pretty show, has for the first time this year produced fruit.

I was fishing a few weeks ago in the Kennet, near Newbury, and was delighted to find in an old-fashioned garden *Monarda didyma*, not the scarlet, but the purplish (puce) flower. One does not often meet with this Bergamot, though probably you may find it on the outside stalls at Covent Garden in the spring. I was delighted to re-introduce it into my garden. I have quite discarded bedding plants, and only grow old-fashioned things. My Antirrhinums are quite a sight. The late Mr. Woodbridge, of Syon Gardens, struck for me a cutting of the old Mulberry tree at Syon. This, as you know, is said to be the oldest in England. My tree was struck in 1876, and is now so large that it covers a great space; but, like the parent tree, it splits terribly, and has to be supported by iron bands, &c.

RICHARD HOOPER.

Upton Rectory.

* * The foliage sent is very large and fine.—T.O.

The weather in West Herts.—Throughout the week the weather has remained remarkably hot even for a summer month. On Monday the temperature in shade rose to 84°, on Tuesday to 85½°, and on Wednesday to 88½°. Not only is the latter the highest reading in shade as yet recorded here

this year, but it is also higher than on any day during the eight years over which my records at Berkhamsted extend. On no night did the exposed thermometer fall below 50°, and on two nights in last week (Wednesday and Friday) it fell only to 57°. The temperature of the soil at 1 foot deep now stands at 71°, and at 2 feet deep at 67°, or respectively 9° and 6° warmer than on the same day last year. During a thunderstorm early on Thursday morning, the 10th inst., over half an inch of rain fell, and for twenty minutes was falling at the rate of 1½ inches an hour. On Wednesday the air proved exceptionally dry, the difference between the readings of an ordinary thermometer and one with its bulb kept constantly moist amounting to as much as 19° at 3 p.m.—E. M., *Berkhamsted*.

THE WASP PLAGUE.

THE following letters on this subject recently appeared in the *Times*:—

Two kinds of wasps are equally abundant this year—the large one, with deep golden colour (*Vespa germanica*), which enters our rooms and attacks the wall fruit, and the small "anchor-faced" or English wasp (*Vespa vulgaris*), which is very vicious if the nest be approached, and, in a less degree, injurious to fruit. Many nests of both species are above ground in old walls, thatched buildings, stables, and even in tree stumps, and not always easy to destroy. Whatever method of destruction is employed, it is imperative that, if possible, the nest should be taken out, as otherwise in about ten days' time newly-hatched wasps will again appear. The grubs make excellent food for poultry and good bait for roach and other fish. The German wasp is a month earlier than the other, and the queens leave the colony the first week in September for winter quarters.—W. H. TUCK.

Cyanide of potassium for destroying wasps' nests should be discontinued. It is a very deadly poison, and although persons mixing the same may not be induced or inclined to take the solution internally, it may still cause great injury, and has, indeed, before now caused death by coming into contact with cuts, wounds, and sore places on the hands and elsewhere of persons not in a healthy state. My brother-in-law, Mr. Edward Mausell, has already since the middle of June destroyed 153 nests within a radius of one mile from his residence; others in the immediate district have destroyed 94 nests. They have frequently taken twelve or fifteen a night. I enclose the recipe for the cartridges which have been used. Nests and their holes may be so placed that it is by no means easy to pour the solution of cyanide into the opening. Paraffin oil and setting light to same is a better remedy than the cyanide of potassium, in my humble opinion, where the nest is advantageously placed.—SLINGSBY BETHELL, *Symondsbury Rectory, Bridport*.

Contents of cartridges: Powdered sulphur, 16 oz.; saltpetre (powdered), 10 oz.; ordinary black gunpowder, 3 oz. Mix well with wooden spatula and make into about forty squibs. These will be sufficient to destroy 25 to 30 nests.

