splendid fruits of *Marie Louise d'Uccle*, *Beurré d'Aremberg*, *Beurré Faltet père*, *Napoleon*, *Leon Leclerc*, *Vicar of Winkfield*, *Beurré Diel* and *Doyenné du Comice*; also over 100 dishes of Apples, a great number being cider fruits of local origin. The fruits were of very fine colour (silver medal). Mr. J. Crump, The Gardens, Madresfield Court, Malvern, staged a very fine collection of Pears, including large fruits of *Forelle*, *Seckel*, *Josephine de Malines*, *Hacon's Incomparable*, *Easter Beurré*, *Marie Louise*, *Beurré Diel*, *Thompson's*, *Pitmaston Duchess*, *Knights' Monarch*, *Doyenné du Comice* and *Catillac* (silver medal). Mr. J. Martin, The Gardens, Buchan Hill, Crawley, had very fine Pears and Apples (silver medal). Messrs. J. Laing and Sons, Forest Hill, had a large collection of Apples and Pears of good colour, comprising many of the best kinds in both classes (silver medal). Mr. Thomas, The Royal Gardens, Windsor, had a large collection of Pears well staged and consisting of familiar kinds—*Prince of Wales*, *Vicar of Winkfield*, *Marie Louise*, *Beurré Rance*, *Triomphe de Jodoigne*, *Knights' Monarch* and *Ne Plus Meuris*. Messrs. Cheal and Sons, Crawley, staged ten dishes of Pears of recent introduction. The fruits were large and very fine—*Princess*, *Duc de Nemours*, *Duchesse de Morny*, *Bon Vicar*, *Belle William*, *Magnate*, *Beurré Lucas* and a fine dish of their new *Apple Atalanta* in particular. Mr. C. C. Tudway, Wells, Somerset, had twelve enormous fruits of *Doyenné du Comice* Pear, weighing over 13 lbs. (bronze medal). Mr. Mancey, Upper Gattou, Merstham, staged four dishes of very large *Pitmaston Duchess* and *Grosse Calebasse* Pears (bronze medal). Messrs. Lane and Son, Berkhamsted, had a splendid lot of their *Prince Albert* Apple, which was of high colour and the fruits large (cultural commendation). Mr. Sidney Ford, Horsham, sent three dishes of *Marie Louise* Pears of large size (cultural commendation). Mr. Thomas, Royal Gardens, sent a superb fruit of *Smooth Cayenne* Pine weighing 9 lbs. and cut from a plant a little over twelve months old (cultural commendation). Mr. J. Masterson, Weston House Gardens, Shipston-on-Stour, sent some fine dishes of *Uvedale's St. Germain* and *Pitmaston Duchess* Pears.

Seedling Apples came from Mr. Watkins, of Hereford, also from Messrs. Laxton, Bedford, Mr. C. Tudway, Wells, Messrs. Saltmarsh, Chelmsford, and others. Mr. W. Taylor, Hampton, Middlesex, sent a variety of Grape grown in the open. This variety was also shown from Chiswick. Mr. Molyneux, Swanmore Park, Hants, sent *Bramley's Seedling* Apple. Mr. P. Veitch, Exeter, examples of Pears grafted on the *Jargonelle*, to show increase of size and vigour in fruit. From the society's gardens came six Grapes, both of British and American varieties, the last-named having a strong musk flavour. They are referred to in another note. Messrs. Cheal and Sons staged a fine dish of their new *Crawley Prizetaker* Potato, which has been recently certificated. Mr. Mortimer, Swiss Nursery, Farnham, had a new Tomato, somewhat after the *Perfection* type. Mr. May, Eden Park, Beckenham, a smooth, round Tomato. Both were too near *Perfection* to gain a distinct award. Mr. Miller, Ruxley Lodge, Esher, sent a very fine *Gourd* weighing 154 lbs., for which a cultural commendation was awarded.

Lecture on Pears.

This lecture was given by Mr. Crump, Madresfield Court Gardens, Malvern, before a larger company than usual. It was certainly an appropriate subject, as these fruits are very fine this year. The lecturer referred to his own experience, and chiefly dealt with his own district—the west of England. He said that whatever kind was grown, the soil, stocks and good cultivation had much influence on the flavour. In this country no other fruit is in better demand than the Pear. He placed it under three heads—that grown under glass or on walls and highly cultivated, that on pyramid or bushes in the open, and the district perry Pears, the latter being much grown in some districts. In

these days of agricultural depression fruit was receiving more attention, and he would call attention to the superiority of our best perry to that of cheap foreign wines, the British produce being more wholesome, and when made from the better quality fruit it was excellent. Pears were peculiar. For instance, some kinds in a favourable situation were not equal in flavour to those grown on bush or pyramid in the open, and some under different systems completely changed in character. Walls should not be utilised for early fruits, but for good late kinds to prolong the season. He recommended where practicable a house for late Pears, these to be grown as cordons. The structure need not be elaborate, but heated sufficiently to keep out frost and amply ventilated. *Beurrié Rance*, *Easter Beurrié*, *Knights' Monarch*, *Bergamote d'Esperen*, *Beurrié d'Aremberg* and other good late kinds well repay for house room. The ripening of Pears is of great importance, as much depends upon their keeping qualities. To get quality fibrous roots are essential, and gritty Pears are often the result of faulty roots. Pears on the Quince have plenty of fibrous roots, and fruit on this stock is often best, because those on the Pear or free stock are often neglected, hence the advantage of the first named. When lifted or retarded there is no difficulty, but to allow a gross growth for years and then lift and destroy a large portion of the roots is mischievous. The operation should be done frequently, care taken to preserve the tender brittle roots. The free stock is necessary for standard trees and for horizontal or trained examples. Relaying is necessary if on the free stock, always keeping the roots near the surface. This latter work is best done in November. It is astonishing what liberties may be taken with Pear roots in heavy or good loam, as the root-growth soon recovers and is fibrous. Feeding is readily accomplished by top-mulching with farmyard manure. Liquid manure is of great benefit, and guano, fish and other artificial manures are helpful. Grow a small number of kinds, choosing those which suited the soil and locality. Single cordons should be planted 18 inches apart on the Quince stock, well preparing the border for the trees at the start by incorporating such materials as good turfy loam, old mortar rubble freely mixed with the soil, and some half-inch bones. Arrange the trees in the order that the fruits ripen. Such trees will only need moderate attention, a slight protection being given from frost when in bloom. A good return of fine fruit would be got in a short time. Mr. Crump advised growing this fruit in the form of cordons by the side of walks. They were profitable and pleasant to look upon. Some varieties do well in bush form; for instance, *Beurrié Hardy* makes a grand bush.

Pruning was an important matter and not always understood. In pruning it is necessary to understand the growth of the tree, as this varies greatly, some making an erect growth, others spreading. A few kinds only bear at the points of the shoots, thus proving the necessity for careful pruning. To get good Pears fine trees are essential. The pruner must avoid crowding, and at the same time get sufficient to replace exhausted wood. Pruning may be done before the leaves fall, as it is then seen what space is required for further development. Pears grow well as orchard standards if the proper kinds are used. In his county there are a great many varieties, a large number local kinds, some of value for making perry, but even for that purpose it pays better to grow a good kind, as the farmer can easily obtain from 1s. to 1s. 6d. per gallon. The gathering of Pears is an important matter. They should never be wrenched off the trees, but allowed to part freely at the juncture of the stock. There was also a saving by making two or three gatherings from the same trees, as this gave a longer succession than when all were housed together. Storing is important, neither too damp nor too cold a place being chosen. If the latter, flavour is impaired. Fruits from a cold room are better flavoured by placing in a warm house a short time before using. Mr. Crump went into insect pests and the means to combat these pests.

Mr. Bunyard spoke at length as to varieties and treatment, and spoke highly of the value of Mr. Crump's paper.

NATIONAL CHRYSANTHEMUM SOCIETY.

The early autumn exhibition was quite a success. It opened on Wednesday and closed yesterday, the Royal Aquarium presenting quite a pleasing aspect with the various exhibits, comprising many kinds of flowers, of course principally Chrysanthemums, and much fruit.

The cut blooms of Chrysanthemums were, as a rule, of high merit, promising well for the season now close at hand. The chief class was for twenty-four blooms, and a very good collection came from Mr. H. Shoosmith, gardener to Mr. W. Hodgson, Shirley Cottage, Croydon, who was first. As our readers may be interested in knowing the varieties shown thus early we may mention that they were *Col. W. B. Smith*, *John Shrimpton*, *Avalanche*, *C. Shrimpton*, *Wm. Tricker*, *Sunflower*, *Mme. Marie Hoste*, *G. C. Schwabe*, *Puritan*, *Kentish Yellow*, *Mrs. Jamieson*, *M. Bernard*, and *Annie Hartzhorn*. The second award went to Mr. Chas. Cox, gardener to Mr. J. Trotter, Brickenden Grange, Hertford, and amongst his finest flowers of special merit set were those of *Etoile de Lyon*, *Puritan*, *Mrs. Chas. Cox* (a sport from *Mons. Bernard*), *Stanstead White* (very large), *Sarah Owen*, and *Avalanche*. The first prize in the following class, which was for twelve distinct, went to Mr. W. Collins, The Gardens, Ponsbourne Park, Hertford. His finest were those of *R. C. Kington*, *Mme. Marie Hoste*, *G. C. Schwabe*, *Puritan*, *Sunflower*, and *Bouquet des Dames*, whilst a distinctly creditable second was Mr. Thos. Wilkins, gardener to Lady Theodore Guest, Inwood House, near Blandford. We noticed especially the varieties *Gloire de Rocher*, *Miss M. Scott*, *Eugénie Gait* and *Sunflower* as worthy of note. The incurved section was an important feature of the show, and the flowers, as a rule, of very high finish. It appears to us, judging by this exhibition, that this will be a fine year for Chrysanthemums. The best twelve blooms were from that now well-known grower, Mr. E. Rowbottom, the Priory Gardens, Hornsey, N. It is impossible for want of space to mention many varieties, but especially fine were the blooms of *Baron Hirsch*, *Mrs. Dixon*, *Refulgens*, and *M. Bahaunt*. The second prize was won by Mr. J. Agate, Havant, Hants, who had excellent flowers of Vice-President, *Jules Barigney*, *Lord Wolseley*, *Baron Hirsch*, and *M. Bahaunt*. The best six incurved blooms were those from Mr. W. Collins, and comprised such well known kinds in fine character as *Jeanne d'Arc*, *Violet Tomlin*, *Princess of Wales*, *Mons. Bahaunt*, *Miss Haggas*, and *Refulgens*. Mr. Agate, second, showing amongst others Vice-President, *Jules Barigney*, and *Mme. Darrier*. The charming little pompons were of much interest, and a very beautiful collection of twelve bunches with foliage was shown by Mr. Norman Davis, Camberwell, who was first, the finest varieties being *La Vierge*, *California*, and *Golden Shah*. There was good competition in the class also for six bunches.

We are pleased to see that amateurs show well at the exhibitions of this society. The chief class was for twelve blooms of Japanese varieties, and the first prize went to Mr. Thos. Osman, gardener to Mr. C. T. Baker, Ottershaw Park, Chertsey, Surrey. The flowers were very fine, especially those of *Puritan*, *Avalanche*, *La Triomphante*, *E. Molyneux*, and *Mons. Freeman*. We should have liked to see some competition, and this remark applies also to the next class, which was for six blooms, the first prize going to Mr. D. R. Crane, Archway Road, Highgate, N., who had very beautiful flowers of leading kinds.

Another section was devoted to single-headed gardeners, and many varieties were exhibited well, although it was only in the more important divisions that the incurved were well represented. The winner of the first prize for twelve flowers of Japanese varieties was Mr. E. Ticker, gardener to

Mr. T. Watney, Reigate, Surrey, who had flowers of *F. Bouchardat*, *Bouquet des Dames*, *E. Molyneux*, *Marie Hoste*, *W. H. Lincoln*, *W. G. Drover*, *Mons. Freeman*, *Avalanche*, *Sunflower*, *Florence Davis*, and *Hamlet*. The same exhibitor also was first in the following class for six flowers of this section. The premier award in the class for twelve bunches of pompons was made in favour of Miss Debenham, St. Albans, and such kinds as *Lyon*, *Piercy's Seedling*, *Alice Butcher*, *Mrs. Cullingford*, and *Blushing Bride* were delightful.

Plants were noteworthy, at least in regard to the groups, in which class there was good competition. The first prize was won by Mr. Norman Davis with a very fine arrangement, who staged his plants well, and they represented a very interesting selection of varieties, whilst the second place was occupied by Mr. H. J. Jones, Hither Green Nursery, Lewisham. Several other classes also were devoted to plants.

A most interesting class was that for six blooms, distinct, of any new varieties sent out in 1892 and 1893. The prize was given by Mr. H. J. Jones, and won by Mr. J. Agate, who had very creditable blooms of *Princess May*, a beautiful pure white Japanese kind of bold size and great beauty; *Miss Watson*, *Chas. Davis*, *Duchess of Devonshire*, and *Beauty of Exmouth*. We have not mentioned names, as they have each been described in THE GARDEN, and further reference will be made to them.

Classes were also provided for table and other decorations. For a table of bouquets, &c., Mr. Chard, Stoke Newington, was first, he having a very varied assortment, many of much beauty, providing effective contrasts of colour; whilst in the class for three vases of flowers, the same exhibitor was first.

Special prizes were offered for vegetables by Messrs. Sutton and Sons, Reading, but we can only briefly refer to them. They comprised *Bet* and numerous other kinds, and the chief prize-winners were Mr. C. J. Waite, gardener to Col. the Hon. W. P. Talbot, Glenhurst, Esher; Mr. Thos. Wilkins, and Mr. C. Osman, South Metropolitan District Schools, Sutton, Surrey.

Miscellaneous contributions as usual formed a very important feature. A splendid exhibit came from Messrs. Cannell and Sons, Swanley. Their vegetables were remarkably fine, and we wish more space was at command to deal with them. Potatoes grown under field cultivation deserve high praise and comprised a large number of varieties. Messrs. J. Laing and Sons, Forest Hill, had a large collection of Apples, and it is noticeable in the various displays of fruit this year that the colour is very brilliant—the result of weeks of sunshine. The same firm also had a splendid bank of tuberous Begonias, arranged with rare taste and comprising both double and single varieties. Mr. T. Ware, Hale Farm Nurseries, Tottenham, had an interesting collection of cut hardy flowers; and Mr. W. J. Godfrey, The Nurseries, Exmouth, had blooms of *Beauty of Exmouth* Chrysanthemum. Messrs. Perkins and Sons, Coventry, showed Dahlias, also Mr. Mortimer, Swiss Nursery, Farnham. Messrs. Pitcher and Manda, Swanley, had new Chrysanthemums. Messrs. J. Cheal and Sons, Crawley, had Dahlias and fruit very fine, and Mr. J. Watkins, Hereford, fruit. There were many other minor exhibits.

On Monday evening last the general committee of this society held a meeting at Anderton's Hotel, Mr. R. Ballantine occupying the chair. After the usual business preliminaries had been disposed of a letter was read from the son of the late Mr. Edward Sanderson, for many years president, offering his father's show appliances for sale, which the committee decided to buy for the use of the society. Mr. R. Dean stated that the prize money awarded at the September show amounted to £14 17s. 6d., exclusive of special prizes and medals. He then presented the financial statement, showing receipts to an amount exceeding £200, which was far in excess of the amount received up to this time last year. Mr. Cox, J.P., of the Yeovil Society, who was present, gave a short outline of the pro-

spects of the Yeovil show, and attributed much of its success to the fact that it was affiliated with the N.C.S. Eighteen new members were elected, and the secretary reported that the number of new names added to the list of membership since the beginning of the year reached a total of 108.

Mr. C. Pearson, of Chilwell, was then called upon to read his promised paper upon the improvement of Chrysanthemum shows, in which he laid stress on certain defects and indicated improvements that might be made. His paper, which was of considerable interest, although not embodying much that has hitherto escaped the committee's attention, gave rise to an interesting and prolonged discussion, in which a large number of speakers took part. Many objections to the present mode of staging groups of Chrysanthemums were stated besides the desirability of exhibiting cut blooms in some other style than that now adopted.

The paper by Mr. Pearson and the discussion will appear in the new schedule.

UNITED HORTICULTURAL BENEFIT AND PROVIDENT SOCIETY.

THE eighth annual meeting of this deserving institution was held in the Cannon Street Hotel on the evening of Tuesday, the 10th inst. Mr. P. C. M. Veitch, of Exeter, who presided, was supported by Mr. H. J. Veitch, of Chelsea, Mr. Clarence Smith, M.P. for East Hull, Mr. Sherwood, of Hurst and Son, and Mr. Moss, of Wrench and Co., London Bridge. The display of fruit and flowers on the tables, thanks to the kindness of gardeners and nurserymen throughout the country, was the best we have seen at this annual reunion, at which quite 150 were present. The chairman, in the course of his remarks, said that there was a sturdy independence about this society, as the members individually put away their money to help themselves, and he believed that this was the right system of old-age pensions. He hoped that all the young gardeners in the country would see their way to at once become members. Another point he laid great stress on was the management fund. The working of this society, he found, was carried on at the lowest figure possible, there being only one paid member—the secretary. The convalescent fund, started last year by Mr. Sherwood, was not quite so satisfactory as it might be and should appeal to every member, as he considered that in a great measure it lessened the amount of sick pay that had to be given, and he hoped that honorary members would aid this fund. Mr. Sherwood, who replied to the toast of the "United Horticultural Benefit and Provident Society," which had been proposed by the chairman, considered that this society is a very important link between the Gardeners' Royal Benevolent and the Gardeners' Orphan Fund, as it taught thrift in that by saving, the members assist each other. He particularly alluded to the convalescent fund, and said that as this was the jubilee year of his firm, he, in order to mark this, would be pleased to add £50 to the fund. He hoped, too, that the fact of the chairman coming from Exeter would tend to bring forward this society in that district, and that many country members would join and thus strengthen it. Mr. Hudson, the treasurer, in proposing the toast of the "Honorary and Life Members" said that a lady had just become an honorary member, and he hoped that many more would be induced to do likewise. In order to stimulate the young men to join he hoped that the list of members would be increased by the addition of head gardeners. He also called attention to the low death-rate, many of the members who first joined it over a quarter of a century ago being still on the books. As regards its stability, he was glad to say that there was now a sum of £8200 invested. He coupled with the toast the names of Mr. Marshall and Mr. Clarence Smith, M.P. Mr. Marshall made a strong appeal for the management fund, and Mr. Smith said that no one need fear joining the society, as the moneys were all securely invested and yielding a good interest.

He was pleased to become an honorary member, and hoped next year he would be able to be present as a member and not as a visitor. Mr. H. J. Veitch in proposing the "Officers of the Society" appealed for assistance to the management and convalescent funds, and said that it would give him great pleasure to contribute £5 5s. to each. With this toast he coupled the names of Mr. Joseph Wheeler, one of the trustees, and Mr. Collins, the secretary. Mr. Moss in a very felicitous speech proposed the health of the chairman. Messrs. Williams and Son, of Holloway, and Messrs. Laing and Sons, of Forest Hill, sent plants for the decoration of the room. The music, which was under the direction of Mr. Schartau, gave the greatest satisfaction to all present.

Gardening and Forestry Exhibition.—On Monday evening Mr. Harry Turner, of Slough, was entertained at dinner by a number of friends at the Gardening and Forestry Exhibition in recognition of his services as president of the horticultural section of the exhibition. Mr. Milner, F.L.S., C.E., presided, and warmly eulogised Mr. Turner's services in organising the numerous floral exhibitions that have been held during the season and in the decoration of the gardens. A handsome epergne was presented to Mr. Turner as a memento of the occasion.

The weather in West Herts.—The temperatures during the past week have been as a rule rather warm for the time of year. There was, however, one rather cold night (Sunday), when the exposed thermometer showed 1° of frost. At the present time the soil at 2 feet deep is 3° warmer, and at 1 foot deep as much as 6° warmer than at the same period last year. The rainfall has been remarkably heavy, amounting since the beginning of the month to over 3 inches, or very nearly the average quantity for the whole month, which by the way is the wettest of the year. Horticulturists will perhaps more easily understand the exceptional character of the recent heavy rainfall when I explain that 3 inches of rain is equivalent to pouring 14 gallons of water on every square yard of surface. A short drenching shower occurred early on Saturday morning, and another shortly before midnight on the same day. During the six hours ending 1 a.m. on Tuesday over 1½ inches of rain fell, making this the heaviest fall recorded here in any one day since July 17, 1890. For twenty minutes during the storm rain was falling at the mean rate of three-quarters of an inch an hour. Until Friday in last week no measurable quantity of rain water had come through the 2½ feet of soil in the light soil percolation gauge for six weeks. Since then, however, the total measurement has amounted to 1¾ inches. So that the memorable drought of 1893, which for all practical purposes may be said to have lasted here seven months, is now at an end. Moreover, as the evaporation from the surface of the soil is comparatively slight after the middle of October, a large proportion of the rain which falls after that time is certain to find its way permanently into the ground.—E. M., *Berkhamsted*.

FRUITERERS' COMPANY AT THE MANSION HOUSE.

THE Lord Mayor and Lady Mayoress entertained the Fruiterers' Company to dinner at the Mansion House on Wednesday evening. The Dean of Rochester (Dr. Hole) in proposing the health of the Lord Mayor and Lady Mayoress said that so few words were necessary for it, that he would interpolate a few remarks on fruit. He was proud of being chaplain to the company, because, though not rich, it was very aristocratic, as would be found if all the names of the noblemen and gentlemen who sold fruit were standing on the list. A chief delight of this *annus mirabilis* had been the abundance and excellence of fruit. He had not so largely partaken of fruit since those days of childhood, when their zeal was not tempered by discretion, and in which the gods were just and of their pleasant vices made whips to scourge them. And Nemesis appeared by the side of the little

crib, with a cup in one hand, a dark phial in the other, and the aspect of Eleanor offering to Rosamund the choice between poison and a dagger. This year there had been no risk; fruit had been perfect. They did not eat half enough fruit, the most wholesome of luxuries. At the great oyster feast at Colchester it was said that no nation could be really great with oysters at 3d. apiece. Without holding with that extravagant language he ventured to think that if England were deprived of her Apple tart, for the first time he would contemplate emigration. From long experience he did not hesitate to say that owner, occupier, and labourer were most profoundly ignorant of fruit. Indeed, he thought we had rather retrograded. He missed the Ribston Pippins of his youth. The gardeners told him the Peaches and Nectarines could not be grown upon the wall. It was their own idleness; they would not clean the trees. Leaving out Hereford and Devon, the orchards of England were a disgrace. In his early days he knew he could always get into an orchard through the broken fences, and there were other evidences of neglect. A good many years ago he planted six Apple trees, and they were liberally sustained and tended. In one year they brought in £40. They had a great future for their fruit, properly tended. The farmer stood still while the manufacturer went on. It would pay the landlord to see to it. Every landlord ought to have an orchard on each farm. Personally he believed in beer, but he did not see why we should be deprived of every fluid but beer. Cider and perry were good drinks—better than much of the champagne, which began to make a disturbance when it got 3 inches down the chest.

NOTES FROM CLITHEROE.

REFERRING to a kind notice of my garden here (p. 279) from the pen of Mr. Wood, Kirkstall, I may say that I have written to him to draw his attention to a slip of the pen which he has made, in attributing to our craven climate the possibility of growing *Trichomanes radicans* (the Killarney Fern) in the open air here. Our West Yorkshire climate, although much contemned by you southerners, is equal to growing fronds of *Polystichum acrostichoides* (which I had under the name of *P. mimum*) over a yard long, and quite persistent in verdure until the new fronds appear in spring, and even later, and fronds of *Adiantum pedatum* over 18 inches high. Still, I dare not claim *Trichomanes* as one of our *habitués* here. Our woods and streams are very favourable for birds of all kinds, and our list of native species is a large one. They are encouraged, and it is a great pleasure to all our family to see them quite at home amongst us. No doubt we pay a penalty in the matter of Currants, outdoor Cherries, &c., but this we willingly concede. Still, it is somewhat annoying that we can never enjoy the sight of the brilliant coral-red berries of *Sambucus racemosa*, of which we have many, raised from Tyrolese and Belgian seeds. These are all devoured by the birds before they attain redness. The Mountain Ash berries are cleared off in like manner, but I wish to draw attention to the fact that the brilliantly red berries of *Cotoneaster frigida* are not, up to the present time, at all touched by the birds. This shrub has fruited profusely this year with us. I am thereby reminded of what I saw last April at Col. Tremayne's fine garden at Carlew, Cornwall, where a large tree—with me they are shrubs—was, whilst leafless, covered with its richly coloured berries, a sight which I have never seen elsewhere.

Holden Clough, Clitheroe. R. MILNE-REDHEAD.

WE regret to hear of the death of Mr. G. Brownett, gardener to Mr. A. Howell, Ribwipport. He was a good gardener.

Names of plants.—*Galathea*.—Scarlet-fruited Thorn (*Cratægus coccineus*).—*T. A. B.*—1, *Eschynanthus Lobbianus*; 2, *Adiantum sentum*; 3 and 4, send better fronds; 5, *Sedum Sieboldi variegatum*; 6, *Selaginella Kraussiana*.—*J. M. W.*—Variety of Scarlet Thorn (*Cratægus coccineus*).

"This is an Art
Which does mend Nature: change it rather; but
THE ART ITSELF IS NATURE."—*Shakespeare.*

ROSE GARDEN.

PLANTED OUT IN POT ROSES.

THE friendly criticism of "D. T. F." in THE GARDEN (p. 309) suggests the following few notes. He states that he does not remember a single planted-out Rose house to have turned out quite satisfactory. To a great extent this has been my own experience, the chief drawback being that some few plants will grow away much more freely than others of the same variety. Many houses that I have seen have also been planted without sufficient thought, and varieties of distinctly different habits of growth have been placed together. A house of planted-out Roses, consisting of several varieties, needs considerable experience and care in planting. "D. T. F." speaks of such diseases as red spider, mildew, &c., being easier to battle against in the case of pot plants than where the Roses are turned out into borders. To a certain extent this is true, but only so far as the more convenient removal of affected subjects is concerned. On page 210 my subject was strictly confined to pot Roses. I have a large house built expressly for Roses. This is divided into two sections, and the plan of combining both pot and border Roses is successful. In the larger section the plants are turned out, but the lower part consists of two side borders and a slightly raised wooden bench in the centre. The two outside borders of the first section have been planted with climbers and ordinary growers. The wall ranges from 2½ feet to 4 feet in height, and I have planted it in the style frequently recommended by me in these pages, *i.e.*, climbers and other growers alternately. Reine Marie Henriette, W. A. Richardson, Mme. Berard, Bouquet d'Or, and Maréchal Niel are planted the most freely, but the following newer kinds have recently been added, *viz.*: l'Idéal, Climbing Niphetos, Climbing Perle des Jardins, and Kaiserin Friedrich. However well the climbers may be grown they will sometimes develop canker, and in the blanks thus caused I have planted the newer varieties. As yet all are satisfactory. Alternately between these are Catherine Mermet, Edith Gifford, Anna Ollivier, and others. The borders are about 4 feet wide, but Roses are only turned out against the walls. The climbers grow away freely and are trained up the roof, almost the whole of the wall being devoted to the shorter growers. Upon the cross-ties of the house other climbers are planted, and as these are some 12 feet apart and 6 feet to 8 feet above the centre border, the house is by no means dark when the whole of the climbers are in full leaf. In the centre border I have planted a couple of rows of medium growers, these being 4 feet or 5 feet apart each way. The plants are doing well, being quite close enough when in full growth. As the centre border has a margin of 2 feet all round it, and the same space is unoccupied in the case of the side borders, with a walk of 3 feet between, it will be seen that there is a very useful space left for pot Roses. However, I may here say that directly the two rows of entre plants get too coarse or unprofitable, I

shall remove them and use the whole space for pot plants, with the exception of the few climbers upon the cross-ties.

The lower section is used entirely for pot plants, and for quite six months of the year can be clear of Roses if desired. I have used it for Tomatoes and many purposes, yet it has been full of Roses from December until June. The upper half is thus treated. The pot Roses, both climbers and others, have been housed as closely as possible upon the borders and among the turned-out plants. Of course, both have been trimmed out where necessary. This house is, therefore, quite full at present, but will not become too crowded until the days turn. By this time the second section will be cleared out and many of the plants removed to it. Much space and also expense in fumigating, syringing, &c., are thus saved. The pot plants consist of the same sorts of climbers and others as are turned out, and these will be arranged in much the same way as in the upper house.

"D. T. F." advises that no pot Roses be shifted previous to being forced. "Let them bloom first and repot in mid-growth" is what he recommends. I take quite the contrary view, and for these reasons: 1. A plant that has become so root-bound as described must necessarily have exhausted the soil to a great extent, and hence be largely dependent upon artificial supplies to keep up its growth and bloom the following season. 2. Plants in smaller pots are easier to handle. 3. The more naturally we feed the roots and the freer run they have, the better bloom and growth we shall secure, always provided the wood is well ripened. Supposing "D. T. F.'s" theory to be the best, instead of planting Roses in trenched or deeply moved soil, why should we not rather endeavour to confine the roots? For pot Roses, the younger the plants are—within reason—the better; and I seldom grow a plant in a pot more than three seasons. After this it is turned out into the open borders. Old plants with an annual, or even an occasional repotting will soon get too heavy and coarse for the average grower.

The climbers were grafted rather less than twelve months ago, and are now placed into 8-inch and 10-inch pots, having previously been in those of a 6-inch size. The Climbing Perle des Jardins have from two to three shoots some 8 feet and 12 feet long, and are splendidly ripened. Other kinds have only one long shoot in the majority of cases, but these are rather longer. My best dwarf pot Roses consist of Teas grafted one year earlier, or of maiden Hybrid Perpetuals and Teas potted up from the open ground last winter. The reason for growing some climbers in pots and some in the border is to get both houses thoroughly full of flowering Roses without occupying the whole of them for twelve months. The planted-out climbers yield larger and better flowers than those obtainable from the same varieties in pots.

By the time the two chief crops of flowers are obtained there will not be the same demand for Roses under glass, warm walls in the open beginning to afford a good supply. The pot plants in both houses may be looked over, and those which are the least tender, and without plenty of young growth for a third crop, may be placed on a sheltered border out of doors, and the upper house filled with the remainder. Later on these, too, may be thinned out, and thus allow of more room to those remaining, and also those which are planted out. The latter need more air and light than the pot Roses, as they invariably grow a little more freely. In the meantime the other

house may be used for Tomatoes, &c., until the following season and the first thinning out of newly-started plants is with us again.

I am unable to keep the lower section much warmer than the other; consequently the bulk of my pot plants comes into bloom a month earlier than those in the upper section. This is a great advantage in two ways: a better succession of flowers, and being able to use the lower half sooner and to greater advantage than could otherwise be the case. Wherever a house is to be devoted to Roses alone plant out a few climbers, as one thus secures a quantity of well-ripened wood that is certain to flower early and freely. "D. T. F." says that red rust does not affect Roses under glass. I have found it do so in very dry and chilly weather. The varieties it most frequently attacks under glass, however, are generally removed to the open before they could possibly be attacked; in fact very few of these varieties are grown under glass at all. Gloire de Dijon is a great favourite, as it is with "D. T. F.," but much as I like it, I cannot give it room under glass in preference to Bouquet d'Or or Kaiserin Friedrich, two Roses equally as free blooming and with flowers of much better colour under this treatment. RIDGEWOOD.

FOUR GOOD NEW HYBRID TEAS.

MESSRS. PERNET AND DUCHER have considerably added to the attractions of this new class of Roses. I write new class because up to this spring it was not officially recognised as such, although many varieties were spoken of as Hybrid Teas. The four varieties I would like to say a few words in favour of are Caroline Testout and Gustave Regis, both sent out in 1890, and La Fraicheur and Mme. Pernet-Ducher, sent out in 1891. We can form a fairly accurate opinion of these new Roses, because they have been good during the past two summers.

GUSTAVE REGIS is a beautiful nankeen-yellow getting paler as it expands. It is very free in growth and bloom, and forms a grand coat flower in the bud.

LA FRAICHEUR also has very long and pointed buds, which open into grand blooms. The colour is carmine-rose, taking on lighter shades with age. More than one has already written highly in favour of it.

MME. PERNET-DUCHER is not sufficiently large for exhibition, but, like the others, forms a grand coat flower, and is also a good Rose for garden decoration. It is a deep canary-yellow, with perhaps a shade deeper colour in the centre, especially when it first opens.

CAROLINE TESTOUT.—Young as this Rose is, it is already acknowledged as one of the very best, and is quite likely to be soon declared as the best of all of the Hybrid Teas, being a good grower, free bloomer, quite distinct, and equally good throughout the whole summer and autumn. Quite recently I have gathered some splendid blooms. I like it better than La France; the colour and shape of the flowers are much the same, but deeper
R.

Rose Crimson Rambler.—This Rose, which has attracted more attention than any other during the present year, is the subject of an article in a contemporary in which the following occurs: "Certificated by the Royal Horticultural Society about four years ago under the name of The Engineer, when shown by a nurseryman in Lincolnshire, its value seems to have escaped the notice of some of our Rose nurserymen until it came into the possession of Mr. C. Turner, who will distribute it in the coming autumn." Would any reader of THE GARDEN kindly say if such is the earlier history of the Rose in question, and, if possible, its origin? Concerning this last part of the question, we have been told that it is a direct importation

from Japan. Referring to past records, I see that the Rose Engineer received an award of merit from the Royal Horticultural Society, July 8, 1890.—H. P.

Rose Mrs. Paul.—The past summer has not suited this Rose so well as did 1892. I am alluding to its blooming qualities. As regards growth, that seems particularly clean and vigorous. This is certainly one of the very best Bourbons, but I doubt if it ever will become so popular and generally useful as Souvenir de la Malmaison. Mrs. Paul is one of the most distinct Roses grown, having a beautiful soft blush-white shade with rosy peach flushes throughout. It is peculiar in shape, the petals being reflexed in quite a distinct way from those of any other variety. It will doubtless be grand upon pegged down shoots during a favourable season, but the old Malmaison, sent out fifty years earlier, is always good late in the autumn let the season be what it may, and the present is no exception.—R.

Rose Ruby Gold.—I have grown this ever since its introduction, and the flowers have been the exact counterpart of those of Jean Ducher. In growth and foliage it also resembles Jean Ducher. From the first I had very little doubt about its being synonymous with this older variety, but now I am quite positive that the plants I purchased for Ruby Gold are neither more nor less than Jean Ducher. I have been in communication with several upon the subject, and all confirm my opinion, and more than one firm has ceased to catalogue it. It was sent out by an American firm as being the result of grafting Catherine Mermet upon Maréchal Niel, and was much praised.—R.

ROSE NOTES FROM ESSEX.

AMONGST the more successful exhibitors of Roses this year are Messrs. D. Prior and Sons, whose nursery is within a few minutes' walk of Colchester station. Although many things are grown besides Roses, these are the leading feature, and cover much space on an exposed hilly spot, where the soil is of a good deep loam. The majority of the plants are upon the cutting Brier stock, and throughout they are in the best of health, being lately in full bloom, although early in the season they were in perfection.

For many years this firm has been established here, and we are pleased to see such a healthy collection of the leading types, both of Hybrid Perpetual and Tea-scented. Even now we see much written about the tenderness of Tea Roses, but on this exposed position they thrive remarkably well. The plants are cut hard back, and no protection is afforded except in very severe weather, when a little Bracken is placed amongst them. All classes are grown, standards, dwarfs and pot plants, whilst the stocks also comprise the usual kinds, but the cutting Brier predominates. We do not want to make merely a list of varieties, but may point out a few of those that have been exceptionally fine this year. It is important to know which succeed best in such a year as the present, one of the most trying on record.

Hybrid Perpetuals are largely grown in this nursery, and, as we had occasion to previously remark, the dark-coloured varieties have proved highly satisfactory. Louis van Houtte is certainly one of the best of this class, the flowers exceptionally fragrant and brilliant red, suffused with a crimson tone. Fragrance is not characteristic of many of the newer Roses, and this is a failing that must not be overlooked. We consider a scentless Rose of comparatively little value, however beautiful its form or colour. Beauty of Waltham is a fine kind, and well represented in this nursery. The flowers are bright red, of splendid shape, and sweetly scented. Gustave Piganeau is considered one of the leading kinds amongst Hybrid Perpetuals, and this opinion is held by all the best Rose growers, although it is chiefly as a show Rose that it commands attention. A variety not yet very common is T. W. Girdlestone, a good exhibition kind, the flowers highly fragrant and of a vermilion shade of colour,

deepening to crimson at the base of the petals; and Silver Queen is also thought much of, the flowers of excellent cupped form and silvery blush in colour, deepening more to a rose tint in the centre. Prince Arthur, Victor Hugo and Prince Camille de Rohan amongst the dark coloured Roses have appeared to distinct advantage. We think the last-mentioned kind is one of the most fragrant Roses in cultivation, and is of superb colour, velvety crimson, the form of the blooms very full. We singled these out of the representative collection grown on the hilly slopes as of especial beauty in this year of uninterrupted sunshine.

In the eastern counties, amongst the Tea Roses Jean Ducher seems to have succeeded better than other varieties, as from notes we have made it has been good in almost every nursery and garden where Roses are grown. With Messrs. Prior exceptionally fine also have been the leading varieties, such as Anna Ollivier, the beautiful Ernest Metz, one of the best of all for the garden or exhibition; Edith Gifford, Mme. Hoste, Mme. Lambert, Marie van Houtte, Princess of Wales, The Bride, and Viscountess Folkestone, which properly belongs to the much confused Hybrid Tea class.

Much attention is given to the garden Roses, which will be largely grown in the future, as a love is springing up for these charming types. Many are unfortunately very difficult to get, but we hope that they will soon be in the reach of all who require the fine old favourites that made gardens gay in years gone by. Amongst the Noisettes, Caroline Kuster has been remarkably good, and it is a lovely Rose when in full beauty, the flowers large, of globular form, and pale yellow, whilst they are produced very freely. The Polyantha class is of great importance for the garden, and the leading kinds are grown in this nursery. Scarcely sufficient use is made of the many beautiful varieties in cultivation, as they are for the most part of vigorous habit and exceptionally free, making a gay show during the summer and autumn. We recently saw a large bed of them which was as bright as in midsummer. One of the best kinds is Anna Maria de Montravail, producing clusters of good double, sweetly scented white flowers, each like a little rosette. Gloire des Polyantha is a charming kind, the flowers rich rose, shading off to white at the base of the petals, and another gem is Mignonette, which bears a profusion of neatly shaped flowers of a rosy colour. A good mass of this is full of charm, and to this selection may be added Perle d'Or, the flowers of a nankeen-yellow, deepening to orange in the centre.

The China Roses are also, we are pleased to see, becoming popular, and when planted in bold groups they are exceedingly bright, forming neat dwarf plants smothered with bloom throughout the summer, continuing far into the autumn when the weather is favourable. Such a variety as Fabvier is most effective in the garden. The flowers are somewhat thin, but the colour is brilliant scarlet, a peculiarly bright and showy shade, and the plant is dwarf. Mme. Laurette Messimy is a beautiful kind, but not so well known as some of the older varieties. It undoubtedly will get popular by reason of the bright rosy coloured flowers. The common China Rose is delightful in the garden, and the plant, like the majority of its class, is exceptionally free. Although we do not say a word against exhibition Roses, it is satisfactory to know that the true garden Roses are becoming more grown each year, and deserve to be planted freely in bold masses.

Those who are ardent exhibitors should read our reports of the earlier shows to know the varieties that have proved most successful this year in particular with this firm, although we have in these brief notes pointed out a few that deserve special attention.

Notes on Roses.—September and October have been splendid months for Roses. During the former I had a good show of bloom, and the splendid rains of October have made it easy and safe to lift such of the Hybrid Perpetuals as were ripe. I have been busy potting up the latter, and also those of the dwarf Teas that had become

well matured owing to the dry autumn. If mild weather should last for any length of time, the recent rains will have a tendency to cause late and somewhat injurious growth upon those plants which are already matured, but the young wood upon Teas and Noisettes will continue to produce a few very good blooms. Plants look remarkably well; they are sufficiently strong without being in any way coarse or sappy, and are likely to pass through the winter well. Those upon walls are ripening satisfactorily, and do not carry so much young growth at the end of strong shoots as is usual during a mild autumn. Climbers in particular are very healthy. Early planting is a great advantage. The sooner after October that one can secure a stock of hedge Briers and get them planted the better. In planting these for stocks the majority of amateurs do not trim off the coarse, knobby roots freely enough. The medium-sized roots should not be removed. When hard trimmed, the root is more healthy and not so apt to split off when lifting the future Rose tree for transplanting to its permanent quarters. These older knobs of sucker-like growth also produce a quantity of suckers year after year, while much of the wood dies as time goes on. If the hedge Briers are collected and planted early, they root more freely, often becoming fairly well rooted before hard weather sets in. This is also the case with other stocks as well as with early-planted Roses. Cuttings of Manetti, De la Grefferie, Brier, Polyantha, &c., should all be made as soon as possible. Strong growing Roses of the Duke of Edinburgh and Ulrich Brunner class will root almost as freely as the various Rose stocks, and where own-root Roses are in request it is well to propagate a few in this way. The Chinas and Mosses are easily increased from cuttings, wood that is about three parts ripe rooting freely.—R.

Rose Pride of Reigate.—Of all striped Roses this seems to be the best, but, like the majority, it is not constant. One of my plants produced a few true flowers early this year, and a short time afterwards the same plant was carrying a fair example of Comtesse d'Oxford. This autumn I had a bloom upon it that was a counterpart of Pride of Waltham at the same time that it was carrying striped blossoms. I am not writing of more than one plant, as I have a bed consisting of a specimen of each variety, so that I am quite certain it is the same root which has varied so much. I believe that both Pride of Reigate and Pride of Waltham sported from Comtesse d'Oxford, and it is interesting to note that my plant evidently partakes of all three. Most of the striped Roses are very variable, and I shall watch closely for similar freaks in the case of Merrie England and Mrs. Harkness, both sports from Heinrich Schultheis.—R.

CHRYSANTHEMUMS.

NOTES ON NEW CHRYSANTHEMUMS.

THERE are several novelties in bloom here at this early date, which will, if I mistake not, take a high position in collections for some time to come. I have heard it stated by an eminent Chrysanthemum expert that any noted variety of the Japanese type remains popular only four or five years, and after that time is either superseded or, through the high cultivation which obtains at the present day, degenerates. To support the latter view Mme. C. Audiguier may be cited. This variety exhibited in such splendid form a few years back, although still grown by many, is seldom now seen in anything like perfection. On the other hand, E. Molyneux appears to have come to stay longer indeed than the term mentioned, but whether this kind, Viviani Morel, Sunflower, and the like will ever be beaten in their respective colours remains to be seen. The first four to be named were raised by M. Calvat,

Grenoble, France, a name of recent prominence in connection with the Chrysanthomum, but, judged by the standard of his first efforts, we may expect from him varieties of surpassing excellence.

MME. THERESE REY is, I think, the handsomest creamy white variety yet seen. It is of graceful form and large size, the florets remarkably rich. It has in addition a remarkably dwarf growth and good constitution.

PRESIDENT BOREL is another loose-flowering Japanese kind of a fine type. The colour is a rich shade of purple-rose and the reverse of the florets yellow. This combination gives a capital contrast and is very showy. The plant grows about 3 feet high.

MME. EDOUARD REY has a pleasing blush-pink tint and is of large dimensions. At first it opens with the tips of the florets turned up, but when fully developed they recurve and give a bloom of not too formal symmetry. It is a strong grower of medium height.

VICE-PRESIDENT CALVAT belongs to the large, wide-petalled class like Mrs. Wheeler, and is the stoutest in wood and leaf I have yet seen. The flowers are not of remarkable diameter, but of great depth. Its colour is a chestnut shade of crimson with old gold reverse. As an exhibition bloom it will be esteemed, but for other purposes it is too stiff and heavy.

KENTISH YELLOW will add to the fame of Messrs. Cannell, who have either raised or introduced such sterling kinds as E. Molyneux, Avalanche, Sunflower, Col. W. B. Smith. The new one may be classed with them, as it is the finest light yellow Japanese variety in cultivation. The bloom is massive and graceful, and colour remarkably clear, while the plant is short in growth. My plants of this are not a yard high.

IDA PRASS is an incurved Japanese that was sent from America a couple of seasons ago, but it does not appear to be much known. The flowers are of large size, flesh-pink in colour. It is a capital grower and should become a popular sort with exhibitors.

MME. MARIE CONSTANS—This variety was noted last year as of much promise. Another season has confirmed my view of it as an early Chrysanthomum for any purpose. It is a capital grower. The bloom is composed of a mass of long, thin, and narrow florets of lovely hanging form. The colour is creamy white.

BARON HIRSCH.—In this we have the most notable incurved variety of recent years. It resembles in character of growth and flower, as well as earliness, the variety Refulgens. It is, however, freer and the bloom larger and more double. The colour is a bright dark buff. An English seedling.

VICE-PRESIDENT JULES BARIGNEY.—This is a seedling from France, and likely to be useful to those who exhibit incurved Chrysanthemums. Its fault, as a useful kind for other purposes, is a rather tall habit, my plant being 6 feet high. The flower is of large size, somewhat after the variety Lord Wolseley in build and petal. Light buff in colour.

M. MARTIGNAC is a rich yellow incurved of fair size. The florets are well formed. It is of medium habit and a most useful addition. H. S.

Chrysanthomum Charles Davis.—When it was known in the spring of this year that Mr. Norman Davis, of Camberwell, had succeeded in fixing a yellow sport of Vivand Morel, it created much interest. I lately had an opportunity of seeing this novelty in its various stages of development in Mr. Agate's Chrysanthomum nursery at Havant, and I must say that I admire it very much. In habit of growth Charles Davis is the counterpart of its parent, the flowers being produced on plants barely 3 feet high. The blooms vary much in colour according to the "taking" of the buds. The blooms opening from early formed buds are pale primrose, decidedly pleasing. The second buds develop blooms of the colour most

required in the Japanese section. The centre opens deep yellow, which passes to a lighter tint towards the outside of the blooms with age. The petals have here and there a tinge of colour in them. The later blooms correspond with the published description—canary-yellow, beautifully tinted with rosy bronze. They measure fully 8 inches in diameter, and promise to be of proportionate depth and solidity.—E. MOLYNEUX.

Chrysanthomum William Tucker.—This Japanese variety is of American origin. Owing to its carliness it is seldom seen upon the exhibition table, but this year it promises to take a high position. The plants were much later in making the customary natural breaks, so that the formation of the buds was prolonged sufficiently to ensure the blooms expanding later than usual. As a specimen plant this promises to be an acquisition. In colour W. Tucker is described as being delicate rose.

Chrysanthomum Miss Watson.—For grouping or decoration this reflexed Japanese is worth a note. As a front row bloom in a large collection in a cut state it is not to be despised, the colour being charming, one of those warm shades of yellow that at once catch the eye. In formation the flowers closely resemble those of Avalanche, and it would not be amiss to call it a yellow Avalanche. The habit is good, not too tall, and the flowers are freely produced.

EARLY CHRYSANTHEMUMS.

If we have one cause of complaint this year, it must certainly be the very disappointing results that have attended the cultivation of the newly-introduced early-flowering Chrysanthemums, which, so far as I can learn, have scarcely flowered at all. Whether the season is at fault or that growers have not been sufficiently interested in these novelties to do them full justice, I do not know; but the inquiries I have made certainly have not been productive of anything like the favourable responses expected, considering the way in which these new varieties were praised a few seasons since. It seems to be the fact that, with a few exceptions, we are almost in the same position as we were years ago, viz., that the old-established sorts are still the best, and that the new ones stand a very good chance of being discarded almost entirely.

Three weeks ago I paid a visit to Mr. Jones, of Lewisham, and to Mr. Davis, of Camberwell, in the hope of seeing all the best of the new earlies, but with what results the reader will best judge when he peruses the following notes. Dealing with those at the first-mentioned place, Lady Fitzwygram, a pure white Japanese, very dwarf and almost as large as those of the Desgrange family, was good; General Hawkes, a dwarf Japanese, colour amaranth, with a silvery reverse, and Rycroft Glory, a deep golden yellow flower of the same type, with medium-sized flowers, were also attractive, but these were not of Continental origin, as those of which we have heard most are said to be. Nearly all the early sorts recently sent out by M. Délaux and grown in the open at Lewisham were not even showing colour, being about as forward as Lady Selborne and Margot grown under similar conditions. This seems to me to be most unsatisfactory, because earlies are of little service elsewhere than in such a position. The old pompon early-flowered Chrysanthemums like Lyon, Alice Butcher, Flora, La Vierge, White Lady, &c., were much more advanced and appeared to maintain their right to be called earlies far more than the new ones. All I could discover worthy of attention were Mme. B. Yung, a Japanese crimson-coloured flower; Mme. Mario Constans, a light

lemon-yellow Japanese, with long thin florets; Gloire de Mezin, another Japanese, rather globular in form, of a pretty shade of golden bronze; M. le Ministre Léon Bourgeois, a Japanese flower of good size, colour violet-rose, with golden centre; Mme. Jeanne Failligret, another Japanese, colour blush-pink; Georges Devered, something similar to an early Source d'Or; and Louis Lionnet, a pretty flower of the Japanese type, golden salmon and yellow.

The blooms at Camberwell consisted mainly of a different sort, being varieties of what we might term semi-early or October-flowering kinds, and in size more like the later kinds for exhibition. L'Ami Etienne, a light mauve-coloured flower, a Japanese incurved, was in good form; l'Isère, another of similar massive build, colour pure white; Louise, a deep massive incurved Japanese, tinted blush, and Fredk. Hausford, creamy white, tinged chamois in the centre, a good flower; were perhaps the best. Mlle. Thérèse Rey, a large white Japanese, and Charles Davis, the bronze sport from Vivand Morel, were also well out; but perhaps all those mentioned might, with a little less skilful cultivation, be retarded, and consequently come into flower very little, if at all, before the time of the ordinary shows. Here also was a goodly array of the well-known, old-established, early-flowering sorts, for which Mr. Davis has long been noted.

It seems to be more than probable that we are still a long way off securing anything like thoroughly genuine large-flowering early Chrysanthemums. CHRYSANTH.

SHORT NOTES.—CHRYSANTHEMUMS.

Chrysanthomum Mrs. Nisbet.—This Japanese variety is likely to be useful for grouping, being rich in colour and of dwarf habit. The colour is amaranth.

Chrysanthomum Anna Hartshorn.—For October flowering this Japanese variety deserves a foremost place. The petals incurve loosely and are of good substance, the colour being of the faintest of blush-pink on a white ground.

Chrysanthomum Excelsior.—For exhibition this Japanese kind promises to be a decided acquisition, the colour bright rose-cerise, with a silver reverse. The bloom is large, but of a depth quite in proportion to the width; the habit of growth is not too tall.

Chrysanthomum Marquise de Paris.—This Japanese kind is one of the finest of its class yet introduced. The blooms are of large size, quite full in the centre; the colour white, flushed with pink in the centre, which passes to pure white with age. As an October exhibition flower it is decidedly one of the best yet introduced.

Chrysanthomum Puritan.—Whether this kind is pure white, characteristic of those blooms that expand during the month of October, or the pink colour of the broad incurving petals in November, it matters little; both are decidedly attractive. This is one of the finest of the Japanese section of recent introduction, and the habit of growth is excellent.

Chrysanthomum William Seward.—The present condition of the plants of this Japanese kind, bids fair to sustain last season's reputation. In habit of growth it is dwarf, yet robust; the blooms are opening in that free manner so pleasing to cultivators. It is a great improvement on Jeanne Délaux, the deep rich blackish crimson colour being more attractive than in that old variety.

Chrysanthomum Vice-President Jules Barigney is an incurved kind, raised by M. Délaux presumably from seed, and sent out first under

the name of President Carnot, but since altered to the above. In colour it is chestnut, suffused with buff, the petals being of medium size. It is described as rich crimson on the inside of the petals, but a true incurved bloom ought not to exhibit the inner part of its petals.

Chrysanthemum Mrs. C. H. Payne.—This has a very large, but, unfortunately, coarse flower. Evidently it is very vigorous. Strong plants must bear half a dozen blooms instead of the orthodox three to reduce their size, when they are rich in colour and more even in the petal. It is the irregular manner in which the outer florets are arranged in the largest blooms that gives it a coarse appearance. The colour is rosy blush.—E. M.

NOTES OF THE WEEK.

Antirrhinum Hendersoni.—We have a very pretty Snapdragon under this name from Messrs. Dicksons & Co., of Edinburgh, in which the edges of the flower are marked with magenta. It is a very beautiful and striking flower, and we should like to see its effect in the open air.

A mammoth flower.—In the window of Mr. Watkins, of Slindon, is a large Sunflower of extraordinary dimensions. It measures 3 feet 1 inch in circumference, and weighs 3½ lbs., being the largest that has ever been seen in the village. Mr. Watkins is also in the possession of a Laburnum tree, which has bloomed a third time this season.

Chelone barbata, although usually seen dotted here and there in the border, is really a fine plant for massing or to fill a distinct bed. We recently saw it used with excellent effect in this way, the tall slender spikes of brightly coloured flowers making a beautiful show. It is easily grown and blooms late, lasting in beauty over a considerable season.

Chrysanthemum Coral Queen.—This is a welcome addition to the October section of decorative Chrysanthemums. It is of free growth with a good habit, and also free flowering. The colour of the flowers resembles that of Carnation Mrs. Reynolds Hole, with a tint of rose. Altogether it is a very desirable variety for conservatory decoration or for cutting.—A. Y.

Begonia Martiana gracilis.—The note on this beautiful Begonia from Mr. Smith in THE GARDEN (p. 310) is opportune. Mr. Smith's remarks will doubtless induce those who grow the plant in houses to try it out of doors, where its lovely pink flowers and fine leafage would tell. We seem to be getting away from the ordinary tuberous Begonias in the garden, and planting such things as the semperflorens type, which certainly are very showy, whilst creating a change.

Zinnias have been remarkably beautiful this year, evidently enjoying the hot weather. We never remember to have seen them finer, and when planted in bold masses they have a rich effect. The deep crimson colours are the best, and show up well if kept distinct. In visiting gardens and nurseries recently we have been surprised at the freshness of Zinnias even after many other things have been long past. They are rather stiff, but so showy and bright, that in every garden good use should be made of the best colours.

Michaelmas Daisies at Camberwell.—It is worthy of note that the Starworts are excellent town flowers. A large collection of all the best varieties is grown by Mr. Davis, of the Lilford Road Nursery, Camberwell, and they flower with remarkable freedom, although this nursery is in one of the most densely populated districts of the metropolis. An increasing interest is taken in this charming family, and we are pleased to see that the best kinds are more grown than formerly.

The Winter Cherry (Physalis Alkekengi) was very bright recently in the Swanley Nursery. This is a fine hardy plant for late autumn and winter effect, and should be grown in bold clumps

or colonies. We once saw a large bed of it, which supplied many bright shoots for decoration. The large orange-red calyces last well when cut, never losing in any degree their distinctive colouring. A warm position is essential, and the soil must be light. The present year has exactly suited the Physalis, but it is usually very free if the position is not too cold and damp.

Funkia grandiflora has proved a splendid hot weather plant. Certain things, as the Belladonna Lily, have flowered remarkably well this autumn. This Funkia is very uncertain, as it blooms late, and frosts often spoil the lovely white fragrant flowers. The position must be warm and the soil light, otherwise failure results. It is hopeless to expect good flowers unless these conditions are given. In ordinary years the only good results are got from pot specimens, and it is well worth growing largely thus for greenhouses and conservatories. It is synonymous with *F. japonica*.

Plumbago Larpentæ.—This is a bright and attractive plant when one can induce it to flower freely, but according to my experience of it, unless in hot, dry summers like the past, it is rather shy in this respect. I do not think there is the slightest doubt as to its being a thoroughly hardy plant but it evidently likes hot weather, and then it appears to flower freely enough. But, like its, greenhouse relatives, the flowers only last a couple of days. It enjoys a rather poor, but warm, dry soil at the foot of a south wall if this can be afforded, although the plants under my care are out in the open border.—T. A.

Camellias in fruit outdoors.—I send you a seed-pod cut from a plant put out in April, 1885, and fully exposed to east and north winds. It has flowered freely every season since planted. This season it flowered in the latter half of March and throughout April. It is a dark crimson semi-double variety. I have forty-six of the best varieties planted out. They all flourish and flower equally well and in all situations, and I have never had a plant hurt with frost. The two first were planted out in 1881 on a sandy clay subsoil. There are about a dozen pods on the plant.—F. T. BARRY, *St. Leonard's Hill, Windsor.*

Michaelmas Daisies from Ireland.—I send you a box of new Michaelmas Daisies, all self-sown seedlings; some of them are fine. Magnifique is by far the best blue Aster yet known. Grandis is also good, but different in habit, being very erect, while Magnifique is semi-prostrate. Delicatus is one of the prettiest, a beautiful lilac-blush. This weather is most satisfactory for the white flowering kinds, of which Purity, Madonna, and Niveus are all excellent in their way, but the prettiest of all is White Queen, one of this year's seedlings, and only 18 inches high. As it is upon a rather poor bank it may grow taller under better conditions.—T. S.

Zauschneria californica.—Until the past hot summer the above plant has been more or less disappointing. The difficulty has been to establish it, and even when fortunate enough to get it to grow a little, the flowers were very few; but during the past summer it has flowered continuously and has been one of the brightest hardy plants in the garden. It evidently succeeds best in a hot, dry summer, for it must have been as dry at the roots as a bone for months together, yet it grew rampantly and flowered profusely. I have to-day divided it into a number of goodly sized pieces and made a mass of it a yard or more across. Perhaps I have done wrong by interfering with it, but I like good bold masses of everything in the hardy plant borders, and detest puny dot plants.—T. A.

Seedling Disaa.—At Kew several new kinds have been raised of recent years, and a good hybrid is Premier, which was given a first-class certificate at the meeting of the Royal Horticultural Society on October 10. It is a cross between D. Veitchi, itself a hybrid, and D. tripetaloides, which is a remarkably robust and free blooming species, exactly the type to use as a parent. Curiously, the hybrid named Premier has got comparatively little of the D. tripetaloides character, the flowers showing few traces of the spotting, characteristic of that species.

It is more like *D. grandiflora* as regards the habit and foliage, the spike rising about 2 feet in height and bearing a number of flowers, each of a bright rosy colour and about 1½ inches across. Such Orchids as these are likely to get really popular, as they are bright and easily grown, simply because vigorous.

Iris alata.—This is one of the most interesting hardy things that bloom in late autumn and winter. It was recently in bloom with Mr. T. S. Ware at Tottenham, and is pleasing either in pots or at the base of a warm, sheltered wall. Like the Colchicums and autumn Crocuses, the flowers get splashed by heavy rains if on a border. The bulbs should be planted amongst Stonecrop or similar creeping plants to prevent the delicately coloured blooms being sullied. There are many sheltered spots in gardens where they are seen in perfect beauty. The flowers differ considerably in colour, but the prevailing tone is a kind of mauve-blue, the veins of a deeper shade, whilst the fragrance is like that of the Lilac. The growth is sheathing, and may be compared to that of the Leek. A few potfuls of this Iris in the greenhouse in late October or November are very pleasing.

A large Holly tree.—A Holly tree within ten paces of my house, which is 1040 feet above the sea, is, I venture to think, the largest in Great Britain. I have in my possession a report which was made on it in January, 1836, and at that time the tree "measured in circumference above the roots thereof 27 feet 6 inches, and estimated to be 60 feet in height and is very branchy, and the general opinion is that it is 400 years old." The circumference of the tree now is 30 feet and its height 43 feet. It has sixteen main branches, measuring in circumference 11 feet 7 inches, 8 feet 2 inches, &c. It covers a circle the diameter of which is 54 feet, and its branches have numerous initials and dates cut on them, those which can be still deciphered ranging from 1700 to 1864. The most legible is that of J. Broughton, Aug. 22, 1756, which is almost as clear as the day on which it was cut. Many of the branches are half eaten through with rot, and I have had all the sixteen supported by iron rods. The tree still shows great vitality, each year numerous young shoots being produced. It is rather curious that on the opposite side of the valley is another large Holly tree which measures 17 feet 6 inches in circumference.—GEO. H. LLOYD-VERNEY, *Clochfaen, Llanidloes, N. Wales.*

The leaves of October.—After such a marvellous summer it is reasonable to expect that the autumn glory would be rich beyond that of ordinary years. The glowing tints of scarlet, purple and gold defy description. The Chestnuts, Birches and Poplars never were of purer tone in their rich golden drapery. The Maples are conspicuous in every patch in which they stand. The scarlet Oaks are superb. Willows, Thorns and the Mountain Ash shine and sparkle in the denser masses of yet green clumps. On the houses the Virginian Creeper is beautiful. A walk through the nurseries at this season of the year could not fail to offer valuable suggestions to planters and those contemplating garden extension and improvement, and who would, in their prospective plans and arrangements, make provision for autumn effects and surprises. We send you a box of leaves of the following:—

Amelanchier canadensis	Hamamelis virginica
canadensis ovalis	Liquidambar styraciflua
Ampelopsis Engelmanni	Quercus coccinea
Hoggi	nigra
Veitchi purpurea	palustris
Acer rufinerve	robur laurifolia
tataricum ginnale	Rhus Cotinus
Azalea pontica	glabra
Berberis Thunbergi	radicans
Cornus mascula	Spiraea prunifolia flore-
sibirica	pleno
Crataegus crus-galli	Vaccinium pennsylvani-
Layi	um
Oxyacantha multiplex	Vitis vinifera purpurea

The marks of drought are now nowhere to be seen, but everything is splendidly matured, and trees and plants are in rude health and the wood is so well ripened up as to mark the season all the way through as exceptional.—DICKSONS, *Chester.*

FLOWER GARDEN.

THE WINTER DAFFODIL.

(STERNBERGIA LUTEA.)

FOR nearly three hundred years at least this old plant has occupied a place in books and gardens, but it is far from abundant even today. I have seen it in the Cambridge Botanic Gardens in the form of spreading tufts or masses, each bearing a hundred or more of its golden yellow flowers, and nowhere else have I seen it quite so beautiful and free. It is hardy enough in most gardens, but seems to require a warm stony or sandy soil and plenty of sun heat in order to make it bloom in a satisfactory manner. Here for years I had large clumps of it that threw up rich green leaves every autumn, but never a flower, until I removed the bulbs to a dry and sunny border where Belladonna Lilies do well, and now they are very pretty as seen side by side. This is a by no means had combination, since the naked flower stalks of the Amaryllis look all the better for the dark green herbage afforded by the Sternbergia. This plant is very variable, being distributed over a wide area in Eastern Europe and the Mediterranean basin, and it is also found in Northern Africa. *S. exigua*, *S. Fischeriana*, *S. sicula*, *S. ætensis*, *S. græca*, and one or two others are merely forms of *S. lutea*, varying but little in size and hue. There are two well-marked forms of *S. lutea*, the one having much larger foliage than the other, and my own experience is that the narrower and smaller leaved form is far more free-flowering than the other. Boissier, in his "Flora Orientalis," mentions several fine kinds of Sternbergia not as yet in cultivation. Flowering as does this plant along with autumnal Croci, Zephyranthes, Cyclamens, and Colchicums, it adds the one note of warm yellow that they all lack to the rock garden or the bulb garden.

F. W. B.

GLADIOLI IN 1893.

THIS season, which has been so full of disappointments to nearly every one connected with horticulture, has not spared the growers of this beautiful autumn flower. Especially has it been hard upon amateurs, of whom, to tell the truth, there are but very few in the southern part of the kingdom. Never during the twenty years that I exhibited were there more than three, or at the most four competitors, and now that I have practically retired from exhibiting the number is reduced to two—Mr. E. B. Lindsell, of Hitchin, and Mr. W. H. Fowler, of Taunton. It is not remarkable then that so little scope is given for their exhibition either in the metropolis or its neighbourhood, and that the managers of shows prefer offering prizes for a collection which induce the trade to send up stands of 100 or 120 blooms, which, of course, add to the size and beauty of the exhibition, although not in themselves so interesting to the amateur. The manner in which the season has affected the few amateurs whom I have the pleasure of knowing may be exemplified by the case of Mr. Fowler. He has been in the habit of exhibiting in the last few years not only at Taunton, but at Bristol, Chester, Exeter, and other places in the west. This season he could only exhibit at the exhibition in his own town, Taunton, his flowers—for I saw his garden at the time of the show—being all past. So far as the metropolis was concerned, there was no autumn show at the Crystal Palace, and at that at Earl's Court, which to some extent

took its place, I was not able to be present, but I believe no amateur entered into competition. The Aquarium had, I believe, to tell the same tale, but at the exhibition of the Royal Horticultural Society held at the Agricultural Hall, Islington, there was on August 24 a field day for the growers for sale. But here again the character of the season showed itself. Three collections were shown by Messrs. Burrell, Harkness and Sons, and Kelway and Sons, who obtained prizes in the order I have named them. Anyone looking at the stands could not have a moment's hesitation as to the correctness of the adjudication. From what I have already said, it will be assumed that the celebrated Somerset growers were considerably handicapped by the earliness of the season, and making all allowance for this, the superior character of the flowers which obtained first prize was manifest to all. I have for some time maintained that Mr. Burrell's flowers are the finest shown by any exhibitor. He has for some years grown them on the splendid loam of Cambridgeshire, and has got into a strain of seedlings which I believe are likely to surpass even the best of the French

a delicacy of constitution which detracts from their commercial value. Thus Mme. Desportes, which was sent out some thirty years ago, is now as clear as some of these of last year, while Albatross, a flower of three years ago, does not seem to fall in price, probably owing to the same cause. It is not until a sufficient number of roots has been procured from spawn that a variety can be sent out.

But to return to the flowers exhibited at the Agricultural Hall, the following are some of the most striking in Mr. Burrell's stand: Auntie, pale creamy rose, shaded with straw; Archiduchesse Marie Christine, white, tinted and flaked carmine; Atlas, pale porcelain, lightly tinted and striped violet; Baroness Burdett Coutts, lilac, tinted rose and purple; Camélion, slaty lilac, striped white, pale orange blotch; Carnation, pale flesh, suffused and tinted carmine; Conquerant, dark purplish carmine, with clear white blotch and bands; Crépuscule, pale porcelain, tinted lilac; Cygnet (Burrell), pale lemon-white, very much like Albatross; Dalila, bright rose, blotched and striped white; Daubenton, lilac, suffused violet; Dr. Bailly, bright scarlet, blotched carmine on white ground; Enchanteresse, pale rosy white, lightly striped violet; Eugène Souchet, bright rose, large white blotch and stripes; Flambeau (Burrell), orange-red, white lines and white blotch; Formosa, pale satin rose, striped carmine, with creamy white blotch; Grand Rouge, a scarlet-crimson, with small violet blotch; Horace Vernet, purple-red stripes and white blotches; Iolanthe (Burrell), reddish pink, with the lower petals banded white and feathered crimson; Le Phayre, bright red; Le Vésuve, fiery red; Mascarille, salmon-rose, with large sulphur-yellow blotches running through the petals; Matador, bright cherry-red, striped and blotched white; Néréide, pale lilac-rose, with small violet blotches; Ondine, white, tinted lilac and bluish violet stripes; Ovide, purplish carmine, stripes and blotches

Winter Daffodil (*Sternbergia lutea*).

flowers. He has not saved seed at random, but has been careful to hybridise for the purpose of obtaining good form and substance, and anyone who sees the new kinds which he has brought forward will, I think, agree with me in this statement. As to colour, it seems to be almost impossible to say in what direction this will be found.

There are so many tints in those already in cultivation, that any one of them may assume the predominance in the seedlings, and they may run into the most unlocked-for variations. Nothing seems certain in this respect, and the same is conspicuous in other things; thus two white Grapes crossed with one another have produced a black Grape, and I have a seedling Gladiolus which I have no doubt was saved from flowers at which the bees had been at work amongst flowers of most diverse colours, and yet it has not a spot or stain of any colour, being pure white. It obtained a first-class certificate three years ago, and has fully maintained its character. Probably, however, the finest white which has ever been raised is one called Snowdon, a seedling of Mr. Burrell's, but, unfortunately, it produces hardly any spawn, and therefore will be of very little use; indeed, in many white flowers there seems to be

white; Pasquin, bright scarlet-crimson, edge of petals slate, and white stripes; Pasteur, rose, slightly tinted with orange and white blotches; Pollux, carmine, with white blotches; Pyramide, clear delicate orange-rose, shading to amber in the centre; Rayon d'Or, yellow, with red stripes and purple blotch; Stanley, salmon-rose, with deeper shading, and small rosy yellow blotch; Sultane, bright carmine-rose, with purple blotch on white ground; Teresita, pale pink, suffused rose with violet blotches; Tour du Monde, dark cherry, shaded violet, with white blotches; Vicar of Westwell (Burrell), cerise, lightly feathered and suffused crimson. But I think the chief interest in the stand was centred in the four seedlings exhibited by him. There was a novelty of colouring and grandeur of spike which fairly earned for them the rewards of merit which they obtained. As in most of Mr. Burrell's seedlings, the flowers were well formed and produced close together on the spike. They were Bernice, a fine large spike with flowers of soft creamy shade tinted pink; Cassandra, a very fine flower, dull white or heavily shaded yellow and pink; Gertrude, a grand variety with delicate flowers, creamy white, tinted pale pink; and Orlande,

a fine variety with very large deep salmon-pink flowers.

With regard to the so-called hardy varieties of the Lemoinei and Nancianus types of which Mr. Burrell exhibited a good stand, I have seen no reason to alter the opinion I have already expressed, viz., that they are not a bit more hardy than the hybrids of *gandavensis*. Two years ago I lost my whole collection (through believing that they were hardy), with the exception of one variety, *Duguesclin*. Why this should have survived I know not, but I have had the same thing happen with those of the *gandavensis* section, and I find from his catalogue that Lemoine recommends a slight protection during winter; but this same protection would preserve the hybrids of *gandavensis* from frost. Still, they may be recommended, especially as there are some novel shades of colour amongst them. They do not, in my estimation, as yet rival those of the other section.

I regret to find that the amateur exhibitors do not increase in number. In the west of England, around Mr. Kelway's celebrated *Gladiolus* farm, I never see more than two stands. In the neighbourhood of the metropolis I know of but one, and consequently in this early season, when the R.H.S. offered prizes for them on September 26, I was not surprised to find that the only exhibit came from Northumberland. It is a pity, but I fear that we shall never see them much grown as an exhibition flower. I have given my reasons for this, and shall only be too glad to find that I am mistaken.

DELTA.

LATE SUMMER IN THE PINES.

DESPITE the unusual dry summer in the Pines, I see little, if any, appreciable difference in the abundance and beauty of the flowers. While our cultivated plants droop and suffer, the wild ones show no lack of life or lustre, and the varied hues of leaf and blossom seem as clear and fresh as ever. The *Gentian* family is now well represented among the plants in flower. The lovely fringed *Gentian*, the Closed *Gentian* (*Gentiana Andrewsii*), and the Soapwort *Gentian* (*G. saponaria*) are flowering on every side, and here, too, is the more exclusive *G. angustifolia*, with its narrow leaves thickly set along the stem and an open corolla of a deep rich blue. Always excepting the fringed *Gentian*, this is our most handsome species. The *Sabbatias*, too, are still beautiful among the Sedges and Grasses in the wet Pines. Both *S. stellaris* and *S. gracilis* are delicate and slender, and while they have a unique charm here on account of their appropriate setting amid their wild surroundings, one who studies them here can get many a hint for their effective use in decorating house grounds. The white-flowered *S. lancolata* is also here, but with its flat-topped cyme it is stiff and unattractive compared with its more graceful relatives. The *Mist Flower* (*Eupatorium (Conoclinium) celestinum*) has also a flat-topped inflorescence, but no one would charge its *Ageratum* like flowers with being stiff. Our tall Swamp Lily, which well deserves its name *superbum*, is now at its best, and its showy flowers tower above their humble companions in a grand pyramid of orange and scarlet. It is certainly one of the stateliest of Lilies. The *Rose Mallow* (the large-flowering *Hibiscus moscheutos*) also makes an impressive display of its great pink and white blossoms, which are larger and quite as showy as the cultivated *Hollyhock*, and many of them opening high above our heads. But the plant is rather coarse, or at least less graceful and delicate than the lower plants and Grasses around and below it; still, it attracts the attention of the most careless observer, and it is an important feature in many of our swamps and woodland landscapes. Both species of *Trichostema*, or *Blue-curly*, are here, with blue flowers and long exerted slender stems prettily curled, from which peculiarity is derived the botanical as well

as the common name of these plants. The foliage has a pleasant odour, like most of the other plants of the *Mint* family. Several of its relatives are now in flower. Among them is the strong-scented *Horse Mint* (*Monarda punctata*), gay with the highly coloured bracts about its heads of flowers. The brilliant scarlet of the *Cardinal Flower* glowing in the distance always indicates that we are approaching a pond, for it is by water margins that these plants flourish in the greatest abundance and brightness. None of our wild flowers are more vivid, and they never appear to better advantage than when they stand with an expanse of water dotted with white *Pond Lilies* on one side, and on the other a border of Sedges and Grasses and the delicate plants which they shelter. A slender little relative of the *Cardinal* is *Lobelia spicata*, with small blue flowers and weak slender stems upheld by the Grasses. Another is *L. puberula*, with a stouter stem and a spike of large handsome blue flowers. And here, too, is the marsh *Bellflower* (*Campanula aparinoides*), with dainty white bells scattered over the weak straggling plant, and holding on to the tall Grasses with the rough edges of its stems. Along the border of the pond is *Coreopsis rosea*, with rose-coloured rays and yellow disc. Some of the flowers are almost as handsome as the rose-coloured *Sabbatias*. In the shallow water several forms of *Sagittaria* mingle with the *Pickerel* weed. The pure white blossoms of the one and the blue of the other always group with good effect. The curious *Eel Grass* (*Vallisneria spiralis*) is now in flower. The water is so clear, that we can see the staminate buds at the base of the long grass-like leaves 2 feet or 3 feet below the surface. Slightly agitating the plants we see the buds break from the short flower-scape and quickly come to the surface, where they soon expand to shed their pollen on the pistillate flowers, which are now raised to the surface on long spirally coiled stems to meet the loosened staminate flowers which are floating around them. After fertilisation the thread-like stems become more closely coiled, so that the seed may ripen under water. Still more curious is the *Bladder-wort* or *Utricularia*, of which there are several species here in the pond. Thickly scattered over the submerged stems are little bladders or utricles. We can see with the unaided eye untold numbers of small mosquito larvæ, and also of the *Chironomus* caught in these utricles, never to be released, but to be slowly macerated and apparently absorbed by the plant. But we need the microscope to reveal the wonderful mechanism and structure of the utricles and to see how the various victims are caught and held.—MARY TREAT, Vineland, N.J., in *Garden and Forest*.

Plumbago Larpentæ.—This plant flowers freely here in the open border with no special shelter or extra sunlight; indeed, the position is somewhat shady. The border, however, in which it grows is light and sandy, into which peat has been freely worked, and it is badly infested with the roots of the *Portugal Laurels* to which it forms a fringe. The soil is shallow and dry, so the plants get ripened quickly. The foliage is now turning to a brilliant red, and as the group is fairly large, it forms a warm patch of colour.—J. C. TALLACK, *Livermere Park, Bury St. Edmunds*.

Zinnias.—*Zinnias* have been exceptionally fine this year, and again have proved themselves to be among the very best of annuals for a dry season. Though the plants showed signs of distress at times, they got bravely through, and have been, and are still finely in flower. The range of colour is varied, and if a collection of seed in assorted colours is procured, the seedlings will come nearly true, and can be used with great effect in masses of each shade. The so-called white, however, should not be used too freely, as it is a dirty white at the best, and some flowers are very badly stained. I find *Zinnias* most useful for planting between dwarf Hybrid *Perpetual Roses*, especially of those kinds which do not flower freely in autumn, as the *Zinnias* enjoy the rich soil and branch out freely, fill-

ing beds that would without them look bare and unsightly in autumn, with masses of colour, and doing the *Roses* no harm except when planted too thickly. *Zinnias* are often spoiled in their early stages by being sown too early, when they have either to be planted out too soon, and probably become crippled by frost, or stand in the seed boxes till they become weak and drawn. I find that sowing in the middle of April is quite soon enough for giving a good display of flowers during the autumn.—J. C. T.

HERBACEOUS LOBELIAS.

THESE are certainly amongst the brightest ornaments of the autumn garden. Their requirements are not many or rigid. Here in a deep and fairly damp granitic, very gritty soil they succeed, but I have seen them grow even better in a stiff lime soil. They do splendidly in peat, and will grow in wet land. I generally cover them up during winter with a few inches of dead leaves.

L. CARDINALIS.—This is the true plant, and is very distinct, having narrow light green leaves and a tapering scape, often 4 feet in height, of light scarlet flowers, with very narrow divisions. It is a common practice with writers to call every scarlet *Lobelia* "*cardinalis*."

L. FULGENS also has green leaves, but deeper green than the above, which are slightly hairy, and tall spikes, 4 feet to 5 feet high, of bright scarlet flowers. It is a good plant, and has given rise to the following very much improved varieties:—

L. F. FIREFLY.—This brilliant broad-petalled kind has been often referred to in THE GARDEN, and always in flattering terms. No amount of flattery could, however, overpraise it.

L. F. HUNTSMAN.—In this the brilliant scarlet of the last is deepened and intensified in a manner difficult to describe.

L. F. VERMILION, perhaps the nearest approach to vermilion to be found in any flower, is a tall growing robust kind. The individual flowers are borne on rather weak peduncles, with the result that they are held in various positions, and in this the plant is distinct.

L. IGNEA QUEEN VICTORIA has dark coloured leaves. It is a good plant with bright scarlet flowers, never, however, growing so tall as the varieties of *fulgens*.

L. I. MAGENTA QUEEN is a most taking kind, the colour of the flowers true magenta. It captivates everyone.

L. SYPHILITICA is a very hardy kind with green leaves, somewhat rough, and scapes of blue flowers. It usually grows about 3 feet high, and is good enough for a wet ditch, but scarcely so for the choice border.

L. S. ALBA COMPACTA grows about 2 feet high, many-branched, forming quite a sheaf of white, very pure in colour. It is a good thing.

L. S. CHALLENGER grows about 3 feet high, with purplish flowers; a free growing kind.

L. S. MILLERI is rich purple, and usually produces a number of scapes from a crown; good in colour, free in growth. One of the best.

L. S. MIRABILIS is from 3 feet to 4 feet high, with distinct red flowers.

L. S. ROSEA, one of the most charming of all, has bright clear rose-coloured flowers. It grows 3 feet in height.

L. KERNERI is a new introduction with light green leaves, and spikes 2 feet high, of very narrow-petalled, intense crimson flowers.

L. TUPA is here a fine plant, growing luxuriantly. The leaves are broad and handsome, the flowers crimson, and produced in a somewhat conical head.

L. SESSILIFOLIA is from 2 feet to 3 feet high, leaves green, flowers blue, and crowded amongst the leaves at top.

The following two species have only recently been re-introduced. They are not autumn flowering kinds, but are desirable garden plants. Several other species are being grown, about

which something will be heard by and by, as well as probably of sundry hybrids.

L. KALMI is quite a gem. It forms a low tuft of crowded leaves, nearly purple in colour, out of which the slender 9-inch spikes of clear blue flowers spring. They are usually produced in June and July. For the select hog this is an indispensable plant.

L. SPICATA has nearly orbicular bright green leaves which form a close rosette on the ground. The spikes are about 18 inches high. The flowers are pale blue and produced in June. T. SMITH.

Nerby.

CARNATION GLOIRE DE NANCY AND CLOVE CARNATIONS.

I WAS surprised to read some weeks ago (p. 188) a note by "A. D." asserting that the fine white Carnation Gloire de Nancy is a sport from the old crimson Clove. Will he very kindly state what historical proof there is of this origin? In asking for this I do not by any means wish to cast doubt upon the truth of his statement, which may be quite correct for all that I know, but am simply desirous of information. In habit of growth and time of flowering Gloire de Nancy shows features of difference from the old Clove, but a sport may, of course, often diverge from the parent plant in some of its characters. Beyond this, however, I should like to know whether there are any well-established instances of white sports from red Carnations, or, indeed, of any Carnation sports in the proper sense of the expression, except the well-known phenomenon of "run" flowers.

To my mind, Gloire de Nancy is altogether unrivalled among white Carnations. In my own garden the great drought of the past summer suited it admirably, while other sorts were literally burnt up, and the plants, never watered and almost entirely undisturbed, were sheaves of immense pure white blossoms, absolutely perfect, without a single split calyx. The flower is so redundantly full of its great satiny petals, crumpled like Rose leaves, and foaming up to a crested centre, that in some years it too readily bursts; but in this summer of wonderful sunshine not a pod was marred; and as for fragrance, my garden was brimming with its perfume for weeks. Surely a scentless Carnation is scarcely worthy of the name, just as a scentless Rose is unfit to bear the name of Rose. In this respect the old Clove and its white companion Gloire de Nancy are peerless. No variety known to me approaches them in sweetness with one exception, a dwarf crimson Clove, probably a very ancient plant, which some years ago I chanced upon in a Worcestershire cottage garden, and which now bears my name. Here it is excellent in habit, forming dense, free-flowering tufts almost like the white Pink, but it does not everywhere succeed so well. It is most powerfully scented, and I hoped to perpetuate its perfume in some seedlings which I raised from it. The best of these was a very brilliant vermilion-scarlet, ultimately sent out by Messrs. Dickson, of Chester, but neither this nor any of the seedlings were fragrant. I mention this in order to induce other contributors to THE GARDEN to touch upon the important question of the possibility of securing the Clove scent in Carnation seedlings. Its absence is a most disappointing character in the yellows and scarlets, the former being altogether scentless, and the latter nearly so. Some pink Carnations smell sweet, but many of the finest exhibited and even prize-winning roses, whites and dark crimsons too (in which one always expects the Clove perfume) altogether lack fragrance. It

is possible that this appears only fitfully and without rule or law. In the Jubilee summer many Carnations ripened seed in my garden, the old Clove among others, and from it I raised a batch of rather remarkable plants, large of leaf and with flowers as large as Malmaisons, of several shades of crimson, some almost black. Not one of them, however, was fully double, and as the scent was almost entirely wanting I destroyed them.

It would be interesting to learn from some of our foremost raisers whether anyone has made a systematic attempt to secure this most valuable element of rich Clove fragrance in their seedling Carnations, and with what amount of success or failure. And I should like to have some scientific explanation—if there be any—of the curious fact that this sweetness is associated most strongly with dark crimson and white Carnations (though even in these it is often entirely absent), less strongly with pink and rose colour, seldom with scarlet, and never with yellow. G. H. ENGLEHEART.

AUTUMN CROCUSES.

THERE are a number of lovely species of Crocus that are rarely seen in gardens. Though they are seldom thought of except as spring flowers, their season of bloom embraces quite six months of the year. One or two species and the varieties that have sprang from them alone are popular, and these are the spring-flowering kinds. There are others equally as pretty, as easy to grow, and as profuse in bloom flowering in the autumn when the season is drawing to a close, and, therefore, attracting notice through the lovely effect they make. A few kinds flower during mid-winter, but these are of little use except in the most favoured localities. The autumn kinds, however, which bloom in September and October, merit much more attention than is at present given them. Recently when in Mr. Barr's nursery at Long Ditton we saw nothing so refined and beautiful in colour as beds and little groups of the autumn Crocuses. To see them coming day after day in freshness and plenty is a revelation of beauty that many should see and enjoy in their own gardens. The kinds are not scarce nor very expensive, and yet there is very little demand for them. One of the very best is *C. speciosus*. It has flowers of a deep purple-blue shade, veined with a darker hue, and in quantity it makes a great display of rich colour. *C. pulchellus* is a charming kind of a pale lavender-blue colour with soft yellow throat and white anthers. *C. zonatus* is another most distinct kind with flowers of a lilac or mauve tint. *C. asturicus* has flowers of a more purple tint, and *C. medius* is especially attractive. It is of a purplish blue colour with darker veinings, and the branched stigma, almost scarlet, is very brilliant. *C. adriaticus* with white flowers is worthy of mention. The old *Crocus nudiflorus* must not be omitted, although it is fairly well known and abundantly naturalised in some parts of England. In varied delicate shades of blue the autumn Crocuses surpass those that come in spring, and their effect is very cheerful when the ground is strewn with fallen leaves and winter is approaching. A. H.

Petunias and white Snapdragon.—The value of Petunias in a dry season and their strong liking for a chalky soil is well shown in the Connaught Park at Dover. As lately as September 24 I saw a remarkably fine display of these flowers bordering one of the lawns there. It consisted of a broad band about a yard in width, and I should say at least 100 yards in length, completely covered with flowers, and, as may be imagined, the effect was gay in the extreme. They were planted along the top of a bank or Grass wall, which brought the flowers up near the level of the eye, and this dry position they seemed to thoroughly enjoy. They

were mostly of the mixed single strain and in great variety of colour. In a very long band such as this the mixing of colours and shades did not look out of place; certainly nothing else in the garden was so strikingly effective. Amongst other things I noticed here was a large number of plants of a pure white Snapdragon. It looked larger and more robust than any other white variety I have ever seen, and the plants must have been effective when in full bloom, for though the flowers were nearly over, there was plenty of evidence of a good display earlier in the year.—J. C. TALLACK.

Gunnera manicata.—I can quite bear out Mr. Sangwin's remarks that the illustration of *Gunnera manicata* on p. 297 in the last issue of THE GARDEN gives but a very faint idea of the gigantic proportions of the plant growing at Trelissick (Cornwall). It was my good fortune to see this same plant about two weeks ago and to witness the actual measurement. The plant spreads over 30 feet, and the largest leaf measured 9 feet 3 inches across. The pink crowns, looking like huge buds, are about 18 inches long and 12 inches in diameter. It is when one sits down beneath the shade of the huge leaves that the enormous size of the plant is fully realised. The plant at Trelissick has its roots immersed in a deep sheet of water going by the name of the "Lily pond" on account of the large number of Arum Lilies luxuriating there without protection, and furnishing an abundance of flowers from March to May. Mr. Sangwin tells me that although last winter there have been 17° and 18° of frost at Trelissick and the ice on the very same pond was strong enough for skating, he was able in April, nevertheless, to cut over 1000 blooms of Arum Lilies within three days. I believe this *Gunnera* to be the largest in the British Isles, though there is one at St. Austell (Cornwall) which runs it very close. The latter plant is in the gardens of Mr. Lakes, Trevarrick; it has leaves measuring about 8 feet across, and grows near a stream of running water.—F. W. MEYER, Exeter.

GENTIANA VERNA.

ANYONE who has not succeeded in growing this plant to his satisfaction may find the following account of a method, which has been most successful with me, of some interest, especially as my garden is within a mile and a half of a large manufacturing town. This makes it by no means the best place for such pure air lovers as alpine plants. The plants were put in last October on a flat border devoted to alpine plants and bulbous Irises. They are fully exposed to the sun from 8 a.m. to 6 p.m. in summer. The soil, a strong loam well drained, was prepared for them by burying pieces of limestone and sandstone at a depth of 10 inches to a foot to form cool, damp runs for the roots. Above these the soil was mixed with smaller pieces of limestone, and finished off with a mixture of limestone grit and soil, about two parts of stone to one of soil. The limestone grit consisted of the washings carried by the rain off limestone walks into the water gulleys. All this was done with the object of making the surface soil as dry and poor as possible to force the plants to root deeply into the soil that would always be cool and moist. My soil is on clay. On a gravelly subsoil it might be necessary to prepare a deeper stony bed, and perhaps deepen the soil below. In this gritty soil the plants were placed and surrounded by small pieces of limestone and limestone grit, with a few tufts of Sphagnum Moss to hold the dew and create a moist atmosphere, but this proved unnecessary. During the hottest weather the Moss never got damp, being under the top layer of stones. No protection was afforded them during the winter, but they did not suffer from damp owing to the

surfacing of small stones, and during the summer they flowered well, did not require watering, and now are in perfect health without a yellow leaf to be seen anywhere, and have increased considerably in size. H. L.

Stockport.

LILIES AT HEATHERBANK

My annual note on our Lilies might have been sent sooner, as the unusual heat and drought made them bloom early, and with most species made the flowers short-lived. The first Lily which showed its appreciation of the fine weather was *L. Humboldtii*. In most seasons when the weather is cold and rough this is apt to have spots both on flowers and leaves. This year there was no trace of these and all the varieties were very fine. The effect of the weather on *L. auratum* depended on situation. Where the subsoil was damp both growth and flowers were first-rate. In one bed in our wood at Oakwood, about 60 yards long, with different widths, there were about 2000 plants of all heights, the tallest ranging from 7 feet to 9 feet high; a large number of these were cut at the same time, and the effect was finer than we have ever had before. Happily, Mrs. Duffield was staying at the cottage and painted a large group of them so as to preserve an admirable remembrance. In drier situations it was a very different story. In our small hill field of Lilies, which in wet seasons gives the finest show, both growth and flowers were stunted, and what proved that it was the drought that caused this was that, having moved some fruit trees from this field, we had filled up the vacant spaces with *L. auratum* bulbs taken from the wood bed, so that exactly similar bulbs were in one place very fine, and in the other very poor. In another part in the wood where Rhododendrons and Oak trees had exhausted the moisture there was such little growth, that I took up some bulbs to examine them. They were sound and healthy, and I expect that they will tell a different tale next year (perhaps I should say that we have no artificial watering). *L. Krameri* and *L. auratum rubro-vittatum* in some places were good, but in most were much below par. The Lilies which rejoiced most in the hot weather and early season were *L. speciosum* vars. These, with the exception of some which had been moved into newly-prepared ground, and so more susceptible to drought, were in all sorts of situations finer than we have ever had them before; no rough cold weather injured the late blooms, which is often the case in later seasons. *L. pardalinum* and *L. superbum*, being always planted in more or less damp places, were as usual, but the flowers were short-lived. Most of the other Lilies were the worse for the drought. G. F. WILSON.

Michaelmas Daisies.—In the south these lovely flowers are not more forward than they usually are at this date, and Michaelmas Daisies are not touched by recent heavy rains. As soon as the water leaves them they open again as fresh and fine as ever. It did really seem once as though, like all other flowers this year, they would come out of season when such kinds as *elegans* and the purple New England variety were flowering in July, but even of these the great display is in its proper season. Now that we have got as far as calling seedling forms by popular names, it is sincerely to be hoped that the thing will not be overdone. The old way of trying to classify all under some specific type was very unsatisfactory and resulted in confusion. Since the conference, however, there has been a more general agreement as to the names, and if one only goes to good sources for stock, the best kinds can be obtained true to name. In the near future, however, I fear we are likely to get confused with a long list of popular names given to varieties of certain types that increase freely from seed. I would make special allusion to *A. Novi-Belgii*, of which the varieties are more numerous than of any other. Of these there can be little or no doubt as to the value and

distinctness of such a kind as Robert Parker and the newer, at least more recently known, *Arcturus*, or the white one named *Purity*. To these, however, I could add about a dozen other names, all belonging to kinds of the *Novi-Belgii* type, and if this is the beginning, where are we to end? I have no doubt in garden-raised seedlings among thousands there will be very few meriting special attention. If it means the trial of thousands and long waiting for new things, provided they are of undoubted distinctness, we shall prize them all the more when they come. There is no doubt that Michaelmas Daisies will reproduce themselves readily, inferior forms predominating. I have noticed them lately springing up freely in places situated at some distance from the garden, seed having no doubt been carried there by the wind or in some other way.—A. H.

Lantana Drap d'Or.—This is a dwarf *Lantana* which, when not more than 6 inches high, will flower freely. Of late years a dwarfer class of *Lantanas* has come into cultivation, and very useful they are for the greenhouse during the summer and autumn months. For this purpose some good showy kinds have been long employed in No. 4 greenhouse at Kew. They are all of very easy culture, but where required to flower for a lengthened period, the best results are obtained by growing the plants on in two or three batches, as good free specimens are more effective than partially exhausted ones. A batch of plants just commencing to flower about the middle of August will, under favourable conditions, keep up a display till winter. Cuttings formed of the young growing shoots of these *Lantanas* strike root readily.—H. P.

FLOWER GARDEN NOTES.

THERE has been a great demand ever since the middle of August for cuttings of *Pelargoniums*, and now all old stuff that in past years has been consigned to the rubbish heap readily finds a customer, partly due, no doubt, to the little growth made and the consequent difficulty in obtaining cuttings, and also from the fact that the best of the *Pelargoniums* have been much appreciated in a season when their great rivals in summer bedding arrangements, viz., tuberous *Begonias*, have made a somewhat indifferent display. There is not the slightest doubt that where a glowing mass of colour is required, *Pelargoniums* are bad to beat; indeed, there is nothing likely to touch them until we get a race of perfectly erect, very free-flowering *Begonias*, and, given judgment in planting, they are likely to hold their own for some time, not to monopolise the whole of the flower garden, but just enough of them to give some fine bits of colour. Whether for large or small beds, I like to use only the one colour, relieving it with a few taller plants; thus, for King of Bedders, Jacoby and Beckwith's Pink—three good things in their respective colours—there is nothing better than a few plants of *Francoa ramosa*, or, better still, from an endurance standpoint (if seed-pods are promptly removed), the white form of *Campanula pyramidalis*. If two varieties of *Pelargoniums* are used in the same bed, one may act as dot plants to the other in a similar way that the Chimney *Campanula* or the Bridal Wreath are employed with the shades of scarlet and pink above mentioned. Loosely grown pyramids of *Beauty of Jersey* and *Jeanne d'Arc* (Ivy-leaved varieties), for instance, are seen to great advantage on a carpet of *Manglei* and *West Brighton Gem*. Mention of the latter reminds one that it is still about the best dwarf in its particular colour. Other good things are *Surprise*, *Little Trot*, *Robert Fish*, and *Golden Harry Hieover*. I do not know a dwarf zonal in the pink shades to correspond in height with the above-named varieties, and so use *Rubens*, pink Ivy leaf. About the best dot plants I know for the variegated section, such sorts, for instance, as *Blushing Bride* and *Flower of Spring*, are *Cannas Bihorelli* and *Warszewiczii*. I can recommend a couple of beds arranged in this way another year, they will be pronounced very satisfactory.

HERBACEOUS BORDERS.—A resting place for the clumps of *Aster bessarabicus* mentioned last week as on the point of removal has been found towards the front of a deep border filled in the background with standard *Roses* and large clumps of tall herbaceous plants. A charming combination in this background, by the way just at present well worth a note, is to be found in the close companionship of the old *Fuchsia coccinea* and *Robert Parker Starwort*. Some 6 feet in width from the edge of this border has been ribbon-bordered, and with a view to alter this arrangement I have decided to put bold clumps of the *Bessarabian Starwort* at intervals, the intervening spaces to be filled in in early spring with a good strain of white *East Lothian Stocks*. Three breaks in this planting some 12 feet long will be reserved for bold clumps of *Murillo Carnation*, and will, I think, help to make a brave show for another summer. Long borders that consist of a mixture of tender and herbaceous things, the latter greatly predominating, are now claiming attention. We have in two cases a good broad edging of *Crocus* and *Chamomile* planted together, so that the bulbs push up through the green foliage, and any gaps in the old herb are now made good before the *Crocuses* get on the move. A good many clumps of *Viola* in the purple and lilac shades to afford a pleasing contrast to the *Chamomile* flowers occupy positions immediately behind the edging, and these as they go out of flower will be overhauled, lifted, split up, and replanted where necessary. An old favourite that in one or two places backs up the *Violas*, the double Peach-leaved *Campanula*, has apparently suffered a good deal this summer; it must be lifted, cleaned, and replanted in a bit of good stuff. The mention of the relative positions of *Campanula* and *Viola* in this particular case reminds one that in all rearranging old or planting new herbaceous borders points worth studying are the nice contrasts that can be made. Thus *Campanula glomerata* may back up *Violas Ardwell Gem* and *Duchess of Fife*. *Zauschneria californica* is seen to advantage with clumps of *Pinks*, white *Snapdragons* or herbaceous *Phloxes* with *Veronica spicata*, white *Spiraea* with *Campanula carpatica*, and many such like effective contrasts that will be suggested to the planter. A very pleasing contrast just at present is presented by a mixture of flower and foliage, bold clumps of *R. Parker Starwort* among hardy *Azaleas*. This is an arrangement flanking a broad belt of deciduous shrubs, and is very effective viewed from either the top or bottom of the slope. All the tall non-rambling *Starworts* of a suitable colour whose season of flower is contemporary with the bright autumnal dress of the *Azaleas* are admirably adapted for planting in such positions; indeed, if one has the advantage of a slope, they can be worked in their respective heights so that a splendid bank of colour is obtained.

Claremont.

E. BURRELL.

Schizostylis coccinea.—This bulbous-rooted plant is useful for autumn blooming, although not so much grown as one might expect, as at times it is attacked with a disease which disfigures the leaves. In favoured localities it grows freely in the open ground, being nearly hardy, and in such positions largest stools can be easily lifted and protected in cold frames or potted up for the conservatory. At this date the plants are pushing up freely their *Gladiolus*-like spikes, these being valuable for their scarlet colour and the length of time they remain pleasing in a cool house. The *Schizostylis* is one of the best things for autumn decoration and grows rapidly. It must be divided yearly to get strong spikes. I never allow the roots to get too much dried when at rest. They are divided, and the strong growths sorted and repotted just before new growth commences. Small shoots soon make rapid progress if given ample room and rich soil, such as sandy loam, leaf-mould, and dried cow manure. When repotting, place from four to six pieces in a 6-inch pot and from six to nine smaller growths in a 4½-inch pot. The latter will bloom freely the following season.—G. W.

ORCHARD AND FRUIT GARDEN.

POT VINES AS TABLE PLANTS.

IN Mr. Barron's popular work on the Vine a chapter is principally devoted to a description of the method of preparing pot Vines for table decoration adopted by Mr. Sage when at Ashridge. I very well remember seeing a pot Vine exhibited at South Kensington exactly similar to the sample, an illustration of which accompanies these remarks, and in all probability it was the specimen from which it was

Pot Vine for the table.

taken. At the time I was greatly impressed by the great weight and general excellence of the crop, eight or more bunches of good size and well finished on a Vine established in an 8-inch or slightly smaller pot being an "eye-opener" indeed. I had previously thought it good work to produce six good bunches on a Vine trained round a hoop and rooting in a 10-inch pot, this being done within sixteen months of the date of putting in the eyes, but Mr. Sage's achievement quite put this in the shade. When, however, this grower's method of obtaining these satisfactory crops transpired there was less cause for wonderment. At the same time he deserved all the praise accorded him then and

since for the admirable condition in which the crops were produced and brought so far to exhibit. As a matter of fact, it is simply impossible to grow and fruit Vines so heavily as those shown by Mr. Sage in such small pots, and it would only be a waste of time and space to attempt it. What is wanted, to begin with, are either well placed young canes formed by older Vines, or, better still, young Vines planted in a forcing house or as supernumeraries in a newly-planted viney. These young canes being formed this season, say, and well ripened—they cannot well be too hard, great size not being particularly desirable—they will

be ready either for forcing or starting naturally next spring. Before the buds have bursted the canes should be passed through pots varying from 6 inches to 8 inches in diameter, so as to have about 6 feet beyond the pots, the latter to be securely supported well above the ground, in order that they may get the full benefit of the warmth of the house, and be then firmly filled with rich loamy compost. Training ought not long to be deferred, as the canes will break more evenly when coiled round a trellis, and delay also renders it a difficult matter to train without snapping off some of the buds or shoots as the case may be. A neat trellis may be formed with the aid of stout wire, four

lengths, each about 4 feet long, being needed, these to be twisted together to a length of 3 feet, and the remainder brought down to a horizontal position at equal distances apart. Next form a strong wire hoop 18 inches or rather more in diameter, set this on the four wires, give the ends of the latter a sharp curve with the pliers so as to clasp the hoop securely, and the trellis is ready for thrusting deeply into the pot. Take the rod straight up the wire stem and then train round the cross wires, finishing off with a circle 5 inches away from the hoop. If taken round the hoop, the laterals could not be laid in neatly later on. Thin out the worst placed buds in the twined part of the cane and remove those that form below the pot. The stem of trellis should be furnished with leaves and one or two bunches of Grapes, the laterals being treated accordingly; these to be fruited to be stopped one or two leaves beyond the bunch, and the rest at the first or second joint. More laterals ought to be reserved and duly stopped with the view to having two bunches midway between the hoop and stem, five being a good number to hang from the hoop. In a young state the laterals will not stand hard training, but it may safely be done when the flowering period is past. This training cannot well be carried out too neatly. Tie the reserved lower laterals close up to the stem, and all ends that protrude beyond the hoop should be closely trained to the latter; disbudding, stopping and thinning out of berries to be carried out in the usual manner, avoiding, however, the retention of too many leaves, a crowded appearance being undesirable. It ought, perhaps, to be pointed out that there is no necessity to nick the cane where enclosed in the pot, the roots being emitted readily enough without this, and, besides, bleeding to an injurious extent might take place if any wounds were made. All that is necessary is to keep the soil just moist, more water being given as the pots become filled with roots, liquid manure, not strong, being applied daily, or as often as the soil becomes somewhat dry, after the roots have well taken possession of the soil. This, coupled with liberal treatment below, serves to amply support a heavy crop of bunches, and the "finish" of these will be good if plenty of air is given during the ripening period. From the first the trellises will be rather top-heavy, and should be supported if need be by stakes thrust into the ground. When the Grapes are ripe and some time before they are wanted for table decoration or to take to a flower show, gradually cut through the cane close up to the drainage hole of the pot, and when finally detached there will be no flagging unless water is not given in sufficient quantities. Before they are moved, strong Oak or Elm stands, after the pattern shown in the wood-cut, should be got ready, and the pots, fitting tightly in these, will travel and stand quite firm. Mr. Barron suggests covering the tops of the pots with Selaginella, and this should be done. Either dibble in small pieces all over the surface of the soil when first placed in the pots, or else have pans of the Selaginella ready for turning out and placing on the pots when required. It only remains to be added that the Black Hamburg and Foster's Seedling are the varieties best adapted for this method of fruiting Vines, though I have helped to grow very showy crops of the common Sweetwater, Buckland Sweetwater and Alicante in comparatively small pots.

The one fault of Vines trained according to Mr. Sage's method is their heavy appearance. They look well enough on a side-board and also on the exhibition table, but do not correspond

with present ideas of table decoration, being both too high and too heavy.

In Mr. Barron's "Vines and Vine Culture" there is a brief allusion to another very pretty mode of obtaining small fruiting Vines in pots for dinner-table practised by Mr. Lewin, gardener at Drumpellier, Scotland. In this instance a strong pot Vine is set on a shelf and trained along horizontally. A certain number of joints, about six I should say, would be enough, being pegged down to 5-inch pots filled with soil. Roots are duly formed in these pots, and the shoots each bearing a bunch are trained upright. Eventually a number of miniature Vines, each with a bunch attached, can be detached from the parent, these being admirably adapted for table decoration. I can suggest an equally pretty and more interesting modification of this practice. In this case either young canes trained up a roof or laterals on old rods may be utilised. Instead of pots substitute neat glass jars, or such, say, as are sold by grocers with 1 lb. of jam inside. Suspend these either at a joint of young cane or close up to an old spur, fill with water and bung up the neck with fresh Moss, some of this surrounding the joint from which roots are to spring. The jars being kept full of water, the Moss will constantly be moist overhead by absorption, the effect of this being to start roots early and strongly. After the roots have reached the bottom of the jars, they soon form a beautiful network of fibres and absorb a surprisingly large quantity of water, twice a day being none too often to refill the bottles. The roots thrive surprisingly in clear water, but are very sensitive, a little liquid manure or even stagnant soft water quickly killing all the points. After repeated experiments I found it advisable when adopting this system to use nothing but clear soft water, and in the case of large bottles full of roots, upwards of two quarts of water have been drawn out on a clear, hot day. I am not prepared to assert that the Vines derive very much benefit from their supplies of water, bottle-feeding evidently not being to their taste; but when the laterals are cut away from the parent Vine, the roots in the bottle will keep the leaves fresh and the berries of the bunch plump. Supposing that the laterals were duly stopped one, or at the most two joints beyond the bunch, they would be somewhat heavy and cannot be very well staked upright. As it happens, a slanting position shows off the Grapes to the best advantage, but in any case stands would be needed for small jars or bottles. These small Vines are not suitable for the centre of a table, but look well either at the ends or down the sides not far from the central line.

W. IGGULDEN.

Growing Melons in gravel.—The kind of material in which cultivators generally grow this important summer crop varies, but usually loam and clay in suitable proportion is employed. Until this season, however, I have never heard of or seen recommended such an infertile material as gravel for Melon-growing, nor do I expect that many would be inclined to adopt it only in a case of strict necessity or for experimental purposes, of which the case under notice forms one. A few spare plants remaining after the usual complement had been put out and an unoccupied frame suggested this course, but as the store of soil considered essential for Melons was exhausted, attention was directed to a heap of gravel. Of this some few barrow-loads were placed in the frame, thoroughly moistened with tepid water, and then made quite firm with the back of a spade. Holes were formed with a trowel only sufficiently large for the reception of the ball of roots and soil, and this afterwards made quite firm with the same

material. In this the Melons grew with remarkable freedom, and set their fruits as easily as they would do under more favourable conditions. They also carried to maturity two and three fruits on each plant, weighing about 3 lbs. each, as perfect in colour, shape, and netting as could be wished. The same fruits were equal to others better favoured in winning praises for flavour at the table; indeed, they held their own at an important provincial exhibition. Watering is very systematically carried out by the grower under notice, and there is no stint of liquid stimulants after the fruits are set and swelling. There is, I am aware, nothing very remarkable in this example of Melon culture, especially when it is known that fine fruits and healthy plants may be grown in heavy clay without any admixture. I have practised this on many occasions, and have noted the same in other gardens, but it has never suggested itself to me that gravel might be put to such a use as that I have described in this note, and it would be interesting to know whether any of your numerous contributors have done so, and with what results.

—W. STRUGNELL.

Wasps and fruit.—There is something curious in the way that these troublesome insects attack fruit. I cannot imagine on what principle they make their selection. Take Grapes for instance. They will invade a vineyard and play havoc with its contents, and leave another close by untouched. A market grower here, who has two large houses, has suffered much loss, whilst in a private garden adjoining hardly a berry has been eaten, although the Grapes there were perfectly ripe some weeks ago. Why should the wasps attack one lot of fruit and not touch the other which was equally ripe and good and within a stone's throw? I have grown Black Hamburg Grapes a good many years, and although I live in the midst of fields bounded by old hedgerows where wasps' nests are sure to be more or less abundant, I have never lost any fruit worth speaking of. Some of my neighbours have at times been sorely troubled, but I should be within the mark in saying that during twenty years I have not lost £2 worth of fruit from wasps. This year I could count twenty nests within 200 yards of my dwelling, and until they were taken we daily killed hundreds of wasps in the house. They came in quantity into the Grape house, but although the berries were as sweet as sugar, they only attacked an occasional cracked berry until quite the end of September, and then they took to one bunch, and in the course of a few days ate every berry. All the wasps in the house came to that one bunch and left the rest untouched. A similar instance occurred to a friend; some three bunches were eaten up, and then the wasps abandoned the house. The same thing has happened with Pears and Plums this summer, one tree having all its fruit eaten, whilst its neighbour was not touched.—J. C. B.

Apple Hollandbury.—I used to grow this variety in Herefordshire, but my experience of it there was that, although a very large and showy Apple, it was not of good quality when cooked and did not keep well. Although to outward appearance sound, the fruits were really rotting. It is not worth growing.—Y. A. II.

Apple Frogmore Prolific.—This variety has been exhibited well this season, particularly at Earl's Court. It was staged in various collections. It is a constant bearer and a first-rate cooking kind. As a pyramid or standard it does well, the tree being hardy and the fruits large and handsome. It is not a keeping Apple, being somewhat soft and very juicy, but for early use it is first-rate and of good flavour. I saw some very fine trees (pyramids and bushes) bearing enormous crops in Messrs. Veitch's Langley Nursery a short time ago.—G. W.

A beautiful Crab Apple.—Looking over Mr. Bunyard's excellent fruit nurseries lately, we were astonished at the beauty of the Dartmouth Crab, which, in the early days of September, was like a lovely Plum. Like many Crabs, it seems to be a cross between some highly coloured Apple and the

Siberian Crab. Its value as a fruit, perhaps, in the face of the beautiful Apples that now come to us both from America and England, is not great, although it may be when ripe equal to the many worthless Apples which are grown in our gardens. It would be useful for preserving, and is certainly worth growing for the beauty of its flowers and fruit. Mr. Bunyard also sends us some of the Fairy Crab, which is a very pretty fruit and has a highly piquant flavour; indeed, it is large enough to rank as a pretty eating Apple. The Americans and Canadians have been busy of late years in raising Crabs, of which the Yellow Transparent is a very pretty form, and useful for making jelly.—Field.

WALL PEAR TREES.

Is it general experience that horizontally-trained Pear trees always bear more freely on the upper and younger branches, especially at their extremities, than they do elsewhere? The accepted theory in relation to horizontally-trained Pears is that by this method sap flow is equally distributed, each side branch deriving the same share of sap from the main stem. That may be correct, and so far as growth is concerned seems all right, but I do not think, so far as fruit production is concerned, that it proves to be correct in practice. I have not only this season, but frequently in previous years been struck with the abundance and fine appearance of the fruit found on the top and younger growths as compared with the meagre produce on other parts of the trees, and if results of this kind indicate that something is not quite right, it is but fair that growers should be set thinking as to what in a now old-fashioned method of training is wrong. Is it the case that the constant hard pinching and pruning which go on from year to year over all the lower and older branches presently result simply in the production of small and sterile fruit-buds, or is it the case that because of the vertical form of the main stem the sap flow is necessarily strongest towards the top branches, and that on these the spurs or buds are stouter, and hence more fertile? Of course on these for some years, because the branches are younger, the spurs are few; indeed the finest crops of Pears on these wall trees I have seen this year have been borne on two-year-old wood that has hardly been spurred at all. Before the introduction of the horizontal method of training, and that was some fifty years ago, Pears trained fan-shaped produced grand crops, although it happened even in their case that they became eventually somewhat stunted or over-spurred. Is it wiser to convey all the sap to the tree from the roots through one erect channel, the top branches, of course, getting the best supply, or is it better to divert it into several main channels at once, as is the case with fan-shaped trees? We see this principle operating with great success in the case of stone fruits, Peaches and Nectarines, for instance, trees that with comparative ease set crops equally all over their areas, whilst with horizontally-trained trees the case is almost always different. I have frequently observed how different is the treatment of this class of tree in diverse gardens. In one case all the summer shoots are pinched back in summer, and although the object is to promote the production of fruit buds, they seldom are strong enough to be fertile, the check to sap development in these side branches, by thus removing actual operating growth in the form of young shoots and leaves, largely prevents the production of stout bloom buds and the treatment fails. Then in other gardens these summer shoots are largely left growing all the season to bring about the very results referred to; not that all the growths are left, as the weaker ones are cut clean away early, but stout ones at frequent intervals are left, and these in the winter are cut hard back. But still, under this form of treatment success seldom ensues, because buds are not created, but simply a succession of other strong runner shoots. Now we will suppose that when old trees have got into this state and it is desired to renovate them, what would happen

were every other lateral branch sawn clean out, and from the one below at intervals of about 2 feet strong summer shoots were laid in, thus quite filling the wall space the removal of the branches had made vacant? Of course these one-season shoots would give no fruit the next year, but the second year might find them full of bloom-buds and probably of fine fruit. The strong young growths would exercise very potent force in attracting sap from the main stem, and we should then probably see crops all over the trees of that same very fine and abundant order I have seen in numerous cases this year. The present season has been a very marked one for Apples and Pears on standard trees, not that these large trees do not usually bear freely; indeed, I think as a rule far more so than do bush or pyramid trees. The cause, I take to be, is that heads of standard trees get an equable supply of sap from the main stems, and because the summer growth is free and unchecked, every branch on the heads gets fed alike. Bush Apples, where several main branches break out obliquely from the main stems, are invariably far more free fruiting than are espalier trees, especially when the latter are old; whilst old bush trees will fruit freely till the last. Espalier trees are all very well whilst moderately young, but they, so far as fruiting is concerned, soon wear out. The method of training, as with horizontal wall trees, is too unnatural. Of course, much that is said applies mostly to the older wall-trained trees, and especially to those which have their lateral branches crowded with spurs. Up to a certain age even horizontal-trained trees may be fertile, but the stage of comparative barrenness comes when the various side branches have filled their allotted spaces and have to be rigidly stopped. This defect comes to the lower branches early, and whilst the upper ones have ample room for expansion, it is but natural that the sap force of the tree should be carried to them, and is not again diverted to the older branches, as was the case when they were lengthening. The point raised seems to be well worthy of careful attention and criticism. A. D.

Plum McLaughlin's Gage.—Those who are adding to their stock of this fruit would do well to include the above variety. Ours is not a Plum soil, but this sort rarely fails to crop, and, what is better, is of first-rate quality, and being a small tree, is more noticeable, as some kinds do not crop freely when young. It may be described as a large and delicious Green Gage, a roundish fruit, flat at the ends, skin bright yellow flushed and mottled with red, and with a fine grey bloom, the flesh yellow, firm, and very rich. It is in use from August to September. The tree is hardy, vigorous, and most prolific, and one of the best of the Green Gage types. It does well in various positions. I have seen it very fine as a pot fruit this season, and it bears freely, making an excellent pyramid. As a wall fruit in cold exposed places it cannot be beaten, and in the last-named position it rarely fails to crop. This Plum is far better than many of the large coarser varieties grown merely for their size.—G. WYTHES.

Apple Annie Elizabeth.—I was glad to see "Y. A. II.'s" note (p. 319) on this variety. It is an old favourite with me. This season it is really fine, and is a valuable Apple for its good keeping qualities, as there is little trouble in keeping fruit late in the spring if carefully gathered and stored in a cool place. I have kept fruits of this variety good for eight months, and it does not shrivel like some kinds. It is an excellent kind for orchard culture. This season standard trees have borne fruits of large size and highly coloured. As a pyramid it makes a grand tree and bears fruits freely of large size in most seasons.—G. W.

Plum Grand Duke.—This is a valuable kind for its keeping qualities, as it gives a succession long after the early kinds. The fruit is of fair quality for cooking, also for exhibition. This season it is over much earlier than usual, having been gathered in September, but in past seasons the fruit lasted or hung well into October, thus

proving its lateness. It is a large oval fruit with a short neck, skin very dark purple, and covered with a beautiful blue bloom, the flesh being firm, of a yellow colour, and the flavour brisk. The tree is a good bearer, very hardy, and may be planted in a cold district, doing well as a standard. On a north wall I do not know of any more valuable Plum, as it bears abundantly, and as a wall fruit it possesses a rich flavour. For preserving it is much esteemed, and in places where Plums do not bear freely this in a suitable position will often give a good crop.—S. H. B.

FERNS.

NEPHROLEPIS.

MR. WATSON may be glad to hear of other species of *Nephrolepis* besides those mentioned by Mr. Gower on p. 333. The genus comprises some of the most useful of all stove Ferns, every one of the species in cultivation being exceedingly decorative and very easy to manage. There is a good collection of them at Kew, some of the specimens there being large, so that anyone who wishes to make the acquaintance of the rarer species can easily do so there. The names employed by Mr. Gower are not the same as those in use at Kew. Thus *N. biserrata* is here called *N. acuta*. There is a fine specimen of it hanging from the roof of No. 2 house; it has fronds 5 feet long, with pinnae 4 inches long, wavy, soft green, and is a noble Fern in every way. There are several varieties, one of the best being *rufescens*, which has fronds 3 feet long and 4 inches wide, the pinnae wavy, very closely set, not overlapping at the base on the under side, as in the type.

N. cordifolia is the accepted Kew name for the plant called *N. tuberosa* by Mr. Gower. It is one of the best known stove Ferns, and deservedly so, as it keeps green and healthy all the year round under the most ordinary treatment. It is a fine plant for covering back walls or furnishing a rockery in the stove. There are several good named varieties of it, viz., *pectinata*, with rather rigid fronds about 1½ feet long, an inch wide, pale green, and most prolific in fronds and runners. It is one of the most striking of the large basket Ferns in the Kew fernery (No. 2), the specimen being 4 feet through and a perfect ball of green. *Compacta* is another good variety, which has fronds 2½ feet long and 3 inches wide, the pinnae slightly serrated at the apex.

N. davallioides is the best in the genus for furnishing large houses. At Kew it is plentiful, some of the largest specimens being huge masses of fronds, each 6 feet long, the longest pinnae being fully 10 inches long. A peculiarity of this species is the serrated and narrowed form of the sori-bearing pinnae, the barren pinnae being an inch wide and entire. The variety *furcans* has fronds 3 feet long and 8 inches broad, the pinnae being forked half way up, and these are again forked, so that they are really bifurcate, a character not shown in the picture on p. 332. *N. undulata* is not considered distinct from *N. cordifolia*.

The species not mentioned by Mr. Gower are the following:—

N. DUFFL.—This is a very remarkable Fern introduced by Messrs. Veitch and Sons and Mr. Bull from Duke of York's Island in 1877, when it was awarded a first-class certificate. It forms a compact tuft of nearly erect fronds 1½ feet to 2 feet high, crowded with small roundish pinnae, arranged in pairs, and of a brownish green hue. This species is largely grown by Mr. May, of Edmonton, as it forms an attractive little specimen in a 4-inch

pot. Mr. Baker says it is an extreme form of *N. cordifolia*.

N. PLUMA was described by the late Mr. Moore in 1878 from plants introduced from Madagascar, and distributed by Messrs. Veitch and Sons the year following. Moore describes the fronds as 1 foot in length, but at Kew they do not exceed 2 feet, by 1 inches broad, slender, nearly erect, pale green, the pinnae narrow, and, as the name indicates, very elegant and plume-like. It is a pretty plant for pot culture. I have not seen it tried in baskets. According to Mr. Baker this also is a form of *N. cordifolia*.

N. RUFESCENS TRIPINNATIFIDA is a long and unwieldy name for an exceedingly noble and distinct Fern. It was sent to Kew from Fiji by Sir John Thurston, the Governor of Fiji, in 1884, and was distributed by Messrs. J. Veitch and Sons in 1887. It is one of the best Ferns introduced in the last ten years, requiring only to be understood to become generally grown. It has dissatisfied some cultivators, owing, I believe, to their having relied upon old stools instead of growing on young plants every year. It is impossible to describe a good specimen of this splendid Fern, the semi-erect fronds, 2 feet to 4 feet high, the stalks polished brown or clothed with reddish hairs, and the pinnae crowded, divided and interlacing in the most extraordinary manner. No collection of tropical Ferns should be without this plant. It likes plenty of water, plenty of root room, a rich soil and the hottest and moistest place in the stove.

N. BAUSEI is of supposed hybrid origin, and was raised by Mr. Bause, of Morland Nursery, South Norwood. It was distributed by Messrs. Veitch and Sons in 1885, and is now fairly well known. It has erect fronds a foot long and bipinnatifid pinnae, and is of dense habit. It obtained a first-class certificate in 1884. Mr. Baker says it is a variety of *N. acuta*.

N. RECURVATA was sent to Kew by Mr. May in 1892. It looks like a slender form of *N. cordifolia*, differing, however, in its thin, wavy, recurved pinnae and its soft green colour. Its fronds are 1½ ft. long, but as the Kew plant is in a cool house it is possible that the fronds get much longer when grown in a stove.

N. BARTERI is a well marked variety of *N. exaltata*, differing from all the forms of that species, however, in its short, rounded, almost leathery pinnae, which are of a glaucous green colour, and in the fronds not exceeding a foot in length. It was introduced to Kew many years ago from W. Tropical Africa by the collector Barter. Lately it has attracted the attention of Fern specialists, and I see it is offered by Mr. May in his catalogue for this year. W. W.

LARGE-GROWING ADIANTUMS.

I AM asked by "T. R." to name a few of the large-growing Maiden-hair Ferns which would succeed in the open rockwork of a fernery. As the majority of the *Adiantums* are natives of tropical climes, they are well suited for the position indicated, and have a pleasing aspect when well grown. These plants are widely distributed throughout the tropical and temperate countries of the world, and upwards of fifty species are in cultivation, all resembling each other, yet sufficiently distinct to plant side by side and form a good contrast. Many of the kinds are of slender growth, but these I have not treated upon here. Tall fine-growing kinds are asked for, but the smaller kinds are not omitted from their want of interest. I hardly know a single species or variety of *Adiantum* which does not deserve the attention of everyone. The tall-growing kinds when planted out require to be thoroughly well drained, and the soil should consist of about equal parts of nice fibry peat and turfy loam chopped up roughly and made fairly sandy, some pieces of sandstone being well mixed with it in order to keep the whole free and open. If the plants are required to make a quick growth the soil should have a larger admixture of peat. *Adiantums* require a liberal supply of water to their roots at all seasons, and the atmosphere should be kept well charged with moisture. Avoid

wetting the points. "T. R." is recommended to get the following kinds, some of them attaining large dimensions, and the positions which they are to fill must be regulated accordingly: *Adiantum cardiochlaena*, *A. cristatum* (does best in limestone), *A. cultratum*, *A. formosum*, *A. intermedium*, *A. Henslowianum*, *A. Kaulfussi*, *A. macrophyllum*, *A. microphyllum*, *A. palmatum*, *A. pentadactylon*, *A. peruvianum*, *A. prionophyllum*, *A. pulverulentum*, *A. tenerum*, *A. tetraphyllum*, *A. trapeziforme*, *A. venustum*, *A. villosum*, *A. velutinum*, *A. Wailesianum*.

W. HUGH GOWER.

Brainea insignis.—This Fern is so distinct and peculiar, that any information with regard to its behaviour under cultivation is of interest. Mr. Gower asks (p. 334) for the experience of those who have raised this plant from spores. It has been done at Kew several times, and I know it was done by Messrs. B. S. Williams about ten years ago. There is nothing special to record with regard to the sporelings beyond the fact that whilst the spores vegetated freely only very few plants developed from them. There are some good specimens of *Brainea* at Kew, where two of them I know have been in cultivation twelve years. They have stems 2 feet high and good heads of fronds. A beautiful character of the fronds is their rich coppery-red colour when young. The longest fronds on the Kew plants measure 3 feet. A position not far from the glass in a moist stove suits the plants, and they appear to like water all the year round. This is quite different from what this Fern gets in a wild state in South China and Hong-Kong, as is shown by the following information sent to Kew some years ago by Mr. Ford, of the Hong-Kong Botanic Gardens. He says the *Brainea* grows invariably in full sunshine among stones on hillsides where the sun is felt in all its fierce intensity. From May to October it gets frequent and heavy rains, and scarcely any for the rest of the year, when the ground becomes very dry and the atmosphere drier than it ever gets in England. Now I know from experience that anything like an imitation of these natural conditions is fatal to *Brainea* in this country.—W. W.

ORCHIDS.

CELOGYNE CRISTATA.

THE time of year is fast approaching when we shall see dazzling white and yellow flowers of this gem amongst the winter-flowering Orchids. I am asked by Mr. A. Cargill how to grow this. He says, "I have some nice little pieces of *C. cristata* just finished growing. Will you kindly tell me through THE GARDEN the treatment to make them bloom?" When strong enough there is no difficulty in getting them to flower either in 5-inch pots or as large specimens. I do not know a more easily cultivated plant in the whole Orchid family than this, and the pure white flowers are suitable for any purpose, either on the plant or when cut, as they mix well with other flowers. It is just over fifty years ago since this *Ceogyne* was first seen in flower in this country from plants sent home some few years previous by Mr. Gibson, then engaged in collecting Orchids for the Duke of Devonshire at Chatsworth. Since then it has frequently been introduced. I introduced a large quantity, and amongst them were some of the varieties which have since obtained special names. None are shy flowering. It seldom flowers the first year after being parted, and sparingly in the second year. The species appears to be common in Northern India, but we do not know from whence the pure white form called *hololeuca* or *alba* was introduced, and which was first flowered by Mr. Richards when gardener to Mr. Titley, of Leeds, and which will prove very

acceptable where pure white flowers are required. The yellow blotch of the typical plant is objectionable. A few years ago this variety was very expensive, but it is less so now. These plants I have found for some years to thrive well in the warm end of the Odontoglossum house, the pseudo-bulbs come stronger and the whole plant is of a richer green in such a situation than when grown in the East Indian house. I do not object to see the thermometer running up pretty well in the daytime, and during the growing season the atmosphere should be moist. They like also a good supply of water to their roots; therefore ample drainage is necessary to carry off undue moisture, not allowing anything to remain about them in a sour or stagnant condition. When the bulbs are made up, as my friend "A. C." says his are, the quantity of water given the plants when growing should be considerably decreased and the atmosphere kept drier. I like to remove the plants to a situation some few degrees warmer, still keeping them supplied with sufficient water to prevent them suffering, when if the bulbs are strong enough the flower-spikes will begin to show. After the flowers fade the growth for the following season soon spreads out. I like to grow *Ceogyne*s in large, broad shallow Orchid pots or pans, taking care to raise the peat fibre and Sphagnum Moss well mixed into a fair-sized mound, so as to enable the thick scaly rhizomes to extend. The flowering bulbs then swell up to a good size. Some prefer hanging baskets, but I am under the impression that well-drained pans suit them best. To get a good succession of bloom, anyone having a number of plants should remove some of these as soon as the spike begins to show up from the base of the pseudo-bulbs to a warmer house, and give them a larger amount of water. This will forward them considerably. The following are the principal kinds:—

C. CRISTATA.—This, the typical plant, has flowers some 4 inches across, the petals broader than the sepals, wavy at the edges, of the purest white; lip also white, having a large blotch of orange-yellow on the disc.

C. C. LEMONIANA.—This flowers usually later than the typical form. It has the sepals and petals slightly broader, and the lip is stained with paler lemon instead of orange.

C. C. MAXIMA is a superior form of the type, introduced by Mr. Sander, of St. Albans. All the segments are broader, and it produces more flowers on the raceme. It is a fine variety, and it was figured in THE GARDEN some six years ago (Vol. XXXI., t. 585).

C. C. HOLOLEUCA—This, the pure white-flowered form, flowered first with Mr. Titley, of Leeds, but from what part of India it had been introduced appears unknown. It is still a rare plant and valuable as a pure white variety.

C. C. TRENTHAM VARIETY is a grand flower of good form and substance. It is late in flowering, and I have seen this come into flower after all the others had past. WM. HUGH GOWER.

Cypripedium albanense (*T. Burns*).—This is the name of the flower you send, saying it is the result of crossing *C. Sedeni* with *C. Schlimi*, only I should think the cross is reversed—*C. Schlimi* and *C. Sedeni*. It seems a somewhat poor flower of *C. Sedeni* and not worth recommending. We want bright colours in these Slipper Orchids, which we are now in a fair way of getting.—W. H. G.

Cypripedium Hornianum.—Flowers of two seedling forms of this variety come to me from Mr. Macdonald, who says that they are from plants obtained by crossing *C. Spicerianum* with *C. superbiens*, the latter being the seed parent. The foliage is pale green tessellated with fine lines of dark green; flowers large, the dorsal sepal white, hav-

ing a central stripe of chocolate, green at the base, the sides flushed with purple; lower sepal small, suffused with green; petals slightly deflexed, undulated at the margins, green shaded with purple, a median line of purple and several lines of black dots on either side; lip large, brownish purple tinged with green, inside wholly dark purple freckled with black dots. This hybrid was first raised by Mr. Horn, gardener to Baron Nathaniel de Rothschild, near Vienna a few years since, and to whom it was dedicated by Reichenbach, but the flowers now before me sent by Mr. Macdonald are much finer than those from the original plant.—W. H. G.

GARDEN FLORA.

PLATE 932.

CENTAUREA RUTHENICA.

(WITH A COLOURED PLATE.*)

SPEAKING of this grand old-fashioned flower only as a garden or decorative plant, much need not be said of its beauty and noble character when such a faithful coloured plate is given. This species is not old-fashioned in the sense of being an old denizen of our gardens, for it was only introduced in 1800, but rather that it belongs to an old and favourite type of flowers. Not that it has much to thank its genus for either, because many of its big sisters are coarse and ragged and have a most ungainly habit. I refer to these features of other *Centaureas* because I wish to strongly recommend this Russian species. It is well known that some genera that are mainly composed of coarse species often divert our notice from really good ones. I fear it has been so in the present case, though the plant in every way is vastly and distinctly superior to most, if not all, of the other *Centaureas*. With me the plant grows 4 feet to 5 feet high; the foliage is of a thick texture and dark, glossy green; the heads or flowers, as figured, are of the natural size, and nothing can be nobler and more beautiful than its big feathery flowers of pale yellow on the dark stalks, and contrasted with the almost Palm-like foliage. The plant is a reliable perennial and perfectly hardy, and is without the bad manners of most other *Centaureas* of running at the root. It will thrive under ordinary conditions, but it has a preference for deep, rich land, as I have proved, and as its long tap roots would indicate. Lovers of hardy plants may safely take a note of this for roomy and conspicuous positions. It is one of those garden subjects which we have been slow to appreciate, but it is a plant which sooner or later must meet with acceptance in all gardens of carefully selected things. J. WOOD.

Pilea muscosa as a bedding plant.—I was agreeably surprised to find that this is a very useful plant for bedding. I saw it used as a carpet plant quite recently at Bowden House, Chippenham, and with marked effect, the colour and character being so distinct. Spring-struck cuttings

* Drawn for THE GARDEN in Mr. Woodall's garden at St. Nicholas House, Scarborough, by Miss Edwards. Lithographed and printed by Guillaume Severeys.

SCITAREA PITHYLLA

were employed, and these being planted thickly and not topped made a dense and even mass of growth, quite unlike any other plant used in the extensive arrangement. It was as healthy and luxuriant in this case as it is often seen in the plant stove; indeed, I have often noted the plants looking much less vigorous when grown in pots than they were in the beds at Bowden House.—W. S.

THE WEEK'S WORK.

PLANT HOUSES.

PLANTS AND THE AUTUMN FROST.—In advising the completion of the housing of greenhouse plants in the last calendar no allusion was made to such things as can be stored away under stages in dry sheds, cellars, &c., where it is possible to just exclude the frost, the plants thus coming to no material harm. Fuchsias belong to this category, but it is hardly advisable to house them just yet, for in their case a few degrees of frost will help to clear away any insects, as well as hasten the fall of the leaves before storing. Provision should, however, be made for them, so that when it is found needful to bring them under cover it may be done straight away rather than have them standing under temporary shelter for a time. Old plants of Fuchsias if not of any further use in pots can be turned to a good account oftentimes in the flower garden, flowering far more freely than young ones will do under the same conditions. Lantanas can be housed with the Fuchsias whether they have been grown in pots or outside by keeping the roots well covered up. Brugmansias in large pots or tubs should not be exposed to more than a few degrees of frost; these will, however, stand a trifle more cold than those which have been planted out, owing to the growth of the latter being more hardened with less tendency to gross or sappy wood. It is regrettable that these fine old plants are not more often met with than they are. Exposure late in the autumn with after-neglect in the winter has ruined many without a doubt. Myrtles in pots must not be risked outside too long; a slight frost or two will not injure them it is true, but the roots must be thought of, which in the case of pot plants are more liable to injury from cold. All that has to be done in the more favoured southern localities is, of course, to protect the roots and the growth during sharp frost when they are planted out, but in the majority of cases by a long way this will not suffice; hence we do not see nearly enough of this fine old shrubby plant from which it is far better to just exclude the frost. Green Bays in tubs must not be risked too long outside. When these are not wintered where the frost can be excluded the tubs and the surface soil should be well protected so as to prevent the roots from being in the slightest way frozen.

Agapanthus umbellatus will resist some few degrees of frost without any injury, but it is never advisable to run the risk if it can be avoided. By the end of the month the stock should be brought under cover where not planted out. In the latter case a good protection should be afforded them, but then even there is danger to be apprehended in severe weather. The scented *Verbena*, or *Aloysia citriodora*, can be housed or protected in the same way as the Fuchsias; so long as the roots are not frozen no harm will come to them. Against walls in sunny situations this old-fashioned plant will survive several winters in succession with a fair amount of protection at the roots and of the main growths. A dry situation I have found to be favourable to it outside. *Eulalia japonica variegata* and *E. japonica zebrina* are hardy enough when planted out, but if in pots the plants must be protected for reasons already given. Bamboos, even, if they are grown in pots or tubs for decoration, must not be left so exposed as if they were planted out, otherwise the roots must inevitably suffer. Should it not be possible to protect these

plants under cover, plunge the pots over the rims in a sheltered spot.

BULBS.—Of these the Lilliums which are in pots must not escape notice. It is not at all necessary that they should occupy otherwise valuable room in greenhouses, but they can be kept under stages, standing upright rather than laying the pots on one side to prevent excessive drought. In frames they will be safe enough so long as the soil in the pots is not frozen; this may be easily prevented by a good surface covering on the pots, whilst by reason of the position no watering would be required for months together. *Tritonias* and *Montbretias* in pots should be stored away under stages rather than be left in cold frames even. *Hedychiums* in variety if in pots, also *Cannas*, should not be risked in too low a temperature, an ordinary greenhouse temperature being low enough.

Hardy exotic and other Ferns if in pots should at least be plunged over the rims, but a cold frame or pit would be better still. Other plants may occur to the readers of *THE GARDEN* which have not been enumerated. These should all be looked after according to their hardiness in time to prevent any possible injury thereto. Oftentimes the complaint is heard that the frost has destroyed plants or materially weakened them, when by a little forethought all loss might have been averted. A deal will depend upon the locality as to the amount of frost these and other semi-hardy plants will withstand, but in no instance is it advisable to run undue risks with all of the stock even if a few are experimented with.

Mats for protecting should be held in readiness for use, the earliest opportunity being taken to have the new ones tied. The drier these are kept the more effective will they be. Canvas covers are now greatly approved of for houses and large pits; they are in every way excellent for the purpose; these also should be looked to in case of emergency. J. HUDSON.

FRUIT HOUSES.

PINES—Where a considerable number of plants are fruited each year it usually happens that a few fail to start with the rest, but show fruit in the autumn. This season is no exception to the rule, but, on the contrary, there are more of the late starters than has been the case for some time past. They ought not to be neglected or lightly valued, as there is every possibility of the fruit ripening at a time when choice fruit is none too plentiful. Arrange the plants at the sunniest, hottest end of the house, and give them the benefit of a moist, brisk bottom-heat of say 90° or rather more, the house temperature being kept at 70° by night, increasing to 80° in the daytime. Those more forward, the fruit swelling fast, must also have plenty of bottom-heat, from 90° to 95° being none too much. Keep them uniformly moist at the roots, cease overhead syringings, syringing among the plants and into the collars occasionally and damping down the floors being still persevered with. Colouring will soon be taking place in the case of the bulk of late Cayennes, and the plants must then be kept rather on the dry side at the roots, or otherwise some of the fruit may decay at the heart. A drier atmosphere and rather more air are also beneficial, this greatly improving the flavour of the fruit. Ripe fruits keep best on the plants in a cool dry room or in ainery where late Grapes are hanging. The batch of Queens that are to be started early should be kept well plunged in a bed of fairly moist tanner's bark or leaves the temperature of which does not exceed 70°. If the plunging material is dry, owing to the heat being principally generated by hot-water pipes, then the pots must be gone over occasionally and watered before they become dust-dry, further perfect rest being promoted by keeping the top-heat at about 60° by night and not much higher in the daytime, air being given at 65°. Well-rooted suckers in 6-inch or larger pots must not be allowed to become very dry, or this may result in premature fruiting next spring. All ought to be examined at least once a week, and any

approaching dryness watered. Also give them good room, this being the time of year when many plants are greatly weakened and practically spoiled by overcrowding. A temperature from 60° to 65° by night is sufficient heat for these, the bottom-heat being at or about 80°. Canvas or thick cotton blinds run over the roofs of houses, and mats on pits on cold nights are great economisers of fire-heat and obviate the necessity for injurious hard firing.

LATE GRAPES.—These, thanks to the extra amount of sunshine registered this season, are more perfectly ripened than usual, and should keep well accordingly. In some instances there is a tendency to shrivelling, this somewhat spoiling the appearance of the bunches without, however, impairing the keeping or eating qualities of the berries. The last two or three weeks as well as the next few weeks have tried or will try the skill of those in charge, dull, warm showery weather being responsible for very many damaged bunches. Especially is this the case where the top air is admitted by means of running sashes, or, worse still, where the roof is in a bad state of repair. Drip where it comes into contact with bunches, soon ruins nearly all the berries, and if the bunches cannot very well be shifted out of the way of the falling water, then it ought to be warded off by means of strong paper arched over them. Faulty ventilation may also be quickly followed by many decaying berries. Now that the Grapes are thoroughly ripe, high temperatures, unless accompanied by abundance of air, are undesirable. A drop to 45° during the night with a little front and top air, the circulation being further aided by a very little heat in the hot-water pipes, answers well. Before the heat rises sufficiently in the morning to greatly exceed the temperature of the berries, and which are always naturally cold, this resulting in condensation of moisture on the latter, give air freely along the front as well as at the top of the house, always provided the latter does not admit rain to the topmost bunches. Neglect this early ventilation and the chances are all the berries will become dewed over, trickling soon following unless a better circulation of dry air is at once brought about. A few such narrow escapes greatly soften or weaken the skins of the berries and an early decay is certain. Keep a close look out for cracked or decaying berries, unhesitatingly cutting all out that are touched, however slightly, to the extent even of sacrificing half the berries to save the rest of the bunch. It is the freely-thinned, medium-sized to small bunches that keep best, and which should be principally reserved for bottling. All sub-laterals should be removed, and dead or dying leaves removed as fast as they fall, as these latter in the course of decay seem to keep the atmosphere moist and tainted. The borders ought not to be allowed to become very dry, and water should be given when needed, choosing the morning of a clear day for the work, and afterwards re-covering the soil with clean dry litter.

EARLY VINES.—Those to be started early enough to give ripe Grapes in April and May ought now to be pruned, the rods thoroughly scrubbed with hot soapy water, and the house generally also receive a good cleaning. When Grapes are wanted thus early they are really best obtained with the aid of pot Vines, or else strong young Vines well established in narrow borders in forcing houses. In each and every case they start all the more strongly for having a thorough rest after pruning has taken place, and in particular break more surely and evenly after being subjected to a moderately severe frost. Instead, therefore, of shutting up the house and turning on the fire heat when a frost is anticipated, the better course to pursue is to leave the lights wide open. Vines are perfectly hardy till such times as the sap is in upward movement, and the less frost is excluded from those cleared of fruit and leaves the better it is for them. Vines with their roots wholly inside are naturally the best adapted for hard forcing, but it is not an absolutely essential condition, as it is possible to warm up outside borders with the aid of hotbeds of leaves and manure formed on them. If, therefore, there are

any old Vines of Black Hamburgh and other varieties that it is intended to get rid of, they can be forced hard and the house cleared in time for planting strong young Vines in May or early in June, the loss of a season being thereby guarded against. The first proceeding with all outside borders containing the whole or the bulk of the roots of Vines to be forced early should be to heavily cover them with fresh dry leaves, these answering the double purpose of conserving heat in the horder and warding off cold, heavy rains. Later on a gentle hotbed can be substituted. Only borders containing the roots of Vines to be started any time before February should thus be covered up, the action of frosts being beneficial rather than otherwise in all other cases.

PRACTICAL.

THE KITCHEN GARDEN.

SPRING LETTUCE.—Lettuce planted now of either Black-seeded Bath Cos, Hicks' Hardy White, and amongst the Cabbage forms All the Year Round and Hammersmith Hardy Green will winter better than those planted two or three weeks earlier. Hicks' Hardy White will be ready quite a fortnight earlier than the Bath Cos; therefore the two form a good succession. It is better to plant on two positions, on a west border and in a more open position well exposed to the sun.

EARTHING UP CELERY.—It is time that the final moulding of all Celery other than the very latest was finished. Some care is needed with this latest moulding. With the soil loose and thrown up roughly wet penetrates, engendering decay; frost will be found to take a greater hold than it does with well-formed ridges. If more care were taken in the earthing, complaints of Celery being injured by frost would not be so numerous, and besides there would not be so much trouble in covering and uncovering when frost does occur. Some people consider this quite necessary to prevent injury. The soil must be brought up sharply, working it well around the plants, leaving about 6 inches of the tops exposed, the whole being finished off smartly with the back of the spade. It is not often that wet gets between the ridges, and when it does the position must be very low-lying and badly drained. In this case it should, if possible, be drained away. The very latest may be left until the appearance of frosts.

PARSLEY FOR WINTER.—As long as the weather remains mild and open, the Parsley which is being retained for winter and early spring use may be left exposed, keeping it, however, free from decaying foliage, tree leaves, and weeds. A free circulation of air promotes a matured growth. Have in readiness glass lights or whatever is to be adopted for protection. Parsley which is expected to keep if it once becomes exposed to a severe frost or a heavy fall of snow is apt to decay quickly. Parsley which is being reserved for use during an inclement time should not be gathered from until such weather really does occur. With a little timely protection that which may be growing in the open may be long preserved for use by a little forethought. A few wooden borders or any framework of wood should be covered with either mats or oil-canvas.

DIGGING VACANT GROUND.—Whether ground may be dug to advantage during the early autumn months will depend upon the nature of the soil. Trenching or bastard trenching of lighter soils so as to make a greater depth of well-worked fertile ground cannot be over-estimated, but this was referred to recently. Trenching of soils is different to digging. Digging over all vacant ground in the autumn is frequently recommended as the best method of getting the soil into a well worked state. With many soils this is undoubtedly so, but not all; for instance, certain kinds of clay soils. Those clay soils which are benefited by the process should be thrown up roughly with digging forks. Spades are not the best implements for manipulating heavy land. Those of a more sticky nature should be left until February. This is the better period for digging very light soils, but if the

soil is not dry, the surface should be quite clear of weeds and rubbish, so that it will be open to the action of frost.

WINTER TOMATOES.—The weather has been favourable for the fruits setting freely on Tomato plants provided for winter fruiting, and as long as they will keep on setting nothing should be done to prevent them. As the same conditions as regards temperature and ventilation are needed for both setting the fruit and swelling it off afterwards, the temperature should be about 60° during the night, with a little ventilation at the front and upper ventilators so as to maintain a buoyant atmosphere. What Tomatoes dislike is a close and stuffy house, which promotes disease. Water must also be sparingly applied, that is by damping, as unless for a week or two longer on fine mornings the less moisture that is thrown about the better. Rub out superfluous growths, the energies of the plants being concentrated on the main stems and swelling fruits. The soil must be kept just moist, a little very weak liquid manure being also applied. An occasional dusting of an approved fertiliser to the surface will be of service. Over-gorging with either liquid manure or water will soon cause the plants to collapse.

A. YOUNG.

ORCHIDS.

The effect of the sun upon the glass is not strong enough now to injure the plants in any of the divisions, and if the blinds have not been removed, see that it is done at once. I chose a fine dry day, and had all ours taken down and stored for the winter. If they are put away rolled up with the least damp upon them, they may be taken out in February or March perfectly rotten. Even if made of the best material, the blinds do not last more than about two years, through the wear and tear of running them up and down and the constant soakings of rain. We use our blinds only in summer to protect the plants from sunshine, but some Orchid cultivators prefer to use them in winter as a protection against frost. I tried this one season, but found it was a very troublesome system. There was undoubtedly a saving of fuel, as the blinds prevented the frost from acting upon the glass and made a difference of at least 5° in the temperature of the houses; but in the morning, when we wanted as much light as possible for the Orchids, it was not possible to obtain it owing to the blinds being frozen. They could not be rolled up until they had thawed. The Rev. F. D. Horner, of Kirkby Lonsdale, uses a thick material to cover the roof of his Orchid houses during frosts, and finds it not only saves fuel, but that the plants do better with the less artificial heat, the atmosphere being more congenial. When the blinds can be pulled off as soon as daylight comes in and put somewhere to dry, use them by all means, but even under the most favourable conditions the plants never get enough light from November to February. To leave the roof-glass covered for two or three hours after daybreak during that period cannot fail to be disastrous to plants which require full light. This being the case, see that the glass roof is made quite clean, for the glass soon becomes very dirty, especially inside, and it is well to rearrange the plants at this season. The laps of the glass become quite green also, and should be cleaned out with a feather. It is well to rearrange the plants at this season, for some that have been in a certain position during the summer are better removed to another and lighter position for the winter. I never think of removing them without their being cleaned, and this thoroughly. Nearly all parasites, whether scale or thrips, disfigure the foliage and sadly cripple the growth. If any really need re-potting let it be done without delay, and at this time of the year I am always more careful if possible to prevent injury to the roots. In the case of Cattleyas or Lælias I chip the pot to pieces bit by bit, and remove them carefully. If a few small pieces hang on to the roots no harm is done. Some persons, instead of turning their plants out of the flower-pots, place one within the other, and allow

the roots to ramble over the rim of one pot into the compost placed between the two. I tried this plan, and certainly do not like it. The flower-pots become too large by the transference of one to another in this way. Another plan I have tried was to break the flower-pots in pieces, or rather crack them badly, knocking the bottom out, &c., but not parting the pieces from the roots. This is better than transferring one flower-pot into another entirely. I mention both of them because some growers treat all or part of their Orchids in that way, but my own experience suggests the removal of the old flower-pots entirely; the fewer roots that are injured so much the better will the plants succeed. Beware of over-potting. It is much better to err on the other side; a plant from a flower-pot 6 inches diameter to one 8 inches is a good shift. Some of the Cattleyas and Lælias are pushing young roots freely from the base of the last formed pseudo-bulbs. See that slugs do not find them out. They can only be caught feeding by the aid of a lamp. The succulent young spikes of *Oncidiums* and *Odontoglossums* are devoured even before they are seen, as they push out between the bulbs and the leaves. The garlic-scented snails can be detected by the offensive smell they give off. We have been placing slices of Carrot which attract them, and by looking over the plants about seven and again at ten o'clock at night most of them may be caught, for they all turn out to feed after lightfall. They are generally most troublesome in the cool house, and we could get rid of them altogether, but that the eggs and very small specimens are constantly being introduced with the Sphagnum Moss. Many Orchids do not require much water now, and unless great care is taken, some of the Cattleyas will start into growth again, especially such as are at the height of their vigour, and if an unseasonable growth takes place the plants are thrown quite off their balance, and may not flower for one or two seasons. Another class of Orchids requiring to be comparatively dry at the roots during the resting period, which for them is now commencing, is the *Cycnoches*, *Catasetums* and *Mormodes*. They should be placed in a light position in the Cattleya house near the roof glass, and until the leaves decay, give water once a week or so; when the leaves are removed give none for some time. They want watching and the pseudo-bulbs ought not to be allowed to shrink much. I have before urged cultivators to take more to the culture of these quaint and interesting Orchids. The curious formation of the flowers and their distinct if not brilliant colours are interesting, and as a study of curious form they are amusing even to those who are not far gone in their love for Orchids. Some Orchids do well with their foliage near the glass in summer, but are too sensitive to the effects of sudden changes of temperature to be allowed to remain in that position during the winter, and in this class many Lælias and Cattleyas are included. Amongst plants that may be quite near the glass roof are such things as *Dendrobium Falconeri*, *D. Devonianum*, *D. Bensoniae*, *D. formosum* and some others of the nigro-hirsute section. The deciduous species may be almost or altogether without water, but all the evergreen section should not be so dusty that the stems become shrivelled, but it is well to keep them on the dry side. *Vanda teres* we have placed at the end of the Cattleya house, and the tips of the growths close to the glass roof, and they do not receive a great deal of water, just enough to prevent the part of the stems furnished with leaves from shrivelling. *Renanthera coccinea* should receive very similar treatment. The flowers of the old *Cattleya labiata* are now to be seen pushing up out of the sheaths, and we look forward to a good display of bloom from this brilliant *Cattleya* during the dullest, dreariest period of the year. Although the flowers are showing there is no need to be too free with the water, as a constant moist state of the roots would be injurious to them. The flowers open best in a temperature of about 60° as a minimum. Our *Cattleya* house ranges now between that figure and 55°, the warmest house 65° to 70°, and the cool house about 50°, less or more.

J. DOUGLAS.

THE FRUIT CROPS.

SUPPLEMENTARY.

Warfield Hall, Bracknell.—The Apple crop in this neighbourhood is very partial; some trees very good and others very thin. Pears thin as a rule. Plums fairly good, but much thinned by frosts in April. Cherries were fair; Morellos plentiful. Peaches set a good crop of fruit, but the trees suffered from want of water and from red spider and aphid. Apricots set well, but suffered from frost. Gooseberries were abundant and good considering the drought. Black Currants abundant from old trees. Red Currants very abundant, but not up to average quality. Raspberries almost a failure from want of water. Strawberries most abundant, and size and quality superb where well watered.

Vegetables generally suffered much from the long drought, but Peas did splendidly up to end of July, and salads succeeded well where they could get a little water occasionally. On the whole (in spite of the long drought) we stood in a much better position in the middle of July than I found it here at the same date in 1868.—H. SWANSBOROUGH.

Holker Hall, Cartmel, Carnforth.—The fruit crops in these gardens, with the exception of Plums, are abundant and of good quality. Sir Joseph Paxton Strawberries, being mulched early with stable litter and copiously watered, withstood the drought well and gave good crops of fruit. The excessive heat ripened them so quickly that their season was soon over. Gooseberries were heavy crops, but suffered severely from caterpillars and red spider. Red and Black Currants very good, also Raspberries. Cucuries, both sweet kinds and Morellos, are heavy crops. Moor Park Apricots above the average, ripening to perfection, which is a rare occurrence here; the plague of wasps spoiled many of them. Peaches on open walls have done well, the fruit highly coloured and of good flavour. Apples are good crops, and some remarkably fine fruits have been gathered of Ecklinville Seedling, Roundway Magnum Bonum, Golden Noble, and King of the Pippins, the last very highly coloured. Pears on walls good crops and larger than usual, Williams' Bon Chrétien and Marie Louise especially so.

Both first early and second early Potatoes good crops and free from disease; late kinds not grown in garden. Peas were never gathered so early in these gardens as this year, being ready at Whitsuntide (May 21). All Pea crops have done well, particularly McLean's Best of All, which was one mass of fine pods from top to bottom. Dickson's Champion Cos Lettuce attained a remarkable size, being very crisp and good.—WM. FOX.

Croydon Lodge, Croydon, Surrey.—Apples here are an average crop, some kinds bearing very heavy crops. Lord Suffield, Alfriston, Keswick Codlin, Lady Hennifer, Manks Codlin, King of Pippins, Blenheim Orange, Cellini, Mère de Ménage, Golden Noble, Ribston Pippin, Devonshire Quarrenden and Peasgood's Nonsuch had very good crops. Rarely indeed are such fine crops of Marie Louise Pear to be seen as are hanging on the trees this season. Knight's Monarch, Windsor, Williams' Bon Chrétien, Louise Bonne of Jersey, Glou Moreau, Passe Colmar, Catillac, very heavy crops and large fruit. Wall fruit, such as Peaches, Barrington, Royal George, Golden Eagle, Dr. Hogg, Hale's Early, Sea Eagle and Grosse Mignonne, grand and well-coloured crops. Of Nectarines, Lord Napier, well coloured and large fruit, Albert Victor, Elruge, Rivers' Orange, Spencer, Victoria, Violette Hâtive have good crops. Apricots, although thinned out considerably, were a heavy crop and have ripened well. Cherries were a very good crop, May Duke being very large. Plums a total failure. Bush fruit, Currants (Black, Red and White) abundant and good. Gooseberries very good crop, bushes clean and healthy. Raspberries very small and poor. Strawberries have been plentiful; Noble, General McMahon, Sir Joseph

Paxton and Auguste Nicaise have been the best.—WILLIAM CARR.

Uppott, Barnstable, N. Devon.—The crops of fruit and vegetables in these gardens and neighbourhood have on the whole been satisfactory. Peaches have been abundant and good; so also Apricots, which ripened off much quicker than usual, so that the season has been short. Apples are a rather partial crop, but the fruit is large and well coloured. Pears are a good crop, the fruits large and clean. Plums and Cherries good. Small fruits have not been quite so good as usual. Strawberries a good crop. Black Currants abundant; Red Currants light, Raspberries light. Gooseberries a good average crop.

Potatoes have been good, but not a heavy crop. This applies to early and second early varieties. I cannot yet say how the late sorts will turn out, especially Magnum Bonum, which is our principal winter variety. Peas have been a light crop; so have Broad Beans. Onions are good. Carrots, Parsnips, Beet, &c., very good. Runner Beans did not set well at first, but are now abundant. Late Turnips and also winter crops are looking fairly well. The year 1893 has been remarkable here, as in most other parts, for its dry tropical weather, commencing early in March and continuing up till the middle of July, when we had some heavy rains, which thoroughly soaked the land, causing all kinds of vegetation to grow rapidly. The local markets have on the whole been well supplied with fruit, but during part of May and during June and July vegetables were very scarce. We picked Sutton's Ringleader Pea in the open on May 14, and gathered our first dish of Strawberries from the open on May 10, which is about three weeks or a month earlier than in other years.—W. HARRIS.

Castle Hill, Englefield Green, Surrey.—In this neighbourhood Apples and Pears are very abundant. Pears first-rate, but Apples with me are rather small. Strawberries were a complete failure. Bush fruits are an average crop, but soon over. Raspberries a fair crop. Peaches and Nectarines average. Apricots were a very fair crop, but eaten by wasps before they were ripe. Plums and Cherries were a very good crop, but trees covered with black fly and red spider. Nuts a heavy crop.

Early and second early Potatoes are good crops, late varieties promising well at present. Spring Cabbages were good. Peas a very heavy crop, but soon over. Cauliflowers a failure. French Beans good; Scarlet Runners very poor crop. Carrots, Parsnips, Beet doing well. Onions with me a complete failure, not one left, being eaten up by grub.—H. ADAMS.

Eynsham Hall, Witney, Oxon.—The fruit crops here are the best we have had for some years; although we generally have an average crop. Fruit large and well coloured. I may say the same of Pears, most kinds carrying a heavy crop, fruit being much larger than usual. Plums are an extra heavy crop, and where thinned the fruit is very fine. Apricots and Morello Cherries good crops. Gooseberries a very heavy crop. Raspberries have never done better. There are good crops of Currants, Red, White, and Black. Strawberries were a very good crop, size and flavour good, but the season short.

Vegetables have done well with the exception of midseason Peas, but late sowings doing better. Early Potatoes have been a light crop, but late varieties in the fields have never looked better and promise to yield a heavy crop, and as yet are free from disease.—JAMES ANDERSON.

Fota, Co. Cork.—Like most other parts of the British Isles, the south of Ireland has been very dry, but we have been more favoured than the south-west of England, the absence of spring frosts and the dry weather being most favourable to all kinds of fruit blossoms, with the result that there is an over average crop of nearly all kinds of fruit. The Apple crop is the largest I have seen for many years, and the quality all that can be desired, although the fruit is not so large as usual, in consequence of the dry season and over crop.

W. E. Gladstone was our first to ripen. This is not a profuse bearer, but a nice looking Apple and as good as most very early Apples are. King of Pippins, Ribston, Cox's and Sturmer Pippins, Lord Suffield, Tom Putt, Tower of Glamis, Blenheim Orange, Annie Elizabeth, Lady Hennifer, Bramley's Seedling, a very heavy late Apple; Worcester Pearmain, a nice looking early Apple, but quite second-rate; Small's Admirable, as usual, heavily laden; Lane's Prince Albert, Roundway Magnum Bonum, Dutch Mignonne and Alfriston are bearing very heavy crops, but other varieties are well laden. The Pear crop on pyramids is over average, not so on walls. Duchesse d'Angoulême, Williams' Bon Chrétien, Beurré Hardy, Comte de Lamy, a fine flavoured small Pear; Gratioli of Jersey, Mme. Treuve, Louise Bonne of Jersey, Flemish Beauty, and Beurré Diel are bearing the largest crop. Cherries were an under average; Morellos quite an average crop and very fine. Figs a light crop. Plums much over average; Jefferson, Hicks' and Coe's Golden Drop on walls very fine; Victoria, Prince of Wales, The Czar, Prince Englebert overlaid. The Strawberry season was short and fruit not so large as usual. Gooseberries were the heaviest crops known for many years, and other small fruits an average crop. Peaches on walls a good crop and very highly coloured.

Early Potatoes are a very good crop and the quality is first-rate. Myatt's Ashleaf, I think, is yet as good as any for quality, and a very good cropper. Late kinds promise well. All kinds of fruit and vegetables quite three weeks earlier than usual.—W. OSBORNE.

Broadlands, Ascot.—The fruit crops under glass here have been a great success this season. We began with Peaches, Early Louise May 13, following with Hale's Early in June, both good varieties. With me Early York came in next, followed by Stanwick Elruge Nectarine, Royal George Peach, Frogmore Golden and Sea Eagle. The above selection gave a good supply till end of July; the second house giving us some fine examples of Stanwick, Early York, Rivers' Orange Nectarine and Princess of Wales. Melons also have been very good, one of the best being Sutton's Triumph, a good setter. Our Grapes are Black Hamburg, Muscat of Alexandria, Foster's Seedling, Buckland Sweetwater, Madresfield Court quite free from cracking, and bearing very heavy crops; Alicante, Gros Colman, Gros Maroc and Lady Downe's. The fruit crop out doors with us commenced with bush trees, which produced a good all-round crop, but over very quickly. Apples very scarce. Pears the same except on the walls. The following varieties are conspicuous: Williams' Bon Chrétien, Marie Louise, Louise Bonne of Jersey, Beurré Diel, Glou Moreau, Easter Beurré, Eyewood, Bergamote d'Espereou, Doyenné d'Été, Winter Nelis, Souvenir du Congrès, a very handsome Pear, and Duchesse d'Angoulême. Plums were a good crop. Strawberries gave us good crops, Vicomtesse Hélicart de Thury and Elton Pine being the only kinds we grow.

The season has been most trying for the vegetable crops. We began with Peas on May 16, Sutton's Mayflower being in before William I. The green crops hold their own better than in a rainy season, being quite free from club; young spring-planted cuttings of Seakale are looking most promising. The root crops are good, Onions excepted, as they are almost a failure. Beet is also good. Potatoes small, but sound, Sharpe's Victor, Early Regent, Beauty of Hebron and Reading Giant being our selection. We have had to keep the water cart hard at work all the season, only getting a few thunder showers since the first week in March. I think the season teaches us a great lesson—that is, nothing beats good deep cultivation in winter.—J. GUYETT.

Castle Gardens, Highclere, Newbury.—Apples are this year a very heavy crop and early in maturing, such kinds as Irish Peach, Juneating, Early Margaret, Mr. Gladstone, Lady Sudeley, and others being ripe at the end of June and beginning of July. The same applies to Pears, Plums, and, in fact, outdoor fruit as a rule, Jargonelle Peas

being quite a thing of the past at the end of July, but very fine nevertheless. Plums are very plentiful, but small with us; the same remark applies to Peaches ripening out of doors. Pears are not a heavy crop on the whole, some usually free-bearing kinds, as Beurré d'Amanlis, failing altogether, the most conspicuous failures being on west aspect walls, whilst standards and fully exposed espaliers are carrying good crops. Gooseberries plentiful and good. Strawberries very good, but soon over. Small fruits good and abundant. Raspberries and Cherries, especially Morellos, very good.

The season has been a trying one in the vegetable department, many seeds failing to germinate till after the July rains, notably Carrots, Onions, and Beetroot, much the best results being obtainable where sown rather deeply in drills. I never experienced such a trying season for keeping up a succession of Peas. Broad Beans set very badly too, while early Cauliflowers were infested with maggot at the root. I fancy Potatoes are turning out quite a surprise crop to many people, except, perhaps, on very dry, gravelly soils. At several cottagers' shows I have visited in this neighbourhood the tubers have been of good size and very clean; in fact I have been surprised at the good quality of vegetables generally after such a season. Tomatoes are cropping outside better than I have seen them for years, whilst late vegetables look very promising.—WILLIAM POPE.

Flixton Hall, Suffolk.—The fruit crops in this district, speaking generally, are fully up to the average. Of Peaches, A Bec, Dymond, Dr. Hogg, Violette Hâtive, Bellegarde, Sea Eagle, and Walburton Admirable were the best. Amongst Nectarines, Lord Napier, Stanwick Elrge, Violette Hâtive, and Rivers' Orange were very good. Apricots were also good, particularly Shipley, Large Early, Roman and Kaisha. Pears are below the average, but the fruit is of first-rate quality. Apples are plentiful and the fruit clean and good. Cherries on the whole were an average crop. Plums (both trained and standards) carried good crops. Amongst small fruits, Raspberries were a fair crop, but the fruit was not so fine as usual. Gooseberries and Currants suffered from the continual frosts in April; consequently the crop was below the average. On our strong soil Strawberries were plentiful and good, but on the light land along the Waveney valley the plants suffered much from the drought. Walnuts at one time promised to be a heavy crop, but latterly a large quantity have dropped, owing, I imagine, to the want of moisture at the roots.—H. FISHER.

Deepdene, Dorking, Surrey.—Apples on the whole a fair average, Lord Suffield, Hawthornden, and Cox's Orange Pippin carrying heavy crops. Apricots were a wonderful sight, the crops being far too heavy for the trees to carry with safety. Pears on the Pear stock are carrying good crops. Cordons on the Quince, and moved last winter, despite a heavy mulching, have done badly. All bush fruit's were excellent, Strawberries being good, but the fruits ran small. Prodigious crops of Plums were the rule.

The year so far has been very trying. I never saw kitchen gardens look so bad. Early sowings of vegetables have done much the best. Potatoes with me will yield a satisfactory crop.—J. SHAW.

Stcke Court, S'ough, Bucks.—In reply to your letter as to state of fruit crops in this neighbourhood, I must say Strawberries and all small fruit have been abundant and good (our Strawberries were only planted in August, 1892). Pears on walls very light crop, on bush trees in open garden a very heavy crop of fine, clean fruit. Apples, Plums and Nuts are also very good. Apricots, Peaches, Nectarines and Cherries have been a splendid crop. Peaches well coloured and of good flavour. They are nearly over now. We are picking Barrington, Walburton and Late Admirable, that in an ordinary season would not be ripe before the middle or end of September. Everything is quite a month earlier than usual.

Vegetables are very good considering the season. Early Potatoes are small. Some Sharpe's Victor we had on a south border were lifted ripe for seed in

twelve weeks from planting. Late kinds are not ripening off so quickly, and are of a good size, clean and no disease. Tomatoes are a fine crop on the open walls. Good plants put out after danger of frost was past gave us ripe fruit at the end of June. Peas have done fairly well all summer, but now they are not doing at all well. Early Cabbage was good, but later lots were burnt completely up. Beans, Marrows and all other crops are good.—F. W. BEEVERS.

Cobham Hall, Gravesend.—Of Apricots there is an average crop, and of Apples a good crop on most trees, Lord Suffield, Manks Codlin, Lucombe's Seedling being above the average. The Cherries (Bigarreaus) under average, but good, and not much spoiled by cracking. Morellos good crop, but small, especially on the chalk. Figs are an average crop, but not many are grown. Nuts are an average crop, Cobs being above the average. Pears are a good average, fruit small except on walls, Doyenné d'Été, Brown Beurré, Marie Louise, Louise Bonne of Jersey, Williams' Bon Chrétien being good in most places. Plums are plentiful, above the average, the following sorts being the best: Angelina Burdett, Coe's Golden Drop, Early Prolific, Gisborne, the old Green Gage, and Jefferson. These are good on walls. Peaches and Nectarines are a good crop. Black and Red Currants are an average crop on heavy land, but on the chalk very poor. Gooseberries are a good average crop in most places, but very much damaged with caterpillars. Raspberries are an average crop in places, a great number of the maiden canes fruiting, which will reduce next year's crop. Strawberries are an average crop in places, best on heavy land; of good flavour. The season's picking was soon over, and, in fact, I have not known a season for picking so short as the present one.

Potatoes of early sorts are a light crop in most places, but good, Veitch's Improved Ashleaf being one of the best. Of second early varieties, Covent Garden Market and Chancellor are good sorts.—F. DEUXBERRY.

MARKET GARDEN NOTES.

COPIOUS rains have at length fallen, and work that has long been delayed can now be pushed on. The most important operations at present are:—

CARBAGE PLANTING—This is one of the most important crops of the whole year, and all available land that has been cleared of crops, manured and cultivated is now being planted under very favourable conditions, for the soil being warm and moist and the weather mild and showery, the plants soon start into active growth. Soot is freely applied to this crop, as it keeps slugs and other pests away, and when washed into the soil acts as a manure. Great care is taken to have sturdy, short-legged plants by sowing thinly and giving plenty of space from the first.

CAULIFLOWERS of the Autumn Giant kind are now coming into market plentifully, but as a rule they are not of such good quality as in moister seasons, the drought having checked the formation of the crown in its earliest stages of growth. Plants of the Early London and other kinds for standing the winter are now being put out under hand-glasses or in cold frames.

CARROTS are now being pulled in quantity for market from sowings made at midsummer, as the earliest sown crop failed to a great extent, owing to exceptional drought.

CELERY is now being supplied more plentifully, as few crops suffered more from lack of moisture than this; late crops are now making rapid growth, and earthing up is being pushed on rapidly.

POTATOES—All the late sorts are now being lifted and stored, and, as a rule, the crops are not only very fine, but exceptionally free from disease. Early and midseason varieties have been light crops, but very clean and bright, but late crops will make up for any deficiency in bulk.

TOMATOES have been the crop of the year, not only under glass, but on walls and in the open field

fine crops, well ripened, and free from disease. The latest gatherings are now being placed under glass to finish off their colouring.

FRUIT of all kinds has been abundant and cheap. Apples have been a wonderful crop, the oldest trees as well as those in their prime being loaded. All keeping sorts are being stored, and probably prices will get better shortly.

PEARS have, if possible, been not only more abundant than Apples, but remarkably fine—in fact, considering the drought the weight of crop produced was remarkable. The storing of latest sorts and cooking Pears is now nearly completed.

Preparation for planting fruit trees and bushes is now being made, the soil being in splendid condition, and, in spite of the low prices, there seems no slackening in the work of planting. A good deal of clearing away of useless sorts is likely to be done, as the past season has fully confirmed the advice so often given, that it is only good fruit that pays.

JAMES GROOM.

Gospport.

TREES AND SHRUBS.

THE JUDAS TREE.

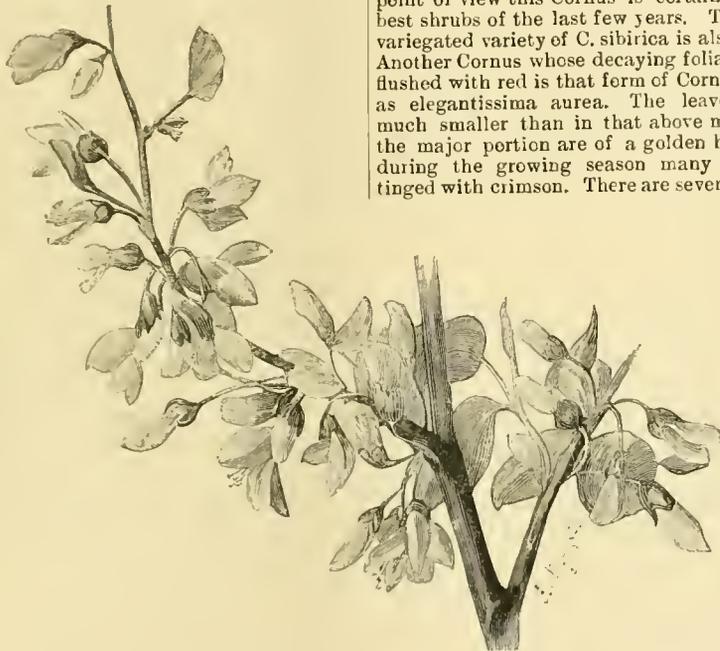

(CERCIS SILIQUASTRUM.)

THIS is one of the oldest of exotic trees. According to Loudon it was introduced into this country in 1596; still it is uncommon, especially in recently planted gardens. The Judas Tree is very distinct in aspect. It will flower freely when only a few feet high, and from its numerous branches it then often forms quite a shrub. Its flowering season is during the month of May, when the leafless branches are covered with deep rose-coloured flowers. They are borne not only on the smaller shoots, but on the large branches and main trunk. Directly after flowering the kidney-shaped leaves are developed, and when fully expanded their peculiar light bluish-green tint is conspicuous. When young it usually branches freely, but after a time the style of growth becomes more irregular. An old tree has usually a flat-topped, wide-spreading head. In this stage it forms a highly picturesque tree, especially where isolated on a lawn or in a similar position. The flowers are succeeded by pods which attain a length of about 6 inches, and they are noticeable especially after the leaves have fallen, for the pods remain on some time longer. Among other ways in which the Judas Tree may be planted is in the form of a small group, which will be especially bright during the flowering season. Though it does not attain its picturesque style of growth for some years, yet it flowers freely enough when small. It is of slow growth, so that there is little danger of even a thriving plant outgrowing its allotted space. Occasionally quite an old specimen of this Cercis is seen with not always a tree-like habit and a spreading head of branches, for sometimes the branches are pushed out not far from the ground, and continuing to grow they gain considerably in weight. It is necessary then to support them. The Judas Tree reaches a height of 20 feet to 30 feet, but it takes many years to reach that size. The tree is a native of Southern Europe and Asia Minor, and derives its popular name of the Judas Tree from its being thought by some that it was the tree on which Judas went and hanged himself. I once saw a bush of it forced gently into bloom a few years ago, the result being towards the end of March it was profusely flowered, the blooms of scarcely so deep a tint as when they are allowed to open outdoors, but still they were very distinct and pleasing.

The various kinds of *Cercis* are scattered over a considerable part of the world, for though we have but three species in cultivation, the above-mentioned Judas Tree is a native of Southern Europe and Asia Minor; *C. canadensis* occurs through a considerable tract of country in North America, while *C. chinensis* as implied by its name, is a native of China, but also found in Japan. The most ornamental of the three is, however, the old European form. The Judas Tree and its allies are not particular as to soil, though a rather deep open loam suits them best. Their roots, like many others of the Leguminosae, go down deeply. They may be increased by layers, but are usually raised from seed, and to this circumstance is no doubt owing the fact that a certain amount of variation is to be found in the colouring of the flowers, some being richer in colour than others.

T.

Cratægus pinnatifida major.—Some cut sprays of this comparatively new and uncommon Thorn were very noticeable among an exhibit of

Flowering shoot of the Judas Tree (*Cercis siliquastrum*).

hardy trees and shrubs shown at Earl's Court by Messrs. Veitch. The most conspicuous feature was the large, oblong-shaped fruits, which were of a deep bright red colour. These berries were not many in a cluster, but being as large as Cob Nuts they were showy. This Thorn is especially noticeable in the spring months, from the fact that, with the exception of the Glastonbury Thorn, it is the earliest of all to come into leaf, and the foliage is very handsome. It is when first expanded of a light green, and the deeply lobed leaves are borne on unusually long stalks, on which account they are partially pendulous. The flowers are white. As the season advances the foliage deepens in tint. This Thorn is a native of Northern China and the Amoor district, and is perfectly hardy in this country; indeed, the tender unfolding foliage resists the sharp frosts and cutting winds of early spring better than would be generally supposed.

—T.

Veronica Reine des Blancches.—Though I have not seen this variety mentioned in any of the horticultural journals, I was very much struck with it when shown by Messrs. Veitch at Earl's Court on September 27. It is one of the shrubby section, among the flowers of which various shades

of purple and blue predominate, but in this particular variety they are pure white, and borne on good showy spikes. Certainly as shown the plants were small and the spikes of flowers by no means numerous, yet they were full of promise. Where a few good varieties are needed, to this may be added *Imperialis*, amaranth; *Celestial*, pale blue; *Crème et Violet*, pink; *Jardin Fleurie*, carmine-red; and a second variety shown by Messrs. Veitch—*Purple Queen*. *Veronicas* of this class being of such easy culture and nearly hardy, are useful for the greenhouse or conservatory during the winter months. In the more favoured districts of England, and particularly near the sea, the shrubby *Veronicas* are beautiful in the open ground. A variety of *Andersoni* has the leaves very prettily variegated, and it is often used as a bedding plant during the summer months.—H. P.

Cornus sibirica Spathi.—This beautiful golden-leaved shrub which has resisted the burning sun of the past summer has now entered upon another phase of beauty, for the decaying foliage is of a deep scarlet, very showy in itself, and especially striking when the leaves have only partially changed colour. In some cases while the more mature foliage is scarlet, the younger leaves still retain their deep golden tint. From a foliage point of view this *Cornus* is certainly one of the best shrubs of the last few years. The pure white variegated variety of *C. sibirica* is also very pretty. Another *Cornus* whose decaying foliage is brightly flushed with red is that form of *Cornus* mas known as *elegantissima aurea*. The leaves of this are much smaller than in that above mentioned, but the major portion are of a golden hue, and even during the growing season many of them are tinged with crimson. There are several variegated-

(with an occasional turn over during winter) tilt next February, when they can be sown broadcast on beds 4 feet or 5 feet in diameter, transplanting the young plants into rows 2 feet apart in the autumn of 1895. When only a few are desired the seeds can be sown in drills. The few seeds of the Golden Yew may be sown in a shallow box or pan and plunged in soil out-of-doors. It is doubtful, however, whether anything different from the common Yew will be obtained; these garden forms (even the Irish Yew) do not come true from seed. They should be increased by cuttings or layers.—B.

Hydrangea paniculata.—The *Hydrangea* referred to on p. 309 as an inferior variety of the plumed *Hydrangea* is doubtless the typical *H. paniculata*, whose ornamental features are vastly inferior to those of the variety *grandiflora*. From this latter, which is more commonly met with, the typical plant differs in being rather more vigorous in growth and the leaves of a deeper green, but above all in the large sterile blooms, which form by far the most conspicuous part in the inflorescence of a *Hydrangea*, being limited to a scattered few; whereas, in the variety *grandiflora* they are sufficiently numerous to form a massive pyramidal-shaped head. The variety being so superior to the typical form should be always obtained when planting; indeed, but few of our nurserymen keep the type, and, except in a botanic garden or in the collection of some specialist, it is certainly not worth a place, and where it does exist it should be destroyed in favour of the variety *grandiflora*.—H. P.

Hibiscus syriacus totus albus.—The varieties of the autumn-flowering *Hibiscus syriacus* are very numerous, but as far as I know there is only one with pure white flowers, and that is the above-mentioned. The flowers are single and of a good clear white without any colouring whatever. There is a double-flowered form known as *albus plenus*, but in this the base of the petals is marked with crimson, and consequently the centre of the flower is of that tint. The fact that pure white flowers are so generally sought after is my reason for noting this particular variety, for a bush of this is when in bloom quite distinct from any of the others. All the forms of this *Hibiscus* have flowered beautifully this autumn; in fact, one seldom sees them so satisfactory as they have been this season where they were so situated as not to suffer from the drought. In dry soils, however, many of them had dropped the greater part of their leaves before the flowering period, and consequently their beauty was largely lost.—T.

TOWN TREES.

I do not know whether the Fig may be classed as a tree; certainly it is not usually grown as a standard, but in any case it matters little. It is true that the Fig seems to thrive best against a wall, but why not equally well for purely shrubby purposes in a border? There is growing on an east aspect in front of a school-house here, and in a wind-swept road, a fine tree that never seemed to have looked more dead than last winter, and has never been in more glorious leafage than now. It gets sun only in the early morning. I remember having seen Figs thriving well, but of course never fruiting, in the yard of the Charterhouse, Smithfield, and if well there, why not in parks and forecourt gardens? Then what a beautiful town tree for its foliage is the Sumach. It certainly never grows tall or gross, but its foliage is splendid, and as I saw in a walk round the suburbs of London a few days since, when Limes and many other trees were brown or almost leafless, the Sumach was in beautiful leafage. It does open late in the spring, as does the Fig, but at least it presents a green oasis amid the desert of brown withered leafage that is seen so prematurely in the autumn around all our towns or populous districts. For tall trees none excel the oriental Plane. Probably we never shall see it excelled. It is naturally a strong-growing tree, and it carries large leathery leafage which certainly can withstand town deposits

and vapours better than can the thin leafage of the Lime and similar trees. But even of the Plane I noticed recently the finest foliage and freshest, greenest aspects on trees that had been somewhat hard pruned last winter. It does seem as if any check to a too early spring growth produced by hard pruning tended to create later leafage in the autumn, but, still further, in such strong succulent shoots the leafage is always finer, fresher and more enduring. No one wants large trees in towns except in large open spaces. In streets, and especially in forecourts, it is a great mistake to allow trees to reach the height of the tops of the houses, shutting out light and air from the rooms. If all such trees were occasionally hard pruned in the spring, not in the middle of winter, as is sometimes done, leaving a lot of hard ungainly stems for several months before they break growth, but pruned early in April, then they would never become unduly large, would give far more luxuriant and enduring leafage, and serve to ornament our streets and roads admirably where now so many trees do the reverse.

A. D.

KITCHEN GARDEN.

ASPARAGUS ON HEAVY LAND.

IN a natural state the roots of Asparagus grow in a very sandy alluvial deposit, and this gives the key to the system of culture we must adopt. Not but that excellent Asparagus can be produced on heavy land, but the beds must be prepared to suit its requirements and the system of culture also. Wet kills more Asparagus roots than anything else other than heavy cutting, and this is what must be guarded against. The heavier the soil is naturally the more reason is there to adopt precautionary measures against its destructive powers. A practice that is very prevalent is that of top-dressing in the autumn with rotten manure. Now, judging by the nature of Asparagus roots, this covering over the surface cannot but aggravate the evil of destruction from wet, that is where growing on heavy land, as on lighter and consequently warmer soils the injury is not so apparent. If anyone doubts this, let him examine the roots and the soil about them in the dead of winter, that is where the Asparagus is growing on heavy land and the surface top-dressed with rotten manure, when he will soon find that it is both wetter and colder than where left uncovered. Frost in itself will not destroy Asparagus roots if they can lie comparatively dry. The surface being left exposed will certainly assist in maintaining this, and this is a course which I can highly recommend with established beds, the top-dressing being left until the period just preceding growth in the early spring.

In the formation of new beds the first point to consider is whether the site be well drained, and this point being settled satisfactorily, then proceed with other details connected therewith. An Asparagus plantation will last for many years where a good foundation for the plants is made at the start. I am well aware that on some soils where the position is naturally drained, Asparagus will last and remain productive with very little preparation other than attending to annual surface dressings. In a general way, it is very rare that the position of a kitchen garden is fixed upon because the soil is suitable for vegetable culture, this being often only a secondary consideration.

The general way when dealing with Asparagus on heavy land is to have a series of raised beds running parallel with each other. This certainly is better than having the roots planted on the ordinary level. The soil in this garden is about

as unsuitable for the cultivation of Asparagus as it is possible to be, but yet by having the quarter raised above the ordinary level to the height of 18 inches a capital bed was formed, and by attention to annual surface dressings has every appearance of remaining productive for many years. The advantage of this is that the roots have an unlimited root run by being enabled to take possession of the intermediate space usually given up to alleys. Another advantage is that the beds are not likely to become so dry during the summer months as with narrow raised beds. The latter must have been very dry during the past season, as however good the water supply may have been, it was certainly not possible to keep the roots well moistened. But sufficient material cannot always be raised to bring the surface to the desired level. Of the materials which may be used with good effect, garden refuse—burned and decayed—dry road scrapings, road grit, sand, well-rotted manure, also ditch and pond clearings, are suitable. A heap of the above materials collected and turned two or three times during the early part of the winter, may be wheeled on during frosty weather, when it would pulverise down and be in good condition for spring planting. Certainly if there is no great hurry to form the beds, the material would be the better for being laid up for twelve months, and during that time turned occasionally. In such material as this the growth made is very strong and succulent, and the whole bed being raised above the surface there is no danger of stagnant moisture accumulating or the roots dying off during the winter.

A. YOUNG.

Abberley Hall.

Course vegetables.—In reference to what "A. Y. A." has written about unduly large vegetables getting awards at exhibitions, I am very glad to find so able a gardener on the side of quality and excellence as compared to mere size. I was much interested in a communication which came to me from an entire stranger in Cornwall who grows Cucumbers for market, and who stated that his fruits (17 inches to 18 inches long, and doubtless relatively large round) were much too big for the local taste, and asking for a pretty short green variety that would better suit his purpose. I have recommended him Lockie's Perfection. Now it is an odd fact that whilst so many vegetable judges will go for size in Onions, Carrots, Cauliflowers, Potatoes, Celery, &c., they will never as a rule favour large Cucumbers. The merest tyro knows that a large Cucumber is always past its best and lacks flavour, crispness, and those elements which alone make the fruit worth eating. If this be so in one case, why not in all? Whoever found merit in any big fruit or vegetable product except bulk? It would be a great service to vegetable growers could so strong a force of public opinion be formed as to make awards to mere size in vegetables henceforth difficult, and even ridiculous. It is not the show table or what certain judges may think should be the dimensions of products there, but rather the known requirements of consumers, especially of gardeners' employers, that should govern judgment in vegetable classes. Some clearly defined basis for judging is badly needed in the interests of exhibitors, who never know how judges' tastes will run. It is also badly needed in the interests of visitors to shows, who think these huge samples represent normal culture and look for the same results; and it is needed for the seed trade, who find that customers are disappointed because their products of the same varieties are never one half the dimensions as are the prize exhibits.—A. D.

— It will take something more than "A. Y. A.'s" assertions to convince me that large Cauliflowers are uneatable compared with smaller ones. I have no hesitation in saying that I will produce an Autumn Giant 1 foot to

15 inches in diameter (which I presume is the largest Cauliflower grown) that will be equal in flavour to Walcheren or any other kind of smaller habit. The only objection to large Cauliflowers is, that they do not dish up so nicely as smaller ones. "A. Y. A." is again mistaken when he states that quality in vegetables is sacrificed by the application of liquid manure. Anyone will tell him that a well-grown, highly-fed vegetable is superior to a starveling. Liquid manure hastens them on, and every gardener knows that the more quickly vegetables are grown the better and the more succulent they are. Reference is made to Celery as another vegetable which is very often seen so large that the texture is positively coarse; but are not coarseness, toughness and pithiness as often present in smaller heads? I have grown heads over six pounds each equally as crisp and sweet as others one fourth the weight. The good flavour of vegetables depends on good culture and cutting at the right time. A tirade against large Onions is occasionally made and their keeping quality is assailed, but I have not perceived any difference between them and smaller ones, taking one season with another. Nor has the question of flavour been raised. Certainly the Spanish Onion is said to be milder, and for that reason it is appreciated. "A. Y. A." states that "as the general public are much against large Tomatoes and give preference to smaller ones, it shows an improvement in the public taste." There are as many small bad-flavoured Tomatoes as large ones. Quantities of Tomatoes are consumed uncooked, and it is more convenient to pick up a medium-sized or small one and eat it than it is a large one. Besides, a Tomato weighing something like half a pound is too much at once for the majority of persons, and many would consider it extravagant. Another reason that preference is given to medium-sized or small ones is, that they are more readily distributed amongst friends.—W. P. R., *Preston.*

A good outdoor Tomato.—This has proved a good season for outdoor Tomatoes, those who planted early having reaped great advantages. I planted a large number of varieties for trial in the open, and the two most satisfac ery kinds were the Large Red and a new kind named Ladybird, specially recommended for the winter, but it was put out with others. It is certainly a splendid cropper, bearing enormous clusters of bright red fruits. I have not grown it for winter. The fruit's, produced in abundance, are of first-rate quality and have very few seeds. I saw this variety planted largely for market in Kent, and producing extra large fruit, but these of smaller size are much better.—GROWER.

Early Celery.—For the past three seasons I have grown Veitch's New White Celery, and last year it did so well, that I have grown more this, and it justifies the space given to it. It is of splendid flavour, solid and very early. The seed was sown in frames in April, and I am now getting good heads. Having given plenty of moisture, I never saw better results in so short a time. Where moisture has been deficient the sticks will be hard and somewhat flavourless, lacking that solid, juicy, nutty flavour so characteristic of Celery. Veitch's New White is not unlike Major Clarke's Solid Red as regards growth, habit and quality, but of course is white. This excellent variety is one of the best grown. The newer kind named above is also good, not belting as many do. This is important after a long hot, dry summer.—G. WYTHES.

CUCUMBER ROOTS DECAYING.

MY Cucumber plants seem to succeed well until they begin to fruit, when they flag. My opinion is that it is a root disease, something like the club that comes in Cabbage plants. They are planted in fibrous loam with leaf soil and manure. Melons have done well in the same soil, only for these the leaf soil was omitted.—FOREMAN.

* * This disease is most troublesome, as it usually occurs when the plants are in full bearing and at a time when it is difficult to replace them. Various

causes have been suggested for the above disease, but I have found that too much leaf soil in the compost will promote it. This is a great evil, but much depends upon the quality of the leaf mould, as this is frequently obtained from most questionable sources, such as the sweepings of the walks and from trees quite unsuitable. Oak and Beech leaves make the best leaf mould, but I have seen so-called leaf soil with the refuse of Conifers, Laurels, and other obnoxious subjects indiscriminately mixed together and used in a decayed state for various purposes. With good loam and manure, leaf soil is not advisable for Cucumbers. It is most troublesome, as it rapidly dries, gives the plants no nourishment, and produces long-jointed thin leaves and long-necked fruit. In winter a lighter loam is admissible. Leaf mould may be omitted with advantage if such aids as old mortar rubble can be used and a liberal quantity of decayed manure mixed with heavy soil. I find old Mushroom manure free of the top soil of the bed, fairly good yellow loam, and some mortar rubble one of the best composts for Cucumbers. In heavy clayey loam, charcoal refuse mixed with the soil is excellent, and to this may be added bone meal for top dressings if the soil is poor. I have seen the roots of Cucumbers club badly when in a soil to which a liberal proportion of leaf mould has been added. This occurs when an increased demand is made upon the roots. Often top dressings may not be given just at the moment required and the leaf soil is not rich enough to give the food required, and decay of the roots begins, this being accelerated by the heavy crop on the plants. Dryness at the root is often an evil, and this is usually caused by leaf mould, as it allows the water to run rapidly through without much benefit to the roots. When they are on a heated surface, dryness occurs at times unless care is taken. Cucumbers are frequently planted on elevated mounds, and dryness is more apt to occur in such cases, as with a large top growth the liberal syringings given earlier are now absorbed by the leafage or thrown off to parts of the house other than the roots, which formerly received most of the moisture. Again, in dull weather there are perhaps less moisture given and more heat in the pipes. This causes root decay whenever the plants receive a check through dryness, and, as previously noted, leaf soil does not tend to retain the moisture if mixed liberally with light fibrous loam. There are often portions of old roots and dead wood even in the best leaf mould, and these used in quantity are not conducive to strong root growth. For many purposes it may be employed, but I would omit it where food is required to support strong top growth.—G. W.

LARGE ONIONS.

I SHOULD be perfectly content to leave "Allium's" criticisms of my previous remarks respecting large Onions as seen now at certain shows, with the queries, Would such samples ever be grown unless wanted to gain prizes, and would they prove one half so useful or profitable for ordinary domestic uses as are what may be termed good bulbs from any ordinarily grown crop? But other matters arise from out of his criticisms, especially as to the keeping or non-keeping properties of these giant bulbs. I should be very surprised to learn that, taking an average of seasons, 50 per cent. could be kept over till April for planting. No doubt big Onions will keep better this winter because they have had a season out of a hundred to mature in. That is, however, such an exception, that it is not worth while to lay special stress upon it. If these giant Onion growers would but give their impartial experience with them, I should be found in my estimate to be well within the mark. But I admit fully that for what may be called special purposes, as mentioned by Mr. Crump, these large Onions are mild and delicious when properly cooked and served. I have constantly advised the consumption of Onions, boiled and baked. But then what does it cost to produce such bulbs, and when we have got them, are they milder or more nutritious than are the Spanish and Portuguese Onions which

we can purchase so cheaply in every grocer's shop all through the winter? No one will suggest that; indeed, unless from 4d. to 6d. per bulb were obtained, having regard to the necessity for raising the plants in heat, for pricking them out into boxes or pans, housing them in frames, and then planting out in soil so enriched with manure, that the dressing is fully double that applied to soil for ordinary Onion crops. All this is very costly, and when these huge bulbs, usually grown in rows from 16 inches to 18 inches apart and from 10 inches to 12 inches apart in the rows, are got, they do not represent so heavy a crop as obtained from an ordinary bed where the rows are 12 inches apart and the bulbs average in the rows four to the foot run. An ordinary crop thus produced of clean, even bulbs may be the most profitable of any vegetable crop a given area can produce. Can so much be said of a crop of giant bulbs grown under what may not unfitly be described as artificial conditions? Now I do not at all quarrel with the plan of sowing seed under glass and thus raising Onion plants, and planting them out later into the open ground. It is old practice and well known, and especially so to escape both mildew and maggot attacks. I have frequently advised cottagers and allotment holders troubled with these Onion pests to adopt that practice. It has also long been well known that if young Onion plants be lifted carefully from the winter bed and be planted out with care thinly on good soil in the spring, very fine bulbs result. That, however, differs materially from the artificial practice adopted to secure these giant show bulbs, and it is a practice created entirely by the custom of giving prizes for the largest. I read with much interest the report of the recent Banbury show. I had just previously seen all the grand samples that Mr. F. Wilkins, of Inwood House Gardens, exhibited, and also saw where and how he grew them. But then I noticed in the report also that in all cases but one, the weights being given, the judgment as to the respective merits of the bulbs was given by the scales and not by the judges. Would "Allium" or anyone else favour from 2 lb. to 3 lb. Potatoes or Turnips or Tomatoes, or giant Carrots, Parsnips, Beet, or other roots? The production of these fine bulbs does, perhaps, help to improve a seed strain, but then it is obvious that fully as great good, if not more, can be produced by the hard selection for seed stock of the finest bulbs from an ordinary stock, and whilst of the former so many will decay, the latter at least will all keep. That there has been a gradual increase in the ordinary dimensions of Onions there can be no doubt, but many of the monsters of the show table do not cut such a tremendous figure under ordinary cultivation as I have seen frequently, and as was manifested at Chiswick this year under a most impartial trial. One thing to be deprecated with regard to the exhibition of these huge bulbs is that persons purchasing seed think that under ordinary culture similarly big bulbs will be produced, but they soon find their error.

A. D.

PREVENTION OF ONION MAGGOT.

RECENT communications that have appeared in THE GARDEN show a very imperfect acquaintance both with fly and maggot, and, so far as the former is concerned, still more imperfect ideas as to the prevention of its attack, although the note on page 309 should do much to make matters somewhat clearer. That certain localities are peculiarly subject to the fly, and *vice versa*, is evident, or how can it be possible to grow Onions year after year on the same piece of ground, taking annually first-rate crops quite free from maggot. Again, it cannot be too clearly pointed out that, so far as this particular pest is concerned, nothing dug in in autumn or forked in in spring into the plot of ground destined for the Onion crop in the way of lime, gas lime, soot, or ashes is of the slightest use. One might almost as well dress the root of any member of the Brassica family to prevent butterflies from settling

on the foliage. Again, another remedy propounded—careful thinning—sounds very strange in the ears of those who have been accustomed to hold a directly opposite opinion. I should think where the fly is troublesome, thinning had best be left severely alone in the hope that some of the plants at any rate may be saved. The able note on page 309 is of great service, even though it be in a negative form, as it proves that the pest in the chrysalis and grub state is impervious to the powder and liquid agencies therein mentioned. Knowing so much, therefore, and also that the immediate cause of the destruction of the crop is the deposit of eggs in the top of the Onion bulb by a fly, it is manifest that the only way of successfully combating the evil is to attack the fly, or rather to render the grass and that portion of the bulb above ground so distasteful to it, that it will leave this particular hunting ground for other spots. Here is the problem not yet satisfactorily solved—the best ingredient for the purpose, always remembering it must be something in no way interfering with or arresting the growth of the bulb, and the best way of applying the same. Experiments in this direction should be made in a garden where the crop has practically failed for several seasons and remedial measures thoroughly applied, that is, the entire portion of the Onion above ground must be thoroughly dewed over with the mixture, and in the event of showers washing it off, a second and third application given if necessary. The preparation most strongly recommended is compound quassia extract, 1 pint to 6 gallons of water. What we want to know, however, is, if this has had a thoroughly satisfactory trial; that is, if any given portion of a bed has been thus dressed, leaving other parts to take their chance. There would be no mistaking the completeness of such a trial, for there would be ample proof of the presence of the fly in great numbers, and a certain prospect of discovery as to whether the "doctored" grass was sufficiently distasteful to prevent the deposit of eggs.—E. BURRELL, *Claremont*.

—"W. P. R." in his notes on my article on the "Onion Fly," says he was not aware that the pupæ of the said fly "had a relish for Cabbage roots." Neither was I, or rather that in this stage it fed upon anything, being torpid throughout the whole of this period. As both the Onion and Cabbage fly are two closely allied species, I should not be surprised that during the grub or feeding stage it feeds upon other subjects. For this reason, and as a precaution, I advocate the practice of cleaning away any material that the grubs, or rather pupæ, are likely to harbour in. According to good authorities, the pupæ do harbour in the ground as well as in the trimmings and refuse of the stored Onions, which should also be cleared away and burned, not be dug in, whatever crop was intended to follow. It is usual to see such material with Cabbage and other refuse taken to a heap to decay, if not dug in at the time, to be afterwards wheeled back and dug in. Much as I favour "green manuring," I should never think of wheeling back garden refuse of this description if root-eating insects were known from previous experience to have destroyed crops. If the pupæ harbour in the plot previously cleared of Onions, it should prove easier still to effect a clearance, giving a dressing of gas-lime to this particular plot. It is likely that freshly slaked lime and soot will not destroy the grubs when in an active state; they evidently showed their dislike to it. Now it is from their dislike for the presence of soot and lime that I advocate their application to grub infested soils. The syringing with well-diluted petroleum which I recommended was not supposed to kill the grubs, but as a preventive against the flies settling to deposit their eggs, just the same as Celery is dusted with soot and syringed for the same object, viz. to make the foliage obnoxious, and this should be at the period just before the fly emerges from the pupæ stage. But as two or three generations occur throughout the summer, this would also have to be done at intervals. "W. P. R." has evidently experimented in a wrong way, or he would not write so positively that he has tried all the

remedies or precautions I recommend and failed. One might just as well say that it is impossible to keep fruit trees free from the attacks of insects.—A. Y.

Use of Cucumber frame (Beginner).—A two-light frame may be used for various purposes during the winter. For forcing, as "Beginner" has plenty of stable manure, Seakale, Rhubarb, or Asparagus can be forced regularly, taking care not to overheat the frame, but to mix sufficient leaves with the manure to keep up a steady temperature. It is late to strike cuttings of soft-wooded plants, as these would not winter in such a structure. I would advise lifting old plants and housing till early spring. Then a good use could be made of the frame with plenty of heat at command, as the tops of Abutilon would strike readily. The frame may now be utilised to strike such cuttings as tufted Pansies, Calceolarias, Pentstemons, Antirrhinums, but not with bottom-heat, as these root freely in a sandy soil on a firm bottom. There are other uses such as wintering half-hardy plants, the choicer Echeverias, Cannas, Fuchsias and Francoas. Bulbs for early bloom all do better with frame treatment whilst making root growth, also to protect from frost. The more tender Carnations require shelter in frames; indeed many things may be placed there.—G. W.

PARIS MARKET BRUSSELS SPROUTS.

I HAVE this season heard of breadths of Brussels Sprouts failing to produce sprouts, and such failures are more common with the larger kinds than the dwarf or medium growers. For small, hard, and compact sprouts I rely upon this kind, which is of far better quality than the coarse growers. This season our quarter of this vegetable does not show to such advantage as in more favourable seasons, the growth being more irregular and taller, but good, hard, firm sprouts are plentiful. The season has been unfavourable for vegetables requiring abundance of moisture, especially in light or gravelly soils, this being to a great extent the reason why solid sprouts are not abundant. A check was given during the growing season. Those who grow this vegetable on heavy land were better able to keep the crop growing during the drought. It is on light land that failure is experienced. During the hot weather a thorough soaking with a hose for several hours once a week kept them growing; but even then failures would arise if early planting, giving ample space and deep cultivation, had not been resorted to. I do not like the large sprouts. They are never of such good flavour when cooked. After a trial of most kinds I like the Paris Market best. Coarse kinds are also not so hardy as the smaller, and they run much sooner. Our second sowing of seed of this variety was made early in March in the open ground, and the plants are now very promising. These are utilised for the late supply. They are very dwarf, not more than 2 feet in height, and feathered to the ground with foliage, which is a great protection in severe weather. Sowing seed in frames in February results in a long supply, so that by these two sowings good sprouts may be had for six months in the year. Formerly I grew a good breadth of the imported seed, but one cannot depend upon it, the plants varying both in size and quality. Paris Market is very productive, and to get the best results good cultivation and change of ground yearly should be given. G. WYTHES.

Eulalia gracillima univittata.—As I think it desirable that all plants should be, if possible, correctly named, I write to inform your correspondent "H. P." that the graceful Grass he so accurately and appreciatively describes on p. 323 of your last issue can no longer bear the somewhat lengthy name above mentioned, by which it has been hitherto generally known. It has been for some time doubted at Kew whether this Grass was a *Eulalia* at all, but it could not be accurately

ascertained whether it was so or not till it matured its panicle of inflorescence, which this fine summer has enabled it to do. This inflorescence having been critically examined and compared by the learned graminologist, Dr. Stapf (assistant for India in the Kew Herbarium), he has pronounced its correct name to be *Miscanthus sinensis*, under which name it is figured on plate 7304 of the number for July of the *Botanical Magazine*, to which all careful lovers of plants should refer for further details and botanical particulars. This Grass is a native of both China and Japan, and has been described by various botanists under the synonyms of *Erianthus japonicus*, *Ripidium japonicum*, *Saccharum japonicum*, and *S. polydactylon*, but Hackel, the latest and best authority on the andropogoneous Grasses, is responsible for its present name.—W. E. GUMBLETON.

STOVE AND GREENHOUSE.

PLUMBAGO CAPENSIS.

THIS easily cultivated plant should not need any recommendation; its rapid growth and

Cape Leadwort (*Plumbago capensis*).

lovely pale blue trusses of flower should alone be sufficient in this respect. Yet it is not seen nearly so often as one could wish, being in large establishments even often more conspicuous by its absence, or, if present, not always in the best possible condition. There are certain conditions to be observed in order to ensure the best results. It should first of

all be noted that this species is an introduction from the Cape of Good Hope (hence its name); it may therefore be fairly surmised that plenty of sunshine and not too much atmospheric moisture are essential points to be noted. That these are facts have been proved over and over again, for if at all shaded the growth is inclined to be weakly with less disposition to flower, and if grown in too moist an atmosphere the growth will be far in excess of all needed requirements. If the plant be grown in the open border of a light cool house, to which there is no objection, the soil should not be too rich or of a great depth; it should consist for the greater part of light loam and road grit or sand, and this should be made as firm as possible. In pots the same soil will suit well with a little peat added thereto. The sunniest spot, even in a light house, should be chosen for its culture, and as far as is practicable freedom of growth should be allowed, close pruning being the rule during the resting period, and that well in advance of the starting into activity again. To tie in the shoots as they grow for the sake of trimness is utterly wrong and out of all character; only just sufficient of this kind of work should be allowed to keep the shoots from breaking down with their own weight. If it is seen that the growth is too free, of which there is more danger than the reverse, then less water should be given for a time; this will have the desired effect of producing flower trusses plentifully in due course. As a bedding plant *Plumbago capensis* is admirably suited. If grown as standards in 10-inch or 12-inch pots and plunged the effect is excellent, sufficient room being allowed for an appropriate undergrowth. Smaller plants can be planted *en masse* with good effect, and taller ones of long rambling growth will be quite at home when trained against walls or verandahs in sunny positions. In a cut state the flowers quickly fade, and are in nearly every case disappointing. H. G.

Dipladenia atropurpurea.—This is a fine species now flowering in Mr. Sander's establishment at St. Albans. It is a companion plant for the delicate *D. boliviensis*, but it is more free blooming than the white-flowered plant just named. This plant produces large trusses of blooms. In that now before me there are some fifteen buds, which before opening are of a bright crimson, but when the petals are unfolded they are of a deep velvety maroon. I hope to see this plant become plentiful in our plant stoves, its colour being so rich and charming.—W. H. G.

Abutilon Anderken An Bonn.—This *Abutilon*, which was alluded to on p. 296, was shown in good condition at a meeting of the Royal Horticultural Society on April 25, when an award of merit was given to it under the title of *Souvenir de Bonn*. It is a good free-growing variety, and will doubtless be useful where the mixed style of summer bedding is carried out. The creamy white margin to the leaf is clearly defined and very constant. I have also seen a second new variegated *Abutilon* during the present season, viz., a variety of the showy-flowered *A. igneum*, or *insigne*. In this the large leaves are marked with varying shades of green and yellow, arranged in a tessellated manner somewhat in the way of the older *A. Darwini tessellatum*. *Abutilon igneum* is better treated as a roof plant than as an outdoor subject, as it needs a little more heat than most of the others, and consequently its variegated variety is hardly likely to be so useful as *Souvenir de Bonn*.—H. P.

Tecoma Smithi.—There are very few, if any, greenhouse plants introduced within recent years which promise to be so useful as this. The plant is a hybrid of Australian origin, its parents being *T. venusta* and *T. capensis*. It has been in culti-

vation at Kew for two or three years, and since its first flowering there has been regarded as a valuable new plant, but it is finer this autumn than we have seen it before. Some half dozen or so plants are now in flower on the shelves of the temperate house, and they give a singularly bright and pleasing effect. The racemes are terminal and carry from twenty-five to thirty flowers, these being tubular, 2 inches long, and of a bright yellow, tinged with orange; the whole inflorescence is a dense cluster of flowers 6 inches high. The method of culture adopted is one which has been recommended in these pages for *T. capensis*. The cuttings should be taken as early as possible and struck in moderate heat, growing the young plants on in an intermediate temperature and treating them liberally until June or July, when after hardening off a little they are stood out-of-doors in full sunshine. For the first year at any rate the plants should be restricted to a single stem, which will be no more than from a foot to 18 inches high, and, therefore, of a convenient size for the shelves.—B.

SPRING-FLOWERING BULBS IN POTS.

A VERY great point in the pot culture of Hyacinths and other bulbs is often overlooked, namely, a good supply of roots before placing them in a forcing house, or otherwise putting them under glass to flower. To ensure success this is absolutely indispensable. We often hear blame cast upon those who sell the bulbs when really the grower was at fault. I have noticed persons potting up such bulbs as Hyacinths and Tulips and at once standing the same in a forcing pit, with the result that they either rotted or refused to flower in anything like a perfect manner. Therefore, it is necessary that the bulbs named, with Narcissi, which are not the least important among spring-flowering subjects, should be potted without delay, and a lengthy season be thereby given to become well rooted previous to coming into bloom. Hyacinths, &c., like a rich, open compost. That employed by me is made by well mixing the following proportions. One bushel of loam, half a bushel of cow manure well rotted, and a like quantity of road sweepings. Bulbous plants are very partial to the latter gritty material. A 5-inch potful of soot may be added to the above quantity of soil with capital effect. The soil should be allowed to become in a nice workable condition, that is, if at all inclined to be pasty, it may be turned in the sun to dry, and if very dry, water should be sprinkled on it whilst being mixed. The size of pot used for one Hyacinth bulb is the popular 4½-inch or 5-inch. This is not only a convenient size, but I think quite large enough even for exhibition. The spikes of bloom can be made to look larger if the pots be put into others of greater size. This is the mode adopted by those who show these spring bulbs publicly. Three Hyacinths placed in an 8-inch pot answer well for conservatory decoration. Tulips for exhibition are generally grown three bulbs in a pot. When this number is not stipulated and for other purposes, I much prefer five in a 6-inch pot, or seven in an 8-inch size. But for the decoration of vases in rooms three or four bulbs are placed in the smaller 4½-inch pot because of its convenience. In the case of Narcissi the bulbs are put into the pots as thickly as possible. Sometimes three bulbs of the Polyanthus kinds are sufficiently large to fill one of 6-inch diameter. When potting use one good crock over the hole and then a portion of the rough part of the compost, and fill the pot so that about half of the bulb is on the surface. Do not fill the pot with soil and then push the bulbs into it, but make a hole to receive the same with the fingers, and press the

soil firmly around them. If the former be done the compost is too firm, and when roots are made they sometimes push the bulb out of place, when injury to it becomes easy.

I prefer after potting to stand them on a firm bottom really out of doors, but in frames, so that the lights may be readily put on in the case of continued wet weather, when there is a likelihood of the soil getting soddened. It is a good plan to put a small pot inverted over the bulb of each Hyacinth. This will keep the bloom-spike clean and often prevent its rotting, but with Tulips and Narcissi such a precaution is not necessary, as these are not so ready to show bloom before leaves. Cover the whole with about 4 inches of cocoa-nut fibre or sand. Do not on any account use ashes. Sulphurous matter resting in these may be the cause of utter failure. With the exception named of covering with glass, or for that matter anything to ward off excessive rain, the bulbs should remain in the dark until the end of the year. This does not, of course, apply to the early Roman among Hyacinths, the Paper-white among Narcissi, or Tulip Duc van Thol of that ilk, which may be had in flower before that time, but to the general list of varieties, which are much better if not forced into bloom by the aid of fire-heat. In January, then, take the pots from their covering and put them in other cool frames, but inure them to the light and air in a gradual manner, and in the meantime carefully protect them from frost. When the young growths are well used to these, the pots may be stood on greenhouse shelves as near as possible to the glass where abundance of air may reach them and where the temperature is kept between 40° and 50°. In this position the leaves will be sturdy. Water, which up to this time has not been needed, not even when the bulbs were first potted, may now be given if the soil is at all dry; but although Hyacinths, for instance, develop in water alone, it must be sparingly given when the roots are in soil and there is little top-growth. As the growth gets larger, there will be greater calls for moisture, and when the blooms show, it is not an easy matter to over-water Tulips or Narcissi. From the time the flowers show colour, give the plants manure water. If treated as advised, there will be abundance of roots and they will be in a condition to respond to feeding. Sulphate of ammonia used at the rate of an oz. to three gallons of water may be employed with safety and is a first-rate stimulant, so also is soot-water. Well-grown Hyacinths, Tulips or Narcissi should have short sturdy foliage with the bloom thrown well above it. I give the names of a few of the most esteemed sorts. Hyacinths: Koh-i-noor, Macaulay, Von Schiller, Roi des Belges, Moreno, Vuurbaak, shades of red; La Grandesse, Mont Blanc, Princess Amelia, white; Czar Peter, Queen of Blues, Grand Maître, King of Blues, shades of blue; Ida, yellow. Tulips: Proserpine, rose; Keizer Kroon, scarlet and yellow; Ophir d'Or, yellow; Joost van Vondel, crimson and white; Joost van Vondel, pure white variety; Vermilion Brilliant, scarlet; Van der Neer, purple; Duchesse de Parme, bronze and yellow. Narcissi: Empress, Horsfieldi, Emperor, Sir Watkin, Golden Spur, Orange Phoenix, Sulphur Phoenix, Barri conspicuus. Polyanthus varieties: Bazelman major, Her Majesty, Grand Monarque, Newton, Gloriosa. H. S.

Cordylone (*Dracæna*) indivisa.—Although the plant itself is very little known in gardens, this name is quite a familiar one to horticulturists. This is mainly through its having been

applied to the wrong plant. The true *C. indivisa* is very rare and quite distinct from the variety of the well-known *C. australis* which figures so frequently under this name. I saw the other day, planted out in Mr. Rashleigh's garden at Menabilly, Cornwall, two remarkably fine specimens of the true thing. The largest of these is 9 feet high, and its effectiveness in the outdoor garden may be imagined from the fact that each of its leaves is 3 feet 6 inches long and 6 inches wide at the middle, tapering thence to a long fine point. They are, therefore, much larger than any of the forms of *C. australis*, and are besides very distinct in the markedly glaucous tint on the upper surface. Unfortunately, neither of these *Cordylines* is hardy near London—in ordinary situations at any rate—but in the gardens of South Cornwall *C. australis* makes a common and very striking feature. In these gardens and in the greenhouses of less favoured localities *C. indivisa* deserves to be better known.—B.

Gomphocarpus sinaicus out of flower appears identical with the better-known *G. fruticosus*, and when in bloom so nearly approaches it, that it may be readily taken for a seminal variety, but, as the name implies, it comes from quite another part of the world. The flowers, instead of being wholly greenish white, as in *G. fruticosus*, have the disc stained with purple. The inflated seed vessels of each are exactly alike. It is worth while to grow them side by side, as both are ornamental greenhouse shrubs.—J. M., Charmouth, Dorset.

THE HIPPEASTRUM.

It is very interesting to a student of the life-history of any plant to carefully note the changes of growth through the growing and flowering period and from the time the flowers fade until the growth is fully matured again. The *Hippeastrum* is a singularly interesting genus of plants, and the rapidity of growth and development of the flower-scapes in spring are certainly very interesting to the cultivator. The bulbs when well grown are plump and heavy at the time of repotting, and remain so until the flower-scapes appear, when they shrink up gradually, and continue to do so until little else is left but the skin and internal tissue, the fleshy portion having gone to make up the scape and leaves, for those that produce no scapes are also liable to shrinkage. This period is the half of the season's growth, and when the flowers are fully developed the bulbs are a mere wreck of what they used to be. It is at this point that there is danger of the plants being put aside and not receiving so much attention as they ought to have. A plant out of bloom with long leaves flopping about is supposed not to be an object of beauty, and it is pushed into some corner as much out of sight as possible. There is an old saying, and in most cases it is a true one, that out of sight is out of mind, and the plants are neglected at the very time the bulbs ought to be plumping up for next season's bloom. As soon as the flowering period is over, my plan is to place the plants in a bed of spent tan, with the flower pots in which they are growing plunged over the rims. I believe M. de Graaf, of Leyden, was the first to grow the *Hippeastrum* in this way. I saw them growing in a span-roofed house there with greater vigour than I ever remember to have seen them. The tan seems to be best adapted for the purpose after it has been used for a year to plunge other plants in, and the little bottom-heat they require is obtained by hot-water pipes under the bed. The plants make fresh roots very rapidly. The roots run over the rims of the pots into the bed of tan, and seem to obtain a great deal of nourishment from it. The bulbs which were so utterly exhausted now rapidly fill up again, and if they do well increase greatly in size. If seed is obtained from the plants, it exhausts them a little, and may be the means of preventing the flowering of some of them next year, but it does not do so to a great extent. A well-grown collection of plants should produce such bulbs that 90 per cent. or more of them would flower next year, but this success can

only be attained by careful attention to the plants from April until their resting period, which has now commenced. It is necessary to be even more careful in the watering, keeping the plants clean, damping down and shading the house, than during the early stages of growth when the flowers are in course of development. Water must now be altogether withheld, and when the leaves become flaccid they may be cut off; it is not necessary to wait until they quite decay. The seed ripens about the end of July or early in August, and should be sown at once in a hothouse, and if bottom heat can be afforded, the seeds will vegetate more readily, and the plants push ahead more rapidly afterwards. As soon as they are large enough to be pricked out this can be done. About a dozen plants in a 5-inch or 6-inch flowering pot will give them enough space until the end of the season, but with good management they will make nice bulbs, and it is a characteristic of the seedlings that the leaves remain in quite a green state all through the winter. They must not receive a very great deal of water, and should be kept in a warm greenhouse temperature until January or early in February, when they can be turned out of the flower-pots, the roots carefully disentangled, and the plants repotted this time three only in the same sized pots. If these are plunged in bottom heat and the temperature of the house kept at 55° as a minimum to start with, growth will be very rapid. The flowers of these plants are very easily fertilised, and large numbers of the seedlings have a tendency to produce flowers as good and sometimes better than the parents. This being so, it may well be supposed that many beautiful varieties far surpassing those of ten years ago or less have been raised.

The fully developed flowering bulbs either of seedlings or named varieties should now be quite at rest. Let the ventilators of the greenhouse be quite open by day, but it is getting damp and sometimes very cold at night, so that it is necessary to be careful that they are not exposed either to the one or the other. It is as well to leave them in the tan just as they are until the end of the year, when they may be taken out and examined, removing all the decayed material from the crown of the bulbs. Nestling securely in this decayed outer coating may be bug or thrips, and when it is removed give a good dusting of tobacco powder. This is a necessary precaution, for it is far better to make sure that there are no chances of any parasites remaining after the bulbs have been repotted and started into growth again for another season. The operation of repotting should be done from the middle to the end of January. I have the bed prepared for them a week or ten days previous, so that there is a mild bottom-heat to plunge them in as they are repotted. At this time the pots are plunged as deep as the rims, but not over them. The temperature of the house ought not to exceed 50° at night for the first three weeks or so, and no water should be given to them for even a longer period than that, as water applied before the roots have made some growth is injurious, causing the base of the bulbs to rot sometimes. Do not over-pot. This is easily done. Some growers anxious to excel will place a bulb in an 8-inch or 9-inch pot that would do much better in a 6-inch or 7-inch one. Drain the pots well so that there may be no stagnant water. A good potting soil is composed of two parts loam to one of leaf-mould, and some good fibrous peat is an excellent addition. A barrow-load of decayed manure should be added to four barrow-loads of the loam, and an addition of coarse white sand to keep the compost open.

J. DOUGLAS.

Salvia splendens var. compacta.—There are very few plants more useful for brightening up the greenhouse in the rather dull time which precedes the Chrysanthemum season than the old *Salvia splendens*. Its scarlet racemes are very bright. There are several forms of it in cultivation differing not so much in flower as in habit, and the one which is best adapted for flowering on the shelves is the variety *compacta*. A batch of

well-grown plants is now making quite a brilliant show in the temperate house at Kew. They are about 18 inches high, but more in diameter, and being covered with bloom, form quite fiery globes of colour. The ordinary form of *Salvia splendens* is useful for standing on the ground level. The species is a native of Brazil, and was first introduced to cultivation seventy years ago. The variety here noted is of garden origin, and probably originated in the south of France, where this and most of the *Salvias* are grown permanently in the open.—B.

Primula obconica.—In "A. D.'s" note on this plant (p. 327) he alludes to it as having been successfully cross-fertilised with other *Primulas*. This may be so, but all the distinctive points noted by your correspondent may be found in any batch of seedlings raised from an ordinary packet of seed, or from home-saved seed which has been subjected to no attempts at cross-fertilisation. I raise a batch of seedlings every year, as I find that seedlings make healthier plants than divided pieces, and the variation in size, colour and form of the flowers is great, the lemon eye with a flush of crimson surrounding it being by no means uncommon. I have never yet been able to see the slightest departure from the normal type of leafage, as one might expect to see if cross-fertilisation had been effected with such a different type of plant as the Chinese *Primula*. I should imagine that *P. cortusoides* would be a good plant with which to work in conjunction with *P. obconica* in any attempts at crossing, as the former possibly might impart the necessary colour to the flowers, which now are somewhat dull, without spoiling the neat habit of the plant.—J. C. TALLACK.

THE EUCHARIS.

At a recent meeting of the R.H.S. at Westminster, Mr. Iggulden read an interesting paper on the *Eucharis*. My object in sending this note is to point out the excellence of the paper as showing that the mite is not so much the cause of failure as bad culture. Mr. Iggulden's remedy in the long run was high culture and no coddling—an excellent one. A few years ago I had two old rather flat-roofed Pine stoves filled to overflowing with *Eucharis* in the luxuriant condition referred to by Mr. Iggulden and was frequently asked how they were grown. The answer was by letting them alone and allowing them to remain in one place. This latter point is a strong one in the paper referred to. This I consider sound advice, as a few years later a larger house or plant stove was considered a better place to show the proportions of such fine masses in 18-inch and 20-inch pots, and the old despised pits were used for other purposes. A greater mistake was never made. There are now no *Eucharis* plants worth the name, and this failure is attributed to the mite; whereas it is quite the reverse. Another point is to pay careful attention to the watering. In our young days most of us remember how carefully the hard-wooded plants were attended to as regards watering, and my opinion is that the *Eucharis* requires equal care in watering as in temperature and to be kept like an *Erica*, always moving, with partial rest at certain seasons when growth is complete. This rest is effected by lowering the temperature and giving less water. Another matter of equal importance is cleanliness. How often do we see the *Eucharis* under other plants and the dirt from the roof plants daily washed down into the bulbs. I also consider excessive overhead syringing most injurious and the forerunner of disease. Keeping the surface on which the pots stand damp and syringing under the foliage are of greater benefit than syringing overhead. Mr. Iggulden does not advise a low winter temperature, but

it all depends upon the quantity of roots and the use of the water-pot, as I wintered very fine plants for years in a night temperature of 50° to 55° and could not wish for better results. These were, however, large masses full of roots and in a dry house. Another point is pure water, as I believe there are few plants more fastidious as to purity of water and free drainage. Shade is also an important matter and one overlooked. I do not think the plants will thrive long without shade; indeed, I believe in partial shade especially from the bright light of a modern house, as I found they did best where a piece of tiffany covered the plants as a permanent summer shade, a heavier shade during bright sunshine being added. I also have a great liking for charcoal in the soil, no matter whether light or heavy, as it prevents clogging—so injurious to the fleshy roots. I am sure such papers as Mr. Iggulden's will go a long way to re-establish these beautiful plants and bring them into favour. I, like many others, feel sure superior culture is the best remedy, and am delighted that we are not advised to try more of the many remedies so freely prescribed by some for the ills this plant is subject to.

G. WYTHES.

THE FRUITING OF CYCAS REVOLUTA.

The plant in question of *Cycas revoluta* is the female variety, the fruiting of which is not of common occurrence until the plants have attained age, and then only periodically. By the description given by "W. A. G." the crown of flowers is a fine one, being the result of good culture. The berries are usually of an orange-scarlet colour, almost hidden from view by the downy bracts on which they are placed. These will be useless for purposes of seed-sowing without the presence of the male parent for fertilisation. They may be removed, however, and utilised for decorative arrangements in a dry state, lasting thus for a length of time. The plant will not come to any harm or be weakened by this occurrence if it be in a healthy state at the root, less effort even being required to develop the flower than in the case of a dense crown of young foliage. The plant under notice not having made any leaf growth for two years will in all probability do so next season. In order to encourage this result, it would be better to keep the plant on the dry side, but little water being given through the winter. Then with the approach of warmer weather in the spring it should be transferred to a house with a higher temperature and a moist atmosphere. This change usually has the desired result of inducing leaf-development in course of time. I once had a very fine specimen which flowered in similar fashion, and not the slightest harm came to the plant. That season it stood out of doors until the late autumn, when the flower-heads were removed and the plant housed. It is possible that the foliage will become a trifle faded-looking, but this is only the result of age provided the roots are healthy. In this case I should advise the removal of the flower-heads at once if fully grown and matured, and then, as aforesaid, let the plant have a good rest. In the spring if the plant has not been recently potted, it will be just as well to give it this attention prior to a young growth appearing. The plant will, presumably, be already of specimen size and in a good-sized pot or tub; if this be so, the old ball should be carefully reduced by the removal of all loose soil and unhealthy-looking roots, so as to admit of a fair amount of good fresh compost. This should consist chiefly of turfy loam with a little rough peat, the potting being done in a sound, firm, and enduring manner.

CYCAD.