National Rose Society.—Allow me to make a few remarks on the communication from Mr. Grahame, which appeared in your last issue. As Mr. Grahame resigned his membership of the committee after the last meeting of that committee, few even of his late fellow committeemen were aware of his resignation, and there was not a word in his circular to show that he was not still officially connected with the society; hence the appearance of the explanatory note issued by the secretaries. After referring to this circular, Mr. Grahame goes on to give his reasons for retiring from the committee in the following words: "I found it worse than useless to belong in any way officially to a society in which stolid opposition is offered at committees to all suggestions and propositions made in the society's best future interests by the younger members of it." Since reading the above I have looked carefully through the minutes of all the committee meetings held by the society during the past year, and fail to find the slightest foundation

for such a statement. For my own part I can only say that I have never seived on any committee where the opinions and suggestions of the members present have received such impartial and careful consideration as at our committee meetings of the National Rose Society—a committee numbering among its members nearly all the leading rosarians throughout the country. Referring to his resolution carried at the annual meeting of the society in 1891, that exhibitors should be required to show according to the number of Rose plants grown by them, Mr. Grahame states that "the most strenuous opposition was offered to my proposals, notably by the secretaries, who have now addressed you." To this remark it is only necessary to reply that at the annual meeting in question I for one spoke in favour of the resolution, and both before and after the meeting assisted Mr. Grahame in putting the new scheme into practical shape.—E. MAWLEY, *Hon. Secretary, National Rose Society*.

Zauschneria californica is generally supposed to require a warm, or at all events a sheltered position, but large clumps of it have done admirably for years (and were unhurt by the severe cold of 1890) in the garden of Mrs. Onslow Parson, of Lynchmere, near Haslemere. This garden stands very high, and is very much exposed to winds. There were fine large patches in brilliant bloom this July.—M. A. R.

Mr. W. Goldring has returned from India after a very interesting tour through Ceylon, Japan, the Sandwich Islands, and California. He does not intend to return to India for a year or more, and will, we hope, in the meantime be busy in England.

Peat Moss litter as manure.—Could I trouble you to give me your opinion in your next issue of THE GARDEN as to the value of Peat Moss litter as a manure for vegetables and fruits? Our soil is very light and stony, and very poor.—W. B.

Planting Cupressus Lawsoniana in a bog.—I want to plant an avenue of *C. Lawsoniana* in a bog on each side of a newly-made road. Will it grow? It would be very expensive to make the soil for it. An avenue of the same tree in cut away reclaimed bog with a subsoil of marl in the immediate neighbourhood has done extremely well, and has now been planted for more than twenty years.—HIBERNIA.

Names of fruit.—C. J. W.—Small Keswick Codlin.—F. J. P.—4, Pitmaston Duchess; 5, Louise Bonne of Jersey; 6, Bergamote Esperen.

Names of plants.—W. B. S.—Not equal to others in cultivation.—W. A. G.—1, *Saccolabium Blumei*.—C. Short.—Flower entirely shrivelled.—D. M.—*Taxodia mollissima*.—Mrs. Blankwell.—1, *Hypericum patulum*; 2, *Funkia lancifolia*; 3, *Rudbeckia orientalis*; 4, *Chrysanthemum maximum*.

"The Garden" Monthly Parts.—This journal is published in neatly bound Monthly Parts. In this form the coloured plates are best preserved, and it is most suitable for reference previous to the issue of the half-yearly volumes. Price 1s. 6d.; post free, 1s. 9d. Complete set of volumes of THE GARDEN from its commencement to end of 1892, forty-two vols., price, cloth, £30 12s.

"Gardening Illustrated" Monthly Parts.—This journal is published in neatly bound Monthly Parts, in which form it is most suitable for reference previous to the issue of the yearly volumes. Price 5d.; post free, 8d.

"Farm and Home" Monthly Parts.—This journal is published in neatly bound Monthly Parts, in which form it is most suitable for reference previous to the issue of the yearly volumes. Price 5d.; post free, 8d.

"Hardy Flowers."—Giving descriptions of upwards of thirteen hundred of the most ornamental species, with directions for their arrangement, culture, &c. Fifth and Popular Edition, 1s.; post free, 1s. 3d.