The weather in West Herts.—A very warm week, particularly at night. On Monday the highest temperature in shade was 66°. On Satur-

day night the thermometer exposed on the lawn did not fall lower than 55°. This is the highest reading yet registered by this thermometer in October during the eight years over which my observations extend. At both 1 foot and 2 feet deep the temperature of the ground now stands at 55°. At the same date last year it was 6° colder at the depth of 2 feet, and as much as 9° colder at 1 foot deep. During the week about three-quarters of an inch of rain has fallen, bringing up the total for the month, as far as it has gone, to 3½ inches, or more than half an inch in excess of the October average. Of this quantity about 2½ inches has already come through the 2½ feet of soil in the percolation gauges—equivalent to about 10 gallons of water through every square yard of surface of uncropped ground.—E. M., *Berkhamsted*.

BOOKS.

ART OUT OF DOORS.*

THIS work is pleasantly and sensibly written; the main things necessary to be considered in creating, ordering and adapting a garden to a home thoughtfully enumerated. It is likewise in a handy form and not too long or elaborate for the many who do not wish to wade through long treatises before arriving at notions how best to set about arranging their grounds. As the authoress remarks, "good judgment in art is rare." She feels vividly that the importance of caring to have artistic gardens cannot be too strongly insisted on, and wishes to impress upon the general public that much more care should be taken to produce beautiful pictures even in the smallest plot which the owner has destined to hold his cherished plants than is usually done. One feels how much is required in this way when passing through the suburbs of London, or of, indeed, any place, the little spaces at command being commonly choked with the most unsuitable trees possible, not only rendering the individual garden unsightly, but spoiling the general effect of the thoroughfare at the side of which they are situated. At page 16 she says:—

The true artist will not go about with a store of ready-made features and effects in his mind, and strive to fit some of them into the task of the moment as best he may. He will conceive his general idea in deference to the local commands of Nature, develop his general scheme as artistic fitness counsels, discover the special features which are needed to complete it (considering which Nature will permit among those he might desire), and then half unconsciously perhaps search for memories of natural results which may teach him how to achieve his own.

Among the many who are fond of Nature, gardens, and flowers, how rare is it to find people who have a

taste at all analogous to what we understand by a taste for art, *i.e.*, an appreciation of organised beauty, a love for the charm of contrasting, yet harmonising, lines and masses, colours, lights and shadows, a delight in intelligent design, in details subordinated to a coherent general effect. Yet it is only such a taste as this which means a real feeling for Nature's beauty, and which can make the surroundings of our homes really beautiful (page 30).

Mrs. Van Rensselaer quotes Ruskin's definition of a good composition as one in which every detail helps the general beauty of effect, and says "that it may also be defined conversely as one which brings out the highest beauty of each of its details."

It is indeed difficult to attain the "vision of an artist" in gardening as in every other art,

* "Art Out of Doors." By Mrs. Schuyler van Rensselaer. New York: Charles Scribner's Sons, 1893.

but this book does a beneficial thing in endeavouring to bring home to us that we should aim at it. I think she hardly does the author whose work she quotes the justice he deserves for his well-known and strongly reiterated opinion, that a garden should always be laid out in keeping with the house, and that the plants in it should be of a kind that their right association will make a beautiful whole, when she says (p. 58) that his decision,

that the true use and reason of the home grounds is "to grow for us plants not in our woods and mostly from other countries than our own," is a very mistaken one.

The author whom she quotes said this truly, but much more also, and has strenuously insisted frequently and emphatically on harmonising the house and grounds as the great point to be kept in view.

The authoress points out usefully, how trebly needful is the planter's aid when a house stands on a flat site to prevent it having a casual, inconsequent air, like a box standing upon a floor; likewise that a house should never stand on a line of empty earth which causes the want of harmony with its surroundings to be painfully apparent, and also very rightly animadverts on the too lavish use in the present day of the striped, speckled, blotched and golden curiosities and novelties of the nursery gardens. I cordially agree with her in disapproving entirely of the ungraceful and uninteresting fashion of surrounding masses of shrubs with rows of plants. Nothing can be prettier than here and there stealing in groups of such things as *Bocconia*, *Spirea*, *Delphinium*, or *Anemone japonica* in front of shrubs, but in some of our own public parks we see them throttled with stripes of inharmonious stiff *Pelargoniums* and other bedding plants instead of their own sprays feathering on the grass. A suggestive and well-described account is given (p. 151) of French flower beds on the site of the old Tuilleries, and how preferable they are to brilliant, formal, and stiff bedding on lawns, and how far more artistic in many situations than the clipped pattern bed could be, as showing more variety in detail, while general harmony is well preserved. "The true lover of plants," she notes, "should prefer them, for they allow their furnishings to grow in free development." Sound advice is given (p. 175) as to the treatment of villa gardens and the disfigurement so often caused by

a greedy love for conspicuous plants as such and bits of grass splashed with chrome-like flower beds, the result being that the unity which alone can give relief and value to variety has been entirely lost. The garden has no coherence, no character; it is a place in which plants are grown, but not a place which as a whole makes any impression upon the eye, except to confuse and pain it.

It may also be well to quote page 187.

We shall never be well served by theories that this style is right and this is wrong; that one method of treatment or one kind of feature is beautiful, and other methods, other features are *is* artistic. We shall be well served only by good sense, taking account of particular local facts, and based upon principles which themselves are based upon the same great laws that direct intelligent effort in all the other arts. Simplicity, harmony, appropriateness, variety in unity—clear expressions of clearly conceived and fitting schemes.

In the chapter on architecture, it seems wonderful that now in this century it should still be necessary to dwell on the wrongness of false rusticity, *i.e.*, rough barbaric work suitable for a woody glen being employed in the polished precincts of an urban park, as it appears has been done at Boston. Mrs. V. R. also alludes

to the draping of gateways, not to disturb the rural effect, this again to be noted as false, since their eminently artificial character cannot be disguised, and to cover them with foliage is to sacrifice art and appropriateness to an unattainable end. Thus she adds

that while the art which really conceals art may be great, the art which tries to conceal what cannot be concealed is always mistaken.

In the chapter on trees, she observes how much more care is needed at the present time in forming plantations, as we have a far more varied store from which to select than in past centuries, and consequently it is much easier to make glaring mistakes. To quote again—

Taste is the guide we need, and taste means the cultivation of our own perceptive powers, not the learning of cut-and-dried formulas. To study art as a preparation for the study and appreciation of Nature may seem at first thought a reversal of the right order of things. But it is a very wise thing to do. If a painter were never anything more than a mere recorder of natural facts, a mere reporter, in prosaic speech, of things actually seen in this spot or that, his results would still be of service, enlarging our field of observation by the addition of his field, and preserving for constant examination effects which are transitory in Nature. . . . He has at his command the power to preserve general truth of effect, and yet accentuate certain special truths more forcibly than, to our eyes, Nature has presented them. . . . They should be consulted as stimulants and explanations, as cultivators of taste, as teachers of what is meant by beautiful associations, by strong or graceful contours, by effective or subtle contrasts of light and shadow, by satisfactory contrasts of textures, by variety in unity, by diversity in harmony, by dignity, breadth, simplicity, repose, and charm. . . . These are the things we must learn in advance of any planting if we are to make a work of art of our result.

On one point I do not agree with the authoress, namely, her dislike of the Weeping Willow and her notion that hardly any place where it can be put will have its beauty enhanced by its presence. In my estimation its appearance is superior to that of the Weeping Beech, which she prefers to it.

In the chapter on books, Mrs. V. R. makes some sensible remarks on the pleasure and use of even a smattering of botanical knowledge, as helping to put us on friendly terms with Nature in her gardening work and landscape painting. M.

The Shrubs of N.-E. America.*—This is an American book on a very interesting subject, illustrated with outline drawings, and very useful ones, of the plants talked of, but the printing is very large and open and done in a most "bumped-out" way, as if the object were to make the book as large as possible; there is often nearly half an inch of space between the description of the leaves and that of the flowers. We think we have never seen so great a waste of space in a book; notwithstanding which and the fact that it is well printed, the type is all so open, that one cannot easily get at the individual names. The author follows what we think the evil way of European writers, of giving precedence to technical details, such as the flower, and saying very little about the general aspect of the thing, its size, uses, beauty, &c. In fact, however botanically correct, it is made as dry as possible, and we think without reason. The author appears to have written another book on the trees of North-eastern America, but as it is often so difficult to separate trees from shrubs, it would be much more reasonable to treat of all in one book. In our own country in some cases, and no doubt

* "The Shrubs of North-eastern America." By Charles S. Newhall. G. P. Putnam's Sons, 27, West Twenty-third Street, N.Y., and 21, Bedford Street, Strand.

also in America, a shrub in one part of the country may in more favourable conditions deserve the name of a tree.

PUBLIC GARDENS.

PRUNING LONDON TREES.

If Colonel Bushe, who writes to the *Times* advising the pruning of London trees, is open to reason, he will find proof enough in the streets and squares of London against pruning. A walk to Berkeley Square and then down the Mall in St. James's Park, where the wretched trees are disfigured by pruning, would convert him. If people are so unwise as to put very big trees in very little streets, in time they must lop them; but in our regions it is a mistake to put trees in narrow streets. There is reason for pruning in certain cases, but not for the pruning of forest trees, even when these are grown in towns. When a man gets the pruning-hook in his hand to deal with these, he generally puts his reason to bed. In our own day we have trees of all sizes for street and every other purpose of planting, and both from a cultural and artistic point of view it is best to leave them with the forms that heaven gave them. That there is a need of "regulating the height and giving the necessary symmetry and formality of shape which are best adapted to their purely abnormal and artificial conditions of cultivation," as expressed by Colonel Bushe, is a delusion of his own, and we hope of only a few others, because anyone who takes the trouble to look at the trees in Gray's Inn and some of the west central squares, and also many parts of the parks, where they are let alone, will see plenty of proof that there is no such necessity.

LONDON TREES.

ON page 338 of THE GARDEN you published an interesting letter from Mr. W. Paul as to the varieties of trees suited to London. There is, however, an important question not touched upon, and that is the way that trees, of whatever varieties, should be planted in streets. In our damp climate we want light and air, and, much as the planting of trees is to be desired in London, they will become simply nuisances if they are to be planted close against the houses on the skimped pavements of our narrow streets. Let anyone who doubts this go and look at the Planes in Northumberland Avenue. This fine street is far too narrow for the height of the houses on each side, and when the Planes have had a few more years' growth, the place will be so dark that the trees will have to be cut down. A similar state of things exists elsewhere in London and other large English towns. It may do in the brighter and drier air of Paris, with broad pavements and broader streets, to plant trees close to the houses, but in England such a practice can only end in the removal of the trees. What is wanted is a totally different system, better for the trees, prettier in itself, and better for human beings subject to rheumatism and other ailments arising from damp. Let the trees be planted down the centres of the streets in a straight row, in narrow islands with curbed edges, and with frequent openings to let wheel traffic through. The effect say in Portland Place, which is a fine broad street, of a row of trees planted in this way would be very fine. The trees would have light and air all round, and they would not grow in the lopsided way which is inevitable when they are placed against houses. The dwellers in Portland Place would have pleasanter things to look on than the bricks of their opposite neighbours, and the trees could be varied by many suitable sorts being planted.

J. I. R.

Metropolitan Public Gardens Association.—At the monthly meeting, the Earl of Meath,

chairman, presiding, a letter was read from H.H. the Maharajah of Bhavnagar, enclosing a donation of £21. It was reported that the association had completed and opened Goldsmith Square, Shore-ditch, and St. Olave's Churchyard, Silver Street, E.C., and that the Duke of Westminster had kindly consented to prolong the summer opening of Lower Grosvenor Gardens, S.W. It was agreed to offer seats for certain roads in Dalston, Deptford, Stamford Hill, and for St. Peter's Churchyard, in Upper Thames Street, to offer assistance in the acquisition of some additional land adjoining Barnes Common, and to contribute £200 towards the laying out of a plot of land near Gloucester Road, provided it were secured as an open space. Progress was reported in the laying out of Victoria Park Cemetery and in the negotiations being carried on with the object of securing several new gardens and playgrounds in Walworth, Deptford, and Bethnal Green. The secretary stated that the association had erected a covered shelter on Wandsworth Common, with funds provided by one of its members, that £1000 had been received from another member towards the formation of a riverside space in Battersea; that the Earl of Meath, the chairman, had presided at a meeting in West Hampstead in favour of acquiring St. Mary's Fields, about eight acres in extent, as a recreation ground; and that the association had also been represented at a meeting recently held for the preservation of Leyton Marshes.

The Stockton park, which was opened on the 4th inst. by the Duke and Duchess of York, is in the south-west portion of the borough. The land purchased and presented by Major Ropner, being a plateau, to render the park somewhat naturally picturesque and more romantic, the Corporation purchased an additional 3 acres, 1 rood and 37 $\frac{1}{2}$ perches, to the east of the land given, at a cost of £1026 11s. 3d.

National Chrysanthemum Society.—We are requested by the hon. sec. to state that on the occasion of the exhibition at the Royal Aquarium on November 7, 8 and 9, the flowers competing in class 27 of the amateurs' division will be considered when the special *Gardener's Magazine* medals are awarded. This class was unfortunately omitted from those mentioned on page 64 of the schedule of prizes. Also that the awards in class 48, being special prizes by Mr. E. C. Jukes, will be the silver-gilt, silver and bronze medals of the society. The floral committee will meet on the second day of the show, Wednesday, November 8, at two o'clock, and not on the first day, as heretofore.

—A meeting of the floral committee of this society was held at the Royal Aquarium on the 11th inst., Mr. W. Herbert Fowler occupying the chair. There was a good display of novelties, and the following received first-class certificates: Charles Davis, a deep bronzy yellow Japanese bloom, a sport from Vivian's Morel. This was staged by several exhibitors, the colour varying in every case. The award was, however, made to Mr. H. J. Jones. Mme. Edouard Rey.—A fine incurved Japanese variety, deep purple-amaranth with a rosy pink reverse. Exhibited by Mr. E. Beckett. Eda Prass.—Another Japanese of somewhat similar type, but much lighter in colour, being of a delicate blush. Mr. Godfrey received the award. Louise.—A very large white incurved Japanese of good form. In its early stage the flower seems to be shaded blush-mauve. It has long deeply grooved florets. Staged by Mr. N. Davis. Mme. Thérèse Rey.—A large white Japanese flower with long drooping florets. Shown by Mr. H. Shoemith. Edith Rowbottom.—A seedling Japanese of a deep lilac-amaranth colour and rather narrow florets. Raised by Mr. E. Rowbottom, who exhibited it. Among other striking novelties presented to the committee were Duchess of Devonshire, a rosy-pink Japanese with golden centre; l'Ami Etienne, a large light mauve Japanese of the Audiguer type; Lizzie Seward, a deep amaranth Japanese with silvery reverse; Rose Wynne, a large loose-petalled white Japanese; Mrs. Conway, a light yellow Ja-

panese of a rather delicate shade; and Miss Muiel Scott, also a yellow Japanese. The exhibitors were more numerous than on former occasions, and as the season advances we may confidently expect a large addition to the meetings, as the flowers hitherto staged appear to be of uniform good quality.

Royal Horticultural Society.—The next meeting will be held on Tuesday, October 24, in the Drill Hall, James Street, Victoria Street, Westminster. The council of the society have offered special prizes for Apples and Pears grown in the open air and also for Grapes. At 3 p.m. Mr. A. Dean, F.R.H.S., will deliver a lecture on the "Cultivation of Onions," examples of which would be welcomed at the meeting.

OBITUARY.

Mr. W. Y. Draper.—We regret to hear of the death, at the age of sixty, on the 7th inst., at 14, Addison Crescent, Kensington, of Mr. William Yates Draper, the head of the firm of Messrs. J. W. Draper and Son, the well-known salesmen of Covent Garden.

Mr. H. E. C. Beale.—We are also sorry to hear of the death, on the 12th inst., of Mr. H. E. C. Beale, eldest son of Mr. E. J. Beale, of the firm of Messrs. J. Carter and Co. The deceased, who was about thirty years of age, was educated at King's College. He then took a prominent position at Holborn, but his health broke down, and we understand he has spent most of the last two or three years in California, Jersey, and the south of France.

A curious Cucumber (*F. Stubbs*).—We do not think it is a cross, as you say, but the Japanese Cucumber sent out by Messrs. Carter and Co. and others this year.

Names of fruit.—*R. C. Cooke*.—1, Minehal Crab; 6, Court of Wick; 3, Braddick's Nonpareil.—*J. S. Cornwall*.—1, Doyenné Boussoch; 2, Duchesse d'Angoulême; 3, Beurré Rance; 4, Knight's Monarch; 5, Napoléon; 6, Beurré d'Aremberg; 7, Apple Bess Pool.—*A. C. H. O.*—A, Cox's Pomona; B, not recognised.—*J. W. Aylton*.—1, Winter Strawberry; 4, Schoolmaster; 6, Court of Wick; the others are unknown to us.—*W. Darker*.—1, General Todtleben; 2, Baronne de Melo; 3, Beurré Rance; 4, Glou Moreau; 5, Thompson's; 7, King of the Pippins; 8, Cox's Pomona; 9, Rymer; 10, Hanwell Souring.—*W. P.*—1 and 6, not recognised; 2 and 3, Marie Louise; 4, Eyewood; 8, Apple Fearn's Pippin.—*A. P.*—1, Blenheim Pippin; 2, Hoary Morning; 3, Cellini; 4, too bad a specimen.—*B. Wells*.—42, King of the Pippins; 40, Margil; 41, Emperor Alexander; others not in character.

"The Garden" Monthly Parts.—This journal is published in neatly bound Monthly Parts. In this form the coloured plates are best preserved, and it is most suitable for reference previous to the issue of the half-yearly volumes. Price 1s. 6d.; post free, 1s. 9d. Complete set of volumes of THE GARDEN from its commencement to end of 1892, forty-two vols., price, cloth, £30 12s.

"Gardening Illustrated" Monthly Parts.—This journal is published in neatly bound Monthly Parts, in which form it is most suitable for reference previous to the issue of the yearly volumes. Price 5d.; post free, 8d.

"Farm and Home" Monthly Parts.—This journal is published in neatly bound Monthly Parts, in which form it is most suitable for reference previous to the issue of the yearly volumes. Price 5d.; post free, 8d.

"Hardy Flowers."—Giving descriptions of upwards of thirteen hundred of the most ornamental species, with directions for their arrangement, culture, &c. Fifth and Popular Edition, 1s.; post free, 1s. 3d.

"The Garden Annual" for 1893.—Contains Alphabetical Lists of all Branches of the Horticultural Trade. The Lists of Gardens and Country Seats (containing over 9000) have been very carefully and extensively revised, and are admitted to be the most complete ever published. Price 1s.; by post, 1s. 3d.

All of our readers who are interested in the improvement of cottage homes are invited to help us to make **Cottage Gardening** known. It is published at the very lowest price to meet the wants of those for whom it is intended, and copies will be sent for distribution, free, by the publishers, Messrs. Cassell and Company, La Belle Sauvage, Ludgate Hill, E.C.

"This is an Art
Which does mend Nature: change it rather; but
THE ART ITSELF IS NATURE."—*Shakespeare.* (1)

CHRYSANTHEMUMS.

NATURALLY GROWN CHRYSANTHEMUMS.

THE term "naturally grown" is usually given to Chrysanthemums that are made to develop a bushy form and which are not subjected to the severe disbudding necessary if flowers of exhibition quality are desired. It is, however, a misnomer, for, strictly speaking, a naturally grown plant would have neither its shoots stopped nor any of its flower-buds removed, both of which operations are nearly always practised. In growing Chrysanthemums of what may be termed the exhibition type, the sole object in view is to obtain flowers at once of the largest size and as near as possible of the form that has been set up by the florist as an ideal one. In the cultivation of that class with which the present observations deal, the aim is entirely different; it is, in a word, the beauty and effectiveness of the plant as a whole rather than that of the individual flower. In growing this class of plants, it is of great importance that each should be clothed with foliage almost or quite to the base of its stems, and that whilst the shoots should be disposed and supported so as to secure sufficient symmetry of form, the stiff outlines and unwieldiness of the "specimen" plant of the exhibition should be as carefully avoided. With regard to the flowers themselves, the aim should be to obtain them large enough to show the true and distinctive character of the variety, and yet in sufficient number to fully furnish the plant, thus avoiding the wasteful process which accrues from restricting the energies of the plant to the production of two or three flowers. For some years past this system has been adopted for the plants grown in the large temperate house at Kew, and this year they are unusually fine. In this house, with its broad walks and splendid background of greenery, Chrysanthemums are shown off to perfection, and I think that, as seen here, few will dispute their being shown in as beautiful a shape as pot culture will admit of.

It is questionable whether, by encouraging so exclusively as exhibitions do the big flower and the conventional specimen plant, the true interests of horticulture are furthered as much as would be done by adopting a system of culture that requires as much real gardening skill to obtain the best results, and which, from an artistic standpoint at least, are infinitely more pleasing. The groups of plants seen at even our best shows, with their carefully sloped surfaces, look brilliant and gorgeous enough at the top; but to the inquisitive eye that searches below there is revealed a huddled mass of long stalks and pots (the latter not unfrequently stood one above another), which is to the last degree unsightly. Looked at singly, such plants are hideous, and even when massed together in a formal sloping bank, which is the only arrangement they are presentable in, the few square yards of colour they give cannot be said to be an adequate return for all the expense and labour they have entailed during the previous twelve months.

To obtain plants of the character now in question, cuttings may be taken at any time between the end of November and the middle of February. I have not been able to see that any advantage is gained by taking them very early, cuttings taken in February rooting sooner and growing away more freely than those taken two or three months before. I prefer to strike them singly in 2½-inch pots, placing them in a frame close to the glass and using no artificial heat so long as the temperature is above 40° Fahr. As soon as rooted they should be removed to a cool frame, and still be kept near to the glass, giving air on all favourable occasions. When the pots are filled pretty full of roots a shift into 4-inch pots should be given, and as soon as the plants are 5 inches high they should be stopped for the first time; from this stopping three or four shoots generally appear; if more than this number, the lower ones should be removed. From this time right through the summer the chief thing to aim at is a free and uninterrupted growth. It is of the greatest importance that no check should occur, either by under-watering or under-feeding, or by allowing the roots to become pot-bound before the final shift. During April the plants are mostly ready to shift into 6-inch pots, stopping the shoots a second time when about 6 inches long. For the majority of the varieties two stoppings suffice to produce from eight to twelve shoots, but this matter will have to be regulated in accordance with whatever number may be considered sufficient according to the variety. Some, such as Mrs. Beale, do not branch freely, and have to be stopped three or four times to obtain even seven or eight breaks. The final shift into 10-inch pots will be necessary during the last week in May or early in June. This, however, should be done whenever the 6-inch pots are fairly well filled with roots, the different rates of growth rendering it advisable to repot at different dates. In the last two pottings care should be taken to make the soil very firm; if it is in a proper condition and not too wet, the potting-stick may be freely used. I am convinced that to obtain the dwarf, stocky habit and firm, woody growth which so much improve the appearance of Chrysanthemums grown in this manner, firm potting is essential. Of chief importance in making the compost is, of course, the quality of the loam. It should be of a rich, turfy character, and care should be taken to avoid one that is too light and sandy. Of the two, indeed, I would prefer that of a rather heavy and clayey nature, modifying it afterwards by a sufficient mixture of clean, coarse sand. A good proportion of well-rotted cow manure is usually advisable, to which, before adding to the loam, a thorough dressing of soot should be given. This not only acts as a manure, but destroys the worms and larvæ, and renders the cow manure drier and more workable. Finally, a little bone meal is a useful addition. This compost should if possible be made five or six months previous to using, and be turned over two or three times in the meantime. It should be kept dry by being built up in a ridged heap or covered with shutters.

Perhaps in all the matters relating to Chrysanthemum culture, the one on whose proper manipulation the difference between mediocrity and the greatest success most depends is that of the application of manure, or "feeding," as it is popularly termed. It is evident that whatever system of culture we pursue, the plants will require very much more food than can be obtained from the soil in a 10-inch pot, and, in fact, from June right up to the end of October

the application of manure either in the form of artificial fertilisers or as manure water is a continual necessity. As soon as the roots have found the sides of the pots, a bag of soot should be sunk in the tank from which the plants are watered, and the soot should be renewed about twice during the season. About six weeks after the final potting the first weak manure water may be given to plants that have grown strongly, and from this time onwards until the plants are housed it must be given regularly, increasing its strength as they get older, and finally supplying it to them twice every other day. In addition to this, a top-dressing of artificial manure will probably be necessary about the middle of July, repeating this at first once a week, afterwards oftener. The practice of deferring the application of artificial manure until the flower-buds are beginning to swell is not a good one for bush plants, whatever it may be for those intended to produce large blooms. It is a good plan to use two or three sorts of fertilisers in rotation in preference to one for the whole season.

It need scarcely be said that Chrysanthemums must never be allowed to get dry, more especially later in the season; on the other hand, some care is needful in the early stages to avoid over-watering, particularly just after repotting. Some difference of opinion exists as to the advisability or otherwise of plunging the pots in ashes. Where, through pressure of work, there is a danger of the plants not obtaining full attention in watering, it is certainly better to plunge the pots. But where no difficulty of this kind is likely to occur, I should prefer to stand the pots, without plunging them, a yard apart each way on a hard bed of ashes, believing that this is more conducive to the formation of firm and well-ripened growth.

With regard to the amount of disbudding to be done, it varies considerably according to the variety. The "crown" buds are only to be taken in a very few cases. In some varieties, however, the characteristic form of the flower necessitates the allowing of but one flower to each of the seven or eight shoots. A marked instance occurs in Edwin Molyneux; in the Queen family, too, the crown bud is always taken unless it is formed too early. It is the Japanese section, however, that lends itself to the natural style of growth better than any, and from pretty nearly all these the crown bud is removed, and three or four shoots beneath are allowed to grow. A single flower is permitted to develop on each of these, and thus, as a rule, from thirty to forty are produced. On some varieties twice or thrice as many may be carried without detracting from the beauty of each flower. The finest plant of *La Nymphé* in a 10-inch pot I have ever seen bore just under 200 flowers, some of them 6 inches across. Such single-flowered varieties, too, as *Miss Rose* should not be disbudded at all. But a single season's experience is sufficient to enable anyone to judge for himself in this matter.

W. J. B.

CHRYSANTHEMUMS AT CAMBERWELL.

CAMBERWELL is not altogether an ideal spot for flowers, but the Chrysanthemum is grown in perfection by Mr. Norman Davis in his Lilford Road nursery there. This year this well-known grower has an exhibition, and Chrysanthemum enthusiasts will be interested in the splendid novelties to be seen in the several houses. One structure in which the chief mass of plants is arranged is large, and in the course of a few days will be a sheet of colour, each variety disposed in blocks to give a rich effect. Of course, every novelty worthy of the name is in the collection, besides the ordinary va-

eties that are known to all who really care for the flower. We are concerned here alone with the newer varieties, and every one is cultivated with remarkable success, in spite of the crowded surroundings. But this testifies to the great usefulness of the Chrysanthemum as a town plant and also its brilliancy in the late months of the year, when few other greenhouse things are in bloom. The Japanese section is remarkably strong, and although the several kinds were not in perfection at the time of our visit, many beautiful novelties were in bloom. One of the finest was Mlle. Thérèse Rey, the first flowers of which were expanding. This is a magnificent kind, the flowers of very large size, but not in any way coarse; the petals broad and composing a massive bloom, whilst the colour is delightful—a rich, almost creamy tint, a shading of yellow appearing in the centre. It is the finest acquisition to this section of recent years, and the growth is dense, compact and vigorous. Another fine novelty which we made note of was Col. W. B. Smith, a variety shown well on several occasions last year. The flowers, although of very large size, are not coarse, and it is pleasing to see that many of these monster kinds are really refined in aspect—very different to the first acquisitions of this type. The colour is a golden bronze, shaded with a brownish tone, and we must also mention that the habit of growth is excellent. This is of great importance. We care little for the tall kinds, and it is to the reduction of habit that raisers have been directing their attention with so much success. Andrew Felaciers will take a high place as a flower for decoration. More thought is given to these kinds purely for this purpose, leaving out the question of exhibition. Too often a variety was condemned simply through failing to attain a certain standard of excellence from the exhibitor's point of view. Such charming things as this were overlooked. The flowers are rich orange, neat, borne very freely, and remarkably bright. Another of this type is Charles E. Shea, which is too well known to need description. Rycroft Glory is a very beautiful decorative variety, the flowers orange-yellow, and smothering the vigorous shoots. Louise belongs to the Japanese incurved class. It is a very fine flower, white touched with magenta, and the habit of the plant very dwarf, not more than 3 feet in height. A distinct improvement on the popular Mme. Bernard is Commander Bluset. The flowers are best described as deep amaranth-crimson, with silvery reverse to the petals, and the plant naturally dwarf. It is much freer and more easily grown than Mme. Bernard, the colour also deeper. A very pure white Japanese kind is Mme. Chater, the flowers exceptionally pure, and in other respects this is a desirable kind. Mr. Davis has a splendid batch of the now well-known Vivand Morel, which has given rise to considerable controversy regarding the white sport. One sees the flowers here of various colours, the early crown bud giving pure blooms, and those from the late buds deep lilac, whilst the intermediate or second crown buds bear flowers of varying shades of lilac. It is very interesting to thus see a collection representing such remarkable diversity. A variety named Mme. Charles Moulin is very much like a white Vivand Morel, the petals broad and firm, whilst the habit of growth is quite as free as that of the kind to which we have compared it.

This representative collection is very rich in what we may call the deep chestnut-crimson class. One house is filled with the variety William Seward, comprising hundreds of plants, all in splendid health. It will be remembered that this variety created quite a sensation when exhibited by the raiser, Mr. W. Seward, at the Royal Aquarium last October. It is a remarkably beautiful kind for colour in particular, which is best described as purple-crimson. The flowers are not unlike those of Cullingfordi, but more purple, the reverse side of the florets being gold, seen especially when they are unfolding. They are absolutely devoid of coarseness, each bloom a model of symmetry, smoothness and beauty. John Shrimpton was also shown by Mr. Seward at the Royal Aquarium last year, and in both cases a first-class certificate was at once given. The flower reminds

one of Jeanne Délaux, the colour a rich velvety crimson, the florets of a golden shade on the reverse side. It is as distinct in habit almost as in colour, the majority of the plants 2 feet in height, some less. Mr. Davis has a large number of plants of that very fine kind named C. Shrimpton, which is catalogued as a reflexed Japanese, but these various distinctions are a trifle puzzling. The flowers are large, but not coarse, and deep chestnut-crimson, the reverse of the florets bronze. When writing of Vivand Morel, we ought to have mentioned that fine variety Charles Davis, which sported in this nursery from Vivand Morel. It is a noble flower, a decided yellow in the earlier buds, but the later ones are rich rosy bronze, broad, full, and similar in expression to those of the parent, whilst the habit of growth is of the same character. Mr. Davis has so many fine novelties, that it is difficult not to make a particularly long list, but in the Japanese section we must mention as of merit: H. Shoesmith, a lovely straw colour; Cæsar Costa, Viscountess Hambleton, lilac, turning to white; L'sere, which is like Yellow Dragon, only white; and Alice Rowbottom, a seedling raised by Mr. Davis, amaranth-rose, with silvery reverse, and recently certificated.

The incurved section is thoroughly well represented, and the flowers of many excellent kinds were expanding. Baron Hirsch was one of the finer kinds, and this is now well known. Mention may also be made of Emile Parli, rich bronze and of the Princess of Wales type, besides many other beautiful novelties.

What is known as the hirsute section is of course a feature. But we care little whether a flower has this distinctive character or not, the chief thing being its colour or form. Louis Boehmer was never a favourite, its colour is too dingy, but William Falconer is a step in the right direction; and then Mr. Davis has the white Louis Boehmer, also Queen of the Hirsutes, rosy crimson, and W. A. Manda, yellow.

Every phase of the Chrysanthemum is seen here, and the borders near the houses are gay with many kinds of well-known hardy kinds. It is surprising how well they are flowering amid the smoky surroundings, especially such varieties as La Vierge, Mrs. Cullingford, Alice Butcher, Anastasia, Little Bob, Lyon, Roi des Precoces and Mlle. Foucher de Careil, which is of a bright orange shade, very free, and in all respects a showy and useful outdoor kind.

NOTES ON NEW VARIETIES.

Mlle. THERESE REY.—Although white-flowered varieties in the Japanese section are numerous, there is still room for more, especially when of the quality of the above, which is without doubt one of the finest introductions of recent years. Well-developed blooms measure from 7 inches to 8 inches in diameter and of corresponding depth, a point that should always be present in typical flowers. The petals are of medium width, incurving slightly at the point until fully expanded; the colour white, with just a faint tinge of cream in the developing florets. In habit of growth it is all that can be desired, being robust, yet not too tall. I should advise exhibitors to make a note of this novelty.

PRESIDENT BOREL.—This belongs to the flat-petalled section of Japanese, and is in every way promising. The florets are of medium width, very full in the centre; the colour is rose-magenta, or a very warm rose; the reverse, pale gold, which gives the flower when half expanded a novel, yet striking appearance. Well-developed blooms are large enough for any purpose. This new introduction is likely to take a foremost position on the exhibition table in the near future.

MME. EDOUARD REY.—Early blooms of this Japanese open pale lilac in colour, being spotted and suffused with rose. Those from a later bud have more colour, being a warm rose-pink, and are more pleasing. The florets are broad, incurving at the tips. The flower is of full size, and a decided acquisition as an exhibition variety.

KENTISH YELLOW.—This is a desirable Japanese variety; the colour rich yellow, most striking in its tint, as we have not too many of that type of colour. The flower is devoid of anything approaching coarseness of petal, and is of great depth, carrying a full centre.

EDITH ROWBOTTOM.—This French-raised seedling belongs to the narrow-petalled section of Japanese. The blooms are very full in the centre and of great depth, the colour warm rose, deepening in later blooms.

MISS MURIEL SCOTT.—This promises to make one of the best decorative varieties we have in the Japanese section; the colour is most desirable for that purpose, being what is perhaps best termed a golden primrose. The florets are narrow, flat and full, making a bold bloom of medium size, and just the kind for the purpose named.

PROFESSOR WHITMACK.—As an exhibition variety this Japanese is likely to become popular; the colour is a desirable one, rose-magenta, with silver reverse; the florets incurve at the tops, showing the silver until fully developed. The blooms are not extra large, but solid and in every way desirable.

LOUISE is one of M. Calvat's latest introductions, and a great acquisition, from the fact that magnificent blooms are produced from plants but 2 feet 6 inches high. For this reason Louise is bound to take a high position with all exhibitors whether for cut blooms or for grouping. The florets are broad and massive in appearance, loosely incurving toward the centre. The colour, flesh-pink, is unique. This novelty was finely shown by Mr. N. Davis in his first prize group at the late October show of the N.C.S.

M. ULRICH BRUNNER has narrow petals of a rich magenta-red colour; the blooms are well built, being full and deep, of medium width. As a front line bloom it must take a high position in the Japanese section on account of its colour and solid form.

EDA PRASS.—This Japanese, which belongs to the incurved section, was finely shown by Mr. Godfrey at the late October exhibition of the N.C.S., and was unanimously awarded a first-class certificate by the floral committee. The colour—a warm peach—is most pleasing.

PETIT DELAUX.—This has broad incurving petals of a rose colour, very promising as an exhibition variety.

MISS ALICE WILSON may best be described as an improved Stanstead Surprise. In formation the florets much resemble this variety, but the colour is richer, while the blooms are more massive; therefore will be more effective.

MRS. CHARLES COX is a sport from M. Bernard, possessing all the characteristics of that favourite in habit of growth and formation of flower. The flower has a golden base, dashed and suffused with red. Blooms developing from later buds will show a richer tone of colour, which is a characteristic of its parent. Taken altogether, in Mrs. C. Cox we have a decided acquisition to the large show varieties.

DR. MRS. WARD.—The florets of this American-raised Japanese are broad, the tip of each recurves, giving it a novel appearance, but exhibiting fully the surface colouring of golden amber edged with brick-red. The blooms are full, quite solid.

GOLDEN WREATH is a rich golden yellow; the long, though loose florets are of fair substance. Japanese. E. MOLYNEUX.

Chrysanthemum C. B. Whitnall.—From the description accompanying this variety in catalogues, I gather that it received a certificate in America. From my point of view, instead of its being a perfect incurved variety, I call it an ill-formed Japanese. In point of colour it is perhaps remarkable—purple-red, but we here in England look upon a flower with the eye of the florist, and I consider this variety is not deserving of attention. Were we to include such badly formed flowers in our list of incurved sorts, it would be difficult to say where Japanese begin and incurved leave off.—E. M.

FLOWER GARDEN.

DAFFODILS ON THE GRASS.

AFTER a somewhat long and careful study of the native conditions under which the Daffodils are found wild, added to considerable observations of these plants as naturalised in our fields and gardens, we have arrived at the conclusion that they never look better, and in many cases never succeed better than when carefully and thoughtfully planted in the meadow or on the outer fringes of the lawn. In England we find, especially in the south, that these flowers affect the woods and hedge banks, as well as, and sometimes apparently, in preference to the open fields or downs. One of the sights in

England and Wales, and in Scotland, whence we have seen from Dr. Stuart, of Chirnside, a very remarkable series of dwarf yellow, and other larger Daffodils distinct from named and known kinds, which he was so fortunate as to recover from an old garden some few years ago.

Then in England we have the instance of Finnerne's Flowers growing in a spot to-day, from which the old family of Crusaders, the Finnernes, have vanished, followed by every stock and stone of their castle or dwelling, but their flowers, or at least some of them, remain, as related in THE GARDEN (Vol. XV., pp. 75 and 134). The Rev. Harpur Crewe took some trouble to verify this fact, and found that one of the flowers of the Finnernes was *Narcissus poeticus*. Then in Wales there was the cropping up of the giant Star *Narcissus*

of Daffodils and of Star *Narcissus* is an accomplished fact to-day in many places. *Narcissus poeticus*, varieties *ornatus* and *recurvus*, *N. incomparabilis*, or the Star *Narcissus* in variety, and several of the trumpet Daffodils, and especially *N. obvallaris* (Welsh or Tenby Daffodil) and *N. princeps* (so-called Irish Daffodil), have improved as here naturalised in grassy meadows for three or four years. Nor must it be supposed that the soil in the scene shown in the engraving is a good one. On the contrary, it is a heavy, greasy clay lying over ironstone—a soil in which forest trees and Roses and other hardy shrubs and flowers grow vigorously; but not exactly the kind one would select for choice bulbs. Nevertheless, as we have said, the above *Narcissus*, *Tulipa sylvestris*, various *Squills*, *Anemone*

Portion of field of Poet's *Narcissus* in bloom. Late variety, planted six years; soil stiff loam. Meadow mown every year; plants never degenerating, but improving yearly, and showing very great differences as to size and height according to the amount of rain. No preparation of the soil ever given, or anything beyond turning up the sod, placing the bulbs beneath and standing on the turf.

Normandy in April is the woods beside the railway from Dieppe to Rouen, as they are gold-flecked with Daffodils by the million. In a lesser degree this is true in Kent and Hampshire, and even in Ireland, where no form of Daffodil is really wild or indigenous. They were long ago introduced into gardens from the Continent, and are now frequently found in quantity as naturalised on sites

Where once a garden smiled,

a fact Goldsmith chronicled long ago, and one we have observed with much pleasure in more recent times. Such choice kinds as Colleen Bawn, Minnie Warren, Rip van Winkle, Leda or albicans, Countess of Annersley, Ard-Righ, princeps, and several others have thus been found not really wild, but apparently so in Irish fields and parks and derelict demesnes. To a lesser extent this much is also true in

Sir Watkin in a semi-naturalised state, and there are the curious white Daffodils found on an old religious site near Bicester, and even *N. capax*, or Queen Anne's Daffodil, has been found on a hedge bank in Wiltshire; while in Cornwall and the Scilly Isles various forms of the bunch or tufted *Narcissus* (*N. tazetta*) of the Mediterranean region have been naturalised for years, and from this fact arose the suggestion for and likelihood of the enormous trade in *Narcissus* flowers carried on there to-day.

Our object is not so much to speak of or write the history of these flowers as to allude to their adaptability and beauty as cultivated in quantity in the Grass in suitable positions, where they may escape the mowing machine or the scythe, at least until their leaves wither in hay-time, or say June and July. We are not recommending a novel practice, for the naturalisa-

apennina and *A. Robiusoniana* have done well, improving in strength and vigour of blossoming year after year. Other bulbs have also done well, none better, perhaps, than the various forms of our native meadow *Fritillary*, or "Chequered Daffodil" of Parkinson, which in April or early May hangs its curious lamp-lit or lantern-shaped flowers by the thousand above the lush young Grass of early summer-tide, succeeding the Snowdrop, *Crocus*, *Aconite* and other harbingers of spring.

The essential practical points in this question are first the obtaining of good sound bulbs in quantity early in the season, and not later than August if possible. The golden rule is to plant only the best and strongest kinds, and to use these boldly by the thousand. Then they must be well planted 5 inches or 6 inches deep in bold clumps or masses, and not dotted

about singly or planted in lines or any set pattern. If several groups of the same kind are planted, the groups should themselves be arranged in relation to one another, with one group larger and bolder than the rest, so as to give more mass towards the centre on which the eye may rest, and not be led to wander about, as it inevitably will do if several adjacent masses are of equal importance. As in colour inequality means brilliancy, so in groups or masses inequality means an added interest, but one point in a line or in a group should always be denser and bolder than the rest, or it will never satisfy. The very best rules on compositions of this kind are those in Ruskin's "Elements of Drawing," which should be studied by all who attempt the planting of flowers or trees. The engraving may be taken as a good example of the kind of natural grouping we mean.

Planting itself is best done with a spade or draining tool, and in hard ground or among tree roots a pick or axe may be necessary. Loosen the soil to a depth of 12 inches to 16 inches if possible, and if leaf soil and sand can be added in the planting, so much the better. Two or three labourers with a cartload or two of sand and mould well mixed will soon put in a few thousand bulbs, but there should be some supervision, unless the size and shape of the groups be marked out beforehand, as they were by one friend of mine with the lawn-tennis marker! After planting the turf is relaid, and all after culture consists in giving the annual top-dressing of soil and manure usual for meadows early in the year. In a word, the naturalisation of bulbs in meadows is not in any way inimical to their due and proper use from the home-farmer's point of view. Mowing does not take place until after the leaves wither. Then they may go to swell the bulk of the fodder without injury, even if not with some slight advantage, since we read and heard of the cows in Scilly having been fed on Narcissus leaves during the drought of the past summer.

What we especially plead for is a greater general extension of bulb planting in Grass in all suitable positions. Once well done, results are good for many years, and, as we have shown, the art of the gardener and planter often survives after that of the builder is decayed or swept away. It is no new hobby, but has long been practised in the best of old country places, until in some cases quite a character has been added to domains, and bulbs on the Grass herein constitute the essential charm. It is so at Straffan, Kildare, and Dunrobin Castle, Sutherland, where the Snowdrops form a turf where Grass can but barely grow under trees, and now the same is true at Carton, where the Duchess of Leinster has jewelled the turf near to the ancestral Cedars and other lawn trees with the choicest bulbous flowers. It is also the case at St. Anne's, Clontarf, of recent years, and at Belvoir. It may thus be seen that Nature's own way of growing flowers amongst other herbage is the best way after all.

F. W. BUREIDGE.

Tuberous Begonias in beds.—During the early part of the summer, and in fact up to the time the rains fell heavily and the weather became cooler, these flowered none too well; whereas zonal Pelargoniums never looked gayer. Then came the turn of the Begonias. No amount of rain seemed to hurt them, and at the present time (October 12) the beds are as brilliant as I have ever seen them. The Pelargoniums, Calceolarias and such like have for some time past cut a sorry figure, the first-named soon collapsing when rainy weather sets in.

All things considered, tuberous Begonias have no equal for flower garden decoration, and that they are steadily gaining in favour in small as well as in large gardens there is no gainsaying.—I.

Rhexia virginica.—I notice that Mr. J. Wood, in his interesting notes on hardy plants in THE GARDEN for September 23, expresses some fear lest this plant should not be entirely hardy. It is one of our most plentiful wild flowers in New Jersey, where one may often see a swampy meadow simply a mass of its beautiful flowers, and as the winters there (in the latitude of New York) are usually severe, there can be no doubt of its perfect hardiness. The specific name is rather a misnomer, for it is not by any means confined to Virginia, but extends over quite a wide range. It may be relied upon wherever *Lobelia cardinalis* is hardy.—E. L. TAPLIN.

OCTOBER FLOWERS.

SOME of the hardy flowers that render good service in the outdoor garden during this month are this year over-forced into bloom prematurely by the great heat of the past summer. Fortunately, frost has spared the tender ones, and some of them, favoured by the refreshing rains enough to moisten the roots and not sufficiently heavy to wash the beauty out of the flowers, are still in this second week of October more beautiful than in the height of summer. Dahlias, for instance, are fine in colour and form, and still expanding their buds, for in the home counties at least, although the nights have been cool, the temperature by day has been high enough to promote development. Few tender things have come quite to a standstill. Had a national Dahlia show been held in the last week of September, the average quality of blooms exhibited would, I imagine, have been high. French and African Marigolds are still a mass of bloom. Gaillardias are as good as two months ago, and zonal Geraniums are more effective than is often the case with them in the height of summer. Those who grow the early-flowering Chrysanthemums will have been well content this season. Early autumn frosts have spared them, and rain came in time to assist development of the blooms. I do not think the flowers are individually so fine as is generally the case, but none have been destroyed, so that this year may be considered as having been favourable for this section of the family. When Mme. Desgrange and its varieties as well as those kinds that bloom from mid-September to mid-October escape autumn frosts, one may rely on having a fairly attractive garden till late in the latter month, when the late blooming hardy ones come in. The annual Chrysanthemums seldom fail us in late autumn. It must be a hard frost that stops their blooming, and they bear a lot of wet weather without suffering any great diminution of their blooming powers. One of the most valuable of October flowers is *Pyrethrum uliginosum*; it can be grown where many things would fail, large well-established specimens being remarkably effective where the dense masses of pure white bloom are shown up by the rich green of evergreen trees and shrubs. One may cut a bushel of flowers from two or three fair-sized plants. Only a few years ago one rarely saw it in any but the largest gardens; now I see it frequently in cottage gardens. The Ivy-leaved Cyclamen is generally in good bloom with me during the early part of October, but this year the flowers were thrown up in profusion by the first week in September. The great heat quickly spoilt them, and now there is but a bloom here and there to be seen. Everyone ought to find a place for this Cyclamen, which can be grown under trees and in other situations where flowering plants could not thrive. Few things of its size are more effective, but to fully appreciate its beauty one ought to have bulbs that have seen a decade. Some of mine are twenty years old, and they yield individually over 100 blooms. Perennial Sunflowers and Michaelmas Daisies no garden should be without. The latter are becoming more and more

valuable. I am looking to the time when this flower will be as valuable for the outdoor garden as the Chrysanthemum is under glass. Seeing what marvellous work has been done in improving the latter, there is every reason to believe that a similar change will be effected with the hardy Starworts. We shall probably get varieties with blooms six times the size of the largest we have now, and why not a race of double flowered ones? When this good work is done, we shall be able to have a gay garden quite up to November. The dwarf German Scabious may be classed among October flowers. It looks best in a mass, and furnishes an abundance of flowers for cutting. In ordinary years *Viola* can be relied on to give some blooms through this month, but this season I cannot now find a single flower, and to my sorrow a large proportion of the plants are dead. Pansies of the large flowering type, on the contrary, are giving plenty of good blooms on seedlings raised in July, and Fuchsias, such as *Rose of Castile*, seem to enjoy the rains and cooler temperature immensely.
J. C. B.

FLOWER GARDEN NOTES.

THE mild weather following the heavy rains we had early in the month has given a rare impetus to September planted border Carnations, and it is seldom we get in the middle of October a better or more even lot of plants. The only thing one fears is that the succulent grass, which is a natural outcome of this late and rapid growth, may not stand the winter so well as that of a firmer and more wiry nature. The planting was accomplished in good time this season, good layers being quite three weeks earlier than we generally get them. A spell of dry weather succeeded the planting, but has apparently had no prejudicial effect on the layers; they received their usual dose of horse droppings worked well in about the roots, and then to prevent the ground drying out about them an inch mulching of rotten leaves. The report of many new varieties on trial another summer would seem to indicate that our stock of this favourite flower is likely to be largely increased. The more the better if they are really good, only it is to be hoped that those answerable for the trials will insist strongly on a thoroughly hardy plant. Nothing should pass muster as a *bonâ fide* border Carnation that has to be coddled in frames all through the winter.

PLANTING BULBS.—If a start is to be made with a few Babianas, *Ixia*, *Sparaxis* and *Tritonias*—and they are so beautiful in a cut state that a corner ought to be set apart for them in all gardens—they should be seen to at once. A corner, by the way, is not meant to signify any out-of-the-way place, as all these Cape bulbs like a warm, sunny spot. A south border in front of a plant house—just such a one as would be dear to the Tomato grower—would suit them admirably. The ground should be deeply forked and well broken throughout the depth of the spit, and any manure added must be thoroughly broken up and well incorporated with the soil. If the plantation is to be a permanent one—and much trouble in annual lifting and replanting will besaved thereby—6 inches must be the recognised planting depth, and a heavy mulching of leaves with just a slight topping of Fern will be necessary through the winter months. A similar site and the like cultural requirements apply to the *Montbretias*, only they may be planted somewhat further apart, and instead of the mulching, the surface of the soil may be covered thickly with some dwarf hardy carpet plant. October is, too, a suitable month for planting *Alstroemerias*, among the most lovely of early summer flowers. A border, or at any rate some particular part of a border, should be reserved for their special benefit; they are better so than when mixed with other herbaceous plants of a different nature. A sandy loam suits them well, and the place destined for them should be deeply dug, or, better still, bastard trenched, working in a liberal dose of manure. It is well to make sure they are not likely to be disturbed, as the forma-

tion of a plantation of *Alstromerias* is a job that need only be performed once in a lifetime. Plant deeply and firmly, and mulch after planting and each succeeding winter with half-rotten manure.

It is not often that Dahlias last out well until towards the end of October, but such an experience has to be chronicled this year. I reserve a border annually to be planted with Cactus, decorative and pompen varieties to supply cut flowers, and immediately the glass is inclined to drop low at night, some upright irons are placed here and there along the border, so that a piece of tiffany can be run quickly over the plants if the weather necessitates the operation. If due regard to selection of varieties and judicious blending of colours are attended to at planting time, a very fine and effective display will be obtained from such borders, only it must be borne in mind that in all three sections above named some varieties are much longer in the stalk than others, and consequently better adapted for cutting, also that decided colours will be found most useful. Sorts in the pompons that have proved very free and are still full of flower are Guiding Star, white; Catherine, yellow; Darkness, very deep maroon; Brilliant, a rich crimson; Hector, a pleasing lilac, and E. F. Jungker, of a somewhat amber shade. In the decorative class for cutting, if flowers are required in quantity, it is well to grow plenty of such old favourites as Constance, Cochineal, Fire King, General Gordon and Panthea. All these are of good bushy habit and will furnish an enormous quantity of cut bloom. A decided feature of the autumn of 1893 is the quantity of outdoor flowers available for cutting. Besides plenty of Dahlias, *Pyrethrum nigrinosum* and a wonderful wealth of Starworts in different shades are still to be found. So useful are the last named, that one is apt to wonder sometimes how people managed without them in the old days when only the old variety *spectabilis*, now all but discarded from the borders, was to be seen. Long stems of *Asparagus* splendidly berried are good companions for equally long spikes of the best Starworts for tall trumpet vases; so, too, are the plumes of the Pampas Grass or *Arundo cespicia*. There are splendid tints in the autumn foliage, too, this year, some trees wearing an aspect one does not remember to have noticed before. We have plenty of leaves on a fine plant of *Laurus Sassafras* that would be bad to beat in any stove or greenhouse, splendid blendings of crimson and gold on the same leaf. I think the peculiarity in the autumn tints may be attributed to the fact of an early ripening of the leaves, and then just as they were putting on their autumn dress some refreshing showers came and arrested to some extent the rapid decay. The absence of frost is also naturally responsible for the length of time the half dead foliage continues to hang on the tree. *Ampelopsis* foliage is very bright and looks well with some lighter foliage in shallow bowls, and long pieces of the double *Spiraea prunifolia*, just now of a bright scarlet hue, associate admirably with the feathery Aster, A. *Tradescanti*.

Claremont.

E. BURRELL.

DAHLIAS IN OCTOBER.

UP to the time of writing these lines when three-fifths of the month have passed away, there has not been any frost in our district to affect Dahlias, Heliotropes, or Alternantheras, whilst the Begonias are still flowering profusely. The Dahlias never carried more flower all the season than during the past fortnight, the Cactus and pompon varieties being alike valuable for cutting; the latter kinds, however, keep fresh the longer of the two in a cut state. The rains, which have been exceedingly heavy, have apparently put fresh life into them, encouraging the backward flower-buds to swell up and expand beautifully. The Dahlia season always appears to me to require lengthening; we want, in order to see their full beauty and to enjoy their varied forms and colours more fully, another month sandwiched in between the end of September and the beginning of October, or, in other words, September should consist of eight weeks in

order to extract from the Dahlia as a garden flower all the wealth each plant is capable of developing. As the season approaches the end, or at any rate up to the end of September, the brilliancy of the colours seems to be intensified. Not only in my own case, but in others also have I noted this, and I have been led to wonder if this be the reason why more Dahlias get certificates after what are termed the best weeks for the Dahlia shows are passed than whilst they are on. At the last Royal Horticultural Society's meeting in September at the Drill Hall there were, I think, more certificates given than at any two previous meetings, and this year is not, unless my memory serves me wrong, any exception in this respect. Possibly seedlings are in a measure more backward, but I am disposed to think the brilliancy of the colours late in the season adds greatly to their attractiveness, standing them in good stead. Taken all in all, the Cactus and the pompon sections are the most useful for purposes of decoration in a cut state. The former fade all too soon, but if they are inserted into several inches of water by using deep vases, the result is better in every way. As a foliage accompaniment the common *Berberis Aquifolium* is excellent; it will last out three or four cuttings of Dahlias. Just recently I have noted a sport on a pompon which might be useful. This I am going to try to retain by taking off the growth immediately below the flower in question. I do not know if this will strike, but, at any rate, no harm will have been done. It appears to have been a season fruitful in sports, many of the fancies having, I observe in one collection, reverted to plain colours entirely, being quite distinct in every way.

SOUTHTRON.

LILIES AT KEW.

THE systematic cultivation of Lilies on a large scale at Kew is a somewhat recent development of the outdoor gardening in that establishment. Formerly many attempts were made to grow them in specially made beds in that portion of the gardens devoted to the cultivation of monocotyledonous plants, but these all failed, and so—with the exception of a few species which thrive even under the most depressing conditions—Lilies played little or no part in ornamental gardening at Kew until within the last six or eight years. The success which has attended the new departure, and the wonderfully fine effects produced by masses of the showier species and varieties, are so great that an outline of the methods pursued may be of general interest.

SOIL AND POSITION.

Most of the Lilies at Kew grow well in peat; some few refuse to grow in peat, but do well in loam; some do equally well in loam and peat. But, generally speaking, the key-note of success was struck when the bulbs were planted among low-growing shrubs. Behind the Palm house is the so-called "American Garden," containing masses of ericaceous and other plants in large beds; among these are *Rhododendrons*—low-growing species—*Azaleas*, *Ledums*, *Callunas*, *Ericas*, *Pieris*, *Leucothoë*, *Daphne*, &c. These shrubs serve a double purpose; they keep the ground cool about the Lily roots and shelter the young growths from the late spring frosts. Every few years, as the shrubs grow too dense, it is necessary to replant them and space them out properly, so as to give the Lilies a fair share of light and air. Replanting, by the way, is better than pruning, as each time replanting takes place a number of fine shrubs are obtained, which are available for new plantations. At the same time the Lilies—at any rate, the great majority of them—pay for being lifted and replanted, the smaller bulbs being retained and placed in nursery beds to grow on. *Lilium auratum* is one which pre-

fers being let alone, and, given a well-drained peat bed, should not, if possible, be disturbed. *L. auratum*, by the way, being a taller grower than most of its congeners, we grow in beds of taller *Rhododendrons* than these which find a place in the "American Garden," and these can from time to time be pruned in so as to allow the Lilies light and breathing space. In the beds of *Rhododendron*—principally hybrids of *R. ponticum*—along the Broad Walk we have had hundreds of stems of *L. auratum* 6 feet high (many have attained 8 feet or more), with fifteen to twenty, or even more, perfect flowers. This year, however, owing to the excessive drought, few stems have attained the dimensions or have produced the number of flowers just mentioned. *L. longiflorum* does best with us in peat and must be replanted every second or third year, or there would be a falling-off in the size and number of the flowers. The fact is the bulbs increase so fast that they crowd each other out and impoverish the ground; the small ones are planted at once in other beds or are grown on in nursery beds for stock. *L. speciosum* and its numerous varieties increase so rapidly that they quite exhaust the ground; replanting is necessary every second, or third year at the outside. Fresh peat should be added and only some of the large bulbs replaced; the others may be at once utilised for forming new plantations.

RAISING FROM SEEDS.

The bulbs of some Lilies, after flowering well for several seasons, disappear apparently without cause, and the better and the more freely have they grown and flowered the more apt are they to disappoint their possessors. It seems probable that the bulbs of these kinds are in reality always rather short-lived. An excellent way to keep up a stock of young, vigorous bulbs is to make a sowing every year. If treated properly, seedlings arrive at the flowering stage very quickly. The seeds should be sown as soon as ripe—if possible, in prepared beds (not in pots or pans) under glass. A cold frame will do well, but results are more speedily attained if seeds are sown in a bed in a slightly heated greenhouse. For instance, seeds of *Lilium longiflorum* var. *formosanum*, a beautiful variety from Formosa, developed rapidly, some seedlings flowering in little more than a year from time of sowing. The bulbs in that time had attained about the size of small Hazel nuts; last year they were planted in the open ground, and during the past summer have flowered profusely.

SCALES AND BULBILS.

The former method of propagation—when seeds are not to be had—is one which allows the stock of a given kind to be rapidly increased. A good-sized bulb will furnish a large number of scales, each of which may develop into a good bulb in two or three years. The scales should be planted in silver sand—over prepared soil—and kept in a frame or greenhouse until young plants have developed, when they are better planted out in the open ground. The third year from scales we have had *L. Hansoni* 5 feet high, bearing from nine to twelve flowers on a stem. Bulbils, as of the Tiger Lily (*L. tigrinum*) and *L. sulphureum*, furnish an easy way of propagation; the former will flower the second year from the bulbil, all that is necessary with the Tiger Lily being to sow the bulbils when ripe in the open ground and leave them to their fate. A slight covering of Fern leaves, &c., during winter is, however, beneficial. With *L. sulphureum*—owing to its being much more uncommon—we act differently, planting the bulbils in pans

or beds under glass. The first year these will get as large as small Hazel nuts—after this they are better planted outside; some planted out this spring in an Azalea bed, fully 6 inches deep, have grown freely this past summer, producing numbers of bulbils, which, in their turn, will be carefully treated as above described. They will, doubtless, flower well next year.

LILIES WHICH GROW BEST IN LOAM.

The Martagon Lily (*L. Martagon*) and its varieties album and dalmaticum will not grow in peat at Kew, but do well in loam. The Tiger Lily (*L. tigrinum*) and its varieties, although they will thrive in peat, do well in almost any garden soil. The Pyreneau, or Yellow Martagon, as it is sometimes called, requires loam; if chalky in character so much the better. *L. testaceum* and *L. caudatum* like good loamy soil. *L. pardalinum* grows very freely in a damp loam; the third year we have had it 7 feet high, with thirty flowers on a stem. When this species is transplanted, unless clumps are moved with masses of soil attached to their roots, it is never so fine the succeeding year; one must wait until it is thoroughly established before the best results are obtained. *L. Hansoni* will grow well even in a hot dry spot. The Scarlet Martagon, or Scarlet Turk's-cap, *L. chalcedonicum*, and its varieties, like a moist, but well-drained, good strong loam; this is not an easy species to manage, but where it does succeed it is one of the most beautiful of hardy Lilies. *L. croceum* (the Orange Lily) does better in loam on a damp subsoil than in a bed, no matter how well prepared, on a dry gravelly or sandy subsoil; it is a beautiful plant, and by no means common in gardens. *L. davuricum* and the numerous forms of the garden *L. umbellatum* thrive admirably in almost any garden soil; among dwarf-growing shrubs, as recommended at the commencement of these notes, the bulbils increase in size and number to such an extent that, although planted originally 6 inches or 8 inches below the surface, in about three years they will almost lift themselves out of the ground. The Chinese *L. Henryi* grows in both peat and loam; in peat, two years after planting, the stems measured 5 feet in height, and bore as many as nineteen flowers; in loam, however, the second year after planting, the stems had attained a height of 6 feet or 7 feet, and some bore upward of thirty flowers. *L. candidum*, as far as Kew is concerned, is one of the most refractory of Lilies; imported bulbs flower well the first season, but afterward, as a rule, fungoid disease attacks stem and leaves, and both dry up and wither before the flowers open. *L. longiflorum* will grow well either in loam or peat, and *L. Szovitzianum* likes loam with a clay bottom.

LILIES WHICH DO BEST IN PEAT.

First and foremost is the Golden-rayed Lily of Japan (*L. auratum*), which has already been mentioned. *L. superbum*, a noble species, with which, doubtless, your American readers are familiar in a wild state, does best in peat with us; the second and third year after planting it has reached 7 feet in height and upward, bearing from twenty to thirty flowers on a stem. Some seasons many of the bulbils will remain perfectly dormant, but the following season they will start again. *L. Grayi*, from Roan Mountain, does not, as far as my personal observation and inquiries on the spot go to prove, ever attain anything like the proportions in a wild state that it does at Kew. We have had our bulbils since 1891; they were planted early in that year in a bed of Azalea amoena, and most of the stems bore but one flower; the

following year the flowers numbered from two to five on a stem, the present season the stems have grown 5 feet high and borne from five to twelve flowers each. The little Japanese *L. concolor* (bright scarlet) and its variety, *Coridion* (bright yellow), the second year after planting among dwarf Azaleas have grown 2 feet high and borne from four to six flowers on a stem. *L. speciosum* and its varieties like peat, but soon deteriorate unless replanted and the smaller bulbils removed; with this species not more than two years should elapse without replanting. If arranged in clumps among low shrubs it is easy to move the clumps 1 foot or 2 feet, and so obtain fresh soil for the hungry roots to work in. The second year after planting we have measured *L. speciosum*, and found the stems to be 5 feet high, bearing from twelve to twenty flowers. *L. canadense*, *L. elegans* and its numerous forms, *L. Browni*, *L. japonicum*, *L. pomponium* and *L. sulphureum* are other Lilies which, in Kew at least, do best in peat.—GEORGE NICHOLSON, *Kew, in Garden and Forest.*

TUBEROUS BEGONIAS AT BEXLEY HEATH.

The tuberous Begonia is grown on a large scale at Bexley Heath, where Mr. T. S. Ware has established a nursery devoted entirely to this fine plant. A few days ago the plants occupying about 2 acres were a sheet of bloom. The several colours are kept quite distinct, and thirty-five long beds form the frontage, so to say, to the nursery. Generally each colour is represented by two beds, yellow, crimson and so forth, with the double varieties kept apart from the singles. The double Begonias in particular were remarkably fine, the plants very free, and bearing flowers individually of much beauty, especially the Picotee-edged and the yellow types. The Picotee-edged forms a charming class, the flowers each like a rosette, the segments white, margined with rose or shades of this tone. During the summer these beds have been as gay as later in the season in spite of the long-continued dry weather, which has not exactly suited the tuberous Begonia. We must draw special attention to the double yellow or rather a golden yellow shade, a very telling and handsome flower, either by itself or grouped in the bold way one sees it in this nursery. The double crimson is a very showy variety, especially when the sun shines upon the bed, lighting up the intense colour, and the double white besides the other colours are also worthy of note. We are pleased to see such prominence given to the double varieties, and also that the plants are robust, compact, and dwarf in habit, bearing the spikes well above the base of luxuriant leafage.

It says much for the value of such flowers that from early summer until mid-October they keep gay, and nothing but frost stops the season of blooming, whilst the varieties now are of great value for cutting. They last well in water, do not drop quickly, and the more delicate shades are useful for the most refined decorations. We saw a basketful of blooms of the soft-coloured kinds, and they were as acceptable as any exotic from under glass.

The same high character that distinguishes the double Begonias is also conspicuous in the single varieties. The several kinds are planted in distinct beds, and the flowers are of large size for October Begonias; but the fact is there is little to choose between those raised under glass and in the open, the flowers of the latter being quite as large and, if anything, more refined in colour. Size is not perfection, however, and it is noteworthy that the flowers here, although so big, lose nothing in beauty from this cause, being so firm and delicate in expression. During recent years a great advance has been made in the direction of getting good yellow-coloured kinds, and, as in the case of the doubles, the singles are just as effective, the various shades clear, decided and attractive. Vermilion in the sunlight is remarkably brilliant, so also the

crimson, crimson-scarlet and salmon varieties, besides many others too numerous to describe. In front of the grower's house (Mr. Pope) are many kinds grouped in beds, one variety in each bed, and this illustrates the beauty of the tuberous Begonia in even small gardens and its long continuance in perfection. Only a few days ago the flowers were as fresh as in midsummer and will continue so if frosts keep away. Several of the kinds here are named, which is not the case with the seedlings in the open, although well worth distinction. But the list of names would be of inordinate length, perplex the purchaser and soon prove valueless, as each year the flowers seem to improve in some particular, as the colour, shape, or new shades are got through skilful hybridisation. In the small beds is Beauty of Belgrove, a double kind, the flowers rich pink in colour, produced with freedom, and the plant is of good habit. Henshaw Russell, scarlet; Marquis of Stafford, crimson, and Hecla, rose, are all good double varieties, and in one case the bed is edged with a variety named Marie Lentz, which should be made note of for this purpose. The growth falls over on the turf, and the white flowers have the same drooping tendency. It is a delightful variety to form a graceful edging to a bed filled with more erect and taller things.

The tuberous Begonias at Bexley Heath are not all in the open, and a large collection is grown in pots, as those who visited the exhibitions this season know well. Many beautiful groups have been shown by this firm, and the plants are not yet over. Seven houses are practically filled with Begonias, comprising seedlings and cuttings. In one structure we see the double varieties, more particularly the rosette Picotee-edged type, so conspicuous in the open field. A few of the finer double varieties we noted were Bexley Gem, carmine-rose, a distinct and pleasing shade; Princess May, white, the inner segments fringed; Golden Empress, deep golden yellow, one of the finest of its colour we have seen, the plants of excellent habit; Queen Victoria, deep pink, the flower like a Camellia in form; Iona, golden bronze; Duke of Teck, splendid crimson; Mrs. Fell, salmon-rose; Duke of York, crimson; Leviathan, an immense rose-coloured flower, but although so large, not coarse; and PAVONIA, pink. Of the singles the best white is Bexley White, a pure, charming flower, and other very fine varieties are Vigilant, crimson; Valkyrie, salmon; Champion, bronze; and Alma, scarlet, besides many fancy colours, the outcome of crossing certain varieties to get new breaks.

During the summer one house was filled with plants in baskets, the growth of a distinctly pendent character. Salmonea, salmon, is one of the best for this purpose, but all shades of colour are represented. The tuberous Begonia is not made sufficient use of for this purpose, and varieties are grown ill-adapted for baskets. When a proper selection is made there are few prettier plants for baskets than this, and a few specimens create much needed variety.

SHORT NOTES.—FLOWER.

Violet Wellsiana.—This is a splendid Violet, the colour being very deep. A great advantage is also that it blooms early and continuously. The foliage, too, is not so coarse as in some other varieties, Victoria Regina, for instance. On light soils this may not be noted so much, but on heavy land it is undoubtedly so.—A. Y.

Pentstemon barbatus.—This plant has flowered more freely during the past summer than I ever remember to have seen it. This appears to enjoy hot dry weather. According to my experience it dislikes disturbance, and should be left alone when doing well and allowed to grow into a bold mass, which it will quickly do, and then flower freely enough. It is perfectly hardy.—T. A.

Pentstemons.—Among the most showy of all half-hardy herbaceous plants we must include the Pentstemon. Flowering freely from August until October, and being so easy to cultivate, I have for a long time been struck with their scarcity in all

but a few old-fashioned gardens. Pentstemons come very true from seed, and, unlike the majority of florists' flowers, do not produce inferior plants to the seed-bearing parent. But the best method of propagation is by cuttings taken off now (middle of October). The young growths, removed in the same manner as the cuttings of Phloxes, &c., will root freely in a sandy compost. It is best to insert them in small pots and plunge these in a cool frame where they can be kept close for a time. Pentstemons are more than half-hardy, and will generally go through the winter safely, but wet, with severe frost, is very injurious to them. Those struck now and turned out into good soil in the spring will bloom during the ensuing summer and autumn. There is no doubt that our wet winters are the worst drawback to their successful cultivation in heavy soils, but they are well worth a little protection and care, while a stock for the coming year may easily be made secure by propagating now and keeping them in a cool frame or pit until the end of March next.—R.

A protest.—Lilies and Roses, or rather one Lily and 4000 Roses, on October 6 graced our

ing power. For, alas! long before the end the tables were littered with the fallen Rose petals; whereas the one Lily present, in my button-hole (a solitary protest against the neglect of its race), a beautiful bloom from a bulb of *Lilium Henryi*, last year in China, was at the close of the feast as fresh as ever, and that evening was despatched by post to be viewed by one of our eminent Norfolk rosarians. This is but one of many instances how the popular taste flies to the Rose and neglects the Lily. Four thousand Roses to one Lily! Yet I venture to say that at this season of the year cut flowers of the speciosum and longiflorum Lilies, such as are grown at Colchester, in a decorative and lasting point of view put Roses completely in the background. Why, then, are they so neglected? —ALEXANDER WALLACE, M.D., Colchester.

The white Cosmos.—Penny packets of flower seeds have brought many pretty things within the reach of the humblest cottager, and now one frequently sees uncommon plants in cottage gardens. In Cuckfield recently I saw the white Cosmos in several gardens. The plants were strong, graceful in leafage, and covered with large pure white

tions. If once the custom of employing whiteflowers exclusively for this purpose is broken through, it may be taken for granted that for some time to come at least comparatively few wreaths will be made of white flowers alone. It has hitherto been a matter of sentiment, for the future it will probably be a question of taste as regards the choice of flowers for wreaths and crosses. It is to be hoped that the change of fashion will be decided and permanent, as we have so many flowers so suitable for this purpose that have hitherto been put aside on account of their colour. Coloured flowers are now much used for the decoration of graves, as many cannot command a supply of white ones.—J. C., *Byfleet*.

TREES AND SHRUBS.

MAGNOLIAS AT WASHINGTON CITY, D.C.

THE species and varieties of Magnolia indigenous to the States, as well as those from China and Japan, succeed admirably in Washington. Our warm, dry autumns mature the wood and perfect the flower-buds for spring. These plants are perfectly hardy. Our winters, in which the temperature occasionally goes down to 10° below zero, never injure wood or bud if the cold is uniformly steady. What we have most to fear is mild weather in January or February, followed by a cold snap. This injures the flower-buds. The past winter has been unprecedentedly cold, yet on the return of spring our Magnolias were very fine. *Magnolia stricta* (see the annexed engraving) looks like a cross between *M. Soulangeana* and *obovata*. The purple in the flower is deeper and richer than in any of this strain of Magnolias, crosses of which the original types were conspicua and purpurea, and of which we have now such a number of beautiful forms. JOHN SAUL.

Washington Nurseries, August 12, 1893.

Magnolia stricta in flower in Mr. John Saul's nursery at Washington, D.C., U.S.A.

unique Colchester oyster feast, when the Mayor of Colchester entertained royalty for the first time in the person of H.R.H. the Duke of Cambridge, with the Lord Mayor of London, the mayors of several East Anglian boroughs, and many other distinguished guests. Our Corn Exchange never looked better; the wall decorations were excellent and appropriate to the occasion, and the tables were adorned by a magnificent display of Roses and autumnal foliage. Four thousand Roses were sent to this feast by our local Rose growers. Rosarians were well represented by Mr. Mawley, secretary to the N.R.S., by all our local rosarians, and by Dean Hole, who delighted the company by an excellent and humorous speech. But—and in matters human there is always a but—where were the Lilies? Not only for oysters and Roses, but also for Lilies is Colchester celebrated, and the liliarians (why not, if there be rosarians?) of Colchester could easily, had they been asked, have placed on the tables 5000 Lily blooms, mostly of the speciosum group, which would have equalled the Roses in beauty and colour, and beaten them easily in last-

flowers. No doubt the season has favoured it, for the Cosmos is not generally adapted for open-air sowing.—A. H.

Linaria spartea.—This is a very old garden annual, having been in cultivation over 100 years, but one does not often see it now. It is, however, very pretty, neat in habit, the flowers bright, and altogether attractive when in sufficient quantity. It has a close, upright habit of growth, branches freely, and blooms profusely for many weeks, the flowers being of a clear rich yellow colour.—A.

Wreaths and crosses.—The use of coloured flowers for wreath and cross making appears to be on the increase. I lately saw a wreath made of Vallotas, and it is not uncommon to see wreaths in Covent Garden almost entirely composed of coloured flowers. I remarked one a few days since made of purple Asters. Autumnal-tinted foliage is also used, and has quite a nice effect. There is something appropriate in the employment of foliage in the last stage of its life for funeral decora-

Barberry berries.—The bright-coloured berries of the common Barberry, borne as they are in long drooping clusters, have a very pretty effect when used in a cut state for table decoration. They were employed in this way at the recent Aquarium show, and the vivid tints of the berries were very noticeable by artificial light, especially when contrasted with light-coloured Chrysanthemums. Hardy kinds of flowers, fruit, and foliage undoubtedly get more popular year by year, and this is as it should be, as the pleasures of hardy subjects can be enjoyed by nearly everyone; whereas both house plants are for a limited few. To return to the common Barberry, the great profusion of its berries this season may be especially noticed, while I was recently much struck with a nursery bed of the smaller *B. Thunbergi*, which in a sunny spot was an entire mass of scarlet leaves and berries. This Barberry is certainly a very beautiful shrub, which, though now pretty and well known, is not half enough planted.—T.

Caryopteris mastacantha.—Beautiful though it be most seasons when planted under favourable conditions, I never remember this Chinese shrub to be so full of flower as it is this year, and the clear bright weather of which we have had so large a share for some months past has caused the colour of the flowers to be much brighter than when we have a dull and damp season. It belongs to the order Verbenaceae, and forms a much-branched bush, clothed with ovate leaves of a hoary character, while the flowers are borne in great profusion on the upper parts of the shoots, and arranged in closely packed axillary cymes. The colour of the flowers is a rich lavender-blue. A succession of blossoms is kept up for some time, and some bushes of it that com-

menced to bloom in August are still—two months afterwards—quite a mass of blue. At Kew in front of the museum it has been an object of great beauty for some time, and it is equally fine at Coombe Wood, from whence it has been shown by Messrs. Veitch at some of the horticultural meetings. I note also that a certificate of merit was bestowed upon it at the October meeting of the Horticultural Society of Ghent. This *Caryopteris* cannot be considered thoroughly hardy in all parts of England, though in the southern counties it will thrive as an outdoor shrub. If given the protection of a wall it will in exposed situations be greatly benefited thereby. A light open soil of a loamy nature suits it best. It can be propagated without difficulty by means of cuttings of the young growing shoots put in a close frame during the summer months. This *Caryopteris*, which is a native of China, is said to have been introduced in 1844, but it is only within the last few years that Messrs. Veitch have made us familiar with it. Besides the generic name of *Caryopteris* it is also known as *Mastacanthus sinensis*.—T.

The Sea Buckthorn.—In common with other things this year, the Sea Buckthorn (*Hippophae rhamnoides*) is loaded with its orange-coloured fruit. This fine shrub is a native of Britain, but, unfortunately, seldom used to advantage. It makes, however, a beautiful winter picture. The growth is loose and the leaves have quite a silvery tint. It prefers a deep moist soil. It is useful to plant by the sea, but the sides of lakes and streams in inland gardens should be judiciously planted with it.

Hypericum patulum.—Very few shrubs flower so late in the season as early October, but such St. John's Worts as *H. patulum*, *H. oblongifolium* and *H. Moserianum* are still in full bloom. We saw recently two beds each of the Japanese *H. patulum* and *H. oblongifolium*. Those of the former were rectangular in shape, well exposed, and containing about forty plants each, arranged in rows, but the growth had met, thus relieving the beds of formality. It is when thus used that the *Hypericum* shows its true beauty. Each plant was in full bloom, the rich butter-yellow flowers borne on graceful shoots that touched the surface of the soil, and a display of flowers will be maintained until quite the winter. A moderately light soil and sheltered position, as far as possible, are desirable, as the plant is not so hardy as one would like. *H. oblongifolium* is more erect in habit, but very graceful and pleasing, the flowers also yellow. There is, however, a great difference between the two, and both may be planted without fear of sameness. Their late-flowering character is a great charm.

Hydrangea vestita var. pubescens.—We have more than once spoken of the value in our northern gardens of this hardy shrub. It is the most beautiful of all the *Hydrangeas* which are absolutely hardy in New England, and the earliest of all the species to flower in this climate. It is a shrub 4 feet or 5 feet high, with slender branches which form a dense broad mass 6 feet or 8 feet in diameter, ample pale green ovate leaves acute at both ends, and large flat cymes of flowers 5 inches or 6 inches across. The ray-flowers are numerous, an inch or more in diameter, and are at first pure white; in fading they turn rose colour, and, although they begin to open towards the end of June, remain quite fresh on the branches until November. It is a native of Northern China and Manchuria, and was one of a remarkable collection of trees and shrubs raised several years ago in the Arnold Arboretum from seed sent from Peking by Dr. Bretschneider, the learned botanist and physician for many years attached to the Russian Legation in China.—*Garden and Forest*.

Ampelopsis muralis.—There is a confusing list of Virginian Creepers in most catalogues, but names are more numerous than distinct varieties. That which bears the above name, however, is very distinct, strikingly beautiful, and cannot be too widely known. Some plants planted against a wall in April of the present year have made shoots 11 feet in length. It has the close clinging characteristic of *Ampelopsis Veitchii*, but the free,

graceful growth of *A. hederacea*, of which it is probably but a variety, but so good that we would prefer it to either. It clings tenaciously, but its leaves are as large and long as those of *A. hederacea*. In its present autumn tints it is quite as bright as any other kind. For quickly covering bare walls it is a valuable plant.

AN OCTOBER RAMBLE.

THE glorious weather we are now experiencing makes an October ramble a source of great pleasure, for although the gorgeous hues of summer have given place to the more sober tints of autumn, yet these will be found sufficiently lovely to well repay attention. Nowhere are the autumn tints more apparent than in the Dogwood (*Cornus sanguinea*), and as we may as well gather a bouquet as we proceed, we will commence with this, which will form a grand background and also work in as sprays among other subjects. On chalky soils this shrub is this season a mass of colour, forming a pretty contrast with its black berries. The same may be said of the Privet (*Ligustrum vulgare*), whose black fruits are finer than I have ever seen them, reminding one of small bunches of Grapes. The Traveller's Joy (*Clematis Vitalba*) sometimes has its foliage tinged with lovely hues, but even were this not so, we should find its feathery inflorescence, or rather seed-vessels, quite indispensable to our bouquet. No climber in my opinion equals this either in appearance, quickness of growth, or length of time it remains in beauty, as neither frost nor wet appears to affect its beauty. In fact, the finest display I ever saw of this was on a moonlit night in early December, the white fluffy sprays looking almost like feathery wreaths of snow. When, as often happens, the White Bryony (*Bryonia dioica*) entwines with the Clematis, an added charm is derived from the bright scarlet of its berries, these latter, although poisonous, materially helping to enliven our bouquet.

What can possibly be more beautiful at this season than the coral and orange berries of the Spindle Tree (*Euonymus europæus*). Near the Spindle Tree we shall find the Hawthorn (*Crataegus Oxyacantha*), the foliage of which yields to none for richness of colouring, and the red berries of which are always attractive and beloved by birds and children. Another favourite of children may be found in the hedges on the Dog Rose (*Rosa canina*) close by. These are a very necessary adjunct to our nosegay, supplying, as they do, a brightness of colour not excelled by any other berries. The mossy excrescences on the branches, which, as children in Berkshire, we called "Robin's Cushions," must not be overlooked. Neither must the fruit and foliage of the Bramble (*Rubus fruticosus*), which we shall find threading its way through the hedge, or hanging its tempting clusters of fruit far beyond our reach, be overlooked. It is a pity this is not more generally cultivated in gardens, for with very little care it gives as good or better returns than the Raspberry, while its flavour leaves nothing to be desired. All the berries have now disappeared from the Wayfaring Tree (*Viburnum Lantana*), but the foliage is sufficiently beautiful to command attention, as is also that of the Guelder Rose (*Viburnum Opulus*), with its ornamental red fruit, which may be eaten if desired, and is by the Norwegians esteemed when served with honey and flour. The Crab Apples of various shades also lend a charm to our hedgerows. The country folks gather these to perfume their clothes' chests, and I well remember when a boy storing them in hay until Christmas-time, when

they were not half bad eating, or, at least, were then greatly relished.

The Oak, Elm, Maple, Beech, Chestnut, &c., are now conspicuous objects in the landscape, and will all furnish their quota to our bouquet. Nor must we overlook the claims of the Mountain Ash (*Pyrus Aucuparia*). A few fronds of the Bracken (*Pteris aquilina*), now a golden yellow, will help our bouquet, and if flowers are desired, these may still be found in the Knapweeds (*Centaurea scabiosa* and *nigra*), Field Knautia (*Knautia arvensis*), Campion (*Silene vespertina*), Blue Succory (*Cichorium Intybus*), Toadflax (*Linaria vulgaris*), Yarrow (*Achillea Millefolium*), Golden Rod (*Solidago virgaurea*), Harebell (*Campanula rotundifolia*), Hawkweeds, Thistles, Mints, and many others, while a few sprigs of Burdock, coloured leaves of the Cow Parsley or Cinquefoil, and a head or two of the Teazle may be added for variety.

If we have gathered a few sprays of each as we proceeded, we shall have at our journey's end a bouquet which will well repay our trouble.

EDWARD JAMES CASTLE.

AUTUMNAL TINTS.

THE beautiful and varied leafage colouring which we all admire so much in autumn seems likely to be of short duration this season, owing to the long drought experienced during the last five or six months. Trees have suffered greatly, as the rain we have had has been insufficient to penetrate any distance, the surface layers absorbing it rapidly, so that the roots of the larger trees have received a scant supply. In consequence many trees are already denuded of their foliage, especially the Limes and Horse Chestnuts; some of the latter indeed have been bare for several weeks. In the case of other trees also the change of colouring is not so gradual as usual, nor so bright; the leaves have lost their vitality, they turn to a dull yellow or brown and fall almost immediately. The Elms are carrying their foliage well, as also are the Planes, but the Beeches are changing rapidly. The soft yellow hue of the last named in early autumn is only less pleasing than the delicate green of the young leaves in spring, and a background of tall Beech trees brings plantations of dark conifers into fine relief now. The Oaks are with a few exceptions less effective than usual, but *Quercus coccinea* is handsome, and on a bright day a fine specimen of this beautiful Oak under my notice has still a grand appearance, though its leaves are falling fast. These are crimson and brown, the under surface very richly coloured, and those not quite so far advanced have rich red margins and yellow or green centres—a pleasing variegation. The Black Oak (*Quercus nigra*) is far from black at the present time, as the leaves are of a uniform deep red and brown that impart a telling effect. The Cockspur Thorn (*Crataegus Crus-galli*) has been heavily laden with its bright red fruits, and now the leaves are assuming varied tints of crimson and yellow in contrast with some remains of their original green hue. Much the richest colouring is, however, displayed by a small tree not by any means widely known, *i.e.*, *Parrotia persica*, a relative of the Witch Hazels. This forms an elegant tree of pyramidal habit, and the leaves, which are turning colour at the present time, present a range of bright shades from crimson to yellow and green. Some of the leaves are wholly crimson of a brilliant tint; others not so far advanced have a fine metallic appearance. Masses of *Cornus sibirica* are also effective, the nearly leafless branches and stems being deep red.

OBSERVER.

The Tamarisk.—It seems strange that the common Tamarisk (*Tamarix gallica*) is so seldom planted away from the sea-coast. Undoubtedly it enjoys the sea air, and it is seldom injured by stormy weather, but it succeeds equally well in-

land, and is so well adapted for a variety of purposes, that it forms an object of grace and beauty in the shrubbery or other parts of the garden. When allowed to grow at will its habit is very elegant, the feathery and supple sprays being full of grace. As a hedge plant, too, where strength is not so much the planter's object as the forming of a screen, no plant looks better or better answers the purpose, for it bears the knife well and grows quickly when young. Quite lately I saw such a hedge near the roadside between Sandgate and Hlythe, and although the plant lost something of its beauty by the formal shape into which it had been cut, most other hedge plants would have suffered more by the same treatment. The hedge was studded over with small sprays of foliage delicate in form and colour. Sprays cut from freely grown plants are often very useful and last fairly well in water.—J. C. TALLACK.

AUTUMN BERRIES.

THE autumn berries and fruits of many plants are so brilliant and beautiful, offering such rich opportunities for special and seasonable effects, that one wonders more attention is not given them, and good things boldly planted for the development and enjoyment of this feature. Special prominence should be given to those things that are full of variety and seasonable changes in preference to the broad expanse of common Box and Laurel or the muddled, tangled thickets that pass as ornamental shrubberies in public and private parks and gardens.

The Sweet Brier has several aspects of beauty—the budding of the leaves, the delicate beauty of the flowers, and then the after-glow of its hews in autumn, this the most enduring charm of all, for they usually hang upon the bushes till another year dawns. Among single Roses there is for the garden a goodly number of fine things whose autumn display of fruits is very striking. The Japan Rose, with its great Apple like fruits, is in the zenith of its beauty in autumn, and nothing could be finer than the scarlet fruits in clusters among the rich yellow leaves. The Water Elder everywhere on the margins of our Sussex woods is borne down with the weight of its profuse clusters of coral berries, and proves that we lose something in neglecting it and giving preference to an abnormal form that has no interest whatever beyond the week or two it remains in bloom. Cotoneasters are at their best in autumn, and there is variety among them, too, with microphylla for clothing banks and rocks; Simoni to associate with other shrubs, its long wand-like covered in berries, and the tree-like frigida and affinis, which have their berries in great flat clusters at the ends of the shoots. Hollies and Hawthorns are hosts in themselves for autumn and winter effects, and few things are more brilliant in the sun on an October day than the Spindle tree laden with pendulous fruits. From the wild Roses that are happy in heavy clay to the Pernettyas, rambling shrubs most varied in colour of fruit and lovers of peat and sand, there are berry-bearing shrubs for all situations, and an abundance of them to enable the planter to use them in a bold, free way.

A. H.

Two rare Pines.—In Mr. J. Rashleigh's garden at Menabilly, in Cornwall, are growing two Pines, which are very rarely to be seen in England, and nowhere, I believe, so fine as here. They are *Pinus Montezumæ* and *P. oocarpa*, both natives of Mexico. Of the two, *P. Montezumæ* is the handsome, and it is now about 18 feet high, broadly pyramidal in habit, and furnished with branches to the base. The leaves are produced in tufts of five together, and give the tree a particularly striking aspect by reason of their length and peculiar blue-green colour. *P. oocarpa* bears a considerable resemblance to its companion, having the same style of growth and foliage. It is not so shapely, neither has it leaves the distinct colour of those of *P. Montezumæ*. Neither of these species can be grown in this country except in the south and west, which is

certainly a matter for regret. They are two of the most interesting objects at Menabilly, full as that garden is of interesting trees and plants.—B

Pseudolarix Kæmpferi.—From the time of the introduction of this conifer by Fortune in 1816 till within the last few years its proper position in the natural order was a matter of very diverse opinion, and it was successively known as an *Abies*, a *Larix*, and a *Pinus*. In 1884, however, it was fixed by Dr. Masters as a new genus—*Pseudolarix*, as had, indeed, been surmised by Gordon long previously, and it is now definitely known under the above name. It is a native of Northern China, and is known in English gardens (from its close resemblance in foliage and habit to the true Larches) by the names of Chinese Larch and Golden Larch. According to the "Report of the Conifer Conference" (1892), the largest example growing in Britain is the one in Colonel Tremayne's garden at Carclew, near Falmouth. I had the pleasure of seeing this tree a few days ago, and it certainly deserves all that has been said in its praise. This specimen is over 30 feet high, and the stem measures nearly 1 foot in girth at 2½ feet from the ground, and is clothed from the summit to the base with the beautiful semi-pendent branches. The beauty of the tree is greatest, perhaps, in spring when the tender green leaves are unfolding, but it is also very charming in autumn when they put on a golden colour. At present the species is not common in trees of any size. Fortune described it as very difficult to introduce, owing to the loss of vitality in the seed during transport, but now that plants have been raised from seed ripened in Europe it will, no doubt, be extensively planted as an ornamental tree. From the midland counties southwards it is quite hardy.—B.

ROSE GARDEN.

INSECTICIDES FOR ROSES.

HOWEVER thoroughly the cultivation of Roses may be understood, whether grown in large or small numbers, reliable insecticides judiciously used are one of the chief factors towards satisfactory results. This fact is so fully recognised, that a large number of insecticides have been put upon the market, all of which are probably of equal service when properly used. But there is considerable art in applying them at the exact strength to be effectual, and yet avoid the least injury to the young growth of Roses. One may easily kill the insects attacking the plants, but it is not so simple to do this in a satisfactory manner without occasionally going so far as to harm the tender growth which the majority of insects affect. As we shall so soon be among the young growth of forced Roses, and there is a wonderful advantage in early operations, I propose giving a few practical hints upon this important matter.

The old proverb or "prevention being better than cure" is particularly applicable to the subject now in hand; indeed, I may say that, whereas prevention of serious attacks is easy enough, it is almost impossible to effectually cure or eradicate an insect pest when once a good footing has been obtained. The fact of insect life being capable of surviving the fumes of tobacco or the properties of soluble insecticides to so nearly the same extent as the tender young growth of Roses makes it more than ever necessary to commence operations in time. Immediately the Roses are potted and pruned, they should be carefully looked over to see if any insect pests exist. The only one likely to be upon plants in this stage is scale, one of the hardest insects affecting the Rose. As it is so difficult to kill and mostly affects the older wood, it is, fortunately, easily got at during this stage. It is impossible to eradicate scale after young growth has commenced, the older insects being particularly hardy and prolific. In fact, their miniature tortoise-like covering renders them impervious to most insecticides, and also acts as protection to

the young until they, too, are difficult to kill. Scale spreads over a plant much faster than many would imagine after noticing how permanently the full-grown specimens take up their quarters. It is the young insects which travel in search of fresh spots whereon to camp. As soon as the plants are introduced to a genial temperature, the scale breeds apace, and the young may be seen moving with considerable rapidity; therefore we see an excellent reason why measures should be taken to kill the parents, and at the same time render the bark of the Rose wood distasteful and probably fatal to the young of any survivors. To secure this, I would recommend the use of insecticides at quite double the strength advertised for syringing purposes. It is also more effectual if a few drops of paraffin oil be added. A solution of this strength must not be applied with a syringe. Not only is it too expensive, but the effects when used so strongly are often injurious to the roots. Use a soft hair brush, or else a small piece of sponge; anything, in fact, that will allow of your slightly touching the whole of the Rose wood. Nor is this absolutely necessary if a due amount of the paraffin oil be used. This will cause the solution to spread over the wood freely and reach all parts, while at the same time there will not be enough to run down to the base of the plant, and so cause too large a quantity to accumulate at one point. When applied with a syringe a considerable amount runs down the wood, and is often injurious at one of the most important and vital parts of a Rose. This strong solution will kill the scale and still leave a certain property upon the wood which will be very distasteful and oftentimes fatal to the young of any survivors. It is obvious that such strong measures could not possibly be adopted at any other time than the one pointed out, and this is the only instance in which I can recommend a strong insecticide.

Other insects and diseases attack the young growth and foliage in preference to older wood; and as the insects are, if anything, a trifle harder than the young growth, we need to be very careful in applying any remedies. My own plan is to commence as soon as young leaves appear, whether I detect the presence of aphids, &c., or not. This is cheaper in the end, and invariably effectual if properly done. Use any of the insecticides which have a reputation, but when using them thus early, confine yourself to half the advertised strength. Insecticides sufficiently strong to kill full-grown insects at one application cannot fail to afford more or less of a check to the very tender points of young growth. This is more likely to be the case for the two following reasons; both the young leaves and points of growth naturally retain a greater amount of the solution on account of their closeness through partial development, and also because the insects, through congregating at these points, have more of the insecticide directed against them. A weak solution, applied with more freedom, is equally as effectual and far less likely to do harm.

In fumigation a considerable amount of discretion is also necessary. This is not in favour with me among Roses, because early and judicious syringing is almost as effectual and tends to keep the pores of the foliage open and clean. The drying properties of tobacco close these, and oftentimes injure them; still, there are times, especially during very dull winter days, when the syringe would be keeping the foliage and atmosphere too moist, that a judicious fumigation is preferable to other methods, also when the growth and foliage have become too dense for the syringe to reach the whole. In these cases the tobacco fumes are valuable, but are rendered doubly effectual if a weak application be prolonged for more than the usual time and then followed by a free use of the syringe early the following morning. A short and strong fumigation seldom kills all of the insects, while it invariably injures the young growth more or less; indeed, I have seen scores of instances where the loss of a valuable crop could be readily traced to this cause. Many Roses, more particularly *Niphetos* (the best of all whites under glass), are exceedingly susceptible to the effects of fumigation,

This variety will often cast the whole of its flower-buds during the week or two after fumigation, even when other kinds have apparently received no injury. The buds turn black and the whole crop is lost.

I have avoided recommending any special preparation in these notes, as all of the tried insecticides are about equally effectual; but I may call attention to the free use of soft water at a temperature of 70° to 75°. This will often remove many insect pests from the foliage and is always well worth the trouble of application on account of its cleansing and beneficial properties in keeping the foliage free from dust and other impurities, thus encouraging healthy growth and putting the plants into better heart for withstanding the attacks of the numerous enemies the Rose is subject to.

RIDGEWOOD.

THE PLEA OF CLIMBING AND RAMBLING ROSES FOR A SOAKING.

No rosarian with his eyes and heart wide open can pass through garden or landscape without reading the signs of distress writ large on most of the larger Roses of ruder growth. True, the screens and sprays of beauty have shut out some of the fierceness of the sun's heat from the parched roots. But, on the other hand, these beauty screens have proved drains for moisture as well as displays of grace and beauty, and the signs of distress are everywhere apparent in falling leaves and deepening tints of autumn and traits of winter. These, in spite of many autumnal blooms, are the heavy footprints of the long-continued drought.

Passing along the front of a south wall clothed with Tea Roses the other day, it was deeply marred and scarred with the victims of the feverish heat. Here a plant had been dried up bodily, and there a huge branch, and further on other smaller boughs and branches, and yet others as bare of leaves as the same plants in December or January—all and sundry the victims of an almost unbroken year of drought, so far as reaching or relieving the climbing Roses was concerned. The surface had been sprayed occasionally, dwarf and standard Rose roots just slightly refreshed, but that was all. And still the rain holds off, and the great masses of Rose roots that send those graceful tops far and wide in ever welcome sprays of grace and beauty are as hard as rocks and as dry as bones. The drought has had its way so long, that it may be assumed to have done its worst among the Roses. But it has not. For the latter end of these parched roots may prove worse than the first. They have been semi-parched, baked and starved for months. That must have proved hard measure for our Roses. A water famine of such severity for so long has had to be endured. And now the Rose roots are in imminent peril of a plague of fungi, which may prove far more disastrous. It is, therefore, worth while to turn a deluge of water wherever practicable over our climbing, rambling, and other Roses as our surest antidote to a plague of fungi. Most of the latter may be flooded out or prevented from weakening or crippling our Rose roots through liberal waterings with water, clean or foul. Perhaps as antidotes to fungus on roots, the fouler in reason the water the better, for fungoid pests are fastidious as well as powerful. A fume or a taint in the water may make all the difference between a stimulus to fungoid life or a potent means of death.

As a mere moistener of roots it makes little difference whether the water that shall saturate our Rose root-runs shall be clean or heavily charged with other elements of life or death. But as an antidote to fungoid growth on or among the roots of Roses, and as a source of Rose food, the balance is all in favour of foul—that is, manure water, such as liquid excrements or house sewage.

Watering with such material will virtually kill three birds with one stone—that is, quench the thirst of our Rose roots, deliver them from the paralysis of root fungus, and feed them promptly and abundantly with the richest and best Rose food. Much splendid saving, feeding, strengthen-

ing, and feeding materials are also mostly within easy reach of our Roses. All that is needful is to search out, convey, mix, and apply them. Here also we do two most useful things at once—improve the sanitary surroundings of our homes and gardens, and improve the health, perhaps save the lives, of our Roses. The most dangerous liquid refuse is sent deep down to refresh and strengthen the parched roots of our Roses, and reappears transformed into flowing wreaths of fragrance and beauty.

D. T. FISH.

Pot Roses.—Now that cold and wet weather combined with rough winds is upon us, it seems a pity to lose any of the numerous buds showing on the latest batch of pot Roses, more especially as we are getting so short of these and other flowers. It is always a trying time to provide cut flowers in any quantity between late autumn and early winter, and they are often in greater demand at this time, a sharp frost causing a sudden cessation out of doors. Even if we were to allow these plants to remain out in the open with the object of ripening them more thoroughly, I do not think this would be accomplished in a more satisfactory manner than by givingslight protection during the roughest weather. My own pot plants that were removed from the houses last, and which will not be needed for forcing until I want my latest batch, are now carrying quite a respectable show of bloom. A few days ago I had the whole of them placed in a deep pit, and have found some clean and very acceptable blooms during the recent rough weather. The lights are only put over them upon a clear night when frost threatens and during heavy wind or rain. By this means the complete ripening of the plants is not hindered in the least, and I get the full benefit of this late crop. When Roses are in this stage, and removed to the greenhouse where full exposure cannot be given when needed, mildew generally sets in strongly; nor do we secure such desirable firmness in the wood for next spring's forcing. Frost with rough elements is certain to spoil many of these valuable late blooms unless partially protected in the way I have pointed out.—R.

Rose Aimée Vibert.—My previous note on this Rose was prompted by the profuse bloom of some plants of the climbing variety which grows on a wire trellis. In either of its forms it is a free and lovely old Rose, and happily lives yet in not a few cottage gardens, in one of which I saw it recently clustering round the window a perfect wreath of bloom. I agree with "D. T. F." that it is much hardier than Lamarque, but nevertheless very susceptible to injury from severe and prolonged frost. Both these fine Roses, however, have great recuperative powers. One result of this is that they are often bursting into bloom between the summer and autumn displays, and such was the case with Aimée Vibert, which had been closely pruned in spring through injury to its strong, but soft pithy shoots.—A. H.

Rose Caroline Testout.—I was surprised to see Mr. Piper's remarks in THE GARDEN (p. 361) on this Rose and to read that he "liked it better than La France." At the present time, when La France and its white counterpart, Augustine Guinoisseau, are and have been for some weeks the best autumnals of the season, I fear it is a somewhat unhappy sentiment to have expressed. But I do not write this note in defence of about the fairest and sweetest production of Guillot, as La France requires no champion; as yet in her way she has no rival worth mentioning. Caroline Testout I have grown for three seasons, and my opinion of it is very favourable as regards its colouring, fairly favourable as to its growth, but unfavourable as to its value when fully developed. Several times this season when in the bud state I entertained hopes of at last seeing a perfect flower, but as soon as the flower was fully formed it became a ball in the centre, and so it seems to go throughout the Rose season. As to its being declared the best of the Hybrid Teas, I am quite certain it never will be, as, putting La France aside as in-

initely superior, the Rose Viscountess Folkestone is also far preferable to it. I think most people would class other Hybrid Teas also as superior, and I will instance Grace Darling, Kaiserin Augusta Victoria, and the before-mentioned Augustine Guinoisseau.—CHARLES J. GRAHAM, *Croydon*.

GARDEN FLORA.

PLATE 933.

LYCASTES.

(WITH A COLOURED PLATE OF *L. AROMATICA*.)

AMONGST Orchids which require to be grown in cool or intermediate temperatures the Lycastes must always occupy a prominent place, more especially in the collections of those who are just commencing Orchid cultivation. They are all easy to grow, and, given anything like fair treatment, never fail to flower abundantly; their initial cost, too, is with few exceptions very small. To be in strict accordance with the latest classification of Orchid genera, Lycaste should be made to include the older divisions of Colax and Paphinia. But however just such an arrangement may be from a botanical standpoint, it is inconvenient from that of the Orchid grower. Neither Colaxes nor Paphinias bear much superficial resemblance to the true Lycastes, and although of great beauty, they cannot be spoken of so favourably in the matter of cultivation. The present remarks, therefore, apply only to the older Lycastes.

One great point in favour of this genus is the handsome and luxuriant habit of nearly all its species, their leaves (two or three of which are borne on each pseudo-bulb) being large, plaited and bright green. As the older ones remain in most instances until the young foliage is developed, the plants are always ornamental; it may, indeed, be said that no Orchids present a more uniformly pleasing appearance in regard to foliage than well-grown Lycastes. Their flowers, whilst somewhat stuff in outline and pose, are always handsome and striking either by reason of their size or colour. They are produced singly (very rarely in pairs) on upright scapes springing from the base of the matured pseudo-bulbs, and as a rule last long in perfection. Lycastes are now frequently made use of for room decoration, for which purpose the firm texture of the flowers and the robust constitution of the plants make them better fitted than most Orchids. They should, however, be kept in rooms only when the flowers are at their best, and whilst there, should be guarded from the scorching heat of fires, and, on the other hand, from cold draughts. The genus is an exclusively New World one, being spread over an immense area of the tropical part. Representatives are found in South Mexico, whilst others reach as far south as Brazil and Peru.

CULTURE.

One of the good qualities of Lycastes is their amenability under cultivation to different conditions, which enables those without houses specially set apart for Orchids to grow them successfully. In regard to temperature, they may, for instance, be grown in an intermediate or cool house. The temperature which best suits them is probably one between the two, so that if grown in the intermediate house, the coolest part should be given them; if in the

* Drawn for THE GARDEN in Mr. Sander's nursery at St. Albans by H. G. Moon, June 8, 1893. Lithographed and printed by Guillaume Severeys.

cool house, the warmest part. Of the two the former is preferable, although I have seen *L. Skinneri*, *Deppei*, *aromatica* and other species kept in perfect health year after year in a house where *Odontoglossums* and *Oncidiums* are grown. Greater care, however, is required in watering, especially at the time the flower-spikes are pushing up; if given too much, they are apt to decay. *Lycastes* should be grown in pots, or, in the case of large specimens, in pans, and as they require water in great abundance in summer, the importance of perfect drainage is very necessary. The most suitable compost for them as a whole is one of fibrous peat and chopped living *Sphagnum*, but for healthy plants of *L. Skinneri*, *Deppei*, *gigantea* and other strong growers I should recommend a modicum of loam fibre in addition—say a proportion of one-fourth—and a little coarse silver sand or fine broken potsherds may be added along with the loam. Notwithstanding the size of the pseudo-bulbs of *Lycastes*, which seem to indicate a power of withstanding long periods of drought, it is found under cultivation that they should not be "dried off" when at rest; but, on the other hand, kept fairly moist, more especially when grown in the *Cattleya* (intermediate) house.

The number of species now in cultivation is probably not far from thirty. Of these it is not necessary to grow more than one-third, as several of the species closely approach each other and others are scarcely worth cultivation, except by those aiming at a complete collection. The first undoubtedly in beauty and importance is

L. SKINNERI, introduced from Guatemala in 1842. This plant is a remarkably variable one, so variable indeed, that it has been said large importations have reached this country in which no two plants had flowers exactly alike. In what may be termed the typical form the sepals are bluish-white, the smaller petals deep rose and the lip white spotted and stained with crimson; but the range of colour found in this species may be illustrated by var. *nigro-rubra*, with deep mauve and purple flowers, on the one extreme, and var. *alba*, wholly pure white, except for a faint patch of yellow on the lip, on the other. Var. *alba* was for many years a very rare and expensive Orchid; latterly, however, it has become more plentiful and cheaper, occasional plants being imported and the older ones propagated. It is the most delightful of all *Lycastes*. The flowers of *Lycaste Skinneri* measure from 5 inches to 6 inches in diameter, and, considering their large size and the substance of the segments, the number produced by vigorous plants is extraordinary. On one pseudo-bulb of an imported plant I have counted the remains of seventeen flower-spikes, and on plants that have been in cultivation for many years I have had as many as fifteen produced at one time by a single pseudo-bulb. The normal flowering season of this species is the first three months of the year, but one sees them as early as November and as late as May.

L. AROMATICA.—This is a Mexican species introduced in 1828. Its flowers are very pretty, being of a tawny yellow with a greenish tinge on the outside and orange spots on the lip; they are also noteworthy for their pleasant aromatic perfume. Each blossom is $2\frac{1}{2}$ inches across, and the species possesses in the fullest degree the profuse flowering character of *Lycastes*. It blooms in May and June.

L. CRUENTA, which by mistake is named *L. aromatica* in the plate, is really related to *L. aromatica*, but differs in its larger flowers and the more tawny greenish colour of the sepals; the lip also is distinct by reason of its reddish spots and deep crimson blotch. This species comes from a more southern locality than *L. aromatica*, being a native of Guatemala, whence it was introduced in 1841.

L. DEPPEI is an old and well-known kind, of Mexican origin. It is a vigorous growing plant,

and flowers with great freedom. The blossoms are 1 inches across, the sepals being of a soft green marked with purplish brown, the petals pure white and the lip dotted with crimson. In the fine variety *punctatissima*, introduced by Messrs. Williams, of Holloway, the whole flower is freely spotted with dark purple.

L. PLANA, a native of Bolivia, originally found in 1841, has olive-green sepals and pure white petals—a very pretty contrast; the lip also is white, but spotted with blood-red. This species, like several of the *Lycastes*, is variable, some forms having an unspotted lip. One of the best varieties is *Measuresiana*, the sepals of which are reddish brown, the petals and lip white spotted with light rose.

L. GIGANTEA is a strong growing plant, with leaves upwards of 2 feet long. The flowers are large, having olive-green sepals and petals, and a lip rich velvety maroon bordered with orange. It is, however, more striking than beautiful.

There is a section of *Lycaste* not yet mentioned which contains two species different in several respects from any of the preceding. These are *L. Harrisonia* and *L. tetragona*. They have four-angled pseudo-bulbs, tapering towards the top and carrying only one plaited lance-shaped leaf. The flowers are distinguished also by the petals being of about the same size as the sepals; whereas in the species previously mentioned they are much smaller. The flowers of *L. Harrisonia* are 2 inches to 3 inches across, and produced in pairs. The sepals and petals are creamy white, the lip purple in front and yellowish at the base. A native of Brazil, introduced in 1828. It is known also as a *Bifrenaria* and as a *Maxillaria*. A fine variety of it is named *eburnea*, the flowers of which are pure ivory-white, except that the lip is striped with crimson. The second species, *L. tetragona*, is similar in habit and inflorescence to *L. Harrisonia*. The sepals and petals are green with reddish brown lines and blotches, whilst the lip is white, stained with purple inside and crimson without. This species comes also from Brazil.

THE WEEK'S WORK.

ORCHIDS.

WE are now getting into the period of the year when Orchids try the patience of the best cultivators. The great factor in building up a healthy growth in our plants is light. Those plants that are quite in their resting period do not require so much light, but plants in growth or in the process of ripening their bulbs certainly do require a great deal of light, and this we cannot obtain for them near London at any rate. Next in importance to light is heat; by the use of the modern heating apparatus we can obtain almost any degree of heat we require, that is if the houses are efficiently heated. They should rather have an over than an under supply of hot-water pipes, for if it is necessary to make the pipes very hot, in order to get up the temperature, the air is thereby made unwholesome, and not such as Orchids can thrive in. Air is almost of equal importance to heat; a supply of fresh air for the plants is needed even in cold weather. Orchids feel the effects of the want of air very much indeed, and probably are quite as sensitive to the influence of impure air as human beings. I have often advised admitting air by the side ventilators, so that it passes over the hot-water pipes before it comes into contact with the plants. On all favourable occasions the top ventilators must be open a little, thus causing the fresh air to filter slowly through amongst the plants. Lastly, moisture in the atmosphere must be considered, and at this season it is easier to have too much moisture than too little, although over-dryness causes the leaves of *Cattleyas* and some other things to be-

come yellowish. During summer we obtain a great deal of moisture from the water in the evaporating troughs cast on the hot-water pipes, but from the end of October until March it is better not to have any water evaporated in this way. In dull moist days damping down once will be sufficient, but when it is bright sunshine it is better to damp down twice, and on such days the temperature of the houses may be about 10° higher than at other times, for the sun has still considerable influence upon the temperature, and its effects upon the plants are excellent in preparing them for the still more gloomy period into which they have yet to pass. The difference between the temperatures at the cool and the warm ends of the house is greater in winter, and this is rather an advantage, for plants that have quite made their growth and are at rest may be placed at the coolest end, and those yet struggling to make their growth may be placed where they get more heat. Even in our house, only 50 feet in length, there is at present a difference of 5° between the coolest and the warmest end.

The first flowers of the old *Cattleya labiata* opened last week, and they certainly develop best at the warmest end of the house. There also should be the *Lælia purpurata*, *L. elegans* and the slender-growing *L. harpophylla*. All the *L. elegans* and *L. purpurata* types should be at some distance from the side of the house; the cold wind sometimes finds its way through the sashes, causing much injury to the plants. I shall ever remember losing a very fine variety of *L. purpurata* over a quarter of a century ago. The house had been kept up to the regulation temperature, and the slightest opening, not an eighth of an inch, caused the loss of the plant. A frost wind had been blowing directly upon the glass for two or three days and no other plant suffered. If it had been on the centre stage, as it might easily have been, it would have been all right. Houses cannot be, as it were, hermetically sealed, and it would not be well if they could, for the air filtering through the slightest opening at the sides of the closed sashes is essential to the well-doing of the plants. We are now getting some very beautiful flowers in the warmest house, and very lovely indeed are the long handsome spikes of *Vanda cærulea*. This delightful *Vanda* does not succeed equally well in all collections even if the utmost care is bestowed upon it. I bought half a dozen plants about ten years ago and they grew away very freely at the lightest, coolest end of the *Cattleya* house, and for a period of about four years they produced splendid long spikes with a score or more flowers upon each, but afterwards they gradually declined in vigour and seemed as if they would pass out of existence until I removed them to the warmest house, where they have greatly improved in appearance and most of them produce good spikes. The most noteworthy specimens of this *Vanda* have made their growth in the warmest Orchid house, but it is certain they do well for some years after being imported at the coolest end of the *Cattleya* house. The great point seems to be to allow the plants to have a decided season of rest. The resting period of *Vandas* may be known by their roots, which become covered at the tips with a greyish film. *Vandas* of the *V. suavis* and *V. tricolor* type do better in the *Cattleya* house, and those who manage them so that the leaves nearest the base are retained may be thankful, for many good growers fail in this. Probably the form of the house has something to do with it, for the best growers are sometimes baffled to grow their plants satisfactorily. They flower quite as well when the stems are somewhat bare, but the appearance of the plants is not improved by the loss of the foliage. A great deal depends upon the atmospheric conditions and the manner in which the plants are rested. I have seen remarkably healthy specimens in a house wherein the temperature fell to 50° very frequently in the winter.

In the *Cattleya* house the well-known *Lælia autumnalis* and *L. albida* will now be in flower; both are very lovely, but the perfume of the former is not pleasant. These Mexican *Lælias* are not easily managed—at least few growers can keep

them in good health for six years or so; the native energy of the plants seems to be expended in three or four years, and although they will flower for a little while longer, the spikes possess none of the vigour of the native growth. It is certain the plants do better close up to the glass roof, and scarcely shaded at all even in summer. The plants of *Lælia anceps* in variety are flowering very freely this year, and the white varieties are certainly amongst the most beautiful of Orchids, and there is no difficulty at all in keeping them in good health. I think the great charm of Orchid culture is to keep plants from year to year, and see them growing larger and flowering more freely as they get older. It is best to keep the plants of *L. anceps* as near as possible to the glass, but as the spikes develop the plants must be lowered, so that the tips of the spikes do not come into contact with it. Plants of the *Lælia pumila* type that I have passed out of bloom should still be kept up to the glass, and when it is seen that the bulbs are fully developed the plants should be kept rather dry at the roots. *Cattleya marginata*, *C. Pinelli*, *C. spectabilis*, and *Lælia Dayana* all come under the *L. pumila* group. They are all charming Orchids, and should be grown in small teak baskets with but little peat and Sphagnum about the roots. Orchid blooms last a long time in good condition upon the plants at this season if the atmosphere is not kept so moist as to cause them to spot; if this happens they soon decay.

J. DOUGLAS.

THE KITCHEN GARDEN.

ASPARAGUS.—In the majority of cases the tops of Asparagus are fit for removing, and they should be cut off close to the surface with a scythe, afterwards clearing off all weeds and rubbish, so that the frost may have free access. It is also advisable to fill in the soil about the stems with the back of a fork or rake. Especially is this necessary if there is a cavity around the stems from the effects of wind-waving, and into which, if not filled in, the wet is apt to find its way and so cause decay of the roots. The practice of surfacing the beds over in the autumn with rotten manure is not a good method, for although injury may not accrue to the roots when growing on light or gravelly soils, on heavy soils it undoubtedly does so by causing the roots to lie cold and wet, and consequently they decay or become greatly weakened. By leaving the surface exposed the roots lie warmer, and there is no fear of injury from frost. Spring is the best season to apply a top-dressing just in advance of growth taking place. The same remarks are applicable to Asparagus growing on any kind of soil; but in those cases where it is decided to surface-dress in the autumn, the best material for the purpose will consist of equal parts of rotten manure and burned refuse. This will keep the soil open, for when manure only is applied year after year, the texture of the beds becomes what is termed soapy, and the roots suffer accordingly. In the case of raised beds, the tops of the crowns are apt in time to become too deep, this also being a source of partial failure of the crop. Where this is the case the better course would be to remove some of the surface soil into the alleys between the beds or to within 2 inches or 3 inches of the crowns, the surface dressing being placed direct on this. Where the beds are raised and narrow, and the produce from them is not satisfactory on account of want of support or through dryness, a course of renovation I can strongly recommend is to fill in the intervening space between the beds with some rich and open material, into which the roots will ramify and the crowns derive great support. Such material as decayed vegetable and burned refuse, road grit, sand, manure and such like material will be found excellent for the purpose. This may be collected together during the winter, be turned occasionally and wheeled on at any time before growth commences. The benefit of this will not be seen the first season, but afterwards, on account of the increased growing force, a marked change will be apparent.

PROTECTING BROCCOLI.—Veitch's Self-protecting Broccoli has grown wonderfully well of late, and although good heads are now forthcoming from the open, yet it is not safe to depend upon these, for although with a continuance of fine open weather good heads might, perhaps, be cut for some time longer, some kind of protection will have to be devised so that the most is made of them. Especially should this be done where, on account of the late dry weather, the plants were slow in starting into vigorous growth. The means at command will, of course, gauge the kind of protection which can be adopted. Rather deep brick pits where the heads would have room for free development without the foliage touching the glass are excellent places; so also are vacant spaces on the floors of vineries or Peach houses, where such a proceeding will not interfere directly with the borders. In either case the plants must be taken up carefully with a fair-sized ball. This is all the more necessary where the heads are not fully developed. To facilitate the work, it is advisable to draw the foliage together and tie with a piece of matting, cutting it after the plants are in position. Some fairly rich and moist soil must be provided for packing about the roots, as if only poor soil is used, and this dry, the plants will not derive sufficient support to develop the heads. A good watering directly to the roots will settle the soil and start the plants into root action. The pits must be freely ventilated on all fine days, protection also being needed during frosty weather.

PROTECTING IN THE OPEN AIR.—Failing any suitable position under glass, the plants may be taken up and planted rather closely together on a sheltered border. In this case erect a framework over the plants, so that mats may be thrown over them at night-time. Often there is a warm corner where such plants may be protected for a long time. Any heads which are already formed will keep for some time if the foliage is well trimmed back and the plants placed rather closely in a cold frame. It is also advisable to keep them covered with a mat, so as to exclude direct light, or the heads will become discoloured. The heads will also keep for some time if cut with a fair length of stem and inserted in damp sand in a cool shed.

FRENCH BEANS.—These must now be kept gently growing. A night temperature of 60° will suit them, for if placed suddenly into a high and moist temperature, both the leaves and flowers are apt to drop. Elevate the plants well up to the light and take care in the watering, this being required more or less according to the size of pot they are growing in. Heavy supplies are not needed. Neither must the plants be deluged with liquid manure, this soon souring the soil. Where the plants are well rooted and growing in 7-inch or 8 inch pots, alternate waterings with weak and clarified liquid will prove advantageous.

A. YOUNG.

PLANT HOUSES.

PROPAGATING STOVE PLANTS.—With a well-constructed propagating frame or box and a good command of bottom-heat, there is no reason why there should be any standstill as regards the manufacture of future plants. For my own part I prefer to strike several things at this season of the year, more particularly such as require some degree of bottom-heat. This essential can now be supplied with less difficulty than a few weeks back, when scarcely any fire-heat at all was required. Now it is different, however, whilst at the same time, by reason of the decline in the sun's power, it will be all the better for the cuttings as regards speedy rooting, without any check through flagging. Every possible use should now be made of the propagating pit before very severe firing comes on with sharp frosts to contend against; the bottom-heat may then be more than is desirable for a week or two.

Ixoras strike freely enough now, making nice stuff to commence the season with, being six months' gain on spring cuttings at the least. Clean and healthy wood should be chosen, that which

does not show any signs of forming a late flower truss being the better of the two as a cutting. Each cutting should be inserted singly in a 2½ inch pot, using peat and sand in about equal proportions. The cuttings may be immersed in the water tank for an hour or two with advantage previous to insertion. Each cutting should be examined for insect pests, so as to have a clean start if possible, the common enemies being the mealy bug, the thrips, and the brown scale, neither of which are wanted. Long cuttings are not desirable, two joints out of the soil being quite enough. For a supply of cut flower or as plants the following are excellent, viz.: *I. coccinea superba*, *I. javanica floribunda*, *I. Fraseri*, *I. Williamsi*, *I. Westi*, and *I. Prince of Orange*. Other flowering plants, as *Dipladenias*, may also be propagated now under the same conditions, except that less moisture is needed in the soil. *D. boliviensis* should not be omitted. Gardenias will also strike well now; these will do capitally with the *Ixoras*, but instead of taking single shoots a branch with from four to six shoots will be better; not only being a saving of time in forming a young plant, but providing at once a bushy example. Of course, like the *Ixoras*, these should also be quite clean. Amongst other things (which are indispensable in a stove) cuttings of the *Stephanotis* may also be taken, shoots taken with a heel being the better for striking; these should not be more than 4 inches or 5 inches long. *Allamandas* will also strike very well now, likewise *Bougainvilleas*, *Clerodendron fallax*, *Hibiscus* in variety, and the *Combretums*, but they may take a little longer than the plants first alluded to.

Of fine-foliaged plants, the *Crotons* can be strongly recommended for autumn propagation. With bottom-heat and a close frame, there is never any need for partially striking the cuttings on the plants with Moss, &c. This, which is more of a coddling process, is only advisable when the convenience is not what it should be for rapid propagation. The best-coloured shoots which are growing erect or nearly so make the better cuttings; side shoots will do when the stock of any kind is scarce, but these do not form such well proportioned plants, the growth being sideways. The shoots can be cut off in fairly good lengths according to the variety, from 4 inches to 9 or 10 inches being very reasonable limits. The cuttings should have all but the two lower leaves left on, the others the young plant will retain for twelve months and sometimes longer when a successful strike has been made. Plants that are likely to be too tall another season should be headed down and the best shoots taken for cuttings, good colour, of course, having the priority. After these shoots have lain for two or three hours in the water-tank, insert them singly in 2½-inch or 3-inch pots according to their sizes, and see to it that the soil does not at any time become at all dry. If a future specimen rather than a decorative plant is the object in view, then select a cutting with several lateral shoots.

Tall *Dracenas*, like surplus *Crotons*, often take more room than is desirable through the winter. Where any tall plants can be dispensed with they may also be cut up for further increase, the top going as a cutting and the rest as eyes in the soil with the large fleshy roots also utilised in the same way. There may be a little difficulty about the tops striking, but these do not make such good plants as those started from the eyes, although when they strike all right there is a saving of time. Pinch the eyes in cocoa fibre and keep well moistened, these also having been left for a few hours in the water as in the case of the *Crotons*. Old stools of such as *D. gracilis* should be kept for supplying cuttings after the top has been taken off, each young shoot being afterwards taken as soon as it is long enough. This is a better plan than working a stock from eyes. *Pandanus Veitchi* should not escape notice. Of this the small grass-like shoots make by far the better plants, being more symmetrical whilst still of small size. These small shoots can be found clustering around the base of the stem, each one generally having a root of its own. Sucker-like cuttings of stronger growth are

not nearly so good. A close atmosphere is not needed, nor is it so safe for striking this *Pandanus* as a cozy corner in the house. J. HUDSON.

HARDY FRUITS.

THE PLANTING SEASON.—It is a decided gain to get young trees from the nurseries and plant them properly before the winter fairly sets in. Before the late heavy rains, the ground, both in the open and in particular against walls, was much too dry for transplanting operations to be carried out without risk of failure, and it is doubtful if the borders, sheltered by walls, are yet well moistened. Before, therefore, trees are moved the border should be examined and water given freely if the soil is found at all dry, while if the soil that surrounds the roots after planting is done is also dry, or even on the dry side, a good soaking ought to be given before the surface is levelled over and mulched with straw litter. These waterings help to settle the soil well about the roots, doing this more effectually and better in every way than it can be done by trampling. Especially should water be given when trees are moved while yet some of the leaves are green. In each and every case allowance must be made for a settlement of the newly moved soil, and it should also be remembered that there is a tendency for the soil of a border to increase in depth farthest away from a walk. If, therefore, the trees are not planted rather high, the collars being kept well above the ordinary ground level, there is every likelihood of their becoming too deeply buried, not thriving or proving so profitable as desirable accordingly. More particularly is high planting advisable in the case of trees on cold, heavy soils. The roots are only too liable to strike downwards into cold or poor subsoils; whereas they render the best service when kept active on or near to the surface. A rich compost should not be given to quite young trees, as this may promote a too rank, unfruitful growth. On the other hand, when fairly large trees are moved from strong ground, many roots being unavoidably, and in some cases recklessly damaged, undue exposure to drying winds also doing much injury, then they must not be given a poor soil, or they are not likely to grow satisfactorily next season. Sometimes the trees received have been already badly started in the nurseries, and must be grown out of it before they prove profitable. If newly purchased trees cannot be properly planted soon after arriving, then ought they to be laid in thinly by the heels, taking good care to surround the roots with good fine soil in a moist state. Laying whole bundles of them in together will not do, as in this case the bulk of the roots do not come into contact with the soil.

APRICOTS.—These will not succeed in some districts, and are as easily grown as Plums in others. Where they fail, one more attempt to grow them might yet be made, this time mixing old mortar rubbish or chalk rather freely with the fresh loam used, as it may have been an absence of lime that was the cause of failure. The trees require a south or south-east wall to grow against, and should be planted rather high, the site being also well drained. Starting with maiden trees instead of any that have been cut back two or three times before leaving a nursery is an experiment worth trying. If only dwarf trees are grown, plant these about 15 feet apart, but if the walls are high and bare, allow the low-stemmed trees rather more room and plant "riders" or others with long clear stems midway between. Where the old trees are apt to die piecemeal, cut out the dead branches, bring the rest up closer together, and plant young trees between. In this way it will then be possible to keep the walls fairly well clothed with trees. Early Moorpark, Large Early, Hems Kirk, Royal, and Moorpark are all good, the last being the least reliable.

PEACHES are less fickle than Apricots and more reliable than Plums, always supposing they are grown against a sunny wall not badly exposed to easterly winds. Order either maidens or trained trees, arranging these 15 ft. apart, riders also being worked

in between if the walls are 12 feet or so in height. When long-stemmed trees are planted, it is in some cases intended to either move these or cut them out when the low-stemmed trees want all the space, but it not unfrequently happens that the standards succeed the best and outlive the others. It is not wise to wait till the old trees are completely worn out before planting others to take their place. Failures, partial or complete, should be anticipated by planting young trees where possible between the older ones while yet in fairly good health. Plenty of good fibrous loam with a sprinkling of "burn-bake" and mortar rubbish added suits Peaches well. Waterloo, Early Alexander, Hale's Early, Crimson Galande, Bellegarde, Dymond, Barrington, Sea Eagle, and Walburton Admirable would form a long and good succession of fruit, Salway being added if a few extra late showy Peaches are desired.

NECTARINES.—These are far less reliable than Peaches, most of the fruit cracking or refusing to ripen properly in wet or sunless summers. Room might perhaps be found for trees of Lord Napier, Advance, Rivers' Orange and Humboldt. If given the benefit of a glazed coping and blinds during wet weather, the fruit would not crack so badly and ripen more surely.

FIGS will, as a rule, only succeed against the hottest walls, angles formed by the junction of west and south walls suiting them well. The site ought to be well drained, either mortar rubbish or chalk freely added to the soil and high planting being resorted to. Brown Turkey, Brunswick and White Marseilles are the hardiest and most reliable.

CHERRIES.—These are not very fastidious as to the nature of soil, but a deep sandy loam suits them well. They can be had ready trained for walls with either long or short stems and as bushes and standards for the open. Fan-shaped and horizontally trained trees should be planted 15 feet apart, bushes 6 feet apart and standards 20 feet. Some of the best for east or other moderately warm walls are Early Rivers, Frogmore Bigarreau, Governor Wood, Elton and Black Tartarian, Florence being a large late variety. Dessert Cherries will also succeed against north walls, but these might be better covered with Morello Cherries. Frogmore Bigarreau, Napoleon, Kentish and Black Heart are also good as standards, May Duke, Archduke, Morello and Kentish being recommended for bush culture.

PLUMS.—A good depth of loamy soil suits Plums well, especially if the drainage is good without being excessive. They will succeed against walls with either a northerly or easterly aspect. A distance of 15 feet or rather less apart should be allowed and the trees be trained fan-shaped. For walls some of the best are Oullin's Golden, De Montfort, Early Transparent, Kirke's, Jefferson, Guthrie's Late Gage and Coe's Golden Drop, the last being adapted for either moderately early or late sites. For standards some of the best are Rivers' Prolific, Czar, Gisborne's, Early Orleans, Prince Englebert, Sultan and Victoria, and for bushes or pyramids, Green Gage and Kirke's may also be added, Coe's Golden Drop succeeding well in some localities. Standards should be planted 15 feet apart and bushes 6 feet.

W. IGGULDEN.

Fruit and vegetables in London.—The past exceptional summer seems, says the *Daily News*, to have had hardly so great an influence on Covent Garden supplies as might have been expected. Through the drought, supplies of green stuff fell off enormously, so far as our own market gardens within a short distance of London were concerned. The superintendent of Covent Garden tells us it frequently happened that the supplies from the gardens around London were fifty waggon loads short of what they would have been with a normal amount of rain. But the falling off in Fulham and Kent was to a large extent compensated for by an inflow from the Fens and from Yorkshire. The recent rains have, of course, rapidly brought on crops nearer home, and prices will soon drop to a point at which it will no longer pay to send pro-

duce to London all the way from Yorkshire. Very large consignments of Apples have come up to London from our own orchards this autumn, and foreign supplies have been quite out of it. In scarce years we get large quantities of Apples from Germany, Belgium, Holland, and Denmark, as well as France. French growers send us some very fine fruit, and we can always do with some of their Apples, but the other countries named grow chiefly very inferior fruit, and have no chance at all when our own orchards are fairly fruitful. We are getting some from France, but Worcestershire and Devonshire growers have of late years recognised the importance of growing only the finest kinds, and they are able to hold their own against all comers, and this year their consignments are very fine indeed. We get our late supplies from America ordinarily, and a good many Apples of very fine quality have been coming to us from Australia. Both have imported some of our very best kinds, and have been very successful in their cultivation, but English growers who have been careful and enterprising are now holding their own against all comers.

ORCHIDS.

CATTLEYA ALEXANDRÆ.

I AM in receipt of flowers of this plant from several readers of THE GARDEN all asking my opinion. The flowers from "W." are the finest in the colour of the lip, while those from Mr. Seeger are the largest, but the colour is not quite so good; the others, although very pretty, are poor. I observe one marked feature in all the flowers. In the centre of the claw of the middle lobe of the lip is an oblong white spot, which shows out a little on to the blade. This feature is apparently a permanent one, for in all the flowers before me it is conspicuous. It would also appear to be a very free-flowering plant, for "W." says his plant grew upwards of 2 feet high, and had a scape equally as long. He does not say anything of the number of blooms it bore. Its introducers, Mr. Sander and M. Linden, both say it flowers freely. In the flowers from "W." the sepals and petals are nearly equal, the lateral ones, however, being the largest. The petals are beautifully frilled at the edges, of a rich, dark bronzy hue, lip large, distinctly three-lobed, the side lobes of a rosy purple colour, anterior lobe of a rich bright reddish purple, having a large oblong streak of white upon the claw. The flower from Mr. Seeger is larger, but of a paler colour, the sepals and petals being of a light bronzy brown, and the side lobes of the lip white, tinged with lilac, the anterior lobe rose, tinged at the base with a deeper shade of the same colour, and having the oblong white blotch on the claw. We have not yet learned where or at what altitude this plant is found, but growers will do well to treat it as they would C. Mossie or C. Mendeli, and all will go well. I do not complain of importers of a new species not disclosing its native home, but I do think that they should, in justice to the purchasers and the growers of these plants, state correctly whether it is a cold, cool, or hot atmosphere that any such plant requires. This should be ascertained from the collector that sends the plants home.

WM. HUGH GOWER.

Cypripedium Normanianum.—This is a very pretty hybrid now flowering in the gardens at Laurie Park, Sydenham. It has a branching spike and bears quite a quantity of flowers. To speak generally, it has much of C. Sedeni in it, but it is

finer and larger, with more colour, having the whole back of the flower of a rich crimson. The dorsal sepal is greenish white, the colour from behind showing through; the lower sepal large and similarly coloured; petals spirally twisted, ivory white in front, rich crimson at the back. The pouch-like lip is large, deep rosy crimson, the large infolded lobes creamy yellow, profusely spotted with brownish rose. The plant, although rear to *C. Sedeni*, is superior to that hybrid in the size of the flower, in its colour, and in the great number of the flowers borne upon the spike.—W. H. G.

Dendrobium taurinum.—"H. H." sends me a flower which is much crushed and spoilt through bad packing, but it resembles this species very closely, and the growths would appear to be identical also. The colour of the flowers is in the long twisted petals of a purplish lilac, whilst the sepals appear of a greenish white, the lip rose colour. This plant is a very unsatisfactory subject under cultivation. It comes from the Philippines and grows frequently within the reach of the sea.—W.

Oncidium Forbesi.—A spike of a large-flowered variety of this comes to hand from Mr. Crispin, and on the spike is a veritable double flower, having two lips and two columns, three finely-developed petals and three connate lateral sepals and a pair of dorsal ones. This produces a greater amount of colour, but it is not nearly so elegant as when the flower is in its normal condition. This is a valuable kind for flowering at this season. It should be kept in the cool house during the winter and not dried off.—H.

Vanda Kimballiana.—J. Murdoch sends me a bloom of rather a thin flower of this species. It is one of the very prettiest of the small-growing members of this genus, the petals being white and the middle lobe of the lip bright amethyst-purple. I advise "J. M." to put this plant into the *Odontoglossum* house; he will find this the best place for it, the plants which I have seen growing in the cool house at the Messrs. Low's nursery being very much finer than those grown in greater heat. It was figured in THE GARDEN three years ago (Vol. XXXVII., t. 747).—W. H. G.

Vanda lamellata Boxalli.—J. Murdoch sends a flower of a very nice variety of this plant asking for its name, which I here give. It is an extremely pretty plant, having creamy yellow sepals and petals, the inferior half of the lateral sepals reddish purple, the lip tinged with purplish magenta. It is a very handsome variety now becoming scarce in collections. It requires a warm atmosphere, as it grows naturally in low places in the Isle of Luzon.—W. G.

Cypripedium purpuratum.—It is seldom one sees this species so fine as I recently observed it. This species remained scarce for many years, through being said to be found in the Malay Archipelago. It was eventually found to be a native of Hong-Kong and the opposite Chinese coast. It has very much the aspect of *C. barbatum* to a casual observer, but if looked into it presents several marked distinctions. It is between fifty and sixty years ago since it first flowered in this country.—W.

Cypripedium Spicerianum.—In the cultivation of this I find the best results are obtained by using a fair proportion of good fibrous loam in the compost, as in this the plants increase rapidly, the foliage taking on a dark green hue. The flowers are also produced on longer stems and are altogether much finer. I must, however, point out that when loam is used, it is very essential that the plants be repotted annually, as the loam, on account of the quantity of water required during the growing season, loses its vitality and becomes too pasty for healthy root-action and free growth.—A. Y.

Odontoglossum Inseayi splendens.—A very fine spike of this variety comes to me from Jacob Armstrong. The scape bears six flowers, which each measure close upon 5 inches across;

the sepals and petals are of a rich deep brown, tipped with yellow, with a few spots on it of the same colour; lip large, very rich deep yellow, having a broad marginal border of reddish brown spots. This is a remarkable variety of a beautiful plant. It belongs to the *O. grande* section, which likes a few degrees more warmth than *O. Alexandræ* and *O. Pescatorei*, and also to be kept drier through the resting season.—H.

Odontoglossum hybrids.—"F. T." sends three flowers for names. No. 1 I certainly think is a poor form of *O. Ruckerianum*. No. 2 is distinct, apparently a natural hybrid between *O. crispum* and some other form. No. 3 is, I should say, the plant that Reichenbach made a species of under the name of *O. hebraicum* when introduced by Mr. Bull, of Chelsea. More recent authorities make it a variety of *O. gloriosum*. The flower sent is a pleasing shade of primrose-yellow, heavily spotted with chestnut-brown. It is by far the best of the three flowers, which are all undoubtedly natural hybrids.—G.

SHORT NOTES.—ORCHIDS.

Masdevallia maculata flava.—This is a variety of the fine old *maculata*, which was imported by Mr. Sander some twelve years ago. It differs from the species in being of a somewhat bright yellow throughout and in the smaller size of the flowers. It is a very handsome variety.—W.

Lælia grandis tenebrosa.—Although late in the season, I have flowers of this plant from "T. M.," of Liverpool, and from C. Malton, but neither of these is equal to the kinds previously noted. I also saw this species recently flowering in the collection of Mr. Dorman, of Sydenham.—W.

Cymbidium giganteum.—The present is a very curious time to have a flower of this species sent for a name. It is a rather small bloom, but it is quite like the flower of the variety known as *giganteum* at the present day. The flowers of the olden times were far greener and not nearly so gay.—W. H. G.

Catasetum Bungerothi.—From G. M. Glover comes a part of a raceme of this beautiful species, having two of its large ivory-white flowers, and between them a small green flower of the opposite sex, but which does not add to its beauty. It is the first time I have seen flowers of both sexes on the one raceme.—W.

Miltonia Schroederiana (D. McLennon).—The flower sent represents a very good variety of this plant. The sepals and petals are pale yellow, profusely spotted and blotched with brownish purple, the lip pure white in front, stained at the base with purplish mauve. This plant thrives best under the same treatment as *M. vexillaria*.—W.

Dendrobium leucolophotum.—This very pretty species is now flowering in Mr. Dorman's collection at Sydenham. It somewhat resembles *D. Phalenopsis* in its growth, and the flowers, too, are similar in shape, but much smaller, each being an inch or more across and pure white, having the inner side of the lateral lobes tinged with very pale green.—W.

Cypripedium leucorrhodum.—A grand specimen of this hybrid is now in full bloom in Mr. Dorman's collection. It is a cross between *C. Roezli* and *C. Schlimi albiflorum*; the flowers are large, pure ivory-white tinged with rose-pink. The plant is a bold grower and a remarkably free bloomer. It must and will always rank as one of the very best of the Veitchian species.—H.

Oncidium heteranthum.—A spike of this comes for a name from Charles Leslie. At first I took it for *O. abortivum*, but the lip of that species is differently shaped. The sepals and petals of the flower now before me are small, of a creamy yellow, with a few bars of brown across them, the lip yellow in front, brown at the base. The plant is of no interest to the amateur, and would only be

grown as an absolute curiosity by anyone, as it never by any chance produces but one flower upon the terminal shoot of each branch.—W. H. G.

Pilumna nobilis.—This sweetly scented Orchid, I find, succeeds best in the cool house along with the *Odontoglossums*. I have three plants of the above species and they keep on improving since they have been placed in this structure. Each of the plants has now two spikes. Whilst the plants were in the *Cattleya* house the pseudo-bulbs became smaller each season, and now they are gradually getting larger.—A. Y.

Lælia præstana.—A flower of this species comes from "W." for an opinion. It is a very pretty and nice coloured form, wanting, however, in the rich yellow in the throat, which sets off so well good forms of the species. A flower of this species also comes from Mr. Crispin, of Bristol, under the name of *L. Pinelli*, which is only a synonym of *L. pumila*. It is very similar to the form sent by "W." and is also deficient of the colour in the throat.—G.

Cypripedium Barteti superbum.—This is a very beautiful plant raised by Mr. Norman between *C. barbatum* Warneri and *C. insigne* Wallisi. It is now flowering for the first time in Mr. Dorman's collection at Sydenham. The dorsal sepal is large and bordered with pure white, the colours of the original hybrid of this name being intensified. It is far superior to it or to *C. Laforcadei*, raised by M. Bauer, of Paris, between *C. barbatum* and *C. insigne* Chantini.—H. G.

ORCHARD AND FRUIT GARDEN.

OUR FRUIT TREES.

FORTUNATELY for fruit growers, the past drought is still with us; had it been otherwise, Apple and other fruit blossoms and second crops of fruit might have been as plentiful as Blackberries this first day of October, 1893. The consequences of such a condition of our fruit trees after such an abnormal season could not fail to have been most serious. Fortunately, however, the drought lasted, and the dry autumn held the trees back out of the more serious difficulties and dangers of a second growth and blooming in September and October. The chief effects of the season's long and persistent drought on our fruit trees are the premature falling of the leaves and a certain thinness and smallness of the buds. The first matters but little, provided the functions of the old leaves were fairly well performed before they withered and fell. Time is hardly the chief factor in the elaboration of the sap, but rather the energy of light and of life, and both of these have been working with compound energy and force throughout this abnormal season. Hence it is not only probable, but almost surely certain that the leaves of fruit trees did as much or more vital work before the middle of this September as they generally get through before the end of the year. If so, then the drought has neither lessened nor weakened the resources of our trees by stripping off their dead or dying leaves a month or six weeks before their normal time. The rest may only be the more profound and complete, and the start and the progress all the more satisfactory in consequence of the longer rest enforced on our fruit trees through the persistent drought in the autumn tide as well as through the spring.

But the rain must needs be coming, and how will it affect our fruit trees? Our first examination of their actual condition suggests two

reflections. The trees need rain, that is obvious on the face of them. The leaves are brown and dry, many of them have already fallen, and the buds, both fruit and wood-buds, are thinner and smaller than usual. But these are small drawbacks—if indeed they prove drawbacks—contrasted with the solid advantages of the fact that, writing generally of the buds of our fruit trees, they are solidly dormant and fast asleep. Enough buds in full growth and brilliant blossom may be found in most districts to make a good crop of newspaper paragraphs. But, nevertheless, the buds in the mass are rather more than less dormant than usual on this first day of October, 1893.

While the drought lasts this state of semi-safe dormancy will continue. The drought may be said to have lasted up till now. Cultivators who have had occasion to disturb the roots of their fruit trees find the roots, as a rule, as dry as they were in June. The rainfall has hardly as yet wetted the smallest fibres of the roots. There has been no penetrating downfall to touch them in the mass, far less to soak them through. Until this comes, the life, the growth, the safety of our fruit trees are in the keeping of the persistent drought. True, the buds will continue abnormally thin and small, but what of that? It is a long call from October to April or May, and all these quiet months are filling times for plumping up the buds to full size before they break into leafage or blossoming. The longer, therefore, the rain is in coming the better for the trees. Provided the buds are healthy and the germs of life are intact, there is every likelihood they will be fully furnished with vitality and material sufficient for forthcoming crops in time. The coming rains are bound to plump up the buds beyond all expectation. The cultivator's chief danger is that these rains will fill the trees too full and plump up their buds too soon and too far. The rains are needed for these purposes, and would do only good to all fruit trees now, only for fear of the coming frosts. But as the ratio of hardness in fruit trees is the exact ratio of their dormancy, it follows that it must be a somewhat risky proceeding to encourage a free circulation of the sap or prodigal filling up of fruit trees with vital force in October. Especially must this be dangerous after such a long spell of drought as we have not yet quite passed through. However, should a wet and mild November set in, we might do something to protect our fruit trees from the severe frosts which may follow on the heels of the rain by cutting off part of the supplies through root pruning.

Most experienced fruit growers are familiar with the fact that newly-planted or transplanted fruit trees, or those recently root-pruned winter more safely or securely, or bloom later in the following spring than those that have not been disturbed. Such restraining influences frequently suffice to save our fruit crops. Through the accidents of the seasons our fruit trees are just now in a very critical condition. On the verge of winter the trees are on the brink of growth. The intense heat and the long drought have thrown them out of season. Should we have early frosts, the trees will be forced into semi-rest or kept dormant through cold, and all may be well with our fruit crops in 1894. But should the coming rains force growth and flood the trees with sap while mild weather prevails, something may yet be done to arrest growth through cutting off excessive supplies of sap through prompt and vigorous root-pruning. This would relax the pressure on bursting buds, moderate the energy of vital force, practically increase the dormancy, and

so augment the hardness of our fruit trees throughout the approaching winter.

D. T. F.

Pear Van Mons Leon Leclerc.—I am rather surprised that this handsome Pear is so seldom noticed in THE GARDEN, at least I do not remember to have observed its name once. It is a very fine fruit and of first-rate quality, at least this season. I gathered a fruit from a cordon (single) which weighed nearly 1 lb. I think it will become one of the finest of our exhibition Pears when better known.—T. A.

Apple Chatley's Kernel.—Does any reader of THE GARDEN know anything of this variety? In a garden the other day where there is a very fine collection of fruit trees, my attention was called to this Apple as being an excellent late variety, a heavy cropper, and also of fine quality when cooked.—Y. A. H.

Apple Ecklinville Seedling.—My experience with Ecklinville Seedling is very similar to that detailed by "W." (p. 317), and I note also that buyers are beginning to fight shy of it. Very large quantities are grown hereabouts, growers being much taken with its wonderfully healthy and fruitful growth, and also the size of its fruit. But now the cry out is that it is too soft to carry. I had a lot of fine fruit this season greatly injured by hailstones, as where the fruits were marked, there decay very quickly set in. I fancy also its cooking qualities are vastly over-rated. Juicy and of good flavour it may be, but it is most deceptive, as I know of no other variety which shrinks to such an extent as to appear when the pie or pudding is opened as if hardly any fruit had been put in. Two or three trees are enough for any moderately-sized garden.—Y. A. H.

Figs for forcing.—In Mr. Wythes' excellent article on the above (page 319) he asks if there are not various forms of Brown Turkey Fig, some far superior to others. I think most gardeners who have grown this variety will agree with Mr. Wythes' remarks, as there is certainly a very inferior type of Brown Turkey distributed about the country. Its fruit is a little smaller than that of the true variety and not produced so freely, more liable to drop and of very poor flavour. The true variety is still one of the best Figs in cultivation for either inside or outside work. On a wall here facing south-east it has not failed to bear heavy crops of large fruit for years, and is now (October 9) ripening up a very good second crop; in fact, several good dishes have already been picked, which is a very unusual occurrence for Figs on outside walls quite unprotected. Writing on inferior varieties of Figs reminds me that the same remarks as above on the subject apply to Keens' Seedling Strawberry. A very poor variety, which I knew as a youngster as Sir Harry, is frequently bought as Keens' Seedling. On three different occasions I have had this practically worthless Strawberry sent me as Keens' Seedling. When at Syon House at the end of August I noticed that Mr. Wythes had a grand stock of the true variety in pots for forcing.—W.

Bramley's Seedling Apple.—This useful variety was admirably represented at the Earl's Court show recently when over fifty dishes were exhibited from Southwell. The fruits were fine, even, solid specimens, and had been gathered from standard orchard trees which were said to have yielded 25, 30, and even 40 pecks of 16 lbs. each per tree. The variety possesses many excellent qualities. The tree has a strong constitution, makes good clean growth, is free from canker, and is regular in cropping, as the flowers are seldom injured by frost. It is a good cooking Apple, keeps well until the spring months, and with ordinary care in packing it can be sent any distance without the slightest injury, as its firm substance and skin protect it to some extent from the bruises which so readily show in several varieties, disfiguring and spoiling them for sale or keeping. Several accounts have been given at different times, but the following is the most authentic, as it comes direct from Mr. H. Merryweather: "It is

a chance seedling, raised by a lady named Brailsford, but she did not live to see the tree produce fruit. The garden was taken by Mr. Bramley, who soon found out its good qualities and took some scions for grafting to Mr. Merryweather thirty years ago, at the same time praising it highly. A stock was gradually worked up and the merits of the variety fully established, but years elapsed before it became known out of the district except to a few, who turned their knowledge to profitable account. It was first brought into prominent notice at the Chiswick conference in 1883, when a first-class certificate was awarded to it, and in the ten years which have elapsed since then many plantations have been made that are now yielding handsome returns for the expenditure."—OBSERVER.

HOW TO TRANSPLANT A PEACH TREE.

MANY amateurs would like to be able to grow a few Peaches and Nectarines under glass, and there is no reason why they should not succeed if only they go the right way to work. In the first place it must be thoroughly understood that they will do no good under the shade of Vines, though there is nothing to prevent the successful cultivation of both Peaches and Grapes in the same house. High back walls of either lean-to or three-quarter span-roofed houses suit Peaches and Nectarines well, always provided the Vine rods are not less than 5 feet apart up the roof. The trees do remarkably well when trained over or to wires strained 9 inches to 18 inches away from the glass of the roof, and there is, therefore, no good reason why a tree or trees should not share a roof with Grape Vines. Instead, however, of planting the trees along the front similarly to Vines, the better plan is to purchase trees with stems long enough to reach the roof not far from the centre of the house, the branches spreading in all directions, that is to say down as well as up the roof. It is not my intention, however, to enlarge upon Peach culture generally, the original idea being to advise owners of good-sized trees at present growing against open walls how they may transplant these to a house without the loss of a crop next season. Not a few amateurs' fruit houses—"orchard houses" many prefer to call them—have been constructed against walls where there were already one or more good-sized Peach trees, and this is one way of getting a good return for their outlay during the first season. Intending builders who cannot well cover in trees—and there is no sense in constructing a house at inconvenient spots—may do the next best thing, and transplant trees to where they have built houses or intend building. Transplanting the trees, instead of having an ill effect, may even prove most beneficial to them, the roots having the benefit of a fresh loamy compost being soon followed by an improvement in the health and productiveness of the top-growth. Very much depends, however, upon the work of transplanting being done well. The best times for doing it is either in the autumn before all the leaves have fallen or directly after, or else in the spring just when the buds are moving. I have already moved several trees under glass while yet in full leaf, and most of those in the open will also be sufficiently matured for lifting before these lines are in print. The exceptions to this rule are comparatively young, strong-growing trees, the younger wood in this case being soft and green. If transplanting is attempted while yet the young wood is green it is liable to shrivel badly, and all such trees should be left where they are till nearly all the leaves have fallen. In the case of trees that have been planted five or six years, or say long enough to arrive

at a good bearing state, the young wood will be quite firm, and moving now will be followed by a re-commencement of root-action before the winter arrives, so that they will have partially recovered from the severe check given.

Before interfering with the roots first prepare the new site for the tree. There must be no cramping up of the roots into holes much too small to hold them properly. If a wholly new border is not made—and it is not always convenient that this should be done—then for each fairly large tree dig a circular hole with a radius of about 2½ feet. Throw the best of the top soil, unless all is very hard and poor, on one side, and wheel away any had subsoil there may be down to a depth of 30 inches. Next throw in about 6 inches of brick ends, stones, clinkers, cinders, or old mortar rubbish, the coarsest at the bottom and the finest at the top. If the site is badly drained, then a small pipe drain should be taken from each station to the nearest main drain, but in most gardens the ordinary drainage is ample. Over the drainage dispose either fresh turves, grass downwards, or else some strawy litter, and on this form the border. Some of the common garden soil that was reserved may be placed in the bottom, the rest of the soil used being a mixture consisting principally of the best loam, fibrous if possible, good garden soil, a little old mortar rubbish or pounded chalk, some of the burnt soil and ashes from a garden slow fire or “smother,” with a very little good flaky manure being added, this latter in the event of the soil being somewhat poor. A compost thus formed and well mixed would grow any kind of fruit, and Peaches and Nectarines in particular. Place some of it over the soil in the hole and make all firm.

All being thus in readiness, the next proceeding ought to be the lifting of the tree or trees. Commence by cutting a trench 4 feet to 5 feet away from the tree to be moved and two spits deep. Then gradually undermine and fork away the soil from the roots, taking the greatest care of the latter, till within 18 inches of the stem of a large tree, and 6 inches nearer if not more than two years planted. The aim ought to be to preserve a ball of soil about the roots about 1 foot in depth, and not any larger generally than two strong men can lift out of a hole. Undermine this ball so as to leave it at last resting on a pedestal of soil. Have a stout board about 1 foot in width and rather shorter than the diameter of the hole in readiness for sliding the ball on to directly the branches of the tree are loosened from the wall. If the tap or deep running roots have been cut through, no difficulty will be experienced in sliding the ball on to the board, but if the hole has not been kept cleared of loose soil and the tree not properly undermined, there will be no getting it well on to the board without greatly loosening or breaking up the ball of soil. With the latter nicely balanced on a board, a strong man at each end of the latter, and the owner steadying the tree, the removal to the fresh site will be a success. Once more let me strongly advise that the bottom of the ball be made quite flat, and also that the top soil, in which there are but few roots, be reduced somewhat with the aid of a pointed stick or fork, as, unless these precautions are taken, there is every likelihood of great lumps falling away, carrying valuable roots with them. Before placing the tree in the fresh site see that there is enough soil in the hole to raise the ball slightly above the ordinary level, some allowance being made for sinking. It is a golden rule to keep the collars, or that part of the stem where the top-most roots are connected, slightly above the or-

inary ground level, those that are much deeper never thriving so well, the disease known as the “yellows” being a frequent outcome of too deep planting. After the tree has been carefully slid off the board and is deposited well back against the wall, or in the exact position desired, spread out the roots and then do what trimming of these is necessary. Cut out all the badly bruised or broken roots, and cleanly shorten the broken ends of all the rest, this being done to facilitate healing. Do not throw soil on to the roots in a haphazard fashion, thereby driving them all closely together, but dispose the latter in different layers, and very much as they start from the stem. Surround all with some of the finest of the soil, the topmost only being just covered. Give a good soaking of water, this well settling down the soil, and next day level over the rest of the soil, the top tier of roots not being buried more than 2 inches deep. At first the trees should only be lightly fastened to the wall or trellis, as the case may be, as the mass of soil will be certain to settle somewhat. When trees are transplanted before the leaves have fallen, flagging is apt to take place on bright days, and a little shade and frequent overhead syringings will be necessary by way of a preventive. The time has also arrived for transplanting or regulating the distances of trees against open walls. Very much the same methods should be adopted as in the case of any moved to a house, the advice to keep the collars high being carefully observed, and a mulch of strawy manure given after first the watering and then the final addition of soil have been made.

M. H.

Doyenne du Comice Pear.—The fine qualities of this Pear are becoming gradually known, but it is destined to become far more popular than it is at present. Many of the leading fruit growers and exhibitors have proved its merits, and most first-class collections now include specimens, but it has made but little way with those who are specially concerned in the cultivation of fruits for sale, and perhaps this is due to the uncertainty that characterises so many fine Pears. It does not apply to this variety, however, with so much force, and wherever a moderately warm and sheltered position can be devoted to Doyenné du Comice good results may be safely anticipated. In the Channel Islands it has been planted largely by at least one grower, and both from there and France grand fruits are now finding their way into Covent Garden Market, and will probably do so throughout October and November. In quality this Pear is unsurpassed, the flavour is delicious, and fine even fruits weighing over 1 lb. each can be grown on dwarf trees on the Quince stock, which seems to suit it best. The fruit is rather more turbinate in form than that of Duchesse d'Angoulême, being broad and flattened at the apex; the colouring is somewhat like that of Louise Bonne, but not so deep.—OBSERVER.

—If asked to name the best all-round Pear that I know, I should name the above. It is equal in flavour to the famous Marie Louise, and will succeed either on a wall or in the open. If allowed to hang on the trees as long as possible, the fruit will keep until the end of November. Some trees trained as cordons annually give us some grand fruit, many of them over 1 lb. each, but the heaviest crops are borne by our bush trees. When other trees have failed to crop, Doyenné du Comice has always had a fair to heavy load, excelling such prolific varieties as Louise Bonne of Jersey and Marie Louise d'Uccle in that respect. As a market Pear it fetches a very good price if put on the market in a fresh and attractive state, and buyers that have purchased once soon inquire for more of the same kind. With such fruit the home grower need fear no competition, as the demand is always greater than the supply. I find that this Pear succeeds best and gives the best crop of fruit if the

trees are lightly pruned, merely thinning out any weak or crossed shoots and shortening back any growths that tend to throw the head out of balance. If care were taken that every portion of the tree had plenty of light and air for the development of the wood and buds, little or no root-pruning would be required to bring trees into a fruitful state.—W.

PLUMS FOR MARKET.

ACCORDING to the Board of Trade returns, vast quantities of Plums have arrived in this country from the Continent, in spite of heavy crops and low prices realised at our best markets. Unfortunately, the actual grower does not obtain so much for good fruit as he ought to do. This year the first Victorias only sold for about 9s. per cwt., or say 1d. per lb., while the consumer had to pay double and treble that price for the same fruit. It has been stated repeatedly that growers do not put their fruit on the market in the best form to secure the highest value, the same people urging the producer to pack his finest Plums in shallow boxes tastefully, each box to contain two or three dozen fruits. If such advisers would only start fruit growing and put their theories into actual practice, they would alter their statements or advice considerably. With many other growers I have tried the system, and have always found it did not pay, but was an actual loss, the box and tissue paper costing as much as the Plums realised. The best mode of packing that I know is to use the ordinary half sieve, putting a thin lining of soft hay or similar material at the bottom and round the sides, covering the whole with clean paper and allowing a sufficient quantity of paper to hang over the sides to turn over the fruit when the half sieve is full. Then the paper is turned over and a little straw or bracken is placed on the top and two pliable sticks are crossed over the top securely, the fruit being rolled as it were in paper, and the sticks keeping all tight, they arrive in the market looking as fresh as if just picked from the trees; consequently the highest prices are made. Large packages for Plums are objectionable, as the bottom fruit becomes crushed, and if allowed to stand a day or two without unpacking, sweating sets in, and the whole very soon decays.

Early Prolific is still the most profitable of all Plums, as it always meets with a good sale, and the trees being relieved of their fruit about the end of July or early in August, they have ample time to recover from any weakness in producing a crop and form plenty of fruit-buds for the next season. The Czar is a fine market Plum, as it comes into use as soon as the Early Prolific is over and before the Victoria is ready, thus filling up a gap in the succession. The trees are also very prolific, vigorous, and grow into good shape. No doubt the Victoria is the most popular of all Plums and the most largely planted for market, but it is an open question if there is not danger of the markets becoming glutted in the near future with this fine variety; it has been planted by thousands in counties suitable for fruit culture, and it will be wiser to not put in such large quantities for the future, but rely more on varieties that will come into use before or after the Victoria. Pond's Seedling with me is about a week or ten days later than the preceding and realises good prices, as Plums are getting less plentiful at that time and the demand is improved. Another advantage of Pond's Seedling is the fruit will keep a week or so in good condition after it is ripe. On some soils the tree is not so prolific as could be wished, but on the

majority of soils it is very free, the fruit of extra size and splendid colour. Where Pond's Seedling will not succeed properly Cox's Emperor or Denbigh Seedling will be almost certain to do so, and come into use about the same time. The fruit is large, varying from oval to round, of a deep red in colour, and produced in great abundance. Coe's Golden Drop is a magnificent Plum for home consumption, but not very profitable for market, being too shy in bearing, and though such a late Plum this does not compensate for its light crop. A great number of varieties of Plums are not advisable for market, rather a few sorts well known to be suitable to the district and in demand in the market. Not only with Plums, but with Apples, Pears, &c., there is a great tendency to plant too many varieties, some of which are of little or no market value, and consequently entail a serious loss. W.

Pear Souvenir du Congrès.—This Pear with me is far superior to its parent, Williams' Bon Chrétien, as it crops more heavily both on walls and on bush trees in the open. The fruit attains a larger size, is of a more attractive colour and does not go bad so quickly in the centre. Very heavy fruit of a beautiful rosy colour on the sunny side may be secured by liberal feeding, and I have never yet tasted a Pear that was inferior in flavour owing to its size; in fact, rather the reverse. A large well grown fruit is generally of much better quality than a smaller one of the same variety, and appreciated accordingly by employers.—W.

Apple Duchess of Oldenburg.—This is a good early cooking Apple, and, as far as appearance goes, I think it is the prettiest of all. The quality is also excellent when cooked. In growth the tree is very free and of remarkably fruitful habit. One or two trees, however, are enough for private use, as the fruit does not keep very long and is best when used from the tree. As stated by "W.," it shows its bruises very quickly, so requires very careful handling. It makes a fine standard and comes very quickly into bearing.—Y. A. H.

Plum Coe's Golden Drop.—This is one of the best Plums, and certainly has been the most profitable this season. There is no fear of a market glut when this Plum is ripe; consequently it will always realise a good price. Another great advantage is that it comes too late for the wasps, as in most seasons the fruit will hang on the trees till quite late in the autumn. Birds are very partial to the buds. From a tree in the garden I have never secured a crop, and I suppose nothing short of netting will save the buds, but in the open plantation the young bushes have been heavily laden.—E. W. B.

Nectarine Darwin.—This delicious Nectarine deserves more extended culture than at present, as the tree is of vigorous growth, a very free bearer, and the fruit of large size and beautiful appearance. For early or midseason forcing it has no superior, and during the eight years I have grown it no failure has occurred. A dish of this variety in a collection of fruit will carry a full number of points, and in a single dish class it will be difficult to excel. At the Shrewsbury show a fine dish of Darwin took first honours in a spirited competition.—W.

Pear Thompson's.—This variety was one of those selected by the editor of THE GARDEN a few seasons back as being worthy of being placed in his list of standard Pears for Britain, sure evidence of its high quality. My reason for just now calling attention to it is to note how admirably it is adapted for growing as an orchard standard, as very few of the higher quality Pears will conform to this mode of culture. In fact, I find that to bring out the character of the variety a more natural growth appears necessary, as under this form the tree is most fruitful, the flavour also being first-rate. As a bush on the

Quince stock it will not succeed at all, the growth being quite stunted. Marie Louise will not succeed at all with me in the open, the ends dying back in the winter, but Thompson's does splendidly. Its natural season of ripening is November, but this year it will be a little earlier. It may be as well to mention that this cannot be strictly classed as a vinous-flavoured Pear, having more of a honeyed sweetness, so it might not suit all palates.—A. H. S.

Pear Beurre Superfin.—This is very fine this season, the fruits being of a good size and the flavour also superb. I also notice that the fruits are more russetty than usual. I allowed the fruits to hang on the trees as long as possible, knowing that this is a variety that does not deteriorate in quality when allowed to hang. With me it succeeds the best on a west wall, but further south it does well in the open. As a cordon it succeeds well, being admirably adapted for growing under this form of culture either against a wall or against a trellis in the more southern counties. It is often offered as a standard, but I never yet met with it succeeding well under this method, the fruits being small and not nearly so freely produced as when the tree is grown under more favourable conditions.—Y. S.

PRUNING: SHALL WE LOP OR THIN?

TO THE EDITOR OF THE GARDEN.

SIR,—If anyone desires to read a suggestive sermon on this subject, I would recommend him to peruse carefully the first article on Apples in the second volume of "The Fruit Grower's Guide" (Wright) just issued. Before dealing with the article here, however, it is needful to recapitulate a bit. Since the articles on the extension system appeared in THE GARDEN about thirteen years ago, and afterwards in book form from your office, a good deal has happened. It is pretty well known that previous to that time the extension system had no defined existence, never having been previously described in books on fruit culture, nor found a place in them. I am speaking just now of Apples and Pears more particularly. Since THE GARDEN dealt with the subject, it has, however, been often enough discussed in the gardening papers. Some have condemned extension out and out; some adopted what they cautiously described as a "mean between the two extremes," not being quite sure on which side of the fence to sit just at the time, especially those who were committed to extreme restriction beforehand. A few—wise in their generation—adopted extension here and there at once, and now you can hardly go in any direction without meeting good examples of the system which is fast superseding every other. True, there is still some reluctance in certain quarters to acknowledge the situation, but the facts are too strong to be ignored; and while the extension system is advocated and its merits acknowledged, no one need mind very much the occasionally transparent device of writers disguising their obligations under new names, however questionable such a course may be in itself, especially in writers whom we know have studiously thrown cold water on the system before and lauded to the skies those practices which they now condemn. In what I think Mr. Iggulden has called the "pioneer" papers in THE GARDEN by an extension-trained Apple or Pear tree was meant and described a tree that was "permitted, under proper guidance, to extend itself naturally and to grow, &c.," and it will be seen, as I proceed, that this is exactly the tree that is now coming to the front with quite a high character for general utility.

The "Fruit Grower's Guide" does not, I apprehend, so much aim at advocating particular

systems as it does at simply describing faithfully the merits of each and their application. In the chapter on Apples (applicable also to Pears) three systems of training are described that I purpose alluding to here. These are the much "restricted pyramid," the "ordinary bush," and the "open bush." The "ordinary bush" appears to be a hybrid that I confess never to have seen before, unless it happened to be in the form of a neglected pyramid, of which Mr. Wright's fig. 5 is a faithful representation. I would like to know what particular niche this abortion is supposed to fill in the fruit garden and where the author discovered it, but the next edition would be much improved by its omission, and with that it may be dismissed here.

The next in importance is the "open bush," or, in better understood parlance, the naturally formed extension-trained dwarf tree. An actual portrait of a tree of this kind is given, and is, I believe, the only figure of its kind ever published, except the photo described in THE GARDEN articles of an Apple tree "naturally inclined to grow in an open manner," of the same age or thereabout, and which, but for the difference in kind and time of year, might well stand for the twin-brother (cf fig. 7 or 8 in "The Guide." It is the position assigned to this open bush or extension-trained tree, and its comparison with the pyramid and other restrictive trained forms, that I wish to draw attention to. First, however, it should be pointed out that the term "bush" does not clearly denote the kind of tree now catalogued by Mr. Wright, because a bush tree can be, and sometimes is, just as easily subjected to the restrictive method of pruning as a pyramid, and it was to distinguish the one from the other that the better term "extension" was adopted, and I notice that Mr. Wright very properly uses the words "restriction" and "extension" in his instructions as regards the branches. So far as I am aware, Mr. Wright's pretty little extension-grown Apple tree (p. 14) is not found in any of the English books acknowledged in his preface, and I take it it is an original portrait. The simplicity of the extension system, as applied to Apples and Pears, has often been dwelt on in THE GARDEN, and it speaks volumes on this point that in the "Fruit Guide" two simple cuts and two paragraphs suffice to make the whole system clear to anybody, and this is supplemented by a description of the advantages of the system that completely cuts the ground from beneath the feet of the restricted pyramid and its near neighbours. In fact, Mr. Wright has shown that there is no reason for the latter's existence except it be in the eyes of those who prefer to grow their trees in the shape of candle extinguishers, with all the attendant trouble. Why Mr. Wright under these circumstances has devoted some ten pages, twelve elaborate figures and nearly sixty references to particular "quips and cranks" in the training of the restricted pyramid is beyond my comprehension, more especially as he gives the pyramid no character for utility worth recording; whereas, his description of the "bush" form is worth giving in full. First of all, the portrait of the tree given shows an example in which hardly any more pruning is required than the shortening of the tops of the wobbly branches and no training at all, and the tree delineated, aged three years "from the maiden," shows on the side next to the spectator nearly four dozen fine large Apples; whereas, the figure of an "advanced" pyramid—a "restricted tree in bearing"—makes no pretensions to equal this. In short, I can conceive of nothing more likely

to frighten the learner from the study of a stupid system of culture than the chapter on pyramid training in the "Fruit Grower's Guide," although, in the multitude of diagrams and references to operations given, I do not suppose there are more than are necessary to make the system understood as long practised by its advocates.

The character given to the general "bush" or extension form of tree by Mr. Wright is as follows: "Bush Apple trees are the simplest and most easily managed of all forms. . . . They are especially adapted for small gardens, generally very productive, and require but little space, affording much interest and enjoyable, profitable occupation. For planting in borders along the sides of paths they are ornamental and readily accessible for manipulating the growths and supplying all cultural necessities." Referring to the "open bush," he continues: "These trees are principally employed for commercial purposes. The principles upon which they are managed are, first, allowing varieties to assume their natural forms; second, reducing pruning to a minimum. . . . Such trees are equally adapted for garden and field culture. They are excellent for cottagers and persons generally who are not skilled in the art of training, and who cannot devote a great amount of time to their trees." Fig. 8 represents this form—three year-old from a maiden—with the heavy crop of fruit before mentioned. Now in this description every good quality that the restrictive-trained pyramid possesses is given, with the additional advantages that the "natural form" is much more prolific, better for commercial purposes, and, according to the measure assigned to it in the "Fruit Grower's Guide" in the shape of illustrations and space, &c., it is just about ten times easier to manage. It is with much pleasure that I welcome the author of the "Fruit Grower's Guide" as one of the champions of the new school. There is just one hitch here that wants explaining, and that is the remarkable difference between Mr. Wright's opinions on "training in the abstract and training in practice." How does he reconcile his opening statement in the second vol., that cultivated Apple trees "if left to Nature assume forms not pleasing and proportions exceeding the limits available for them" with the words italicised in the above quotations? J. S. W.

STOVE AND GREENHOUSE.

THE JAVA HYBRID RHODODENDRONS.

Go when one will to Messrs. Veitch's nursery at Chelsea, flowers of this valuable class of Rhododendrons will always be seen, and every year their value is more clearly shown. They have no rivals amongst those plants which require an intermediate course of treatment; nor, indeed, is there anything to approach them during this the dullest season of the year either among stove plants or those that only require the temperature of the greenhouse. We frequently see some twenty or more trusses shown at the Royal Horticultural Society's meetings, but the effect of a large number can only be partially imagined in comparison when seen upon the plants. These most distinct and ornamental Rhododendrons have undoubtedly a brilliant future in store for them. There is already a great call for the better-known kinds, but I am fully persuaded that many more will be grown in the near future than in the past. Once their culture is more thoroughly under-

stood, and in which there is no difficulty at all, their cultivation will considerably increase. They have this most decided qualification in their favour, *i.e.*, they are not in any sense common flowers, nor will they be met with in every florist's window for a long time to come. Their very appearance when in flower, as seen in the many varied shades—from pure white to the richest and deepest crimson, the lovely tints of orange, the full and deep (also pale) yellows, and the delicate shades of pink gives such variety as to betoken a decided superiority in every way. There is also a great diversity in the kinds now in cultivation. Some have large flowers, and trusses too, looking splendid upon the plant, while others are comparatively small; hence they are most useful for button-hole bouquets and sprays. Then there are the double varieties, which last a long time in flower, each pip of the larger sorts rivaling a Tuberosa bloom in size. Added to these, there are those of the multicolor section. These are quite distinct from the foregoing; the individual trusses are smaller, but the growth of the plant is very compact—more like that of an Azalea. They flower freely, even plants in 3-inch and 4-inch

Rhododendron multicolor Mrs. Heal.

pots. These were obtained by crossing the Java hybrids with *R. multicolor*, a species from Sumatra. The variety (Mrs. Heal) here figured belongs to the multicolor section. The parents are *Rhododendron multicolor*, with a lemon-coloured flower, and *R. Princess Beatrice*, a javanico-jasminiflorum hybrid, the flowers a pale yellow, suffused with pink and a light pink centre. This is the only pure white kind amongst the Java or Sumatra hybrids. It is of free growth and dwarf, bushy habit, and a very profuse bloomer. Plants in 3-inch and 4-inch pots flower freely. J. H.

The zonal Pelargonium house.—No brighter display of colour right away from Michaelmas to Christmas even from Chrysanthemums is obtained than that to be found in the above structure, always supposing the temperature is maintained at a sufficient height. Amateurs starting the winter culture of Pelargoniums are apt to make a mistake in this matter, and to imagine that simply keeping out frost is all that is required; whereas, to maintain a constant supply of flowers and the plants in good health a mean temperature of close on 55° is necessary with the house always rather on the dry side. To the admirable varieties in the double and round-flowered single sections adapted for this work must now be added the gigantic

nosegays as represented by *Aurora Boreale* and *Gloire Lyonnaise*. These throw very fine trusses of flower with individual pips of immense size, some of them measuring nearly 3 inches across; flowers, too, of good substance, not the light flimsy petals of such sorts as *Stella*, *Bonfire* and other old varieties. Pelargoniums for winter flowering may be propagated in March, single cuttings in 3-inch pots. These may be transferred to 6-inch pots so soon as they are well rooted, using a compost that is nearly all a friable loam, the object being to secure through the summer a short, stocky growth. Keep all the flowers off until the beginning of September, when they may be allowed to stand, and stimulants can then be freely employed. The plants should be in their winter quarters about the third week in that month. A nice airy position fully exposed to the sun suits them best all through the summer. In a season like that we have just experienced—I mean with any amount of sunshine and a hot, scorching temperature—it is advisable to shade lightly, say with thin tiffany, for a few hours during the middle of the day to prevent the plants drying out so quickly.—E. BURRELL, *Claremont*.

Dwarf Abutilons.—A great many garden varieties of Abutilon are apt to run up tall and naked at the base, but still there are among them some forms much dwarfer than others, and a couple sent from the Continent about seven or eight years ago are the dwarfest and most free flowering that I am acquainted with. They are *roseum compactum* and *Vivid compactum*, the flowers of the former being soft rose, and of the other bright red. They will both branch freely when not more than a foot high, and produce an abundance of flowers not only on the central or main stem, but also on the side shoots at the same time. For small greenhouses these two Abutilons are very useful, for effective little plants can be grown in pots 5 inches in diameter, and it was a pleasing group of them grown in this way that suggested this note. A few good varieties are very useful for flowering during the autumn and winter, but there are far too many names to be met with in some nursery lists, as the range in colour among them is really not great.—T.

Siphocampylos Humboldtianus.—This has been referred to as a summer-flowering plant, but while it often does bloom at that time, there are really very few subjects to which the term perpetual blooming might be more appropriately applied. It is a member of a large genus (for according to the "Dictionary of Gardening" it consists of nearly 100 species), and among them are several very pretty flowering plants. That under notice (*S. Humboldtianus*) forms a freely branched plant of a half-shrubby character, and when grown in pots it is usually as a neat little bush clothed with dark green leaves, while the flowers are freely borne on the points of every shoot. They are somewhat tubular in shape and of a bright scarlet colour, with the interior of the throat yellow. Plants of this *Siphocampylos* will often bloom throughout the greater part of the summer, the entire autumn, and well on into the winter. It is not at all difficult to strike from cuttings of the young growing shoots taken during the spring months. A soil consisting of loam with a liberal admixture of leaf-mould and silver sand will suit it perfectly. So free-flowering is it, that when the young plants are required to grow freely the blooms should be pinched off in order to encourage growth, for they will

often flower even in the cutting pots. Grown in suspended baskets, too, it does well, and in this way displays the bright coloured blossoms to great advantage. An ally of the above and another continuous flowering plant is *Centropogon Lucyanus*, said to be a hybrid between *Siphocampylus betulafolius* and *Centropogon fastuosus*. The long curved flowers of *C. Lucyanus* are of a bright rosy carmine colour, very telling at all seasons, but especially so during the dark days of winter.—H. P.

SOCIETIES AND EXHIBITIONS.

ROYAL HORTICULTURAL SOCIETY.

OCTOBER 24.

COMPARISONS are at times very difficult to make, but it is extremely doubtful if ever during the time the R.H.S. has held its fortnightly meetings in the Drill Hall a better display in all respects has been at any one time seen there. It mattered not to what particular branch of horticulture one turned his attention, each was represented thoroughly well both in quantity and quality. Four tables as long as could be arranged for in the body of the hall were filled to overflowing, whilst another extended around the other end with several exhibits as well upon the floor. The facts of such displays as these being so repeatedly held should be a sufficient reason for the revival in some form or other of a permanent building exclusively devoted to horticulture. It must be further borne in mind that the present is usually considered a dull season of the year prior to the advent of the *Chrysanthemum* in all its glory. All who visited the show on Tuesday last could but be gratified with the inspection. Orchids were present in great profusion from the large trade growers, the most noteworthy features being the magnificent display of *Cattleya labiata*, finer than which has never before been seen. These came from various sources and added largely to the attractiveness of the show. Hybrid Orchids were also largely shown, hybrid *Cattleyas* and *Cypripediums* being of very superior character, these testifying to the skill and patience of the hybridiser. Miscellaneous stove and greenhouse plants were not present in large quantities, well coloured *Crotons* being the best things; but *Chrysanthemums* were of first-rate quality, indicating a good season without a doubt. As an illustration of the still remarkably open weather, the Dahlias, which were staged in large numbers, may be taken as an example. Of these the *Cactus* varieties and the singles were pre-eminently the best. A further instance of the mild weather was to be seen in the fine quality of the tuberous *Begonia* flowers from plants grown in the open ground. Fruit was chiefly confined to Grapes (of which there was a fine exhibit of Black Alicante) and to collections of Apples and Pears, highly coloured and in all respects excellent. A splendid exhibit of Onions was made, showing superior culture as regards size and perfect finish, but of doubtful utility as far as the kitchen is concerned, smaller ones being favoured by the cooks. Other vegetables and salads were to be seen, all showing first-class culture. Shrubs were represented by some fine examples of deeply tinted autumnal foliage and by densely-berried plants of *Pernettyas*.

Orchid Committee.

First-class certificates were awarded to the following hybrids and species, viz. :—

CATTELEYA LORD ROTHSCHILD (*C. Gaskelliana* × *C. aurea*).—A truly splendid hybrid in which traces of both of the parents can be most clearly seen. The lip in size, colour and general contour is that of *C. aurea*, having the deep golden veins and markings in the throat, whilst the labellum is broadly margined with velvety crimson tending to a purplish shade, and of large size, with a beautifully fimbriated edge. The sepals and petals are of a faint blush-pink, paler than in *C. Gaskelliana*, but with no tracing of the colour peculiar to *C.*

aurea. The plant is of vigorous growth and good free habit, having been raised from seed in a little over five years. From Messrs. Sander and Co.

CATTELEYA LABIATA SANDERIANA.—A choice and distinct variety almost self-coloured, the sepals and petals, also the column of the labellum being of a deep rose-pink, inclining to mauve, the lip itself of a purplish crimson, but not of extra size, the whole flower of beautiful form and outline. From Messrs. Sander and Co.

CYPRIPEDIUM CLONIUS (*C. caudatum* Lindeni × *C. conchiferum*).—This is a remarkable hybrid, entirely distinct from both the parents, being one of the very best yet raised in this section of the Slipper family; the pouch is large and of an ivory white shade, with faint spots, the inside of a purer white, with larger chocolate-coloured spots; the tail-like petals were as shown about 10 inches in length, but had not probably reached their limit; these were faintly striped with light green on a lighter ground. From Messrs. Jas. Veitch and Sons.

LÆLIO-CATTELEYA PISANDRA (*C. Eldorado* × *Lælia crispata*).—In form and size this very pleasing and distinct hybrid resembles *C. Eldorado*, the sepals and petals being of a blush shade suffused with purple; the lip is large and of a rich crimson-purple colour, being slightly reflexed; in the throat is seen the golden yellow of *C. Eldorado*. From Messrs. Veitch and Sons.

CIRROPETALUM ORNATISSIMUM.—A remarkable novelty, the plant bearing slender spikes with a crown of flowers on each; the colour of the central portion of the flower is a deep maroon; the sepals, which are about 4 inches in length, are of a lighter or tawny orange shade. From Sir Trevor Lawrence's collection.

CYPRIPEDIUM STATTERIANUM (*C. Spicerianum* magnificum × *C. vexillarium* superbum).—A very distinct and remarkably fine hybrid, having the dwarf habit and character of the former parent, more particularly its distinct dorsal sepal; the colour is, however, of the darkest, a deep vinous-purple, white around the edges and greenish at the base; the pouch and the petals are of a deep bronze shade, the spike twin-flowered. From Mr. Statter, Stand Hall, Manchester.

Awards of merit were given to—

CATTELEYA HARDYANA (Selwood var.).—A fine form of this excellent Orchid, with the sepals of a pale blush shape, the petals deeper in colour with lighter veins; the lip extra large and of a bright velvety crimson, with two distinct yellow spots and golden veins in the throat. From Mr. G. D. Owen, Selwood, Rotherham.

CYPRIPEDIUM INSIGNE ALBENS.—The ground colour of this is a pale green with faint shades of bronzy brown; the dorsal sepal, which is the most distinctive feature, is large, the upper half a pure white, the lower portion pale greenish-yellow; a distinct variety. From Messrs. Heath and Co., Cheltenham.

CATTELEYA LABIATA (Appleton's var.).—This is a distinct looking variety, the sepals and petals rather pale, but the lip remarkably rich in colour, a deep crimson with violet shading, and a clearly defined white edge, with an edging finely fimbriated; the plant bore nine flowers. From Mr. W. W. Appleton, Weston-super-Mare.

DENDROBIUM PHALENOPSIS SCHROEDERIANUM (Appleton's var.).—A bright looking form of this lovely Orchid, the sepals and petals at the base being pure white, and deepening into rosy crimson towards the extremities; the lip of a deeper crimson. From Mr. W. W. Appleton.

CYPRIPEDIUM INSIGNE CLARKI.—A vigorous form of this old species, the distinctive feature of which was the dorsal sepal, the spots upon the lower part of which were unusually large, whilst the upper half was a pure white, the ground colour of the flower being a pale greenish-yellow. From Mr. W. C. Clark, Sefton Road, Liverpool.

CATTELEYA WAROCQUEANA (LABIATA ?) VAR. **IMSCHOTTIANA**.—An extra fine variety, shown in remarkably good condition; the flowers of large size, the sepals and petals of a deep pink-mauve, a very rich shade; the petals were of unusual breadth

and the entire flower of fine proportions, the lip being of a deep crimson shade, with a lighter edging. From Mons. Linden, Brussels.

PAPHINIA GRANDIS.—A singular, but attractive looking Orchid of Lycaste-like character; the lower part of the sepals and petals was of a dull yellowish brown blotched and barred with dark chocolate, the rest being entirely of the latter colour in a deep shade, the lip lighter and fringed. From Mons. Linden.

Botanical certificates were awarded to *Pholidota convallarioides*, a choice and attractive little plant, with erect spikes of small greenish white flowers, in fragrance closely resembling the Lily of the Valley, the foliage also and style of spike, save that the flowers are more densely placed thereon, being likewise after that well-known plant; and *Dendrobium lamellatum*, an Orchid not remarkable for the beauty of its flowers, the most singular feature being the flattened bulbs, after the manner of some Cacti. Both from Mons. Linden. Cultural commendations were given to *Odontoglossum intermedium*, a finely-grown plant bearing two fine spikes of handsome flowers, with seventeen or eighteen blooms including buds on each spike, and *Cynoches chlorochilum*, another vigorous example, with several of its singular looking, greenish white flowers of wax-like substance. Both shown by Mons. Linden.

To Messrs. Jas. Veitch and Sons a silver-gilt Flora medal was awarded for a very comprehensive group of choice species and hybrids, amongst the latter being several of their choicest seedlings. Of the hybrids there were two plants of the lovely *Cattleya Harrisii* (*C. labiata* Mendeli × *C. guttata* Leopoldi), in which the form and substance are those of the latter parent, the petals being of a deep blush, suffused with violet, the lip self-coloured, a rich crimson-purple. *Lælio-Cattleya Cassiope* (*C. exoniensis* × *C. pumila*) was also shown. *Lælio-Cattleya Eumœa*, another hybrid, with light purplish mauve sepals and petals and a light lip, partaking most of the former parentage, and *Cattleya porphyrophlebia*, another beautiful light hybrid, were also shown. The *Cypripediums* were well represented by the finest hybrids, amongst which were C. T. B. Haywood, with grand flowers; *C. Arthurianum* and the variety *pulchellum*, a fine hybrid; *C. macrophyllum*, with large flowers; *C. Leeanum* superbum, *C. Galatea*, *C. Ianthæ*, *C. Ashburtonæ majus* and *C. cœnanthum* superbum, a grand hybrid. Of species there were *Cattleya labiata* and *C. Bowringiana*, both in good form; *Dendrobium Phalenopsis Schroederianum* and *D. P. Statterianum*, also *D. Dearei* and *D. formosum*, the latter remarkably vigorous. *Aerides suavissimum* as well as *Oncidium tigrinum* were shown, the latter being particularly fine.

Messrs. Sander and Co. had a silver Flora medal for a very fine group of *Cattleya labiata* in great diversity of shades, both light and dark forms being well represented; all were, however, beautiful varieties of this grand old *Cattleya*. The flowers were individually of large size, whilst the labellum in each case was notable for the fine colouring. One of the light varieties had but the faintest trace of the crimson colour in the lip, being a very delicate combination of shades. With these was a good example of *Vanda cœrulea*, three spikes upon the plant; also three plants of *Dendrobium formosum*, with large flowers; the beautiful little *Lælia pumila* Dayana was also shown here in good condition, having faint blush-coloured sepals and petals and a velvety crimson lip.

Messrs. Charlesworth, Shuttleworth and Co., Bradford, were awarded a silver-gilt Banksian medal for a very fine and extensive display, composed chiefly of *Cattleya labiata* in great profusion and variety, the dark and light forms being alike well represented. The light variety *C. labiata vivicans* was particularly beautiful. These plants alone of *C. labiata* made a splendid show. *Cattleya Schofieldiana*, a very fine variety of *C. guttata*, distinct from it, however, in the dense violet spotting on the sepals and petals, was also shown in excellent condition. Another form called *C. Scho-*

fieldiana aurea was much less spotted. The plants of this *Cattleya* appeared to be flowering for the first time since their importation. *Lælia grandis tenebrosa*, of intensely deep colour, was shown here, also *Cattleya granulosa*. *Cypripediums* were represented by *C. Charlesworthi*, previously certificated; also by *C. selligerum majus*, *C. euryandrum*, *C. Spicerianum* and *C. nitens*. *Oncidium tigrinum*, *O. varicosum*, and *Sophronitis grandiflora* were shown well.

Messrs. Hugh Low and Co. received a silver Banksian medal for a smaller group comprising several varieties; the best of these were *Phalenopsis grandiflora*, a good spike, *Odontoglossum Roezli*, *Cattleya labiata* (the old variety), *Oncidium tigrinum*, fine spikes, *Odontoglossum Alexandræ* and *O. grande*, *Saccolabium bellinum*, *Pleione lagenaria*, *Cattleya Bowringiana*, *Cypripedium Haynaldianum*, very fine and distinct (its use by the hybridiser should be productive of good results), *C. bellatulum* and *Lælia Dormani*, with *Vanda Kimballiana*. Messrs. Lewis and Co., Southgate, also received a silver Banksian medal for a neatly arranged group, comprising *Cattleya labiata* in good variety and capital condition; also *C. Bowringiana* and *Lælia elegans*, with *Oncidium orri-thorrhynchum* and *O. crispum*, both bearing good spikes.

Other exhibits comprised a fine plant of *Cattleya labiata* from Mr. W. C. Clark, bearing two spikes of six large and finely coloured flowers. Mons. Linden also showed *Odontoglossum Mooreanum* (*tripudians*?), *Cattleya Alexandræ elegans*, paler in colour, but larger than the type, and *Maxillaria callichroma*, with chrome-yellow and maroon shaded flowers. Mr. Little, The Barons, Twickenham, showed *Cattleya labiata* (Little's var.), a very brightly coloured form with flowers of medium size; also *Cypripedium Nicholsonianum*, a form of or closely allied to *C. Rothschildianum*. Sir Trevor Lawrence had *Cypripedium concoclawre* (previously certificated), a fine hybrid bearing three flowers on the one spike. Messrs. Heath and Co., Cheltenham, showed *Lælia Euterpe* (*L. crispa* × *L. Dayana*), a hybrid which has quite inherited the distinctive lip of *L. crispa*, but has the other parts of the flower much after *L. Dayana*. *C. Swinburniana* came from the same source. From Mr. G. D. Owen came a lovely form of *Cattleya labiata*, delicate in its colour, the lip having a faint trace of clear lemon-yellow; the flowers of this plant appeared to be hardly fully expanded. Mr. W. W. Appleton exhibited *Cattleya Hardyana*, a fine variety in beautiful condition, also *Oncidium Jonesianum*, a very pretty autumnal variety.

Floral Committee.

First class certificates were awarded to—

ANTHURIUM LINDENI FLORE-CARMINEO.—A remarkably fine variety, with stout erect spathes of a deep carmine colour, medium in size, the spadix of a pale purplish shade. From Sir Trevor Lawrence.

BEGONIA GLOIRE DE LORRAINE.—A most decided acquisition to the late autumn and winter-flowering varieties, with medium-sized flowers produced in the greatest profusion, the colour a bright rosy pink; in habit and flower it is not at all unlike *John Heal*, and is, we surmise, a hybrid with some affinity to the tuberous section. From Mr. Jennings, Ascott, Leighton Buzzard.

Awards of merit were voted to the following:—

CHRYSANTHEMUM THE TRIBUNE (Japanese section), having pale sulphur-coloured flowers of medium size, with reflexed and broad petals, a distinct variety. Shown by Mr. C. E. Shea, Foot's Cray; by Mr. H. J. Jones, Ryecroft Nursery, Lewisham; and by Messrs. J. Laing and Sons, Forest Hill.

CHRYSANTHEMUM HERBERT FOWLER (Jap.).—A deep yellow, with fluted petals, darker, but of the form of *Sunflower*. From Mr. Owen, Maidenhead.

CHRYSANTHEMUM MISS M. SIMPKINS (Japanese).—An incurved variety with a large and full flower, creamy white in colour, extra fine. From Mr. Owen.

CHRYSANTHEMUM RYECROFT GLORY (dec. Jap.).—A most promising decorative variety with deep golden yellow flowers of medium size, freely produced, the habit good. From Messrs. H. Cannell and Sons.

CHRYSANTHEMUM MME. RICHAUD (Jap.).—A distinct variety with large, bright, rosy pink flowers, very full and reflexed. From Mr. George Stevens, St. John's Nursery, Putney.

CACTUS DAHLIA SIR MOSES MONTEFIORE, an intensely dark new variety, darker than *Empress of India*, and richer in its shading (from Messrs. Cheal and Sons), and Cannell's *Brilliant*, an extremely bright variety, velvety crimson in colour, flowers of medium size (from Messrs. H. Cannell and Sons).

SINGLE DAHLIA MRS. PARROT.—The flowers of excellent form, the colouring irregular, lake and white predominating, very distinct and showy. From Messrs. J. Cheal and Sons.

A silver Flora medal was given to Messrs. Jas. Veitch and Sons for a group of finely grown *Chrysanthemums*, amongst which were many flowers of unusual size and good quality; the finest were Col. B. W. Smith, extra large, full and fine in colour; G. C. Schwabe, also large and very bright; Bouquet des Dames, large, massive flowers; Miss Anna Hartshorn, one of the finest whites, pure in colour, and above average size; Wm. Seward, very fine bold flowers; Mrs. C. Harman Payne, with six large blooms on the plant, very fine; Vivand Morel, with magnificent flowers of remarkable size and quality; Edwin Molyneux, very good; W. H. Lincoln, one of the best yellows, extra fine; G. W. Child, rich dark velvety crimson, a fine colour; Louis Boehmer, good; and Mons. R. Bahuant, large and full. Also bush plants in decorative style of O. I. Quintus, a rosy lilac, and Madame F. de Cariel, a terra-cotta colour, a variety of much promise. These made in all a splendid group, and were a very fine feature.

To Messrs. Jas. Cheal and Sons a silver-gilt Flora medal was awarded for a truly magnificent display of Dahlias, amongst which the singles and the Cactus varieties stood out as the finest. Of the former all the best known kinds were represented, many of which are of the firm's own raising. The latter were of very superior quality and in large variety, the colours surprisingly rich and the flowers very fresh. Crawley Gem, a deep crimson, with medium sized flowers and dwarf habit, was shown in quantity. Shows, fancies and other sections were also represented.

To Messrs. B. S. Williams and Sons, Upper Holloway, was awarded a silver Flora medal for a large group of exceedingly well-grown and coloured Crotons of useful sizes, from small specimens downwards, the best being Williamsi, Queen Victoria, majesticum, Princess of Wales and Mrs. Dorman. To Mr. T. S. Ware a silver Flora medal was awarded for a fine selection of Cactus and decorative Dahlias in large bunches, the finest kinds being represented. As in other instances, the colours were rich and the flowers fresh and good. Mrs. Peart, a straw-coloured new Cactus variety, stood out as one of the best. With these were a few good examples of *Lilium neilgherrense*, a rarely seen Lily, but a very beautiful one, with pale straw-coloured flowers of large size, tubular in shape.

Messrs. J. Laing and Sons were awarded a silver Flora medal for a well-grown group of miscellaneous stove and greenhouse decorative plants, amongst which were a few Orchids, tuberous Begonias and *Chrysanthemum* blooms being also included. Of the fine-foliaged plants there were good examples of *Dracæna Doucetti*. Mr. A. Waterer was awarded a silver Flora medal for *Andromeda arborea* with exceedingly brilliant foliage, and for *Quercus coccinea* of remarkably deep colour; the latter was a very fine example, the leaves being retained in quite a fresh state, although of such an intense colour. A silver Banksian medal was awarded to Messrs. W. Cutbush and Son for a group of *Pernettya mucronata* in the utmost profusion of berry, both light and dark kinds being shown; when grown thus these *Pernettyas* are valuable as late autumn decorative plants. A bronze Banksian medal was awarded to Mr. E. Holden, The

Park, Ealing, for an immense specimen of *Sour Melanie Chrysanthemum* some 8 feet through, bearing nearly 2000 flowers and buds, an excellent example of good culture, the training being free and informal.

Other exhibits comprised several cut spathes of *Anthuriums* of the large-flowered section from Sir Trevor Lawrence; the finest of these were *A. Andreanum sanguineum* with intensely deep blood-red spathes, and *A. Laingi*, with large ivory white spathes of extra size. Messrs. J. Veitch and Sons showed blooms of *Papaver glaucum* (the Tulip Poppy), with deep scarlet-coloured flowers; also *Begonia Buikci*, a species from Burmah. Messrs. H. Low and Co. had fine examples of *Lilium nepalense*, a splendid Lily of novel colouring. From Messrs. H. Cannell and Sons came a grand display of cut blooms of tuberous Begonias of extra size and fine quality, all colours from the darks to the yellows and whites being represented; with these were Dahlias and several capital cut blooms of *Chrysanthemums*, a Japanese variety called *International* with large, light coloured flowers being one of the best. A bronze Banksian medal was awarded to the above. Mr. Owen staged some grand flowers of *Chrysanthemums* other than those to which certificates were awarded; these were chiefly English-raised seedlings possessing remarkably good quality. Messrs. Keynes, Williams and Co. had several varieties of the single Cactus Dahlias, which bid fair to be capital novelties; the most promising as shown was a yellow called *Meg Merrilies*, with true Cactus character.

Fruit Committee.

There were numerous exhibits both of fruit and vegetables, taking up quite half of the hall. Probably the finest collection of Onions ever staged was put up by Messrs. Deverill, and a very large collection of vegetables came from Messrs. Sutton. The prizes given by the society for Grapes, Apples, and Pears were poorly contested, and only medium quality fruits were staged. This is unfortunate, as with such a favourable fruit season in many parts of the country there should have been a brisk competition for the limited number of prizes offered.

An award of merit was given to—

APPLE BOW HILL PIPPIN.—A valuable fruit on account of its fine brisk flavour. It is above medium size, highly coloured, and of fine shape. It is a seedling between *Blenheim Orange* and *King of Pippins*. From Mr. A. S. White, Bow Hill, Maidstone.

Seedling Melons were sent by Mr. Perkins, Thornham Hall Gardens, Eye, Suffolk, and Mr. Thomas, The Royal Gardens, Frogmore. Seedling Apples came from Messrs. Paul and Son, Waltham Cross, and Cooper, Taber and Co., Rivenhall, Essex. A variety named *Captain Tom* came from Mr. Crump, Madresfield Court, Malvern. It is a variety of local origin, and not much known. Gros Colman Grapes, fairly well coloured, grown on an open wall, berries of large size and of good flavour, and a dish of Tomatoes grown entirely in the open were sent by Mr. Allis, Old Warden Park, Biggleswade. A collection of about 100 dishes of Apples was contributed by the Nova Scotia Government. Some of the fruits were small, and others did not come up to home-grown fruit. Only a few of our really good varieties could be distinguished, such as Cox's Orange, Winter Nonsuch, Beauty of Kent, and King of Pippins. The flavour of these was not of the best. A silver-gilt Banksian medal was awarded to Mr. S. Mortimer, Farnham, for a very fine exhibit of black Grapes, no less than forty-eight bunches being staged; this was a most meritorious collection, as each bunch was good, well finished, and nicely staged. The bunches of Alicante and Gros Colman were large and well coloured; Black Hamburg was also good and of fair proportions. A small collection of Apples and Pears was also staged in front of the Grapes by the same exhibitor, the fruit being good and forming a pleasing finish to the group. Mr. J. H. Goodacre, Elvaston Castle Gardens, Derby, sent a collection of Pears and Apples of

well-known kinds. The best Pears were Thompson's, Vicar of Winkfield, Marie Louise, Marie Louise d'Uccle, Beacon, Marie Benoist, Beurré Bachelier, Catillac, and Pitmaston Duchess. Among the Apples were good Waltham Abbey Seedling, Stone's Pippin, Rymer, Mère de Ménage, The Queen, Peasgood's Nonsuch, Margil, and Adams' Pearmain (silver-gilt Banksian medal). Messrs. Rivers and Son, Sawbridgeworth, sent a collection of Apples and Pears, notable on account of the rareness of the varieties, several being seedlings and of considerable merit. Some of the finest Pears were Triomphe de Jodoigne, La France, Nouvelle Fulvie, Marguerite, Doyenné du Comice, and Beurré Rance. Among the Apples were Bijou, Belle Dubois, very fine; Rymer, Belle Pontoise, Wagener, good; Cox's Orange, Schoolmaster, Peasgood's Nonsuch, and several seedlings (silver Banksian medal). Messrs. Sutton, Reading, occupied one side of the hall with an extensive collection of vegetables. This was a fine exhibit, but marred by a group of huge Cauliflowers, some being past their best and of little value. The *Magnum Bonum* Cauliflower was excellent, the heads of a nice size, white, and compact. Kales of the curled green type named Arctic Green Curled and Purple Arctic Green were shown in very fine condition; also very fine Early Gem Carrots. This is distinct, and should be excellent for shallow soils, having little core with a great depth of flesh. A large quantity of Sutton's A 1 Onion, selected Ailsa Craig, Crimson Globe, and others were also staged; and a collection of their Snowball Turnip, nice roots of medium size, solid (silver-gilt Knightian medal). Messrs. Deverill staged a magnificent lot of Onions occupying much space. Lord Keeper was extra large, six bulbs weighing 15 lbs. Jubilee was shown in quantity—hard, solid bulbs of immense size; Ailsa Craig, Anglo-Spanish, Rousham Park Hero, Cocoa-nut and others were equally good. A silver-gilt Knightian medal was worthily awarded. A nice collection of Endives was sent from the society's gardens at Chiswick, the Broad-leaved Batavian being staged both blanched and green; this is an excellent kind. Queen of Winter is also a large type, but not so good as the first-named, being more bitter and of looser habit. These were sent to Chiswick by Messrs. Vilmorin, Paris. Broad-leaved Green Batavian, Messrs. Barr's selection, was also very good. This is a dwarf, compact grower, with full heart and readily blanched, of excellent flavour, much like *Cos Lettuce*. Improved Round-leaved, a very hardy and compact grower, was also shown. A new Savoy named Silver-laced, a variety with white edges, but of no special value from a culinary point of view, was sent by Mr. Carmichael, Edinburgh. A new variety of Savoy, intermediate between the old green Curled and Drumhead, also an early Cabbage called Early Dwarf, with firm, close heads, were shown by Mr. T. Basham, Monmouth.

The prizes given by the society for the best six bunches of Grapes (three varieties) brought only one competitor—Mr. Osman, Ottershaw Park, Chertsey, who was awarded first, having Alicantes, Trebbiano and Lady Downe's. The same exhibitor had the only lot of six bunches for flavour, staging good bunches of Mrs. Pince, some small Muscat of Alexandria and Alicante. For four dishes of dessert Apples and six cooking, there was no competition. For six dishes of Pears there were three lots. Mr. J. Nicholson, Sewardstone Lodge, Chingford, was first, having a nice dish of Beurré Dubinson, a little-known variety, good; Beurré Baltet père and Beurré Diel. Mr. Osman was second, with smaller fruits. Mr. Iggulden, Marston House Gardens, Frome, staged very fine dishes, but overripe.

Mr. A. Dean, in the course of his remarks on the Onion, said that the subject of his lecture was appropriate, as the society had this year an extensive trial at Chiswick, some forty varieties being grown. Some of course were duplicates, but on the whole the rows were very even, the bulbs solid and true to name; indeed, there was great credit due in these trials, as in many places there

had been failures, and the drought was not favourable to the Onions. These Onion trials had been severely handled; some people would not give certificates to varieties if not new, but new or old if good should be recognised. Only seven certificates were awarded by competent judges, and at the vegetable conference at Chiswick in 1889 no less than twenty-two certificates were given. Passing on to varieties, the shape of bulb and colour of skin were the distinguishing features. The green section was very hardy, the Southport Globe or Silver Globe being a grand type. He would not refer to mere names, as there are about a dozen of the distinct Globe section, and these comprised the largest bulbs. He found the white-skinned or flat types were the earliest to decay. Such varieties as James' Keeping, Brown Globe, and Bedfordshire Champion were noted keepers, but why should flatter kinds decay sooner than others? He thought this a point worth attention. He considered the Globe kinds ripened more thoroughly, therefore contained less water. As to soils, a light soil was considered suitable for this crop, but he quoted an instance where heavy clay land had produced at the rate of £20 an acre, so that little could be said on culture. If the soil was light, much treading and rolling were necessary, so that in seasons of drought heavy land was not unsuitable; indeed, if well worked, it would annually give good results. As he had previously stated, there was little to add as regards culture, but no doubt those who grew large bulbs for exhibition went to more trouble, as they could not produce the big bulbs under ordinary culture. Of late years there had been a great increase in size of bulb. He could scarcely call this improved culture, as these large bulbs were not the best keepers; they entailed more trouble, and he questioned if they paid for the labour and expense. To get these extra large bulbs, sowing in heat in January was necessary, gradually hardening off and pricking out on a warm border 18 inches between the rows, and 12 inches from plant to plant. These require very rich soil, abundance of liquid manure, and attention to details. He mentioned several growers who made a speciality of these bulbs, and recently he had had an opportunity of seeing some of the largest ever grown, and here the ground was simply a mass of manure. He would ask what was the market value of such large bulbs, and he failed to see what advantage there was in this fattening process. No doubt Onions after such a season would keep, but it was not always so. Large Onions were only grown for prizes, and if it was not so, they would soon die out. Even for seed or stock purposes medium-sized bulbs were more reliable. We should fight against mere size, as often size meant water and not quality. Onions were liable to several diseases; the maggot was a great scourge. Those who suffered badly would do well to adopt the old plan of sowing in boxes and planting out. It was also essential to remove all traces of disease by burning the refuse of the previous crops. Quassia chips, soft soap, petroleum and soot were excellent remedies; gas lime was also beneficial used between the rows. The Bordeaux mixture also cured mildew, the latter a troublesome pest. He went at length into the various ways of cooking. He explained the formation of the various types, and in doing so discarded those large, coarser kinds.

NATIONAL CHRYSANTHEMUM SOCIETY.

A MEETING of the floral committee of this society was held on Wednesday last at the Royal Aquarium, Mr. George Gordon occupying the chair. The meeting was largely attended, and there was a very fine display of novelties staged for the inspection of the committee. The principal exhibits came from Messrs. Cannell, of Swanley; Mr. R. Owen, Mr. H. J. Jones, and Mr. N. Davis. Among the best flowers we noted Belle Janne, a remarkably fine deep yellow Japanese, exhibited by Mr. C. W. Knowles, which was commended. Richard Dean, a deep crimson Japanese with

golden reverse, but too closely resembling W. Seward; W. H. Fowler, a perfectly formed flower of the Japanese type, colour deep yellow; Ada Strickland, a deep cinnamon-yellow self Anemone; Mme. Richaud, a Japanese of bright deep rosy blush, reflexed petals, and golden centre, shown by Mr. Geo. Stevens, and commended; G. W. Childs, an American Japanese, of a peculiarly bright chestnut-crimson and golden reverse; and Snow, a large white Japanese with long drooping petals, which the committee wished to see again, and many other good sorts were shown. For the choice collections of new varieties staged at the meeting the committee passed special votes of thanks to Messrs. Cannell and Sons, Mr. H. J. Jones, of Lewisham, Mr. R. Owen, Mr. N. Davis, and Messrs. Rochford and Sons, all of whom really contributed to make the meeting a very interesting and unusually busy one.

The following Chrysanthemums were awarded first-class certificates:—

THOMAS WILKINS (Owen).—A Japanese with flat spreading petals, colour deep chrome-yellow.

MRS P. BLAIR (Owen).—A very large massive bloom of the Drover type. It is deep in build, and the inner florets incurve, while those of the exterior are long and drooping; the colour is light purple with silvery reverse.

VIOLETTA (Beckett).—Another very large Japanese with deep drooping petals; colour a soft shade of rosy violet.

Mlle. NATHALIE BRUN (Rowbottom).—An Anemone with a fine high disc, light lemon-yellow, and quilled guard florets of pure white.

TRIBUNE (H. J. Jones).—An American seedling Japanese of globular form, colour light lemon-yellow, rather deeper towards the centre, but very pure in tone.

YELLOW LADY SELBORNE (Rochford).—A yellow sport from Lady Selborne, which was a sport from James Salter about eleven years ago. Certificated as a market and decorative variety.

MME. CAMBON (C. Gibsen).—An enormous flower as shown. It is of the Japanese incurved type, and has long twisted incurved petals, dull chestnut-red inside, but pale straw reverse, the higher tone of colour being almost hidden by the folding over of the florets.

A first-class certificate was also awarded to—CACTUS DAHLIA BRILLIANT (Cannell).—A very fine brilliant crimson flower of the true Cactus type.

The light in the room where the meeting was held was very bad during the meeting, rendering it very difficult at times to form a proper opinion of some of the colours.

NOTES OF THE WEEK.

Apple tree bearing fruit and bloom.—I send you a photograph of a branch of an Apple tree carrying a truss of bloom and a fully developed fruit. It was picked last week. The Apple is a Hawthornden, full-sized, ripe, and full of colour.—W. R. BLOXHAM, *The Gardens, Tipton Grove, Chesterfield.*

A white Tritoma.—*T. modesta* is now in flower here, and a really beautiful plant it is. It is of the purest waxy white, the scape is quite 3 feet high, and the flower portion about 1 foot; the leaves are narrow and the scape very tapering, so it is distinct in every way from the ordinary kinds.—T. SMITH, *Newry.*

Hardy Heaths from Matlock.—Herewith I send you a few hardy Heath flowers. They are the last of the season. I also send a sample of *Kalmia rubra*. It is the second time of blooming this year. Some few of the hardy Rhododendrons are also blooming the second time. I suppose it is the extraordinary weather that is the cause.—C. REEVES, *Flash Nursery, Two Dales, Matlock.*

Solanum jasminoides.—This beautiful climber was in full bloom a few days ago in Mr. Kingsmill's garden at Harrow Weald. It was a picture of bloom, and the growth had reached

considerably, being smothered with the clusters of large white flowers. The position is sheltered and many tender things thrive well. From quite a distance one could see the bold flowers of the So'anum standing out against the dark green leafage.

Rhododendron retusum.—Since the first week of September a large bush of this Rhododendron has been flowering here with about 200 trusses of ten to twenty flowers each. When so profusely in bloom this Rhododendron is very beautiful and valuable, as no other Rhododendron is flowering at this season. Why is this fine plant so rarely met with? Its culture is very easy, as it only requires a greenhouse temperature. Even a degree or two of frost does not harm it.—O. FORSTER, *Lehenhof*.

The winter Daffodil (*Stenbergia lutea*).—This was in full beauty recently at The Holt, Harrow Weald, and clumps of it on the rocky were delightful in the bright sunlight of an October day. The soil is warm and the position sunny, exactly the conditions that suit the bulb, as mentioned in THE GARDEN by "F. W. B.," Oct. 21, p. 365, where an illustration of it is given. It is a charming companion to the autumn-flowering Croci, Colchicums, and Cyclamens.

Anemone japonica var. Lady Ardilaun.—This form of the white Japanese Windflower we noticed in Mr. Kingsmill's garden at Harrow Weald. It seems to be a really good form and the plant more robust. It remains to be seen whether it will revert to its original form, and we think this probable, unless the plant is grown unusually well. The common white alba or Honorine Jobert is so beautiful and graceful, that it is very hard to get anything better.

Bocconia cordata.—A fine mass of this, which we saw recently in a clearing in the wood in Mr. Kingsmill's garden at Harrow Weald, showed how much beauty is lost by cutting away the beautiful nut-brown stems of decayed flowers. They are an autumn picture and as pleasing as the gradations of tones one gets earlier in the flowers. The *Bocconia* is a fine plant in a suitable place, the leaves veined, and the spikes of flowers, if not showy, are very charming in the wilder spots of the garden.

Lilium auratum.—I take the liberty of sending you a bloom of this grown in the open ground and cut to-day. I send it not only on account of its size, but as showing that *L. auratum* does as well in the open as under glass. I have had a succession of bloom since the middle of summer—magnificent spikes as well as flowers. The principal petals measured each over 6 inches long and 3 inches broad.—J. B. D., *North Laurielnove, Dumfries*.

** A noble flower.—ED.

Dahlia serratipetala var.—This comes to us from Messrs. Kelway, and is very bright and singular looking. What a lovely improvement has taken place in the Dahlia owing to the Cactus and other forms having "knocked the sawdust" out of the old dumpling-like forms. Pretty as they were in their stodgy way, surely no flower shows better the folly of a few men setting up rules that flowers shall be all made like buttons. Alas! poor old Glenny and all the long-clay and gin-and-water set, and all their lost ideas. Happily, the Dahlia is ten times better than ever it was under their stupefying influence.

Plumbago capensis in the open.—A few days ago we saw a large number of plants of this in full bloom in the Chiswick gardens, where it is planted in small beds and flowers freely through the summer if the weather is favourable. In wet years the plant runs too much to leaf, but in a dry bright summer, leafage is not produced at the expense of bloom. In Hyde Park and other parks large specimens are grouped on the turf, but we like the *Plumbago* in small beds quite as well, and there is no difficulty in getting a good display. The position must be sunny, not too exposed and the soil light.

The Hop-leaved Vine (*Vitis heterophylla humulifolia*) is very charming in Mr. Kingsmill's

garden. This is a quick, vigorous-growing climber that might be planted in the place of many common things one sees constantly repeated in gardens. Even the best plants are tires of when present everywhere. The leaves are small and like those of the Hop, as suggested by the English name, the berries of a pure turquoise-blue colour. This climber or creeper is exceptionally beautiful this year through the profuse crop of berries, although it rarely fails to fruit freely. It is also fine at Syon House this year.

Water Lilies in October.—In the future we shall have Water Lilies blooming for quite six months. I did not record the date when the first flowers opened this year, but it was some time during the month of May. The low temperature of the water now prevents the buds of many kinds expanding, but the new *N. Laydekeri rosea* has two brilliant flowers out in this the last week of October. *N. tuberosa* has been opening flowers throughout the month, and the canary-coloured kind has buds showing colour. These if cut and put in tepid water indoors open after a day or two, and, though not quite full-sized, they have all their charming delicacy and freshness of colour.—A. H.

Violets from Wales.—Mr. J. Roberts, The Gardens, Tan-y-bwlch, N. Wales, in sending us a very beautiful lot of these flowers says: "Having to-day (Oct. 24) gathered and sent away some hundreds, if not thousands, of Violet blooms, I find after supplying all commissions that I have still a few left in the bottom of the basket; therefore I take the liberty of sending them to you, well knowing their delicious scent will be highly appreciated by you in town. They are picked from the open off the quarters they were grown on during the summer, which speaks much for the fine autumnal season, and I also trust they are a slight proof of the soundness of my way of growing them I have so strongly advocated in the pages of THE GARDEN. We have had a good supply of bloom—even this scorching summer—since July, and, as the foliage shows, no red spider."

Notes from Almondsbury.—I was pleased to see *Camellia Sasanqua* illustrated. I have had four varieties; one, pure white, I gave to Kew; one perished; one, the variegated form, has made no growth in three years; one is now (October 25) nearly past its best. It stood out all the summer and bloomed in the open on October 1. I feel sure it would make a fine plant to grow in the open. We have had magnificent rains here, more than 6 inches in thirty days. *Brugmansias* are blooming with me for the third time, the yellow and the red forms doing as well as the two commoner forms. I conceive this dry summer and wet autumn will make the treatment of some plants very difficult. *Eremurus robustus* refused to show any bloom and withered away early in the summer. The vigorous leaves now appearing make me anxious lest the spike should also appear, and how to protect that I do not know. *Anemones* are in bloom; *Crocus Imperati* is showing strongly; *Irises* like *aurea* and *Monnieri* are throwing up strong shoots, and a few *Hepaticas* are out. We want a little cold weather very badly down here, or else spring flowers will be soon appearing.—C. O. MILES.

Mr. H. J. Veitch.—La Société royale d'agriculture et de botanique de Gand. At a meeting of this society held on the 16th inst., Mr. H. J. Veitch, of the Royal Exotic Nursery, Chelsea, was unanimously elected a membre d'Honneur in recognition of his services to botany and to horticulture.

The weather in West Herts.—Another warm week, with lower temperatures towards the end of it. During Friday night the exposed thermometer never fell lower than 45°, and on the following day the temperature in shade rose as high as 65°. On the coldest night (Sunday) the thermometer on the lawn showed 3° of frost. The temperature of the soil at 2 feet deep is now 7°, and at 1 foot deep 8° warmer than at the same period last year, but then it must be remembered that October last year proved a singularly cold month throughout. More than 4 inches of rain has already fallen during the present month, of which amount over 2½

inches has come through the percolation gauges—equivalent to 12½ gallons through every square yard of uncropped ground.—E. M., *Berkhamsted*.

PUBLIC GARDENS.

Metropolitan Public Gardens Association.—The Prince of Wales has been pleased to signify to the Earl of Meath that it will afford him much pleasure to accord his patronage to the Metropolitan Public Gardens Association, and at the same time to send a contribution of ten guineas to its funds.

A riverside improvement.—Battersea, which is already fairly well provided with open spaces, is to have yet another. The vestry has lately improved the Vicarage Road, which runs by the side of the Thames near Old Battersea Church. It is decided now to claim the foreshore adjoining the road, and by building a concrete embankment enclose an open space of 2800 square yards. This space when railed in and planted with shrubs and trees will make an open and delightful promenade with a river frontage. The cost is estimated to be £2040, towards which the Metropolitan Public Gardens Association will contribute £1000.

Gladioli in 1893.—Will you permit me to correct an error I inadvertently made in my paper on Gladioli, viz., the statement that Messrs. Kelway and Sou were awarded third prize at the Agricultural Hall; whereas I am informed their collection was not staged for competition.—DELTA.

Names of plants.—*Plant.*—*Sedum* Ewersi.—W. A. G.—1, fine form of *Oncidium Forbesi*; 2, *Ornithocephalus grandiflorus*.—N. B., *Moor Hill*.—*Dendrobium Draecnis*; *Dendrobium Lowi* is a yellow flower with a fringed lip; *Catasetum* species near *luridum*; *Epidendrum longicolle*.—W. Appleton.—1, the *Epidendrum* I cannot name, now at least; 2, *Zygopetalum maxillare*; the *Phalaenopsis Esmeralda* are only varieties.—G. H.—Beans certainly.—C. Dunning.—*Trichocentrum orthoplectron*.—C. S. P.—*Centaurea ragusina*.—C. Gardner.—1, *Coronilla varia*; 2, *Poinciana Gilliesi* (?).

Names of fruit.—G. B.—1, apparently a small *Blenheim Orange*; 2, *King of the Pippins*; 3, *Yorkshire Beauty*; 5, *Hanwell Souring*; 6, *Ribston Pippin*.—W. Cunningham.—*Hoary Moring*.—W. J. C.—1, *Uvedale's St. Germain*; 2, *Brown Beurré*; 3, probably *Vicar of Winkfield*; 4, *Doyenné du Comice*.—W. Thompson.—1, *Golden Noble*; 2, not recognised; 3, *Round Winter Nonsuch*; 4, *Vicar of Winkfield*.—A. H.—1, *Swan's Egg*; 3, *Emile Bivort*; 4, *Duchesse d'Angoulême*; 5, *Comte de Lamy* (?); 6, rotten; 10, *Pearson's Plate*; 11, *Bess Pool*.—W. G. Novell.—1, *White Doyenné*; 2, *Beurré Bachelier*; 3, *Beurré Diel*; 4, *Souvenir du Congrès*; 5, *Beurré Superfin*.—H. Prothero.—1, send better specimen; 2, very small *Adams' Pearmain*; 3, *French Crab*; 4, looks like small specimen of *Golden Noble*.—T. Denny.—*Pear Baronne de Mello*; *Apple next week*.

"The Garden" Monthly Parts.—This journal is published in neatly bound Monthly Parts. In this form the coloured plates are best preserved, and it is most suitable for reference previous to the issue of the half-yearly volumes. Price 1s. 6d.; post free, 1s. 9d. Complete set of volumes of THE GARDEN from its commencement to end of 1892, forty-two vols., price, cloth, £30 12s.

"Gardening Illustrated" Monthly Parts.—This journal is published in neatly bound Monthly Parts, in which form it is most suitable for reference previous to the issue of the yearly volumes. Price 5d.; post free, 8d.

"Farm and Home" Monthly Parts.—This journal is published in neatly bound Monthly Parts, in which form it is most suitable for reference previous to the issue of the yearly volumes. Price 5d.; post free, 8d.

"Hardy Flowers."—Giving descriptions of upwards of thirteen hundred of the most ornamental species, with directions for their arrangement, culture, &c. Fifth and Popular Edition, 1s.; post free, 1s. 3d.

"The Garden Annual" for 1893.—Contains Alphabetical Lists of all Branches of the Horticultural Trade. The Lists of Gardens and Country Seats (containing over 9000) have been very carefully and extensively revised, and are admitted to be the most complete ever published. Price 1s.; by post, 1s. 3d.

All of our readers who are interested in the improvement of cottage homes are invited to help us to make Cottage Gardening known. It is published at the very lowest price to meet the wants of those for whom it is intended, and copies will be sent for distribution, free, by the publishers, Messrs. Cassell and Company, La Belle Sauvage Ludgate Hill, E.C.

No. 1146. SATURDAY, November 4, 1893. Vol. XLIV.

"This is an Art
Which does mend Nature: change it rather; but
THE ART ITSELF IS NATURE."—Shakespeare.

ORCHARD AND FRUIT GARDEN.

EFFECT OF HEAT ON PEARS.

A HOT summer is undoubtedly most favourable to the production of extra fine clear-skinned Pears. During the average British summers it is only in favoured localities and under high culture that they attain anything like their full size or are so attractive in appearance as could be wished, though the keeping and eating qualities of the under-sized fruit may yet be perfectly satisfactory. All things considered, however, it is doubtful if we are the gainers by the improved size and appearance of the fruit this season, as far as any rate as the bulk of Pears obtained from wall trees is concerned. In many cases there is little or no improvement observable in the quality of the fruit, and even if the fruit were rather more luscious and richly flavoured than usual, this gain would have been more than counterbalanced by the trick nearly all have developed of ripening too soon and keeping badly afterwards. When Pears are most wanted, or, say, during November, December, and January, there will not be many available, that is, unless some of the naturally late varieties keep very much better than they give promise of doing. At the time of writing this (October 14) we have not a sound fruit of Marie Louise left, Beurré Hardy, Brown Beurré, Louise Bonne of Jersey, Pitmaston Duchess, Comte de Lamy, Conseiller de la Cour, Marie Louise d'Uccle, and several other varieties that ought to be available to the end of October, if not later, being also either used or spoiled. Beurré Diel is coloured and will soon be at its best, and so also are Huyshe's Prince Consort, Duchesse d'Angoulême, Beurré Clairgeau, Durondeau, and Van Mons Leon Leclerc. Winter Nelis, of which excellent crops were stored, is likewise, I regret to observe, beginning to soften, and late-gathered Doyenné du Comice will scarcely keep till the second week in November.