"The Garden Annual" for 1893.—Contains Alphabetical Lists of all Branches of the Horticultural Trade. The Lists of Gardens and Country Seats (containing over 9000) have been very carefully and extensively revised, and are admitted to be the most complete ever published. Price 1s.; by post, 1s. 3d.

All of our readers who are interested in the improvement of cottage homes are invited to help us to make Cottage Gardening known. It is published at the very lowest price to meet the wants of those for whom it is intended, and copies will be sent for distribution, free, by the publishers, Messrs. Cassell and Company, La Belle Sauvage, Ludgate Hill, E.C.

"This is an Art
Which does mend Nature: change it rather; but
THE ART ITSELF IS NATURE."—*Shakespeare*.

ORCHIDS.

ONCIDIUMS OF THE CRISPUM GROUP.

I HAVE had a quantity of flowers of this section of the genus *Oncidium* during the past week from various readers of THE GARDEN, all asking for a name, and a few wishing information as to treatment. One thing surprises me somewhat, and that is so many flowers of this opening together, some of the forms which I had thought were later bloomers flowering at this season. *Oncidium crispum* appears to have been introduced by the Messrs. Loddiges, of Hackney, over sixty years ago, and I recollect this Orchid I always dreaded coming into the garden, because there were no means of keeping it alive for very long. In the year 1856 a cool house for Orchids was built in the garden in which I was, and *Oncidium crispum* was removed with others to this. Here it grew well, and I saw some plants that I had in this house flowering grandly some ten years afterwards. These had been grown cool. I have frequently advised friends to put plants of this section into the cool house when I have seen them stewing in the hot steaming houses, but have been told that as the plants come from Rio Janeiro, there was little chance of their succeeding in such a low temperature. I think there is a great error made in the heat of Rio, which is after all only the port of shipment, for I am told that the mean temperature of the year is about 72°, and the Organ Mountains rise in the neighbourhood to nearly 5000 feet altitude, clothed more or less with virgin forests. As these plants grow on the trees in the mountains and not in Rio, it does not to me appear strange that they revel in cool treatment, whilst they sicken and die when grown in the hotter houses. One point I would particularly draw the attention of those sending me flowers is not to allow the newly-imported plants to exhaust themselves in supporting flower-spikes the first year after receiving them, for these stout branching spikes rob them of an immense amount of vigour, which they can never pick up again. If these are cut away, saving just a flower or two which may be left to show the variety, the second year they will flower beautifully, but even then and at no time would I allow the spikes to remain on the plants longer than a fortnight or three weeks. After the flowers are cut they may be placed in water and arranged about through the plants. *Oncidium crispum*, I find, likes to have its roots in the air, and therefore the block system of culture is the best. On account of these blocks becoming so soon decayed, I have adopted a shallow earthenware hanging pan as the best substitute. The plants will do best with very little soil about their roots. This must be one part of good fibrous brown peat, from which all the fine particles have been shaken, and some fresh Sphagnum Moss. Hang the plants up at the warm end of the Odontoglossum house and in the sun, shading when the heat is too strong. Plenty of air should also be admitted, for I do not know an Orchid which suffers more through being pent up in a close, stuffy atmosphere. Let the plants have

a good supply of water when growing, and the atmosphere must be kept well saturated. During the winter season, or when at rest, much less will be requisite, but I should not advise that the plants be subjected to a long period of drought at any time. Treated as above recommended, *Oncidium crispum* and its allies can be kept for many years, increasing in size and vigour and producing large branching spikes annually. The following are the chief forms of the *O. crispum* set of plants, and my correspondents will see answers to their questions in connection with each species or variety:—

O. CRISPUM.—Flowers of this species come from "D. M." and also from T. Clarke. All are well coloured and excellent varieties, the flowers each measuring nearly 3 inches across, the sepals and petals large, crisp at the edges, and of a rich brown, the lip round the front portion of the same colour as the petals, the centre being deep yellow, with some reddish brown dots. The last-named tells me that his flowers are from a fine spike bearing thirty-five blooms. I would remind him of my advice anent cutting the spike and placing it in water. Flowers of this species also come from "F. W. G.," but beside the others it may be called a very poor form.