There are, however, a few varieties of which I hope better things. A hot summer evidently suits Glou Moreceau, Easter Beurré and Beurré Rance admirably. With us these are usually badly spotted, the fruit being attacked by one of the Cladosporiums or fungoid diseases so difficult to combat and very hard of prevention. Instead of being disfigured by these black patches, and badly cracking in the worst cases, the fruits are perfectly clear skinned and of large size. Even Glou Moreceau in the open has done well, good gatherings of fairly large, clear-skinned fruit being had from our pyramids. It is my belief the quality of these three varieties will prove better than usual, and in any case those who have a good supply of them will have every reason to be well pleased that they have not destroyed their trees owing to previous disappointments. With me Josephine de Malines is generally presentable from wall trees, but the crop is heavier and the fruit finer than has been the case for several years past. The question now arises, ought we not to pay greater attention to the cultivation of the last four varieties I have alluded to? Instead of the trees of these good old sorts being relegated to

the coldest walls and the open ground, they ought really to have the warmest positions that can be assigned them. With me much the best crops are had from trees growing against a high wall facing south-west, and which was previously occupied by a long row of comparatively valueless Fig trees. Glou Moreceau nearly always does well against a wall facing south-east, and in spite of the poor opinion Mr. Blackmore has of this variety, I would yet advise planting it most extensively against moderately warm to quite the sunniest walls. Pyramids, if planted in a warm part of the garden and kept rooting near the surface, also crop freely, and the fruit, if sometimes spotted, is yet of excellent quality. As much cannot be said of Easter Beurré, as there are seasons when the fruits are never really good, being somewhat dry and mealy. It is a late variety, however, and fills up an awkward blank at times. I do not say plant it extensively, but give it a good trial, preferably on the Pear stock, and in a warm position. Josephine de Malines sometimes fails to ripen at all unless the fruit is subjected to a dry heat for a few days before it is wanted for use, but this treatment will scarcely be necessary this winter, and I also anticipate a treat as regards quality. That Beurré Rance does best in warm positions and favoured localities is demonstrated by the fact that it is by far the best late Pear grown in the neighbourhood of Bath. Fruit from one large old tree has been repeatedly shown and invariably took the first prizes at both the bulb show and also the May show when these used to be held at Bath, good quality being the test. It is anything but attractive in appearance even when ripe, but is juicy and fairly melting, keeping, as before hinted, remarkably well after it is ripe. In Essex I have seen really good crops gathered from standard or orchard trees, the crops being particularly heavy this season, while the quality is generally passable. On our heavier soil the fruit from trees in the open and cool sites generally is liable to crack badly, and that is my principal reason for assigning the trees warm positions. Beurré Sterckmans is not so free bearing as the foregoing, otherwise it would be a worthy companion. According to the "Fruit Manual," it is an abundant bearer, succeeding well on the Quince. My only tree is a three-branched cordon on the Pear stock, and it only bears a crop occasionally. Instead of ripening in January I am afraid our fruit will have to be used in November. There is yet another old and somewhat despised variety that the hot summer of 1893 has developed to an extra large size, and, as it happens in this case, done exactly what was desired. I refer to Ne Plus Meuris. Unless this variety can be grown to its full size, the individual fruits weighing on an average say about 9 ozs., they are largely composed of core. Given the benefit of a warm wall and good root culture, the Pears, which form in great clusters, being also freely thinned out, will attain a good size, the quality being passable during January and the next two months. On a tree against a north-east wall the fruit was too small to be of any value, and it is a warmer site the neglected Ne Plus Meuris should receive.

Assigning late Pears the warmer sites may necessitate the removal of early and successional varieties to cooler positions, but it does not necessarily follow that this is greatly to their detriment. As a matter of fact, too much of the best wall and garden space is devoted to early and successional Pears, to the almost complete exclusion of the more needed later varieties. If this were not the case, there would be far better stocked fruit-rooms than at present,

the weakness of the prevailing fashion becoming still more apparent long before November is past. The fruits of Jargonelle, Williams' Bon Chrétien, Beurré d'Amanlis, Beurré Superfin, Marie Louise, Louise Bonne of Jersey, Doyenné du Comice, Pitmaston Duchess, Durondeau, Beurré Hardy and such like may not be so fine and clear-skinned from pyramids, bushes and standards as they are from wall trees, but there is ample compensation in the shape of heavier crops of richly flavoured fruit, the quality not unfrequently proving much superior. The fruit generally produced by trees in the open during 1893 was finer than usual, but at most other times it is quite large enough for all ordinary purposes, and why, therefore, continue to let those varieties that do not require so much heat occupy the positions that the extra heat of the past summer has amply proven would be all the better for more warmth!—W. I. M.

— Notwithstanding the clean and fine appearance of Pears this year, the fruits are keeping badly after ripening. This, combined with their earliness, is a serious matter to those who have to keep up a varied supply of dessert fruit during the winter months. Unless some kinds, which usually are only fit for stewing, ripen up sufficiently for dessert, I shall be practically without good Pears by the end of November. Even now I have plenty of that good old stewing Pear Vicar of Winkfield quite ripe and buttery, with no grittiness. The flavour is by no means rich or pronounced, but many worse Pears have before now had to play their part as part of the dessert. Already I have almost finished the following varieties: Beurré Clairgeau, Beurré Diel, Brown Beurré, Conseiller de la Cour, Doyenné du Comice, Duchesse d'Angoulême, Pitmaston Duchess, Forelle, Knight's Monarch, Louise Bonne of Jersey, Marie Louise, Marie Louise d'Uccle, Napoleon, and Thompson's, to say nothing of earlier kinds. Seasons like the present go far to prove your contention (which was published in a somewhat similar year, viz., in 1887) that we are overburdened with kinds of Pears, most of which are far from good. This is certainly the case with midseason fruit. Late kinds I find to be either very shy bearers or of very poor quality, and only fit for stewing. The ground on which the trees stand would be better employed in growing recognised stewing kinds which bear good crops of large fruit or in growing good Apples.—J. C. TALLACK.

Apple Golden Harvey.—With early Apples and Pears keeping badly, good late kinds are sure to be doubly valuable. The useful little Apple mentioned above is larger and better in appearance this year than I have ever before had it. Last winter I had a very large and handsome old tree of this variety well thinned out, as the branches had become very thick and the fruiting spurs long and straggling, so that the fruits were very small and insignificant looking, giving a lot of trouble when picking. The improvement is so marked, that I hope to do some further thinning when the crop is off. I estimate the present year's crop at from six to eight bushels, and almost all the fruits are of a very useful size. They will be very useful when all but the latest kinds are over.—J. C. TALLACK.

Manuring Strawberry beds.—To get fine fruit it is necessary to feed, and when the plants remain more than one season in one place it is of advantage to mulch at this season. I have noticed on light thin soils that the plants suffered much by drought this season and are much weaker than usual, so that it is more than ever necessary to give some support to plump up the crowns for next season's fruit. In many instances the quarter is patchy, and before mulching is a good time to make any losses good, taking care when planting to firmly tread round the newly-planted roots, also to firm light soil by treading before planting, as this prevents injury by frost and creates a sturdy growth. The late autumn rains well wash the

manure down to the roots, and the small portion of fine material left will serve as a protection to the roots in severe weather. When manuring at this date it is essential to use rich or well-decomposed material, strawy litter being of little use now. Before mulching I would advise a slight hoeing between the rows to get rid of weeds, removing also old or useless leaves and thus making the beds neat for the winter months.—G. WYTHES.

GRAPES NOT KEEPING WELL.

CAN you give me any information respecting the Grapes enclosed? I took charge of the Vines about a month ago, and finding the Grapes were shanking and shrivelling very badly, I examined the border, which I found was very dry from top to bottom. The border is inside and out on the ground level, about 2 feet deep, resting on the solid limestone rock. The house is a lean-to facing west, about 100 feet long, and glazed with rolled glass a quarter of an inch thick. The front ventilation is obtained by small shutters 18 inches by 6 inches, 6 feet apart. All the top ventilation that can be put on is 6 inches, which runs the whole length of the house. A soaking of water was given to the Vines on Oct. 4. The ventilation is open day and night, and if at all damp a little fire is put on to keep the house dry. Some of the berries have small drops of purple juice oozing from them, some are split across, and when the bunches are cut most of the berries drop off. The Vines have finished growth; the leaves are yellow, covered with red spider and mealy bug. I thought the cause was owing to the Vines being kept so dry and then having a supply of water started the sap again, and there being no growth to carry it off it flowed to the bunches. The bunches that were shrivelled are quite plump now, but of no good, as you will see by the enclosed. The house has been filled with plants for about ten days.—A. G. H.

* * The cause of the Grapes cracking and the berries afterwards dropping from the bunches is the ultimate result of excessive drought during the intensely hot weather towards the latter end of the summer. The watering afterwards given was without doubt essential to the health of the Vines for another season; this, as described by "A. G. H.," caused the berries to plump up again after having shrivelled when the border was dried up. The leaves at the time through not being in a healthy condition could not take up the sap which was again set in motion more actively; hence it flowed to the berries, and when these were swollen up again to their full capacity the cracking commenced. The case in point is an illustration of the old saying, "Of two evils choose the less;" the lesser evil has resulted in the decay of the berries, the greater evil would have resulted in the weakened condition of the Vines another season. Such instances will at times occur, making it extremely difficult how to act for the best. The after treatment could not, I think, be improved upon from the description given. I would advise the continuation of a gentle warmth in the pipes as one of the best remedies. Probably the worst of the case has already been seen, and that some at least of the bunches will survive. By the further information as regards insect pests, it is evident that the previous treatment was far from what it ought to have been, independent of the dry state of the border. The insects would weaken the foliage and render it less capable of taking up the additional flow of sap, and from the description of the leaves as being "yellow," the lateral shoots would presumably be in the same state with no real growth. The amount of ventilation at the top of the house does not appear to be sufficient to meet the case. Additional ventilation in the back wall would undoubtedly be desirable before another season. This instance of Grapes not keeping well induces me to relate my own experience of the past two seasons, the result of which has solved in my mind one at least of the causes of shrivelling. About this time last year my Vines in the lateinery were carrying rather too heavy a crop of fruit; the consequence

was the colouring was longer about than I thought desirable. In order to render assistance, the fire-heat was kept up longer than usual. This ultimately produced shrivelling, more particularly in Lady Downe's Seedling, this being the variety carrying the heaviest crop. The Vines in this case were healthy in every way and the border as moist as was desirable, but with the extra late firing the growth continued longer than it should have done; and when the roots were not so active, through the border, an outside one, being cooler, the leaves drew without a doubt some of their sustenance from the berries themselves. I thought this matter out for some time, and could come to no other satisfactory conclusion than that the leaf growth had robbed the bunches. This year I resolved to reduce the lateral growth in good time, and gradually remove it so that only the main shoots with about two leaves beyond the bunches were left. Less firing was also needed, this of course being explained in a measure by the condition of the weather. The border would have had another watering had the manual labour and convenience been sufficient, but, as it was, I do not think it actually became too dry. The result has given me every satisfaction; there is no sign of shrivelling, and the fruit keeps well in every other respect. Proportionately I have a heavier crop of Grapes fit for the table than last year, the berries individually larger and the colour excellent. This instance has convinced me that one at least of the causes of shrivelling has been unravelled in a satisfactory manner. I have no doubt others have had similar cases to contend with. Only last week I saw two of our finest autumn Grapes exhibited in a shrivelled state; these were Muscat of Alexandria and Mrs. Pince's Muscat. I can only surmise of course as to the cause, but I think it may be plainly put down to one of the two described—either drought, as in the case of "A. G. H.'s," or, as in mine, through the leaf growth robbing the fruit. I am quite convinced that with late firing and too much leaf growth there is a great danger of shrivelling. It is only natural, if viewed in a practical light, that the foliage when excessive would, as the roots become less active, rob the bunches. By the early removal of lateral and sappy growth this is prevented. In support of this, it should be borne in mind that it is not the fully matured leaves that take the most sustenance late in the season, it is rather those of later formation. To prove this one has only to cut examples of each and see which will wither up the first under similar conditions. There is an additional cause in "A. G. H.'s" case that should be noted; it is more than likely that through the previous drought and the presence of the insects the fruit had not arrived at a state of maturity. The skin would in such a case be thinner and the flesh more watery. I have noted more than once that Black Alicante conforms to this description when not thoroughly ripened. When well managed in other respects I have never found it necessary to cover borders so as to ward off the autumn rains, and I very much doubt if it ever need be done at all. I hope other observant readers will give their opinions on this subject for one common good.—VITIS.

A PLEA FOR SECOND-RATE PEARS.

LOUISE BONNE OF JERSEY, Marie Louise, Doyenné du Comice, and the delicious Thompson's possess every good quality that is to be expected in a Pear, but then even in ordinary seasons, and more particularly in the present exceptional one, all or nearly all of these will be clean gone long before the month of November is over. I admit there are other good sorts which ripen at a later date, but most of them are somewhat capricious in growth, and will not grow everywhere. Of these, Winter Nelis and Glou Morceau are amongst the best, but both require a light sandy soil, resting on a perfect drainage. The latter grows and fruits best in gardens close to the sea, the finest examples I have ever seen having been at Gunton Park and Blickling Hall, Norfolk. It does constantly and well in our own garden, but in a

garden some four miles from here, and planted in a holding loam, it fails, and is doomed to be headed back and grafted with other varieties. It is a mistake to allow all the best walls in any fruit garden to be entirely occupied by such varieties, however good they may be, that will only tide over a portion of the winter to the utter exclusion of later sorts, which after all have to come to the rescue, and help us out in time of need. My experience proves that circumstances alter cases as much in fruit culture as in any one thing, and that as soil, situation, and general surroundings influence in a great degree both the growth and flavour of Strawberries and Grapes, so do they in an equal degree both the growth and flavour of Pears. I know that Beurré Clairgeau, Vicar of Winkfield, and the old Beurré Rance here had hard things said against them from time to time, but I for one cannot afford to lightly regard them, inasmuch as, favoured with a southern or western aspect, planted on a somewhat elevated position in a warm and genial soil, and further judiciously nourished by manurial waterings, they have produced fruit which has often stood us in good stead by bridging over a period of scarcity.

Many would, I am sure, be astonished were they to give these second-rate sorts the treatment above referred to, so great is the change wrought in them. Moreover, fruit is often found on these when after an untoward spring it is looked for in vain on the higher class, but more delicately constituted varieties. So much then for second-rate Pears from a dessert point of view.

Speaking now of their value for stewing, I would ask what is more delicious and refreshing than a dish of these prepared by an experienced and competent cook? Why, then, should they be planted, as more often than not they are, behind north walls, or in some other unfavourable situation, where the sun's rays and southern breezes, which are alone capable of laying on luscious pulp and of developing the flavour, never reach them? I apprehend that after such a superabundance of sun as we have had during the past summer, our stewing Pears will be richer and better than ever—at least, where they occupy respectable positions—and that hoping for a continuance of it in the seasons that lie before us, those who are rather partial to them will throw more and more enthusiasm into their culture. Finally, I would say, plant Pears of the richest flavour by all means, even though their fruits be of short duration, but do not ignore those which, if only second-rate, often fill a blank.

JOHN CRAWFORD.

Coddington Hall, Newark.

Late crop of Raspberries.—In addition to the ordinary autumn-fruiting Raspberries doing better than usual this season, all the other varieties are also producing ripe fruit freely. We have gathered several quarts of large full flavoured fruit, and there are many more to ripen. They are produced by the young canes in some instances at the points, but principally about three-parts up the stems. Not being very thickly produced by the individual canes, I do not anticipate any ill effects from this abnormal state of affairs, though the precaution will be taken of laying in rather more for next season's fruiting in case they break irregularly. Unfortunately, our Red Currants are not keeping well, or otherwise the popular mixture of these and Raspberries would have been more often sent to the table this autumn.—W. I., Somerset.

Apple King of the Pippins.—Years ago, before so many new varieties came into general cultivation, I used to say if I had to choose one Apple to the exclusion of all others for propagation, it should be King of the Pippins (or Prince's Pippin). Although I may not hold to that opinion now, it has still so many recommendations, that a place should be found for this variety in every garden, plantation and orchard. When well grown, of good size and colour, growers for market will find a demand for any quantity they may produce. I have had returns up to 32s. per cwt. for prime samples. As is the case with fruit in general this season, the quality of this Apple is much better

than usual. Unfortunately, it is an off-year with me, the crop having been unusually heavy the last season. The tree is a strong, upright grower and does equally well as a standard, pyramid or espalier. When the wood is liable to canker, which on some soils it is, as little pruning as possible is to be recommended; but where pruning is really necessary, the shoots should be cut clean away in preference to shortening them, as the latter is apt to induce a lot of young sappy growth, which is frequently killed by the frost, giving the tree a very cankered appearance. Seek-no-Further is somewhat similar to King of the Pippins, but inferior as regards flavour and keeping properties.—E. W. B.

MONSTROUS PEARS.

VISITORS to the last of the exhibitions of hardy fruit at Earl's Court must have been interested in the great size of very many Pears there shown. But so little do the leading salesmen in Covent Garden Market care about having them, that they could not be induced to fetch one of the best exhibits at Earl's Court. A few extra fine Pears are seen in shop windows, and also as centre dishes at banquets, but no fruit should be put on a table that is not fit to eat. Even if large Pears were in demand, the Jersey growers have such an advantage in the important matter of climate, that those who are situated on this side of the English Channel cannot hope to eclipse or even equal, as far as great size is concerned, what is sent across in large quantities. Quite recently a Jersey fruit grower said that English growers knew next to nothing about Pears, and boasted of having fruit of Doyenné du Comice 3 lbs. in weight. Some of the more delicious Pears we own are very small ones, and we think many persons who have to eat them prefer them of convenient size rather than as big as a small ham. Doyenné du Comice, Pitmaston Duchess, Duchesse d'Angoulême, Glou Morceau, Easter Beurré, Beurré Diel, and Chaumontel are all very extensively grown in Jersey for the London and provincial markets, and, thanks to careful packing, arrive in excellent condition. The question is, however, who eats them? They are distributed and do duty at various luncheons and dinners, and on side tables at restaurants, but they are of such dimensions that very few people venture to eat them—more probably being spoilt by being kept about too long than there are eaten.

In the more favoured parts of England it is possible to grow remarkably fine Pears, and, as a rule, of superior quality to Jersey fruit; but it is to be hoped that the more serviceable varieties and ordinarily good cultivation will not generally be superseded in favour of large and often ill-flavoured fruit. What are most wanted are small or medium-sized and well-flavoured fruit. Such a variety as Marie Louise is worth a dozen of these large, over-grown fruit. Wall trees, pyramids, bushes and standards under ordinarily good cultivation rarely fail to produce fruit of the best quality freely. In Louise Bonne of Jersey we have another very handsome and sure-cropping variety, and, though the flavour is not always approved of, there are plenty who do like it. Both Beurré Brown and Beurré Hardy are suitable for all methods of culture, and these good sorts ought to be included in most collections. Comte de Lamy, not being a large variety, is too often overlooked, yet it is one of the most delicious Pears in cultivation, being perhaps a trifle too sweet. British Queen, which also ripens in September and October, is somewhat neglected, owing to being rather small, yet it is remarkably sweet, especially from trees against a sunny

wall. Large varieties are also crowding out the good old Fondante d'Automne; but this ought not to go on. Emilie d'Heyst, to which equally all the foregoing remarks apply with equal force, ripens later. Thompson's, another October Pear, does not succeed well other than against walls; but it repays for being thus grown, as it is one of the very best-flavoured varieties. Passe Colmar is still to be found in gardens where good quality is preferred to great size, and those who have large old trees of it will this season have good reason to be thankful. It should have wall protection, and is early productive on the Pear as well as on the Quince stock.

There are a few still smaller varieties that ought not to be ousted out of cultivation, foremost among these being Winter Nelis. Given the benefit of a wall with any fairly warm aspect, the trees of this excellent small Pear never fail to bear very freely. This season the fruits are particularly good, and will be of first-rate quality in November. If Jersey growers would turn their attention to the cultivation of the last-named and also Josephine de Malines, sending both over in large quantities in November and December, they would find a ready sale for them. Josephine de Malines is essentially a wall Pear, the habit of growth not lending itself to open gardens. Both the old Bergamote Espere and Olivier de Serres are much neglected in favour of the large-fruited varieties, but they are good Pears. In all probability they will be amongst the very latest to ripen this season, and, if they are small, will be welcome next March and April. Instead, therefore, of raisers of novelties and planters generally turning their attention to none but large Pears, they will do better service by looking up the smaller sorts. The proper and only course is to grow well-flavoured Pears that ripen in England, and not Pears like Duchesse d'Angoulême, which rarely ripen in England, however good they may be in other countries. People say that they grow these Pears for stewing—as if it were worth while for anyone to grow more than one Pear for this purpose.—*Field*.

LIFTING FRUIT TREES.

THE lifting of fruit trees is often overlooked, and many good fruit growers object to this. I question very much if the term lifting is not often misapplied, and root-pruning practised instead. I think there is no surer or safer system than lifting or relaying nearer the surface the roots of gross-growing trees. I am fully alive to the serious difficulties of root-pruning in the case of old trees with only a few large roots deficient of fibre. The safest method is not to allow too long a time to elapse in the case of young trees before lifting is undertaken; then I contend the work is beneficial. We see this work going on continually in our large fruit tree nurseries. It is quite impossible to have a mass of fibrous roots unless lifting is done when required. It is clear to everyone that the greatest success is obtained where lifting is systematically carried out, as such trees being a mass of fibrous roots rarely fail when planted often in adverse soils and with only scant attention. With large trees root-pruning needs special care, and I have secured the best results by doing the work piecemeal. When the Pear is grafted on the free stock, a coarse, gross growth results. This is often aggravated by hard pruning, and when severely root-pruned there is a total collapse. With large trees much may be gained by doing the work by degrees, and I am a great advocate for lifting as early in October as circumstances will allow. Of course the season, state of soil, and other details must be taken into consideration, and just now everything is favourably for lifting trees. We have had some very heavy

rains that have made the soil suitable for the work. Two years ago I root-pruned a large Beurré Diel Pear tree half round and completed the other half last year. This year it has done grandly, giving a heavy crop of very fine fruit, clear-skinned and of perfect shape. To have lifted or root-pruned so old a tree all at once would doubtless have ended disastrously. Trees often get too low down, but it is an easy matter to bring the roots nearer the surface, and they remain there if given good food in the way of fresh loam. One of the great advantages of lifting young trees is that the roots can be brought nearer the surface. Apples on the Paradise stock should get similar treatment, doing the work before severe weather sets in. I prefer to lift Cherries, Apricots and Peaches in October, as there is then little fear of loss of vigour. After lifting, mulching is important, but in no case should manure be incorporated with the soil for young trees, as it is far safer to apply it to the surface. G. WYTHES.

PEACHES IN THE OPEN AIR.

"D. T. F." on p. 354 rather surprises me when he says that an east wall for Peaches has been looked on as a certain road to failure. I certainly cannot boast the same length of experience as "D. T. F." in Peach growing, but that which I have gained in several good gardens convinces me that an east wall is better than a west one for Peaches, Nectarines, or Apricots. In these gardens there is a Peach case 180 feet in length on an east wall, the trees in which, although it is unheated, bear heavy crops annually; the only difficulty experienced is when the trees are in bloom. In a cold house there is the risk of the flowers being injured by frost, which in some springs is very severe about the time the Peaches are in bloom. If the genial west is so much more preferable, why was it this house was built over thirty years since on the eastern side of the garden when the same extent was available on the opposite side? On the lofty west wall the sun shines but a short time in early spring when the trees are in bloom, and without this aid they often set indifferently. In my last situation a Peach house facing west gave a deal of anxiety at the time the flowers were setting, and, indeed, before that time, for all the trees had a great tendency to cast their buds on the first movement of sap. If this occurs under glass where the trees are assisted by fire heat, is it not feasible enough that the same failing will happen outdoors? In my first charge I had trees on south, east, and west walls, and, therefore, ample proof for comparison was furnished, and, as I intimated in my previous article, there was less blister on the trees facing east than on others with a southern exposure. I could point to one instance where south and east walls are completely furnished with Apricots from thirty to fifty years old, which seldom fail to bear well; and another instance I know of where Apricots furnish but indifferent crops on a west aspect, so much so in fact, that the space is fast being filled with Pears. I may be reminded that Apricots are not Peaches, but "D. T. F." will, of course, admit that the same favoured positions are needful for the one as the other.

I can give yet another instance of the greater length of sunshine, or at least the favourable influence of sunshine, obtained from east over that of west walls in the earlier ripening of Plums. We have trees of several sorts growing on both sides in duplicate, including Kirke's, Jefferson, Washington, Green Gage and Pond's Seedling, which not only were earlier in maturing, but were of better colour and larger sized than those gathered from the west side. All these facts seemed to point out that the east wall was more favourable than the west one for open-air Peaches, and I certainly did not expect that the experience of other growers would differ from mine in that respect. South walls are not always available for growing outdoor Peaches, because usually a large portion of these is utilised for the erection of fruit and plant houses, and this creates the necessity of using the warmest portions of the east and west walls

for these tender crops. As regards extremes of pruning, I am no advocate for either, nor do I practise it, but I am in favour of the dis-budding being carried out in such a manner that the growth remaining has sufficient space to develop without any crowding, and if the bearing wood is cut away as soon as the crop is gathered, it must effect a good as well as a two-fold purpose in relieving the tree of the unnecessary strain in maintaining useless branches, and exposes that which is to furnish the next year's crop to sunshine in order to bring about a proper maturity in leaf and branch. In doing this no extremes need be permitted, because if disbudding is well done in spring and summer, there will be no pruning away of waste growth other than that which has done duty in fruit bearing. Individual judgment alone must govern the details in pruning and training, there being no general regulation standard as to what should constitute a proper distance for training the growths asunder, opinions differing in this matter, although I think the crops under notice would be greater if crowding of the trees was less frequent.

W. STRUGNELL.

Road Ashton Gardens.

NOTES OF THE WEEK.

Single Dahlia Mrs. Bowman.—This is one of the finest single kinds for effect. A large bed at Kew has been bright with the large rose-purple, smooth, well-shaped flowers until recently. Many of the single Dahlias are of this shade of colour, at least similar, but not so bright and pure as in this variety.

An October gathering of Raspberries.—I have to-day (October 31) picked 7 lbs. of good fruit. Previous to this I have been picking daily for dessert, and should the present fine weather continue I shall be able to gather for a considerable time yet, as there still remains a good crop.—H., *Witney, Oxon.*

Schizostylis coccinea.—It is not often one sees this fine plant grown better than at Syon. When there a few days ago we noticed several specimens in $4\frac{1}{2}$ -inch pots in full bloom, and the Gladiolus-like spikes of carmine-rose flowers are very bright. In favoured spots in the more southern counties of England it may be grown in the open.

Trichosma suavis.—This is a delightful Orchid, easily grown and very robust. A plant in quite a cool house at Syon carries ten sturdy spikes, and only in a $4\frac{1}{2}$ -inch pot. The flowers, borne closely together and deliciously fragrant, are ivory white in colour, the lip yellow on the side lobes. It requires little heat, and is a good Orchid for amateurs.

Cereus hexagonus is not a plant for ordinary gardens, but it is interesting to know that the immense specimen towering up many feet in height in the conservatory at Syon House is blooming freely. The long gaunt stems bear very large flowers of a creamy white colour, and individually are extremely handsome. This *Cereus* was introduced from Surinam in 1690, and the specimen at Syon is probably the finest in the country.

Pernettya mucronata.—In Mr. Kingsmill's garden at Harrow Weald there is a large bed of *Pernettyas*, and the plants are covered with berries, the pink variety in particular. We have noticed how freely the *Pernettya* is fruiting in other places this year. There is a long list of varieties, the berries ranging in colour from white to deep purple. The soil must be peaty or of a loamy character, and if too heavy be made light by the addition of well-decayed leaf-mould.

Tropæolum Fireball.—As a greenhouse climber in the winter season nothing could be brighter than this *Tropæolum*. It is commencing to bloom freely with Mr. Wythes at Syon, and

before spring the growth will have entirely covered the rafters, being smothered with the deep scarlet flowers. The way to treat it is to put in cuttings in March, stand the plants out during the summer, and transfer to the greenhouse in September. The brilliant flowers are of much value for decoration, and the only drawback near London is the injury fog inflicts upon them.

Asparagus plumosus nanus.—It is not often that this is seen seedling freely. At Messrs. Miles' nursery, Hassock's Gate, I saw two plants seedling freely. I was under the impression that it was only in a dry atmosphere that the plants would seed, but those in question were growing in a moist stove. I have seen plants bloom freely under the same conditions, but all the flowers have fallen off. I also find it is difficult to get *Asparagus decumbens* to set, although the plants bloom freely enough.—F. H.

Amasonia punicea is very handsome at this season of the year. We noted a number of plants in full beauty a few days ago in Messrs. Veitch's Chelsea nursery. It is a pity this fine plant is not more grown in private gardens, as it remains in perfection a considerable time, the bracts, arranged in pairs, being of a brilliant crimson colour, and the tubular flowers pale primrose. A warm temperature is necessary, as it comes from British Guiana, from whence it was first introduced in 1825. It was lost to cultivation, but was re-introduced.

Choisya ternata.—We noticed this blooming freely recently at Kew, where a large bed near the pond is planted with it. It is not, however, a shrub that can be recommended for general planting, and, except in the extreme southern counties of England, it should be grown against a wall. It grows quickly, and the fragrant pure white flowers are in exquisite contrast to the wealth of foliage. It often succeeds in northern counties where the position is very favourable, but as a rule it should have the shelter of a wall. The position must be sunny to well ripen up the growth, and either in a bold mass or singly the *Choisya* is effective.

Cypripedium inaigne is one of the most interesting Orchids in bloom now. It is an old and familiar kind, but not too much so for a note when a mass of it is seen in bloom. This is the case at Syon House, where Mr. Wythes has a large number of plants in full beauty. We may remark that they receive no fire-heat whatever, except a little in the winter to dispel damp, and that this treatment is suitable is evident from their appearance. Of course they are not exposed to actual frost, although bordering upon it. In the summer months they are grown in a cold frame. The *Cypripedium* is one of the only Orchids practically unhurt by fogs. Amateurs should treat *C. inaigne* more as a hardy plant, and not coddle it in warm houses.

Vine with crimson leafage.—In THE GARDEN of October 14 (p. 353) I observe a notice of a Vine growing at Chiswick under the name of Trahurier with crimson leafage. I think this must be a Vine which I sent to the Royal Horticultural Society some years ago, and which is remarkable for the beauty of the autumn foliage. The true name is Tinturier. The Grapes produced by this Vine contain a juice so deeply coloured, that it is easy to write with it by simply dipping a steel pen into the Grape. This Vine is well worth growing in the open air in the south of England for the sake of the beautiful foliage, but it should be worked on to a strong stock such as Muscat of Alexandria or, better still, on to a wild American stock such as Othello, Riparia, or Noah, which are strong growers and resist several degrees of frost.—A. W. TAIT, *Oporto.*

Saxifraga Fortunei.—A few days ago several plants of this were in full beauty on the Kew rockery. It is the latest species to bloom and is really a delightful plant, the white flowers being produced in long panicles, which spring from the rosette of foliage. Usually it gets cut down by frosts, but less than a ago week it was in perfection in the open. Such a Saxifrage is worth

growing well in pots, and a few examples in the greenhouse in November or December would create variety. There is too much sameness in the plants used as a rule in greenhouses. An interesting note appeared on this Saxifrage in THE GARDEN, November 26, 1892 (p. 471). It there was said that S. Fortunei enjoys division every two years. The reason why so many plants suddenly collapse is often because "the big white grub of the coal-black weevil eats its way up and scoops out the vital part of the crown." S. Bursariana is often troubled in the same way. The remedy advised is to repot or transplant a portion of the stock annually, preferably about the month of August. After the roots have been thoroughly shaken out they are not only cleared of the pest, but have time to get established again before the winter.

Angræcum pellucidum.—This very interesting and uncommon Orchid is flowering now in the Kew collection. It is, perhaps, the smallest-flowered of the *Angræcums* worth cultivating, the flowers individually being about a quarter of an inch in diameter. They are, however, produced in great numbers on scapes 6 in. to 8 in. long, several scores occurring on one spike. The flowers are of a pure sparkling white, and are interesting because of the peculiar pouch-like form of the tiny spur which is filled to over-flowing with sweet nectar. The general appearance is quite pretty and distinct from that of any other cultivated Orchid, and the species is well worth growing, especially by those who like to possess out-of-the-way plants. It is also handsome in habit, having its erect stem clothed with strap-shaped leaves 7 inches long, unequally notched at the apex and deep green. It is a native of the west coast of Africa, and was first introduced from Sierra Leone in 1842.

Winter-blooming Carnations.—I herewith send you a few blooms of various Carnations. The plants are now safely housed, and promise to afford an almost unlimited supply during the coming winter. No. 1 is *Alegatiere*, an old and tried variety, and not easily beaten as a scarlet. It is somewhat shy of making grass, perhaps, but its free-flowering habit partly atones for this. No. 2 is the newer *Winter Cheer*. I am somewhat disappointed with this variety this season, as many plants are producing striped flowers instead of pure scarlet, thus showing it to be inconstant. No. 3 is *Mme. Carle*, which was for many years the best white in cultivation, so far as my knowledge goes. It is, however, a poor grower. No. 4 is the new white *La Reine*, which promises to eclipse its predecessors in every respect; in fact, I am so pleased with it, that I intend growing no other white in future. One great recommendation is its fragrant clove perfume. The flowers sent of it are, however, small, having been cut from lateral shoots. No. 5 is the old *Miss Joliffe*, still indispensable.—JOHN CRAWFORD, *Coddington Hall, Newark-on-Trent.*

* * * Very bright and fragrant.—ED.

Market flowers.—For many years London has not been so abundantly supplied with flowers in late autumn as is the case this season. The flower hawkers' barrows are loaded with Dahlias in prime condition. What a fine time by the way growers of this flower for profit have had this autumn, and Michaelmas Daisies, Cornflowers, Corn Marigolds, Violets, perennial Sunflowers, and other things are brought into Covent Garden in quantity. Some things, such as Camellias, Paper-white Narcissi, Freesias and Bouvardias are weeks in advance of their usual season, and hardy flowers being so abundant, they are but little needed. As they cannot in this warm autumn be retarded, they have to be sold for what they will make, which is very little. Chrysanthemums are abundant and cheap, and unless there is soon a change in the weather there will be a difficulty in keeping the late kinds till after Christmas. Zonal Pelargoniums are as fine and plentiful as two months ago, and can hardly be got rid of even at exceptionally low rates. The outdoor hardy Chrysanthemums are naturally unusually good in quality, the fine weather giving them size and colour.

FLOWER GARDEN.

THE PRICKLY RHUBARBS.

(GUNNERA MANICATA AND G. SCABRA.)

It seems to be fairly settled at last that the largest simple-leaved plant in our gardens to-day is *Gunnera manicata*, which has wrested the palm from the Victorian Water Lily. A few days ago I saw the gigantic *Gunnera*—a tuft about 30 feet in diameter—in the rock garden at Narrow Water, Co. Down, the largest leaf out of the twenty-five or more which it bears having a blade 9 feet 6 inches across, and standing fully 10 feet in height. When well grown, no hardy foliage plant can compare in size of plant or in leaf dimensions with this stately inhabitant of deep valleys and gullies full of rich alluvial earth and decayed leaves in Southern Brazil. *G. scabra*, a nearly allied species, seems to have a still more southern distribution, being found in Chili and on the outlying islands, including Juan Fernandez, or Robinson Crusoe's Island, while travellers tell us that it extends still further south on the mainland into the colder regions of Patagonia. One of the earliest allusions to these giant *Gunneras* is that of Charles Darwin in his now celebrated first book, viz., "The Voyage of the *Beagle*," unless we take the language of the shipwrecked Crusoe where he mentions "the luxuriant leafage of plants tropical" around his lonely hut, as applying to these as then almost unknown herbaceous giants of the vegetable world.

As a genus, *Gunnera* consists of some ten or twelve species distributed over the South American, Malayan, and Australasian regions. They exist in the more sheltered valleys of the Andes, as far north as the Gulf of Mexico, and some are found as far south as New Zealand, but the finest kinds, so far as at present known, for garden uses are *G. manicata* and *G. scabra*. Of the latter I grow two distinct forms, the one having spreading leaves with green venation, while the other variety has longer foot-stalks or petioles, with more erect or cupped leaf-blades and bright red veins.

The name of the genus was given by Linneus (in his "Genera Plantarum") in honour of John Ernest Gunner, a Swedish or Norwegian bishop fond of plants, who wrote a flora of his native land some time about 1766-1772. In general appearance these plants remind a careless observer of ordinary Rhubarb much magnified, but the stout prickly petioles, often 6 feet or even more in height, and the scarious and spiky, club-like inflorescence and leaves at once distinguish these plants from all others.

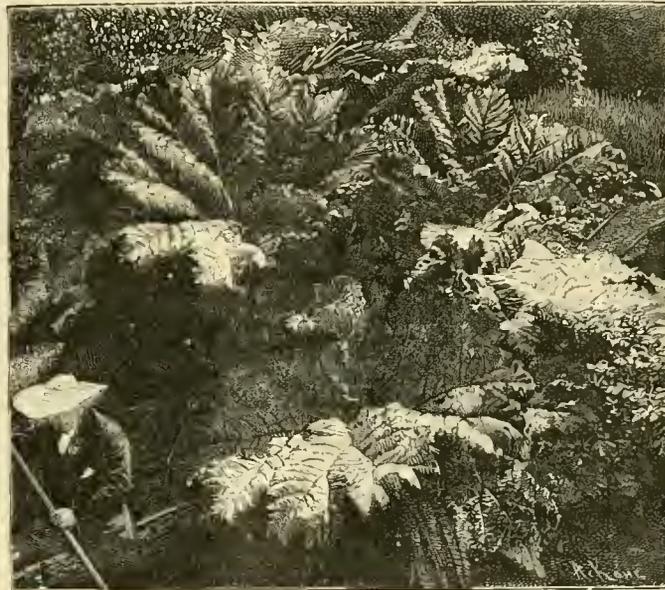

To see these plants at their best they should be grown quite near to the margin of a pond or stream, or in a swampy spot, and in the deepest and richest of soil. Even then their most ample dimensions are only reached after a copious addition of cow manure top-dressings, or by deluging the ground around the leaves with liquid manure.

The illustration represents a portion of a plant beside the pond in the College Gardens at Dublin, and some idea of its size is indicated by the figure in the boat below. The leaves are about 7 feet in diameter, but the plant is a small one as compared with the gigantic specimen at Narrow Water Park above described. It is, nevertheless, a most effective and picturesque object as seen here, contrasted with light and feathery Bamboos, the cardinal and golden Osiers, and other water-side vegetation. A good deal has been said of these line-

leaved plants in THE GARDEN from time to time, but they are so strikingly handsome as well grown, that too much cannot well be said of their management. F. W. B.

Tropæolum tuberosum.—This handsome Peruvian species is not often met with in cottage gardens, and it was recently an agreeable surprise to me to see it growing up and around a cottage porch which was veiled in beauty of leaf and blossom by this plant alone. It is not quite hardy, and therefore generally neglected. As its roots may be lifted and easily preserved through the winter, and it requires but average soil to grow in, a little spot might be found for it in most gardens. Flowering in late summer and autumn, it is valuable when the beauty of most things has vanished.—H. II.

The blue Rock Bindweed.—We have previously called attention to the graceful growth and exceeding beauty of the blue Rock Bindweed, but it merits another note, for no plant in the garden has given such a long and beautiful display of bloom. Even now late in October its effect on fine days is splendid. Apparently it will not

Portion of a plant of *Gunnera manicata* in the College Gardens at Dublin.

cease to bloom till it dies down for the winter, and as it commences in early summer when its shoots are but a few inches long, its blooming season lasts for several months. All who have a sunny, fairly dry border under the wall of the house should try and grow this plant, for its greatest vigour and longest profusion of bloom follow upon its being thoroughly and permanently established. Where it will not stand the winter very good results are obtained by treating it as a summer plant.

Oxalis rosea.—This is one of the few annual species of this large family, and is a very pretty little plant to have near the edge of a border or in a nook on the rockwork. It grows about 6 inches high and branches into a compact tufted plant of a very light green colour. It blooms long and freely, the flowers in little racemes being of a deep rose colour. There is also a white variety which comes true from seed.

The Belladonna Lily.—Several notes have appeared recently in THE GARDEN about the Belladonna Lily, which seems to have been very fine everywhere this year. The present summer suited this warmth-loving bulb, and a few days since a bold clump was in full beauty in a warm border in Mr. Kingsmill's garden at Harrow Weald. We do not advise too free planting of such capri-

cious things, but they might be tried in many places, as in warm, sheltered spots where the soil is light they grow to perfection. It is useless to put them in cold, clayey ground or exposed positions.

LILIES.

LILIES are perhaps, on the whole, the greatest of all our garden favourites, or if not quite that, they share their position in our esteem with Roses. Dr. Wallace gives Lilies the first place, I believe, and I am inclined to agree with him. Lilies are more or less troublesome plants to cultivate, and they require some attention to their respective demands regarding the soil in which they are grown and the situation in which they are placed. Nevertheless, I feel inclined to protest against such a very depressing article on Lilies as that which appears on p. 91 of the July number of THE GARDEN, written by "J. C. L." "In the death-rate," he says, "I am always up to date," so we need not be surprised to hear of the "trouble and disappointment" which are supposed to be the fate of all who try to cultivate Lilies in any quantity or variety. *L. chalcedonicum* is very highly

spoken of, and it deserves such praise. "No better Lily than this when well grown," and "J. C. L." acknowledges that, although he fails, he sees this Lily doing finely in one or two cottage gardens in his neighbourhood. Surely, then, he makes a mistake in attributing the failure of his own plants to soil. I have been most successful with this beautiful Lily without taking any special care of it, and I very much hope that no one will be deterred from trying to grow this scarlet Turk's-cap on account of what is said about it in the article referred to above.

Following Ruskin's advice, I placed in a somewhat shady spot on the lawn a very large stone. The stone itself is half covered with green Moss, and some Saxifrage grows luxuriantly under the highest part of it. Amongst this Saxifrage some plants of *L. chalcedonicum* grow

and flourish, coming up in increasing numbers every year and looking extremely well when they flower amid the green of the Saxifrage and by the side of the grey tints of the stone. My own experience with this exceedingly fine Lily would lead me to suggest its cultivation to a much larger extent than we now see it. In one old-fashioned garden in this place it grows like a weed, and notwithstanding all my protestations it is treated as such. There are just two things necessary for success in growing this Lily, and they are first, shade, or partial shade, and secondly, a good rich loamy soil.

Under these conditions I have had no trouble with *chalcedonicum*, though moved at the very worst time apparently, viz., in the flowering season. Plants so moved have flowered well with me the following year and increased and multiplied afterwards. Of *L. pardalinum* we hear enough to deter any ordinary person from attempting to grow such an ill-natured thing. "They gave up flowering," and yet for some unexplained reason a lot given away to a lady friend "had been highly successful." What is this but to acknowledge some failure in the cultivation? All the Turk's-cap Lilies are great favourites with me, and this one specially bears looking into, with its gracefully recurved petals so beautifully spotted with dark spots on a

yellow ground. Given deep rich soil, plenty of water and semi-shade, pardalium will improve after a period of rest subsequent to transplantation.

One of the glories of our summer days is *L. tigrinum* when well grown either in pots or in the open. In pots a group of this Lily is a fine ornament either for the conservatory or the drawing-room; but I prefer seeing them out of doors, where they will best show off their large heads of finely spotted flowers. As the very finest bulbs of this Lily can be had for 1½d. each, they are certainly within the reach of all. I send herewith a photograph of a group of this Lily growing in my garden last summer. They cover the ground with their black bulbils before they die down in the autumn.

I have only had *L. Martagon dalmaticum* one year. It was sent to me from Scotland in the autumn of 1892, and this year it sent up a fine tall spike of its very dark purple Turk's-cap flowers. There are few things in our gardens so nearly black as this Lily. One of the herbaceous *Geraniums* comes, perhaps, nearest to it in colour. This *Martagon* is a remarkable and striking plant, as well as a beautiful one, and I hope I shall succeed in increasing it. The common *Martagon* grows like a weed with me, but I should be sorry to treat it as such. That at least will give no trouble when once established in any shrubbery or shady garden. "J. C. L." does not notice the tallest and most stately of all our Lilies—*giganteum*. Why not? It cannot be because it is unworthy of a place among its congeners, but because it too has been perhaps laid aside as a difficulty. It seems to be a shy bloomer; at any rate, you cannot depend upon having flowers every year unless you have a strong group of this Lily, but it will grow away well enough in a warm corner and with plenty of good food. I expect flowers next year, but if so, I shall probably have none the following. Still, this Lily is such a grand thing that it is worth while growing it, even if it does try your patience a little in waiting for its fine spike of bloom.

To pass on from Lilies to Fritillaries, I have not found that Crown Imperials will grow anywhere at all. On the contrary, mine have dwindled until I have found it necessary this year to replenish them with a fresh importation. I am very fond of them, they come so early in the year, and stand up so well to exhibit the fine crown of bell flowers on the summit of their strong stalks. The smell of the roots is remarkable, rather "foxy" in its nature, and it is not easy to get rid of it after handling the bulbs.

Crown Imperials are very soon out of the way when done flowering, so that in later summer other things may be grown close to where they stood. This is a great advantage shared by these with other liliaceous plants, so that they do not take so much room in small gardens as they otherwise would. The common Snake's-head (*Fritillaria Meleagris*) looks very pretty in spring when dotted about in Grass or about the roots of trees. It likes damp retentive soil, but I do not think it is very particular. It grows wild at Pinner in the stiff London clay, and it does well with me here in our less retentive soil. Other Fritillaries, unless it may be aurea, are not so pretty as the common *Meleagris*. A GLOUCESTERSHIRE PARSON.

Hardy flowers in kitchen gardens.—In the kitchen garden at The Priory, Hornsey, flowers are largely grown, and late in October the annual *Coreopsis*, *Salpiglossis*, *Marigolds*, perennial *Sundewers*, *Dahlias*, and *Stocks* were still in bloom. The *Coreopsis* were delightful, giving a wealth of bloom and of varied colour, yellow to deep purple-maroon. These plants may be cut from without spoiling those in the more conspicuous parts of the garden.

The origin of Carnation Gloire de Nancy.—At page 367 of THE GARDEN G. H. Engleheart appears to have doubts as to the origin of this fine Carnation, so perhaps you will kindly allow me to say that in the autumn of the year 1891 I planted a small bed of the old crimson Clove Carnation.

During the following summer of 1892 the plants bloomed very profusely, and during the late summer they also bloomed, if anything, still more abundantly. But, to my surprise, several of the plants produced pure white instead of dark crimson flowers, and the blooms on careful comparison were found to be in all respects identical with those of *Gloire de Nancy* which grew in another part of the garden, so that I think there can be little doubt as to the origin of this beautiful Carnation. The plants in question continued to produce flowers in abundance of both the white and the crimson varieties until about the middle of last month, when the white-flowering varieties were taken up and given to a friend who has facilities for striking such plants from cuttings, and which has no doubt been by this time effected, and should either you or your correspondent wish for a plant, I have no doubt I can procure the same, and will have pleasure in forwarding it. It is remarkable that the plants produced no sport during the first season, but did so in abundance during the second. Still I think there can be but little doubt of *Gloire de Nancy* having originated as a sport from crimson Clove; and while each variety may be considered as unrivalled in its respective class as a pure white and a dark crimson Carnation, the only improvement that can be desired for each is a stronger calyx, as this in each variety is very apt to split.—P. G., *Bury St. Edmunds*.

Aster tataricus.—One of the finest things in flower in the garden at the present time is a group of this Starwort. It is late, being just now at its best, and therefore valuable for succession, in addition to which it is so very distinct, that in this large family there is nothing at all like it. In growth and before the flower-stalks begin to shoot up it might be regarded as anything but an Aster. It has a rambling disposition, spreading underground and shooting up, making a large wide mass of leafage. The leaves for an Aster are very long and broad, ranging from 1½ feet to 2 feet in length and from 2 inches to 5 inches in width. The flower-spikes stand up quite erect from a carpet of rich leafage, the tallest and best of them being 6 feet high and terminated by a branched head of flowers, large, handsome and of a rich deep purplish blue. The buds have a decided reddish tint. The flower-stalks are so thick and strong, that they need not the slightest support, and they stand apart from one another just sufficient to give the plant a bold and stately character, yet sufficiently close to produce a fine rich effect.—A. H.

AUBRIETIAS.

I AM frequently surprised to find how little *Aubrietias* are grown in private gardens. Were we limited to the old forms of *purpurea* and *Campbelli*, such total lack of interest in these very beautiful hardy creeping plants might be understood. There seems to be some sort of impression that *Aubrietias* transplant badly. That may be so in the case of small plants, but if cuttings be inserted thickly under a handlight in the spring, or, simpler still, seed be sown, it is very easy to have a good stock of plants in the autumn to lift and plant out where needed to give a good mass of colour in the spring. Certainly *Aubrietias* do best when planted where they may grow as they like, especially on the margins of stone or rubble work, as they are particularly fond of the cool clean base which such material affords. One of the best examples of what *Aubrietias* could do in this way used to be seen at Ealing Park, where they grew down over rough rockwork to a depth of 2 feet or 3 feet, and produced in the spring a charming effect, whilst all the summer and winter a bright green covering was produced.

But many gardeners appraise hardy plants of this description for the facility with which they may be transplanted and the effect they produce in masses in the spring. The *Aubrietias* are naturally long and thin, going down deep, and doubtless are most at home when they can penetrate into fissures such as are found in rockwork, natural or artificial. For that reason perhaps they do not

constitute ideal stuff for transplanting, but young plants from cuttings or seed have not developed such long roots, and will transplant very well. The bunchy or tufted nature of the plants also fits them well for transplanting, and if when this work is performed the roots be shortened back somewhat, they the better produce clusters of fibrous roots close home, which so much accord with the short, dense growth of the plants. Whilst *Aubrietias* are so hardy, that in my experience they seldom die from frost, yet the growths often are killed back by severe frost; but no sooner is the frost gone than they break up again with wonderful reproductiveness, and are only a week or two later in blooming than would have been the older growth had it remained uninjured. The older sorts, such as those named previously, seeded but very little. Some of the stronger-growing, larger-flowered and altogether more effective varieties seed freely. That is particularly the case with the variety named *violacea*, of which I have had tufts 20 inches across, literally masses of violet-purple flowers early in the spring and then as full of seed-pods later. Seed almost invariably reproduced the parent variety, certainly always in size of flower and robustness of growth, but varying slightly in shade. That, by dint of following up the richest colours and selecting the reddest tints, it would be possible in time to obtain a good distinct red, I believe. Such varieties as *Hendersoni* and *Leichtlini* have been termed red, but they do not very materially differ from *violacea* in colour, especially in the reddish tints seedlings will produce. In all cases, however, the flowers have more of violet or purple in them than red; hence, there is a good deal to do ere true reds result. All the same, the present best forms are most beautiful and create masses of colour that in the spring are exceedingly attractive. As a rule, where it be practicable, it is best to plant high, as the plants are impatient of moisture hanging about them.

A. D.

Transplanting the white Martagon Lily.

—I shall look forward with very great interest to the future of those Lilies that were transplanted on August 5, as detailed in THE GARDEN, p. 325, for I am fully convinced that a good deal of the non-success in Lily culture is owing to the bulbs being moved too late in the season, or if lifted early allowed to become too dry before they are replanted. It is more than probable that these white *Martagons* will continue to improve in their new quarters, and I trust such will be the case.—H. P.

Aster Arcturus.—This is a fine Aster. It blooms rather early as a rule, but is constant; the stems almost black, the leaves deep green, and the flowers rich lilac-rose. A good group of it would be very effective, and even a single plant shows up above others for its very rich colouring of leaf and flower.

Alonsoa Warcewiczii.—This charming little annual should be included in any selection however small, the flowers being very bright and glowing with colour, while they are produced with great freedom. The past summer has suited it admirably, and I never remember to have seen it in quite such good form. Even now, in the middle of October, groups of it are still flowering freely, many of the flower-stems being over 2 feet high and much branched.—J. C. T.

Hardy Fuchsias in autumn.—Anything that keeps fresh in spite of heavy autumn rains and makes the garden gay commends itself to special notice. At the present time the hardy *Fuchsias* are delightful. One sometimes meets with great bushes in old gardens, but they should be freely planted by all who have the slightest opportunity of growing them. They are quite at home, with in a few cases slight protection, from Land's End to John o' Groats. If we cannot have the great tree-like bushes that grow in the west and south, there is still a lot of brightness and beauty to be seen and enjoyed from these *Fuchsias*. They always spring up with renewed vigour, make a

goodly growth during the summer months, and from then till the time of sharp frosts their shoots are covered with bloom. Masses of them are delightful. Colour effect in the garden is their chief value, as they do not last well as cut flowers. The chief kinds are *globosa*, *Riccartoni*, *gracilis*, *myrtifolia* and *coccinea*.

Cassia corymbosa.—This is a really fine plant for the garden in summer and autumn. We recently saw a bed of it which was quite a picture, the foliage luxuriant, of a tender green shade, while the bunches of yellow flowers were borne in profusion. One may go into many gardens without seeing the *Cassia*, a good thing to group on the outskirts of the lawn or to create a fairly bold effect in the flower garden. It may be treated like *Fuchsias*, as it will not live out through the winter. It is grown in greenhouses, and is useful there, but it is as an outdoor plant that one wishes it were more used.

Carnations.—These from layers in the open ground have in my case made better progress this season than usual, in spite of the hot and dry weather. Probably the fact of the ground being so dry was the cause of more frequent waterings being given, the layers profiting thereby to a large extent. All are now planted out in their flowering quarters save the old crimson *Clove*, which has to wait a while longer for convenience sake, but I observe that the layers are making rapid growth, and the plants will be of large size when put out in their place. Seedling Carnations, of which a few are grown every year, have also been put out; these also are good plants, quite large enough for any purpose. In preparing the ground soot and lime were used in fair quantity; both are good manures for the Carnation, and should be more freely used. Neither the wireworms nor the slugs fancy the soot and lime, but as these both lose their effectiveness as preventives after a time, other surface-dressings will have to be given. Some plants of *Winter Cheer* which flowered in pots last winter and were afterwards cut up for cuttings, after a time broke away fresh from the base. These were planted out early in the summer, and in due course grew sufficiently to be layered. A young stock has thus been got which should prove useful for early flowering next year. I see no reason why this system should not be followed both with this kind and *Miss Joliffe* also when large plants to flower early are found to be of the most service.—GILLFLOWER.

NOTES ON VIOLETS.

RED SPIDER is the greatest enemy the cultivator of Violets has to contend with. In some gardens it is always more or less troublesome, this being especially the case where the soil is of a gravelly nature, and therefore not retentive of moisture. This year the great heat and long-continued drought proved particularly trying, and a breadth free of red spider was quite a rarity—no matter how suitable the soil for Violet culture and how much care was taken of the plants. In many cases the crowns are very weak and the foliage is quite yellow, and, as a consequence, the flowers will be both small and sparingly produced. Acres of plants in this bad plight have recently come under my notice, and, judging from inquiries that are being made for Violets by London and other florists, the supply generally is not equal to the demand. This means a considerable loss to the growers, some of whom depend largely upon Violets for their livelihood, and doubtless a certain amount of disappointment to very many buyers, for it is almost needless to add that Violets will usually sell readily when other flowers will not. Where, as in my case, the plants are only partially injured by red spider, that is to say, leaves have not been wholly overrun by them, flowers are being freely produced and are of good size and colour. All the same, the plants will not stand against either a very wet, foggy time or a severe frost nearly so well as when wholly free of red spider, the leaves lacking the substance and vitality to survive any ordeal out of the com-

mon. These remarks apply not merely to the Russian section, but are equally applicable to the less hardy Neapolitan section, including the popular *Marie Louise*. Well sulphuring the leaves of the plants when growing in the open did much in our case towards keeping red spider in check, but it is a very difficult matter to reach the undersides of all the leaves with an ordinary syringe.

The weather since the double-flowering varieties were lifted and replanted in pits and frames has been very favourable to a quick recovery, and it is not often that double Violets are so plentiful in October as they are this season. Owing, however, to the weakening effects of red spider, more than ordinary care will have to be taken of the plants, or otherwise there is every likelihood of wholesale damping off, first of the leaves, and then of the crowns. More than ordinary care does not mean more coddling than usual, but quite the reverse. Violets must not be coddled. Instead of being given the benefit of either a moist or dry bottom heat, accompanied by a somewhat close atmosphere in the pit or frame, the first should be wholly dispensed with, and abundance of air be given whenever severe frosts, very cold frosty winds, or snow-storms are not being experienced. Instead of the lights being merely run down a short distance at the backs or else blocked up a short distance, they ought to be pulled clean off when the weather is at all mild, the next best thing being blocking up from the centre of each light. What is wanted is a good circulation of air, and not a close, stagnant atmosphere. The former serves to keep the foliage strong and the plants free flowering, while the latter ends in either an early collapse or a leafy growth, flowers not being produced at all freely after the first burst. It may be that Violets that receive a little bottom-heat flower the most freely early in the winter, though this is questionable, and in any case those the least forced hold out very much the longest. The advice I invariably give to those who solicit it in the matter of growing Violets in frames is to prepare strong young plants, and transfer these to the pits and frames about or not later than the middle of September. They ought to have the benefit of good loamy soil, be planted firmly, thinly, or well clear of each other and raised well up to the light, not being more than 6 inches from the glass when the lights are put on. Supposing the plants are moved with a good ball of soil about the roots, there is no need to put the lights on till frosts are anticipated, a good soaking of rain doing the plants good. Being grown hardily, they will stand a moderately severe frost, but rather than run any risks of loss of flowers it is advisable to cover the frames with both mats and straw litter whenever an extra severe frost is imminent.

GROWING IN POTS.

Where Violets are in great and constant demand, a few score or even hundreds of plants ought to be flowered in pots, that is if there are suitable conveniences for the purpose. These also are best dug up from the open ground, and should include the old Neapolitan as well as *Marie Louise* and *Comte de Brazza*. There must be no coddling in this case any more than in that of Violets in frames. At present my pot plants are in a shallow pit, the bulk being in 7-inch pots. They are very freely ventilated and will be kept where they are till there are signs of hard weather setting in—whether this be in December or not till January—when their destination will be swinging shelves in a greenhouse kept warm enough to suit Chinese *Primulas* and such like. Then if those in the pits either fail, owing to excessive cold, or are snowed in, there will yet be a quantity of bloom available from the pot plants at a time, too, when they will be most probably of the greatest service. The plants in pots are at the present blooming quite as freely as those in pits, but will be sustained in their free flowering by the aid of weak liquid manure. Moreover, they will not be so closely gathered from as the rest, and most probably will have large numbers of fine, because fully-blown flowers on them. Here let me add that owners of Violets in frames will do well not to insist upon

the flowers being so closely gathered as of old. If left on the plants long enough to attain their full size, one such Violet is equal to three of those too often seen bunched up. It is the double-flowering varieties that are too closely gathered, very few people thinking of gathering single Violets in a bud state.

VARIETIES.

Next a few words concerning the relative popularity of varieties. *Comte de Brazza* has never been much sought after, probably because the flowers are white. Where, however, button-hole flowers are in great demand, several dozen little honquets having to be made nearly every evening throughout the winter, this good double white ought certainly to be grown. It certainly is not so free-flowering as *Marie Louise* and *Neapolitan*, but it pays well for frame room all the same, and with me is already blooming very well in pots. *Marie Louise* and the forms closely resembling it, curiously enough, are not so popular as they were, and we find more asking for the *Neapolitan*. The latter also does well in pits and is very free-flowering under frame culture, the delicate shade of blue being well brought out in the former case. Personally I have not met with many instances of single Violets being preferred to double ones, but am assured by a florist in a fashionable town that well-grown flowers of the *Czar* are disposed of in larger quantities and more readily than anything else, and that, too, at good prices. Anyway, the singles are not likely to be despised in most private places, and seeing that the plants are liable to be badly crippled by the first severe frost experienced, the question is, would it not pay well to give a few dozen plants the benefit of frame or pit protection? Strong, healthy and not very old plants could be moved without sustaining a severe check, and not being coddled or covered in any way other than during the prevalence of wintry weather, they would most probably produce a serviceable lot of fine richly coloured long-stemmed flowers when none were forthcoming from the open. M. H. F.

FLOWER GARDEN NOTES.

TUBEROUS BEGONIAS.—I have been greatly struck this year with the very excellent strain of these obtained from a packet of seed, and the cheap and easy manner in which a nice collection of these favourite flowers, either for in or outdoor work, can be obtained is worth a special note. Some years back if one purchased a packet of seed, the chances were that very few doubles worth keeping were obtained; whereas, now a large percentage—I should say 75—of really excellent flowers are forthcoming, the only drawback being that in nearly every case one gets a large majority of the colour more common than any other—a light pink, with white centre. The seed was, as usual, sown the last week in January, the seedlings pricked out in boxes so soon as they could be handled and planted on the trial border the first week in June. They were by no means happy for some time this year, the weather being too hot and dry for them, and although shaded with light tiffany during the hottest part of the day, mulched and watered, they were a long time in making headway. It appeared, indeed, at one time as though many would not flower, but the showers and spell of cloudy weather in the early part of September, although of short duration, freshened them up wonderfully, and the frost holding off, I was able to run through them a fortnight ago and select the best. Nearly all the flowers are good, but the object is to secure varieties of dwarf, compact habit, free, and with an erect-flowering tendency.

Autumn flowers hold out wonderfully, and at the time of writing (October 25) the mixed borders are very gay. A very pleasing contrast is afforded by *Aster ericoides* and *pompon Dablia Dandy*, a crimson-purple variety, wonderfully free and throwing its flowers well above the foliage, also between the same *Aster* and the old *Fuchsia coccinea*. I never remember such a splendid display of flowers on the

hardy Fuchsias. They have for some time been among the brightest of border plants. It may not be generally known that both the flowers and foliage of these Fuchsias stand well in a cut state at this season—very different to the experience with them during the summer months before the wood is matured. We are cutting them in considerable quantity just now, finding them among the most graceful of present flowers for vase work. The autumn of 1893 will be memorable for furnishing delightful contrasts in flower and foliage, such as we shall probably not see again for many years, owing to the exceptionally brilliant colours of the leaves and the long endurance of the flowers. A portion of an old wall covered with *Ampelopsis Veitchi* has a good batch of *Nicotiana affinis* facing it. The Tobacco was planted somewhat thinly, so that now portions of the bright foliage show through as well as over it, and the effect is very pleasing. A somewhat similar contrast in colours is effected on a portion of a large border where clumps of the white Japanese *Anemone* are associated with bushes of *Spiræa prunifolia*. In any alteration in large beds that may be contemplated this autumn it would be well to consider the advisability of a more extensive planting of ornamental shrubs either alone or as suggested above in connection with larger herbaceous plants. A large bed, for instance, that has been started with a few clumps of *Prunus Pissardi* may be filled in sparingly with *Hydrangea paniculata* and sown down in spring with *Mignonette* or any dwarf free annual that would serve as a carpet for the shrubs. Varieties of *Ribes* and *Weigela* may also be cited as interesting shrubs for similar planting, and they can always be kept within bounds by the judicious use of the knife, just heading back strong leaders and any such straggling shoots as threaten to get beyond bounds. The same remarks apply with equal force to many varieties of conifers of bushy habit which have been planted in prominent positions, and which, if left entirely to themselves, would encroach too much on their surroundings. I aware that wherever practicable such trees are best left alone, save, perhaps, to nip out a straggling shoot and help another into a better position, but it is impossible always to avoid the knife, and where this is necessary it should be seen to every year. If a longer time intervenes and there is two or three seasons' growth to tackle, a hard pruning in is often required, and this means a hedge-like appearance that is decidedly objectionable. It cannot be too often enforced that the true aim in pruning such trees (I am writing of nice specimens, say from 12 feet to 20 feet high by the side of walks or at the back of large borders) should be the endeavour to leave them so that no trace of the operation is visible save that the trespass on forbidden space or against surrounding objects has been decidedly checked. Where labour is somewhat scarce, work of this description may be contemporary with the fall of the leaf from deciduous trees, so that one general clearing up may suffice. Other pleasure ground work that will be put in hand as soon as time will permit will be the replanting portions of a slope from whence the depredations of rabbits have compelled us to move a nice collection of Starworts. In such positions there is nothing for it but to fall back on small seedlings of *Rhododendron ponticum*, and to relieve, at any rate for some portion of the year, the flat surface, I shall dot in liberally seedling Foxgloves and occasionally clumps of the giant Mullein, reserving the bottom of the slope for some good breadths of Daffodils, if we can get these in sufficiently early. To all three of the above-named flowering plants as well as to the *Rhododendron*, the rabbit has a decided objection, and they are consequently in great request for all work in the wild garden where they can be used with advantage.

Claremont.

E. BURRELL.

Aster paniculatus.—This is a graceful Michaelmas Daisy. Its slender habit is one of its special charms, and if left untied it falls about

in a pretty way, always showing itself to the best advantage. It has very long panicles of bloom, and differs from most of the Asters, nearly all of which have their flowers at the top of the shoot. In this kind the flowers are borne on slender branchlets, one of which springs from the axil of each leaf for quite three parts of the length of the shoot. The opening buds have a reddish tint, but the flowers are of a rich purple-blue.—A. H.

NOTES FROM A NEW ZEALAND GARDEN.

As many as eleven years ago, *à propos* of Crocuses, I wrote in your journal these sentences: "But the most poetic of the bees, the big, lazy, hirsute bumble (*Scoticæ*, bumber)—'the red-hipped bumble-bee' of good Monsieur Cobweb—we have not yet succeeded in importing, notwithstanding the praiseworthy efforts of the late Frank Buckland to send us some. Our wish to have the humble-bee is not a mere matter of sentiment, its presence being necessary to effect the fertilisation of the red Clover, of which at present we must receive all the seed supplies from England and America." Now for a few years we have had the humble-bee. Seven or eight years ago it was introduced into the Canterbury province, from which, thanks to mild climatic conditions and immunity from enemies, it has spread over the greater part of this island. Whether we now raise our own supplies of red Clover seed I cannot say, but that the humble-bee is having a very appreciable effect on the fertilisation of plants I need not go outside my own garden to see. I need instance only two plants to show the results of the introduction of this bee—the Primrose and the common Ivy. Before the arrival of the bee I cannot remember having seen a single self-sown Primrose or Ivy plant in the garden; now the borders would be full of seedlings of variously-coloured garden Primroses if they were not dug in. The first time I observed such seedlings was some two years ago round a mixed patch of yellow and crimson self-coloured Polyanthus. The experience was so new to me, that I transplanted the seedlings carefully, and when they bloomed I had some fairly good border flowers. If I were to go on transplanting the seedlings, I find I should never be doing anything else, and the humble-bee's principles of hybridising are not such as to make it worth while to save the seedlings. There is, however, now the possibility of seeing some of the varieties of Primrose become naturalised in suitable places in this colony. Interesting as our flora is from a botanical point of view, everyone misses here the delightful wild flowers that are so plentiful in British woods. To have the common Primrose and the Wood Hyacinth abundant in our copses and woodland places would be a great gain. The common Cowslip, with which I have seen Sussex meadows yellow, is a flower for which I have an affection, both for its own peculiar grace and sweetness and for reasons of association. But I have not been very successful in growing it. In the first place, I believe it

ought to be grown in Grass, whereas I have always grown it in a border. In the second place, seeding and not division is the proper way of increasing it. I observe that, thanks to the humble-bee, there is quite a young colony of seedlings growing up round a patch in the garden. These will presently be transferred to the Grass of an orchard, and we shall see with what results as regards increase.

Again, as to the common Ivy, I find seedlings coming up in many places in the garden, more particularly under shrubs like *Rhododendrons*, where birds roost. Ivy has been a plentiful plant in my garden ever since the garden has been mine, but only within the last year or two have I seen seedlings. Indeed, the first time I observed the cotyledons pushing above ground I was not a little puzzled to know what the plant was, and only discovered its identity after the first proper leaf appeared. An old Ivy bush grows on the wall of my house. After reaching the roof, having no more wall to cling to, it gives up its climbing habit and branches out into a globular shape like any ordinary shrub. These top branches, which form quite a thicket, flower and seed abundantly, and when the berries are ripe the Ivy bush becomes a noisy, quarrelling place of birds—thrushes, blackbirds, and starlings—which devour the berries eagerly, seeming to find them anything but "harsh and crude." There cannot, I think, be any doubt that the Ivy will presently become here a naturalised parasite, because not only will the seed be carried by the birds and deposited in the rich and moist vegetable soil of the bush-lands, but it will stand a better chance of being allowed to grow than wild flowers like Primroses and Foxgloves, being inconspicuous and not specially attractive in the young condition.

I have just been watching a humble-bee harvesting the honey from a clump of *Erica herbacea*. Having no knowledge of the species of humble-bee, I cannot say of what kind ours is. It has a yellow band running across the front of the thorax, and a still yellower and broader band across the fore part of the abdomen, whilst the hinder part of the abdomen is also yellow, but of a duller colour than the bands. By my observation, the first humble-bee moved from winter quarters this year on August 11, and one or two have been visible since that date foraging amongst the flowers. Great fussy, fertile matrons they are at this season, weighing a very respectable amount avoirdupois, and they create no small disturbance when they enter the chalice of a flower. It is interesting to watch the thorough way in which the humble-bee exploits the bells of a Heath. The bell of *Erica herbacea* is relatively long and narrow, and would be found by a bee, one would suppose, a difficult subject. So at least a common hive bee seemed to find it, for it fussed and fumed in a perfunctory sort of way over the clusters, making much noise and doing little work. Very different was the style of attack adopted by the humble-bee on the same plant. Each head of bloom was thoroughly gone over, the pro-

hoseis being quickly inserted into each bell in turn for an instant and then withdrawn. This Erica, like others of the family, hangs its bells, so that the humble-bee had to do its work face upward, clinging to the cluster, and it is wonderful to see how well this seemingly clumsy insect does its work. I could see rills of pollen streaming from the rifled bells like flour from little mills. Up through the middle of the Erica clump there grows a clump of purple Crocus, the cups of which were wide open to the morning sun. Now and then the humble-bee would tumble into one of these pollen tubs, and, seemingly with great enjoyment, bathe herself in the saffron dust. So far as my observation goes, I cannot see that the humble-bee does much harm to the Crocus flowers. Heavy and apparently rough as it is in its motions, it does not break the flowers. But I should think that it probably hastens the fertilisation of the white and purple varieties, and so perhaps shortens the period of flowering.

As for the flower which set me writing about the humble-bee, what can I say about the splendour of the Crocuses this year? Mine are varieties of the ordinary Dutch Crocus, but they run through a considerable range of colour—orange, purple, from black-purple to mauve, and so on to pure white, to say nothing of endless variety of beautiful streaking, pencilling, and shading. It may well be called Dutch Crocus, for what other flower has so much "Dutchness" about it? It is the one flower that looks the better for being grown in a formal way. I grow it in various ways. In the Grass it does not seem to do well with me; probably because the foliage gets mown before the corms are properly ripe. In patches here and there in the borders or amongst the stones or rockwork it is quite in place. But it shows best when it is planted as an edging, straight or curved. I have about a hundred yards in various parts of the garden planted in this way, the breadth of the edging varying from 9 inches to 1 foot, and the sight they make when the sun shines in the forenoon is equalled, at least in my garden, only by the splendour of the Daffodils that follow. The great charms of the yellow Crocus are the warmth of its colour and the wonderful shadows inside the cup, the warmth of colour being due to the large amount of scarlet in the yellow and the exquisite shadows to the inward curve of the petals. If I am to have but one flower, give me the Daffodil. If I may have a second, give me the Crocus; and if I may have but one Crocus, give me the yellow. The other colours are, I dare say, more exquisite, but they require looking into. The yellow is good to look at from your window, or to look at closely, peering into its cup. Besides that, on its outside petals it has those delicate olive-green pencillings like a bird's feather.

DAFFODILS.

I noticed to-day (August 26) in the garden a curious instance of ingenuity in the humble-bee. One of these insects was busy amongst a patch of *Chionodoxa*. Apparently

for some reason it was unable to extract the honey in the usual way, for after sounding the inside of the flower it would go round and puncture the bell from the outside, sinking quite a little shaft into the ovary. I have seen Columbines with the spurs of the flower quite riddled in this way, and have been told also that in other places the Daffodils have been spoiled by this way of carrying off the honey—by the back door, as it were. Up to this date a good many Daffodils have bloomed. The double pseudo-Narcissus is not yet at its best, but it is very fine, the garden being yellow with it. What a fine thing, and how variable this common flower is. I grow it everywhere, and though in its season the garden is a mass of yellow, yet I go on multiplying the flower. All those in my possession are the progeny of a few bulbs I got a good many years ago, so that the various forms that appear must be all the result of different conditions of growth. One bed this year, for instance, has given flowers of the Rose type, showing no distinction of crown and perianth. The reason for this is the richness of the ground where they grow, which for two seasons has been made a receptacle for the lawn clippings—of course after the Daffodil foliage had ripened. Formerly this bed had been starved by the roots of trees, and gave small flowers and poor foliage. The result of the first year beneath the Grass heap was great increase of strength in the Daffodils, both in flowers and grass. The result of a second year of the same treatment has been to kill all the bulbs in the centre of the bed where the Grass heap was highest and fermented most briskly. The outside bulbs, on the other hand, have come up very strong, with burst rose flowers. I have noticed also that strong bulbs of this variety when newly planted in Grass will flower in this very double way. The flower looks very coarse in this form, but one does not object to a few for variety's sake. You will find a complete series of intermediate forms between this over-full form and that which has the tube long, narrow, and double, and as sharply distinct from the perianth as it is in Emperor. Shallow planting, I observe, throws this Daffodil out of flower, however good the soil, but leads to a large increase of bulbs. On the other hand, with very deep planting it flowers in abundant quantity and in beautiful compact form, but seems to make few offsets or none. In Grass, though they will not increase at all, they will go on flowering year after year even in shade; whereas, planted in a border in shade, they by-and-by give up flowering, showing little but grass. This is, I suppose, the commonest and the coarsest in growth of all the Daffodils, but, taking all its points into account, its readiness to grow and increase, the size and number of its flowers, their great substance, and the richness of its magnificent golden colour, it is the most useful of them all.

All the Daffodils have now shown their grass; even the double poeticus. The sulphur trumpets (of the *cinnus* type) are now hanging their heads over the borders, looking

so delicate that one expects the first wind to shrivel them up. I find these Daffodils easy to manage, and they increase at a fair rate. The variety I have most of I got some years ago without name, but I suspect it is *tortuosus*. The tube is about $1\frac{1}{2}$ inches long, of a deep sulphur when it first opens, the perianth very pale. A variety which I have as albicans, and which increases at a very slow rate, is smaller in its parts and more flimsy in its texture than the other. The fault I have to find with these delicate flowers is that the perianth hangs down over the tube in such a limp way. As to that dog's-eared class represented by *Humei albidus*, of which I cut the first expanded bloom to-day, it is to be hoped that hybridists will not encourage this habit in the Daffodil. I have two varieties of the Hume Daffodils which I shall keep, partly because they are so easily grown, and partly because they show what curious forms this flower sometimes takes; but I shall seek for no more dog's-eared varieties.

I note to-day (August 31) two Daffodils in bloom for the first time. The first is *Ard-Righ*, which I have added this year to my collection. It is a fairly good self-coloured golden-yellow trumpet Daffodil of medium size. The trumpet is somewhat long and narrow, and flounces out prettily at the mouth of the tube. It would be a desirable sort to have in large quantity in the borders, though I do not think it so fine as a Daffodil of the same style that blooms in many free-flowering clumps in my borders. The second of the Daffodils to which I made reference above is a bicolor which I received from a dealer here under the name of *Romanus*, which name I cannot remember ever to have seen in a catalogue. It is the earliest bicolor to bloom with me and is a good flower, about two-thirds the size of *Empress*, the segments of the perianth, however, being narrow and limp compared with those of that splendid variety. Take it all round, it is a fine variety, strong, and easily grown, and I should like to know something more of its history, for I suspect that *Romanus* is not its true name. Another valuable Daffodil expanding its first flowers to-day for the first time is *Leedsii anabilis*, a very graceful, delicate Daffodil, which grows with great luxuriance and increases rapidly. It is not very pretty when it first expands, but shows its true form and colour when it has been out a couple of days. One of the prettiest sights in the garden during the past week has been a clump of *Narcissus minimus*, and it would be hard to find a prettier sight anywhere. The foliage is very like in size and colour to that of the ordinary single *Snowdrop*. The flower on first showing colour rests actually on the ground, but by-and-by the stalk lengthens till the flower is some 3 inches or 4 inches above the soil. This is one of the most charming of all the Daffodils, and quite as indispensable as the glorious *Emperor* which it mimics. Several new varieties of *Narcissus* are out to-day (September 2). Amongst others an imported *Sir Watkin* has shown its first

flower. I possessed this variety before, but was in doubt as to whether it was the genuine Sir Watkin, because, though it was a fine large variety, it did not come up to the expectations which the coloured illustration in *THE GARDEN* had led me to form. There are two things I note about it: first, that the segments of the perianth in the real plant do not imbricate one over another so finely and broadly as is represented in the plate; and in the next place, that the chalice of the flower is almost too long to permit it to be classed with the Peerless Daffodils, reminding one rather of the deep cup characteristic of the Nelsoni class of Narcissus. So far as I can judge, the flower of my imported bulb is identical with that of the Daffodil I formerly had as Sir Watkin. The flower is not so large nor yet is the grass nearly so strong as in the older established bulbs; but probably Sir Watkin is one of those Daffodils, like *maximus*, which wants working up to its full size. One thing is satisfactory to me: it promises to grow as strongly and increase as rapidly in my soil as the common double pseudo-Narcissus. *Cernuus* is also in bloom, though I possess few as yet of this variety. It is a pretty thing; the segments of the perianth shorter, broader, and more overlapping, and the tube shorter and squatter than in the variety which I have in larger quantity, and which I suppose to be *tortuosus* or *moschatus*, if indeed these two are not identical. But the name of *cernuus* is not nearly so applicable to the true variety of this name as it is to other long-tubed, gracefully bending sulphur Daffodils, that swing with such grace over the borders in spring. Last year I flowered the double *cernuus*, to my great contentment; only one bloom, which was cut as soon as it expanded, put in a vase all to itself, and worshipped every day for a week. This year there is no flower, to my regret. Judging by the foliage, the bulb must be forming offsets. It is of course pleasant to think of one's stores being increased, but the grass looks too weak to be reassuring. I should be glad if some of your readers or contributors who have more skill than I have with difficult Daffodils would tell me how to grow the double *cernuus*.

This evening (September 4) I did not get into the garden till towards five o'clock, just as the sun had gone, leaving behind it a sort of afterglow, in which the air seemed somehow to grow thicker and to be saturated with some golden colouring matter. All colours in this rare light, the green of the Grass and trees, and the reds and blues of flowers, have a warmth and mellowness never seen in the full sunshine. This state of the air—for I am sure it is a state of the air—is accompanied with a perfect calm, with rich golden reflections on the surrounding hills, and with great placidity and depth of shadow on the water of the bay and the ocean. The sight of the Daffodils in the garden this evening will long remain a memory. The bright sunshine of the day had brought out hosts of all kinds. Mine is a very planless and unmethodical garden, full of ups and down and cranks and turns, where flowers, shrubs, and fruit trees are mixed

without any rigorous lines of demarcation. The Daffodils are everywhere, on banks, in borders, under trees, in the Grass, and are of all sorts and sizes. Although they are not in thousands, there are still many to come. I do not know whether the Lent Lily grows in all places with the same luxuriance as here, but I cannot get my fill of this glorious flower, plebeian as it is. In the golden air of an evening like this its colour becomes refined and doubly beautiful. It is to-night, I believe regretfully, at its best. In other gardens I see it has actually gone off, but it occupies so many positions in mine, that masses are still in bud and will come in later. During the last two days the Peerless Daffodils have come with a rush, and this evening they are in masses; all the old-fashioned double kinds, Collins and Cream (not plentiful with me), Butter and Eggs, and Bacon and Eggs, with simple single or semi-double varieties which I have long had, and know by my own names, but by no others. One of these days, when they are further expanded, I shall pass in review all the fat double varieties of the Peerless Daffodil in my garden. Those old names given to Daffodils by the country folk have for myself, I confess, a charm. I cannot say the same for the hideous nightmare of modern names that now fill the dealers' catalogues. Think of having to tell a friend who inquires that a certain rather pretty Daffodil is called John Absolon! I suppose that such a nomenclature is necessary, but it is a necessary evil. One of course requires to know what varieties are referred to when he reads about Daffodils, but at the same time one would wish that descriptive names were in all cases possible. I do not object, for instance, to the name *pallidus præcox*. My first and only bloom of this lovely gem has shown to-day. *Pallidus*, indeed! But *præcox*, only moderately so. Many others were earlier than it. However, it is a new arrival, and therefore, probably, not yet sure of its ground.

To return to the Daffodils as they looked this evening. A shower set in towards twilight, just enough to make the heads of the double Peerless flowers bend in a low salaam to a few crowned heads—Emperors I mean—that made this day their first appearance of the season. The clumps of *tortuosus* (or *moschatus*, or what?) hung most "cernuously," and *albicans*, not numerous, unfortunately, looked too fragile fair for any merely mundane garden. The little *Jonquil*, which I am proud to say is a weed with me, is, like the Lent Lily, everywhere, and will be in more places still if I can manage it. *Olorus*—my invaluable *hiemalis* (?)—has been in bloom six weeks, but this evening it looked its very richest and largest, and I suspect it will continue for a month yet, and will see the poetical *recurvus* fairly in, or even the double Dutch; who knows? A single trumpet Daffodil which I have in great numbers is a really exquisite thing. It is as rich in the yellow as *maximus*, but is of medium size. They are the progeny of a few bulbs I bought years ago in a dealer's shop for Emperor; but though the Daffodil has no resemblance

whatever to Emperor, it is a very lovely thing, and early. Seen growing in the borders you would take it for the common double pseudo-Narcissus, but when you cut it and look into it you see how exquisite it is. In the soft light of this evening the floppy, dog's-eared *Humes* looked positively charming, and I shall never again speak lightly of them. Peerless Daffodils of the single kinds are abloom in great numbers, a rich golden variety, with bright olive-green grass very numerous. Various *Johns*—John Absolon, John Stevenson, John Bull—not in such quantity, but enough to swear by. Of Sir Watkin, from first to last, I believe I shall have a round dozen of blooms this year, and it will go hard with me if they are not three dozen next year. *Polyanthus Narcissus* of several kinds are in bloom more or less plentifully—less rather than more at present. Exquisitely sweet flowers they are, and yet somehow they form the class of *Narcissus* in which I take least interest. It may amuse those who grow the flower by the acre to know of anybody at the Antipodes who is proud of his first flower of the Paper-white; one bulb only which I carried home with me last summer over 1200 miles! But it has produced two trusses of a bloom that is purity itself.

Several truths in respect of Daffodil growing have come home to me this evening, and I shall set them out *seriatim*: (1) Have Daffodils everywhere. (2) Do not choose a flat piece of ground if you wish to grow Daffodils; every step should take you to a different level, so that you can go down and look up, or go up and look down, or go to the side and look up and down and across. (3) Large masses should be visible to the eye at once. (4) Yet the ground should be so varied in its character, that when you think you have seen all there is to see, you may come on corners and beds of Daffodils you had not yet seen. (5) Daffodils look uncommonly well when seen through a fretwork of bare branches, like those of Hazel or Birch. (6) They look even better when the masses or clumps are interfered with here and there by fruit trees bursting into blossom, the Plum being a valuable tree for this purpose, and the Pear little behind it. (7) Daffodils are greatly set off when they happen to grow in front of large masses of *Pyrus japonica*, or even of well-grown red-flowering Currant; or if they have for a near neighbour an early-flowering rich crimson *Rhododendron*. (8) In case that to any peculiar taste Daffodils should ever come to be monotonous, it is well to have the ground between the clumps quite full of such small things as Primroses and *Polyanthuses* of all kinds, Squills, Snowglories, Grape and other Hyacinths, Forget-me-nots, Anemones, Fritillaries, Auriculas, and so on. (9) Do not be stingy in cutting your Daffodils and giving them away. They say that cutting the flowers improves the bulbs for next year. I do not know about that, but it is a good thing to believe. I try not to be stingy myself, but sometimes find it hard work.

Dunedin.

A. W.

FERNs.

SPECIMEN FERNS IN WINTER.

THE treatment accorded to these during the winter season must vary according to the peculiarities of the genus or the variety itself. In some cases it is safe and even desirable to partially dry them off; whereas in others the watering must be attended to in a careful manner. *Gymnogrammas* are an example in which the watering must be looked to closely so as to avoid both extremes. If overpotted in any degree it is quite possible to lose the plants by being too liberal with the water-pot. On the other hand, if pot-bound, the opposite risk of killing the plants by drought may ensue. It is surprising what an amount of water a healthy *Gymnogramma* will take when the pot is full of roots, but even this does not justify an excess. When pot-bound plants are watered, see that they receive sufficient to penetrate the ball. Large plants of the *Nephrolepis* family must not be kept too dry, otherwise the individual pinnae will turn yellow and eventually drop off before their time. A plant of this genus may not be observed to show any signs of distress by the drooping of the points of the fronds when dry, but all the same it may be suffering, and what has been indicated as an after-sign will in due course ensue. The deciduous *Davallias* should be kept quite on the dry side whilst they are resting; a lower temperature by 10° than that in which they thrive during growth will then suffice. The evergreen species of the same family should not be kept more than moderately dry; although no great amount of growth will be made, yet sufficient moisture must be given to keep the plants fresh. *Adiantums*, on the whole, will be preserved in better condition if kept tolerably dry. *A. Farleyense* taking as much or more water in the winter than any kind I know, save the semi-filmy variety *A. reniforme*. *A. Farleyense* cannot resist drought at all; the individual size of the pinnae accounts for this plainly enough. Several varieties of *Adiantum* are partially deciduous, as *A. trapeziforme* and *A. concinnum latum* of the larger sorts, and *A. amabile* with others of small growth. Even *A. cuneatum* may be treated as a deciduous plant, and it will start into fresh growth with renewed vigour in the spring if given a good rest. The *Aspleniums* all need liberal treatment; they will endure a partial drought, but it is not good for them. *A. nidus* (*Thamnopteris nidus*), the Bird's-nest Fern, is more of an aquatic than almost any other Fern. It must not be overpotted, but it requires plenty of water. The *Blechnums* and *Lomarias* must not suffer in this way either, or they will be disfigured with thrips. The *Pterises* are all fond of a liberal supply of water, but especial care must be taken with *P. scaberula* to see that it does not in any sense become dry, or it will soon be past recovery. The *Cheilanthes* thrive best, perhaps, as small plants, but specimens may be grown with care; these also need a liberal supply of water. I do not, in advising this, mean to infer that they may be watered *ad lib.*; this would never do, but they must not feel the want of it. The *Gleichenias* are another case in point wherein a liberal treatment as regards watering is needful. These Ferns are very shallow rooting, whilst the roots are fine and wiry; hence, if they feel the effects of drought, the growth quickly succumbs. These handsome Ferns should not be either overshadowed by others or be kept in too warm a house; a fairly moist cool house will suit the majority, the most notable exception being *G.*

dichotoma, which is seen to far better advantage when grown in a cool stove temperature. The climbing *Lygodiums* make beautiful specimens, but towards the autumn they are liable to be attacked by thrips, more especially *L. scandens*, which is best treated by being dried off about this season of the year, when all the fronds can be removed. The *Marattias* are gross-feeding Ferns, requiring a deal of water to support them in a healthy condition. Quite the opposite is the case with large plants of the *Platyceriums*; these during the winter will remain healthy and fresh with but little attention in the way of watering. When any is given them, it should not merely be a superficial watering, but sufficient to penetrate to all the roots which are oftentimes encased with decaying growths. The *Polypodiums*, the *Platylomas*, and the *Phlebodiums* all thrive best under a medium course as regards moisture. Tree Ferns of the various genera all need a liberal treatment. More harm is probably done to them during the dull season of the year by allowing them to become too dry than at any other period. At no time should they so nearly approach the dry side as to suffer in the slightest degree. Some are more sensitive than others perhaps. I have at any rate noted how soon the effects of drought are discernible in the case of *Dicksonia squarrosa* and *Cyathia medullaris*. Taking specimen Ferns as a whole, a great deal depends upon the healthy state of the roots at all times. If the soil be sour and exhausted, the roots will in due course become weakly, suffer and decay; then it does not take a long time for a specimen to dwindle away. It must be borne in mind that between large plants and small ones there is a considerable difference as to the quantity of soil for the roots to work in; there is never the same risk of the soil in which a small plant is growing becoming sour if overwatered as there is in the case of a larger plant.

GROWER.

***Nephrolepis*.**—I am rather taken to task by "W. W." for omitting to name one or two species in my notes upon this genus on p. 333. There is but one plant described on p. 371 by "W. W." that I regret to have omitted, and that is *N. rufescens tripinnatifida*. This quite slipped my memory, for it is one of the most lovely Ferns which I know. I am only sorry that it keeps so rare. *N. Duffi*, distributed by Mr. Bull under this name in 1877, although a very beautiful plant, I purposely omitted, because I do not think it gets its right place when assigned to the genus *Nephrolepis*; the others are not species, but varieties of those I have given, saving *N. Barteri*, which I regret I do not know.—W. H. G.

***Nothochlæna rufa* (D. Grant).**—This is the name of the specimen you send, and not *N. trichomanoides*. I have specimens of the plant gathered in Jamaica by Wilson. This was called *N. ferruginea* by Hooker, on account of the colouring of the under side. The two plants have been considered identical ever since; therefore I retain the oldest name. It is a beautiful Fern, forming a handsome specimen for a small hanging basket. The plant you have it for, viz., *N. trichomanoides*, is equally well adapted for the same purpose, but is stronger in its growth and the pinnae are larger, the under side coated with a white powder. You should obtain it as a companion plant to *N. rufa*.—W.

***Nephrolepis Bausei*.**—This pretty Fern, which is mentioned on page 371, has one noted peculiarity, and that is it is totally deciduous, for not only do all the fronds die off, but frequently the entire crown and rootstock as well, leaving nothing but a few detached tubers, which when growing were connected with the parent plant by a slender root-like substance. A good way to treat it is to keep the soil slightly moist during the winter, and

early in the year before growth recommences it may be turned out of the pot and the small oblong-shaped tubers searched for. They should then be potted singly into small pots and shifted on as required. Occasionally the crown does not die, and when this happens it pushes up strongly in the spring. This note is prompted by the fact that at the present season this pretty and distinct Fern may be thrown away under the impression that it is quite dead, while a close inspection of the soil would reveal the small tuber-like masses.—H. P.

***Brainea insignis*.**—I am thankful for any information respecting this plant, but yet I do not think that "W. W." has added much to our knowledge of the plant by his remarks on page 372. I am quite aware it has been raised at Kew, for I myself raised three distinct batches of spores from the plant at Kew some thirty years ago. These spores never got beyond the prothallium stage, and it was with the view of finding out how the seedlings developed that I asked for information. I was not aware that seedlings had been raised at Holloway after I left there, or that a plant of sufficient size to produce spores ever existed in the establishment.—W. H. G.

***Lastreas from New Zealand* (T. Anderson).**—I have three species of this genus sent for names, which I here give. No. 1 is *Lastrea hispida*, one of the handsomest greenhouse Ferns that can be grown. No. 2, marked *laurakei*, is *L. velutina*, and is nearly allied to *L. decomposita*, but it is much softer to the touch. It is, I think, a rare plant in our gardens. No. 3 is *L. glabella*, a dwarf form and very elegant. It used to be common in the cool fernery.—W. H. G.

SEASONABLE NOTES.

INDOOR FERNERIES PLANTED OUT.—At this season of the year and onwards until sharp frosts ensue, rather more ventilation, comparatively speaking, should be given than has been the custom of late. Through the hot weather there would without doubt have been sufficient air admitted to keep all things right, but with the cooler days and nights this would possibly be withdrawn to some extent. In doing this whilst there is still but little need of fire-heat, there will be the possibility of an excess of moisture that must be prejudicial to many Ferns if it continues. Not only would it induce damping off, but the growth would also be tenderer and not so well calculated to withstand the more trying days of winter. By maintaining a more buoyant atmosphere with the decline of the sun's power a hardening process will ensue which will be in every sense better for the plants. This advice is all the more applicable where tanks of water, with aquatics possibly as an adjunct to the Ferns themselves, prevail; these tanks tend to render the atmosphere too moist at this season of the year without slightly more ventilation. With a trifle more air both by day and night when possible, it is a good plan to have rather more warmth in the pipes than would otherwise be really desirable. By following this course it may be found necessary to water more frequently, but this is in no sense undesirable—an advantage rather in many instances. Where the use of the syringe is still found needful, it should be attended to early in the day and never towards nightfall. The growth of the Ferns will oftentimes at the end of the season's activity have become in some cases too dense. Where this is found to be the case thinning out may be desirable; this may be done by taking the fronds whilst fresh and good for use in a cut state, or by thinning out the older ones before they actually decay. That most common enemy of Ferns, the brown scale, will possibly have escaped detection during the busier times of the past few months. If this be so, do not let it go on increasing any longer. Badly infested fronds had better be removed where they can be spared, and others be looked over carefully. Transplanting in any case should not for the present be thought of, nor will fresh soil be found desirable, unless it be to fill up cracks or to protect roots

from which the soil has been washed away after several waterings. In some instances a little Sphagnum Moss might be found handy. Slugs and snails will want closely looking after at night; they will find their way inside now wherever they can. A few fumigations would not be at all amiss to check both thrips and green-fly. If there be still any shading on the roofs it should not remain any longer; this also has a tendency to encourage damp, and that more so than some would imagine who have not taken note of it. Of course, if roller blinds have been used there will not be any trouble in this direction, but these should also be taken off now there is no further use for them.

The foregoing remarks have had reference to ferneries in general, but in special cases where the Filmy Ferns are grown to any extent, it is not advisable to materially alter the atmospheric conditions, otherwise these somewhat delicate varieties will suffer. It is possible to grow these beautiful Ferns without the double covering by giving them special attention, but too brisk a circulation of air would act prejudicially on them. If other plants than Ferns form an important feature, their regulation may require some modification. The variegated Panicum, perhaps, will have grown freely; so also would the Tradescantias of scandent growth. These will be all the better if kept well under control now, so as not to injure the Ferns. If the slender-growing and Fern-like forms of Asparagus are present, and these are in any sense of dense character, every opportunity should be taken of cutting out here and there some pieces for using in a cut state. Begonias of the fine-foliaged sections are frequently used, and beautiful objects they make in ferneries, but they should not be allowed too much license, otherwise they will cast too much of a shade on other things. Ficus repens will also need to be kept in check; this oftentimes grows as rapidly in the winter season as at any other; however, as it is very handy in a cut state, it can be kept under when desirable. Large Tree Ferns if planted out in ferneries oftentimes exceed the dimensions one would like to restrict them to. If such as these are imparting more shade than is desirable, I would not hesitate to remove a frond or so at a time, always taking the oldest of them. To try and check them by other means is a risky process; if they be kept at all on the dry side, it is to their material injury, and to lift them is not much better. If in any case they are getting too tall, it is possible to lower them in some places with decided advantage. Such work as this may well be done now; there is more time to do the work well. The raising of the roof would in many a fernery be a very marked improvement. It is possible that all looked well and in proportion until the growth had progressed to a large extent; then in many a case it would be plainly discernible how much better would be the effect if the roof were carried up higher. Such work had better be done now than in the spring.

FILICES.

ORCHIDS.

CATLEYA LABIATA AND C. WAROCQUEANA.

THESE varieties are at the present time flowering very freely in many gardens round London and in various other parts of the country, judging from the numerous blooms that have come to hand during the past week; notably two flowers of a very good form from Mr. Joseph Barclay, gardener to Mr. H. Rowlands, of Alexandra Park, Manchester. Remarkably fine and highly coloured blooms also came from Mr. T. Calverley, Leeds. Several other readers also send flowers, which, although extremely beautiful, are not of sufficient merit to call for any special note. Two of the most beautiful displays that I have seen are in the garden of Mr. J. T. Gabriel, Palace Road, Streatham Hill, and in

that of Mr. Measures, The Woodlands, Streatham. In Mr. Gabriel's collection are many very highly coloured forms and others of a paler shade; indeed, there are one or two very fine flowers which appear very much like the form which used to bear the name of *C. labiata pallida*, but which present-day Orchid growers have named *C. Gaskelliana*. There are also some very broad-petalled and dark lipped kinds which are extremely fine, and amongst them is a very fine form with pure white sepals and petals and a very fine lip, the ground colour being pure white, the entire front lobe being overlaid with the richest purple. This is a gem, and one which appears to crop up amongst the imported plants but rarely. I would advise collectors to look out for such specialities of the variations of the typical forms of the labiata section more often than appears to have been done, for such a consignment, although it might be of small dimensions, would be of infinitely more value than a quantity of the ordinary type. At The Woodlands also these two kinds are blooming very freely, the side stages in one house being devoted to them. There are some exquisite flowers amongst them, but the more I see of the recently imported plants, the more I am convinced that Lindley had a magnificent variety of this plant to name the old labiata by. I had, however, a piece that had been divided from Mr. Cattley's original plant. Many of the growers of the present day form their opinion of *C. labiata* (a few of which have from time to time been imported since) from the fact of the plants having a double sheath, this being sufficient to convince them that it is the true *C. labiata*. I very much doubt if any of the old plant grown by Mr. Cattley is still to be found in any garden. One of the readers of this paper showed me two years ago a plant in flower which was said to have come from the Continent and to be the true form, but the colours of the flower bore no comparison to those of Lindley's plant, and when I disputed its identity I was shown the double sheath as a convincing proof. I was also shown a plant in flower by the late Mr. Hall, but this was not from Lindley's plant, and it is only here and there a plant crops up. Mr. Broome, of Llandudno, sent me a year or two ago a flower which was the nearest approach to it which I have seen. I have not written the above to in any way disparage the flowers we now have, for they are exceedingly beautiful, although not equal to those of the original form. In Mr. Measures' collection is a light form which, if I mistake not, bears the name of *C. labiata Sanderæ*. This is an exquisite flower, being large and spreading, the sepals and petals of the purest white, lip large, also white, stained in the front with a feathery blotch of purple, leaving quite a broad white border. This is a quite distinct plant from the one before mentioned as flowering in Mr. Gabriel's garden in the same neighbourhood. In The Woodlands collection there are also some fine dark flowers of both these plants.

WM. HUGH GOWER.

Cypripedium Lawrebel.—This magnificent hybrid, raised by Sir Trevor Lawrence between *C. Lawrenceanum* and *C. bellatulum*, is now flowering in Mr. Measures' collection at The Woodlands, Streatham, and it is a far finer flower than the original form, which bloomed at Burford Lodge. The scape bears two flowers, which are of great size and very richly coloured, the dorsal sepal being very broad, 2 inches across, and as much in depth, of a rich crimson, with darker veins, the central portion being lighter; lower sepal small and similar in colour; petals $2\frac{1}{2}$ inches long and 1 inch broad, having a ground colour of ivory-white,

heavily spotted with purplish-black, flushed with crimson at the margins. The apical half is wholly crimson, and here the black spots are smaller and much thicker. The pouch-like lip is also of a deep crimson, pale green beneath. This is the most richly coloured and the most beautiful *Cypripedium* I have seen.—W. H. G.

Luddemannia Pescatorei.—This very rare plant I recently noted in the nursery of Mr. Seeger at Dulwich. As I had not seen the plant growing for years, I should scarcely have recognised it from a *Lacæna* or an *Acineta*, to which in fact it is nearly allied, as in its manner of growth and its style of flowering it much resembles these genera. Lindley classes it with the Swan-necked Orchids, which are better known by the name of *Cynoches*, from which, however, it would appear to differ in the shape of its lip. The flower-spike is produced in a pendulous manner from the base of the pseudo-bulb, the raceme bearing from twenty to thirty flowers, the sepals being of a brown colour, the petals and lip canary-yellow. It is a very pretty and elegant plant, and as rare as it is beautiful. It was discovered some years ago in Venezuela.—W. H. G.

Cattleya Bowringiana.—G. Scott sends me a nice series of this beautiful autumn-flowering *Cattleya*, which was introduced a few years ago from British Honduras by the Messrs. Veitch, of Chelsea. Amongst them are some nice flowers of the typical forms, the blooms being large, with the dark blotch in the lip well developed, the colours being exceedingly beautiful and quite unlike those of the ordinary type of *Bowringiana*. They more resembled those of the lovely spring-flowering *C. Skinneri*—W. H. G.

GARDEN FLORA.

PLATE 934.

SCHIZOCODON SOLDANELLOIDES.

(WITH A COLOURED PLATE.*)

IN 1889 lovers of hardy plants were on the tiptoe of expectation on the introduction of the rare and beautiful *Shortia galacifolia*, which we are glad to say is now fairly plentiful in gardens and promises to stay with us. The introduction of the *Schizocodon* is due to the exertions of Captain Torrens, who in 1891 found the plants growing beside sulphur springs in Japan, and after carrying them many hundreds of miles, succeeded at last in bringing home three or four living plants. This species was first found by Professor Zuccarini in the mountains of Japan and named by him as above, in 1843, from the *Soldanella*-like appearance of the flowers, and in which it differs from the *Shortia*. Some years later Dr. Maximowicz found what he considered two new species, one of which (*S. uniflorus*) was recognised by Dr. Asa Gray as his *Shortia galacifolia*, and *S. ilicifolius*, which is near, if not identical with, the original *S. soldanelloides*. The natural order to which the *Schizocodon* belongs contains only six genera, five of which are now in cultivation—*Pyxidantha barbatula*, *Diapensia lapponica*, *Shortia galacifolia*, *Galax aphylla*, and the subject of our note, all of which are growing in the alpine collection at Kew. *Berneuxia* is not, we believe, represented in

* DRAWN FOR THE GARDEN by Clampton Jones, April 7, 1893, in Captain Torrens' garden at Baston Manor, Hayes, Kent. Lithographed and printed by Guillaume Severeys.

ASTERS. SOLIDAGINACEAE.

cultivation, but as it also is worthy of a place among our choice plants, we hope soon to see it in a living state. The flowers of the *Selaginodon* are like those of a large *Soldanella*, prettily fringed, deep rose in the centre, passing into blush or almost white towards the edges. It evidently requires much the same treatment as the *Shortia*, and will not stand coddling.

Captain Torrens, in whose garden at Baston Manor, Hayes, Kent, the drawing was made, sends us the following note about the subject of the plate:—

The plant I found in an overhanging bank surrounded by moss and moisture. Since I brought it home I have kept it in a pot with peat and sand. It is a hardy plant, and I have had it out two winters in a cold frame, and it seems to have stood the climate well. I was successful in getting two seed-pods and have sown the seeds.

THE WEEK'S WORK.

FRUIT HOUSES.

PRUNING EARLY PEACHES AND NECTARINES.—Although the wood has long since become firm and well ripened, the leaves in most cases held on very tenaciously. In but few instances, or where the trees are young and have grown very vigorously, ought there to be any need to longer defer putting both the trees and house in good order for being started towards the end of November or early in December. If the advice to early cut out much of the old bearing wood soon after the crops were gathered has been acted upon, not much pruning will now be needed, but in any case all the trees should be gone over now and the pruning completed. It can always be done most effectively before the trees are taken down from the trellises, the operator being then better able to judge what is best to leave and what ought to be cut out. Crowding the branches should be avoided, though if bud-dropping sometimes occurs, very hard pruning ought not to take place. It is the extra strong young growths that are most likely to cast many or all of their flower-buds between now and flowering time, and seeing that the buds seldom drop from the under-sized wood or spray and short natural spurs, a good proportion of these may well be distributed over the trees. Especially ought spray and short spurs to be retained on Waterloo, Early Alexander, and Hale's Early Peaches and Lord Napier Nectarine, these being great offenders as far as bud-dropping is concerned. A too free use of the knife is most unwise, especially if there is good room for the trees to spread. At the same time they must not be allowed to "have their head" too freely, or the lower branches and centre of the trees may get much the worst of it. Fore-shortening or cutting back straggling branches on fast-spreading trees to better placed inner growths, and the cutting back of end branches on trees that have reached their limit to young shoots somewhat nearer the main stem, ought certainly to be practised. Novices are apt to trim all alike to a regular line, but this will not long prove satisfactory. Unhesitatingly cut out the end branches as much as possible without removing all the bearing wood, enough of the latter being left to thinly clothe the wires or walls to within a few inches of the limit. It is not merely the growths that produced fruit this season that should be cut out where thinning out is necessary, but some of the old wood may well accompany it in many cases, even if this necessitates the use of a pruning saw. All cuts should be close up to another branch or shoot, and the edges of the wounds be rounded off with a knife. Very gross young shoots are best cut cleanly out, while those of about the thickness of a lead pencil and of considerable length may be shortened to about 2 feet, cutting to a well

placed triple bud. The best class of wood is that which is a little smaller, and this should be left from 12 inches to 18 inches long with a view to keeping up the supply of equally good wood. Most of the smaller or thin shoots have wood-buds only at the points and sometimes at the base, and must be well examined prior to pruning. If they can be freely shortened to a triple bud, the centre one of which is small and more pointed than the other two—being therefore a wood-bud—so much the better, as this will most probably strengthen the next breaks.

CLEANING THE TREES.—Where brown scale was not wholly got rid of last winter, it increased and spread with surprising rapidity this summer. The most effective is also the most easily applied remedy. Brushing and scrubbing the trees with strong insecticides are both laborious and only partially effective; whereas, the petroleum remedy, if persevered with, effectually clears the trees of this troublesome and sickening insect pest. After the pruning is completed, the trees loosened somewhat and the borders cleared of all rubbish, the wood-work and glass cleaned and the walls white-washed, syringe the former freely with petroleum, soft soap and water, and if this soaks well into the border, good, rather than harm, will be done, especially if there was any black fly on the trees. Heat the water to about 120°, this condition being insisted upon if the remedy is to have a fair trial, and to every 3 gallons of this add a lump of soft soap about the size of a hen's egg and 6 ozs. or three wineglassfuls of ordinary petroleum, or paraffin, as it is generally, but wrongly termed. The oil must not be permitted to float on the surface of the receptacle, but should be kept mixed with the water, this being done either by returning every second syringe (after the mixing has been accomplished by means of the syringe) forcibly back into the receptacle, or else by keeping two syringes at work, one distributing and the other keeping the oil mixed with the water. This mixture should be used in no half-hearted manner, it being of the greatest importance that every branch and shoot be thoroughly wetted by it. There is no necessity to syringe the trees with clear water a few hours after using the petroleum mixture, and if one application of the latter does not thoroughly clear the trees of scale, a second dose should be given. If it does not also destroy thrips and red spider as well as scale, mealy bug and aphides, it will, at all events, get rid of the greater part of them.

TOP-DRESSING THE BORDERS.—Supposing the trees have not been partially lifted and given the benefit of a good addition of fresh soil, those that are rooting in a border largely exhausted of requisite fertilising elements should now have a top-dressing of fairly rich compost applied to the borders. First loosen the surface, well baring the topmost roots, then, if the soil is at all dry, give a good soaking of liquid manure a few hours prior to top-dressing, this being better than having to saturate the fresh soil in order to well moisten the border previous to starting the trees. For these top-dressings use good fibrous or other fresh loam, flaky manure in equal parts, and old mortar rubble, burnt soil, the ashes from wood, rubbish, and weeds generally, and bone-meal being added with advantage. Where the borders are already quite rich enough and the trees yet present a somewhat sickly appearance, a light dressing of newly-slaked lime, forking this in very lightly, will, when washed down to the roots, act most beneficially.

LATER HOUSES.—The leaves are rapidly parting from all the trees, and a switch would readily remove what remain other than those on very green shoots. They ought not to be left lying on the borders for red spider and thrips, if any, to leave them and seek safer winter quarters. There is no good reason why the pruning and cleansing should not be proceeded with in both succession and late houses, only trees that have failed to ripen properly being left for a time longer. Trees may yet be brought in from open walls when needed for furnishing blank spaces, or newly-purchased trees can be similarly utilised. It is not too late to practise root-lifting, or to raise trees the collars of

which have sunk several inches below the surface. The collars and with them the bulk of the roots being deeply buried is one of the principal causes of the trees having the "yellows;" bringing them up to nearer the surface and a free use of fresh soil are the best remedies for this evil. Let the collars be rather above than in the least bit below the level of the border. All houses should be kept as cool and airy as possible, having to turn on heat for the benefit of other occupants of the house, especially if air is not admitted freely, being a not unfrequent cause of bud-dropping. No excitement to sap movement ought to be given till the time has arrived for starting the trees, and a sharp touch of frost will do good.

PRACTICAL.

PLANT HOUSES.

AMARYLLIS SEEDLINGS.—Where seed was sown as advised in a former calendar some weeks ago, the young plants should now be fit for potting off; to keep them in the seed-pan till the turn of the days would be a mistake. By that time there would be more risk of injury to the roots in the process of disentangling them, whilst by potting now they will be preserved intact. Ours have been potted this week into 2½ inch pots. I prefer to pot them singly, although I know some successful cultivators put a few together into larger pots, but this means that more soil is taken up than is absolutely necessary. Besides this, in giving the succeeding shift in the spring there is far less check to the growth when potted separately at first. Our seed was kept in a stove temperature from the time of sowing and the seedlings will remain there through the winter, as watering is more easily attended to than if in pits. I find a good place to be on a shelf about 1 foot above the hot-water pipes; in that position they dry up sufficiently to keep the soil in good condition. In our case the rate of germination has been 86 per cent. With this not the slightest fault can be found.

YEARLING PLANTS AND FLOWERING BULBS.—Last year's seedlings, now about fourteen months old, have made most satisfactory progress. These by about February will be fit for 6 inch pots. To pot these now would be a mistake, as the growth is not sufficiently active. They have not had any rest from the seed stage, nor will any be allowed for another twelve months. These plants will remain in a heated pit with a night temperature of 55° to 60°, and be plunged in cocoa fibre to the rim of the pots. An occasional watering will be given to keep the soil sufficiently moist so as to preserve the leaves from turning yellow. Older bulbs of over two and three years' growth have been taken out of the heated pit and laid on their sides in a late vinery where the night temperature is about 45° or 50°. These are now going quietly to rest prior to starting again for flower in the spring. One of the greatest enemies to *Amaryllis* culture is the mealy bug; where the plants are infested with this pest every effort should be made to dislodge them. A good plan about now is to carefully remove the oldest and outer scales, not too severely, however, and then to syringe the crowns of the bulbs with hot water. So long as the syringe can be held comfortably no harm will come to the bulbs.

OTHER AMARYLLIDS.—Of these, *A. alicia* will be now in flower or approaching that stage; at such times a little more warmth will assist in the development of the flowers. This variety being more of an evergreen in its habit requires to be kept moist at the roots at all times, more so, of course, during growth; moderately so whilst no growth is apparent. By fertilising the flowers seeds may be obtained, this being a good way of increasing the stock, as in the case of those first alluded to. *Vallota purpurea* (otherwise *Amaryllis purpurea*) should now be kept fairly on the dry side. As this variety can be wintered safely and well in a cool greenhouse, hardly any water will be needed until the spring. I have found a greenhouse shelf to be a good place for the *Vallota*. It is a plant liable to be infested with the *Eucharis mite*, or another insect very similar to it. To this,

I think, is to be attributed its disappearance from many gardens. Where there is any suspicion of its existence, I would at once commence operations against it by first shaking the bulbs out of the soil and then adopting the hot-water remedy as for mealy bug. After this has been attended to, the bulbs should be laid in sand and another turn or two be given before repotting into smaller pots than formerly.

EUCCHARIS AMAZONICA.—Where there is a good stock of well-established bulbs which have recently made a satisfactory leaf growth, and thus far have not shown signs of flowering again, a little more heat should be given them; this with a slightly perceptible increase in the water supply will frequently induce them to bloom. If spikes appear within about ten days or a fortnight, there will be a good prospect for the supply at Christmas. In advising increased warmth and somewhat more liberal watering, it must not be inferred that I am in any sense in favour of what some would call a previous resting in a cool house, or that the plants should be dried up to encourage them to flower. Either one or the other of these extremes will in time produce such a rest as will in no degree be desired. If mealy bug be troubling these plants do not give it any peace, but endeavour by frequent sponging to eradicate it before spring comes round again.

OTHER BULBS.—Of these it is well to draw attention to *Urceolina pendula*, a bulbous plant which for this season of the year is not only distinct and interesting, but of good service also. If not already showing for flower, it will not be long in doing so. Since the dying down of the foliage no water will need to have been given, but when the spikes appear an occasional watering will prevent exhaustion in the bulb and encourage the production of finer flowers. By fertilisation seeds may frequently be ripened, this being a speedier method of increase. Where the Nerites have ceased flowering the leaf growth will be appearing; this must be carefully attended to, for upon its perfect development depends the success of the future season. Slightly more warmth than that of an ordinary greenhouse should be given to encourage this. *Lachenalia*s may be safely left in cold frames for a while longer. So long as they are just protected from actual frost they will be quite safe. It is the better plan to keep them as near to the glass as possible with liberal ventilation in fine weather. JAMES HUDSON.

THE KITCHEN GARDEN.

BRUSSELS SPROUTS.—Brussels Sprouts are far better than was at one time thought would be the case, and on heavy soils, instead of their being below the average, they are better than in the generality of seasons. Where the plants were set out too closely together, the chances are that many of the leaves will decay, and allowing these to remain, besides having a very untidy appearance, will certainly affect the quality of the sprouts. A free circulation of air will, therefore, be assured, and to the benefit of the sprouts. To pull away leaves which are not decayed is a very unwise proceeding, as these, besides assisting in the swelling of the sprouts, form a very good natural protection in time of severe frost. It is a mistake to cut off the tops of the plants for greens at any time during the winter, as the life of the plant is endangered by so doing, frost taking a greater hold of the plants. Decaying leaves should also be cleared away from all green growing crops.

CELERIAC.—Although no harm will come to the roots where these are well earthed up, and further protected with a covering of dry leaves in case of a spell of severe frost, it will be well to lift a portion and store in sand in a cool shed for present and early winter use.

GLOBE ARTICHOKEs.—Every season there are complaints of the stock of Globe Artichokes being either killed outright or so greatly injured, that they are very late in starting into growth, and then only in an enfeebled state. As Globe Artichokes come much earlier from strong stools, an early supply of suckers being also

assured, it is much the wisest plan to look well after these, as, however useful plants raised from seed may be, they are not to be compared to a true stock from suckers. Wet or decayed manure should not be used for protecting the plants in case of severe frost, this being as bad as no protection at all. Some rather long and dry litter is the best, the clumps being surrounded with this, a little also being sprinkled over the tops. Failing litter, dry leaves may be used, with a little soil thrown over them to prevent their being blown away.

LAYING BROCCOLI.—The warm state of the ground and the subsequent rains have caused this to grow very quickly. Plants where growing on rising ground or in an open and exposed site are better able to withstand severe frosts than those growing in low-lying gardens, and where perhaps the ground has been too heavily manured. In the majority of cases a sufficient check to exuberant growth will be gained by thrusting a spade under the plants and gently raising the soil, afterwards treading it down firmly around the stems. It is the plants with long stems that are in most need of a check, as these often are killed, whilst others of sturdier growth are saved. These are best laid with the heads pointing northwards. In this case commence at the north end, taking out a shallow trench, and then heeling the plants over, the soil, as each row has been laid, being placed upon the exposed stems.

STORE POTATOES.—Where Potatoes are stored under cover in sheds and such like places they are apt, especially if in too large heaps, and also when first taken up, to become over-heated. Now as this is much against their quality, it is very advisable, now that more time can be spared, to turn the bulk well over, also laying them out more thinly, as in this way the quality is preserved, and very often much improved.

SPRING CABBAGE.—The earliest planting is now making considerable headway on account of the abnormally fine and open weather. In their case it would be advisable to mould up the rows as a protection from frost. A. YOUNG.

ORCHIDS.

Now that we have entered into November, the sunlight, which was excellent in October, will fail us, and if a long-continued spell of dull, cold weather sets in it is not advisable to force the temperature up by overheating the hot-water pipes. There is now a grand display in the Cattleya house from the different varieties of the old *C. labiata*. Most growers will have found out for themselves that there is great variety amongst the imported specimens, and that the very handsome forms with broad sepals and petals richly tinged with purplish rose and broad deep coloured labellums are few, while the poorer varieties are many. Still there is always the anticipation of something out of the common turning up amongst the unflowered varieties, and all of them are very bright and beautiful at this season of the year. Moreover, many of them are sweetly-scented, and it is surprising how they vary in this as they do in the form and colour of the flowers. At a recent meeting of the Orchid committee it was a very interesting study to contemplate the different varieties of this Orchid in their form and colour. These handsome Cattleyas with the lovely varieties of *Dendrobium Phalaenopsis* fill our Orchid houses with the most attractive flowers at this season, which a few years ago existed only in the imagination. We must also be thankful for *Cattleya Bowringiana*, a quite distinct species also flowering now; it is altogether distinct in character even from *C. Skinneri*, which is the species most like it. There is also a considerable difference in the form and colour of the flowers of this variety; both of them seem to be of easy culture. When there are so many Orchids in flower, it is better to keep the atmosphere well on the dry side, so that the flowers may last for as long a period as possible, but even as regards the health of the plants it is well to err on the dry side at this season, and the over-anxious cultivator

will probably give the objects of his care too much rather than too little artificial heat. The deciduous *Calanthes* are looking remarkably well and throwing up very strong spikes, but they do best in the warmest houses until the flowers commence to open, when they may be placed in the *Cattleya* house. Those who do not care about high temperatures may find much pleasure in the cool house at this season. There is always plenty of flowers upon the *Odontoglossums*, especially the varieties of *O. crispum*, which with good care last long in beauty. But it is well to consider the health of the plants. When it is seen that the bulbs are shrinking owing to the spike of flowers pumping the juices out of them, it is better to cut off the spike and use it indoors.

A plant I think highly of is *Maxillaria grandiflora*. The flowers are white with the exception of a coloured lip, the plants grow with great vigour on the back stage of the house, and each plant produces scores of its handsome flowers. *Cypripedium insigne* and its varieties also do remarkably well in the cool house, the flowers lasting a long time in good condition. The recent importations of this old species have given several very distinct varieties, much excelling the original type in beauty, and it is yet, both for decoration and for cutting, the most useful of the *Cypripediums*. Slugs and other depredators are usually very active at this season in the cool house, and one or two of them can soon do a great deal of damage to valuable plants. As a precaution I place any choice specimens on an inverted flower-pot, which has been placed in that position in a saucer of water, and if care is taken not to allow the plants to come into contact with others not so protected they are safe from injury. I find slices of Carrots laid in the haunts of the slugs are very attractive. They may be found feeding on them at night, and as often as not concealed under them the next morning. I have previously urged the importance of keeping the plants free from insect pests. It is not safe to use tobacco paper for fumigating, as if it is applied strong enough to kill the insects, it also injures the plants. Plants of the various species and varieties of Orchids that have passed into their resting period must not be altogether forgotten, as much mischief is done by what may fitly be termed the over-resting system. This may well be observed in the different species and varieties of *Dendrobium*. The short, thick-stemmed varieties can remain plump much longer than those with slender growths, of which *D. Falconeri* may be taken as the extreme limit. This species may be kept almost without water during the winter, and as a result flowers will be produced abundantly the following season, which will so exhaust the plants, that the growth subsequently will be very poor, and a few seasons of such treatment will quite ruin the constitution of the plants. Even the truly handsome *D. Wardianum* might be kept in vigorous health longer than it usually is if care was taken to rest it just enough—neither under nor over. It is not well to keep them in a place too cool or too dry, and when the bulbs begin to shrivel, give them a little water—in fact, one good watering, allowing them to become thoroughly dry again before they get another. *D. nobile* in its varieties is one that suffers least in health from a rest. The plants may be placed in a warm corner of the greenhouse out of the reach of draughts, and they do not need any attention until they are placed in heat to start them into growth again. They should all be placed in a light position when resting—near the roof-glass if possible. J. DOUGLAS.

Iron spouting and roofing to sheds.—For the past seven years we have made some considerable experiments with iron roofing for farm buildings and garden sheds, and could hardly have suspected it is so bad in use as it has proved. A strongly framed shed in an open pasture was covered with the best quality of iron, not galvanised, the manufacturer telling us that dressing with black paint would save it for many years.

We have only had it up three years, and already the rust is eating into it. Some sheets of which the spouting was of the best quality, but not galvanised, have rotted away like so much blotting-paper under rain. Considerable expense now devoted to the roofing of sheds with galvanised and ungalvanised iron is wasted. Iron is a precious material in its proper place, but everything about a roof should not be of iron. It is enormously cheaper in the end to cover with tile or slate, and much prettier to use the very old-fashioned material, shingle, which is in common use in Switzerland, Northern Europe, and America. Had our guttering been painted about twice since it was fixed, it would have been better, no doubt; but who could devote his time to watching and painting the spouting of sheds? Cast-iron guttering will stand much longer than wrought iron, as it is nearer the natural iron ore; but even that will not stand long without being painted.

KITCHEN GARDEN.

ENGLISH TOMATOES.

WHATEVER may be said about the preference given of late years to novelties of a coarse character among the majority of vegetables, such strictures do not rightly apply to Tomatoes. Not only are the newer varieties of the latter that have come to the front more remarkable for other good qualities than great size, but it is also worthy of note that judges at flower shows are following the line set in the markets, that is to say, good form and colour are the points most considered. The Tomatoes that sell the most readily and realise the best prices are not those which are half a pound and upwards in weight, but rather those which run from four to six to the pound, always provided they are of good form, quite sound, rich red in colour and not too ripe. In Ham Green Favourite we have a model variety for all purposes, though more recent introductions are somewhat superseding it. This very popular variety is of fairly strong growth, very free-setting and productive, the larger fruit being good enough for exhibition and the rest just what suits buyers. Sutton's A 1 with me has repeatedly proved a distinct improvement on Ham Green. A 1 possesses a stronger constitution (this being most apparent in either poor soil or in the open), is equally productive, the later-formed fruit not falling off much in size, the good form—smooth, round, inclining to obovate—colour rich red, and quality being very similar to that of Ham Green. A 1 was also good in the open last year, this being when other varieties failed badly. Challenger has during the present year gained golden opinions, this also being in the way of Ham Green, but quite distinct from both that and A 1. It is a grand cropper, there are no coarse or ugly fruits, and not so much cracking going on as with several other varieties that could be mentioned. Challenger is good for either early main-crop or late planting, and is likely to be a favourite for some time to come, albeit it is not quite large enough for exhibition. Chemin, a variety raised by Vilmorin and Co., Paris, is sometimes said to be identical with Ham Green and occasionally with Challenger. There is certainly a strong family likeness, but when grown together by the hundred, they prove distinct enough. Of the three, Chemin is much the most liable to the black spot or disease that attacks the point of the fruit, and cracks more than the rest.

The Perfection family is a fairly large one, but as far as market growers are concerned is not nearly so popular as formerly. Those who

want fairly large, heavy, well-formed fruit, say, for exhibition ought still to grow the best selections of Perfection, of which there are several in the trade, and further, should take an early opportunity of pinching out all the malformed flowers, or otherwise the largest fruit will also be the ugliest. Hackwood Park Prolific is very nearly allied to the Perfection type, being, however, somewhat coarser and, I think, heavier cropping than the latter. Varieties that are more or less corrugated are numerous, and although, owing to the form of the fruit, not so popular as the smooth round sorts, they are yet remarkably free setting, heavy cropping, and fairly good in quality. The old Orangefield is not yet wholly discarded, and this dwarf early form much resembles the more recently introduced Open Air and Earliest of All, the latter having the advantage in point of size only. Personally I much prefer the American raised Ruby, alluded to on p. 339, to either of them. Conqueror is a heavier cropper than either of the three first mentioned, but not more so than Ruby, and is scarcely so good in form and quality. All the same, it will not be quickly discarded in private places where it has succeeded remarkably well, early and late, under glass as well as against open walls during the summer. To all appearance the newer Ladybird will have to be included in the Dwarf Early Red section. I have had no experience with it as yet during the winter, but under glass and in the open no very remarkable or exceptionally fine qualities have been developed. It is only fair to add that it was certificated owing to the impression conveyed that it is an extra good winter fruiting variety. The Large Red type is distinct from the Orangefield or Early Dwarf Red group, and comprises several reliable and good forms. At one time the old Large Red, and of which Earley's Defiance proved a good selection, was principally grown in the Channel Islands for market, and is still preferred by some. It is of fairly strong and very productive growth, the majority of the fruit attaining a good size, and it is a difficult matter to name a smooth round variety that, plant for plant, will produce so great a weight of Tomatoes. If the best prices could be obtained for them, then Large Red should still be grown, but corrugated fruit will not sell unless at reduced rates. Webb's Sensation, a decided improvement on Large Red, is one of the very best for planting in poor soil or in positions that the more delicate Ham Green family does not thrive in. Although a strong grower, the crops set freely, the fruit being large, somewhat corrugated, though not objectionably so, and heavy, the quality also being satisfactory. Several other improvements have been made by private gardeners on Large Red, two of the best of these being raised by Mr. Crook, Forde Abbey, Chard. From what I have seen of them at Forde Abbey, coupled with my own experience, one or both of them should prove very valuable for winter culture. The fruits set in great clusters, are moderately large, slightly corrugated, and of a bright red approaching to scarlet.

Small or comparatively small-fruited varieties are not likely to long remain popular, especially seeing that several of them are apt to come hollow, the quality also being indifferent. Those that are of the least value, although very heavy croppers, are Chiswick Red and its synonym King Humbert, Vick's Criterion, Golden Nugget, and Horsford's Prelude. The last-named is quite distinct from Chiswick Red, the fruit being flatter and of better quality; but, seeing that the newer Conference comprises all its good

qualities, and is further improved by having Ham Green blood in it, it is no longer wanted. Opinions vary considerably as to the value of Conference. It is undoubtedly one of the best for open-air culture, the plants producing extra heavy crops of medium-sized, well-formed fruit, the quality also being very satisfactory. Under glass it is not altogether an unqualified success. Unless grown very strongly the fruit as a rule is too small, and those who, fortunately, have made a selection from Conference that is equally prolific without extra high culture and the fruit somewhat larger, will do well to grow it extensively. I have seen plants of Improved Conference fully 10 feet long furnished with long clusters of fruit from the top down to the ground. The racemes lengthen out surprisingly, those first formed sometimes being 1 foot or more in length.

Of pinkish red-fruited varieties the best is still to be found in Dedham Favourite, this being particularly good for open air culture. The plants produce a heavy crop of smooth, round fruit, the quality being excellent. Market Favourite is of much the same colour, and is, therefore, wrongly named, none but rich red fruit finding favour in the markets. Of yellows there are not many to allude to. Large Yellow is an enormous cropper, but uneatable. Golden Queen is of much better form, or good enough for exhibition, and of better quality, while the prettily-tinged Blenheim Orange is also good to eat. Yellow King is only another name for Yellow Trophy, which is of little value. Red Currant, Red Cherry, Yellow Cherry, Yellow Plum, Pear-shaped, White Apple and Turk's Turban were, I believe, all introduced into and not raised in this country. They are pretty enough when growing, but very poor things when the flavour test is applied.

W. IGGULDEN.

A GOOD TOMATO.

AMONG the several varieties of Tomatoes grown this season, including different types of Perfection, Ham Green, Challenger, &c., all thoroughly good sorts, none has done better than a sort that came to me under the name of Barpee's Champion. It is a strong growing variety with very deep green foliage, a very free setter, fruit quite smooth and regular, and over average in size, a rich purple-scarlet in colour, thin skinned, flesh firm and solid with few seeds. The flavour is exceptionally good; indeed, for salad no other variety was used all the time plenty of this was to be had. I did not secure the seed until rather late, and am not able to give, therefore, a thoroughly decided opinion as to its cropping qualities given a long season, but should say there are few sorts from which a greater weight of fruit could be taken. The very thin skin renders it a little inclined to scald under the direct influence of a very powerful sun, and no more foliage should be removed from either outdoor or indoor plants than is absolutely necessary. I would strongly recommend a trial of this Tomato another year to all those who want a thoroughly reliable variety of excellent flavour. Some years ago a sort was introduced under the name of Dwarf Champion. It proved a very serviceable variety, a very heavy cropper, but it is far behind the American Champion for shape and delicacy of flavour, and the latter would also throw a greater weight of fruit plant for plant. It is a strong and fast grower. As outdoor Tomatoes continued to grow and set freely later than usual, there will probably be a good percentage of green fruits on the plants at the approach of frost. It may not be generally known that this green fruit will make an excellent pickle if placed in a jar or bottle with alternate layers (thin) of salt, the vessel to be then filled up with vinegar. Whilst on this subject I may be allowed to add a recipe for an excellent

Tomato chutney that is easily made. Draw the juice from 9 lbs. of Tomatoes, add to the pulp (the juice must not be used) 2 lbs. of Apples, half a pound of raisins, and half a pound of Onions thinly sliced, half a dessertspoonful of cayenne, one table-spoonful each of mustard seed and salt, and rather over 1 pint of vinegar. Place all in a preserving pan, bring gently to the boil, and simmer for two hours. Place in small well-dried bottles and cork tightly

E. BURRELL.

Claremont.

The Japanese Pole Cucumber.—This is one of the novelties of the present season, and we have given it a fair trial from seed sent us by Messrs. Carter. It is called the Pole Cucumber because it will climb sticks like a runner Bean. We have some large plants that have grown in this way, and others running over the ground as ordinary ridge Cucumbers. It is evidently a very hardy kind, but when fit for cutting, its fruits with us have been too bitter to be pleasant eating. It would appear to have a value, however, as a gherkin for pickling, the little fruits being just about the right size for such a purpose, and by keeping them cut, no doubt a great quantity could be obtained, as the plants have great vigour. Full-grown fruits become very thick, are about 4 inches long, and if allowed to hang, they become netted like a Melon.

Field Mushrooms.—I have never seen or heard of such enormous crops of outdoor Mushrooms as there are this year. Bushels may be gathered within a radius of a few yards. Tons must have been gathered by the country folks and sent off by rail to the populous centres. A dealer of my acquaintance sells them at 1s. 2d. per lb. The hot and dry summer caused the spawn to run, and now the warm rains, with a comparatively high temperature, are causing the Mushrooms to appear in abundance.—A. YOUNG.

Market Favourite Carrot.—Sown at the same time as the old Nantes Horn—still a variety of great excellence—this sort soon takes the lead in growth and is ready for drawing a fortnight sooner than its companion. It belongs to the stump-rooted section, is perfect in symmetry, carries a fine colour, and, what is more, its fine flavour and almost coreless centre render it a first favourite in the kitchen.—JOHN CRAWFORD.

Spring Cabbage.—Owing to the genial rains of late, Cabbages have made rapid growth; indeed, I fear with mild weather many of the earlier planted will be ready for use in November instead of March. There is yet time to make up somewhat for this rapid growth, as if a good number of plants are raised, which is usually done in most gardens, a late-planted bed of spring Cabbage will prove acceptable. I am aware it is rather late, but with care in lifting and planting firmly, there will be few losses. When planting such kinds as Ellam's—one of the best of all—much closer planting may be practised. Though the heads of the late-planted lot will not be large, they will be useful if there should be a scarcity of spring vegetables. Ellam's turns in so rapidly, that there will be only a slight break between this and the earlier planted lots. I would also advise pricking off out of the seed-beds any left over. These will winter better and be useful in the early spring.—G. WYTHES.

Tomatoes.—With Mr. Iggulden's disapproval of Ponderosa I heartily agree. It should never be grown by anyone who wishes to have credit for being a judge of Tomatoes. With respect to Livingstone's Perfection, does that variety differ from what was several years since grown under the name of Livingstone's Favourite? I first obtained that—a very full, smooth, handsome deep red fruit—from Mr. Dempsey, who brought over samples from Canada with Apples, which were exhibited at the South Kensington Colonial Exhibition. I always regarded that variety as the parent of the Perfection type. It was as handsome as fruits of Excelsior, but larger; it was also a good cropper. Most certainly we have since its

day developed cropping qualities and greater solidity of flesh, but beauty, form and colour have made very little advance. As to cropping, I think we can hardly excel what the best forms of to-day will produce. We may yet develop greater solidity of flesh at the expense of seed production, but that is of no great consequence, as seed is very plentiful. We much want to increase flavour, but that is most difficult; indeed, I fear Tomatoes and Melons are in the same boat—we shall not better them in respect of flavour. One thing is certain: the Americans now have nothing to excel what we have raised for ourselves.—A. D.

Turnip Veitch's Red Globe.—This is a good Turnip without a doubt; no kind has this year given me more satisfaction, not even Snowball, which may possibly be quicker somewhat in turning in for first early use. This selection of the Red Globe cannot be too strongly recommended for private gardens, where mere size should never count as an important factor, but quality be given the premier position. As with other crops during the very hot weather, I found that repeated watering even of the Turnips paid well. Birds were very troublesome as the seed was germinating, compelling the use of nets as a protection for the first two or three weeks.—G.

COOL TREATMENT IN MUSHROOM GROWING.

ON March 18 last there appeared in the pages of THE GARDEN an article by Mr. W. Iggulden on Mushrooms under cool treatment, and which, I believe, was allowed to pass unnoticed. The article was short, but nevertheless valuable, and one which I would strongly advise all young gardeners and all persons about to embark in Mushroom growing for profit to very carefully study. The article suggests some very difficult and interesting questions, such, for instance, as the undoubted fact that an abortive Mushroom bed may yet contain dense masses of what, to all appearance, is living and healthy mycelium. In the first place, however, I shall refer to the main features of the article in question which allude to the cool treatment of Mushroom beds. It is very hard to persuade many people that the wisest and most profitable way of producing Mushrooms is to grow them under cool treatment. They insist that it is necessary to have the structures kept hot, and incur great expense in the purchase and fixing of hot-water pipes, refusing to recognise the fact that an ample supply of Mushrooms can be kept up throughout the year in properly constructed sheds entirely without the aid of fire-heat. Mr. Iggulden instances a bed spawned at a temperature of 75°, which in less than a week became quite cold and afterwards frozen, but which, with the return of a warmer temperature, yielded an immense crop of Mushrooms. My own experience during last winter was almost exactly similar. During the months of November and December, which proved extremely wet, I built a large shed, making the bed and spawning it in sections as the work of building proceeded. Everything was saturated with wet, floor of shed and timber used in its construction, whilst the manure itself was wet enough to frighten the most professional Mushroom grower. A thick coating of straw was placed on the bed after spawning, which was done at a very low temperature, the bed becoming perfectly cold very soon afterwards. Hard frost set in at the beginning of January and continued throughout the month, the straw on the bed and the soil casing becoming stiff and icy, and the inside of the roof clad with icicles. On February 1 the frost was succeeded by rain and much milder weather, and the first

picking of Mushrooms was made on the 8th, from which date till the first day of July the bed kept in bearing, the result being an extremely heavy crop of as fine, large, and succulent Mushrooms as any grower could wish for. The shed being constructed entirely of wood with a tarred felt roof-covering, of course was unfitted to resist the entry of frost to the bed, but given a shed with brick walls and thatched roof I am of opinion that Mushrooms could be produced in the dead of winter without the aid of fire-heat, provided a good straw covering be placed on the bed during very hard weather. As to the superior quality of Mushrooms grown under cool treatment over those produced under artificial heat, there can, I think, be no two opinions. For home consumption they are fleshy and full of flavour, and for market, in addition to the above qualities, they are heavy. Where proper structures are available, and care is exercised with regard to the time of laying down the beds, no one need fear, I think, to obtain a good supply of Mushrooms throughout the year without the aid of fire-heat.

Strong heat in a bed when it is spawned undoubtedly promotes rapid circulation of the mycelium, frequently resulting in the manure becoming a white mass of spawn, raising the hopes of the uninitiated to the highest pitch, but the final result is in many cases very disappointing. Mr. Iggulden says: "To all appearance the bed I have just commented upon was only slightly taken possession of by the spawn, but the manure being in a moist, decaying state afforded the requisite amount of moist food, and without which not many Mushrooms are forthcoming." This I have found to be correct in my case more than once, and I firmly believe that more failures occur from the want of sufficient moisture in the manure than from any other cause whatever. Writers on the subject of Mushroom culture invariably warn beginners against the evil effects of allowing rain to fall on the heaps of manure in the process of "making" or adding water in any form, but I can safely say that, so far as my experience goes, if water be not supplied to the dry heaps of manure before the beds are formed, the chances of a good crop of Mushrooms are very considerably lessened. I have frequently, with excellent results, watered a bed after it was spawned immediately before putting on the soil casing when I considered the manure was in too dry a condition.

Another point I imagine worth noting is the custom in some places of sifting the casing soil before placing it on the bed. I do not hesitate to condemn this practice. I have tried both ways, and find the better plan is to put the soil on the beds in a rough state just as it is dug from the fields, and without the removal of a single stone; the soil has then a less chance of becoming caked and hard by treading and subsequent watering, thereby rendering it in a great degree impervious to the delicate threads of the mycelium.

Under cool treatment, Mr. Iggulden states that after spawning sometimes a period of from two to three months may elapse before the appearance of the crop. In my experience I can amply verify this statement. I have frequently had a long wait, but it would almost seem to be true that the longer the wait the more ample the ultimate satisfaction. It would also seem futile to attempt to account for this occasional delay.

As a rule light and air are carefully excluded from artificial Mushroom beds, but I certainly do not find this of any advantage; on the contrary, sweetening a shed by the admission of air and even sun in calm, mild weather I think

benefits the crop wonderfully. How charmingly beautiful are the Mushrooms picked from a meadow on a dewy morning; how unlike the clammy produce of a dark, dank Mushroom shed or cellar. I believe the more air and light given to a Mushroom shed in suitable weather the nearer the produce will approach the clean, firm texture and bright colour of the wild plant. Of course, it is not admissible to give air in dry, windy weather, as the rapid dissipation of moisture from the beds would be fatal to good results, but I am of opinion that in calm, mild weather it would almost be impossible to admit too much air.

J. LOWRIE.

Autumn v. spring-raised Cauliflowers.—Like A. Young, I am still in favour of autumn-

gardens. The old Early London and Walcheren open more gradually, and one can cut and come again sometimes for weeks together. Moreover, their delicate inner leaves, which I think are a mark of high quality, folding over the flower, protect it from the sun's rays, thus rendering artificial shading unnecessary. Those who have no handlights can always winter a few in a frame. The labour of this is not great, and if carefully transplanted in spring and screened from cutting winds, the difference in the time of cutting will be very little.—J. CRAWFORD.

PASSION FLOWERS FOR DECORATION.

I AM afraid that these beautiful flowers are frequently passed over for purposes of decoration in a cut state. To allow this to happen is, however, a great mistake, whether it occur from

(Granadilla), which is a prince of the family, a truly noble variety, whether it be for the sake of the flowers alone or in conjunction with its handsome-looking fruits. *P. edulis* also is a variety that can be strongly recommended; the flowers, it is true, are not so beautiful as some, but the freedom with which the fruits are produced makes amends for this. Take, for instance, the fruits of *Passiflora cœrulea*, of a beautiful golden yellow, and those of *P. edulis*, of a deep purple, and group them as in the case of the flowers, and a unique effect would be the result. One of the most profuse of the smaller varieties is *P. kermesina*, which is more adapted for a display on the plants than in a cut state. *P. trifasciata* is an ornamental-foliaged variety with white flowers; its foliage would be useful mixed with the flowers of other sorts also. *P. onychina* (*amethystina*) is, as a greenhouse variety, a fitting companion to *P. cœrulea*. Another excellent variety for the cool house is *P. Impératrice Eugénie*; it wants more room, however, than some kinds. Another variety still, and one which is strongly recommended, is *P. cœrulea racemosa* (this might possibly be the one in the illustration). Several others could be named, but attention has been drawn to a sufficient number to indicate their collective good qualities. One fact remains to be noted. It is that of the arrangement in the cut, which is an excellent example of free and informal grouping, wherein both flowers and foliage of the same plant are employed to an excellent purpose.

J. H. G.

STOVE AND GREENHOUSE.

DISTINCT PELARGONIUMS.

SOME three or four years ago no Pelargoniums of the zonal section attracted so much attention as *Souvenir de Mirande*, which was raised in France by M. Herault, and sent out by Messrs. Thibaut and Keteleer in the spring of 1887, but a couple of years elapsed before it was generally known in this country. The colour of its blossoms was somewhat of a puzzle, being variously described as salmon, salmon-pink and shrimp-pink, in all cases with a white centre. Anyhow, when once seen it rapidly advanced in popularity, and was soon to be met with in most gardens. As might be expected, other varieties of the same class soon put in an appearance, so that there are now several forms in cultivation, and Messrs. Cannell showed a very interesting selection of them at the meeting of the Royal Horticultural Society on October 10, and at the early Chrysanthemum show held at the Aquarium on the following day. The varieties represented were the first of its class, *Souvenir de Mirande*; *Jacques Callot*, a larger flower than the preceding, and of a slightly deeper tint; *Mme. de Boudeville*, to which an award of merit was given last autumn; *Etoile de Lyon*, distinct from any of the others, but difficult indeed to describe; and *M. Dutetail*, with more red in the petals than any of the preceding. With these Messrs. Cannell showed a seedling of their own, a finer and richer coloured flower than any of them, and when sent out it will no doubt be much sought after. Pelargoniums of this class lead themselves to winter blooming as well as any of the other varieties, but one of the best for this purpose I did not notice among Messrs. Cannell's exhibit. This is *M. V. Noulens*, which was sent out in 1890 with such a glowing description, that there was a general feeling of disappointment when it flowered. The blooms are somewhat smaller than those of *Souvenir de Mirande*, not quite so perfect, and a good deal deeper in colour. It has, however, proved to be a good winter flowerer, the distinct shade of its blossoms being than especially noticeable. *Souvenir de Mirande* and all its progeny as

Passion Flowers loosely arranged.

raised, handlight-protected Cauliflowers for early summer supplies, and should, indeed, be unwilling to abandon that system. I must admit that since the wet summers commenced and all kinds of seeds have been indifferently harvested, autumn-sown plants have been less reliable than formerly and premature hearting more common. But the spring-raised plants of the small forcing section are by no means free from this defect, and will often disappoint. Only last spring I sowed seed of three separate strains in heat in February, and when large enough, potted the seedlings separately into small pots, gradually hardened them, and finally transferred them to a sheltered position out of doors, screening with Spruce boughs. I felt sure of success at any rate with one of the three lots, but was rewarded for my labour by the entire lot forming heads no larger than a 5s. piece. Had it not been for a handlight batch of Walcheren, I should not have had a single early Cauliflower to cut. Doubtless the dwarf early varieties are most useful in their way, but they are very liable to turn in all together and to afford no succession. This suits market growers, but is an evil in private

actual oversight or from an idea that they are unfit for the purpose. True, they do not last so long as many flowers, but this also occurs in the case of other plants. The blossoms of many a Rose, for instance, have lost their beauty at the expiration of the second day. Possibly it may not be known to some readers that blossoms of the Passion Flower will, if cut soon after they expand, last in good condition until the close of the second day. This period of time may by some be considered as fugitive, but it should not be, nor should the flowers be passed over on that account. In the accompanying illustration two varieties at least are clearly discernible; these are *Passiflora princeps* (known also as *P. racemosa*) and *P. cœrulea*, or its white variety, *P. Constance Elliott*. These are standard kinds, the one for the stove or temperate house, the other for the cool house or for verandahs and the open wall in favourable localities. To these should be added *P. quadrangularis* (known also as the

far as I know have a tendency to run up tall, so in order to ensure good plants they must be stopped rather freely when young. Though our neighbours across the channel send out a great many new varieties of zonal Pelargoniums, yet they appear to aim at novel tints more than good-shaped blossoms, for many of the varieties sent here from the Continent are greatly inferior in shape to those sent out by English raisers; indeed some of the flowers are so winged, that they would be considered to belong to the nosegay rather than the zonal section. Still, as above stated, the colours are often very distinct. H. P.

Breaks in colour of Impatiens Sultani.—It seems likely that this very useful plant will soon give us a great variety of colour. The produce of a single packet of seed sown this year gave several distinct shades, most of them darker and less beautiful than the typical colour, but one is a distinct gain, the flowers being of a delicate salmon-pink colour that is very attractive, while they have lost none of the satiny sheen so noticeable in the flowers of the parent plant. This class of the Balsams has done very well out of doors this year, but I doubt their capacity to withstand the weather of an ordinary summer, and should be chary of using them extensively in prominent positions. Their proper place is in the greenhouse, and they also make capital room plants if given a fairly light position.—J. C. T.

Dalechampia Roezliana.—No particular season can be assigned for the flowering of this euphorbiaceous plant, for though it generally blooms with the greatest freedom in the spring or early summer, yet it is now beautifully in bloom when flowers in the stove are not so numerous as is the case earlier in the year. It is a small growing plant of a shrubby character, that, given the usual treatment accorded to the general run of stove plants, will succeed perfectly. As with many of its allies, the showiest part of the inflorescence is not the flowers themselves, but the large leaf-like bracts which accompany them. These bracts are of a bright rosy pink colour, and being borne in great profusion, they impart a pretty and uncommon feature to a specimen. About a quarter of a century ago, when this *Dalechampia* was first introduced, it was thought a great deal of, and was grown by nearly everyone with a suitable structure; but after a time flowering subjects gave way to fine-foliated plants, the newer *Dracenas* and *Crotons*, as well as other things of this class, which made their appearance in such numbers from the South Sea Islands, and bounded into popularity, being answerable for this. Then the *Dalechampia* was not nearly so much grown, and one may go into many gardens and not see it represented, though it is really very bright and pretty. There is a white-flowered form, but it is not nearly so attractive as the other. Both cuttings and seed afford a ready means of propagating it.—H. P.

Tydeæ Marquis de Guadiaro.—Though *Isoloma* is now, I believe, regarded as the correct name of that beautiful flowering group of Gesnerads long known in our gardens as *Tydeas*, this last-mentioned generic name is now so firmly fixed, that it is not likely to be discarded, except in the case of botanic gardens, or such places where the continual altering of old established names forms such a stumbling-block. A coloured plate of one of the very best *Tydeas*—*Madame Heine*—was given in *THE GARDEN*, Vol. XXXIV., but the form under notice—*Marquis de Guadiaro*—differs considerably from that illustrated; indeed, it is one of the most distinct *Tydeas* that I have seen. The colouring of the flower is pale yellow, but it is so heavily reticulated with maroon and flushed with crimson between the veins, that little of the ground colour is to be seen except towards the edges of the petals, where the marking is a little less dense. Its most distinctive feature is, however, not in the colouring of the flower (as there are several others in the same way), but in the fact that the edges of the petals are so deeply cut as to form quite a

fringe, while in the commonly cultivated forms they are almost, if not quite, entire. The variety in question is not at all common, for though the name occurs in some catalogues for the last six or seven years, I have never seen it until the present season. Like its allies, it is especially valuable for flowering during the autumn and winter months. To bloom at this latter season they need the temperature of a cool part of the stove, or at all events an intermediate house, otherwise they will go to rest, and in this state their caterpillar-like rhizomes can be easily sent by post, it thus being a very suitable season for purchasing where it is intended to commence their culture. Sown in the spring, seed saved from a representative collection will give a very varied and interesting assortment of flowers.—H. P.

Abutilons.—Although there are many grand subjects for winter flowering, I think these are thoroughly deserving of more attention than they generally receive. Very few of the numerous greenhouse shrubs afford more variety of colour or produce so many blooms over the same length of time. From now until next May one may be certain of a crop, and as they are well adapted for a temperate house or conservatory, and are particularly free from insect pests, it is indeed strange that we do not meet with them more frequently. Grown in large pots or tubs, *Abutilons* are easily managed. My plants have just been taken under cover, and are already throwing a quantity of flowers. There will not be the slightest break in this supply throughout the whole winter. Against the back wall of a conservatory, or stood in groups in any corner, they have a unique and pleasing appearance. Almost any compost will suit them, but they enjoy a generous supply of liquid manure while in full growth and bloom. Treated similarly to *Chrysanthemums*, they provide variety of blossom, and also look well when placed in groups of the former flower. All through the summer they will do well in the open air; indeed, full exposure to the sun produces shorter and better matured wood, which provides a larger crop of bloom during the winter and early spring. Each May I prefer to knock them out of the pots and considerably reduce the balls. The plants are pruned back rather hard, and the new growths headed when they have all reached 3 inches or 4 inches long. *Abutilons* flower very freely from the points of all growths, and soon get leggy unless headed once or twice during the summer. As cut flowers they last a long time, but it is necessary to prevent any wet reaching the pollen-bearing parts of the bloom, as the nectar-like matter so soon becomes sticky and unpleasant, and spoils the flower.—R.

Campanulas as window plants.—When in the neighbourhood of Hastings recently we were pleased to see in the windows of the smaller houses baskets filled with *Campanulas*. It is strange that one does not see them more in larger places, although *C. isophylla alba*, the prettiest of all, is much grown as a basket plant in conservatories. The *Campanula* is very easily grown, as is evident from the specimens in stuffy cottage windows, where the shoots that trail over the baskets are smothered with bloom. *C. isophylla alba* is one of the more popular kinds for this purpose; its flowers, of the purest white, are produced with the greatest freedom. *C. muralis* we have also seen grown successfully in a window in smoky suburbs where many things failed. *C. Barrelieri*, which is similar to *C. fragilis*, is another useful type, but *C. isophylla alba* is the best. The plants require plenty of water during the summer months.

Bougainvillea in the open air.—*Bougainvillea glabra* flowered this autumn in great profusion in a little intermediate house here. Two or three shoots found their way, quite unknown to me, out through a broken pane into the open, and these grew as vigorously as those within and flowered as abundantly, though later. The bracts were of a much deeper tint than those inside. On looking over the old vols. of *THE GARDEN* I find one instance noted of this, and one of where the plant was outside altogether. The latter was pre-

sumably in Ireland, as the note was signed "Hibernian," but the exact locality is not stated. With me the *Bougainvillea* usually flowers in early summer, but this year it did not commence till August, and is now nearly, but not quite done. The flowers of this plant look charming on a white table-cloth, especially with amber light, which gives the bracts quite a rosy tint.—GREENWOOD PIM, *Monkstown, Co. Dublin.*

Oxalis lobata.—Of late years Kew has shown us many uncommon, but very desirable plants that may in vain be sought for in most gardens, and among them several very beautiful forms of *Oxalis*, one of which, *O. Bowieana*, grown at Kew, was the subject of a coloured plate in *THE GARDEN*, May 31, 1890. Accompanying the plate was a selection of the best forms, and one of those then mentioned (*O. lobata*) is just now very attractive at Kew. It is a charming little species that reaches a height of about 4 inches, the leaves being small and three-lobed, while the flowers, which are borne singly on erect slender stems, are about three-quarters of an inch in diameter, and of a beautiful golden yellow. It is a Chilean species, and hardy in the more favoured districts of England, but at Kew it is grown in pots in a greenhouse. Each pot is now quite a mass of golden blossoms at a uniform height of about 4 inches. This *Oxalis* is a native of Chili, from whence it was introduced seventy years ago, but is now very uncommon, though where hardy it is a beautiful subject for the rock-work, as well as for the embellishment of the greenhouse when grown in pots, as at Kew.

Two beautiful Solanums are *S. Seafortianum* and *S. Wendlandi*. They are really valuable plants, although, unfortunately, seen only in botanic gardens. We have never noticed *S. Wendlandi* anywhere except at Kew, where there are two splendid specimens, one in the succulent house and the other in the Water Lily house. We have described it before, but mention it again, as it seems always in bloom, bearing a free display of the heavy masses of mauve-blue flowers, which are individually of very large size. It is a superb climber for a stove, and is apparently not at all difficult to grow. The other species, *S. Seafortianum*, is more elegant. It is very free growing, the flowers also of a bluish tone, produced in charming clusters, and with considerable freedom. This is well suited for a smaller house, but *S. Wendlandi* requires a large structure to accommodate its bold growth.

CINERARIAS ATTACKED BY THE LEAF MINER.

I HAVE a very large and forward lot of *Cinerarias* well grown in every respect, but they have been attacked by the Celery fly. I examine and pick off as often as I can, but cannot get rid of them. Can you tell me of any remedy?—W. E. G.

* * * This is one of the worst diseases that these plants are subject to. Mildew is troublesome enough, but it is sooner got rid of. The difficulty lies in the grub or insect being encased in the leaves. Many remedies applied fail because they cannot reach the pest. This is the same insect that attacks the *Marguerite* or *Paris Daisy*, also *Celery*. It increases rapidly, as the larvæ soon spread, fasten upon the healthy leaf, and destroy it. The best remedy is to arrest their progress at an early stage either by cutting off the foliage attacked, or by daily going over the plants and crushing the insect between the finger and thumb. Of course the latter plan could not be adopted with large plants badly attacked, but if noticed when only just attacked, it may be got rid of as described. Another plan is to water with soot water; this checks its ravages, and a dark, healthy foliage is the result. If a close inspection is made it will be found the insect attacks the older leaves, leaving the softer and more tender ones alone. I would also point out that the plants are attacked just at the time bloom is being formed, the pots are full of roots, and with a damper atmosphere less moisture is required, and as the plants have in most cases been given extra food,

there is what may be termed a check. This is the time for the fly, and as the bottom leaves are the first to suffer, the fly soon increases rapidly; indeed in such cases I would advise a little more warmth, allowing plenty of air to circulate, as this allows of rapid evaporation. Cinerarias require more warmth than Calceolarias and such like plants. Mildew is also most troublesome in damp pits, and though by giving extra warmth green fly is encouraged, this latter is soon got rid of, and is far easier to deal with than the leaf miner. Syringing with clear soot water, also tobacco water and shading the plants, will arrest its progress. I would also advise dusting the under sides of the leaves when dry with dry wood ashes mixed with tobacco powder, and also the floor of the stage or pit as if the larvae drop they cannot live under such conditions. Dryness at the roots is bad and encourages the insect. Undoubtedly the best remedy is to promote a free growth, not allowing a check in any way just as the plants are finishing their growth.—GROWER.

Eupatorium Weissmannianum.—This autumn-blooming plant is very beautiful in a cool house. It should be more grown, as its culture is so simple, large plants being readily secured from early struck cuttings. For large houses I find one-year plants cut back answer admirably, as they give a wealth of bloom which lasts a long time; indeed, well treated, they may be had in perfection from October until March. To get a succession, propagate yearly, and by cutting the plants in a little after the first flowers are over, a second bloom soon forms, this latter not being nearly so fine as the first, but most useful for bouquets or vases. For cutting, this Eupatorium is most suitable by reason of its long slender growths and white feather-like blooms, which are very fragrant and last a long time in water. The plants should be grown in the open during the summer and housed in the autumn. I grow several other varieties and find few plants give less trouble, as they are readily propagated, and, given plenty of food and moisture during the growing season, insects pests are little seen. Old plants of this Eupatorium are sometimes grown year after year, but much finer flowers are obtained from young plants.—G. WYTHES.

Tecoma Smithi—In a small state this Tecoma is very useful for pots to add to the attractions of a greenhouse or conservatory in late summer and early autumn. Plants can soon be grown to the height of from 1 foot to 2 feet, and for these when trained to a single stem the usual $\frac{4\frac{1}{2}}$ -inch pot is large enough. Such little specimens can be used with good effect on stages or shelves, and are especially appreciated when the supply of flowering plants is beginning to fall somewhat short. The flowers are borne in terminal corymb-like heads, the corollas being tubular, 2 inches long, the outer surface reddish orange, the lobes and throat deep yellow. In a bright position this colouring renders the plant very noticeable. It is seen to best advantage in contrast with lighter tints, and as far as possible it is desirable to avoid associating the plant with others producing bright red or scarlet flowers, as the Tecoma loses in effectiveness, the flowers then appearing quite dull. A compost of loam and leaf-soil with plenty of sand suits it, an occasional supply of weak liquid manure being beneficial.—OBSERVER.

Iochroma tubulosum.—A bushy little plant or small shrub which is seldom seen in greenhouses is the South American Iochroma here named, though the very distinct colour of its flowers renders it worthy of attention. The plant is a relative of the Solanums, but there is little to suggest this relationship to a casual observer. The flowers are tubular, from $1\frac{1}{2}$ inches to 2 inches long, straight, narrow, and slightly expanded at the mouth into a white ciliated margin. The corollas are violet-purple, glossy, and very dark, nearly black, in the bud state; the calyx is pale green. The flowers are slightly drooping on short peduncles borne in the axils of the elliptical leaves near

the top of the stems. This plant succeeds in ordinary good loam, not too heavy, sufficient sand and leaf-soil or a little peat being added to keep the soil sweet and open. A light position should be allotted to it in the greenhouse during the summer months, but it must not be in too cool a place in winter; at least a warm shelf or corner should be found for it in the structure named.—OBSERVER.

New white Carnation La Reine.—All growers of these popular plants for winter flowering must have felt the need of a good free-growing and blooming white variety. Up to the present year *Mlle. Carle* was the best white so far as my knowledge goes, but at its best it is a poor grower and very apt to split its calyx. In the new *La Reine*, however, we have a long-felt want supplied. It is wonderfully free in growth, an abundant bloomer and deliciously scented. I intend growing it exclusively in future, and would recommend others to do the same. The edge of the flower is beautifully fringed.—JOHN CRAWFORD.

CHRYSANTHEMUMS.

CHRYSANTHEMUMS AT HORNSEY.

ONE of the most successful growers of the Chrysanthemum is Mr. Rowbottom, gardener to Mr. H. R. Williams, The Priory, Hornsey, and a few days ago we made note of a few of his finest flowers. We have seldom seen a collection of greater merit, the plants arranged in a longinery, chiefly given up to the Japanese varieties; the incurved varieties fill a long conservatory. Those interested in Chrysanthemums would find here all the most recent varieties and many seedlings.

The Japanese class is not grown to the exclusion of others, as every type of the Chrysanthemum is represented, particularly the Anemone varieties, which are grown well. It is not everyone that is successful with these, but the promise of fine blooms this year is richer than even last season. As regards the Japanese, we may note, without wishing to make a catalogue of names, some of the best in this superb collection. Col. W. B. Smith's faultness, and one sees here that a flower, although large, need not be necessarily coarse. Some of the gems are the blooms that measure many inches in width. *Mlle. Thérèse Rey* is unquestionably the finest variety in its line of colour. It is in perfection, the flowers ivory white, broad and deserving high praise. This will be seen much at exhibitions during the present season. Another kind that should create some stir is *Excelsior*, a noble exhibition variety, the flowers very broad, deep, and rose-purple in colour, with silvery reverse to the wide florets. Mr. Rowbottom has the most perfect blooms we have yet seen of this English-raised seedling, and has also in full beauty the three new varieties shown by him recently certificated and fully described in THE GARDEN. A very fine kind is *Amos Perry*, the flowers rich yellow with twisted florets, and worthy of note is *Louis Boehmer*, a distinct white flower, full, and far better than the type. It is also a distinct improvement in habit and constitution. Belonging to the incurved Japanese class is *George Savage*, which is said to be a seedling from Mrs. Alphens Hardy, but not hirsute, as is that variety. The flowers are pure white, not cream or ivory white, like so many kinds called white, the florets closely incurved. A great improvement upon *Meg Merrilies* is *Mme. Elizabeth Labat*. The fault of the old favourite is its flimsiness, but this kind is solid, so to say, without losing in grace, with similarly lacinated milk-white florets. *G. W. Childs* is a superb variety, which may be placed with the *William Seward* group. It has been described as a seedling from Edwin Molyneux, but, whether true or not, there is a resemblance between the two kinds. The flowers are of a rich crimson-maroon shade, with old gold reverse to the florets, large and massive. It is placed in the incurved Japanese class. The collection is so rich in novelties and developed to such perfection, that several more

kinds must be described. One of these is *G. C. Schwabe*, a seedling from Edwin Molyneux, resembling that variety in habit of growth, whilst the flowers are pale rose-purple, with delicate bronze reverse to the florets. A lovely new white-flowered kind is *Utopia*, one of Messrs. Pitcher and Manda's additions, the flowers exceptionally pure; and Mrs. H. R. Williams is a novelty not yet sent out, but of great promise. It was raised by Mr. Jones, of Lewisham, the flowers large and white, with a tint of pink. Mrs. E. D. Adams, white; J. Stanborough Dibbens, bronze-yellow, passing with age to yellow; Mrs. Harman Payne, warm rose-purple; Stanstead White, Alberic Lunden rich amaranth, and Kentish Yellow were in full bloom—all varieties that those who wish to exhibit largely must have in their collections. The beautiful bronze-yellow *Falconer Jameson*, F. W. Flight, salmon-red, pale gold reverse; The *Tribune*, a Japanese reflexed variety of a primrose-yellow colour; W. Tricker, a massive rose-coloured kind, silvery white reverse to the florets, and *Chas. Davis*, the light bronzy yellow sport from *Vivand Morel*, are all good kinds. Mr. Rowbottom grows *W. H. Lincoln* to perfection, and the yellow flowers make a brave show of colour in contrast to those of *Hamlet*, pale brick-red.

The incurved varieties are as interesting to the exhibitor as the Japanese, although not so to people generally. The *Rundle* family is splendidly grown this year, Mrs. George Rundle, Mrs. G. Glenn and Mrs. Dixon being in perfection, and the same may be said of the varieties of the *Queen* type. *Mme. Darrier* we made special note of, the flowers neat and bronzy yellow. *Mme. Jules Barigney*, recently described in THE GARDEN, was excellent, whilst *Mons. L. Parli* is a novelty of great merit, like *Mme. Darrier*, somewhat early, very neat and light brown in colour. We seem to be getting much more colour in the incurved section than formerly, and this is welcomed, as until quite recent years it was extremely limited. *Baron Hirsch* was in all stages of development; it is a fine flower, too dull, however, in colour, bronze, shaded with gold, but the petal is broad. It is probably a seedling from *Baron Beust* or *Lord Wolseley*. A gem in the collection is *Mrs. Robinson King*, a worthy acquisition to the *Queen* family. It is deeper in colour than *Golden Empress*. *M. R. Babuant*, *Richard Parker* (the deep coloured *Miss Haggis*), and *Miss Bella Wilson* are a good trio. The last-mentioned has a very large flower, similar in shade to, but deeper than *Violet Tomlin*. A beautiful kind is *Mme. Frederic Mistral*, which is purplish or violet-rose, the fine petals tipped with a salmon shade.

Mr. Rowbottom is one of the best growers of that difficult section to succeed well with, the *Anemone* and *Japanese Anemone*. A good kind is *Mme. N. Brunn*, a beautiful flower, light in the centre, the colour pale yellow, and the florets narrow and white. It is a well-shaped flower and one of the best of its class. It is difficult sometimes to draw the line between the *Anemone* and *Anemone Japanese* classes. Of the latter a good collection is grown, and one of the most characteristic is *Fabias de Maderanaz* or *Fabian de Mediana*, which is very beautiful when grown well. It has a very high disc, rosy lilac in colour, tipped with white, but the florets are distinct, pale pink, with deeper stripes, and 3 inches to 4 inches in length—hence the name *Japanese*. But many kinds have florets very little longer than those of the true *Anemone* flowers. *Souvenir de Mme. Blandinières* was of note, the flowers of a rose-crimson colour, also the well-known *Sœur Dorotée Souille*.

Other sections are also grown to perfection, including the so-called decorative, pompons and *Anemone pompons*, which are of great use for cutting.

Chrysanthemums at Chiswick.—A large and representative collection of Chrysanthemums is grown in the Royal Horticultural Society's gardens at Chiswick. The plants fill the largeinery, and the Fig house is also occupied with them, so that when in full bloom a very fine display will re-

sult. Already many kinds are in full bloom, and one sees the Chrysanthemum grown more naturally here than is usually the case. Very little disbudding has been done, and the plants are smothered with buds. They may not be of exhibition standard, but that is of little account. Each plant is beautiful to look at, and none of the colouring is lost by this natural method of cultivating the Chrysanthemum. Conspicuous amongst those in bloom now are the following: Eynsford White, a beautiful flower of the Japanese class, and E. G. Henderson, also Japanese, rich yellow, shaded with chestnut at the base of the florets. Also worthy of note were such kinds as the yellow-flowered Buttercup, Martinmas, Elaine, W. S. Boyce, Elsie, O. J. Quintus, Thorpe Junior, and Mlle. Elise Dordan, which is remarkably well grown, better than we have seen it. The plants are covered with the neat rose-coloured flowers. It is a very charming pompon variety, but none too easy to grow well.

Chrysanthemums at the last R. H. S. meeting.—There were several most excellent varieties exhibited at the Drill Hall on October 24, more especially of the Japanese section. In Mr. Owen's extensive exhibit note should be made of an English seedling incurred which is to all appearance well named Permanent. The petals are of remarkable substance, the flowers large, but a trifle too much expanded perhaps, the colour very distinct, a shade of light blush, bright and glistening. I shall be greatly surprised if this does not prove a decided acquisition. Baron Hirsch, another incurred, was finely shown in the same stand. It is an improvement amongst the bronzy-brown shades. Rose Wynne, another English seedling (Jap.), has large pure white flowers with fluted petals, after Etoile de Lyon in form. Another of the same class is Thos. Wilkins, which is an improved L'Adorable, whilst Mrs. G. D. Darby surpasses M. Baco. Another called Yellow Avalanche is a counterpart of the white variety save in colour, this one being a pale soft yellow. James Myers (English seedling Japanese) is of a distinct colour, a bright shade of fawn, and Sunlight, a golden-yellow decorative variety, was very promising.—GROWER.

SHORT NOTES.—CHRYSANTHEMUMS.

Chrysanthemum G. W. Childs is like Edwin Molynoux in character, and perhaps it is a seedling from it. The flowers are deep crimson, a good telling colour.

Chrysanthemum Mme. Octavie Mirbeau is a very pleasing variety, which we noted in Mr. Davis' collection at Camberwell. It belongs to the Japanese class, the flowers having a drooping tendency, the florets broad, white, with stripes of rose-lilac.

Chrysanthemum Danæ—This Japanese reminds one very much of Boule d'Or in the formation of its florets when fully expanded, but in point of colour it is richer, the yellow is deeper and the bronze of a deeper hue. It makes an excellent substitute for Boule d'Or, as in some seasons this old favourite is not a success.—E. M.

Chrysanthemum George Savage.—As a massive flower, pure white in colour, I can recommend the above. Another season's trial has fully borne out the high opinion formed of it last year. As an incurred Japanese it is at once one of the best sorts in commerce, but whether this class will remain long in favour is a question.—E.

Chrysanthemum Le Prince du Bois.—This Japanese provides a shade of yellow most acceptable to exhibitors and lovers of Chrysanthemums generally—rich yellow, fading slightly with age. The florets are narrow, twisted, and have a semi-drooping tendency. Altogether this is a promising variety, raised by Mr. C. Gibson, of Morden Park.

Chrysanthemum l'Enfant des Deux Mondes.—Belonging to the class known as hirsute varieties, this bids fair to equal the now well-known Mrs. Alpheus Hardy. Certainly it is a decided advance upon that variety in point of growth;

being a sport from Louis Boehmer, its constitution is robust. The florets are thickly covered with the hair-like appendages which render this section so remarkable.—E. M.

Chrysanthemum John Shrimpton.—As predicted last year, this Japanese is proving itself a worthy acquisition to an already lengthy list. In colour it resembles the well-known Cullingfordi. The florets are rather narrow and perfectly imbricated. One of its best characteristics, however, is the dwarf habit of the plant. Splendid blooms are obtainable from plants less than a yard high. For grouping, cultivators should add this largely to their collections.

TREES AND SHRUBS.

MAGNOLIA STELLATA.

This is one of the earliest to bloom in spring; flowers of the purest white and produced in the greatest profusion. The plant is of dwarf, slow growth in comparison with others. It is a very hardy species, and never fails, even when small, to bloom freely. JOHN SAUL.

Washington.

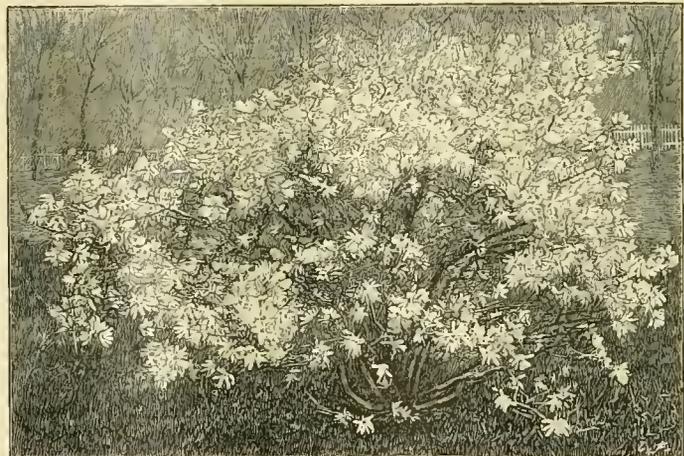

Ceanothus Gloire de Versailles.—Against a wall we have lately seen several fine plants of

a very sweet scent, and look pretty clustering in the axils of the leaves. Apart from flowering, this Osmanthus is a valuable hardy evergreen for small or large gardens. A somewhat similar species, but having yellowish flowers, is named fragrans. It makes a handsome bush, but is not so common either in gardens or nurseries as the preceding species. It may be well to warn those who intend planting these shrubs to see that they are not grafted on the Privet.

Japanese Maples for colour.—The autumn-fading leaves of these are as varied and rich as those of the many forms of Oak. It is a mistake to suppose they are so tender as is commonly thought, and many reputedly more hardy things get killed in severe winters. In the Coombe Wood Nursery of Messrs. J. Veitch and Sons the shrubs are entirely in the open unprotected, and survive well the hardest winters. It is the smaller gardens that should be planted with them, as in these, large growing things are out of place. They grow slowly and to no great height, forming low shrubs or trees. We remember a bed of the crimson-leaved Japanese Maple at The Deepdene, Dorking, and the leafage was remarkably effective.

SKIMMIAS.

AMONG the smaller-growing shrubs remarkable for their ornamental berries we have but few that are of an evergreen character, and of the limited number the Skimmias stand out as a very desirable

Magnolia stellata (Halleana) in bloom in Mr. Saul's nursery at Washington. Plant 8 feet high and 10 feet through.

this covered with the clusters of rich blue flowers. This is the best of the family for colour, and it is free and robust also, though a little tender in cold exposed spots. In the Chiswick gardens it is needful to protect the plants in some way during severe winters. The Ceanothuses are numerous, and one sees many poor varieties, one a kind of coffee-coloured flower, which is scarcely worth space when we have such varieties as Gloire de Versailles.

Veronica Andersoni variegata.—We have seen this fine Veronica well used in the parks this season. A large mass of it was in full bloom a few days ago in Finsbury Park, and though the purple flowers lose by the richly variegated leaves, they are not altogether overshadowed. This variety is of rote, however, for its brightly coloured leaves, glaucous green and creamy white, a most pleasing association of colour. It is a good plant to use when small as a relief to beds of dwarf things, and mixed with Fuchsias is remarkably bright.

Osmanthus ilicifolius.—This is flowering rather freely at the present time—perhaps as a result of the tropical summer. In flower as well as in leaf it shows its affinity to the Holly, but, like the Judas tree, it puts forth flowers here and there from the leafless wood of two or three years' growth. The flowers are whiter than those of the Holly, have

class of plants, though, generally speaking, they are not, I think, met with to so great an extent as was the case a few years ago. Though the different forms of Skimmia are by no means numerous, yet their nomenclature is in a very confused state; for instance, the oldest and by far the most generally grown of them, to which is applied the specific name of japonica, is said by some of our later authorities to be not the true *S. japonica* of Thunberg, but the plant to which that name is applied by other subsequent writers, and which is really said to be a native of China. It is, I see, in the "Dictionary of Gardening" referred to under its best known specific name—that of japonica. In this species the flowers are hermaphrodite, so that a specimen will berry freely without associating with any other plant, which is not the case with the larger-growing forms, as they are dioecious, that is, male and female flowers are borne on different plants. The Skimmia known as *S. oblata*, which is believed by some to be Thunberg's true *S. japonica*, produces only female blossoms, the male being usually met with under the specific name of *fragrantissima*. Thus while *S. oblata* planted by itself will produce an occasional berry, far great numbers will, as a rule, be borne if a flowering plant of *S. fragrantissima* is in close proximity to the other, as many of the blooms will be thereby fertilised. The commonest form

of *Skimmia*—that is, *S. japonica* of gardens—will not thrive where the soil is at all parched up during the summer, but it prefers a cool, fairly moist spot, especially where it is slightly shaded from the full rays of the sun, as where fully exposed, more particularly if the soil is rather dry, the foliage is apt to acquire a yellowish tinge, which is not easily got rid of. From its small size and great profusion of berries this *Skimmia* may be often met with in Covent Garden Market, the plants of which have been lifted from the open ground and potted up when in full berry. If this is carefully done they will with ordinary attention remain fresh and bright for a long time. *S. oblata* is, irrespective of berries, well worth growing as an evergreen shrub, but, of course, when studded with fruits its beauty is greatly enhanced. Both this and the male form are decidedly pretty when in flower, while they both succeed better than most shrubs in the environs of London. The suggestion of Dr. Masters, who elucidated the confused nomenclature of the *Skimmias*, is that the true *S. japonica* of Thunberg is the plant known in our gardens as *S. oblata* (of which *S. fragrantissima* is the male form), while the species usually under the name of *S. japonica* is henceforth to be known as *S. Fortunei*. Messrs. Veitch, I see, in their latest tree and shrub catalogue have adopted this system of nomenclature. The most attractive *Skimmias* that have come under my notice were shown at a meeting of the Royal Horticultural Society in the winter of 1888 under the name of *S. Foremani*. They were certainly beautiful specimens, laden with their bright coloured berries, and formed the most noticeable feature of the meeting. *S. Foremani* is said to be a hybrid between *S. oblata* and *S. fragrans*, but doubts have been expressed as to its parentage. None, however need be entertained as to the great beauty of the specimens shown. H. P.

SPOILED BY LAURELS.

THE common Cherry Laurel and the Portugal Laurel have done more to mar the beauty of English pleasure gardens than any other plants, not excepting the worst weeds. At some past day our planters were attracted by the beauty of the leaves of these plants and their ease of culture; so in many estates they were put everywhere, and as they grow much more rapidly and largely than people allowed for, walks are closed in by them and pretty views are closed up; all character and interest are thus taken out of many of the most beautiful pleasure grounds in England. Many fine trees are starved by these vigorous and voracious evergreens. One would not mind seeing a group or mass of them placed in the full sun, but that every plantation and every beautiful group of trees about a place should be embedded in them is a misfortune. We have just come from some places in the eastern counties where there are miles of Portugal Laurel, robbing and running into everything, making large pleasure grounds gloomy, and in wet weather most depressing. These shrubs do not show the changeable life of our English covert plants, such as Brambles or wild Roses, Hazel or Thorn, but always the same monotonous verdure, and not half so pretty as the wild things of our hedgerows and coverts. Where they run under fine Oaks and Beeches they are quite out of place, being natives of quite different countries from ours. If people would be content with a bold group or two and then stop, all would be well; but the ceaseless planting goes on until they so impoverish the ground that many trees have suffered much this year. As people walking about their grounds see most easily that which comes about the level of their eyes, these bushes get high enough to often take possession of the whole effects of the garden landscape. In innumerable cases the best thing to do in

these pleasure grounds would be to grub up and burn the wretched Laurels in every case where they give a crowded and dismal air to what ought to be a beautiful shrub and tree garden, and where they are likely to rob the roots and mar the beauty of other trees and shrubs. As to many beautiful flowering shrubs, it is quite impossible that they can live among Laurels, and hundreds have been killed by them. Yet such a flowering shrub as *Stuartia* is worth an army of Laurels of the kinds we allude to.—*Field.*

London trees.—Several interesting notes have appeared recently in THE GARDEN about street trees. A great evil is planting them where none are required. The streets are too narrow, and dwelling houses are made unwholesome through the keeping off of the sunlight. Planting Elms, Planes, and Horse Chestnuts in streets scarcely wide enough for a decent path is one of those curious anomalies often presented to us by local boards. Instead of removing the trees when they get too close together, they are pruned, and in such a way that their characteristic aspect is lost. Branches are cut back recklessly and the trees rendered an eyesore, as was the case some time back in the Chiswick High Road. When first planted, too, a great stake is thrust down by the side of them for support, a hideous pole, very unsightly, and hurtful to the roots. A very good way of supporting trees is to have a guard of iron rods, inserting a circular cushion of old india-rubber hose or similar material at the upper end of the guard, inside, to prevent the bark chafing. In suburban districts in particular, late and careless planting and want of a properly prepared soil have much to answer for. The trees are often planted in the spring, and literally stuck into a hole too small for the roots, the soil possibly saturated with gas from pipes. It is necessary to plant well, use good soil, stake firmly, or better, use the iron guards mentioned, and put over the root surface a grating. It is not the proper thing to go to a nursery and take a lot of stuff that the nurseryman wants to get rid of.—T.

PUBLIC GARDENS.

Proposed open space in Clerkenwell.—The Parks Committee reported that they had considered in what manner the money received from the Postmaster-General under the Post Office Sites Act should be used. The money was paid in lieu of a portion of the site of Coldbath Fields prison being sold to the Council for the purpose of an open space, but it did not follow of necessity that all or any of the money need be expended in Clerkenwell, or in any other particular part of London. Their attention had, however, been directed to two sites in Clerkenwell. One was occupied by a small block of houses between St. James's Churchyard and Clerkenwell Green, and the other was some ground in Rosebery Avenue between Lloyd's Row and Rydon Crescent, cleared by the Council in connection with the Rosebery Avenue improvement. They had ascertained that the value of the land in Rosebery Avenue was £10,000, while the cost of acquiring the block of houses between the churchyard of St. James's and Clerkenwell Green would amount to £28,000. Apart from the monetary consideration, however, they had carefully considered the arguments put forward in favour of each of these sites, and thought that the plots in Rosebery Avenue, being adjacent to Spa Green, would, in conjunction with the green, form an open space in a thickly-populated district where it would be greatly appreciated. They therefore recommended the Council to authorise the committee to incur an expenditure of £10,000 for the purchase of the two plots of vacant land on the eastern side of Rosebery Avenue to the north of Spa Green, and lying between Lloyd's Row and Rydon Crescent, the purchase

money being provided from the amount paid by the Post Office authorities under the Post Office Sites Act, 1889. Mr. Elliott moved that the report be referred back, but after a short discussion this was rejected and the report agreed to.

SOCIETIES AND EXHIBITIONS.

NATIONAL CARNATION AND PICOTEE SOCIETY.

(SOUTHERN SECTION.)

THE annual general meeting of the above society was held at the Hotel Windsor in the rooms of the Horticultural Club, by kind permission of the members, on Saturday, October 28. Mr. Martin R. Smith, president of the society, presided. The president, vice-presidents, committee and office-bearers were re-elected. It was decided to hold the exhibition for 1894 under the auspices of the Royal Horticultural Society on July 24. The following alterations were made in the schedule: two new classes were added for twelve blooms and six blooms respectively, with a growth of the plant to each bloom and without dressing. It was also proposed and unanimously adopted that the class for yellow ground Picotees be judged on the same principle as the white ground varieties, that is, a pure yellow ground with a margin the same as the white ground class (fancies excluded). A distribution of seed saved from choice fertilised flowers grown in the garden of the president of the society has been made to the members applying for it, and it was decided to offer prizes for the best seedlings raised from the seed so distributed in the year 1895. The statement made by the treasurer showed that the society was in a very prosperous condition. The subscriptions as per list amounted to £154 9s. 6d.; amount received for special prizes, £18 17s. 6d.; prize money distributed, £99 15s. 6d. The balance from last year was £65 10s. 5d., and the balance in hand is £118 5s. 4d.

National Chrysanthemum Society.—On Monday last the general committee of this society met at Anderton's Hotel, Mr. R. Ballantine being in the chair. Mr. Richard Dean referred to the recent October show, and explained that the sum of about £45, inclusive of medals, had been awarded ten exhibitors on that occasion, but had not yet been paid over. In addition to that amount upwards of £6 had been offered by Messrs. Sutton and Sons for prizes in the vegetable classes. He also presented a rough financial statement showing that about £230 has already been received by him on account of subscriptions, advertisements, catalogues, affiliated societies' fees, &c. Mr. Dean proposed that the members of the floral committee be invited to the judges' luncheon on the first day of the society's show next week in recognition of their valuable services. Several applications and inquiries relating to the show were disposed of, and Mr. Dean reminded the committee that the annual dinner will take place at Anderton's Hotel on the 30th inst. Sir Edwin Saunders will preside on that occasion. New members were then nominated for election, and it was announced that 120 new members and Fellows had been added to the roll this year. One society, the Beckenham Horticultural, applied to be affiliated, which was granted. The schedule sub-committee for 1894 was elected, being composed of the same members as last year.

The Auricula and Primula Society.—The annual meeting was held on Saturday, the 28th, in the Hotel Windsor. Mr. Henry Cannell, of Swanley, presided. The president, vice-presidents, committee, office-bearers, &c, were re-elected, the name of J. T. Bennett-Poë being added to the list of vice-presidents. The exhibition for 1894 is to be held under the auspices of the Royal Horticultural Society as usual, and it was decided to offer the same prizes as last year. The subscriptions as

per list amounted to £63; prizes paid, £60 16s. Other expenses brought the expenditure up to £74 1s. 6d., leaving a deficit on this and last year's working of £8 16s. 6d. due to the treasurer. If all the members would pay up their subscriptions this amount would be materially reduced, and with a very little effort on the part of the members, the deficiency might be made a handsome surplus.—J. DOUGLAS, *Hon. Sec.*

The Gardeners' Orphan Fund.—The monthly meeting of the committee took place at the Horticultural Club, Hotel Windsor, on the 27th ult., Mr. William Marshall in the chair. The minutes of the last meeting having been read, the secretary reported that the sub-committee appointed to act with him during the recess had paid the quarterly allowances to the children due on October 31. The following special receipts were announced. Mr. W. Elphinstone, The Gardens, Shipley Hall, Derby, opening the gardens to the public, £11 1s. 6d.; Mr. J. H. Vallance, local secretary, Bristol, legacy by a deceased lady, £3 3s.; Mrs. Bowerman, Hackwood Park, Basingstoke, sale of flowers, £1 6s.; Mr. J. Plowman, Woodstock Gardens, Long Sutton, per box, 10s.; Mr. G. Tubb, Minley Manor, Farnborough, box, £1 2s.; Miss Barron, Sutton Court Road, Turnham Green, box, £1 11s.; Mr. F. A. Burbury, The Gardens, Highbury, Birmingham, £1 16s.; Mr. J. B. Stevenson, Church Cottage, Bourne-mouth, box, 6s. 5d.; and Mr. C. Sutton, The Gardens, Chevening Park, Sevenoaks, box, 6s. 5d. The secretary reported the receipt of a cheque for £100 from Mr. N. Sherwood (Messrs. Hurst and Son) as a jubilee celebration gift by the firm, and a hearty vote of thanks was passed to this generous supporter of the fund. The death of Mr. Hugh Low, of Clapton, a member of the committee, was reported, and a vote of condolence with his widow and family was passed. A vote of thanks to the chairman closed the proceedings.

PRUNING: SHALL WE LOP OR THIN?

I AM obliged to THE GARDEN for publishing "J. S. W.'s" able and fair critique of the "Fruit Growers' Guide" on p. 401. Endeavour has been made in that work to show different methods of training and pruning for adoption or rejection. Some trees may be appropriate for one position and some to another, and the choice of any particular kind and form to adopt must be left to the intelligence of readers.

"J. S. W." is entitled to a reply to his closing question, "How can the statement be reconciled of Apple trees left to Nature assuming forms not pleasing, and proportions exceeding the limits available for them?" with former expressions to the effect that "trees allowed to assume their natural forms and adapted to small gardens are ornamental and reduce the necessity of pruning to a minimum."

That numbers of trees exceed the limits of the positions assigned them is only too apparent in many gardens, and there are only two ways in which the encroachments could be prevented—(1) the choice of more compact growing varieties, or (2) restricting the strong, especially at the roots. I have no hesitation in saying that I prefer the former, on the simple grounds that if we can get what we want without hacking root or branch—trees appropriate to the positions they occupy, yet abundant fruit-bearers—it is altogether better than accomplishing the object by artificial means. This statement brings me in line with "J. S. W.," but he knows as well as I do that there are varieties of Apples so gaunt and spreading as to be in certain positions in which we see them the reverse of pleasing and productive. The addition then of one word "some" (Apple trees left to themselves) reconciles the apparent conflict that "J. S. W." has been the first to discover, and I should be well pleased if the omission had been noticed in correcting the proofs for press. At the same time there are given in the work in question lists of Apples of "compact," "medium" and "strong" growth with planting distances for each, compiled for the very object that "J. S. W." be-

lieves in as sound, and which I may fairly describe as the reduction of restriction to a minimum. In some cases checks to extension are necessary with trees in the open, as with trees against walls or under glass, and with the two latter restriction follows extension in "J. S. W.'s" own practice, though he would, it may be assumed, prefer more lofty walls and capacious houses to let them "go."

The pruning of trees for the production of fruit, regardless of any particular form or adaptability to circumscribed position, is beautiful in its simplicity, and when this aspect of the case is treated, namely, fruit-growing for commercial purposes, I suspect "J. S. W." will not find very much that widely differs from his views. Moreover, I am one of those who can see as much beauty in a tree that is allowed to display its natural character under good cultural guidance as is displayed by a tree moulded into prim, symmetrical form by elaborate manipulations. The "pretty" little Apple tree that "J. S. W." admires is undoubtedly a correct representation of a growing specimen, but it would not be what it is if it had been wholly "left to Nature," for in that event it would not have been the dwarf bush tree it is, but more of a standard. I like the style of tree just as much as he does, as it combines, in my opinion, beauty with utility. I thank "J. S. W." for his pertinent observations. "Lop" till you get the requisite number of branches, then "thin." J. WRIGHT.

The weather in West Herts.—The St. Luke's summer we have recently been enjoying suddenly gave place on Tuesday to a short spell of quite wintery weather. On Sunday the highest reading in shade was 56°; whereas on Tuesday the temperature at no time rose higher than 44°. During Monday night the thermometer on the lawn registered 11°, and on the following night 12° of frost. The first of these two frosts destroyed all my Dahlias. They were, therefore, killed this year two days later than the average date of their destruction in the previous eight years, and four days later than last year. In 1888 they succumbed to a keen frost on October 3, but in 1885 lasted until November 16. Since Sunday the temperature of the soil at 2 feet deep has fallen 3°, and at 1 foot deep as much as 7°. At the former depth the ground is now (Wednesday) 1° warmer than on the same day last year, but at 1 foot 4° colder. The past week was the only dry one in October. During that month rain fell on sixteen days to the total depth of 4½ inches, which is 1 inch in excess of the October average.—E. M., *Berkhamsted.*

The season in Berks.—It may be worth mentioning to you a very unusual circumstance, viz., that we have to-day had a dish of ripe well-flavoured Strawberries grown in the open air in the gardens here from the same beds that supplied us with a crop in June. The soil is sand and gravel, though the garden is a very old one, and the climate, though dry, is by no means a warm one, being close to Ascot Heath.—T. CORDES, *Silwood Park, Sunninghill, Berks.*

The common house fly.—I promised on my return home to answer "W. M.'s" question in his letter of August 29 about the life-history of the common house fly. I am sorry I have not been able to fulfil my promise sooner, particularly as the interest in house flies is, I am glad to say, over for the season, as they have been very troublesome this summer. The common house fly breeds in horse manure, that is to say, the insect lays its eggs on that substance, and the larvæ or maggots which hatch from them feed on it. This insect undergoes its transformations very rapidly; the eggs hatch in about twenty-four hours, and the maggots attain their full size and become pupæ or chrysalides in a week, and in the course of another six or seven days the flies make their appearance. The flies live for several weeks; some hibernate, choosing for their resting place during the winter a sheltered place in a room or elsewhere. Besides the common house fly there is another which infests dwelling houses, and is at times almost as common as the species just mentioned, but it belongs to a different genus, and is known scientifically as *Homulomyia*

runicularis; the larvæ of this species are found in decaying vegetable matter. The fly is not quite so large as the common house fly, and it is rather lighter in colour, and its body is more pointed. The chief difference is in the nervures of the wings, which are arranged in a somewhat different manner to those of *Musca domestica*. Besides these two kinds there are one or two species of very similar looking flies which are often found in dwelling houses. It is a curious fact that these flies, though bred under decidedly open-air influences, should have such a partiality for rooms in houses, and it is very difficult to find out where these creatures breed in towns so as to infest houses in the numbers they do. I am living in the suburbs, and in my kitchen alone many thousands must have been caught this summer, and I have no reason to doubt but that all the houses round me were infested in the same manner, and yet there were very few stables about or places where there is any accumulation of horse manure. House flies are no doubt very prolific in the number of eggs which they lay; still it is astonishing where all the flies come from.—G. S. S.

Sweet Williams.—The Rev. G. H. Engleheart, Appleshaw, Andover, will be much obliged to anyone who will send him a plant or two, for blooming next summer, of a good variety of deep crimson Sweet William. It is required for a scientific purpose.

Epilobium latifolium.—Can any reader of THE GARDEN tell me whether this is in cultivation in England? At one time it was not uncommon, and F. Wheeler, of Warminster, always kept it in stock. As a low-growing creeping plant easily kept in order, it was useful and pretty, but I have not seen it for many years, and should like to get it again.—E.

Names of fruit.—J. K. T.—Pear Beurré Bose.—T. Denny.—Apple Duke of Devonshire.—Upton.—1, Doyenné du Comice; 2, Beurré Clairgeau; 3, not recognised.—R. C. Coode.—Probably Golden ReINETTE.—Box, no letter.—Pear Vicar of Winkfield; Apple; 2, Brabant Bellefleur; 3, King of the Pippins; 4, Rymer; 5, not recognised (worthless); 1, Gravenstein.—T. Bull.—Large red Apple Mère de Ménage; other Yorkshire Beauty.—George Stairmand.—1, Rymer; 2, Ribston; 3, not recognised.

Names of plants.—E. Semper.—1, Aster Novi-Belgii var. Flora; 2, A. paniculatus variety (?); 3, A. Nova-Angliæ ruber; 4, A. Nova-Angliæ pulchellus; 5, A. ericoides var. Chlo.—T. Ryan.—Catasetum luridum.—S. Emmett.—1, Cattleya labiata, light form; 2, Pleione lagenaria; 3, Cypripedium Scogerianum.—Erin.—Odontoglossum hastilabium.—C. Curtis.—Odontoglossum Lindenii.—Inquirer.—Dionaea muscipula.—C. J.—1, Aralia Sieboldi variegata; 2, Hippomane spinosa; 3, Paulinia thalictrofolia; 4, Aralia crassifolia.—T. Johnstone.—1, Oncidium varicosum; 2, Oncidium tigrinum; 3, Trichopilia tortilis; 4, Cypripedium villosum.—W. M.—Your Fern is *Loxogramma involuta*.

"The Garden" Monthly Parts.—This journal is published in neatly bound Monthly Parts. In this form the coloured plates are best preserved, and it is most suitable for reference previous to the issue of the half-yearly volumes. Price 1s. 6d.; post free, 1s. 9d. Complete set of volumes of THE GARDEN from its commencement to end of 1892, forty-two vols., price, cloth, £30 12s.

"Gardening Illustrated" Monthly Parts.—This journal is published in neatly bound Monthly Parts, in which form it is most suitable for reference previous to the issue of the yearly volumes. Price 5d.; post free, 8d.

"Farm and Home" Monthly Parts.—This journal is published in neatly bound Monthly Parts, in which form it is most suitable for reference previous to the issue of the yearly volumes. Price 5d.; post free, 8d.

"Hardy Flowers."—Giving descriptions of upwards of thirteen hundred of the most ornamental species, with directions for their arrangement, culture, &c. Fifth and Popular Edition, 1s.; post free, 1s. 3d.

"The Garden Annual" for 1893.—Contains Alphabetical Lists of all Branches of the Horticultural Trade. The Lists of Gardens and Country Seats (containing over 9000) have been very carefully and extensively revised, and are admitted to be the most complete ever published. Price 1s.; by post, 1s. 8d.

All of our readers who are interested in the improvement of cottage homes are invited to help us to make Cottage Gardening known. It is published at the very lowest price to meet the wants of those for whom it is intended, and copies will be sent for distribution, free, by the publishers, Messrs. Cassell and Company, La Belle Sauvage, Ludgate Hill, E.C.

No. 1147. SATURDAY, November 11, 1893. Vol. XLIV.

"This is an Art
Which does mend Nature: change it rather; but
THE ART ITSELF IS NATURE."—*Shakespeare*.

ROSE GARDEN.

ROSES IN THE AUTUMN.

ROSES in the summer, that is, during May, June, and July, are decidedly most attractive, no flower more so, but I must confess that I greatly admire the queen of flowers in August, September, and October, when many of the true Perpetuals, the Tea-scented, and the Noisette varieties yield an immense number of useful flowers. No further proof of this could be needed than what could have been seen by inspecting the really beautiful display which was made by several of the chief trade growers at the show held under the auspices of the Royal Horticultural Society in the Agricultural Hall at the end of last August. This was followed by two or three further exhibits of great attractiveness during September at the Drill Hall meetings of the R.H.S. In these cases most of the Roses were shown in bunches, both large and small, and this method of exhibiting deserves more encouragement in my opinion than it receives. It is quite true that the individual flowers are not nearly so large in the autumn as during the height of the summer season, but it is not right to attach too much importance to mere size alone. That this is done, however, by many growers must be acknowledged, more particularly by those who are classed as exhibitors. These large blooms also find favour in the eyes of many who attach more importance to mere size than to other points of beauty. This fact reminds me that in most catalogues there are Roses which are given the additional honour of being best suited for exhibition, whilst others of presumably secondary rank are only termed garden Roses, as if they were not fit to be staged in a flower show. In prize schedules it is customary to state "trusses" rather than individual blooms. This is quite right, but it is more honoured in the breach than in the observance, for are not the majority of the flowers the result of disbudding? How can they, therefore, be termed trusses? A step has been made in the right direction by admitting classes for garden Roses in bunches (I suppose it is, however, only on sufferance, or at least looked upon as a needless innovation). The last few seasons have seen several good exhibits in this way, the only mistake, so far as I have noticed, being that the bunches have been too large and too much packed. This is not what should be aimed at, and in order to stop it the limit of trusses ought to be given (six or eight would be enough). I noted in one case the effort had clearly been to outweigh an antagonist by mere size of bunch alone. This spoils the effect and is in itself absurd.

I have been led away somewhat from my first thoughts in making these remarks. To return to them, however, it is, I think, a point to be noted that more encouragement should be given to such exhibits as I quoted at the commencement. I have myself noted more than once the amount of lingering that was to be seen over Roses in bunches, cut as they were grown with buds and foliage. These exhibits have many admirers, chiefly those who love the Rose for

its beauty in the garden. There are numbers of Roses that are scarcely surpassed for their beauty or their utility, but which, through not possessing more size, are passed over. They shine forth, however, in the autumn, and thus prove their value from a decorative point of view—such, for instance, are Boule de Neige, Perle d'Or, l'Idéal, Homère, Mme. Falcot, Ma Capucine, Safrano, Rêve d'Or, Mme. Pernet-Ducher, Vivian Morel (a new variety certificated R.H.S. 1893), Mme. Caroline Testout, and Grace Darling. Of others which are also known as "exhibition" varieties I have noted La France (always in the front rank), Mme. Cusin, Mme. de Watteville, Augustine Guinoisseau, Mme. Berard (always better in the autumn), Belle Lyonnaise, General Jacqueminot (not yet surpassed), Duke of Wellington, Susanne Marie Rodocanachi (an absurdly long name), Mrs. John Laing (a grand Rose north or south), Francois Michelon, Louis van Houtte, Pride of Waltham, Alfred Colomb, Senateur Vaisse, Star of Waltham, Jean Liabaud, Ulrich Brunner (not the abnormally large flowers as seen in June and July), Mme. Eugène Verdier, Charles Lamb, Spenser (a lovely pale flesh colour with more of the old-fashioned shape), Viscountess Folkestone, Gustave Piganeau, Marie van Houtte, White Lady, Mme. Hoste, Dr. Andry, Etienne Levet, Ella Gordon, Jules Finger, Hon. Edith Gifford, &c. These I have not classified, but merely given the names; a catalogue will in most instances supply the rest. The Dijon Teas, the Hybrid Tea-scented, and the other climbing Teas with most of the Noisette varieties should have every consideration. For these every available space on walls, trellises, and verandahs should be taken advantage of, whilst the hardiest, which comprises nearly every one, may be planted so as to be trained up old tree stumps. Conifers, for instance, which have been cut down for some reason or other may all be utilised for training these autumnal climbers on; it is far better than consigning these old stools to the fire, considering that they have a far better appearance than straight erect stakes of either wood or iron. I have planted Roses around old conifer stools after having prepared the ground well and thus saved their removal. GARDEN ROSE.

Roses in pots.—My Roses in pots are plunged outside, and the soil they are potted in does not suit them. I have some green turf to pot them with. Would it be advisable to leave them as they are until the spring when the loam would be in better condition for them? Would they be fit for forcing if potted now? Will it not be better to force them first and then pot them to make their growth for another season?—CONSTANT READER.

* * * As your Roses are plunged outside, I presume the wood upon them is matured. If so, and more particularly as the plants do not seem happy in their present compost, I would prefer to repot them at once, or at any rate as soon as the wood is sufficiently ripe. You will do little good by forcing them while in uncongenial soil. Unfortunately, you do not state whether the varieties are climbers or not; unless they are, a fair crop of bloom might be obtained if potted at once and allowed to make a few fresh roots before introducing them to any heat. Plants to be suitable for forcing should certainly be in the best of health, there being such a strain upon them. I would strongly advise your purchasing a few additional plants to force, repotting these you already possess, and working them up into good stuff for next year's use. Or you might place the few best into gentle heat and so get a few blooms before repotting in the spring as you suggest. So much depends upon their condition, that it is somewhat difficult to advise you without seeing the plants. I would suggest that you take the advice of some gardener in your neighbourhood,

who would be much better able to say if they or some of them would bear gentle forcing or not with a fair prospect of success. As for pottling material, it is by no means so necessary to have turf as many persons imagine. My own batch of about 2500 plants has not had any of the yellow fibry turf so frequently recommended, nor could I procure it except at an almost prohibitive price. You could doubtless choose a portion of the rottenest turf if you decide to pot them at once. A good mixture of leaf-soil, loam, old vegetable refuse thoroughly decayed, and burnt earth will answer as well as turfy loam, but it is imperative that good drainage be provided, and that the compost be close without being liable to run together from watering. A little sharp sand will secure this.—R.

Rose Caroline Testout.—I am very pleased to see Mr. Grahame's note upon my previous remarks in favour of this Rose. If the impression was conveyed that I considered this grand variety as absolutely the best of all Hybrid Teas, that is a little further than I intended to go. My note was upon four new Hybrid Teas, and it was in this connection that I meant the superlative to apply. But I must say it is one of the very best with me, and not surpassed by any but Augustine Guinoisseau and Viscountess Folkestone. It is very singular how differently Roses behave with growers; for example, Caroline Testout is all I have claimed for it at Ridgewood; while, curious to say, La France comes with me exactly as Mr. Grahame describes C. Testout to behave with him. This only proves how necessary it is not to be too positive respecting the qualities of Roses, and is another instance of their extreme variability. I am by no means alone in my belief that La France would not take so high a position if it was a recent introduction. True, like many other Reses, it is remarkably good in some districts, but I have not cut a good flower during the last five years, although I have about 700 plants to choose from.—R.

Rose The Engineer (now Crimson Rambler).—In reply to "H. P.'s" inquiry in a recent issue as to the origin and after-history of this Rose, I can supply the information. The Rose was purchased by Mr. Jenner by commission from Japan in the year 1878, along with a number of other plants, through Professor R. Smith, then of Tekio, now of Masen College, Birmingham. In the year following its introduction it bloomed so freely and its effect was so striking, that it won Mr. Jenner's admiration. After having been grown for eleven or twelve years in a private garden, Mr. Jenner presented all the plants to Mr. John Gilbert, Bulb Nurseries, Bourne, Lincolnshire, and, with his consent, Mr. Gilbert sold the stock to Mr. C. Turner of Slough. Mr. Turner gave it, with Mr. Jenner's consent, the name of Crimson Rambler.—M. CHAPMAN.

Rampant climbers.—Under the above heading I propose giving a few notes upon the general usefulness of the Ayrshire, Beursault and evergreen classes. No Roses are strict climbers—at least not in the way of Ivies, Ampelopsis and other subjects which cling and support themselves. But perhaps the varieties under notice deserve the term climbing more than any other Roses; they possess a slender and very rapid growth, and will clothe any rough fence, an odd corner of old roots, &c., the gaunt stems of trees that may be carrying a useful top growth, but which are unsightly below; in short, for cultivation where no attention is needed, and with the object of hiding some unsightly corner or building, there are few subjects so useful as those now under notice. During the past summer I have more than once noticed the Ayrshire Rose used to hide the rubbish corner, without which no garden can be properly and conveniently managed. Owing to their being almost evergreen, and the fact that the generality of such corners are beneath the shelter of trees, the screen of Reses is effectual almost throughout the year. Once a few of the shoots are supported, they will intertwine with one another and among any old branches or stakes in such a firm manner, as to need no further support. They are the

hardest of all Roses, and will positively revel beneath trees and in such poor soil that few other subjects can exist in. They are also very useful and picturesque in the shrubbery, either as grand masses supported by a few stout stakes or else planted against the stem of some dead tree. In this latter connection they are seen in all their beauty, it only being necessary to shorten back the branches of the dead tree and plant one or more of the Roses at its base; in a couple of seasons they will have made grand bushes, and carry long weeping branches of graceful growth which will be more or less covered with bloom throughout the season. I can think of no Roses which will bear town atmosphere better than these, nor any more suited for planting over rough places, such as banks, open ditches and unsightly fences. On pergolas they are grand and are certain to please. The flowers are usually small and double, but some varieties are only semi-double. The majority of them possess a beautiful scent. It is unfortunate that so many of the old varieties are only found in out-of-the-way corners of old-fashioned gardens or growing at will over the outbuildings of some cottage.—R.

Rose Mme. Alfred Carriere is a Noisette Rose which hitherto has not met with the notice which its merits deserve. It is a beautiful Rose both as to form and delicacy of colour, but its distinctive merit lies in its exquisite fragrance, which reminds one of the delicate and peculiar flavour of the Muscatel Grape. The foliage is especially good, and it is a vigorous grower and most prolific bloomer. One tree in a garden on the east of Scotland produced hundreds of blossoms this last summer, beginning early in July and continuing without intermission until the middle of October. This Rose was budded on a low standard Brier three years ago and is now a remarkably fine tree fully 8 feet high.—R. L.

MONTHLY, OR CHINA ROSES.

OF all autumnal blooming Roses these are probably the most certain. Whether they were called Monthly Roses on account of their particularly free-flowering qualities or not I am unable to say; but this might easily be the reason, seeing that if a crop of bloom has been realised, there is little fear but that another will be upon the plant within the month. They commence to flower as early as any, are remarkably continuous, and seldom cease to carry some presentable blooms as late as the middle or end of November. The old Blush variety has now been known in our gardens for close upon a century, having been introduced by Mr. Parsons in 1796. The Chinas have close affinity with the Tea-scented class, and exceed the latter in freedom of blooming. I do not consider them quite so hardy as the majority of the Teas and Noisettes, but this is probably owing to the extra late growth they make, and their consequent greater susceptibility to frost. When cultivated in masses, or even as a hedge, they can be pruned in the roughest manner imaginable, and will still continue to bloom as freely as ever. The common China, or old Blush, also Abbé Miellan and Mrs. Bosanquet, are perhaps the best for this purpose. These grow freely, and will bear keeping to any height or dimensions that may be required. For small beds and groups I prefer the shorter growers, which should be planted sufficiently thick to make a good show from the first. Owing to the exceeding freedom with which these Chinese or Bengal Roses can be propagated upon their own roots, the expense of thick planting is not prohibitory to the same extent as when dealing with other classes. When planted in a warm nook or corner, especially if the winter is not severe, it is nothing extraordinary to cut blooms all through the winter, nor does such interfere in the least degree with their continuous flowering during the whole of the succeeding summer. Equally beautiful and useful, no matter what the season may be for other Roses, this old class thoroughly deserves the greater attention and popularity it has been accorded during the

past three years. The blooms being few-petalled and opening freely, it matters little whether the summer be an ordinary one or phenomenally wet or dry; in either case the old Monthlies will be equally happy and showy. If a cold and naturally wet soil be avoided, I do not see that those of any other character are more suited to this class than another, nor does it much matter what the aspect may be. Mrs. Bosanquet is perhaps the fullest and largest of the Chinas, and has been classed both among the Bourbons and the Teas. I have little doubt it should rank among the Chinas; indeed, the National Rose Society and most of the leading Rose growers have classed it as such. R.

NOTES OF THE WEEK.

Osmanthus ilicifolius.—This handsome Evergreen comes from Mrs. Robb at Liphook—all the shoots set with the little white flowers fragrant as any flower can be. In this state it is charming.

Aster cordifolius.—We were charmed with a bed of this late Aster in full beauty on Nov. 5, every shoot crowded with the small delicate lilac flowers. The large masses of bloom weighed down the stems and made a fine autumn bed.

Solidago nemoralis prostrata is worth a note. It is now (beginning of November) coming into full flower. The stems are about 18 inches long, prostrate, the secondary branches ascending, the whole forming a cushion of bright yellow 1 yard across by 6 inches to 8 inches high.—T. SMITH.

The Pennsylvania Blue Berry (*Vaccinium pennsylvanicum*) is one of the finest shrubs for the colour of its leaves in autumn. It is uncommon, but, judiciously and appropriately planted, creates a fine picture. The leaves change to crimson and scarlet tints and remain in beauty a considerable time.—T. SMITH.

Chrysanthemum Jardin des Plantes.—This is a fine outdoor kind. It is a capital companion to Cottage Pink and Jules Lagravère. We saw on November 6 a garden gay with it, and from the profusion of buds a display would be maintained throughout the month, if not into December, provided the weather kept fairly mild.

Calceolaria Kellyana.—This, one of the brightest flowers at Harrow Weald a few days ago, sows itself freely. It is hardy, the stems about half a foot high, the rich yellow flowers being produced over a long season. Their aspect is very distinct from that of the usual run of border and rock plants. This is quite worth establishing on the rockery in light warm soil.

Parrotia persica.—This is one of the finest shrubs or dwarf trees for the colour of its leafage in autumn. The fading leaves change from green to a galaxy of tints—orange, scarlet and yellow. It belongs to the same family as the Witch Hazels, and is an interesting tree to have on the outskirts of the lawn. It is one of the first to change colour, but the leaves are not retained long on the branches.

Camellias in a London garden.—When in Mr. Mills' garden at Highbury New Park a few days ago we made note of several remarkably fine Camellias fully 20 feet high and 10 feet through. When in full bloom they must present a fine picture, and each year they flower profusely. The chief varieties are Lady Hume's Blush, the old Double White, one of the most useful for cutting, the Double Pink, and Donckelaari.

The scarlet trumpet Honeysuckle.—This was pleasing recently in a Middlesex garden. It is known in catalogues and books as *Lonicera sempervirens minor*, and succeeds best against a warm wall and in a well-drained, moderately light soil. The flowers are bright and attractive in colour, profusely borne, and there is plenty of foliage to accompany them. It wants a warm corner, which may be given in many gardens, and is far more

interesting than many creepers and climbers repeated in every garden until one gets tired of them.

The Loquat at Southampton.—I have growing on my house a plant of the Loquat (*Mespilus japonica*), which is at the present time showing for flower for the second time this year, it having already bloomed in the months of July and August. Some of the fruit is set, although I fear in our climate it will hardly ripen. The plant is 24 feet high. It grows tremendously, is very healthy, and is never protected during the winter. I wonder it is not more grown in England.—H. W. HAY.

The Winged Everlasting (*Ammobium alatum*).—This is one of the handsomest of the Everlasting Flowers and very easily grown. It is almost perennial on light warm soils, but the best way to ensure a long and plentiful display of bloom is to sow every year. In good soil the plants grow very strong and compact, and keep blooming till cut down by hard frost. The flower-stems with their curious winged appendages look very distinct, whilst they are tall and showy. The flowers are white with a yellow centre, and make a fine display in the garden apart from their additional value for drying to arrange in winter bouquets.—A. H.

Hardy Cyclamens.—These, amongst the most charming of autumn flowers in Mr. Kingsmill's garden at Harrow Weald, are established at the base of Beech trees in a small break of woodland. They love the shelter of such a spot. The leaf colouring of many kinds is delightful. They grow well in vegetable soil mixed with brick rubbish, and if no such place as at Harrow Weald is available, plant bold clumps in nooks on the rockery. At Kew the Cyclamens are planted in the low-lying stretch of ground at the base of the Cumberland mound, and when in bloom are very effective.

Two good Chrysanthemums for pots or beds at this season are the single-flowered Miss Rose and Mlle. Elise Jordan, a pompon variety. In the greenhouse at Kew is a number of plants quite smothered with flowers, those of the former very neat and rose in colour, those of the latter being pink and like little balls. When grown freely and not stopped too much, they make delightful decorative plants. We noticed also in the open a charming bed of them near the Palm house. The edging, so to say, was of the variety Miss Rose, and the centre of the bed filled up with the pompon kind. Every leaf was hidden with the mass of bloom.

Abutilon vexillarium.—This fine South American plant is even now (Nov. 6) bright with a number of flowers in the Royal Gardens, Kew. There is a large plant against the wall of the Victoria Regia house, and here it succeeds remarkably well, the heat from within and warm sheltered position exactly suiting it. Throughout the summer until now the mass of deep green leaves has been enriched with a profusion of the brightly coloured flowers. It is in this border that the Belladonna Lily and other warmth-loving plants are at home. In many gardens such things as this Abutilon may be grown well against the walls of plant houses.

Vallota purpurea one sometimes sees well grown, but more often than not it is a failure. During the past autumn we have seen excellent specimens, and often in cottage windows, where the plant is left practically to itself. In a paper read by Mr. O'Brien at the Royal Horticultural Society's meeting on April 21, 1891, he mentions that a friend writing to him from South Africa, as regards its culture, says: "Vallota purpurea always dies here if planted in the open. The only way that we can keep the plants alive is to compress their roots into a small space either in small pots or among rocks or stones. They will thrive by keeping them in pots until the roots burst the pots, and they will flower profusely." This is the kind of treatment the Vallota gets in cottage windows, not too much warmth, nor too frequent disturbance of the soil. Under cultivation in gardens it is not left sufficiently alone.

BUCKLAND ABBEY.

ANCIENT buildings of historical importance justly absorb a large amount of public interest, but when a building of this kind is associated not only with well-preserved relics of times long gone by, but also with scenery naturally grand and beautiful, this interest is increased.

Such a spot is Buckland Abbey, formerly the residence of that world-famed navigator, Sir Francis Drake, whose descendants of that name still hold possession of this charming estate, with its extensive woodlands, park and meadows, situated near the valley of the river Tavy about six miles south of Tavistock (Devon). The ancient house, a portion of which is depicted in the annexed engraving, is at present

(Isle of Wight), who cultivated the land, and, besides their spiritual functions, carried on farming on a large scale. The Cistercian monks sprang from the order of St. Benedict, and their history has been chronicled by Brooking Rowe in his "Contributions to a History of the Cistercian Houses of Devon" (Plymouth, 1878). A huge barn and other buildings are still almost as the monks left them, and the remaining witnesses of their industry.

On the landing of the French in 1339 the place was fortified, and the battlemented wall, which still surrounds the abbey buildings, probably dates back to that period. At the time of the Dissolution in 1538 Buckland Abbey was spared the fate of destruction which befell so many other monasteries, because Robert Tucker,

traverses pleasant meadows, which by the recent formation of plantations have been made still more park-like in appearance. In a long curve this drive leads to the heavy oaken doors with iron clappings, supposed to be exactly the same as in the time of the monks. Passing through this entrance we find ourselves in a sloping square piece of pleasure-ground an acre or so in extent and entirely surrounded by the battlemented wall already referred to. There is, however, nothing stiff in this pleasure-ground, which, though probably laid out several centuries ago, is, nevertheless, in the natural style. A striking feature is the magnificent Cedars of Lebanon, many of which are of enormous size, though a few of them suffered severely during the heavy blizzard in March

Buckland Abbey, near Tavistock, Devonshire. Engraved for THE GARDEN from a photograph by Mr. Hayman, Launceston.

occupied by Mr. J. Phillips, and by the kindness and courtesy of Mrs. Phillips I was not only allowed a full inspection of the house and grounds, but I am also indebted to this lady for most valuable information anent the history of the abbey, of which I will here give a brief summary. Six hundred years ago Buckland Abbey was a flourishing monastery of the Cistercian order. It was the Countess Amicia, widow of Baldwin, seventh Earl of Devon, who founded the abbey, and in the year 1273 acquired the land for that purpose from her daughter Isabella, Countess of Albemarle. In 1275 the deed was confirmed by the king (Edward I.). Meanwhile the abbey and extensive farm buildings had been erected and prepared for the monks. In 1280 the foundation-deed was signed and the abbey was colonised with Cistercian monks from the abbey of Quarr

the sixteenth and last abbot, voluntarily surrendered to King Henry VIII., and this accounts for so many portions of the venerable old building being still intact in spite of its conversion into a dwelling-house. In 1541 the abbey was granted by the king to Sir Richard Grenville for the sum of £233 3s. 4d., but in 1580 the abbey and lands were sold for £3400 to John Hele and Christopher Harris, who only a few months later conveyed the property to Sir Francis Drake of Armada fame, whose descendants have held possession of it ever since.

Such briefly is the history of Buckland Abbey, and I will now describe its present appearance. The mansion (for such it must now be called in spite of its ecclesiastical origin) is situated on the side of a gently sloping hill and is approached by two drives through the park. From the south lodge the drive

1891. There are also two very large Tulip trees and good specimens of *Pinus excelsa* and *Abies Smithiana*, with a row of ancient English Yews near the boundary wall. The old house is nearly at the bottom of the hill, and before reaching the front door depicted on the engraving, the drive describes a bold curve almost in a semi-circle. The other approach to the house is by the "North Lodge," and by a longer drive winding through groups of ancient trees and affording delightful views of the wooded hills enclosing the valleys of the rivers Tavy and Tamar. Here also recent plantations have been added to the park, but so as not to mar the scenery. This drive terminates at what was once the porter's lodge with a well-preserved picturesque old watch-tower close to the front of the mansion. A portion of this is now used as stables, from

which a short tunnel leads to the house. Behind the stables is a well-stocked kitchen garden about $1\frac{1}{2}$ acres in extent, and close to the east side of the old abbey is the grand old tithe barn, built entirely of stone, about 180 feet in length with a profusion of buttresses and loop-holes which would suggest its having once been a useful stronghold in time of battle. With the exception of a new roof this barn is exactly as it was built for the monks.

Returning to the pleasure grounds, we find near the old barn the remains of what must have been a gigantic Sycamore tree, which unfortunately succumbed to the great snowstorm in 1891. The pollard (now only 10 feet or 12 feet in height) has, however, been re-erected in its place, an Ash tree is growing from its top, and what the bulk of the original tree must have been like may be judged from the fact that the diameter of the stump is about 7 feet or 8 feet through.

On the west side of the battlemented wall is the "fishing door," leading from the pleasure grounds through extensive orchards to the river about a quarter of a mile distant. The flower garden is a small one; it is on the south-east side, and consists of a small plateau reached by steps, and bordered on the east side by a wall covered with Magnolias and various creepers. The flower beds are of the diamond pattern and planted with Begonias, Calceolarias, &c. The exterior of the house itself is highly picturesque. By far the greatest portion of the building consists of the ancient walls of the original abbey. The tower especially is well preserved, and no modern architectural additions have been made since the time of Sir Francis Drake, whose arms are emblazoned over the entrance. The north front, which is shown on the engraving, is covered with Ivies, Clematises, Escallonias, Berberis Darwini and Roses. On the south side the spaces between the Gothic windows are covered by Magnolia, Passion Flower, &c., and from the wide door on this side a good view is obtained over the lawn, skirted by pleasant shady walks. On the same side of the house and over a small side door is a head carved in stone supposed to represent the foundress (Amicia).

Entering the house itself, the visitor is at once struck with its quaint antiquity. The hall is a spacious compartment, decorated with panels and Jacobean carvings in Oak. Some parts of the panelling are supposed to be of ebony, but unfortunately the whole of the woodwork has been painted. Engraved over the fireplace is the date 1576, and it is, therefore, assumed that it was during the possession of Sir Richard Grenville that most of the work of converting the abbey into a mansion had been completed. On a side wall above the panelling is a plaster cast of a knight meditating over a skull; his war-horse stands beside him, but he has cast off his armour, which is lying on the ground before him. On the opposite wall is the bust of Sir Francis Drake, and close beside it the sword and shield he used. Here is also the drum he had with him on his voyage around the world, and another drum taken by him in battle. The old capitals and corbels of the abbey and also the arches supporting the tower are in an excellent state of preservation. On the north side of what was once the nave of the church is "the little vaulted chamber," supposed to have been once a porch leading into the cloisters; here also the ancient arches are beautifully preserved. The staircase is illuminated by a beautiful Gothic window, whose delicately

stained glass is presumably the same as when the monks left the place several centuries ago. In this staircase also hangs the portrait of Don Pedro de Valdez, vice-admiral of the Spanish Armada, who had been taken prisoner by Drake. Another celebrated portrait hangs in the dining-room. It is that of Sir Francis himself, painted by Cornelius Jansen, and dated 1590. The drawing-room affords a capital view of the grounds, and is panelled in Oak in the Jacobean style. The corridor leading to this room is covered by seventeen large engravings representing battle scenes from the Armada, and, according to the inscriptions, these were published in 1739 by John Pine. The tower is almost intact, with the exception of being divided into several floors. On the second of these floors is a large mantelpiece beautifully executed, and representing the crest and motto granted to Sir Francis in 1581.

Altogether Buckland Abbey is one of the most delightful relics of olden times, and interesting not only to the lover of picturesque scenery, but also to the historian and the archaeologist.

F. W. MEYER.

Bæter.

ORCHIDS.

BATEMANNIA BURTII.

I AM asked by "H. J." what is the cause of this and others of this section losing their leaves. I have no hesitation in saying, judging by some of the leaves which have been sent, that it comes about through the attacks of red spider and thrips which have spread over the plants through their being kept in too dry an atmosphere. Your plants are in a very bad state, and unless they are put into more warmth and a moister atmosphere and well washed with soap and water, you will stand a chance of losing them altogether through the winter months. Batemannias are usually considered difficult to grow and unsatisfactory when grown. The only time that I have seen the plant called Batemannia Burtii was when exhibited before the Horticultural Society some twenty years ago by Mr. Murrell from the collection of the late Burnley Hume, Winterton, in Norfolk. This plant, although classed by Reichenbach with Batemannia of Lindley, appears to differ widely from the typical species, and also appears to differ quite as much from the genus Zygopetalum, into which modern authorities put it. The present plant, Batemannia Burtii, we are told, grows naturally in the deep shade of the forests in Costa Rica, where it was discovered by the traveller Endres some twenty-six years ago. It grows upon the stems and the branches of trees, but always in heavy shade. The climate is very equable, and even in the dry season the dew at night is very heavy, whilst in the wet season, we are told, the atmosphere is "quite saturated with moisture," so that "H. J." will see how wrong he has been in keeping his plants dry. Many persons, too, have from time to time complained to me of this and the nearly allied genera, that they cannot make specimen plants of them. It should be borne in mind that these kinds, making no pseudo-bulbs, are not fitted for retaining their leaves to such an extent as are those which have the bulbs to support them. If they are kept in the Cattleya house with the plants always in a state of moisture, they will retain a great many of their leaves. In this way they are grown by Mr. Sander. B. Burtii varies considerably. Mr. Hume's plant was a very beautiful form. It is well figured by Walter

Fitch in Warner's "Select Orchidaceous Plants," 2nd series, t. xxxv. Another form is figured by H. G. Moon in the "Reichenbachia," 2nd series, t. 66, taken from a plant in the collection of M. Otto Frobé, of Zurich. The latter also is a very fine form, yet very different from that previously named.

WM. HUGH GOWER.