O. CURTUM.—When a good variety of this plant is obtained it is singularly beautiful. It is much like *O. crispum*, but the flowers are smaller and the colours are brighter. The sepals and petals are chestnut-brown, having a yellow margin, and the fan-shaped lip is bright yellow with a row of dots round the border.

O. FORBESI.—I have flowers of this species from J. Bonner and Charles Collins. Those from the latter are very fine, being round and full. The sepals and petals are rich bright chestnut-brown and the lip of the same colour. Those from "T. B." are less deep in colour. I have usually seen this plant flowering some two or three months later.

O. GARDNERI.—Flowers of a beautiful form of this come from J. N. Fraser, but the sepals and petals are smaller and the lip is rounder, having a ground colour of rich golden yellow, lined and blotched with rich brown. The lip is golden yellow, having a broad margin of irregular blotches.

WM. HUGH GOWER.

Lælia xanthina (*J. Inwards*).—This is the correct name of the flower you send under the name of *L. grandis*. It is a very large-flowered variety, and it is also very brightly coloured. The lip, however, is shorter and the whole flower is smaller than in the nearly allied *L. grandis*. It is a very pretty form, and if the plant is strong it should produce from four to six flowers on the scape. Many growers discard this plant, but if everyone could ensure such a fine variety as that you send, it would be more frequently seen.—W. H. G.

Lælia callistoglossa (*T. M.*).—This was raised by Mr. Seden. It is one of the most superb plants which I know, and the last time I saw it was in Mr. Tautz's grand collection at Shepherd's Bush. It is a cross between *Lælia purpurata* and *Cattleya gigas*, and takes most after the former parent. The sepals and petals are white, suffused with rosy pink; lip large, beautifully undulated at the margin, of a very deep shade of purple; throat yellow, streaked with deep purple. This Orchid must rank with the very best of the *Lælias* of the *purpurata* section, and, flowering at a later date, it becomes more valuable.—W. H. G.

Cypripediums grown cool for winter bloom.—At this season those who cannot grow their plants in a cool north house will find much difficulty in retarding the flowers of the winter bloomers of which Boxall is the type. There is no better plan to adopt than to place the harder kinds of *Cypripediums* in low frames. I have found low movable frames of great advantage,

placing these on a hard bed of coal ashes under a north wall or house. The lights are drawn down at night, thus allowing the plants to get the benefit of night dews. This prevents the spread of insect pests, keeps the plants sturdy, and gives a much larger percentage of flower-spikes than would be the case if grown in greater heat. For years I have adopted this plan, and in hot weather it answers admirably; of course only small plants can be treated in this way. It is not so suitable for large specimens, but these latter are not so useful for cutting or for decoration, as when plants in pots from 6 inches to 9 inches are used, they give a larger quantity of bloom if well grown. When damping down during the day it is necessary not to use too much moisture overhead, as if the ashes and bare places are syringed there will be no need to apply the moisture too freely.—G. WYTHES.

Masdevallias (*G. Sim*).—No. 1 is the beautiful plant introduced by Mr. Sander, of St. Albans. It was dedicated by Reichenbach to Hermann Wagner some forty years ago, but it is only about ten years ago since it was introduced to us in a living state. It is very handsome, having the sepals of a deep rich purple and the tails yellow. No. 2 is a form of *M. ignea*, but it is much finer than the typical plant, and the flower is of a rich crimson-scarlet. No. 3 is *M. nycterina*, which was introduced by M. Linden about twenty years ago. It is a profuse bloomer.—G.

Dendrobium Dearei.—Flowers of this beautiful white-flowered species come to hand from J. M. Drewett, who says that they have been open two months. It is because the flowers of this variety keep so well that I have before recommended it to the market grower. The flowers are of medium size and pure white, saving a faint tinge of light green in the lip. This plant is a native of the Philippines; consequently it requires strong heat and moisture. I have seen it growing and flowering, too, with the old *D. nobile*, but I do not think it would withstand so severe a rest as we are accustomed to give that plant. During the summer months a strong heat is usually maintained in the stove, which is just the treatment this plant would revel in.—G.