Dendrobium Phalænopsis Schrederianum.—Several fine forms of this variety have been sent me by various readers. Some of them express themselves in terms of surprise at the ease with which it appears to grow and the freedom with which it flowers, a feature which will endear it to the Orchid grower of the present day. Although it requires strong heat, this is amply compensated for by the magnificent display of bloom. From the Rev. E. Handley's collection at Bath comes a very pretty flower of a rich magenta, the base of the lip being bleached with deep maroon. Mr. Kerslake says this is the finest and darkest form he has. From C. Fischer comes a very large flower, but its colours do not recommend it. Mr. Sander sends a very bright magenta flower, the lip broad and large, stained at the base with maroon. I have also from the same gentleman a splendid light form of the same species, the flowers large, the sepals white, the broad petals being also white veined delicately with heliotrope; lip large, white, stained at the base with violet, having bold lines of this colour running out on to the front lobe, the side lobes flushed and streaked with magenta; this is a superb form. Yet another very singular form comes from Mr. Ransom, who has charge of the collection of Mr. T. Gabriel at Palace Road, Streatham Hill. This has the sepals white, and the petals and lip of a rich magenta. The above will show what a number of forms there are.—W. H. G.

Cypripedium Rothschildianum.—With this remarkably handsome Cypripedium Mr. J. Deacon, gardener to Mr. H. Harris, Bowden House, Calne, seems to be more than usually successful. It is a variety not looked upon as one of the most easily managed, but the photograph sent with this note clearly depicts the healthy condition of the small specimen under notice as well as its free-flowering tendency. One remarkable feature connected with it is that the same plant which is blooming now gave a similar display in June last, an instance I presume by no means common in *C. Rothschildianum*. It is by no means commonly grown, because its slow growth commands for it a high market value, but those who are fortunate enough to get so healthy a specimen as that in possession of Mr. Harris may well be proud of the same.—W. S.

** The photograph showed a small plant with two leads, each bearing a spike of bloom. On one there were three flowers and on the other two.—Ed.

Orchids in flower at Bowden House, Calne.—The present is not the most interesting time among Orchids, so far at least as regards a floral display, but at Bowden House, the residence of Mr. H. Harris, on a recent visit I noted among those in flower the autumn-flowering *Cattleya labiata*, comprising some two dozen plants, carrying from five to nine blooms each, of great substance and varied in form as well as colour. Some of these were imported, but are now wonderfully vigorous and healthy. *Dendrobium Phalænopsis* is quite a feature, although the plants have been blooming for some weeks past. There is, too, such a diversity of colour as is not commonly found in this *Dendrobium*, some being pale and delicately shaded, others richly coloured. The old leafless pseudo-bulbs on several of the plants are flowering freely, which, together with the display from the young growths, makes altogether an extensive and varied show. Of other Orchids in bloom in this interesting collection may be mentioned *Vanda tricolor*, *V. Sanderiana*, *Cattleya Bowringiana*, *Lælia autumnalis*, *Lycastes*, represented by L. Skinneri

alba, *Cypripedium grande*, *C. callosum*, *C. Spicerianum* and *C. Rothschildianum*. *C. grande* is a robust-growing plant and flowers freely; so also does *C. Spicerianum*. *Odentoglossums* flowering now are *Röczli* and its allies roseum and album. *Calanthes* will shortly make a good show, *C. Veitchi*, *C. vestita oculata*, and *C. vestita lutea* being the autumn sorts grown in goodly numbers. A large number of *O. Alexandræ* are grown, some being planted out in peat and *Sphagnum* beds. This method restores unhealthy plants to their former vigour, and provides a source for obtaining good strong ones for placing in pots to replace any that may not be thoroughly satisfactory. These which are enumerated are only a tithe of what are cultivated at Bowden House by Mr. J. Deacon so successfully, several houses being filled to overflowing with large healthy plants as well as smaller importations.—W. S.

Cattleya labiata.—Of this species I am in receipt of several flowers from various readers. All of them are exceedingly beautiful, but two of them only are worthy of special commendation. The best form is a flower from the Hon. Miss Winn, of Nostell Priory, Wakefield, from a plant that bloomed last year, and of which I made a note in THE GARDEN. I am glad to see it again, for it is a remarkably fine coloured variety, coming well up to the original form, but I am sorry to find it has not improved in size. From the Rev. E. Handley, of Bath, also comes a very handsome flower of excellent contour, the sepals and petals rosy lilac, the whole of the front lobe blotched with deep magenta, with a light border round the prettily frilled edge. This flower, however, like that of Miss Winn, wants size.—G.

Cattleya Bowringiana.—First introduced by Messrs. Veitch in 1884, this species has now obtained an established position in every Orchid collection of any size. At the time of its introduction it was hailed as especially useful on account of its flowering in October and November, a time when *Cattleya* flowers are scarce. Although the re-discovery and importation of the autumn-flowering form of *C. labiata* have brought into cultivation a rival of even greater merit, the two are so different from each other, that its popularity need not be affected. It is very like the older *C. Skinneri* in the shape and colouring of its flowers, but that species of course flowers in spring. The stems are 9 inches to 15 inches high, bearing at the top two or three oblong leaves. The umbellate racemes carry about eight flowers, each a little over 3 inches across the sepals. Although they are, therefore, small as *Cattleyas* go, they lack nothing in richness of colour. The sepals and petals are deep rosy purple, the convolute lip being white in the throat, but with a blotch of velvety dark purple on the centre. The species is a native of British Honduras.—B.

ORCHIDS AT SYON HOUSE.

DURING the past few years the collection of Orchids at Syon has increased in interest, and several houses are filled with plants representing really useful species and varieties. Considerable trouble is experienced here in the late November and winter days from fog, which often plays sad havoc with the flowers, especially those of the *Calanthes*. When there a few days ago many kinds were in bloom, comprising a large houseful of *Cypripedium insigne*, previously noted. *Trichosma suavis* and *Masdevallia tovarensis* were opening the first flowers. This *Masdevallia* is one of the best Orchids an amateur can grow, as it is easily cultivated and produces a wealth of pure white flowers, very useful to cut for decoration, whilst they remain long in beauty either on the plant or when gathered. *Maxillaria grandiflora* is another good cool-house species in bloom in this collection. It enjoys a very cool, but moist temperature. Amongst *Odentoglossums* many species and varieties might be named, including, of course, *O. crispum* in variety, but in bloom recently was *O. grande*, which during the past few days has been imported largely. At

one time it was so scarce that very few plants were met with, but this is altered now. The flowers in the best forms are very large and rich in colour—chestnut-brown with bands of yellow, and if kept dry they remain in beauty several weeks. Mr. Wythes has some really good varieties of *Lycaste Skinneri*, which display considerable variation in colour, especially in the lip. The pure white alba is a lovely flower, and we hope it will become more common than at present. Some good plants here in bloom were in contrast to the coloured forms of this fine species. *Cattleya Bowringiana* was blooming freely and is a bright Orchid at this season. It varies considerably in colour, the darker varieties being the more striking. *Vanda tores* is well established close to the glass at the sides of the house, and next year we anticipate a good display of this Orchid, which is not one of the easiest to establish well. Sunshine, moisture when growing and comparative dryness in the winter are the chief cultural details. In a few days' time the house, largely occupied with *Calanthes*, *C. Veitchi* in particular, will be a mass of colour. The rising stems are of great vigour and promise spikes several feet in length. We hope fog will not cut short their beauty. This sometimes happens, and *C. Veitchi* is one of the first to succumb. It is exceedingly disappointing to see a splendid forest of flower-spikes, so to say, spoilt by fog, against which there is practically no remedy. The *Pleiones* were going over, at least *P. lagenaria*, and we should like to see these Orchids more grown. A few panfuls are very pretty and they are not difficult to manage. An objection urged against them is the absence of leaves at the time of blooming.

SHORT NOTES.—ORCHIDS.

Cattleya aurea.—E. Jones sends me two flowers of this plant for an opinion. They are remarkably good, but I do not see anything unusual in the markings of either flower. No. 1 is by far the larger and better form.—W.

Cattleya maxima.—From Sir W. Marriott's collection comes a large flower of this species with a very dark and well marked lip; it also is peculiar in having the upper half of the two convolute side lobes pure white, which is very striking when the lip is spread open. I do not remember to have seen a form like it before.—G.

Oncidium tigrinum.—This very beautiful plant is flowering very freely with Mr. Ransom in the gardens of Mr. T. Gabriel, Palace Road, Streatham Hill. The various plants exhibit a considerable difference, but yet the flowers of all of the varieties have the same delightful perfume of the Violet which renders them most acceptable. The plants are put into the *Cattleya* house to open their flowers.—W.

Dendrobium Leeaanum.—This beautiful species I think I have noted on a previous occasion. I now have a remarkably handsome flower from Mr. Sander. Although in growth it much resembles *D. Phalenopsis*, with which it grows naturally, and with which it came home, its flowers are very different, the petals of a rosy-purple hue, lip deep violet, having several raised fleshy plates on the disc, which are fringed; the front lobe is waved at the edges.—W.

Dendrobium Phalenopsis Statterianum.—This, although a very elegant flower, cannot be compared with the fine forms of the typical plant. The present plant is another of Mr. Sander's introductions, but although the flowers are smaller than those of the typical plant they are very rich in colour. In the flowers now before me the sepals and petals are rosy-purple, the lip of a purplish-maroon, becoming deeper in the throat. It likes the warmest end of the East Indian house, and during the growing season an abundance of water. Even at the dullest and driest season it should have moisture enough given it to prevent shivelling.—W. H. G.

Lælia præstana.—“J. H.” sends me a very fine flower of this species, saying it is the second

time it has flowered this season. This is a frequent occurrence with newly-imported plants, because it flowers twice in a state of nature in the twelve months. After plants have been cultivated for a short time they usually flower but once. To induce them to continue to bloom twice the growths now flowering should be finished up well, and to accomplish this the plants should be removed from the cool house to a warm and light place in the *Cattleya* house. The flowers now before me are in the sepals and petals of a deep rich rose colour; the trumpet-shaped lip overlaps and is very thick and fleshy, the front lobe and the tips of the side lobes of a very deep and rich purple with a triangular white blotch in the centre; the throat is very rich orange.—W.

KITCHEN GARDEN.

ECONOMIC VEGETABLE CULTURE.

METHODS in vogue among growers of vegetables for exhibition are anything but economical, and the results are equally unsatisfactory as far as such products are concerned when these happen to reach the kitchen. Coarse or overgrown vegetables have been repeatedly condemned in these pages. As it happens, growers for exhibition are not the only offenders in the matter of growing vegetables to a size not calculated to please either the cooks or those whom they serve, and it is quite time methods of culture were varied with a view to producing better vegetables at less expense than formerly. When I allude to the expense of present methods of production, it is not to be understood any charge of extravagance, recklessness, or even of resorting to needlessly expensive practices is intended. What I shall attempt to prove is that in very many instances heavier crops of smaller, therefore superior, vegetables might be had from a given breadth of ground without any increase in the cost of production, the saving being effected in the labour bill, and the gain in weight and quality of crops considerable. Some of the practices to be advocated may not be altogether the best in the case of poor ground or light hungry soils, but would answer well in the majority of private gardens the soil of which is fairly retentive and the manure supply not stinted. If we crop heavily and closely, it follows that every attempt should be made to sustain the fertility of the ground, or otherwise the exhaustion of such important elements of plant food as phosphates, potash, and nitrogen, separately or collectively, must end in partial or complete failure of such crops as stand most in need of them. When, however, the manuring is heavy and constant and the cropping comparatively light, there is every likelihood of the soil being actually poisoned with manure, and few gardeners need be told that good crops are rarely, if ever, taken from manure-sick ground. The best results, as abundantly proved by market growers, attend the practice of manuring heavily, fairly fresh solid manure and not washed-out stuff little better than a mass of humus being used, and cropping close and heavy.

If we desire to grow extra large vegetables, anything in the shape of crowding is avoided, and crowding is also objectionable sometimes even when only good average produce is wanted. When, however, it is seen that allowing so much space favours coarseness, why, if smaller vegetables are preferred, persist in the practice of over-thinning or wide planting? What gardener has not had a good object lesson in the shape of Savoys left in the seed bed after what were wanted for pulling out had been duly drawn? Unless left very thickly or raised on

the poorest of poor ground, these sprawling plants, left most probably without any thought of their doing any good, will yet form excellent small hearts superior in quality, it may be, to any obtained with very much more labour and expense elsewhere. At the present time we have Savoys with excellent hearts pressing against each other all round, more being obtained from a bed 6 feet square than is often cut from three times that space of ground. Large hard, much-blanching hearts of Savoys are not good eating; whereas the neat, moderately firm, partially blanching hearts and which can be cooked whole are not surpassed or scarcely equalled for mildness, tenderness, or delicacy of flavour by any other kind of winter green vegetable. Instead, therefore, of planting them so far apart it would, as a rule, answer far better to either sow the seed thinly in rows where most of the plants that come up are to remain, or else put them out closer together. One foot apart each way is ample for the Tom Thumb section, 15 inches for the Early Elm and Dwarf Curled, and 18 inches for the Drum-head, rather less space in each instance being allowed when the seed is sown where the plants are to grow. The ordinary Cabbage again is very frequently grown far too large to be good. The neat little hearts produced by the small quick-growing varieties, including those treated as Coleworts, are, I find, always preferred on the dining-table—in fact, when nothing but large close Cabbages are forthcoming there is no further demand for them. Just now we have a great abundance of green vegetables, but of nothing am I so proud as a great breadth of Little Gem and London Rosette Cabbages. These were raised late in July and duly planted out 1 foot apart each way. As yet they are scarcely forward enough to cut, nor do we want them, as any quantity of pretty little hearts are being cut from the plants left thickly in the seed bed. The seed was sown in long drills drawn 9 inches apart, and the plants left about 4 inches apart. Ellam's and other good varieties that do not attain a large size, the seed of which was sown about the middle of July, have been put out in succession to Onions, the distance apart being 15 inches each way, and although somewhat forward, I do not anticipate many failures. Those left in the seed-beds will also most probably do good service.

Borecoles, again, are often grown too strongly—at any rate, such has been the case with me repeatedly. Fully-grown tops or hearts of Scotch or curled Kale are what are most preferred, but these are liable to be badly damaged by snow and frosts, while those that have been left more thickly in the long rows where raised have not been injured in the least. The question is, therefore, whether it is not more economical to either sow the seed where the plants are to grow, arranging the rows 2 feet apart and thinning out to 1 foot apart, than to transplant from seed-beds and allow very much more room. Sowing the Asparagus or Buda Kale where the plants are to remain has always answered well with me, this being done after ground has been cleared of second early Potatoes, and the plants left about 6 inches apart. Lettuces and Endive sown where the plants are to remain are more often than not over-thinned. Supposing the rows are 1 foot apart, if the plants are left from 4 inches to 6 inches apart they will grow quite large enough, the Lettuce hearts being close and good, while the Endive becomes self-blanching. In very many instances Carrots, Onions and Parsnips are over-thinned, large roots not keeping so well as the smaller ones, and are certainly the least

preferred by all good cooks. The large varieties of Beet, and the Turnip-rooted in particular, should not be given very much room, or they become too coarse, and even Turnips "bulb" fairly well when left growing not more than 4 inches apart in rows 15 inches asunder.

Brussels Sprouts, Broccoli and Cauliflowers are among the subjects that it does not pay to crowd in the least, though the owners of small gardens might yet try what could be done in the way of economising space. I have seen really good crops of the first-named obtained by sowing the seed on firm, but not very poor ground in drills 2 feet apart, leaving the plants 18 inches asunder. In this case there is no redundancy of leaves, and no failure of the sprouts "buttoning" properly. Broccoli is an uncertain vegetable under almost any form of culture, and is not therefore worthy of much space being devoted to it in small gardens. It is particularly liable to destruction by frosts if "long in the leg," hence the necessity of plenty of room as well as a firm root-run. A good supply of small early hearts can be had, however, by sowing the seed of Veitch's Autumn Protecting and other early varieties thinly in rows where the plants are to remain, autumn Cauliflowers being similarly treated. My plants of both kinds are usually raised in long rows from 9 inches to 1 foot apart, and unless badly wanted for the principal breadths some are left about 1 foot apart. This season a capital lot of neat hearts has been cut from these cheaply grown plants, and gave as much or more satisfaction as any cut from stronger plants. There is no economy in crowding Globe Artichokes, only those given good room and not starved in any way being really profitable. Nor ought either Peas, Beans, Vegetable Marrows, Jerusalem Artichokes and Potatoes to be allowed to smother each other, this being the reverse of economical. W. I.

A remedy for the Carrot grub.—When walking through the gardens at Gunton Park last September my attention was drawn to an extra fine crop of Carrots growing upon a long west border. Mr. Allan informed me that in early summer, as soon as growth had well commenced, the whole border was severely attacked by the Carrot grub, so much so indeed that the Carrot foliage flagged. Being anxious, if possible, to save the crop, he had a bushel of lime and one of soot thrown into a vessel containing 100 gallons of water. The mixture was well stirred and allowed to stand for a night, after which the border received a thorough soaking with the clear water from the tub through a rosed watering-pot. The result was a complete destruction of the grub. Growth recommenced, and at the time of my visit the crop was a credit to the grower. Such a simple, cheap, and effectual remedy ought, I think, to be widely known.—J. CRAWFORD.

The Onion maggot.—THE GARDEN being always a week old when it reaches me will explain delay in noticing "A. Y.'s" communication respecting the Onion maggot. There is not a particle of evidence that the pest feeds on any other vegetable but the Onion, and no one but "A. Y." has ever been led to suppose that it does. Whether the fly does or does not visit the Cabbage bed, or the grub feeds on the roots, as "A. Y." imagines (p. 379), is of little consequence, as no one but he would think of an old Cabbage bed for Onions. We in this part manage to get another crop, such as Peas or Celery, from the old Cabbage plot before we want to get the Onions in. "A. Y." draws wrong conclusions from the act of the grubs quitting the lime and the paraffin, as stated by me. It was not from any dislike to either of them that they hastened away, but they retreated from a desire to get to their hiding-place and their feeding ground, for the grubs experienced no inconvenience when an Onion containing some was dipped in

paraffin; at any rate they showed no desire to escape. If there is any cure, as Mr. Burrell says (page 379), it must be applied to the plant and not to the soil. Even the application of paraffin to the growing plant, on which "A. Y." lays so much stress, is a questionable preventive, as it does not adhere to the tops, and its odour is so evanescent, that there is very little trace of it in a few hours after it is applied. Wherein, then, lie the distasteful or the obnoxious properties of the paraffin to the Onion fly?—W. P. R., *Preston*.

FLOWER GARDEN.

TRANSVAAL GARDENING.

TO THE EDITOR OF THE GARDEN.

SIR,—Pretoria is the capital of the South African Republic, perhaps better known to Europeans as the Transvaal, and is situated in about 25° 45' 2" S. latitude and 28° 11' 30" E. longitude from Greenwich. The height above sea level is about 4450 feet. It is estimated to contain a population of about 6000, most of whom are of British or British colonial origin, with a fair sprinkling of Germans, Hollanders, French, and Swiss, and a good many Hindoos from various parts of British India. The town lies in a valley having a gentle slope to the eastward until the Apies River, which forms the boundary on that and the north side, is reached. The soil varies from a shallow, but fertile gravel in the higher part of the town to a rich alluvium composed of decomposed shale with a gravelly sub-soil. The climate is very variable, and would lead an English gardener to despair of doing anything with those objects which he loves so dearly. In the winter season, which lasts from the beginning of May to the middle of August, we have seldom a drop of rain, and while the temperature in the middle of the day frequently stands at 80° Fahr., in the night the thermometer shows several degrees of frost. These extremes of temperature, however, are by no means so destructive to vegetable life as might be supposed. We are not able to do much to shelter our plants, as conservatories and greenhouses are not at present available. The chief feature of Pretoria is that nearly every house has a garden ranging from a quarter to three-quarters of an acre in extent, and gardens of larger proportions in the outskirts an area of two to five acres. Generally speaking, Roses are cultivated with great success, as the conditions appear to be very favourable. Many of our rosarians have collections of from one hundred to two hundred and fifty varieties, and can make a brave display at our flower and agricultural shows. Last year about the end of October we had a show of Roses which your nurserymen would have found it hard to beat, whether as regards the quality of the blooms or their variety. I was able to stage thirty-six high-class blooms, and obtained a second prize for them, although I had made no particular preparation for the show. Where you limit the number of blooms to two or three dozen for the professional gardener we do not consider it unduly taxing our amateurs to stage the same number, and I have been assured by gentlemen from England that our displays would have been considered first-rate at your best shows. We have another show coming on on the eighteenth of next month, the prize list of which I send herewith, so that you will be able to form some opinion as to the class of Roses most popular with us.

But Roses are not the only objects of the gardener's attention here. Carnations, Pansies,

and Fuchsias are also in favour. The first-named grow wonderfully well with us, and are laden with bloom for many weeks in the year. Some, indeed, scarcely go out of bloom during the whole year. It is no exaggeration to say that some established Carnations have hundreds of flowers upon them during the height of the blooming season. Tufted Pansies do not do so well, as the climate is too dry during the winter for them, but where a little shade and plenty of water can be afforded they are as fine as you get them in your gardens. Of course the Carnations and Pansies are generally raised from seed, and consequently are not named, however fine in quality they may be. Verbenas grow like weeds. Cinerarias and Cyclamens give no trouble under the shade of a verandah, but Calceolarias are not suited for the climate and such rough-and-ready gardening as we bestow upon most things. I am still in doubt as to how Japanese Lilies will do here. I imported a good variety a year ago, but none of them have flowered yet; indeed, nearly all remained dormant in the ground for nearly a year, and are now only beginning to show signs of life. *L. auratum* is just coming through, and *L. lancifolium* varieties have only grown about 4 inches out of the ground; and this, too, notwithstanding that they were planted early last November and had all the forcing of the sum-

mer weather and abundance of rain. The same has occurred with Lilies of the Valley, which are only now beginning to show through the ground. *Begonia Rex* in all varieties is a great favourite here, and it thrives well without much trouble. The unusually heavy frosts of last winter have, however, tried the plants considerably. Tuberous Begonias are coming into fashion, and several very fine varieties are to be found in many houses. Primulas are of easy culture from seed grown here, but I have had very many disappointments in raising plants from imported seed. With seed of my own saving of two and three years old I have no difficulty in getting young plants, so that I infer the seed sent out to Africa is not so fresh as it should be to secure germination.

it is exactly like the parent plant, but the largest flowers now on it measure nearly 7 inches across, while earlier ones have been larger. There is nothing heavy or lumpy-looking about them, as the stems are slender and the discs characteristically small, being only 1½ in. in diameter in the largest flowers and of a dark brown colour, looking black from a short distance, and making it a very striking object. If the break can be perpetuated it will take the place of the common Sunflower to a great extent, as flowers of the latter, even if of no greater diameter, look lumpy and less graceful by the side of the new one, and the plants bear no comparison with it for length of season and freedom of flowering. Only a small quantity of seed has been saved from this plant, as it seems to be naturally shy in setting its seeds. This of course lengthens the flowering period. Similar breaks may have occurred before, but I have never seen or heard of them, though plants of the type sometimes vary slightly in height and size of flower, but to nothing like the same extent.—J. C. TALLACK.

the following year. Good roots may be purchased from Japanese growers, but they ought to be established in pots or baskets in Japan before being sent over. It is scarcely necessary to urge the claims of the *Nelumbium* in order to its becoming a feature with us. The Americans have succeeded in adding it to their popular garden plants even to the extent of naturalising it, acres of it occurring in the water meadows in some States, and, so far as we can make out, we ought to be able to do as much in some parts of the British Islands. Mr. Sturtevant, of New Jersey, got a plant from Kew a few years ago, planted it in a submerged meadow and it now covers acres, the accompanying woodcut being from a photograph of this most successful experiment. W. W.

NELUMBIUM SPECIOSUM.

HERE is a little picture which tells very plainly the story of the *Nelumbium* naturalised in the Northern United States—in New Jersey, in fact, where the frosts in winter are more severe than they are in England, and yet not so severe

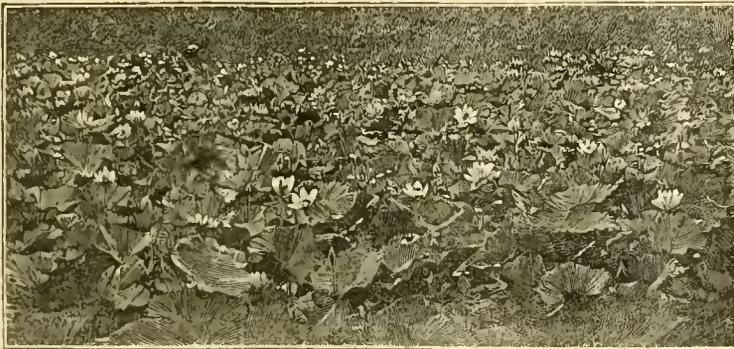

NOTES ON HARDY PLANTS.

Oxalis lobata.—After having been brown or invisible most of the summer, this little species becomes green and pushes forth its abundant orange-yellow flowers in the months of September and October. It, therefore, at this late season presents all the freshness and brightness of a spring plant. It is at most but a few inches high, and the flowers but slightly crop out of the short tufts of delicate pale green leaves. I daresay it is a plant that should be protected in some gardens, especially as it is one of the kinds better for being left in the ground the year round. On a sunny bank of black, somewhat dry soil it remains out with me from year to year without protection, and I should say it would be fairly safe in any garden of moderately light soil if planted at a depth of 5 inches or 6 inches. I would suggest one way of planting it for effect, and that is between the shorter varieties of *Erica vulgaris*; the foliage effect is good from the sharp contrast of dull green to pale apple-green, and the tufts of *Erica* are ample protection for the little tubers in the severest weather. Those who know the plant will readily imagine the pretty effect it has among Heaths.

Helianthus (Harpalium) rigidus.—The kind now in flower is not the typical plant, but a capital variety that, so far as I know, occurred here naturally. It resembles the type in all ways excepting that it is a little taller and its flowers or heads are fuller as regards the ray florets; in short, it is a semi-double flower. Then it begins to flower in early August and never stops until severe frosts come; whereas the older plant stops flowering and gets quite brown by the middle of September. One more good point is that its root-stems do not run to such great distances as those of the presumed parent. My plant is now simply grand; it is 6 feet across, and it keeps compact, and has kept in its place for four years. I not only consider this a better plant and the flowers more valuable than those of the older *H. rigidus*, but I find it by far the most useful of all the Sunflowers.

Aster Novæ-Angliæ roseus.—This, as indicated by the name, belongs to one of the most marked and distinct species of Michaelmas Daisy. There can be no mistaking the species, and the varieties may be identified by the colour of the heads.

Stokesia cyanea.—This handsome and by no means common plant is likely to reward those this season who have persisted in its cultivation. Usually it is so extremely late in flowering as to be practically in these northern parts a flowerless plant. It is proved, however, by the weather conditions of the past summer that it only needs hastening on by mere sunshine, when it may flower freely with or slightly before the Michaelmas Daisies. The habit of the plant and its bold and singular flowers all stamp it as a subject worth having. I believe that our more southern friends, especially those who grow it on the lime or chalk, may fairly well rely on it as an early

Nelumbium speciosum naturalised in New Jersey.

mer weather and abundance of rain. The same has occurred with Lilies of the Valley, which are only now beginning to show through the ground. *Begonia Rex* in all varieties is a great favourite here, and it thrives well without much trouble. The unusually heavy frosts of last winter have, however, tried the plants considerably. Tuberous Begonias are coming into fashion, and several very fine varieties are to be found in many houses. Primulas are of easy culture from seed grown here, but I have had very many disappointments in raising plants from imported seed. With seed of my own saving of two and three years old I have no difficulty in getting young plants, so that I infer the seed sent out to Africa is not so fresh as it should be to secure germination.

as to be injurious to the *Nelumbium* when planted in 2 feet of water. We hear from visitors to the States, as well as from the Americans themselves, how large a place this and other Water Lilies fill in the outdoor gardening there, even the most tropical species being a success with a little simple contrivance to afford artificial heat to the water in spring and autumn. There is a long account of *Nelumbiums* in THE GARDEN, Vol. XLIII. (p. 462), with a picture of *N. speciosum*, to which all who are interested in water plants should refer. There is no apparent reason why the *Nelumbium* should not be made a feature in our ponds, in the warmer parts of the country at any rate. Mr. Smith-Barry might grow it in his water garden at Fota, and it might also be tried in South Wales and Cornwall. The probability is that failure at the start has convinced those who have tried to grow *Nelumbiums* out of doors in this country that the conditions were unfavourable; whereas, the difficulty generally experienced in transplanting them, even under glass, is most likely the cause of failure. There are not a few clever cultivators who cannot establish the *Nelumbium* in their indoor aquaria. On the other hand, when once it gets hold it takes care of itself. Seeds sown in baskets of soil and sunk in a warm corner of a sunny pond out at the reach of birds would grow, and the baskets could be transferred to permanent positions in

Pretoria. HORTUS.

A new break in Sunflowers.—In a garden near here a new and what promises to be a valuable break in annual Sunflowers has occurred. Seed was saved last year from some plants of that excellent variety known as the New Miniature, and among the produce of this seed (which came true in all but this solitary case) one plant grew away rapidly and developed into a very fine and showy specimen over 6 feet in height that has bloomed very freely all the summer through, and still, at the end of October, has dozens of flowers on it. In all its parts, except for size of flowers and leaves,

autumn bloomer. It is a perfectly hardy species, but better in several respects for being deeply planted.

Saxifraga Mertensiana.—I have as yet had no cause for great love for this plant. I have grown it about six years, but never yet flowered it. I am aware that this might not be saying much had I not changed it about, but I have done so, and still I neither get flowers nor, what is practically the same, much vigour of growth. It is, of course, a naturally small species, but, even allowing for that, the plant does not get on. It has the very annoying habit of beginning to grow in the autumn months, and, what is worse, the fresh leaves are injured by the early frosts. This, some would say, is only another way of describing it as a non-hardy plant. That, however, is scarcely correct, because I have grown it quite exposed these six years and the corms never seem to suffer with cold, and in their way do make foliage strongest in the autumn, and after being nipped and killed down in the winter, a more feeble growth starts in the spring.

Polemonium humile.—At the present time the bronzy yellow foliage of this little species or variety, whichever it may be, is most attractive, resembling coloured Spleenworts. It may be that the hot summer has something to do with this pretty feature; still the fact remains. At all times it is a dainty plant, very superior to *P. repens*, which often passes for it.

Dictamnus gigantea.—Whence comes this specific name and why? I have just been reading a description of the plant, evidently by a careful observer, and he speaks of seeing well-grown and long-established plants 2 feet high; but I see nothing in the description that does not apply fully and strictly to the type. I have suspected the *gigantea* for two years. I got a plant three years ago under the name from Germany, and to the present I have seen nothing about it differing from the old species, *D. Fraxinella*. My old plants of *Fraxinella* invariably reach a stature of 2 feet and sometimes 3 feet. In the summer of 1892 they were fully 3 feet high, evidently enjoying the wet season. If there are really special features about *D. gigantea*, I should be much obliged for the information.

Veronica Hectori.—My oldest plants of this are now truly beautiful, their rudimentary and imbricated leaves imparting a cord-like appearance to the forking branches which fairly shine with a golden brightness. The puny shrub of but 4 inches to 6 inches is so distinct and quaint as to be beyond description, and to gain an idea of its form and charms it must be seen. Singular as many of the late arrivals of this shrubby class are, being mostly the conifer tribe, this is the most remarkable of all, and also, though a slow grower, perhaps the hardiest of the batch.

Eremurus robustus.—This is certainly one of the strongest growers and hardiest of the genus, and I think that it does not take quite so long to obtain a flowering specimen from seed as we supposed it necessarily would a few years ago. I know several instances of plants flowering considerably under the age of seven years. After the second or third year the plants make rapid progress, quite out of all proportion to that of the first year or two, which can be easily understood when we allow for the root habit. After the second year the radiating roots increase in numbers, so that the progress of the plant afterwards is commensurate with the root growth.

Arenaria norvegica.—This Moss-like Sandwort is remarkable for its shining character and pleasing deep green shade. Though but an inch high, it stands out distinctly as perhaps the freshest and neatest thing in the way of a winter cnshibition plant. We do not, as a rule, find the Sandworts of much value for their flowers alone; it is the combined characters of the plant and especially the habit that fit them for gardens or rockeries.

Sagina Boydi.—This, I believe, will become a favourite plant for decorating rockeries on the same principle as the *Arenaria* just noted. It is a charm-

ing little thing, found, I believe, by Mr. Boyd on the Scotch hills. Evidently a very distinct variety.

Veronica loganoides.—This is another pretty and very distinct form of the dwarf conifer-like section. Its colour is yellowish green, and the minute leaves, like the merest bracts, are sharply recurved. I suppose it is not of much use to speak of these *Veronicas* in regard to their leaf form, or until the plants have become well acclimatised, for we have proved that according to the way in which a plant may have been raised it assumes a given habit; that is to say, if you raise a plant from a cutting in a warm house, it may be somewhat drawn and the leaves longer than would have been the case if raised out of doors. This we know is common, but the singular thing in these *Veronicas* is that for years a plant will go on giving evidence in its habit of its special treatment in its infancy. I can point to many instances of this kind, and can show examples with such kinds as *Lycopodioides*, *salicornioides*, *Armstrongi*, *Hectori* and *cupressioides*. So different are some of those plants from the cause mentioned, that I would not have believed in their identity had I not known all the facts.

Ostrowskia magnifica.—The Rev. Mr. Ewbank has kindly informed me of his experience with this at Ryde, and as I esteem the hint as very valuable, I produce it now—being exactly seasonable, and that in the double sense of either planting new roots or placing protectors over old roots. The treatment mentioned by Mr. Ewbank is the drying off the roots in summer like *Oncocycylus Iris*, to be done by means of a glass shelter open at the sides. This is said to make all the difference in the world with this plant. I know the plant to be capable of enduring its share of cold, even in Yorkshire, so that we need not suppose the Isle of Wight climate has much to do with results in that respect, that is of cold.

Aster cordifolius Diana = Photograph.—A plant of this given me by the raiser, the Rev. Mr. Dod, has been glorious for the past two weeks, and it seems capable of sustaining its beauty for yet two weeks more. Like the other varieties of this species, the flowers are very small, but the two features of beauty in this case are its enormous panicles and the delicate, very pale lilac or mauve flowers. With me it is 5 feet high. Nothing could be more useful than short sprigs (which may be picked by the score from the enormous clusters and never missed) for bouquet or table work. I believe that Mr. Dod, up to the Aster conference date, spoke of the plant by the name "Photograph." Now we shall recognise it by its new name *Diana*. It has the merit also, like all the varieties of *cordifolius*, of not running at the root.

Morina longifolia.—At present one of the brightest bits of blossom in the garden is to be seen on a plant abnormally late. As is well known, this Thistle-like plant produces a long succession of flowers in whorls, opening velvety white, turning to clear rose, and dying off vermilion. I merely mention it, though a well-known plant, because I think it is not so much grown as it deserves to be.

Morina Coulteri.—I cannot find by my notes how this plant came into my possession, but I think I am right when I say that I have possessed it three years, possibly from seed. Has anyone flowered it? If so, what are its merits, and wherein does it differ from *longifolia*? That it is distinct, though not much in foliage, is evident from the fact that it has remained so long flowerless. Such negative evidence may not be much to go by, but it often puts us on the right track for useful conclusions. I also imagine that I see a difference in the foliage. Certainly in the case of my plants the foliage is longer than that of *M. longifolia*, but that may be accounted for by the fact that plants of three years' growth that have never flowered may have stronger leaves than that of other plants that have bloomed.

Campanula muralis (Bavarian var.)—This is a variety showing an advance in the right direction. Not only is the plant more vigorous, but

its flowers are brighter, bigger, and produced all summer and up to the present time in profusion. Compared with the type, it is thus seen to be more useful.

Aster alpinus speciosus.—What is this by description? Who raised it and authorised the name, and when was it raised? The fact is it is a most distinct and splendid plant by contrast with the type, and there are already signs of disputes as to its identity and origin, and it is also a fact that other varieties of the alpine *Aster* are going under this name. Personally, I believe that, distinct as the plant is, similar ones may be had. Now that plants are being largely raised from seed of the type, many varieties are turning up. I have seen no less than eight, and whereas all seem improvements on the type, I have never yet seen an inferior seedling. If this is a fact that can be relied upon in gardens generally, it is an important one; but we should not forget that seedlings in the first flush of their vigour often display results that are not sustained by the older plants. J. Wood.

Woodville, Kirkstall.

FLOWER GARDEN NOTES.

WEeping ROSES.—The one or two notes that have appeared in praise of *Aimée Vibert* recall an experiment with that variety that has proved a decided success and which may prove worth recording for the benefit of any who are able to place it in a similar position. Some four or five years ago I formed a large bed round the stump of an old *Pinus Cembra* that had been headed back to a height of 7 feet from the ground, intending to plant it in the summer with *Canary Creeper* and allow this to ramble over bed and stump. This was accordingly done, and we had a glowing mass of colour all through the summer; but when the creeper was removed in autumn, the old stem looked bare and ugly, and I shifted a large plant of *Aimée Vibert* from a wall and planted it close up to the old tree. Sufficient shoots were brought round and over to clothe the old stem and the remainder were allowed to ramble at will. Not much growth was made the first season, but all long shoots available at the end of the second season were arched down and the tops lightly pegged into the soil. Certainly all through the early part of the present summer this *Rose* was about the most attractive feature in the flower garden—a mass of white 7 feet in height and 15 feet in diameter. A rather strange thing is that the plant in question is growing in almost pure leaf-mould, that compost having been originally used to make up the raised bed round the tree. Ivy is often recommended for clothing tree stumps, and it certainly may be of use if better things are not to be had; but there is a stiffness about it from which the weeping *Roses* are free, independent of the wealth of flower the latter will furnish.

Besides the increase of many herbaceous plants by division, as mentioned in previous notes, any special sorts of *Phlox*, *Pentstemon* and *Snapdragon* may be propagated by cuttings. They will do fairly well in the ground under a frame or handlight, but are best in boxes or small pots if these can be spared. If a number of mixed beds are contemplated for another year, a few good *Pentstemons* and the white *Snapdragon* will come in well for the purpose, and if so required should be worked on from the cutting pots in the spring so as to have nice bushy plants for turning out. A mixture of these and some good double *Zinnias* thinly planted with a carpet of some dwarfier plant that is in its turn relieved at intervals by a graceful *Acacia lophantha* makes a very handsome bed. If *Lobelia cardinalis* and the varieties of *fulgens* (very beautiful summer plants) are in a position where they cannot be thoroughly protected, it is best to lift them and store away in boxes until the worst of the weather is over. Among the list of grand autumn flowering plants noted for division are *Helianthus Soleil d'Or*, *Senecio pulcher* and *Stokesia cyanea*. The recent interesting note (October 28, p. 391) which tells of the one *Lily* at

the Colchester banquet sets one thinking on the absence of these flowers from English gardens. Is it attributable either to indifference to their beauty or a lack of desire to attempt their culture? I hardly think so, but rather to the fact that they will not make themselves at home in the majority of gardens. Take *Lilium auratum*, for instance, that has been imported into this country in hundreds of thousands, "perfectly hardy," we are told, and "easy of culture." Is it? How comes it then that one may go into so many places and not find in the open air a single representative? I fancy the most of us have yet a lot to learn about the successful outdoor culture of Lilies. With the autumnal alterations in herbaceous borders, replanting, rearranging, &c., comes the question of labels. I have tried terra-cotta labels, which are broken by the foot, hoe, or rake, and vanish; Chandler's copper labels, which require a small iron rod whereon to rest them, and which tarnish badly unless coated with paint previous to writing on them, and the raised letters of metal on a metal ground, excellent in their way, but rather expensive if one requires them in quantity. No one likes to see great heavy labels showing perhaps over some tiny plant, but something in the way of a mark is absolutely necessary, or choice plants of small dwarf habit may be uprooted, consigned to the basket in the company of weeds, and ultimately to the rubbish heap. E. BURRELL.

Claremont.

Cornflowers in autumn.—Cornflowers that stood the winter came into bloom very early. I grow a large patch of both the double and single forms, as they are so useful for cutting in early summer, and the flowers are generally finer on autumn-sown plants than on those that are raised in spring. This season, by reason of the early ripening of the seeds, a good many self-sown plants came up early in August, and these have been blooming quite freely for a month past. I can now, in the third week of October, cut a nice lot of blooms. The blue Cornflower is ever welcome, as we have nothing to cut from of its colour at this time of year.—J. C. B.

Fragrance in Carnations.—In the interesting notes from Mr. Engleheart in THE GARDEN, October 21 (p. 367), he insists upon Carnations having fragrance, and rightly remarks, "Surely a scentless Carnation is scarcely worthy of the name, just as a scentless Rose is unfit to bear the name of a Rose." This is very true, but raisers of late years have overlooked this precious virtue, and many new Carnations and Roses are without the most exquisite charm of the flower—sweet scent. I think fragrance is quite as important as colour or form, and a Carnation without its sweet characteristic perfume should be condemned as much as if the pods burst or the growth of the plant was weakly. Two of the most fragrant of all Carnations are the old crimson Glove and the white Gloire de Nancy. I saw a large bed of the latter in a Middlesex garden one year and the fragrance was delicious, scenting the air for many yards around. We want to get this fragrance into the ordinary garden Carnations. It is almost lost in the winter-flowering or tree kinds, and in the yellows and scarlets, as Mr. Engleheart mentions, the most fragrant of all being the rose-coloured kinds. In July I looked over a very large collection of new Carnations and Picotees, many not yet in the trade, and very few were fragrant. One must not look to the exhibition for fragrant Carnations, as one seldom sees either the old Glove or its white counterpart there. It is the same with the Roses, and many new kinds are absolutely scentless, not a trace even of the characteristic perfume. A Carnation is far more acceptable when strongly fragrant, and by getting the Glove scent into the seedlings this fine garden flower will gain greatly in interest.—F. P.

Verbena venosa.—More use is made now of this fine bedding plant in the parks. It is very rich when boldly massed, as at Finsbury Park, and the purplish violet flowers remain fresh until quite

late in the year. The ordinary type of *Verbenas* is more graceful, and, of course, one gets a greater range of colour, but *V. venosa* is certainly hardier and not so apt to get diseased. Even after a few frosts the flowers look fresh and bright. The roots can be easily stored in boxes during the winter and fresh stock raised in the following spring. It must be grown in good clumps or masses if effect is desired.

Cosmos bipinnatus.—This is a delightful annual, though one seldom sees it grown in a bold way. We saw a mass of the white form recently which had kept blooming from August until late in October. The leafage is quite feathery and the flowers pure white, the whole plant exceedingly pretty and graceful. It should be grouped with other annuals or in a colony by itself. Sow the seed in February in heat, transplant in May, choosing a warm sheltered spot, as it is a little tender. The flowers are pleasing when cut for the house.

IMPORTED LILIUM AURATUM.

THE first consignment from Japan this season of bulbs of *Lilium auratum* has reached here and was disposed of on October 19, this being at an earlier date than the two years immediately preceding, for in 1892 the first sale was held on November 7; in 1891 on November 3; in 1890 on October 7, and in 1889 on October 1. The bulbs this season were in the majority of cases plump and firm and apparently well ripened; but my experience is that the best results are not always obtained from these very earliest importations, as those that reach here about Christmas or a little earlier are generally better ripened than the first arrivals and commence rooting with greater freedom when placed under conditions favourable to growth. The importation was by no means limited to the golden-rayed Lily, as large quantities of both the red and white forms of *L. speciosum* were also sold. The white-flowered variety from Japan consists almost entirely of *Kratzeri*, whose bulbs are distinguished from those of any other form, except the allied *album novum*, by their yellowish colour. Singularly enough, the other white-flowered variety, which is principally grown by the Dutch under the varietal name of *album*, has the darkest coloured bulbs of all the varieties of *L. speciosum*, for they are of quite a mahogany-red tint, though in this respect a considerable amount of variation is to be found, owing to the soil in which they have been grown, the amount of exposure and other particulars. The bulbs of *L. Krameri*, of which 1600 were offered for sale, cannot be induced to thrive in this country unless in a few isolated instances; therefore it is impossible to obtain English-grown bulbs. It is a beautiful Lily, but its delicate constitution is against it ever being very popular. Of this the very largest bulbs are only about the size of a Walnut. The first batch of *L. longiflorum* from Japan was also disposed of on the same day, and of this large quantities are almost sure to arrive later on. Some fine bulbs of a variety of *L. elegans* were also sold, and, concerning them, it may be noted that very superior forms are often sent here from Japan. As an instance of this I may mention that out of a few hundreds purchased just as received, I have had the following varieties in greater or less numbers: *robustum* or *marmoratum aureum*, a large full flower, yellow, spotted red; *pictum* or *bicolor*, yellow, splashed crimson; *brevifolium*, salmon-red; *atro-sanguineum*, deep red; *staminosum* or *flore-pleno*, crimson, and *Van Houttei*, rich crimson, spotted black. H. P.

The Flame Nasturtium.—We were pleased to see this *Tropaeolum* running about here, there and everywhere in Mr. Kingsmill's charming garden at Harrow Weald, its long shoots covered with vermilion flowers twining through a hedge or amongst shrubs. It likes damp and shade, whilst the plant can be quickly increased by taking up bits of root in the spring, putting them into boxes and planting out again the following spring when

they have got thoroughly well established. In Mr. Wilson's Wisley garden it is planted at the foot of a hedge, the flowers gaining in intensity of colour against the leafage.

Setaria macrochaeta and **Milium nigricans.**—These two annual Grasses are very distinct and well adapted for arranging with flowers in large vases, as they grow tall and sturdy, and even alone are effective. Both have broad bristling leaves, whilst the flowers of the *Setaria* are clustered in a close, long head like a small Foxbrush. The *Milium* is graceful and bold, having very strong upright stems, which grow 2 feet or more in height, bearing a large much-branched panicle at the top, the large leaves sheathing the stem quite up to the flowers. This species appears in striking contrast with other dwarf slender kinds belonging to the same family. On looking up the "Dictionary of Gardening," I was surprised to find no mention whatever of the *Miliums*, and yet such a species as this under notice, easily grown as it is, would find favour with many even if only for winter arrangements of dried flowers and grasses.—A. H.

Panicum virgatum.—This is a very handsome North American Grass, hardy, truly perennial, and worthy of a place in most gardens. It makes strong thick tufts of graceful leafage of about 1½ feet high and of a deep green colour, and flowers freely in summer, having a branched panicle borne on a slender, but erect stem 3 feet or more in height. These stems are now of a rich yellow colour, and standing up from the green tuft they show off the plant in one of its prettiest aspects.

FERNS.

FERNS IN THE HOUSE.

No one will dispute for a moment the popularity of Ferns as decorative plants for rooms. If a vote were taken they would probably receive greater support than Palms even. The Ferns at any rate have the advantage as regards variety, whilst if taken one with the other they have also the preference as regards freedom of growth, for a plant of either if taken of the same age would at the end of two years be found to have the balance of size and utility on the side of the Ferns. I have often heard complaints made by ladies and other amateur cultivators that they fail to keep their plants fresh and vigorous. This may be and is undoubtedly a fact in many instances, but it is not so much the fault of tenderness on the part of the Fern itself if properly managed beforehand as it is of preparation by the growers. Ferns as they are offered for sale by market growers are not always at the time they change hands in the best possible condition to resist the change between the humid atmosphere and other essential advantages afforded by a well-appointed glass structure and the more trying atmosphere of a living room. With a slight modification on both the vendor's and the purchaser's sides this might be to a great extent overcome. The vendor before he offers his plants for sale should see that they are well rooted into their last shift, approaching in this respect the pot-bound stage, and they should also be more freely exposed to a greater amount of air, so as to harden them in a measure. This, it may be urged, I know, on the part of the vendor would all take more time before the plants were turned out of hand, but on the other hand if greater satisfaction could be afforded to the purchaser, surely it would be an inducement to extend their cultivation. After repeated failures one is discouraged in his attempts to succeed, and frequently the ultimate attainment of that desired end is finally despaired of altogether. It is this fact that should be

borne in mind by growers who cater more for this class of trade than for those who have every convenience at their disposal.

On the part of the purchaser there are several essential points to observe so that better results may be arrived at. When the plants are first purchased they should not be too freely exposed to draughts, nor should the amount of light be excessive. The plants should be gradually inured to the usual atmosphere of the room, and in this way they will be far more likely to succeed. The watering of plants in rooms is oftentimes very variable; the two extremes of drought and moisture in excess may frequently occur within forty-eight hours. This is altogether irrational, and under such treatment it will be no wonder if the plants soon show marked symptoms of declining vigour. No regular time for watering can be assigned, but those who are conversant with plant culture are often asked, "How often should they water their plants?" To this it is not possible to give such a satisfactory answer as would be expected. It will largely depend upon the state of the weather and the surroundings of the plants. Just now, for instance, less water would be required than in a few weeks' time when fires are more in use, as well as more gas or oil being consumed. The plants can be more easily mauaged now than in a few weeks hence; hence the present is a good time to add to or start afresh in the case of Ferns. Later on there will be the extremes of temperature, a warm room during the day, made warmer still at night, with a drop towards morning of several degrees, with the prospect at daylight of the windows being thrown open whilst the outside temperature is several degrees below freezing point. Under these conditions, and it is not an uncommon thing for them to occur, it is more of a wonder that the Ferns, or for that other plants as well, survive so long as they do. Open the windows by all means, but before doing so the plants should be removed to sheltered corners, or be at least stood upon the floor out of harm's way, it being assumed, of course, that the plants are being grown in or near the windows. Fresh potting should never be attempted for several months after purchase. Plants bought now should not require it before next April, and possibly not then even with good attention given to the watering. Whilst the weather is mild a gentle damping overhead out of doors with a fine rose on a watering-can will wash off any accumulations of dust and be beneficial, and during colder weather the same work can be done over a sink. To sponge Ferns as one would the *Aspidistra* or *Ficus elastica* is not practicable; hence the greater need of the work just suggested. When the soil upon the surface is noticed to be at all loose, it should be pressed down moderately firm. Some lovers of Ferns (and other pot plants) feel at times an uncertainty as to whether they should water their plants or not. The best criterion is to rap the pot with the knuckles; if it sound hollow it may fairly be assumed that the need of water is indicated. The soil also will afford indications. It should not be dust-dry, but in a medium condition, when, for instance, it does not adhere to the fingers to any extent after pressure.

For starting with at this season of the year the following is a good selection of Ferns; others could be named, but the spring would be a more favourable period for such. The best to start with now are *Asplenium bulbiferum*, *A. diversifolium* and *A. lucidum*; *Davallia canariensis*, *Lastreas* in variety, *L. lepida* and *L. Sieboldi* being two of the best; *Phlebo-*

dium aureum, *Pteris cretica* and its variegated form, *P. cretica albo-lineata*; also the crested variety, *P. cretica nobilis* (a grand Fern), *Pteris serrulata*, and the beautifully variegated *P. serrulata Mayi* and *P. tremula*, which is one of the best of all for room culture. FILICES.

SEASONABLE NOTES ON FERNS.

THE work amongst Ferns at this season of the year is of a somewhat limited character in private establishments where entire houses cannot be set apart for their special culture. It is otherwise, of course, in the case of those who, like nurserymen, grow for sale only; in their case there is always something or other to be particularly attended to so as to make the best use of the time. With these latter we have not now so much concern as with the former, who not unfrequently have to grow their Ferns under more disadvantageous circumstances. It is not, for instance, every private gardener's good fortune to have the best possible place for growing that every-day plant, the Maiden-hair Fern (*Adiantum cuneatum*), which for a supply of cut fronds still holds the most prominent position amongst Ferns. Others, it is quite true, have the place to do it well, but do not for some reason or other take advantage of it as they should do. On the other hand, in many private gardens we have noticed this fine old Fern in splendid condition, more so of late years than formerly. At one time, as it may still be in some places, it was a customary plan to grow it under the shade of other plants. This ought never to be the case; on the contrary, all the light possible, save in the hottest weather, should be accorded it, with an abundant ventilation also. At this time a good supply of well-hardened fronds will in many establishments be most desirable. Outdoor foliage now getting scarce must have a substitute, and Ferns which have enjoyed an immunity of late can now be resorted to as a change.

Supposing a supply of cut fronds is required for the dinner-table at night, these should not be left upon the plants until the last moment, but be picked early in the day and then be immersed in water until near the time of use. If needed in the morning, then cast them into a tank for a few hours over-night and afterwards roll them in damp paper until the morning, or cover them with Moss where that useful article is plentiful. In picking fronds of the Maiden-hair it is not advisable, save in exceptional cases, to run over all the plants and take the best fronds only; the better plan is to keep to a few and use all that are fit thereon first. The stock of Maiden-hair Ferns should not now, or at any time for all that, be crowded together, nor should a damp atmosphere be maintained. With a little warmth constantly in the pipes and a little air on at all times save when it is absolutely too cold, a buoyant atmosphere can be had, which has a hardening effect upon the fronds. A temperature now of from 50° to 55° at night will be sufficient, the lower point being preferable to anything approaching 60°; during the day a rise of 10° or so will be enough. The watering should now be in a measure limited; sufficient to prevent flagging, but not enough to excite fresh growth.

Under these same conditions many other useful decorative Ferns can be grown both for assisting the cut supply and otherwise. A close, stuffy atmosphere with an excess of atmospheric moisture may do for some stove plants, but it is not now congenial to many Ferns. True, what is termed a growing temperature will often produce more vigorous growth, but it is not of such a lasting character, nor is it at all desirable from now onwards until the spring comes round. Even *Adiantum Farleyense* is none the better for being grown in a high stove temperature; the fronds may be of a deep green hue and the individual pinnae large and fine, but it is open to serious doubt if the somewhat smaller, but beautifully bronzy-tinted fronds of plants grown in more exposure to light with less heat and more air would not in nearly every instance be preferred. The same remarks apply to

several other so-called tinted Ferns, as *Adiantum Collisi*, *A. tinctorum*, and others.

On the whole, the *Gymnogrammas* require more warmth than most Ferns during the winter months, and they should at the same time have as dry a position as possible. At present it is not at all a bad plan where the growth is dense to thin out the older and partially shabby fronds, either to be cast aside or to be used with others in a cut state. By doing this there will be considerably less danger of damping off, which is a failing to which these Ferns with their dense farinose powder are particularly subject. The best sorts of the Gold and Silver Ferns should receive more notice as decorative plants in small pots; excellent plants may be grown in 6-inch pots fit for many purposes. As vase plants they are peculiarly appropriate where the same colours prevail in the ornamentations. Even in 3-inch and 4-inch pots very pretty plants can be grown that will do good service. A dry atmosphere, as in rooms with fires, does not come at all amiss to these Ferns, but exposure to cold has to be avoided. For every-day use during the coming winter season in favourable and unfavourable positions there are hardly any Ferns to surpass *Pteris cretica* and its crested form, *P. cretica nobilis*; also *P. serrulata* and its best crested variety, *P. serrulata cristata compacta*. Another excellent *Pteris* is *P. tremula*, of which there are also variations, *elegans* and *flaccida* being two of the best. For winter use more note should also be taken of the hardier *Aspleniums*; these will withstand the cold almost as well as some of the British Ferns, particularly *A. bulbiferum* and *A. lucidum*. It is far better to depend upon such Ferns as these than to use tenderer kinds during the more unfavourable weather. What has in addition to be well looked after is to see that no freshly potted or partially established plants are ever employed; it must not excite wonder if these do fail to give satisfaction. G. H. A.

GARDEN FLORA.

PLATE 935.

THE WATER LILY TREES.

(WITH A COLOURED PLATE OF *MAGNOLIA FRASERI*.*)

ALL the *Magnolias* deserve culture in our southern gardens, or the best of them might be grown in tubs in cool greenhouses along with the choicest of Sikkim *Rhododendrons* and other rare half-hardy shrubs. Most of the North American and Japanese species of *Magnolia* are hardy with us in sheltered positions, and in Devon and Cornwall, as also in the south of Ireland and in Co. Wicklow, *M. grandiflora*, *M. conspicua*, and one or two others luxuriate fresh and fair and blossom splendidly every year. Even so we can never hope to see these trees so luxuriantly rampant as in Florida and Carolina and elsewhere towards the Mexican Gulf, nor even so free flowering as they are at Lyons, Marseilles, Genoa, and on the fertile Barmorean Islands in Lago Maggiore, at Palanza, or at Milan. In the parks and gardens and public squares of S. France and Italy *M. grandiflora* forms a free-growing glossy-leaved tree, 30 feet to 50 feet in height, blossoming in spring and again in autumn, when the great ostrich-egg-like buds and great white flowers are seen beside the bright red fruits which result from the spring blossoms.

Still, our climate has possibilities, and when we think of the *Magnolias* in Devon, or the Yulan trees that formerly graced the walls at Rollisson's nursery at Tooting, and those that

* Drawn for THE GARDEN by H. G. Moon from flowers sent by Mr. Latham, Botanic Gardens, Birmingham. Lithographed and printed by Guillaume Severeyns.

MAGNOLIA FRASERI.

are nearly every year so fine at Gunnersbury House and at Syon, we may arrive at the conclusion that these noble flowering shrubs are not so largely planted in our gardens as from their distinctness and beauty they deserve to be. Not only in the south and in sheltered nooks and corners by the sea, but even in the cold midland counties I have seen these plants do well.

Take, for example, the beautiful grove of Magnolias that has existed for many years on a declivity in the Botanic Gardens at Birmingham, where there are specimens of *M. acuminata* 50 feet or more in height, surrounded by *M. Yulan*, *M. conspicua*, *M. Soulangeana*, and other of the smaller or shrubby kinds. Here one lovely fresh morning in April last I saw the fragrant blossoms of *M. Fraseri*, which Mr. Moon has so faithfully portrayed, opening their creamy petals to the sunshine and scenting the air for yards around. The flower-buds, so fresh and Lettuce-like, are so nearly of the colour externally of the young leaves, that had it not been for their exquisite fragrance, one might have passed the open flowers without noticing them. It has long been grown at Birmingham under the synonym of *M. articulata*, in allusion to its having leaves hastate or auricled at the base, but its right name appears to be *M. Fraseri*.

Mr. W. B. Latham (who has had charge of the Birmingham Botanic Garden for over twenty-five years) tells me that Canon Ellacombe admires the group of Magnolias there very much, and well do they deserve the honour, for it is rare to see the like in a town garden elsewhere. Mr. Latham kindly gathered a beautiful group of buds and opening blossoms for me. These were much admired in a big bowl of fresh water before they were divided, half going to Mr. Nicholson, of Kew, who verified the name for me, and half to St. Albans, where Mr. Moon made the original sketch for the illustration. The genus was named long ago in honour of Pierre Magnol, a medical man and director of the Botanic Gardens at Montpellier from about 1638 to 1715. There are in all about twenty species of *Magnolia* proper, and the genera *Drymis*, represented by Captain Winter's Bark Tree from the Straits of Magellan; *Illicium*, or Star Anise; *Liriodendron*, the well-known Tulip Tree of N. America, are near relations pretty well known in our gardens.

The best species for general culture are *M. grandiflora*, especially the sort with rufous under-surfaces to its leaves, known as the Exmouth variety; *M. conspicua* in all its forms and *M. Fraseri*, *M. Umbrella* or *M. tripetala* is well worth culture as a fine-foliaged plant, even if it but rarely flowers in our climate. *M. macrophylla*, another species having gigantic leaves 2 feet to 3 feet in length, is worthy of conservatory culture. Several species, such as *M. fuscata*, *M. pumila* and *M. glauca*, are also worth greenhouse culture for the sake of the exquisite fruity perfume or aroma, even though their flowers are sombre and unattractive in colour. *M. Halleana*, *M. stricta* (GARDEN, Oct. 28, 1893, p. 391), *M. obovata*, *M. purpurea*, *M. glauca major* or *Thompsoniana*, *M. parviflora* and *M. cordata* are other types well worthy of a place in the pleasure ground or arboretum.

One of the very finest species is the Himalayan *M. Campbelli*, introduced from Sikkim about 1868. This, so far as I know, has only produced its flower-buds in Ireland, the late Mr. Wm. Crawford, of Lakelands, Cork, having devoted much care to his specimen, which, when I last saw it, was a branching tree 30 feet to 40 feet in height. The figure in the *Botanical Magazine* was prepared from speci-

mens sent from Mr. Crawford's garden some few years ago.

All the species known belong to two distinct sections, one or two, as *M. grandiflora*, being evergreen; but, as a rule, they are deciduous, and such kinds as *M. conspicua* and its hybrids or seedlings produce their great waxy upturned blooms like goblets at the ends of the naked twigs or branchlets. Although this and most of the other species are hardy in mild, sheltered localities, their flower-buds are produced so early in the year, that they are liable to be nipped and injured by our early frosts and east winds, rendering some slight protection necessary, or at least desirable.

The Magnolias deserve wider and more general cultivation than they have hitherto received even in our southern gardens, and especially are they worth a trial in sheltered sunny localities by the sea. F. W. BURBIDGE.

THE WEEK'S WORK.

THE KITCHEN GARDEN.

MUSHROOMS.—It will have been observed that Mushrooms appeared very plentifully this season after the soil had been fairly soaked with rain, and this, followed by a fairly high temperature for the time of year, gives the key to the whole system of Mushroom culture under cover throughout the winter. Mushrooms will not thrive on almost dust-dry beds, or with the atmosphere in a dry state. Some houses are so situated that the temperature is quite genial for the growth of Mushrooms without much damping being necessary; whilst in others it is the reverse, especially where artificial heat has to be maintained to keep up a growing temperature. Much artificial heat is not needed, a temperature of about 55° being ample. A genial atmosphere may be maintained in some structures without any artificial heat, whilst in others it is needed. In those cases where a genial atmosphere cannot be maintained from the want of artificial warmth, this may be assisted by placing within the structure a heap of fermenting material, or say equal parts of fresh stable litter and leaves. Where artificial heat has to be applied, this may be greatly tempered by laying some old mats or bags across the pipes and keeping them moist. I find it is an excellent method after the young Mushrooms commence to appear to lay a mat over the whole surface, placing strips of wood on bricks to keep it off the bed. This, of course, refers to Mushroom houses where the temperature has to be maintained artificially, as in cooler structures, such as confined sheds, stables and such-like places, a genial warmth must be maintained about the surface by covering more or less, as occasion may arise, with dry hay, turning it as often as is necessary to prevent the surface from becoming too damp. This latter is very necessary. Thick coverings of hay or litter are often placed on beds in artificially heated structures, but this is a mistake, as they certainly aggravate the evil of fermentation.

WATERING MUSHROOM BEDS.—What has to be guarded against is the two extremes, either of keeping the beds too wet, or, on the other hand, too dry. If once the beds are allowed to become over-dry, it is astonishing the amount of water that is necessary to give a thorough soaking, or at least sufficient to permeate the whole bulk of material. Therefore, the better course is to anticipate this state of over-dryness, and apply water when first needed. Some structures, again, cause over-dryness more quickly than others, especially if too much fire-heat has been applied. The better course is, directly the young Mushrooms commence to appear, to give a gentle, but thorough watering. Soft water should be used and at a temperature of 90°, a little salt being added to each canful. It must be applied through a fine rose, and gradually over the whole bed until sufficient has been applied. This watering would be

sufficient until the first crop is gathered, or when signs of exhaustion are apparent. Ridge-shaped beds in the open air if at all dry will have to be watered also. The water in this case must be applied through a covering of litter, or there would be difficulty in applying it effectually; care however, must be taken that the watering is done on the mornings of fine days, afterwards covering with mats. It will be an easy matter to apply a warm covering of drier material afterwards.

GRUB-INFESTED SOILS.—Root-eating insects having caused much havoc in many gardens this season both amongst Onions, Carrots, &c., much may be done to effect a clearance of the larvae, which are now harbouring in the ground, and so lessen the chances of attack another season. Gas-lime is one of the best antidotes which can be applied. Those soils intended to be dressed should now be well stirred, either by deep digging or bastard-trenching, and then have the surface lightly dusted over with the gas-lime, in quantity only just to colour the surface, afterwards pointing it in with a fork, but only whilst the surface is dry. Freshly-slaked lime may also be used, although it does not produce the same effect upon the larvae as gas-lime. It very often produces a marked effect upon the quality of Potatoes grown on such soils. Parsley, again, in some gardens will barely grow at all, but after the application of lime there has been a marked change for the better.

AUTUMN-RAISED CAULIFLOWERS.—These were sown about the first week in September, as advised in a former calendar, are now in good condition, not being any too forward. In many cases they were sown no doubt much earlier, and there will thus be a difficulty in keeping them from growing too freely on account of the very mild autumn. To prevent this state of things as much as possible, the plants must not be coddled, the lights being kept off on all fine days, and also tilted up at other times. Injury from frost will of course have to be guarded against by affording adequate protection whenever necessary. A. YOUNG.

HARDY FRUITS.

PEARS.—This season trees well exposed have produced finer, clearer skinned fruit than usual, the quality generally being good, but, as a rule, if extra good Pears are desired the trees must have the benefit of wall shelter. In any case a good proportion of wall space may well be devoted to Pear culture, supplementing this with a goodly number of trees grown in the open. Pears will succeed fairly well against walls or fences facing any point of the compass, but it is not often that the quality of fruit grown on trees in a cold site will equal what is obtained from those growing in sunnier positions. It is the late ripening varieties that appear to need the warmest sites, and they certainly merit the preference. Reliable selections for all purposes and sites have repeatedly been given in these pages, and need not, therefore, be repeated now, though no collection may be said to be complete unless it includes such old favourites as Jargonelle, Williams' Bon Chrétien, Beurré d'Amanlis, Louise Bonne of Jersey, Beurré Superfin, Pitmaston Duchess, Marie Louise, Doyenné du Comice, Beurré Diel, Winter Nelis, Thompson's, Durondeau, Glou Morceau, Josephine de Malines, Easter Beurré, Beurré Rance, Olivier de Serres and Bergamote d'Esperen, with Beurré Clairgeau, Vicar of Winkfield and Uvedale's St. Germain for stewing.

FORMS OF TREES FOR WALLS.—Horizontally-trained trees are most generally grown against walls and fences, and if these are on the Pear stock they may be arranged from 18 feet to 20 feet apart, while if quick and comparatively heavy crops are desired the Quince stock is preferable, the trees being planted 10 feet to 12 feet apart. When, however, trees on the former are selected, these eventually develop into much the best trees, and can long be kept in a healthy, productive state if prevented from rooting principally in a cold subsoil. Midway between these trees should be

planted two or three-branched cordons on the Quince stock, these quickly arriving at a bearing state and serving to tide over the longer period of waiting for the larger trees to yield good crops. In not a few cases horizontally-trained trees long since planted have failed to cover their allotted space, and cordons ought, therefore, to be planted midway between these instead of Red Currants, as of old, the latter scarcely paying for so much valuable shelter. Pears, whether on the Pear or Quince stocks, succeed remarkably well trained fan-shaped, this certainly being the best method of training in the case of Jargonelle and other strong growers for which plenty of head room can be allowed. Plant fan-shaped trees on the Pear stock about 15 feet apart, and on the Quince 8 feet apart. For clothing walls very quickly, cordons on the Quince stock are recommended. These may consist of a single main stem or have two or three branches. Those with a single stem may be planted about 18 inches apart, the other sufficiently wide apart to admit of a distance of about 15 inches dividing the branches. Training obliquely or at an angle of about 45° answers best, this having a tendency to check undue wood growth. Branches may be laid in from the end trees to clothe what little space needs covering. Palmette Verriers, and which may be roughly described as four or six-branched cordons, are also admirably adapted for quickly and effectively clothing blank walls or spaces between trees already existing. If only four branches are to be laid in, purchase young horizontally trained trees with two pairs of branches and cut out the leader. A six-branched tree may be had by planting a similar kind of tree, only instead of cutting out the leader, this should be shortened to a length of about 12 inches, and two side shoots from this be eventually laid in 12 inches apart, training these after the first curve is given straight up the wall; the lower branches to be trained horizontally at first and then straight up the wall 12 inches clear of each other. These six-branched trees may be on either the Pear or Quince stock, and should be planted not less than 6 feet apart. For clothing archways or doorways and wall space over these, plant single-stemmed cordons or maidens on each side of opening, and when they are sufficiently high lay in side shoots 12 inches apart.

ESPALIER FENCES.—These form a neat and profitable background to herbaceous borders and such like, Pear trees succeeding well under this form of training. These fences should be not less than 5 feet in height, and consist of strong upright stakes, or, better still, be made like an ordinary strong wire fence, having stout posts at the ends to stand the strain put upon them when the wires are strained; these latter to be about 12 inches apart or the distance apart it is intended to lay in the branches horizontally. Ordinary horizontally trained trees are most often planted at the same distances apart as recommended for wall trees, but the cordon system of training may also be practised, the branches or single stems being laid in obliquely. Most of the varieties already mentioned would succeed espalier trained, and so also would Clapp's Favourite, Souvenir du Congrès, Jersey Gratioli, Fondante d'Automne, Beurré Hardy, Maréchal de la Cour, Beurré Bachelier, Zephirin Grégoire, Huyshe's Victoria, Comte de Lamy, Marie Louise d'Uccle, and Eliza d'Heyst.

PYRAMIDS, BUSHES AND STANDARDS.—Formally trained, much-restricted trees ought to be on the Quince stock and not expected to produce other than a few dozen fruits at a time. These may be planted 6 feet apart; small bushes, these differing from the former only so far as having no centre, to be given the same space, all being arranged 3 feet from the garden walks, or else grown among standards. In addition to being on a dwarfing stock, these miniature trees also require good attendance in the shape of annual or biennial root-lifting, and when bearing heavy crops must be mulched with manure and otherwise attended to. Many of the Pears when allowed to grow, after the foundation has been well laid, almost unrestricted develop into fine natural pyramids, or the centres may be taken out of them and a more bush

shape be obtained. In either case trees, if on the Pear stock and not greatly restricted, are not so long in arriving at a very productive state, the fruit being produced by the bushel instead of by dozens, as in the case of the miniature trees. Such trees should be planted not less than 16 feet apart and 8 feet from the edge of garden walks. Varieties that succeed exceptionally well thus naturally grown are Williams' Bon Chrétien, Louise Bonne of Jersey, Pitmaston Duchess, Marie Louise d'Uccle, Duchess of Orleans, Beurré Superfin, Marie Louise, Maréchal de la Cour, Beurré Diel, Huyshe's Princess of Wales, Glou Morceau, Bergamote Esperen, Doyenné du Comice, Beurré Rance, Duchesse d'Angoulême, Durondeau, Althorp Crasane and Vicar of Winkfield. Standard trees to be 20 feet apart, an extra 5 feet each way being allowed when pyramids and bushes generally are planted among them. Some of the best varieties grown as standards are Chalk, Lammis, Jargonelle, Williams' Bon Chrétien, Beacon, Hessle, Beurré Capiaumont, Fertility, Bishop's Thumb, Beurré d'Amanlis, Pitmaston Duchess, Durondeau, Beurré Superfin, Beurré Diel, Beurré Clairgeau, Emile d'Heyst, Maréchal de la Cour and Josephine de Malines, with Catillac and Verulam for stewing.

W. IGGULDEN.

PLANT HOUSES.

FUMIGATING PLANT HOUSES AND PITS.—At this season of the year there is frequently an increase of aphides and thrips, but more particularly the former. This will occur in nearly all houses, be they warm, temperate or cold. This should be nipped in the bud, for it never pays to defer fumigation when even only a few insects have to be destroyed; it is better to destroy the few than the many. When a case becomes a bad one, a strong dose is often given and a repetition within twenty-four hours; the repetition may be all very well, but the strong dose is no more needed than in the case of a few insects only. It takes no more actual strength to kill 1000 than it does to kill 100. Frequent fumigations so as to make it as distasteful as possible for the insects are by far the better plan. Everything in the house or pit should be as dry as it is practicable to make them. By this it is not, of course, inferred that dryness at the roots is intended; it is rather that of the foliage and amongst the plants. Moisture acts as a deterrent to the free circulation of the smoke, and where it exists upon them, the result will not be nearly so effectual. It is not so much that the smoke will act injuriously where there is moisture as that it should reach all parts of the plants.

I note that green fly has made an appearance on Bouvardias that are in a temperate house, and this has been stopped whilst there were yet but a few of them. Pelargoniums are also subject to it. In our case it was appearing on the scented-leaved varieties even before they were housed; now it will on no account be overlooked. Roses and other climbers on the roof will in all probability have some lingering amongst them. A good cleansing would do these good a day or two prior to fumigation by the application of the garden engine. Then when the fumigation is done do not at once syringe again. In fact to syringe in any case after fumigation is a mistake; it may knock down a few insects, but it will revive rather than destroy many more. This fact of syringing after fumigation is one of the popular delusions that should be abolished once and for all. In pits it is just possible that the green fly will make headway before it is so readily detected, particularly where there is a little warmth in the pipes. But in cold pits and frames whilst the weather is mild it will also increase. In the case of Cinerarias, for instance, it may in all likelihood be found on the under sides of the larger leaves. This also applies to the herbaceous Calceolarias that are fairly well advanced.

Thrips will be troublesome on such plants as Ixoras, Pancratiums, Dracenas, Azalcas, and on some of the Palms (those which have been in a dry house more particularly). In every case with

sponging or dipping, syringing or fumigating, or the latter combined with either of the former, they ought not to give much trouble. No quarter should be given them. It is grievous sometimes to see the manner in which they permanently disfigure the foliage of many plants. It is necessary to give stronger doses in order to deal effectually with thrips, but with care this can be accomplished safely. What I would advise is to fumigate three evenings in succession. I consider this better than a morning dose, which is scarcely ever so effective. As to material, I would add that we rely mainly on Campbell's fumigating cones; these deal with scale as well as aphides and thrips in a most satisfactory manner. It is necessary to have them as fresh as possible. I would never advise laying in more than will be used in all probability during the ensuing six or eight weeks. McDougall's sheets are also excellent, but not so well adapted for pits or confined spaces. A large house they will fill more quickly. Of tobacco paper the best quality is most decidedly the best; cheap and inferior articles of this description are the dearest in the end.

OTHER INSECT PESTS.—Of these it is hardly necessary to say much upon the mealy bug now, it having been frequently alluded to in previous calendars. Where it exists no labour or effort to extinguish it should be deemed too great; it is now the best season of the year to make a determined stand against its further increase. The work should be done effectively, but the idea must not be entertained that once going over a stock of plants is sufficient to last for months. It is thus that a great mistake is often made. The better way by far is never to give it any peace, but be incessantly on the watch for stragglers. Remedies have been given to which reference should be made. The white scale is another troublesome pest to many plants; the plants, unfortunately, that this insect is to be found thriving upon most are such as are of a permanent character. The Lapagerias, Camellias, Yuccas, and other succulents, some Cape and New Holland plants, Palms, and Crotons are all troubled with it. The first remedy had better be an insecticide with which one is quite conversant; this should first be used at the maximum strength recommended, and if that be found not strong enough, then increase the strength gradually. The mixture should be used at from 85° to 95°; these temperatures liberate to a greater degree the composing elements from a chemical point of view and thus render it much more effectual. Where sponging is too difficult a matter, a soft paint-brush will be found useful; as long as the composition reaches them in good quantity it is not absolutely necessary to remove them; time will do this, the dose being repeated. In extreme cases syringing had better be the medium of application, taking care that the mixture does not reach the roots of the plants. Where the white scale is to be found most upon old or ripened wood, the dose may with safety be a much stronger one. The mealy scale is a much easier insect to deal with, so also is the brown variety; but there is another small form often found on Crotons which is almost as bad as the white kind, but with the composition at a good strength it may be eventually overcome.

JAMES HUDSON.

ORCHIDS.

I LEFT off last week after remarking about the over-resting of some Dendrobiums, and as they are nearly all in their resting period now, attention must be given to this matter. The least likely to be injured are the varieties of Dendrobium nobile and a few of the more vigorous garden hybrids raised from it, such as D. Ainsworthi, D. Leechianum, &c. The D. nobile varieties are most valuable for forcing early, and a few of the plants which flowered very early last year, and consequently made up their growths early, should now be placed in a warm house. I do not like placing them in the warmest house at once out of the rather cool temperature and dry atmosphere of the vinery

or warm greenhouse where they rested. It is better to place them for two weeks or so in the Cattleya house, and when a start has been made to stand them in the warmest house. This may be done if the blooms are required as early as possible, but if there is no hurry, leave them in the intermediate or Cattleya house, where I fancy the flowers will be larger and the substance better. *Dendrobium nobile* is by far the best for this early forcing. I had a plant which produced upwards of 1400 blossoms at Christmas. Next to it are the garden hybrids between it and *D. aurum* (heterocarpum) alluded to above. They are as beautiful as *D. nobile* and have the peculiar aromatic perfume of *D. aurum*.

We may have handsome *Dendrobiums* in flower all the year round. The varieties of *D. Phalenopsis* are truly beautiful at the present time, and the home-made growths are in some instances stronger than the native ones. I saw a group of plants lately staged by a good gardener (Mr. Lyne) at the Blackheath Chrysanthemum exhibition, the leading feature being varieties of this beautiful *Dendrobe* in flower, and for grouping they are far superior to *Cattleya labiata*, which was also used. The florists' shops are abundantly decorated with this *Cattleya*, showing how free blooming and how abundant it is. The *Pleiones* are now in flower—the well-known species *P. maculata*, *P. lagenaria* and *P. Wallichiana*. They are really very charming arranged slightly above a group of plants of the common Maiden-hair Fern (*Adiantum cuneatum*). If the pretty little flowers are required for decoration, do not cut them. Take hold of the stems with the fingers and gently pull them out. As soon as the flowers are disposed of the plants will need to be repotted, for new roots push out from the base of the current growths almost as soon as the flowers are removed. We usually part out the bulbs and plant from nine to a dozen of them over the surface of the compost, contained in a 6-inch flower-pot, using Sphagnum Moss and good fibrous peat in about equal portions. Careful watering is required at first until the bulbs have rooted well. I have to admit that these little Himalayan *Crocuses*, as they are sometimes termed, succeed better in the collection of Sir Trevor Lawrence, Bart., than they do with me; in fact, I never saw *Pleiones* do better anywhere than at Burford Lodge, and Mr. White, who has charge of them, was good enough to inform me that the bulbs were not parted out every year, but were repotted without disturbing the roots much, leam and leaf-mould being added to the usual peat and Sphagnum compost. The plants may be kept two seasons in the same compost, but not more, and it is better to remove some of the old material and surface-dress with fresh stuff. They will be for some time a charming addition to the occupants of the Cattleya house. The cooler growing *P. humilis* and *P. Hookeri* have not yet passed through their resting period. These are not quite so easily grown as the varieties I have named above, but they may be kept in a healthy condition by being watered whenever the bulbs show signs of shrinking.

On the evening of October 30, or rather the morning of the 31st, the thermometer registered 8° of frost, and on the morning of Nov. 1 10°. Our instrument is by one of the best makers and has been verified at Kew. I mention this, for it seems this wave of cold has been very unequal. Our houses were all right, for the frosts set in steadily early in the night, and the fall was steady, being, as it generally is, lowest about daylight before the sun shows above the horizon. Besides keeping up the temperature when sharp frosts set in, another weak point in the armour of the Orchid fancier is the drip which too frequently comes down from the roof in these cold nights from condensed water. Well-erected modern houses ought not to have any drip from the roof; in none of our houses has drip troubled us. They were erected by Messrs. Fester and Pearson on a plan which they adopted fifteen years or more ago of cutting the panes of glass concave at one end and convex at the other, so that the external water from rain or dews is conveyed down the centre of the panes instead of at the sides, and no water seems to get in

from the outside. The rafters inside are grooved, so that any condensed water filtered down the rafters runs down these grooves and is conveyed outside the house at their base. Old houses or new ones not provided with these grooves should have the condensed water carried down the rafters by means of a narrow strip of zinc nailed to their under side, running the whole length of the rafters and turned up at the edges. Meantime attention must be given to drip; the water falls cold from the roof, and if it finds its way to the heart of the plants much mischief may be done; moreover, certain Orchids at rest may be started into premature growth and be materially injured in that way. Plants in flower if touched with drip for one night would be rendered unsightly by the flowers becoming spotted. We are also careful not to overload the atmosphere of the houses with moisture. The evaporating water troughs over the pipes have now no water in them, and it is easy to control the moisture by sprinkling the paths and stages of the house less or more according to the state of the weather. In damp, dull, foggy weather scarcely any moisture is needed, but when east winds blow dry and cold with a clear atmosphere and much artificial heat is needed to keep up the temperature, then the moisture from evaporation is needed to keep the plants in a healthy state. Those who have not yet cleaned the glass outside and inside should see to it as soon as possible, as light is now of the utmost importance. The woodwork of the houses should also be washed, and everywhere let cleanness be the order of the day.

J. DOUGLAS.

CHRYSANTHEMUMS.

SEASONABLE CULTURAL NOTES.

GREEN-FLY is often very troublesome to the developing blooms, and is difficult to eradicate when allowed to congregate at the base of the expanded florets. Blooms so affected keep but a short time. The best remedy is to fumigate the plants with tobacco smoke on two successive evenings directly the plants are arranged in the house. If this is properly done seldom are the plants or blooms troubled afterwards with this pest. Should by any chance the plants not have had their usual fumigation directly they were housed and there are signs of the presence of aphides collecting about the developing blooms, no time should be lost in filling the house with smoke even if the blooms are partly expanded. Fumigating will not injure the florets if carried out properly, that is, the atmosphere should be dry, so that the petals will be hard and firm before coming into contact with the smoke. No method of fumigating a house with tobacco smoke is better than by the aid of an old worn-out sieve having wide meshes; turn the sieve upside down, standing it on three bricks to allow a free current of air to pass upwards to the fire on the sieve. A small quantity of fire is sufficient to give the tobacco paper a start. Two ordinary-sized sieves will quickly fill a good-sized house with smoke. The next morning it is wise to ventilate the house freely if the weather is favourable, so that the blooms shall be thoroughly dry before the sun shines upon them, as a means of preserving them from damping. To keep the blooms fresh for a long time requires considerable attention. One of the best qualities which *Chrysanthemums* possess is the long time they will remain fresh either growing on the plants or in a cut state; still, much to the disappointment of many growers for exhibition, they often fail to keep long enough; this is, however, very often owing to not knowing how to manage them properly. Blooms are much more difficult

to keep fresh in the south of England than they are in the northern counties, as they develop more quickly in the former than in the latter. The greatest trouble growers situated in the northern counties have to contend against in many seasons is the non-development of the flowers naturally in time for the shows. Those possessing the darkest shades of colour, namely, the chestnuts, bronzes and the deepest lilacs, retain their freshness the shortest period, while the primrose, the white and the yellow shades continue the longest in good condition. Some growers cut the blooms when expanded and strive to keep them a long time by placing them in dark closets in rooms in bottles of water, but I have found that they can be kept a longer period by judicious management upon the plants.

To have blooms in the best possible condition on any given date, four days previous is quite soon enough to cut them. If cut earlier the florets lose their necessary solidity, and in consequence are not so large as they otherwise would be; this is particularly noticeable in the Japanese section. It is useless to cut the blooms after they commence to decay in the hope of arresting their fading; when cut they should be perfectly developed, so that the solidity of the lower florets may be maintained. An experienced person can tell better by the feel of the lower petals than anything else when the blooms should be cut; crisp and solid they should be, not soft and flabby. When this occurs the white varieties will soon assume a pink tinge, and in some other varieties a faint brownness of the lower florets points to waning beauty; therefore, when the centre of the flower is developed and the lower florets fresh, the bloom will be right, and should be cut with a long stem, say 12 inches, so that a small portion can be cut off every day. Place it in a bottle previously filled with water, amongst which a little salt or sulphate of ammonia has been mixed, three-quarters of a tablespoonful of the former to three half pints of water. It matters not whether the water be hard or soft. Half the quantity of sulphate of ammonia will suffice. Place the bottles in a cool, slightly darkened room having a dry atmosphere. I prefer, however, to allow the blooms to remain on the plants until required, or at least two days before, when they may be cut with safety and treated as directed. The moment the blooms are at their best remove the plants to some cool structure which can be partly darkened and where air can be admitted freely. A potting shed having a northern aspect, Mushroom house not in use, coach house, or, in fact, any place having the necessary requirements, viz., coolness, dryness and partly excluded light, will be suitable. No more water must be given to the roots than is absolutely necessary to prevent the leaves and flowers flagging; simply enough to retain freshness suffices, as at this period of the plant's existence the work as regards the development of blooms is completed. Sometimes a week or more will elapse before the plant requires water, particularly if the soil is of a retentive character. The pot when sounded in the orthodox manner may ring clearly, still the soil may be moist enough. The best indication of water being required is by examining the leaves, and if they are in the least soft and devoid of freshness, then apply enough clear water to soak the soil through and give no more till the leaves again feel limp. When the soil is constantly kept wet, a stagnation takes place about the roots, consequent upon the plant not being able to absorb the moisture fast enough to free the roots. The result of such treatment is that many of the lower petals de-

velop small specks on the surface, which come from the inside of the florets and eventually cause them to decay rapidly. The water which drains from the pots should be at once dried up to prevent damping of the florets. Should any signs of this occur, at once remove such damaged florets, which only serve to contaminate others near them. Flowers managed in this manner will keep fresh and in good condition for ten or twelve days—sometimes longer.

E. MOLYNEUX.

CHRYSANTHEMUMS AT LEWISHAM.

MR. H. J. JONES, of the Rycroft Nursery, Lewisham, has at the present moment on view there the largest and probably the most thoroughly representative collection of new Chrysanthemums ever yet gathered together in one place. Mr. Jones' own collection has always been regarded as a remarkably comprehensive one, he having for several years past imported from France, Belgium, Italy, and the United States all the novelties worthy of a trial, but when it is explained that to that collection he has just added 3000 plants in their flowering pots just on the eve of the Chrysanthemum season, it will readily be imagined that such an undertaking on his part is one of considerable magnitude. These 3000 plants, which so recently formed the stock of Messrs. Pitcher and Manda, comprise, besides the best known novelties of the past two seasons, about 1400 absolutely new varieties, which were raised from seed last year in the American establishment of that firm, they being a selection of the choicest varieties out of 35,000 seedlings grown for selection. In passing through the houses at Lewisham, it was quite annoying every time I stopped to admire some beautiful flower unknown to me by sight to be told that it was one of the new seedlings, and was unnamed. There is no doubt that this will be seen to in due course, but on the occasion of my visit it really seemed as if all the largest and most attractive flowers were varieties without a name. There were, however, many of the novelties of recent introduction in fine form, and, considering the flow of visitors through the houses, it is evident that Mr. Jones' reputation is well established, and that the large number of people who were present were much gratified with the grand display and were not much disturbed at the fact to which I allude.

The flowers grown in large quantities are principally Gloire du Rocher, a beautifully bright crimson Japanese, with golden reverse; G. W. Childs, another crimson Japanese already known to English growers; Wm. Seward, an intensely deep crimson-coloured Japanese, with a peculiar metallic reflection; Vivian Morel, the large rosy Japanese from which Charles Davis sported, the latter being very numerous and effective with its deep bronzy yellow colour at frequent intervals among the plants. Col. W. B. Smith, a golden cinnamon-buff-coloured flower of good size, and Lord Brooke, something similar in tone, are both well done; as also is Tribune, a grand light yellow globular Japanese flower recently certificated. All the above-named were in great abundance in the large show house, and furnished a wealth of colour not often seen in many collections where too frequently the presence of blooms of a dirty mauve or washed-out lilac deadens and spoils the effect of a good bank of colour.

Taking individual specimens, President Borrel, a very fine Japanese of bright rosy amaranth and golden reverse, was in capital form; Mrs. T. Denne, with long curly petals, colour deep pink, and much intermingled, was also good; and J. H. Runchman, a fine deep golden yellow, with large blooms, looks a promising sort. Very few incurved of the old type were to be seen, but Baron Hirsch, deep golden bronze, very effective, and one of the novelties of last season, was well grown, and M. R. Bahuant also. A large massive Japanese flower is Pearl Beauty, with deeply grooved petals of pure white; so is Excelsior, with deep purple florets and silver

reverse. Mme. Isaac is a white Japanese, very pure in colour, and a truly grand flower. H. Hammond-Spence, light blush with yellow centre, also a Japanese, and a large one, is very striking. J. H. Taylor, an American seedling, equally as large, with light purple florets and blush-pink reverse, arrests immediate attention; and another close by from the same country, President W. R. Smith, with very long grooved florets of a pale blush, is a fine variety. Florence Davis, the greenish white Japanese; Miss Dorothy Shea, a large deep crimson or terra-cotta-red with fine drooping petals; Beauty of Exmouth, the somewhat famous white Japanese that caused some discussion last season; and Duchess of Devonshire, light rosy pink with golden centre, all English raised seedlings, are well represented.

Among French raised seedlings, especial mention should be made of Mrs. C. Harman-Payne, a large, solid, rosy mauve incurved Japanese; Mme. Ed. Rey, an incurved Japanese, deep purple and silver; Mme. C. Molin, a pretty white Japanese of the Vivian Morel type; Mme. Oct. Mirbeau, long florets streaked light purple; l'Ami Etienne, pale mauve, globular form, and heavy grooved petals; Commandant Blusset, a pretty medium-sized flower of pure bright amaranth; Mme. Calvat, big bloom, pure white and creamy centre; and l'Isère, large drooping petalled Japanese, colour pure white. Most of these are seedlings raised in France by M. Ernest Calvat, and are quite worthy of this gentleman's reputation. Before concluding, reference ought to be made to Silver King, purple and silvery pink, a large and striking Japanese with long petals; Silver Cloud, most distinct in colour, about which nobody present seemed certain, a remark that will also apply to Dr. H. Hull, which has florets of almost imperceptible flesh colour with a shade of pale bistre in the centre. A truly magnificent flower is Mr. R. J. Hamill, with long grooved incurved florets of the purest yellow; and Joey Hill, with deep crimson florets and gold reverse, is very fine.

Hairy varieties are numerous, and there will probably be some curious discoveries made among them. Sautel (1893) is a light rosy amaranth incurved Japanese, with light pink reverse, most hairy, perhaps, of all. *Enfant des deux Mondes* is a pure white, one of the same class. Hairy Wonder is a very deep bronze of similar type, very distinctly marked in this way. Wm. Falconer, a sport from Louis Boehmer, but of a pale blush, is another.

I cannot take leave of the subject without observing that at the time of my visit there were about 7000 plants in large pots, of which the great majority were in full bloom. There had been others in flower before, which were over and cut down. These numbered 3000, so that Mr. Jones has had altogether 10,000 plants under his care this season, which will give the reader some idea of the attention that this popular autumn flower receives at Lewisham.

CHRYSANTH.

French raised Chrysanthemums.—I think it was only last autumn that a correspondent of THE GARDEN ventured to express the opinion that the French raisers of seedlings were "played out." My note-book for the present season has as yet only reached up to Oct. 28, and I find that eighteen new Chrysanthemums have been certificated by the National Chrysanthemum Society, of which six are from French raisers. At Lewisham a very large proportion of Mr. Jones' flowers are new French varieties, some of them, such as President Borrel, Sautel (1893), Vivian Morel, Mme. Isaac, Mme. E. Rey, Mme. C. Molin, Mme. Oct. Mirbeau, l'Ami Etienne, Comte F. Lurani, Commandant Blusset, Mme. Calvat, l'Isère, M. R. Bahuant, &c., will worthily maintain the reputation of the French raisers for some time to come.—C. H. P.

Notes from Kew.—One sees a different class of plant in the Royal Gardens, Kew, to what is common in private places. The Chrysanthemums at Kew are only stopped about twice, and form fine bushy plants crowded with flowers, which, if not big like show blooms, are far more pleasing. In both the greenhouse and temperate house they are in full beauty and make an interesting and beauti-

ful display, many kinds not usually seen being included in the collection. Edwin Molyneux is conspicuous for colour, and, as in other cases, the plants are clothed to the base with foliage. Sœur Melanie is delightful, and also a kind named Tendresse, a Japanese variety, the flowers of a rose-purple colour, yellow in the centre. La Nympe is similar in shade, and a charming kind to grow, so to say, naturally, at least, with little stopping of the shoots. The specimens of this are a picture. It will be noticed that the majority of the kinds are old, but many are rarely seen, although distinct and attractive in colour. Hiver Fleuri is a mass of bloom, so also are Francois Délaux, La Triomphante, the rich yellow Buttercup, Maiden's Blush, Source d'Or, Eynsford White, Lady Selborne, and Mlle. Lacroix. Very fine in colour are W. Holmes and Anatole Cordonnier, deep crimson-purple. Mrs. H. Harrold, white with the centre florets rose-purple, is not often seen, and a mass of yellow is Swanley Yellow, whilst the old Bouquet Fait and the pure white single variety Mary Anderson are in perfection. For several years past this type of Chrysanthemum has been a feature at Kew in the month of November, and this year the display is finer than usual. We hope that in private gardens the Chrysanthemum will be more grown in this way, as its characteristic freedom and beauty are preserved. There is no need to get every new kind with big flowers. Such varieties as Tendresse and La Nympe are quite as charming grown thus, and even the monster kinds, as Etoile de Lyon and Edwin Molyneux, are adapted for this form of cultivation.

CHRYSANTHEMUMS AT Highbury NEW PARK.

WE recently saw a collection of Chrysanthemums in the garden of Mr. C. Mills at Highbury New Park, and we are pleased to see that he takes great interest in the flower, intending to grow it more largely in the future. In such gardens the greatest difficulty is experienced in growing plants well, the fogs of winter playing sad havoc with everything of a tender nature. The spacious and well-built vineries and houses filled with some of the finest specimen Camellias we have seen are made interesting with a collection of Chrysanthemums grown not only for large blooms, but also in a graceful and free way. The Japanese varieties are in fine character, many of the best novelties being included. Vivian Morel is superb for colour and form. We have not seen finer blooms this year, and also of note are Etoile de Lyon and Col. W. B. Smith. The last-mentioned improves on acquaintance. It is pleasing on account of its form, deep colour—a self bronze-yellow, clear and attractive. We should like to see it grown naturally, at least with few stoppings of the shoots, as the colour would go well with decorations of many kinds. Mlle. Marie Hoste is a fine white, the flowers exceptionally pure, and Mr. Easey, the gardener, has also succeeded remarkably well with Condor, Mr. A. H. Neve, Mme. Baco, W. Tricker and other kinds which we have previously mentioned in recent notes. Two varieties not usually seen are Le Melesmie and Cleopatra, both belonging to the Japanese class, the former with rose-purple flowers, margined with a deeper shade, and Cleopatra, a reflexed Japanese kind, pure white, full and pleasing.

We were pleased to see a number of plants grown with little stopping of the shoots and made note of a few of the kinds, as their names may possibly be interesting to readers of THE GARDEN. Florence Piercy is delightful thus grown, the flowers with the florets charmingly arranged and wreathing the shoots. Source d'Or is one of the best for growing in this way, as also are Mlle. Lacroix, Elaine, Gloriosum, Miss Gorton, Mlle. Louise Leroy and Elsie.

The incurved section is grown here exceedingly well, and the collection includes the majority of the best varieties in cultivation. We saw some splendid blooms of Queen of England, Lord Wolseley, Golden Empress, Lord Alcester, Miss Haggas

and Prince Alfred, and it is pleasing to see that there is far more colour in this class than was the case a few years ago, but there is still room for additions to the list. The varieties mentioned by no means represent all that are grown, but one does not want to repeat the names of those already described in our pages. It is sufficient to know they are well cultivated, and the more pleasing because the more natural way of cultivating the plants is not forgotten.

Chrysanthemum l'Ami Etienne.—Not only does this represent almost a new type in the manner in which the florets incurve, but the colour is unique. As a true type of Japanese this variety does not in my opinion come under that heading; the florets have too much of the ordinary incurved style for a Japanese. Catalogue description says it is in the way of Mme. C. Audiguier, but it is a poor apology for that old favourite. The colour is best described as an extremely pale lilac.—E. M.

Chrysanthemum General Hawkes.—This Chrysanthemum, which was first shown last season and received an award of merit from the floral committee of the Royal Horticultural Society on October 4, bids fair to be a useful addition to the semi-early or October flowering forms. It is of a sturdy habit of growth, with good foliage, which is retained to the base of the plant, while the flowers are large, full, and of a bright purplish-claret colour. Good flowering plants that have not been cut down may be had about a yard high. It blooms at about the same time as Lady Selborne, Mlle. Lacroix, and L'Isle des Plaisirs, and is quite distinct in colour from any of them. This Chrysanthemum is, I believe, an English seedling raised by Mr. Owen, of Maidenhead, by whom it was sent out in the spring of the present year.—T.

Chrysanthemum John Shrimpton.—A great future was anticipated for this variety and for William Seward when they were both shown at one of the meetings of the Royal Horticultural Society last autumn. The flowers of the two are of a deep rich crimson, yet quite distinct from each other. Both are largely grown this season, and while it is probable that for cut flowers we shall see more of William Seward than the other, yet where plants are grown for decoration John Shrimpton is sure to be an especial favourite, for it is of good sturdy habit, carries its leaves well, and the large broad petals are of a rich velvety crimson tint. The reverse of the petals is golden. In general appearance it is a good deal like an enlarged Cullingfordi, but a prominent and most desirable feature is that it produces grand flowers when from 2 feet to a yard high. For growing in bush form it should be one of the very best.—T.

New Zealand seedling Chrysanthemums.—Mr. H. J. Jones, of Ryecroft Nursery, Lewisham, besides having recently purchased by private contract the large collection of American seedlings belonging to Messrs. Pitcher and Manda, has also secured some of the New Zealand seedlings that were raised by Mr. J. Earland, and sent over to this country in blocks of ice in September, 1892. A large proportion of the plants despatched by Mr. Earland died in transit or soon after landing, but of those saved, Zelandia, a Japanese incurved flower of rosy amaranth, and Rimutaka, a flower of the same type, colour crimson and gold, are the most interesting.

SHORT NOTES—CHRYSANTHEMUMS.

Chrysanthemum J. H. Runchman.—A fine Japanese variety; large solid bloom of deep golden yellow.

Chrysanthemum Mme. Octavie Mirbeau.—This is a large bloom of the Japanese type; the petals are of good length and the colour white, streaked with light purple.

Chrysanthemum Mrs. Robt. J. Hamill.—This is one of the most beautiful incurved Japanese flowers in existence. It has long, grooved petals, incurving most perfectly and forming a very large-sized

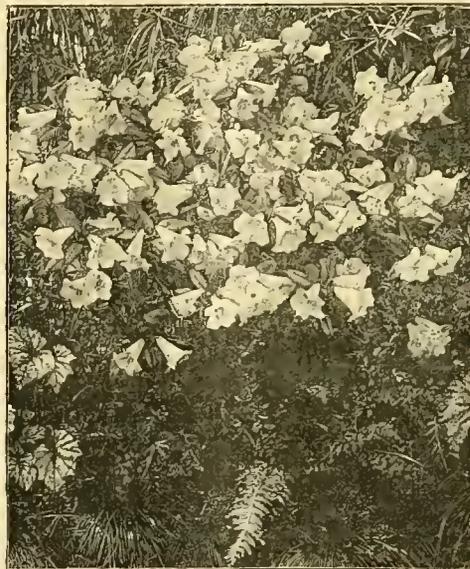

bloom. The colour is pure light yellow of a very delicate shade.

Chrysanthemum Mme. Isaac.—Those who are fond of a good white Japanese will find this a useful variety. The colour is very pure and the size all that can be desired.

STOVE AND GREENHOUSE.

GREENHOUSE RHODODENDRONS.

In the following remarks reference will be made only to those sorts which are, strictly speaking, amenable to greenhouse culture. It is well understood by experienced plant cultivators that the splendid javanico-jasminiflorum hybrids require different treatment to those which form the heading to this article. These are, nevertheless, equally as good and as much to be recommended as the hybrids just mentioned. Their flowering season, on the whole, is during March, April, and May, when they are grand objects for

Rhododendron Countess of Haddington.

large conservatories, winter gardens, or oftentimes greenhouses. These qualifications are given bearing in mind that some of them are of tall growth, and require a fair amount of head room. R. Nuttall is an instance of this. The one point which more than any other is conducive to non-flowering in this section of Rhododendrons is that of over-potting. This more often than not encourages wood growth too much at the expense of flowers. I have noticed in particular how absurdly small the pots of R. Nuttall used to look in the case of some plants grown by an experienced hand, but they produced grand trusses of flowers. Had these plants been too much encouraged at the roots the result would have been different, although they might have, on the whole, looked more robust and healthy. These Rhododendrons will thrive well for years in the same pots provided the soil be of the best description and kept at all times in good condition. When the potting is done, it should be in the very firmest manner, as if dealing with a specimen hard-wooded Erica. The soil should be composed chiefly of peat which is full of fine fibre; such as would suit Orchids would answer; to this might be

added a little fibrous loam of light character and a fair quantity of silver sand. More often than not after a plant has been for some years in the same pot it will be found a difficult matter to remove it without injury to the roots. If this be found to be the case, then smash the pot rather than injure the roots. Another good plan in some cases will be to soak the ball well before potting afresh, in case it may be dry at the centre. Potting should be done soon after the plants have flowered, as then the roots will be the most active, taking more readily to the fresh soil. Only allow a sufficient shift to work down the soil around the ball; a little less than an inch between the pot and the ball will suffice for this, or, in other words, a pot rather less than 2 inches more in diameter than the old one. In treating these Rhododendrons after flowering, a humid atmosphere, as in the case of Indian Azaleas, is not essential in any sense. What has rather to be aimed at is the securing of a short sturdy growth, which is far more likely to produce flower-buds than if it were stronger. Exposure to light and air under glass will tend to produce this result, after which, when the young growth is hardened, the plants can be turned out of doors for a time in a warm, sunny spot not exposed to strong winds, being housed again towards the middle of October at the latest. With respect to watering, it is needful to add that the plants should not at any time suffer; the fact of the roots being in such a confined compass should point to this. When the plants suffer from want of water there is a disposition to cast the leaves prematurely. These Rhododendrons do not, fortunately, lend themselves to a formal mode of training, which when it is attempted is a risky process. In some cases it will be found needful to stop strong shoots; it is better to do this than let them weaken the rest of the plant.

RHODODENDRON COUNTESS OF HADDINGTON is a well-known hybrid, first sent out, I think, by the late Mr. Robert Parker, of Tooting, nearly thirty years ago. It is a grand variety with flowers of a wax-like substance, bluish white in colour, being also a robust growing plant, making with age a fine specimen.

R. SESTERIANUM, a hybrid between R. Gibsoni and R. Edgeworthi, is another beautiful variety, the growth not so robust as in the case of Countess of Haddington, being somewhat scandent; the flowers are large, pure white spotted with yellow, and very fragrant.

R. VEITCHI is one of the finest of all the species; the flowers, of great substance, are pure white and very large, with the margins crisped.

R. WILLIAMSII, which has not been in commerce very long, is a decidedly distinct and handsome plant, with large compact trusses of rather small flowers, pure white, the growth compact and sturdy.

R. CILIATUM is a hardy plant, but on account of its flowering during the winter or extremely early in the spring, it is far better grown in pots.

R. NUTTALLI has immense flowers, white, suffused with rose, and is a grand plant for lofty houses.

R. EDGEWORTHII is a splendid species with flowers nearly 4 inches across, white, suffused with pale pink, and extremely fragrant.

R. HENRYANUM, a cross between R. Sesterianum and R. Dalhousianum, has sweetly-scented, pure white flowers, being a fine conservatory plant.

R. DALHOUSIANUM, already alluded to as a parent of the foregoing, should also be included; it is a grand variety, the flowers white with a tinge of rosy pink.

G. H.

Double Primulas at Brighton.—At Messrs. Miles' West Brighton nursery these plants are

grown well. I noted a large pit full of the white variety, also a fine lot of a pale mauve kind. The white variety, which I was informed was procured from the Continent, was different to that usually grown. I thought it was the variety *grandiflora*, but found it was a little different. The plants were remarkably vigorous and the flowers large and full. At the time I saw them the lights were removed and the plants fully exposed to the sun. Many people ruin this *Primula* through growing it in too much heat and a dry atmosphere. It is best to avoid wetting the foliage during the winter, but a moist cool bottom will suit it much better than a dry shelf, and the plants should not be allowed to become too dry in the pots. If kept in health and the old foliage removed, there will be no fear of damping. No other *Primula* will produce such a continuous supply of white flowers throughout the winter as the old double, that is if the plants are kept healthy.—F. H.

Marguerites in autumn.—I lately saw a fine batch of white Marguerites in Messrs. Miles and Co.'s West Brighton nursery. The plants were dwarf, bushy, and in various stages, some in full bloom and others coming on to succeed them, no sign of the troublesome maggot being apparent. As good pot plants in bloom are generally rather scarce at this season of the year, it is worthy of note that the Marguerites may be flowered so well. The plants referred to were in pits standing up close to the glass and plenty of air given them. The variety represented was that known as *Chrysanthemum frutescens maximum*.—F. H.

Agathæa cœlestis.—This is really a valuable plant for late autumn decoration. When planted out it is apt to run away to leaf, the crop of flowers being correspondingly scanty, but kept in pots all through the summer the growth is sturdy, short-jointed, and flowers are produced in quantity. I used to grow it for winter bloom some years ago, but had lost sight of it till lately when I came across a lot of nicely-grown specimens in a private garden. They were in 6-inch pots carrying individually a score of blooms. We have such a limited choice of blue-flowered plants for conservatory decoration during the autumn and winter months, that one ought not to neglect this *Agathæa*, which in a temperature of 50° will keep on blooming. Like the Paris Daisy, there seems to be no limit to the amount of flowers it will yield, provided the culture is right. Cuttings put in in spring will make good specimens by September, keeping all the buds picked off till that month. From October onwards the plants will make a nice show, and in spring also if encouraged with a little liquid manure. Through the summer the plants should have a sunny position, so that the wood may be thoroughly hardened.—J. C. B.

Streptocarpuses at Chelsea.—When in Messrs. Veitch's nursery recently we were interested in a collection of *Streptocarpuses*, which are steadily increasing in favour. The improvement in the colour of the flowers is great, and Mr. Heal has obtained many shades of superb colour—crimson, purple, maroon and so forth; whilst of lighter tones there is a large selection, ranging through delicate mauve, lilac and pink to pure white. With the improvement in colour has also come a larger-sized bloom, not coarse, but a distinct gain, as the flowers of the original hybrids were rather too small. Seed sown in January will produce flowering plants in seven months, and these will continue long in perfection, blooming again the following year. Those who cannot grow *Gloxinias* or things requiring much warmth cannot do better than raise seedling *Streptocarpuses*.

Russelia juncea.—This is an extremely pretty and graceful flowering plant, which helps to render the stove gay with its brightly coloured blossoms during the latter part of the summer and well on into the autumn—in fact, sometimes until winter. There is nothing else with which it is likely to be confounded, the branches being slender and Rush-like, while the leaves are but sparingly produced. The flowers, which are borne in considerable numbers for some distance along the slender pendulous shoots, are about an inch in length, tube-shaped,

and of a bright scarlet colour. This *Russelia* has a wonderfully pretty effect when trained to a rafter in a small house, as it is unsuited for large structures. In this way the bright green shoots form quite a fringe, and when lit up with its numerous blossoms the plant is additionally attractive. In suspended baskets, too, its various distinctive features are seen to great advantage. It may also be grown in bush form by staking the principal branches and allowing the minor shoots to dispose themselves at will. *R. juncea* will succeed well with the treatment given to the general run of stove plants. It is a native of Mexico, from whence it was introduced about sixty years ago, and at one time was a favourite subject for growing into specimens. There are two other species, *R. rotundifolia* and *R. sarmentosa*, but I am not aware that they are now in cultivation.—T.

Asclepias curassavica.—I should feel much obliged if you would give me the name of the enclosed shrub of which I enclose a flower and leaf. It was raised from seed I found in the jungle in India when shooting some two years since. The seed is contained in a long pod, and has a fly-away attachment. It has flowered and seeded freely this summer in a greenhouse, but I am doubtful whether it will not require more heat to take it through the winter.—W. A. E.

** The specimen sent is this *Asclepias*, which is a pretty flowering plant, though a troublesome weed in some parts of the tropics, and one whose seeds float in the air like those of the Dandelion. It will grow and flower well in a greenhouse during the summer, but it needs a somewhat warmer structure in the winter, though it might pass through the season if kept rather dry at the roots. This *Asclepias* is said to be a native of America, but it is now spread over many parts of the tropics. According to the "Dictionary of Gardening," it was introduced into this country in 1692. All the members of the genus have the silky seed appendages by means of which they are disseminated over a considerable tract of country. There are several hardy species, the best being the autumn-flowering *A. tuberosa*, which produces bright orange-coloured blossoms.—H. P.

Plumbago capensis.—This beautiful greenhouse plant has many recommendations, and I quite agree with all that "H. G." (*GARDEN*, p. 380) has said in its favour. It undoubtedly has the best chance of showing its full beauty when planted out and trained against a wall; yet as a pot plant there is nothing of the same colour to equal it. I have also seen it used as a bedding plant with good effect, but I must say I am no great admirer of the practice of turning our prettiest greenhouse plants out of doors. It may be readily propagated from cuttings, which should have similar treatment to *Fuchsia* cuttings, and those rooted about February will make nice flowering plants the same season; or if propagated later in the season, three plants may be grown in the same pot. The plants may be stopped once or twice, and in the early part of the season should be grown on in warmth, but later on will do well in the cool greenhouse under conditions recommended by "H. G." I may add that the white variety, introduced a few years ago, is a good companion to the blue, differing only in the colour of its flowers.—F. H.

Habrothamnus (Cestrum) elegans is another free-flowering greenhouse plant, and a good companion for the *Plumbago*, the terminal clusters of rich crimson flowers forming a good contrast to those of the *Plumbago*. The same conditions will suit both plants, though the *Habrothamnus* is even more inclined to grow too strong, and should be planted or potted in poor soil. It requires a good deal of space to flower it well, and although not, strictly speaking, a climber, it should be trained against a wall. It is not so well adapted for pot culture as the *Plumbago*. *H. aurantiacus* makes a fine pot plant, not being of such vigorous growth as *H. elegans*. Good strong cuttings propagated late in the summer and kept in a cool house through the winter will flower the following sum-

mer, and the terminal panicles of rich orange-yellow flowers are both distinct and effective. This does not flower so continuously as *H. elegans*, the flowering period being generally confined to August and September.—F. H.

A note on winter-flowering Carnations.—The collection of winter-flowering Carnations in Messrs. Veitch's Chelsea nursery contains the best kinds now in cultivation. One of the most popular is *Winter Cheer*, which has rich crimson flowers and the plants are remarkably compact and free, quite little bushes. We wish, however, that this type of Carnation were more fragrant. Raisers should try and get sweet scent with them. *La Neige* is a good white, the plants compact and free. *Mlle. Thérèse Franco* is a new variety. It is a fairly good grower and bears a large salmon-rose flower, which does not split, and is distinct. This is a fine variety and should be much grown for winter. Its flowers are larger than in the majority of kinds. Improved *Miss Joliffe* is worthy of the name. The flowers are deeper in colour and larger, whilst the plant is not less free than the type. *Mrs. A. Hemsley* is a good deep crimson-purple, and *Sir Henry* a fine scarlet, but the plant does not grow so satisfactorily as one could wish.

Carnation Mrs. H. Cannell.—When looking at flowers of this Carnation last year I was not nearly so much impressed with their value and distinctiveness as during the present autumn. It is without doubt a really valuable acquisition, being one of the finest for autumn flowering that has been introduced, with blossoms of large size. If thinned, as in the case of the *Malmaison* Carnations, the flowers of *Mrs. H. Cannell* would nearly approach them in size. The growth is extremely vigorous, but very compact, an abundance of shoots breaking forth from near the base. The flowers seem to increase considerably in size, even after they are quite expanded, whilst there is hardly any bursting of the pod. The colour is a bright rose-pink, which is well maintained as the flowers gain age. I should not be at all surprised if it will prove as continuous in flowering as *Winter Cheer*; at any rate it promises to do so at present; if so, it will be another point in its favour. Whether cuttings or layers will prove the better and more reliable mode of increase has yet to be ascertained.—GILLIFLOWER.

ORCHARD AND FRUIT GARDEN.

SECOND CROPS OF FRUIT.

SECOND crops of fruit are the order of the day, —in fact, are causing quite a sensation. Never before, probably, have Strawberries produced such extraordinary second crops as they have done this season. It is no uncommon occurrence for forced plants duly turned out or plunged in the open ground to fruit again very freely in August and September, but it is not often that any not forced, or which, say, produce their first crops in the open ground, attempt to fruit a second time. This season the conditions have been very different to what are usually experienced. In the first place the Strawberry season commenced fully a month earlier than usual and was of comparatively short duration. Owing to the drought and great heat the crowns matured very early, a rest also being compulsorily brought about. Then came enough rain in August and September to re-excite the plants, the consequence being the development of a large number of strong flower trusses and an abundance of well-formed fruit. The weather still being favourable, no September frosts severe enough to cripple tender plants of any kind being felt, the Strawberry crop had a good opportunity of ripening properly. In numerous private gar-

dens as well as in the open fields in different parts of the country many gatherings of excellent Strawberries have been made. Of Raspberries, again, large quantities of fine well-flavoured fruit have been gathered during the past six or eight weeks, small plantations yielding several quarts in the course of a week. In this instance all the varieties are behaving very similarly; whereas in the case of Strawberries it is principally, and in some gardens solely, Vicomtesse Héricart de Thury, Noble, Keens' Seedling, John Ruskin, and other early sorts that are fruiting a second time this season.

In some instances Pear trees did undoubtedly flower and set fruit at fairly widely-apart intervals, or sufficiently so to warrant their being termed two crops, but even this is very different to the second cropping of Strawberries and Raspberries. The two latter were from crowns and canes respectively formed this season; whereas most of the so-called second crops of Pears or Apples were from buds formed, if not exactly determined in character, during the preceding year. It has long been my opinion that buds, on Pear trees more especially, are more affected by the weather experienced during the winter and early spring months than scientists are prepared to admit. Not till the trees are beginning to decline in vigour do they as a rule form many flower buds. A severe check to their vigour usually results in the formation of more flower-buds than formerly, and even in changing what was originally intended for wood-buds into flower-buds. This check may be caused either by a severe frost, root-pruning, or great heat accompanied by drought. Last winter we had one long severe frost, and it is to this we very probably owe more than the sunshine of July in 1892. I allude to the wonderful freedom of flowering of fruit trees generally. So freely did the trees bloom, that the loss of a third or more of the flowers by frosts did not greatly prejudice the prospects of a good crop of fruit, but many of the buds were checked considerably, these opening late and being followed by malformed fruit that has done duty as a second crop. What flowers opened still later were I think the outcome of the dry spring, buds flowering instead of developing into short fruiting spurs for next season. In all cases that have come under my notice of flowers produced by wood of the current year's growth none have been followed by perfectly-formed fruit. Both Apples and Pears have apparently set all right, but have failed to swell as large as a Cherry, though whether this is due to imperfect fertilisation or to a deficiency of support from the roots I cannot say. Nor is any of the fruit that set on the trees soon after midsummer of any value, though it has certainly ripened.

The question that most concerns us is, what will be the effect of this second cropping, or attempt at it, on next year's returns? As far as fruit trees are concerned, I am under the impression that there will again be a superabundance of fruit-buds. Already there is plenty of what are unmistakably fruit-buds, including many at the points of short growths made this season, and should we have a severe frost again this winter, then many of what may be termed undecided buds will also flower. There is likewise every possibility of fruit-buds being developed throughout the length of well-matured young wood on somewhat old trees if only these are left thinly at pruning time, and if something is done in the way of autumn or early winter manuring towards assisting in the recouping the strength of comparatively exhausted trees, the good prospect will be even more likely to be realised.

With Strawberries, and to a lesser extent Raspberries also, the case is different. Instead of the late crops of the former being produced by quite young plants, as conjectured by an usually well-informed writer in a daily contemporary, they were had solely from old plants or those that had already fruited once this season. The crowns that gave the flowers are those that ought to have waited till next spring before bursting, and what, therefore, is being had now will be greatly to the prejudice of next season's crop. Doubtless there are a few smaller or later formed crowns that have remained dormant, but it is scarcely feasible that anything like a full crop of fruit will be forthcoming next summer. In this neighbourhood ripe Strawberries are being gathered in nearly every garden where early or second early varieties are grown, and some growers that have neglected trimming off old leaves and runners are acting on my advice to leave a good sprinkling of well rooted plants between the rows, as it is very certain these will give fruit if the old plants do fail. Raspberries are fruiting somewhat curiously. The more advanced of the young canes (the old ones are all dead) have branched strongly, the points of the side shoots and the tips of the canes producing fruit in great bunches, while in other cases a few fruits are formed close up to the leaf axil. How far this behaviour will prejudice next season's crops remains to be seen, but it must have a bad effect. Probably the best plan will be to reserve rather more canes than usual, depending upon the joints that have not given fruit this autumn for producing fairly strong fruiting shoots next season. Most of the lower buds are dormant, and these can be made to break freely by rather hard pruning, so that, all things considered, we need not despair of having good crops of Raspberries as well as of other fruit next year.

W. IGGULDEN.

Gooseberries on north walls.—When I mention that Gooseberries netted on bush trees in the open were literally roasted, it will be seen how valuable a few trees on a wall with a due north aspect are for the supply during the late summer months. I have seen many walls where such trees would have given good returns furnished with fruit trees that rarely give a crop and look unsightly. A high wall of Warrington on the double cordon system would amply repay the cultivator. There are several advantages in having Gooseberries trained on walls in that protection from birds can be so readily performed, pruning is very simple, and the fruits do not decay as on bushes. Now is a good time to plant a wall. For a low wall or fence, trees with three or four upright shoots are very suitable. In selecting trees, only those varieties should be planted which are suitable. Some of the choicer and larger kinds have a pendulous growth, and are not suitable. Warrington always succeeds and the fruit hangs well.—G. W.

Apple Blenheim Pippin.—It has fallen to my lot to attend several public dinners lately, and at each I have taken particular note of the dessert fruit. Of Pears, *Benrre Clairgean*, past its best, and quite ripe *Blenheim Pippin*, or *Blenheim Orange Apple*, as it is more often termed, were principally placed on the table. The *Blenheim* is still the favourite Apple with lovers of good fruit, but it is in December when it is most wanted, and not October. So much is it liked, that it invariably fetches better prices than any other variety, and when available large quantities are bought and stored for future use by very many dwellers in country places as well as small towns. This season the crops were heavy and the fruit of good size and well coloured. The fruiterers were, however, somewhat backward in buying, the prices offered being about 2s. per bushel, sometimes even less being taken by the growers. Householders

being less wary, have bought what they want, also at much cheaper rates than usual, only to find that there is not the slightest likelihood of their being able to keep them much, if any, later than the middle of November. The crops ripened sufficiently for gathering and storing fully a month earlier than usual, and the very mild weather experienced up till the present time (October 26) has been all against keeping fruit. It is much to be regretted that good Apples are fit for use very much earlier than desirable; but there is no remedy, storing in very cool quarters not availing very much. There would appear to be only too much truth in the old saying to the effect that fruit which ripens quickly is also quickly rotten.—I.

STRAWBERRY PLANTS FOR EARLY FORCING.

It frequently happens there are plants left over from those required for the open or for forcing. There are various uses, however, to which these may be put, and I have frequently been glad of them for patching the permanent beds the following spring, and have plunged them in rows thickly together so as to preserve the roots from frost. They also make excellent plants for another season if put out in March or April and the flower-trusses removed. I admit this latter plan does not commend itself to all, as the plants occupy the ground some fifteen months before there is any return in the way of fruit, but the latter is very fine when it does come. I do not advise it myself, as quite five months of the year are wasted, and in gardens with every inch of soil required it is not a wise proceeding, as quite as good results may be secured by layering strong runners and planting in August for next season's fruit. The question arises, What shall we do with the small or left-over stock of late runners? It is well known there is considerable difficulty in getting plants from runners potted, say, in August to throw up their blooms late the same year or very early the next, as the plants have not had a sufficient rest. I find there is always a great difficulty in getting the blooms well above the foliage, and I was told by an eminent practitioner to use older plants, and by this means get early fruit with less trouble. I tried lifting one-year-old plants, but it did not answer, as the plants not being pot-bound, when called upon for increased exertion failed to respond. To get early fruit I tried the small plants left over. Of course, there is the same objection as to length of time these plants are about. They rarely fail, however, and this is important, as very early forced plants often fail badly. The plants at this date may be plunged in ashes in the open or kept in frames thoroughly exposed, as it must be borne in mind only the roots need protection. No harm will come to the plants, as the hardier they are kept the better, provided the roots are preserved. Some pot up at this date into 4½-inch pots and winter in frames. I do not advise this, as there is often loss of plants in a long-protracted frost, as there is little root-action and the pots get soddened with water and the roots decay. I would advise potting up in March or April according to the season. When potting, 6-inch or 7-inch pots should be used, and only pure loam, as it must be remembered these plants have quite four months' start of the plants grown in the usual manner, and during early growth every flower-truss must be removed. Plunging in ashes or fibre is also necessary during the summer months. With late summer-potted plants plunging is not important, as the plants will not be a mass of roots till the cooler weather with longer nights comes. Early varieties should,

of course, be chosen for the work, and the plants kept to two or three crowns at the most. Some kinds split up into various sections worse than others, but there is no difficulty in keeping such good kinds as Keens' Seedling, La Grosse Sucrée to one crown, allowing Vicmtesse H. de Thury two or three. These plants will be ready for forcing any time during the late autumn, and there will be less trouble and anxiety to get early fruit. When I write early fruit I mean during the first two or three months of the year. I do not say that the fruit is as fine as from plants throwing up maiden trusses of bloom and fruiting, say, in April or May, but fruit of fair size in January or February is valuable. Of course, a great number of plants would not be required in a private garden. It is surprising how readily such plants fruit compared with those forced in the usual way. After forcing, these plants, if planted out after due hardening off, will give a lot of small fruit a little later than the plants in the open. These do well for preserving. Runners planted out in the early autumn may be lifted in spring if desired, potted up and treated as advised for plants in small pots. Of the two I prefer the pot system.

G. WYTHES.

PLANTING RASPBERRIES.

ON gravelly or light soils Raspberries require more attention than when in good loam; indeed it seems useless to manure after the roots have gone down into the subsoil in search of food. I do not intend to convey the impression that manures are wasted on Raspberries, but replanting on new land would often be advisable, doing this in the early autumn and in all cases planting good canes with plenty of fibrous roots, so that a good start is made before severe weather sets in.

In a light soil I find none to equal Superlative and Carter's Prolific. The former is a heavy cropper, makes a vigorous growth, and bears fruits of a good flavour for a long time. I consider the latter part of September and the first week in October the best time to plant. Many may think this early, and prefer to wait till the leaves have all dropped, but in mild seasons the canes retain the foliage a long time, and if planted early the canes do not suffer. Raspberries start early in the spring, so that to secure the best results early planting is necessary. Where ground is not suitable it will repay to add good heavy soil of a turfy nature to poor gravelly soils. Trenching the ground is also important, but in trenching it is advisable to leave the poor soil at the bottom, mixing the good soil with the second spit and incorporating with it the manure. In heavy clayey land drainage is important, and such materials as brick rubbish, mortar rubble, charcoal refuse, leaf-mould, burnt soil, road scrapings, river sand and anything which will keep the soil sweet and allow free drainage are beneficial. Another point worth consideration is space. Even on land where the plants do not make a robust growth light and air between the rows are important details.

If space can be allowed I would plant 12 feet apart in the rows and crop between; this allows of greater freedom for the plants to develop, and the fruits do not decay in wet seasons by having the rows wide apart. It is an easy matter to dig out a trench 2 feet wide and fill in with better soil, and in places where failures occur this is the best system and causes the least trouble. Plant the new canes intact without shortening, as this is best done in the early spring, just as the sap is on the move. If cut down now there is danger in severe weather of losing the plants, as frost soon plays sad havoc with the cut portion. In the early spring the canes may be cut lower than is often practised, as the shoots on the planting canes are of little value, two or three strong growths from the base being what are required for the formation

of the next year's fruiting canes. Firm planting and a good mulch of short litter over the roots to protect from frost are essential. A mulch of good decayed manure twice a year in the spring and autumn will keep the roots near the surface. Only allow a few suckers to remain yearly to take the place of the old canes, and remove the fruiting canes at the earliest moment possible after the fruit has been gathered.

G. WYTHES.

Early Rivers Cherry.—This is, I consider, one of our very best early Cherries. With me Early Rivers never fails to crop freely; even the youngest trees bear very well. This variety is a seedling from Early Purple Guigne, a variety of great merit, but not one of the hardiest. Early Rivers is more robust; indeed, this season's crops ripened in the open on standard trees in June. Early Rivers is a large black and handsome fruit with fine flavour and a very small stone. For forcing it is first-rate, and in a cool orchard house it also does well. I would advise planting this variety both on a west and east aspect, as in this way earliness is secured and a succession can be kept up. There are also more chances of success, as often trees on one aspect are injured by frost and escape on a colder one. Those who are about to plant should not hesitate to include this variety where early and good fruits are desired.—G. WYTHES.

Pear Beurre Rance.—This old Pear, said to have been in cultivation about 300 years, is valuable still as coming into use when Pears are scarce. It has been in some seasons our latest of all in ripening, and is considered by many to be the best of our late Pears. To succeed well, Beurre Rance should have a south wall, where it will under proper treatment grow to a large size, and being a lover of warmth, will be improved in unfavourable seasons by being matured in heat. This Pear does not succeed on the Quince. I had a tree which bore well, but the fruit invariably cracked and fell off. Beurre Rance grafted on Pitmaston Duchess has a good head, and produced this season—the second from grafting—a heavy crop of fine fruit.—E. W. B.

Crab Apples.—These trees have been loaded with fruit this season, and beautiful objects they are for shrubberies. I read with interest the note at p. 370 on the beauty of the Dartmouth Crab—a variety with deep crimson fruit and of a beautiful Plum shape. We have it under the name of the Hyslop Crab, but I am sure it is the true Dartmouth variety, its shape and colour being similar. John Downie is lovely this season, the trees being heavily laden with fruit. This is Pear-shaped, and I do not know of any variety that fruits more freely in a young state. I saw some splendid fruits on three-year-old standard trees, the branches being bent down. Transcendent is also worth a note on account of its rich red and yellow fruits of an oval shape. The older forms, or Siberian yellow and red varieties, are well known, but even these are only sparsely planted for effect. The Crab Apples are also most delicious when preserved.—G. WYTHES.

Notes on Pears.—Van Mons Leon Leclerc (October 28, p. 399) is one of our best Pears, a heavy and consistent cropper, fruit large and of very fair quality. It is a worthy successor to Marie Louise and just hits the season between that variety and Winter Nelis. I can hardly, however, understand "T. A.'s" paragraph, "when it becomes better known." It is to be found in very many gardens, and, according to the "Fruit Manual," first fruited in 1828. I should imagine it was introduced into this country soon after this, many of the trees one meets with being of great age. Like many other varieties, the flavour varies greatly on different soils, although it is perhaps better in this respect than such sorts as Beurre Diel, Duchesse d'Angoulême, Baronne de Mello and Marie Louise d'Uccle. Some four years ago when planting a wall with cordons I was strongly recommended to try the last-named as being only slightly inferior to Marie Louise in flavour, and

much superior in constitution and cropping qualities. It certainly bears out the recommendation from the two last standpoints, but is practically useless for dessert—at least I have not had a toothsome fruit in the three seasons since planting. Duchesse d'Angoulême and Beurre Diel are a trifle better from cordon than from old horizontal wall trees, but still far from first-class. The remark one often hears that few first-class Pears are available after the middle of November is likely to be verified this year, most dessert varieties being three weeks earlier than usual. Marie Louise, Doyenné du Comice, Beurre Superfin and Van Mons Leon Leclerc were all over before the end of October, and we have almost finished Winter Nelis. The selection of good late varieties is not an easy matter, many being unsatisfactory in the majority of places. Easter Beurre is often gritty and full of core, Ollivier des Serres very small, and Bergamote d'Esperen not ripening up at all. A fairly good selection, including Winter Nelis, to carry through the latter half of November and December would perhaps be Rivers' Princess, Beurre Sterckmans, Glon Morceau and Thompson's.—E. BURRELL, *Claremont.*

LIFTING AND TRANSPLANTING FRUIT TREES.

FROM experience, there can be no doubt that the periodical lifting of fruit trees on some soils greatly benefits them, and enables us to obtain finer samples of fruit than are possible when the roots of the trees are allowed to follow their natural course and penetrate into the cold, clayey subsoil. As the time of year when it is necessary to commence such work is at hand, a few hints on the subject may not be out of place. I would by no means advocate the lifting of old orchard trees which have stood for years, and whose roots extend to a considerable distance, for by attempting such experiments their lives would be jeopardised. Trees of this description, however, might be greatly benefited by the removal of the soil from the roots, replacing it with some fresh rich earth, this encouraging new fibres and thereby giving renewed vigour to the old trees. If the roots of fruit trees growing on cold, stiff land be allowed to go straight down, few fibres will be made, so that there is not the same number of feeders as there would be if roots near to the surface were encouraged. Nor is this all, for without fibrous roots the fruit does not arrive at the same maturity in wet seasons as it does when grown on ground of a warmer nature. Trees whose roots are brought near to the surface are more under control, and can be fed at the time when the greatest strain is put on them by the growing crop of fruit. Most visitors to the great shows this season have been struck by the fine samples of fruit staged, especially of Apples and Pears. The best specimens were from trees whose roots had received special care. It is still thought by some that to cause a tree to be fruitful its growth must be stunted, but this is not the case, for the choicest samples are the product of the healthiest trees and largest flowers. The better the blossoms are developed the finer will the fruit be provided that receives proper attention while growing. To produce such buds the trees must be in perfect health, and as this cannot be maintained on some soils and in some districts without much trouble, those who have to deal with such must be prepared to assist their trees if they wish to obtain excellent results. It is not merely lifting and transplanting that the trees will require, but careful looking to afterwards, for however painstaking the most practical man may be in doing this work, there must necessarily be the extra watering and so forth the following spring. Trees usually

suller most after being lifted just as they are pushing their buds in April, and unless they can receive attention just at that time, the flower-buds often fall, and so the season's crop is lost. All these things should be taken into account at the present time and no more work be begun than can be done well. It is better by far to lift a few trees each season and give them proper treatment than to attempt to do a whole lot and be unable to look after them later on. For trees that have been planted four or five years, a trench should be taken out at least 6 feet from the stem, and the soil be carefully forked out from between the roots till it can be ascertained whether there are any under the centre of the tree with a downward direction. All such should be carefully cut through with a sharp spade. Some fresh, light, rich mould should now be filled into the hole left vacant, and afterwards the roots should be carefully laid over this and a little more fresh soil added to cover them, filling in the hole with the old soil taken out. If the tree is a large one, the roots should be lifted in sections of about a third each season; by this means there will be no serious check to its growth. Avoid as much as possible severing strong roots, unless they have a downward tendency and are under the centre of the tree. It is better to trace the others to near their points, for the greater the number of feeders the more chances there are of getting a full crop of fruit the following season. Some growers advocate the plan of allowing trees a couple of years to recoup themselves after being lifted, but if the work is done carefully there is no need for any such waste of time, as good crops of the finest fruit are invariably taken from trees the first season after being so treated.

Lifting is done with a view to encourage fruitfulness by preventing over-luxuriance, not deterioration of the tree's growth, for unless it is in the finest possible health, the desired results cannot be obtained. On chalk or gravelly subsoils it is seldom necessary to interfere with the roots for this purpose, but rather with the object of encouraging growth, for on the latter subsoil the upper layer becomes exhausted by the percolation of the vegetable matter through the gravel owing to heavy rains. The roots of trees on chalk cannot go to any depth, so must be supported artificially. Therefore, it is necessary sometimes to give the roots fresh soil to spread themselves in. No better time can be had for this work than the dull days at the beginning of November, for then the soil is usually in a workable condition, and not having a much reduced temperature new roots are soon made, so the tree gets established before the winter sets in. Much mischief is often done by lifting trees too late in the season, for the dry weather sets in before they have had time to make any fresh roots. The buds in consequence shrivel instead of expand, and the result is little or no growth instead of a flourishing tree carrying a good crop of fruit. When lifting has been finished, trees should always be mulched with some kind of litter, and this is best done as the work proceeds, for it prevents the ground from being washed too much by the heavy rains, thus enabling the soil to retain the warmth longer. It also acts as a preventive against frost penetrating the ground, so that root-action may go on for the greater part of the winter. Staking, too, must not be omitted if we would have our trees prosper, for if they are rocked about by the winds it is impossible for the roots to take hold of the soil to establish themselves. Care must be exercised with this, however, for if they are tied too tightly they will not be able to sink

with the soil, and consequently will often suffer. When the trees are well set the ties may be removed, as they are of no further use. Watering must be attended to, especially in the earlier part of the year if the weather be dry, as this causes the buds to burst more vigorously. It is seldom that trees so treated require pruning much, as blossom-buds set freely all up the young growths, and if they have attention during the summer by pinching and regulating the shoots, there need be little fear of their producing poor fruit crops unless the season be very unusual at the time of flowering.

H. C. P.

SHORT NOTES.—FRUIT.

Pear Catillac.—As a market fruit there are few that repay good culture better than this. Even in a year of abundant Pear crops good Catillacs are fetching as good or even a better price than many of the tender-skinned dessert sorts, and with far less loss in the way of decayed fruit. It is surprising that the Catillac is not more largely cultivated.—J. G., *Hants.*

Apple Chatley's Kernel.—I was glad to see "Y. A. H." (p. 399) directing attention to the above. It is all that he describes it, and it succeeds admirably as a bush, which is the only form in which I grow it. During the past five years it has not failed to produce from a fair to heavy crop of medium-sized and highly coloured fruit, beautifully dotted over with small brown spots. As a late Apple it is extremely valuable, keeping sound and fresh until June. Another advantage is that it will cook well at any time, and is worthy of a place in every garden. As a market Apple, I question whether it would pay to plant it extensively, as the public want something "big" in cooking Apples. My experience is that Bramley's Seedling and Lane's Prince Albert pay much better than Chatley's Kernel as market varieties.—W.

SOCIETIES AND EXHIBITIONS.

CRYSTAL PALACE CHRYSANTHEMUM SHOW.

NOVEMBER 3 AND 4.

At this, one of the earliest exhibitions within the metropolitan area of the season, the most prominent feature was the remarkably fine quality of the Japanese section. This was most pronounced in the stronger classes as well as in the champion class for forty-eight blooms, equal number of Japanese and incurved varieties. Of the other Japanese the following stood out prominently as the best, viz.: Edwin Molyneux, Avalanche, Stanstead White, Sunflower, and Val d'Andorre; and of the newer kinds, Col. W. B. Smith, W. H. Lincoln, Viviani Morel, W. G. Bryceson, Mrs. Falconer Jameson, Lord Brooke, Mme. Thérèse Rey, Mlle. Marie Hoste, President Borel, Excelsior, the yellow and white sports of Viviani Morel, and Wm. Seward. In the larger classes as well as the smaller ones for blooms of one variety only the competition was keen. There were fourteen entries for eighteen Japanese varieties, thirteen for twelve vars., and seventeen for one variety, six blooms. The champion class was a fine feature, there being seven entries of forty-eight blooms each. There was not, however, so much competition for the pompons or the single varieties. This is to be regretted in the case of both, but more particularly of the singles. Only one exhibit of these was staged, but it was a remarkably fine one, clearly demonstrating their utility as well as their most attractive features. Plants collectively were good, notably the pompons, the Japanese bush plants and the mixed standards; the only fault to be found was the somewhat formal training. The groups, on the whole, were up to the average, not

so good as on some occasions, but they made a good display.

The class around which was centred the most attraction was that for forty-eight cut blooms, equal each of Japanese and incurved varieties. The competition was keen between all the prize-winners. Mr. Ritchings, The Yews, Reigate Hill, was placed first with a grand stand of Japanese varieties, but a trifle weak in the incurved section. Of the former there was an excellent variety as to colour, being also very fresh and well developed, the best being Edwin Molyneux, Col. W. B. Smith, Viviani Morel, Beauty of Exmouth (a lovely white with twisted petals), Excelsior (deep rosy pink), W. H. Lincoln, Margot, John Shrimpton, Harman Payne (large deep blush), President Borel, Puritan (fine), and Sunflower. Of the incurved, the best were Baron Hirsch, Violet Tomlin, Miss Haggas, Mrs. Geo. Rundle, Mrs. Dixon, Queen of England, and Jeanne d'Arc. Mr. Shoesmith, Shirley Cottage, Croydon, was an excellent second, his best flowers being Col. W. B. Smith, extra fine; Mme. Thérèse Rey, a superb new white; Charles Davis, the pale yellow sport of Viviani Morel; Harman Payne, Mme. Calvat, Viviani Morel, Charles Shrimpton, Anna Hartshorn, Eda Prass, the white Viviani Morel, G. C. Schwabe, and Wm. Seward of the Japanese, the light colours being, on the whole, predominant. Of the incurved there were fine blooms of Jeanne d'Arc, Princess of Wales, Mme. Darrier, Baron Hirsch, Mons. Bahuant, Golden Empress, and Mrs. Coleman. Those well-known and usually so successful exhibitors, Messrs. W. and G. Drover, Fareham, Hants, could only secure fourth place in this class.

The next class, that for eighteen incurved varieties, was not on the whole remarkable for uniform excellence, save in the case of Mr. Lees, Trent Park Gardens, New Barnet, who was easily first for a grand stand of blooms, the finest of which were Mons. Bahuant, fine; Mrs. Coleman, deep colour; Jeanne d'Arc, Hero of Stoke Newington, extra good; Alfred Lyne, pale lilac; Princess of Wales, Alfred Salter, Lord Alcester, Golden Empress, extra colour; Lord Wolseley, Empress of India, Miss Haggas, and Violet Tomlin; these were the best incurved varieties in the show. Mr. Carpenter, Broad Oaks Gardens, Byfleet, who was second, had Refulgens, extra deep in colour, with fine blooms of Mme. Darrier and Golden Queen. For twelve incurved varieties, Mr. Felgate, Burhill, Walton-on-Thames, was first with an even box of medium-sized blooms, the best being Mrs. Heal, Mme. Darrier, and Violet Tomlin. Mr. Jupp, Torfield Gardens, Eastbourne, was a fairly good second, his best being of the Queen family. The next class, viz., that for six blooms of one variety, produced a keen competition. The first place was worthily accorded to Mr. H. Brown, The Gardens, Basingstoke, Hants, for superb flowers of Mons. Bahuant, very large, perfect in form, and of deep colour. Mr. Jupp followed with excellent ones of Princess of Wales, very bright and fresh.

The next class, viz., that for eighteen Japanese distinct, was a particularly strong one, there being no less than fourteen entries. The first prize was adjudged to Mr. Lees in a keen competition; his stand was uniformly good, fresh and bright in colour, forming a very fine exhibit; the best flowers were those of Mr. G. Bryceson, after Etoile de Lyon, but of a much deeper shade, being more of a plum colour; Viviani Morel, extra good; Charles Davis, Florence Davis, pure in colouring; Mrs. Falconer Jameson, Edwin Molyneux, richly coloured; Mme. E. Carrière, a fine white; Sunflower, W. H. Lincoln, and Col. W. B. Smith. The second prize went to Messrs. W. and G. Drover, who had an even lot of blooms; Mr. Wheeler, Col. W. B. Smith, and Lord Brooke, extra fine, were the best. For twelve Japanese varieties, Mr. Tickner, The Gardens, Shermanbury House, Reigate, was placed first, there being thirteen entries. The premier lot was very bright in colour, even in size, and in other respects excellent, the best being Lord Brooke, a splendid flower; Viviani Morel, W. H. Lincoln, Col. W. B. Smith, President Borel, Mlle. Marie Hoste, Mr. Felgate, who was second, also showed well; his best blooms were those of Col. W. B. Smith, Mlle.

Marie Hoste, W. H. Lincoln, and Louis Boehmer. With six blooms of one variety of Japanese, Mr. Macdonald, The Gardens, Clanna, Lydney, Glos., was placed first with extra fine blooms of Edwin Molyneux, grand in size and perfect in finish, the second award going to Mr. Felgate for Col. W. B. Smith, the blooms large, full and bright; the third lot was grand flowers of Vivand Morel, and the fourth very excellent ones of Stanstead White; in this class there were seventeen entries.

The best eighteen reflexed, including those of the Japanese section, came from Mr. Salter, The Gardens, Woodhatch Lodge, Reigate. These were large and very bright, the selection being excellent; the best were Mme. Darquier, Ernest Asmils, a fine chestnut colour; Mrs. Sullivan, Edwin Beckett, Rosy Morn, a pretty blush; J. Shrimpton and Wm. Seward, dark velvety crimson. The second best came from Mr. Felgate, who had good blooms of Criterion, Mons. W. Holmes, President Hyde, a golden yellow, and Val d'Andorre. Mr. Salter was also first for eighteen Anemone and Japanese Anemone-flowered varieties—a class in which he always excels. His exhibit was an excellent one, the blooms staged being in true character. The finest were Delaware, a fine flower with white guard petals and a yellow cushion; Sabine, a yellow self; Sœur Dorothee Souille, very pretty; Grand Alvéole, blush; Mons. Lebosqz, extra good, and Acquisition, pale pink. Mr. Milner, The Gardens, Willenhall Park, Barnet, was a capital second, his best being Mons. Pankoncke, dull red, large; Mme. R. Owen, pure white, and Mons. Lebosqz. With twelve pompon Anemones, Mr. Salter won again, having the best sorts in first-rate condition; one of the very best of these was Bessie Flight, deep pink, with golden cushion. Regulus, bronze-red, Mme. Sentir, white, and Mme. Montels, white, with yellow centre, were also excellent. Mr. H. Harris, Denne Park Gardens, Horscham, was a good second with similar varieties. With twelve pompon varieties, Mr. Knapp, Chichester Road, Croydon, was first with extra large and fine blooms, the finest of which were Florence Carr, bronze; Mlle. Elise Dordan, and Pearl Beauty, a deep crimson-claret colour, and Golden Mme. Marthe. Mr. Salter was a good second, two of his best being Toussaint Mauriot and Prince of Orange. In the class for twelve Japanese Anemone-flowered the only exhibit was disqualified for containing other than those of the specified section—an oversight which could not be passed over. The one class provided for single varieties only brought out one exhibitor, but no stand of blooms in the whole show was worthier of the first prize than this. Mr. Carpenter must be congratulated upon the excellent manner in which he staged in this class, which really ought to be a more popular one. None of the Chrysanthemums are more beautiful, if they really equal these simple kinds. The dozen were Bessie Conway, Miss Crissey, Mrs. D. B. Crane, Sir T. Symons, Miss M. Wilde, Miss Mary Anderson, Rev. W. E. Renfrey, Purity, Oceana, Lady Churchill and White Jane, with another. For descriptions of these kinds reference should be made to a catalogue.

In the open class for a group of Japanese varieties only, Messrs. J. Carter and Co., High Holborn and Forest Hill, S.E., were comparatively easy winners; their group was an excellent one, containing many of the best kinds in excellent variety of colour, the plants bearing individually some fine blooms. This group was well finished off with dwarf plants in the front. The best and most noteworthy kinds were dwarf plants of Val d'Andorre and John Shrimpton; also of W. G. Childs, with taller ones of Mrs. Falconer Jameson, Vivand Morel, Colonel W. B. Smith, Mons. Freeman, Sunflower, Edwin Molyneux, Mons. Holmes and Avalanche, excellent and effective varieties for grouping. The second prize was awarded to Messrs. Mobsby and Son, Thornton Heath, for a good and effective group. In the amateurs' class for Japanese and incurved varieties the best group by far was that from Mr. T. W. Wilks, The Gardens, Cranbrook, Upper Norwood; this was in all respects a superior exhibit, the plants bearing many large

and fresh flowers. The front was tastefully finished off with dwarf plants, and altogether very well arranged. The best examples were those of Vivand Morel, Etoile de Lyon, Val d'Andorre, Mons. Freeman, Avalanche, Florence Piercy and Sunflower, the foliage in each case being very fresh and healthy. Mr. Baker, The Gardeos, Westwood House, Sydenham, who was second, had somewhat overcrowded his arrangement, but amongst these plants there were many finely developed flowers.

The best of the trained plants were the half-dozen pompon varieties shown by Mr. J. Hughes, The Gardens, Eastlands, Dulwich Village; the finest of these were the lilac, white and golden forms of Cedo Nulli, an old variety, but one not yet surpassed in its section for specimens. Another good sort in this exhibit was Maroon Beauty, a rich shade of colour. These plants all bore very fine flowers in profusion. The second prize exhibit was smaller plants hardly so well in flower. For six Japanese varieties and for six incurved varieties, Mr. J. Hughes was first somewhat easily in each instance. The former were of the two the finer; the best of these consisted of extra good plants of Source d'Or, Margot, Vivand Morel and Mme. B. Rendatler, all dwarf and profusely flowered plants. Of the incurved var., the best were Lord Wolesley, Mrs. G. Rundle, Mrs. Dixon and George Glenny, all fresh and good. In this latter class Mr. Cherry was second, Queen of England being one of his best, whilst in the former class Mr. Wesker was second; his two best were Florence Piercy and Margot, being in all a good lot of plants. For twelve standards in variety, Mr. W. Carr, The Gardens, Croydon Lodge, Croydon, was placed first, the plants bearing large heads full of flower, the finest being Source d'Or, Elaine and Margot, all first-rate, with Mrs. Dixon and Alberic Lunden also in good form. The second prize was awarded to Mr. G. H. Cooper, Sydenham Road Nursery, Croydon, who pressed very closely upon the first in every way; the best here were Mme. Lacroix, Mlle. J. M. Pigmy, St. Michael and the Rundle family.

The best new variety, to which allusion has already been made, was Mme. Thérèse Rey (Jap.). It is a pure white, with broad petals, beautifully reflexed, the centre having a faint pale yellow or lemon colour. This was shown by Mr. Shea, Foot's Cray, Kent, and was most deservedly awarded a first-class certificate. It is of medium size, and should form a good show flower. From the same source came another new variety named Miss Dorothy Shea (Jap.), with long drooping petals of a dark chestnut colour, the build of the flower somewhat loose, which in the eyes of many would be a charm rather than otherwise. Mr. Godfrey, of Exmouth, exhibited Beauty of Exmouth (Jap.), a beautiful white, with long petals curled and twisted, the flowers large and full, after Avalanche. To this a first-class certificate was also awarded. No other Chrysanthemum received any award save a very promising looking pompon (presumably a sport) named Florence Carr, in colour a deep bronzy red, of large size, fine substance, and a dwarf habit of growth. It stood out distinctly in a competitive class, being there staged by another exhibitor. A large group of cut flowers, consisting chiefly of decorative varieties (singles, Japanese, and reflexed predominating) with a few large blooms, was shown by Mr. Wells, Earlswood, Redhill. This was a good selection, illustrating the decorative value of the Chrysanthemum. Messrs. J. Laing and Sons staged a group of decorative stove and greenhouse plants and a few good Chrysanthemums; of the latter, Lord Brooke (Jap.) was one of the best, and of the former there were Dracena Doucetti, the new Strobilanthes, the best of the Bertolonias (viz., B. van Houttei, Mme. Auguste van Geert, Ed. Pynaert, and alba punctata), with Sonerila Mme. de Warelles (Mme. Wallers of catalogues?). Fuchsia triphylla, a pretty species, and a few good Orchids were included. Mr. Godfrey received a certificate for Carnation Mary (Free var.), with pure white fragrant flowers; and Messrs. W. Cutbush and Son showed Carnation Mrs. Leopold de Rothschild, a

very free deep rose-pink variety of dwarf growth, excellent for autumn and winter use.

A full prize list will be found in our advertisement columns.

NATIONAL CHRYSANTHEMUM SOCIETY.

NOVEMBER 7, 8, 9.

THE finest exhibition of recent years was held on Tuesday and two following days at the Royal Aquarium, Westminster, and those responsible for the management of the society must be congratulated. As a rule the flowers were of exceptional merit, the Japanese varieties in particular, and every class almost we think without exception was well filled, in some cases the competition being remarkably keen. We were pleased to see new departures from the present style of showing, and an exhibit not for competition from Mr. Jones, of Lewisham, consisted of bold bunches of blooms tastefully arranged in vases, showing the Chrysanthemum as a flower for cutting and decoration. The classes for such flowers as the singles and Anemone pompons were better represented than on any previous occasion, and the less ambitious exhibitors, such as in the metropolitan area, were present in force. It was not an exhibition of a few big classes, but a thoroughly good all-round display.

Cut Blooms.

These formed the chief feature, and it was interesting to see how the new kinds came to the front, such as Colonel E. Smith, J. Stanborough Dibbens and others we have mentioned in the report. In fact the whole complexion so to say of this class has changed within the past three or four years, and a more incurved type of bloom risen in the place of the older and, to us, more graceful flowers. They are now altogether more massive and solid. One great class represented a national competition of Chrysanthemum and Horticultural Societies, members of each society contributing blooms. St. Neots Society won the challenge trophy and £10 offered as the first prize, the flowers to consist of forty-eight blooms, twenty-four incurved and twenty-four Japanese, distinct. The blooms were contributed by one grower, Mr. R. Petfield, gardener to Mr. A. J. Thornhill, Didlington, Hunts. As we thought it would interest our readers, we give the names of the blooms, and of the Japanese very fine were, Mr. E. C. Clarke, Avalanche, C. H. Wheeler, Primrose League, Mrs. Briscoe Ironside, Vivand Morel, G. C. Schwabe, Sunflower, W. W. Coles, Mlle. Marie Hoste, Alberic Lunden, Eda Prass, a lovely flower, white, flushed with rose; C. Davis, Waban, rose, the petals curled; E. Molyneux, W. Tricker, J. Dyer, Pelican, W. H. Lincoln, Gloire de Rocher, Mrs. Hubbuck, Mrs. Harman Payne, Violet Rose, and Lord Brooke. The finest incurved were M. R. Bahuant, Empress of India, C. W. Whitnall, deep crimson-purple; Princess of Wales, Lord Wolesley, J. Lambert, Violet Tomlin, Mrs. Robinson King, Ami Hoste, Queen of England, Alfred Lyne, Novelty, Baron Hirsch, Jeanne d'Arc, Alfred Salter, J. Doughty, Mme. Darrier, Golden Empress, R. Petfield, Mrs. Heal, Prince Alfred, Brookleigh Gem, deep rose, tipped with white; and Miss Haggas. The Havant Chrysanthemum Society was second, the flowers contributed by Mr. J. Agate, Havant, and the Sittingbourne Association third. We may mention that, as a rule, the incurved blooms throughout the show were rather rough. They were scarcely fully expanded. The next two important classes were those in which the first prize in either case consisted of a Holmes Memorial challenge cup and £10. In one case it was for thirty-six incurved blooms, distinct, and the first award was gained by Mr. W. H. Lees, gardener to Mr. F. A. Bevan, Trent Park, New Barnet. His flowers were creditable, especially the Queen family, Mme. Darrier, M. R. Bahuant, Mrs. Robinson King, Chas. Gibson, Lord Eversley, Violet Tomlin, R. Cannell, and Mrs. Norman Davis; whilst the second prize went to Messrs. W. and G. Drover, Farcham, Havant, and the third to Messrs. W. Ray and Co., Mount Pleasant Nursery, Teign-

ham. The other class was for forty-eight Japanese, and a superb collection was staged by Mr. Herbert Fowler, Taunton, the competition being very strong. Especially fine were J. Stanborough Dibbens, Miss Annie Hartshorn, Sunflower, Etoile de Lyon, E. G. Hill, yellow; Miss Dorothy Shea, orange and yellow; Thos. Hewitt, white; Van der Heede, the florets fluted, reddish orange, light buff reverse; Raffello Marshaletta, a Comte de Germiny type of flower, broad florets, deep old gold colour, with inner face crimson; Mlle. Thérèse Rey, and G. C. Schwabe. These were a few of the newer kinds we made note of. A very good second was Mr. Chas. Cox, gardener to Mr. J. Trotter, Brickenden, Hertford. W. Seward, Mrs. J. Fogg, rich yellow, and Beauty of Exmouth were remarkably good. Mr. Chas. Gibson, gardener to Mr. J. Wormald, Morden Park, Surrey, and Messrs. W. and G. Drover were third and fourth respectively.

Four important classes besides those above mentioned were set apart for the incurved blooms. The largest was for twenty-four blooms distinct, and again Mr. W. H. Lees was the most successful. We need not mention names, as the leading kinds were represented. Mr. C. W. Knowles, gardener to Mrs. C. Egerton, Solna, Roehampton, was second, and Messrs. W. Ray and Co. third. A very successful exhibitor was Mr. W. Collins, gardener to Mr. J. W. Carlile, Ponsbourne Park, Hertford, who had the best incurved, especially fine being Mme. Darrier; Mr. A. Felgate, gardener to the Duchess of Wellington, Barbill, second, and Mr. B. Calvert, Bishop's Stortford, third. We greatly like the classes for six flowers of one kind. The best half dozen incurved blooms came from Mr. W. Collins, who had Mrs. Heal; Mr. J. Hewitt, gardener to Mr. H. B. Mackeson, Hillside, Hythe, second with Lord Alcester, and Mr. B. Calvert, third, with Violet Tomlin.

Another very important class was for twenty-four Japanese blooms; the first prize, a silver cup, value five guineas, and £4, the cup being given by Major A. Collis Browne, Broad Oaks, Byfleet. There were no fewer than sixteen exhibitors, and the winner of the premier award was Mr. W. Higgs, gardener to Mr. J. B. Hankey, Fetcham Park, Leatherhead. The flowers were superb, and we singled out as of remarkable merit Col. B. Smith, G. C. Schwabe, Beauty of Castle Hill, Falconer Jameson, Eda Prass, J. Stanborough Dibbens, and G. W. Childs; a capital second was Mr. W. H. Lees; Mr. H. Shoesmith, gardener to Mr. M. Hodgson, Shirley, Croydon, and Mr. W. Collins, third and fourth respectively. Twelve of the finest Japanese flowers we have seen for a long time were put up by Mr. W. Allan, gardener to Lord Suffield, Gunton Park, Norwich. Again the competition was tremendous; Mr. Felgate was a good second. In both cases the newer and larger-flowered kinds were shown. Several classes were for a smaller number. For six Japanese white, Mr. W. Collins was first, and also in the following class for six of any colour except white. He showed Edwin Molyneux. Mr. H. Shoesmith was second with Col. B. Smith, and Mr. Felgate third with the same variety, showing that it has got popular. Another class was for six Japanese incurved, the first prize going to Mr. W. H. Lees. As there is a little question as to this type we give the varieties, which comprised Col. B. Smith, W. Tricker, Mme. Carrière, E. Molyneux, W. H. Lincoln, and Mrs. Alpheus Hardy. An interesting class was for twelve Japanese blooms, distinct, put into commerce in this country in 1891 or 1892. The first prize was won by Mr. W. J. Godfrey, Exmouth, who showed Miss Dorothy Shea, Charles Blick, Duchess of Devonshire, Lizzie Cartledge, Aureole Virginale, broad white florets; John Farwell, deep crimson, buff reverse; Pearl Beauty, white; Van der Heede, Primrose League, white; Mrs. Harman Payne, Princess May, blush-white; and Lilian Russell, bright rose-purple. Mr. H. Shoesmith was second, showing amongst others Eda Prass, fine broad petals, blush-white, and the beautiful Mlle. Thérèse Rey. Mr. H. Fowler was third, Beauté Toulousaine, crimson, old gold reverse, being conspicuous in his collection.

The next group comprised the reflexed, pompons and other classes. We were pleased to see such a fine display. The large reflexed class was well represented, and the finest blooms were from Mr. F. J. Thorne, gardener to Major Joicey, Sunningdale Park. They included Cloth of Gold, the Christines, Cullingfordi, King of the Crimson, Phidias and Putney George; Mr. A. Sturt, gardener to Mr. Cohen, Englefield Green, second. It is not often one sees better blooms. The large-flowered Anemone class is one of the most difficult of all to get in perfection, but the flowers on this occasion were splendid. As usual, the first prize went to Mr. Ives, gardener to Mr. E. C. Jukes, Hadley Lodge, Barnet. We give a few of the best kinds, including Jeanne Marty, Mons. Pankoncke, Le Deuil, Mlle. Cabrol, Sabine, James Weston and Fabias de Maderanz, sometimes labelled Fabian de Medina. Mr. R. C. Noteutt, Broughton Road Nursery, Ipswich, was second. Besides the Japanese class there was one for the large Anemone, in which Mr. Ives was again the most successful with fine blooms of Delaware, Beauty of Eynsford, rose-purple; Gladys Spaulding, Grand Alvéole, rose; Lady Margaret, Acquisition, Mlle. M. Brun, very high centre; Mrs. Judge Benedict, Gluck and Annie Lowe, rich yellow centre, white outer florets. The delightful little Anemone pompons were well shown by Mr. Jas. Myers, gardener to the Earl of Sandwich, Hinchinbrooke, who was first for twelve, three flowers of each variety. Marquise de Croix, Mme. Montels and Astrea were conspicuous. Mr. Chas. Brown, gardener to Mr. R. Henty, Langley House, Abbott's Langley, was first for twelve pompons. The blooms were to be shown with foliage, and the usual kinds were exhibited. To us one of the most interesting classes in the show was that for twelve singles, the silver-gilt medal going to Mr. W. C. Pagram, gardener to Mr. A. F. Hobhouse, The Whin, Weybridge. The varieties were Jane and Yellow Jane, David Windsor, Admiral Sir T. Symonds, Mlle. Agate, Gus Harris, Lady Churchill, Rev. W. E. Renfrey, crimson; Scarlet Gem, Bessie Conway, white, tipped with rose-purple, and Mary Anderson.

It is impossible in the space at command to deal with every division fully, but we may briefly mention that the amateurs' classes were well filled, and the flowers of great merit. The same fine quality and freshness conspicuous in the other divisions were present here, particularly in the Japanese division. We noted as of great merit the flowers of Japanese varieties of Mr. Alfred Holmes, Gosport, and in the amateurs' division the blooms were exceptionally good. Twelve very fine Japanese flowers in the class for these came from Mr. J. Little, Romford, and six good incurved blooms from Mr. W. S. Pagram. In the division open only to those within the metropolitan area of the London County Council the flowers were excellent. The best twelve incurved were from Mr. F. Bingham, of Stoke Newington, and Mr. J. Bury, gardener to Mr. C. Bayer, Forest Hill, had the finest six, comprising Lord Alcester, Violet Tomlin, and Jeanne d'Arc of special merit. Mr. J. Brooks, Highgate, was first for twelve Japanese, and in the corresponding class for six, Mr. Bingham. The beauty and freshness of the flowers showed what a useful plant the Chrysanthemum is for culture in suburban gardens.

The table decorations were exhibited in the library, and were a feature of much interest. A very beautiful set of three vases most artistically filled with flowers and autumn foliage won Mr. J. R. Chard, of Stoke Newington, the first prize in this class; and the best table of bouquets, wreaths, &c., came from Messrs. Perkins and Sons, Coventry, who had many lovely things.

Several special prizes were of great interest. Mr. E. C. Jukes offered prizes for twelve incurved blooms to encourage the culture of the smaller and beautiful type such as Mrs. Rundle. Many kinds were therefore excluded. The premier award went to Mr. Robert Petfield, who had good flowers of Eve, Mabel Ward, Geo. Glenny, and Mrs. Shipman; Mr. W. H. Lees second. Another special prize class was for Mr. H. J. Jones' prizes for six blooms of seedling Chrysanthemums sent out

in 1893. Mr. W. J. Godfrey was first, he showing well Miss Dorothy Shea, Mrs. Harman Payne, Beauty of Exmouth, Van der Heede, Golden Wedding, red, silvery reverse, pleasing; and Pearl Beauty. Mr. W. H. Fowler was a good second. Mr. Owen, Maidenhead, also offered two prizes, one for twelve blooms of not less than four varieties of the six incurved kinds distributed by him in 1893, these being Baron Hirsch, Brookleigh Gem, George Cockburn, Henry Perkins, Lucy Kendall, and Mrs. Mitchell. Mr. J. Agate had the best flowers. Mr. W. J. Godfrey, Exmouth, Devon, offered prizes for six blooms of Beauty of Exmouth, the finest coming from Mr. C. Ritchings, gardener to Dr. Franklin, The Yews, Reigate Hill.

Plants.

Eight classes were set apart for plants, the majority of the usual trained specimen style. The finest group arranged for effect, and to consist of any varieties, came from Mr. H. J. Jones, Hither Green Nursery, Lewisham, the first prize, a silver-gilt medal and £10; whilst Mr. Norman Davis, Camberwell, was second. The best six trained specimens, large-flowered varieties, including Japanese, were from Mr. D. Donald, gardener to Mr. J. G. Barelay, Leyton. They were very fine, and the varieties Mme. B. Rendatler, White Christine, Margot, Dr. Sharpe, Gloriosum and Stanstead Surprise. Another well-known prize-winner, Mr. John Hughes, gardener to Mr. G. R. Higgins, Eastlands, Dulwich Village, was second. Four excellent trained specimens, any varieties, came from Mr. G. W. Hendon, Tottenham Park Gardens, Tottenham. Mr. W. Davey, gardener to Mr. C. C. Paine, Cedar House, Stamford Hill, was first for six, having amongst others the beautiful reflexed variety Elsie and a fine plant of Mme. B. Rendatler. Mr. J. Hughes had the best six trained pompons. From Mr. D. Donald came a splendid single pyramidal specimen of Margot, which won him the premier award in this class. Special prizes were offered by Mr. G. C. Paine for plants little trained, the abundance of bloom the chief consideration. Mr. F. Gilks, gardener to Mr. W. E. Frier, Walthamstow, was first. We are pleased to see that this class was not unrepresented. Mr. E. Vince, Highgate, was second.

Fruit and Vegetables.

The fruit staged was remarkable for its good even quality. Though there were only about a dozen classes, there was a strong competition. Grapes were remarkably good, those shown consisting chiefly of Alicante and Gros Colman. Vegetables maintained their high standard, there being no less than eight very fine lots for the special prizes awarded. Miscellaneous collections of fruit and vegetables from the leading growers were also staged in quantity. For six dishes of dessert Apples, Mr. T. Turton, Maiden Erleigh, Reading, was first with a very good even lot of highly coloured fruit, having very good dishes of Ribston Pippin, Cox's Orange, Adams' Pearmain, and Cackle Pippin. Mr. C. Ross, Welford Park, Newbury, was a close second with fine examples of Baumann's Reinette and Cox's Orange. For six dishes cooking Apples the same exhibitors took the awards in the order named, Mr. Turton's fruit being noticeable for high colour. Mr. Ross had fine Baldwins and Lane's Prince Albert. There was less competition for Pears, showing the effect of the season, the fruit keeping badly. Mr. W. Allan, Gunton Park, Norwich, was first with General Todtleben, Baurré Diel, Glou Morceau, Doyenné du Comice (very good), Durondeau, and Josephine de Malines. In the white Grape classes, any variety, there were only three competitors, Mr. C. Griffin, Kingston-on-Thames, being first with Muscat of Alexandria, the bunches of medium size and the berries well coloured; second, Mr. J. Bury, Tewkesbury House, Forest Hill, with larger bunches of the same variety, but a little past their best. In the class for three bunches of Alicante there were seven lots staged, and all of high quality; here Mr. Griffin secured the premier award with bunches grandly coloured, the berries large. Mr. Allan was second with larger bunches, but more irregular,

having larger shoulders. For three bunches of Gros Colman there were six lots staged, but some of the bunches were badly coloured. Mr. J. Bury was a good first with long tapering bunches nicely finished. There was no competition for the new Grapes Lady Hutt and Appley Towers; this was unfortunate, as these are really good varieties worth extended cultivation. Chasselas Napoleon was staged in nice condition by Messrs. Cutbush, Highgate.

There were eight competitors for Messrs. Sutton's prizes for a collection of vegetables (nine varieties). Mr. Pope, Highclere Castle Gardens, Newbury, secured the first prize, having very fine Sulham Pink Celery (best in show), Student Parsnip, Supreme Potato, Exhibition Sprouts, Ailsa Craig Onion, Prizetaker Leek (very fine), Intermediate Carrot, and Autumn Mammoth Cauliflower of splendid quality. Mr. Waite, Glenhurst Gardens, Esher, was only a point or two behind the first lot. His Carrots and Turnips were remarkable for their colour and symmetry. Some grand Duchess Peas were in this collection—the only lot staged. There were nine exhibitors in the class for twelve dishes of Potatoes, Mr. J. Simkins, Hitchin, being first with tubers of grand quality. In the class for six dishes, Mr. Simkins was again to the front, having perfect tubers. For Messrs. Fidler's prize for six varieties, Mr. Ridgwell was first. In the above collections such varieties as The Canon, Victory, Lord Tennyson, Snowdrop, Windsor Castle, Reading Giant, Satisfaction, Pink Perfection, Robust, Viceroy and The Dean were mostly staged. Messrs. Sutton, Reading, had some fine tubers in quantity of their new Supreme, a variety of great promise; also Abundance, Windsor Castle, Triumph and Satisfaction. Messrs. Cannell, Swanley, had a very large collection of vegetables, including over 100 dishes of Potatoes of the leading varieties. Messrs. Fidler, Reading, showed their Colossal Potato. Messrs. Cutbush, Highgate, sent a collection of Apples and Pears, including good dishes of Doyenné du Comice, Beurré Diel, Beurré Bachelier, Bergamote d'Espere, Chaumontel and Catillac Pears; good Warner's King, Royal Jubilee, Gloria Mundi, Ribston, King Pippin and Blenheim Apples and a new seedling Apple. Mr. Bewnick, Sidmouth, had 100 dishes of Apples and a few Pears of well-known kinds. Messrs. Laing, Forest Hill, had a large collection of Apples and Pears. Among the Apples were nice dishes of Sandringham, Lord Derby, Court of Wick, Fearu's Pippin, Royal Russet, Queen, Gloria Mundi, Lane's Prince Albert, Striped Beefing and others.

Miscellaneous.

The groups and collections not for competition were of much interest, but we can, unfortunately, only briefly refer to them. The flowers from Mr. H. J. Jones, so boldly arranged and comprising many of his best and newest kinds, were a leading feature. We hope others will follow this example. A large collection came from Messrs. H. Cannell and Sons, Swanley, comprising a noble series of the best Pelargoniums in bunches, Improved Raspail, a superb double crimson, and New Life, crimson and white, being of note, besides a series of new Chrysanthemums, seedlings and named kinds, which we shall again refer to. Mr. W. Wells, Earlswood, near Redhill, had a fine collection of Chrysanthemums; also Mr. J. Smith, St. Leonard's Road Nursery, Windsor, the Japanese variety Royal Windsor being of note, the flowers creamy white, with yellow centre, a very beautiful decorative variety. Mr. W. E. Boyce, Archway Road, Highgate, had a large selection, many of them most promising seedlings. Messrs. J. Laing and Sons, Forest Hill, also showed Chrysanthemums in variety, and Mr. Godfrey, flowers of Beauty of Exmouth, besides others. An interesting exhibit was that from Mr. R. Owen, comprising a number of fine English seedlings and such incurved sorts as Vice-president Jules Barigny, The Bride, white, and Robert Petfield, purple. Bride of Maidenhead seems likely to prove an acquisition. The flowers are of the Japanese class and pure white. Besides Chrysanthemums, Messrs. Cutbush and Son, of Highgate, and Messrs. E. D. Shuttleworth, Pockham Lane, had Crotons, Ericas and similar plants; in

both cases the groups exceptionally good. A bright effect was produced by the group consisting chiefly of Orchids from Messrs. B. S. Williams and Son, Upper Holloway.

The floral committee of this society held a meeting on the 8th inst., being the second day of the Aquarium show, instead of the first, as heretofore. Mr. R. Ballantine presided, and the meeting, which was fully attended, was one of the busiest in the history of the society. The percentage of high-class blooms was rather lower than on former meetings during this season, and the awards were consequently fewer than we expected, which shows the committee exercised a very judicious discrimination. The mid-November meeting is always a busy one, and more certificates are generally awarded than at any other, and of course it is only right and proper that a tight hand should be exercised when the quality is not forthcoming.

There were some very fair specimens shown which almost succeeded in obtaining a favourable award, and the voting in these cases were very close. The best of the unsuccessful flowers were Miss Sturgis, a large white Japanese with curly and fluted petals; Good Gracious, a curious tubulated petalled Japanese of light mauve colour; Mrs. H. J. Jones, a very long-petalled Japanese flower with rosy outer petals and deep golden ones towards the centre, all of which the committee asked to see again. A commendation was bestowed upon Florence Carr, a pretty compact pompon with deep orange-bronze blooms. Other good flowers submitted were Mrs. James Myers, a big white incurved Japanese; Mrs. Cox, a crimson sport from M. Bernard; Ernest Gaille, a charming soft yellow-buff Anemone, with a capital centre; Sautel (1893), a hairy incurved Japanese, purple inside, with pink reverse; Lady Saunders, a Japanese with long petals, very delicate shade of pale yellow; Bride of Maidenhead, a white Japanese, almost identical with Avalanche, and a few others.

First-class certificates were awarded to the following:—

GOLDEN WEDDING.—A clear golden yellow Japanese with incurving petals. Exhibited by Mr. Godfrey.

ELSIE NEVILL.—A pretty single-flowered Japanese, with long crimson florets. Raised and shown by Mr. W. Seward.

MRS. C. J. SALTER.—A small Anemone, self-coloured, rosy golden buff. Sent by Mr. W. Wells.

G. W. CHILDS.—The well-known bright crimson Japanese from America. Exhibited by Mr. H. J. Jones.

COL. CHASE.—A remarkably fine Japanese, with long, narrow and fluted florets, pale blush outside, centre shaded deep yellow. Raised and exhibited by Mr. E. Beckett.

ROSE WYNNE.—A large pale blush Japanese flower with massive florets. A seedling of Mr. Owen's, who also staged it.

W. W. ASTOR.—A large Japanese Anemone, long flat guard florets, tinted blush, high disc, golden rose. Also one of Mr. Owen's.

JOHN BUNYAN.—A wonderfully distinct yellow Japanese Anemone; the guard florets are very fine, and the build of the flower is perfect. From the same exhibitor as the two preceding.

There were two French exhibitors, M. Charles Baltet, of Troyes, whose blooms were hardly suitable when judged by an English standard, and M. Ernest Calvat, who sent a dozen very interesting novelties, four of which the committee requested to be sent again. Messrs. Cannell and Sons, Mr. Godfrey, Mr. H. J. Jones, and Mr. Owen also contributed some important collections.

A few miscellaneous exhibits, such as Apples, Carnations, &c., were also staged.

At the next meeting of the general committee on the 20th inst. Mr. Charles E. Shea will read a paper entitled "Judging Chrysanthemums."

Royal Horticultural Society.—The next fruit and floral meeting will be held in the Drill Hall, James Street, Victoria Street, West-

minster, on Tuesday, November 10th, when special prizes for Chrysanthemums will be offered. At 3 o'clock Mr. R. Parker, F.R.H.S., will deliver a lecture on "Chrysanthemums."

The Floral Sketch Book.—The council of the Royal Horticultural Society have granted special permission to Mr. John Weathers, assistant secretary, to publish his plant sketches. Mr. Weathers proposes to publish under the above title five large drawings each month of new, rare, or interesting plants. Each plant figured will be fully described, and historical and cultural notes will also be given. The first number will be ready by January 6, 1894, and the price will be 1s.

The weather in West Herts.—The past week proved cold and dry. On Saturday night the exposed thermometer showed 9°, on Sunday night 7°, on Monday night 8°, and on Tuesday night 9° of frost. The temperature of the ground at 2 feet deep has fallen 3°, and at 1 foot deep 7° since Saturday last.—E. M., *Berkhamsted*.

The Manning testimonial.—After a consultation with Mr. Manning, the disposal of the fund subscribed has been resolved on as follows: To present Mr. Manning with a dining-room suite and clock with ornaments to match, also an illuminated address. The final presentation will await Mr. Manning's return to London in the course of a few weeks.

Epilobium latifolium.—I have grown this plant for many years and it seems to do well. The position that suits it is a north border, prepared for Morello Cherries. I shall have much pleasure in supplying "E." with plants. It is, as described by your correspondent, a low-growing creeping plant, producing large flowers in proportion to the size of the plant.—WILLIAM INGRAM, *Belvoir Castle Gardens*.

Anthracite coal.—Will any of your readers who have used anthracite be kind enough to state their experience with it as a substitute for coke for heating hot-water apparatus? Also how it compares in price and heating powers.—G. H. B.

Names of plants.—*J. Taylor.*—1 and 2, Aster Nova-Angliae, red and purple forms; 3 and 5, apparently forms of Novi-Belgii, which are numerous; 4, longifolius formosus; 6, versicolor (dwarf var.); other good kinds are Amellus, acris, elegans, puniceus, pulcherrimus, versicolor (tall var.), paniculatus, tataricus, Novi-Belgii Robert Parker, N.-B. Arcturus, and N.-B. Purity, the best white.—*Ernest Clark.*—Bousingaultia baselloides.—*Eustace Clark.*—The Alonso is A. incisa; the Sedum is S. Ewersi; others next week. In sending plants for naming please affix numbers.—*W. Herrington.*—Dahlia glabrata.—*G. Thomson.*—1, Cattleya labiata; 2, Epidendrum stenopetalum.—*John.*—1, apparently one of the New Zealand Ti Trees (Dracaena species); 2, not recognised; 3, Polygala Dalmaisia; 4, past recognition; 5, Kalosanthes coccinea; 6, next week.

Names of fruit.—*Fellones.*—Not known, worthless.—*H. Todhunter.*—Jersey Gratioli.

"The Garden" Monthly Parts.—This journal is published in neatly bound Monthly Parts. In this form the coloured plates are best preserved, and it is most suitable for reference previous to the issue of the half-yearly volumes. Price 1s. 6d.; post free, 1s. 9d. Complete set of volumes of THE GARDEN from its commencement to end of 1892, forty-two vols., price, cloth, £30 12s.

"Gardening Illustrated" Monthly Parts.—This journal is published in neatly bound Monthly Parts, in which form it is most suitable for reference previous to the issue of the yearly volumes. Price 5d.; post free, 8d.

"Farm and Home" Monthly Parts.—This journal is published in neatly bound Monthly Parts, in which form it is most suitable for reference previous to the issue of the yearly volumes. Price 5d.; post free, 8d.

"Hardy Flowers."—Giving descriptions of upwards of thirteen hundred of the most ornamental species, with directions for their arrangement, culture, &c. Fifth and Popular Edition, 1s.; post free, 1s. 3d.

"The Garden Annual" for 1893.—Contains Alphabetical Lists of all Branches of the Horticultural Trade. The Lists of Gardens and Country Seats (containing over 9000) have been very carefully and extensively revised, and are admitted to be the most complete ever published. Price 1s.; by post, 1s. 6d.

All of our readers who are interested in the improvement of cottage homes are invited to help us to make Cottage Gardening known. It is published at the very lowest price to meet the wants of those for whom it is intended, and copies will be sent for distribution, free, by the publishers, Messrs. Cassel and Company, La Belle Sauvage, Ludgate Hill, B.C.

"This is an Art
Which does mend Nature: change it rather; but
THE ART ITSELF IS NATURE."—Shakespeare.

ORCHARD AND FRUIT GARDEN.

TREATMENT OF OVER-LADEN FRUIT TREES.

If the laudable practice of pruning orchard and fruit-garden trees were, even ever so little, followed out every year, they would not be exposed, as they have been this season, to the risk of bearing a burden beyond their strength and of being broken down by the weight of their crop of fruit, which, by the very fact of its superabundance, is rendered less attractive in appearance and inferior in quality. The trees feel the strain for a long time afterwards, and show that they do so by falling off in health and productiveness. However, for every disease there is a remedy, and for every effort a compensation. In the present case it is necessary to make up one's mind and act promptly. The treatment which I recommend comprises three points, viz., pruning, dressing, and feeding.

PRUNING.

In the month of September or October, before the leaves fall, prune severely, but with judgment, all the branches and shoots which have borne an excessive quantity of fruit.

The main branches should be shortened with a saw, the cut being then dressed with a knife and covered with grafting-wax or some similar preparation. The smaller branches, twigs, shoots, &c., can be pruned with the *sécateur*, a few snips of which will remove a tangle of branches here and there, while in other parts of the tree shoots are shortened back to a visible bud. None of these shoots should be cut back entirely unless this is absolutely necessary. It would be a wise precaution to tie up on the branches any shoots of the year's growth that may have been made, pruning the longest of them and leaving entire the shorter ones, which will be the first to start into growth.

The Apricot, the Plum, and the Pear are the fruit trees which most of all have produced the heaviest of these abnormal crops. The Cherry tree is an exception as regards the treatment advised, as, no matter how abundant a crop it may bear, the tree does not suffer severely from it. Two or three months' rest in autumn suffices to recuperate it before winter comes on.

The Apricot freely produces shoots on the old wood; but this is no reason for cutting back large, badly furnished branches too far, as the new shoots would be produced in an irregular manner, and would probably perish in their first season from gumming or scorching. A certain number of the larger branches should be cut back and the shoots on them shortened above a visible bud. There is hardly any district except the south of France where one can safely subject the Apricot, the Almond, and the Peach tree in the open air to any severer mode of pruning. I write especially of the tree in the open air, whether it be a tall standard, half-standard, or dwarf-trained subject.

The Plum tree should retain the greater number of its fruiting shoots, while its main

branches are reduced in length. It should be borne in mind that latent buds are of less frequent occurrence in fruit trees of this class. The Plum tree presents an advantage which we also find in the Pear tree and the Apple tree, namely, that of replacing, by grafting, any of the main branches that may have been broken off or mutilated by accident or otherwise. In the case of the Plum tree the mode of grafting which I recommend is cleft-grafting in autumn before the sap has gone to rest. An opportunity is thus afforded for substituting a new variety on the tree if a better kind of fruit is desired. Should this autumn grafting happen to fail, the operation may be repeated in the following spring, when either cleft-grafting or crown-grafting may be employed. The cutting away of the old branches of the tree should be postponed until the sap has commenced to rise, and it should be done by degrees in proportion as the growth of the scions increases.

Pippin-seeded fruit trees, such as Pear trees and Apple trees, should be pruned more severely and always in autumn, and care should be taken not to cut away any of the fruit-bearing wood. It is advisable to cut a very narrow notch in the bark just above a weak shoot or above an eye or bud lying dormant under a wrinkle in the bark. Instead of the notch above the bud I have succeeded by making a longitudinal incision below the cushion or swollen base of the bud, and this simple longitudinal incision is equally applicable in the case of weak shoots and fruit-spurs that have been exhausted by bearing a heavy crop.

DRESSING.

This consists in brushing and cleaning the over-ground parts of the trees. With a rough brush or a scraper clear away the Moss, Lichens, scales, and old bark which are hurtful to the trees and also serve as hiding-places for insects, and thoroughly clean out all the cavities, crevices, and scars. The stem and branches having been thus refreshed, a washing completes the operation. For this purpose a mixture is prepared consisting of lime-wash with the addition of some copperas (or sulphate of iron) and a small quantity of ochre or potter's clay, and applied to stem and branches with a brush or a soft pad.

In addition to the preceding operations, I recommend that the soil around the neck of the root of the tree should be removed for a distance of from 3 feet to 4½ feet from the tree, and to a greater depth as the distance from the tree increases, uncovering the main roots without cutting or bruising them.

FEEDING.

Fill up the space round the tree from which the soil has been removed with a compost of good soil, rich in vegetable matter, and which has been raked, or collected with a hoe, from the surface of the kitchen garden or the flower garden or under trees. If possible, add to it some fermentable materials, preferably such as are produced by making a heap of night-soil, river sand, dead leaves, rags, cleanings of ponds and of cattle sheds, animal or vegetable refuse broken or chopped up small; in fine, all the elements which may be wanting in the natural soil. Moreover, do not hesitate to water copiously with liquid manure.

This three-fold mode of treatment should be carried out without any great interval between its several divisions and before the end of winter. In the ensuing spring, as soon as the sap commences to flow, it will not be amiss if the soil around the trees is broken up, in order to expose it to the influence of the atmosphere,

and any trifling omissions in the pruning which may have come under notice should also then be rectified.

CHARLES BALTET.

Troyes.

APPLES FOR MARKET.

"W." (p. 317) gives valuable advice on this subject. I should like to add the names of a few other sorts that I have found useful for market. In the southern part of Hants, where there is a brisk demand for good Apples, Devonshire Quarrenden is the first sort ready for sale. In spite of the quantity obtained from old trees in the neighbourhood, the fruit readily fetches 7s. per bushel. It succeeds best as a standard, and where the soil is light it grows and bears uncommonly well. Although Irish Peach is so highly spoken of as an early dessert Apple in private gardens, it is almost useless as a market kind, as it lacks colour, is soft, and not suitable for travelling. Red Astrachan is a deserving kind, and should be planted largely where there is a demand for early fruit. Lady Sudeley cannot fail to sell well, the rich streaks of colour on the yellow base rendering it very attractive. Beauty of Bath can hardly fail to be a success; its taking appearance is sure to be a guarantee of a ready sale. Benoni should be planted largely; it comes into use just at a time when dessert varieties are scarce, the earliest kinds being past, and such as Worcester Pearmain, King of Pippins, and Blenheim Orange not ripe. The last-named finds a ready sale. Everyone seems to understand the quality of this old favourite. For giving a quick return, Blenheim Orange is not to be recommended perhaps, but these that can afford to wait a few years will reap a good reward, as when this sort becomes thoroughly established it seldom fails to give an annual crop. "W." does not mention Cox's Orange Pippin; with me this is the best market Apple, and the highest price is realised. It is a sure cropper on either the Crab stock, as a half-standard or as a free-growing bush worked on the seedling or free stock. Cocker Pippin is highly thought of in this neighbourhood, and no trouble is experienced in effecting a ready sale for all the good fruit of it. Baumann's Red Reinette promises to make a good market Apple; its rich rosy cheek is sure to sell it. Lady Henniker sells well; fruiterers like the firm character of the fruit in November; the tree is, however, rather a shy bearer. All the above belong to the dessert section. Amongst varieties of kitchen Apples Lord Grosvenor is by far the best early kind; in our strong soil it is far superior to Lord Suffield, and high prices can easily be had for good fruit in the early part of August. Warner's King is perhaps the best of all sorts here; not only is it a sure cropper, but the immense fruit that the trees annually produce sells readily. Golden Spire is another belonging to the Codlin type that is worthy of note. The fruit is large, the colour a rich golden yellow when ripe; the tree annually bears freely. New Hawthornden finds a ready sale and bears freely. Stirling Castle has but one fault that I know of: it bears so freely that its growth is impeded, otherwise it is one of the best. I, like "W.," am much in favour of Bramley's Seedling, the trees bear so freely in any form and when young; as a standard it ought to be largely planted where it is intended to crop the ground underneath. The natural habit of growth renders very little pruning necessary. I do not think that anyone need be afraid of planting Apple trees largely if he will select suitable kinds that will succeed in the soil, and attend well to them afterwards. Instead of planting many sorts plant many trees of a few kinds. E. M.

Grape Muscat Hamburg.—This magnificent Grape appears to be less grown every year, owing to its colouring badly, and its tendency to shank. That these failings may be overcome, I would suggest working the Muscat Hamburg on the Muscat of Alexandria, which has proved with me by far the best of all stocks for it. What the actual cause may be that makes Muscat of Alexan-

dria so good is somewhat difficult to state, but it influence is very striking, the bunches being very large, berries of extra size and beautifully finished, without any sign of shanking. So satisfactory has it been here, that I grafted another Muscat Hamburg this spring on the Muscat of Alexandria, and the graft has made a splendid cane about 15 feet long with short-jointed wood and plump buds that promise to produce a few good bunches next year. It is to be regretted that the more showy, but inferior flavoured Grapes are knocking old favourites out of time. I think it more than probable that the public taste will change before long and demand really well flavoured Grapes.—W.

Apple Mannington's Pearmain.—This is an Apple of great merit and one worthy of more extended culture. It is a handsome fruit, of fine flavour, and proves a worthy companion to Cox's Orange Pippin. It succeeds best on warm sandy loam, and then it proves to be an Apple that very few people would find fault with. There is one point that I wish to refer to particularly, and that is to allow the fruits to hang on the tree as long as possible before being gathered. The tree is not a strong grower and forms an excellent espalier.—A. Y.

VINE BORDERS.

I HAVE a viney border of which is only 8 feet wide and 2 feet deep, and above ground level. What treatment will it require with regard to watering and manure to grow Muscat Grapes? Soil not heavy. What heat is required? and for how long should it be continued?—BOSTON.

* * If "Boston" had been rather less brief in his letter of inquiry there would perhaps have been a greater certainty of my remarks being of some service to him. Without fuller information as to the description of material used in the construction of the border it is scarcely possible to state when and how manure should be applied. If the border has for two or more years been fully occupied by Vine roots, then either an autumn or early spring top-dressing should be given, this taking the place of the old soil carefully forked away till the roots are reached. This top-dressing may well consist of equal parts of roughly chopped up turfy loam and nearly or quite fresh horse droppings, to every two barrow-loads or three bushels of this being added one bushel of fine mortar rubbish, preferably that obtained when breaking up old walls, one bushel of "burn-bake," or a mixture of wood ashes, fine charcoal, and charred soil, the residue of a slow garden fire or "smother," and for which Vine roots have a great partiality, 30 lbs. or rather more of bone meal, and one peck of dry soot. This with a light summer mulching of farm-yard manure will support and serve to keep the roots active near the surface, a fair amount of fertility also being washed down into the border. During the summer soot applied occasionally at the rate of an 8-inch potful to every 24 square yards of border, and either washed in by rains or with the aid of a watering-pot will do good service, as also would the same quantity of good guano. There is quite a variety of advertised manures suitable for Vines, foremost among these being Thomson's, this also being well adapted for mixing with the top-dressings. Personally I have good faith in well-diluted drainings from mixed farm-yards, but these are not generally available. There should be no fixed times for watering Vine borders, whether they are inside or outside of the house. If allowed to become dry or, say, to reach a crumbling state when tested, the Vines have already suffered from the effects of this, and the border will not readily be re-moistened. On the other hand, when water is applied to an already moist border, this may result in saturation and souring of the soil—a condition most destructive to Vine roots. Water or liquid manure ought always to be applied whenever the soil is approaching dryness, a moderate amount of water then going a long way. Muscat Grapes are among the first to show the ill effects of either too much or too little moisture in the border. In the former case the foliage changes to a sickly

yellow colour, the berries set badly and fail to attain perfection, shanking being very prevalent, while dryness and poverty generally at the roots are responsible for much early shanking and premature shrivelling of the berries. During the average summer two or three waterings are all that are needed by most outside borders, but the summer of 1893 was exceptionally hot and dry, and very much more water had, of necessity, to be applied. If Muscats are started in February, they will not require very much more heat than Black Hamburg, Madresfield Court, Foster's Seedling and such like; but if they are started a month later, then the fire-heat may have to be turned on rather freely early during dull weather in August and September in order to have the bunches thoroughly ripe and well coloured by the end of the latter month. Temperatures usually recommended for Muscats are higher at times than they need be, and I prefer to keep to something like under rather than over the following figures: Commencing at 50° by night to 55° to 60°, another 5° being admissible with sun-heat, there should be a rise of 5° all round when the buds are bursting strongly. When in leaf the night temperature may be kept at about 60°, increasing to 65° in the daytime and from 70° to 75° with sun-heat. During the flowering period the heat should be kept at from 65° to 70° by night, 75° or rather less in the daytime and from 80° to 85° with sun-heat. After the berries are well set, lower the temperature about 5° all round, a slight gradual decrease being permissible, though not absolutely necessary up to the stoning period, or say for the next month, when the figures may well be dropped to and kept at 60° to 65° by night, 70° on dull days, and from 75° to 85° with sunshine and air. During the ripening period these figures ought still to be kept up, only much more air must be admitted, while early closing, with a view to "bottling up sunshine," must be discontinued. When fully ripe, Muscats will keep well in lower temperatures, or say from 45° to 50°, but the atmosphere must be perfectly dry.—W. I.

Apple Flanders Pippin.—The above-named excellent old Apple is plentifully distributed throughout old orchards in this district. At an agricultural meeting which I lately visited this variety was largely exhibited. Its very appearance stamps it as an excellent Apple. Its claim to extended culture does not depend upon appearance alone, as it is of fine quality, and the tree bears freely as a standard. In appearance Flanders Pippin is rather flat and angular, having several prominent ridges with a dull bronzy check.—A. YOUNG, *Abberley Hall*.

Flavour in Pears.—For the first time in my experience Marie Louise d'Ucle has been as melting and fine-grained as Marie Louise, but the flavour has been watery and insipid. Marie Louise d'Ucle is often referred to as being a hardy variety of Marie Louise. So it may be as far as outward appearance goes, but that is all. As a market Pear it sells well and is a profitable variety to plant, as it is a heavy cropper, the tree is a healthy grower and of very pleasing form either as a standard or bush. I could have sold any quantity of fruit this season at a good price. Flavour, as I have previously noted in THE GARDEN, in the case of some varieties depends largely on the time the fruits are gathered. With that hardy growing variety *Maréchal de la Cour* I had a pleasing experience this season, as it confirmed what I had previously expressed in an article on gathering Pears. I then stated that to bring out the quality of this variety it should be allowed to hang as long as possible before being gathered. To further prove this, I gathered several fruits earlier than I have generally done, and as they ripened up they were positively coarse and of poor flavour. The remainder were allowed to hang as long as possible, with the result that the flavour is very good. This is not by any means a Pear of the first quality, but it is passable. With regard to *Doyenné du Comice*, I quite agree with "W." (p. 400), that it will keep until the end of November if allowed to hang on the trees as long as possible—a course I have pre-

viously recommended. There is much to be learned yet as to the best time to gather Pears so as to bring out their good qualities. Almost every variety has its peculiarities.—Y. A. H.

Diseases in fruit trees.—Though much has been said and written on canker in Apple trees, and that the disease is caused by insects, nothing can convince me that the mischief originates in this way; on the other hand, I have seen the evil increased by the action of insects, and that the trees succumbed to the ravages of the almost invisible foes. Trees which extend their roots into cold, wet and unhealthy soil, and at the same time have the knife severely used on the gross wood, are not long before they show canker; some are very subject to the deadly disease. Among Apples none which I have seen are more liable to canker than Ribston Pippin, Cellini and Hawthornden. When planting trees (and many are engaged at such work just now) a good bottom of lime and brick rubbish should be placed a yard wide to prevent the roots from penetrating into bad subsoil. The practice is advantageous for large orchard trees as well as for dwarfs. Trees which I have been able to lift from unhealthy quarters and replant in healthy soil, and even old trees which I have cut bottom roots from, have been cured of canker. The wounds from the disease should be cleansed by an insecticide and filled with a mixture of clay and soot well mixed. Coatings of rank manure are precursors of canker.—STIRLING.

Fruit growing.—Though the finest Apples and Pears ever grown in the British Isles have been exhibited and taken to market during the past season, such is not a guarantee that fruit growing has made great progress. About three years ago I travelled over a great part of seven counties in England, and had opportunities of inspecting the condition of orchards, but really as far as I could see it appeared that improvement by the ordinary farmer was more nominal than real; even in Kent and Worcestershire there remains a great deal to be accomplished. Miles of orchards may be seen with trees choked with dead or dying branches, and in the hearts of the trees one might safely hide from a foe. In Wilts and Somerset there is not much change since my boyhood in the growing of fruit, many of the old orchards being almost impenetrable from the dense thickets of Apple and Pear branches. There is, however, a bright side to all this, but such is mostly with proprietors who have seen the folly of remaining in the old rut. In private gardens there is much enthusiasm in the culture of hardy fruit. In Scotland much progress is being made, but in many parts where there were large orchards no trace of them remains now. What we want now is a class of proprietors like Lord Beauchamp (Madresfield), who is doing splendid work in the advancement of fruit culture under the able management of Mr. Crump.—STIRLING.

GRAPES NOT KEEPING WELL.

I WAS very much interested in the remarks of "Vitis" on the above subject (page 408), and I venture to give my experience of the late Grapes here in regard to shrivelling, seeing it is almost in direct opposition to "Vitis's" experience. The late Grapes Mrs. Pince, Alicante, and Muscat of Alexandria were doing so well during the late hot summer, that I turned the heat entirely off them during July and August, and after that date only gave them enough to dispel damp. During the summer the borders never wanted for water either outside or in. About the last week in September I shortened all the laterals (to within two leaves of those that were carrying fruit, and a little closer on those which had no fruit) with the idea of giving more light and plumping up the buds for next season. Up to that time none of the Grapes had shown the least sign of shrivelling. I noticed in the course of a week or little more Mrs. Pince began to shrivel on the side next the sun, and it gradually wore round the bunch. The same thing happened with the Muscats, though in a less de-

gree, while the Alicantes were not affected at all. This shrivelling went on for about three weeks, and now it seems to have stopped. The Vines in question are young canes in vigorous health carrying a fairly heavy crop. The berries and bunches are large. The same thing happened last season, though a great deal worse, and I put it down to the bad season. I had come to the conclusion the primary cause had been the shortening of the laterals, giving such a check as to stop the flow of sap, hence the shrivelling, but since reading "Vitis's" article I am inclined to look elsewhere for the cause, though I have no doubt taking all the laterals off at once did check the Vines to a certain extent. The border the Vines are in both out and in is well drained and receives a thorough soaking every time it needs water. I am under the impression one reason of shrivelling is that the Grapes are not sufficiently ripened when the Vines begin to go to rest. As the days shorten the sap recedes from the bunch before it does from the laterals, though I have no doubt there are other causes, such as want of water, overcropping, &c. I am more inclined to put it down to want of ripeness in my case at all events, seeing my Alicantes are very little affected, and they were certainly riper than Mrs. Pince when I shortened the laterals. In conclusion, I should say, have late Grapes thoroughly ripe before the end of September, and there will be little trouble with shrivelling.

NORTHERN.

UTILISING WALL SPACE.

EVERY available method should be employed to check the immense importations of foreign fruit. As one means to this end, the wall space in gardens, on homesteads and farm buildings might be utilised and made not only more attractive and pleasing to the eye, but profitable also if covered with some of the many varieties of our best fruits, which are enhanced in value by this culture either in earliness, size or quality. There are few suburban villas or country houses which have not some walls, chimneys or low roofs that might be turned to good account in this way. It is true it is not the fashion, or considered the proper thing, to train fruit trees on the front of a house of any pretensions, though there are many varieties which in their different stages of blooming and fruiting might well compete in beauty with some of our ornamental creepers. But the cottager, to whom every shilling is of importance in enabling him to pay his rent, will have no scruples of this sort, and only needs more encouragement in the way of security for his outlay and industry to make many an improvement in this direction. This (the want of security) is the great drawback to enterprise in our country amongst those who live on the land, and this is consequently the chief reason why we pay so much for imported fruit which might just as well be grown at home. When every tree which a cottager or tenant plants in his garden or orchard is as much his own property as the table he places in his kitchen, we shall be more likely to see our land made the most of. Let other countries send us tropical fruits in unlimited quantities if they choose, but let us grow our own Apples, Pears, Plums, &c., so far as the season will permit.

Fruit trees may be purchased now at a reasonable price, and of kinds that soon come into bearing, so that instead of planting one tree to fill up its allotted space in fifteen or twenty years, a wall may be covered in a short time by planting alternately standard trees and dwarf-trained. Some kinds of fruits are sure to prove more profitable than others, and one great advantage in having variety and plenty of trees is that the least profitable can be pruned back and eventually cleared away to make room for

the more paying or superior sorts. One point of great importance is to select trees of the various fruits most suitable to the aspect and situation, and this can only be done by experience, as the soil and climate vary much in different parts of the country. At the same time there are certain rules which will hold good in most districts. On a southern aspect plant Peaches, Apricots, and Pears. The former should be trained, and will bear right down to the ground, and the latter standard-trained trees if the wall is high. The Jargonelle Pear is valuable coming in early under these conditions, while some of our choicest late kinds will not ripen and finish well without the aid of a south wall. Every foot of room on a warm wall is of value. I have cut this season from a Black Hamburgh Vine in the open, and planted six years, about 140 bunches of ripe Grapes. Some of the bunches weigh over 1 lb. each, and all the fruit, having been thinned, is of excellent quality. Although in former seasons the Grapes have not ripened so well, a successful crop would be generally secured by the aid of spare lights fixed over the Vine during the autumn months. Apricots and most kinds of Pears will also do well on a west aspect. An east wall will do also for Pears and May Duke Cherries, while the Morello Cherry and Victoria Plum, Black Currants and late Gooseberries should thrive against a north wall. If a large Pear tree is found to be unprofitable or cannot be brought into bearing, grafting with a more prolific variety may be desirable. But wall trees are frequently barren through injudicious pruning. Young wood should be trained in as much as possible.

Holmer, Hereford.

E. W. BEAVEN.

EARLY STRAWBERRIES.

MUCH difficulty is often experienced in producing satisfactory results from the earliest forced plants. Many reasons may be given for this, but the chief causes are improperly ripened crowns and too high a temperature at the commencement. To have anything approaching a full crop of fruit it is imperative that the plants intended for very early forcing should make their growth in time for them to have a rest before being subjected to artificial heat, as it is useless to attempt to get fruit from plants that have scarcely finished their growth when it is time to start them again. Suppose, for instance, that it is necessary to have ripe Strawberries in January or early in February, in order to have the fruit ripe at the required date the plants must be started early, and if growth has not been well matured previously, it is doubtful if they will bloom satisfactorily. The necessity for securing the earliest runners and getting them well established in their fruiting pots as soon as possible cannot be over-estimated, and as young plants produce the strongest and most forward runners, a piece of ground should be set aside each season for this purpose. There is seldom any difficulty in getting strong stolons that will make plants ready for the fruiting-pots by the middle of July. If these be potted and grown on without a check, the crowns will be thoroughly developed and ready for resting by the end of September, after which time water should be sparingly supplied to them. Sufficient only is needed to keep the crowns plump and the foliage from flagging. By November the plants will be quite at rest, especially if there have been a few degrees of frost to prevent the sap rising. Plants so matured will start more readily into growth when introduced into heat. If, however, there should have been no frost, but, on the contrary, mild weather and wet, it will be necessary to rest the plants artificially. The pots should be laid on their sides with the plants facing northwards, so that growth may be arrested through the soil in the pots becoming rather dry. Unless this is accomplished it

is seldom that the flower-spikes are perfectly formed, and this is one of the most prevalent causes of failure with the earliest batch. A too high temperature to begin with also prevents the full development of the flowers; hence the reason for their not setting. Shelves for Strawberries should be as near the glass as possible, for the greater the amount of light and air the plants receive the better the results. Fruit from the first lot is usually inferior both in quality and flavour on account of insufficient sunshine while ripening. Every effort should be made, therefore, to expose the fruit to all the sunshine possible. Watering, too, has much effect on the flavour of the fruit, as those who have given this subject particular attention are fully aware. Strawberries are moisture-loving plants, and on that account should never be allowed to become dry at the roots even for an hour, for if this happens, the largest fruit will be deficient in flavour. On the other hand, the plants must never become water-logged or the fruit will be insipid and watery. The house in which they are grown must never have a too dry atmosphere, or red spider will soon show itself, and if this once gets the mastery, it is difficult to eradicate. Of late I have used boxes instead of pots for all but the earliest lots, and I find that they answer the purpose much better, as they require less attention, the plants not being so liable to get dry, there being more earth for them to root into. The boxes I prefer are 2 feet long, 6 inches wide and the same in depth. They are made with rough boards about five-eighths of an inch in thickness. Holes are made in the bottom for drainage, and these are covered with broken crocks to the depth of about 1 inch. Four plants are placed in each as soon as they are sufficiently rooted in summer, and they grow away rapidly. Root-action is very quick, so that the plants soon get established. Where water is scarce, as was the case last summer, much labour is saved in watering by employing boxes. There is also another advantage in using boxes, especially where pots are made of a poor quality of clay, as a great number of the latter get split by the first frost in autumn. This necessitates fresh ones being used before the plants are put in to force. During the bright sunshine towards the latter end of March, plants in pots are liable to suffer unless they get constant attention, so that anything that tends to lessen the work of watering is a great boon. Nothing has yet been said of varieties; each cultivator must decide this for himself, for those that are suitable to one place will not prove so in another. Take Black Prince as an example. Where fruit has to be packed to travel a considerable distance this variety is but of little use on account of its size, but for home consumption it comes in very well. Some people, too, are fond of it. President is a good Strawberry for forcing, and being firm in flesh travels well. Its size, too, is all that could be desired. Vicomtesse Héricart de Thury is very prolific, but the fruit is rather small. Auguste Nicaise is a good one for second early lots, the fruit being large and of good colour. Keens' Seedling, though an old variety, is still a very good one for early work. The fruit, however, is soft and does not travel well. La Grosse Sucrée is one of the best all-round varieties for forcing; the fruit is large and well flavoured, and also travels well. Sir Joseph Paxton also forces well, but the fruit travels badly, and for those who have to pack, such things must be considered. H. C. P.

Notes on Pears.—A comparison of notes for the purpose of securing a short list of the best November and December Pears fully bears out the fact already recorded by several correspondents that they are this year not easily found, and that in any case the selection would be difficult to make, only a few late varieties being of such uniform excellence as to be good alike from all or nearly all soils. In common with the experience on page 408, I have Vicar of Winkfield this year fairly good. It is at any rate very acceptable in the absence of better sorts. Beurré Diel, too, is ripening up fairly well this year. What is the general ver-

dict respecting Princess? Conflicting reports are to hand, the one that it is a valuable Pear of good flavour, the other that it is useless except for stewing. Three fairly late varieties, concerning which a generally favourable opinion seems to be given, are Nouvelle Fulvie, Marie Benoist, and Triomphe de Jodoigne. The last does well as a horizontally trained tree, and from the manner of its growth ought to make a satisfactory cordon. Zephirin Grégoire might also, I think, be included in the list; it is free, and by no means a bad quality Pear. Unless one could obtain in his immediate neighbourhood and from a similar soil favourable verdicts respecting Beurré Rance and Easter Beurré it would be risky to plant them; from some soils they are practically worthless. If, therefore, to the four sorts above-named are added Glou Morceau, Thompson's, Beurré Sterckmans, and Winter Nelis, I think one would get eight of the best winter Pears for cordon treatment. Winter Nelis is not quite so satisfactory as a cordon as one would wish if confined to a single stem, but by planting a little wider apart and running up two or three leaders, better growth and a greater average of fruit are undoubtedly obtained.—E. BURRELL, *Claremont*.

NOTES OF THE WEEK.

The Liquidambar has been one of the finest trees for colour this autumn. It is worth planting for its splendid colour in October alone and makes a brilliant picture.

Cattleya Bowringiana.—We have in flower here a plant of this *Cattleya*, the spike carrying fifteen flowers, which seems to be unusual, and may therefore be of interest. It is a plant with two growths, bought some three years ago.—J. W. M., *The Gardens, Morland*.

Pelargonium Double New Life.—This is a double variety now in bloom in the nursery of Mr. Cannell at Swanley. It is a sport from Wonderful, also a sport from Vesuvius. There is a single counterpart of Double New Life. The flowers of the latter are quite double, borne freely in neat, medium trusses, and the colours are bright scarlet and pure white, a novel and not unattractive combination.

Cytisus filipes.—This is a very beautiful autumn-flowering plant. It comes from the Canary Islands, and will succeed well in a greenhouse, giving in spring again another welcome display of its snow-white flowers. It is very distinct, quite different to *C. racemosus*, the growth being tall and the foliage sparse. The pendent branches are, however, wreathed with numerous white flowers, and when in association with dark green-foliaged plants are delightful.

Chrysanthemums in Ravenscourt Park.—We are pleased to see that in this, one of the newer open spaces near London, there is a small display of Chrysanthemums in the conservatory adjoining the free library situated in the park. The structure is filled with excellent plants, and another year, perhaps, a better house will be provided, not a costly and useless affair, but a house in which it is possible to make good groups for effect. The more elaborate structures are not always the best.

Staging Chrysanthemum flowers.—We noticed at the meeting of the R.H.S. on Tuesday that Chrysanthemum flowers were exhibited in a far more pleasing way than is usually the case. They were set off with Fern and other suitable foliage, the blooms, too, being cut with long stalks, so as to get some of the natural leafage as a foil. We want more of this style of showing flowers at the regular Chrysanthemum exhibitions, and there are signs of improvement in this respect.

Angræcum sesquipedale is flowering freely in the nursery of Mr. Morse. Several plants are in full bloom and have a quaint appearance. The flowers

are too well known to need any description, but it is noticeable that they are amongst the first to succumb to fogs, buds and fully expanded blooms suffering. We have seen a splendid display and a fine promise of flowers utterly ruined by one day's fog. Those situated near large smoky towns should not grow it, as it blooms in the months of fogs—November, December and January.

Yucca gloriosa variegata.—The leaves of this are boldly and handsomely marked with glaucous green and pale gold colour. We noticed several specimens in Mr. Morse's Epsom nursery recently, and they stood out well at this season when the foliage of deciduous trees has fallen. A good group of it on the outskirts of the lawn would make a noble feature, and there can be no question as to its hardiness, the plants having been in the open for the past ten years. It is very ornamental also in pots and might be used in many forms of decoration. Many variegated things are objectionable, but not this.

Cattleya luteola.—This is one of the most interesting Orchids in bloom at Epsom at the present time. It is the smallest of the *Cattleyas*, somewhat rare, and not very easy to grow. The plants at Epsom are growing in a shallow pan suspended near the glass in the warmest house and are blooming very freely. The pseudo-bulbs bear a single leaf, and the flowers are produced at the apex of a short peduncle, being individually of neat, pleasing shape. The sepals and petals are of a pale yellowish buff colour, the lip three-lobed, orange-yellow in the centre, and the margin wavy. It comes from Peru, and also the districts of the Upper Amazon.

Cypripediums at Epsom.—An interesting collection of *Cypripediums* is grown in the nursery of Mr. Morse at Epsom. When there a few days ago we made note of several kinds, as *C. Barteti*, a hybrid between *C. insigne* Chantini and *C. barbatum*; *C. politum*, the best of all the *C. venustum* hybrids; *C. Leeannum superbum*, *C. calurum*, *C. Sedeni* and *C. oenanthum superbum*, which last, we think, is the most beautiful of all the *Lady's Slippers*, the flowers finely coloured and having quite a polished aspect. *C. insigne* was flowering freely, and there are few more useful Orchids than this. We also noticed good masses of the rarer kinds, as *C. Chamberlainianum* and *C. Rothschildianum*.

Campanula muralis (Bavarian variety).—I am hardly disposed to agree with Mr. Wood in considering the greater vigour of this an improvement upon the typical form. Undoubtedly the larger and brighter flowers are desirable, but I have always considered that one of the greatest charms of *muralis* is its dwarf habit. By the way, in how many gardens is *C. muralis* to be found true to name? Very frequently it is catalogued as synonymous with *C. Portenschlagiana*, and although in a few nurseries the true *C. muralis* is procurable, in most cases *C. Portenschlagiana* is sent. Like the latter, *C. muralis* is an admirable wall plant, and this year I saw it growing beautifully in the mortar between the bricks of the outer wall of a greenhouse. Here it is still in flower (Nov. 14).—S. ARNOTT, *Rosedene, Carsethorn, Dumfries, N.B.*

Late Roses.—To-day (Nov. 13) I have cut some really good blooms of Hybrid Perpetuals from the open air. Chief among these were A. K. Williams, Mrs. John Laing and General Jacqueminot. Many Teas are also in flower, Rubens, W. A. Richardson, Kaiserin Friedrich and Safrano being particularly good. This morning we registered 9° of frost in the lowest part of our grounds and 5° on the hill. To cut a good handful of Rose blooms in the middle of November is a pleasure not often experienced, and I quite expect to do so almost daily for some three weeks longer unless exceptionally severe weather sets in. Plants upon the seedling Brier continue to grow late, and if naturally late-growing kinds are placed upon this stock in a sheltered nook, we often get blooms from them when well into winter. A high situation with slight shelter will afford many acceptable surprises both

in early and late Roses. I have recently seen a batch of *Gloire de Dijon* which was carrying a grand crop of buds, and as the plants are in a sheltered spot, I have no doubt the majority of the buds will open. Stanwell Perpetual and rugosa are still fairly well in bloom in a neighbour's garden.—A. P., *Uckfield*.

A fine hybrid *Cypripedium* exhibited by Mr. T. Statter on Tuesday at the Drill Hall is worthy of a note. It is named *C. southgatense superbum*, and is a hybrid between *C. bellatulum* and *C. Harrisianum*. The plant is dwarf and the flower-stem sturdy, but the chief point of interest is the splendid markings on sepals and petals. The dorsal sepal is broad, of fine substance, and crimson, with deep chocolate longitudinal stripes, whilst the petals are crimson also, thickly spotted with a chocolate tone, the lip being of a crimson shade, except at the apex, where it is of a whitish colour. One gets in this hybrid a combination of both parents, the massiveness of *C. Harrisianum* and the fine spotting of *C. bellatulum*, with a sturdy dwarf habit.

Greenhouse Rhododendrons in small pots.—Allow me to say a few words as to "G. H.'s" advice to plant *Rhododendrons* in small pots. *Rhododendrons*, especially large growing species like *Nuttalli*, should always be planted out during summer in order to encourage growth, as these tree-like plants very rarely flower before they have reached a certain age. What is a plant with one or two trusses compared with a small tree showing forty or fifty trusses? Under "G. H.'s" system of culture it would take a lifetime to produce such a plant, but by planting out and careful management you could possess a small tree covered with flower-buds in about fifteen years. The late Mr. Mangles declared several times his accordance with my system, and my own experience tells me that I am right.—O. FORSTER, *Lehenhof*.

Notes from Harrow Weald.—Two corrections I must make for last week's GARDEN:—

CALCEOLARIA KELLYANA (p. 430).—This should be *C. chelidonioides*, a very pretty Peruvian annual introduced in 1852. I only wish that I had *C. Kellyana*. It is a lovely little gem, but in moving my garden from Eastcote I most unfortunately lost it, and shall be only too glad if you can tell me where to get a fresh stock.

THE FLAME NASTURTIUM (page 437).—The roots should be cut up into 1-inch lengths and planted in boxes in the autumn (about this time), and moved to where they are wanted just after they have begun to grow. If these directions are attended to it will be found a very easy plant to manage. It likes damp and shade for the roots, but sun and full exposure for the top-growth; therefore it should be planted to grow through shrubs or on the shady side of a hedge, when the growth will be soon drawn through to the sun.—A. K.

Dendrobium Mirbelianum.—Although this *Dendrobium* was discovered and described over sixty years ago, it is only about three years since it was first introduced to Europe. It is a native of New Guinea, and was sent home by one of Messrs. Linden's (*L'Horticulture Internationale*) collectors. A specimen of it is in flower now at Kew which shows the species to be one of distinct character, and although it cannot be said to possess any striking attraction in colour, it possesses a certain quiet beauty; the fact, too, of its being in bloom at this season and of lasting several weeks in perfect condition gives it a value which it would not possess were it to flower in April and May. Its stems are 1½ feet to 2 feet high, with stout elliptical leaves, the erect racemes carrying about a dozen flowers. They are 2 inches across, with narrow, pointed sepals and petals, the latter larger, but both of a greenish yellow colour marked with green lines. The lip is also greenish yellow, almost white in the centre, and streaked with brown lines. Like many of the Australasian *Dendrobiums*, this appears to possess the quality of continuing year after year to produce flowers on the old stems.

KITLEY.

COUNTRY residences with picturesque surroundings are perhaps more frequent in Devonshire than in any other part of England. But even in this favoured county a more charming situation could scarcely be found than that of Kitley, forming the subject of the accompanying engraving. This beautiful mansion is close to the village of Yealmpton, seven miles south-east from Plymouth and five miles from Plympton. The large sheet of water shown in the illustration is a portion of the estuary of the river Yealm, whose banks are flanked by delightful woods broken here and there by hilly pastures or by bold masses of natural rock. The carriage drives, both from Plymouth and from Yealmpton, are of considerable length, winding through

CHRYSANTHEMUMS.

NOTES FROM SYON HOUSE.

ONE of the finest private displays of Chrysanthemums we have seen this year is at Syon House, Brentford, where Mr. Wythes has filled no less than eight large houses, representing nearly 2000 plants. It is a pleasure to walk through this mass of bloom, as the Chrysanthemums here are not all grown in the exhibition style, but some are leafy bushes smothered with flowers, each shoot bearing six or more charming sprays, far more interesting and beautiful than big specimens. All styles of culture are represented, but the bush plants please most for their elegance and freedom. One house is entirely devoted to that fine late

cutting, and one house is filled with examples solely for this purpose, having been lifted from the open and bedded out thickly.

Besides the popular kinds, the collection comprises all the more recent varieties, grown in a way to get the blooms of true character. Everywhere this season we have noticed especially the beauty of that fine Japanese kind Col. W. B. Smith. The colour is a clear golden bronze, a very distinct shade, with broad petals. It was raised by Mr. H. Cannell, of Swanley, and is an acquisition. Grown with little stopping it would be valuable simply for its fine colour. Alberic Lunden, deep crimson-purple, is a beautiful variety, and also worth note were the following: Etoile de Lyon is largely grown and it exhibits the sportive character as seen elsewhere. We think this is against it and only really care for it on late buds,

Kitley, near Plymouth. Engraved for THE GARDEN from a photograph by Mr. Hayman, Launceston.

an extensive park. Among the many handsome trees passed on the way I noticed in particular some very fine specimens of Planes. The mansion is a very fine example of architecture in the Elizabethan style, and is built entirely of limestone. The main entrance is on the north side of the building. On the east side is a square lawn, forming two tennis courts, and divided through the centre by a broad gravel walk. From the dining-room windows, which overlook this part, a fine view is obtained of the undulating landscape beyond. But perhaps the best view of all is from the south side of the house, where the windows command a broad expanse of river scenery. Here also is a fine terrace garden terminated by a wall forming a sunk fence, and beyond that a gently sloping pasture extending to the river's edge.

Exeter.

F. W. MEYER.

white Japanese variety Duchess of Northumberland, the bushes, for we can call them nothing else, being clothed with leafage to the top of the pots, and every shoot bristling with flower-buds. This is one of the last to bloom naturally, and it would be well if one saw less of growing merely for show. One can scarcely, however, call these naturally grown Chrysanthemums, as the growth is stopped early, and sometimes later in the season, but nothing more than this is done. A good article appeared on naturally grown Chrysanthemums in THE GARDEN, October 28, 1893, and the practice there given agrees with that of Mr. Wythes'. We made note of a few of the best varieties for this purpose at Syon House—Eynsford White, Maiden's Blush, Elaine, Avalanche, Val d'Audorre, Etoile de Lyon, that splendid incurved Mr. Bunn, Mlle. Lacroix, and Mme. C. Audignier. Maiden's Blush was exquisite, the shoots bearing a profusion of flowers, white, touched with lilac. Such plants as these, of course, give a large quantity of bloom for

when the flowers show their true rich rose-lilac shade. Sunflower is a glorious variety for colour, a deep golden yellow, and Mrs. Harman Payne is a welcome addition. This has broad petals of a rose-pink shade with silvery reverse. One often overlooks the fine old kinds beautiful for their colour for the novelties, merely because they are new. Mme. C. Audignier, for instance, here is charming, its flowers a lovely light lilac, and largely grown also is the well-known Wm. Holmes. A good kind is Mons. Freeman, the flowers white and rose and the habit of the plant dwarf. Amongst the newer Japanese we may also mention Kate Spaulding, which has light rose-purple flowers; Sarah Owen, bronze, touched with rose, the petals tipped gold; Lord Brooke, a lovely bronze colour and very dwarf in habit, and Mr. A. H. Neve, a silvery pale rose shade, the florets drooping. W. W. Coles is a good kind for colour, the flower of a reddish shade with old gold reverse, and a beautiful variety is Mlle. Marie Hoste, the flower of a creamy white

shade with drooping florets. Still one of the best in its line of colour is F. A. Davis, the flowers deep crimson, reminding one of the race typified in such recent acquisitions as William Seward. A useful variety is Puritan, which is of a peach tint and very pleasing. Of course, this is by no means all the Japanese varieties grown here, but sufficient have been mentioned to indicate the richness of the collection.

Other classes are grown in proportion, and in the reflexed class one of the brightest kinds was Chevalier Dommage, which has golden yellow flowers, while a large collection of incurved varieties is represented. Lord Wolseley, Jeanne d'Arc, Alfred Salter, the new M. B. Bahuant, Queen of England and Empress of India were in particular remarkably fine.

Very charming, however, are the bush plants, and, as we have so often mentioned in THE GARDEN, this is the true and only way to see the Chrysanthemum in characteristic beauty.

CHRYSANTHEMUMS AT CHELSEA.

THE display of Chrysanthemums in the nursery of Messrs. J. Veitch and Sons is remarkably fine, better than for many years. Some of the flowers were of especial merit, and every new variety is in perfection. The collection fills a large house, and in the corridor many are in full beauty, creating a gay show of varied colour.

The finest varieties are those mentioned, and one of the more important amongst the Japanese was Beauty of Exmouth, a pure white flower, full, massive, and of high exhibition merit. We were a little inclined to think that it would not prove sufficiently solid for the shows, but that impression was removed by seeing Messrs. Veitch's specimens. G. C. Schwabe was in excellent character, the flowers large, salmon-rose in colour, and distinct. This will become a leading variety. Everywhere that fine kind Col. W. B. Smith is worthy of note, and it is so especially in this collection. The flowers are superb for colour and size, a clear bronze-yellow, full, broad, and in every way satisfactory. It appears to be very free, not too tall, and an exceptionally strong grower. Very different to this is Eugène Gait, a full, rosy purple flower somewhat in the style of Avalanche, and of medium size. President Borrel, deep rose-purple, gold reverse, the pure white Bouquet des Dames, W. H. Lincoln, and Vivand Morel were splendid, flowers of the last-mentioned variety measuring over a foot across. A variety that will be much grown is Mrs. Harman Payne, the flowers of which are rose-purple, with a silvery reverse to the petals. W. B. Woodcock we noticed very good, the flowers of the Japanese reflexed style and brick-red in colour, the florets tipped with gold, and broad. The splendid varieties William Seward and John Shrimpton were conspicuous, but we think these have a strong rival in G. W. Childs, a seedling possibly from Edwin Molyneux. It is a fine crimson-purple colour, very rich, and of bold form. Near by was Mlle. Thérèse Rey, which we have already written of in THE GARDEN. It is creamy white and the florets are broad. We have not seen the variety Hamlet better than here, and it is a very pleasing colour, cerise-salmon with a suffusion of gold. Sunflower, the white Louis Boehmer, and Excelsior, which is a great acquisition, were bearing fine blooms. M. Henry Jacotot, a Japanese reflexed kind, is conspicuous for its beautiful colour, crimson suffused with gold, the florets a little twisted and drooping. A massive flower is Viscountess Hambleton, the florets broad, incurving near the apex, and bluish white, shading to a deeper tone at the base. Lord Brooke, bronzy yellow, and J. Stanborough Dibbens, an English seedling, are varieties of commendable growth. The flower of the latter is bronzy yellow shaded with rose. One of the finest introductions of recent years is unquestionably Miss Anna Hartsorn, which from early buds produces fine white flowers, while those from later kinds are bluish, a very pleasing shade. Robert Owen, one of the good things given us by Mr. Owen, of Maidenhead

has a large deep bloom, the colour of which is light bronze-yellow.

The incurved collection contains all the best kinds, and we noticed amongst them Mrs. Robinson King, a sport from Golden Empress of India, but deeper in colour than that variety. Baron Hirsch, the rose-violet Mme. Frederic Mistral, and M. R. Bahuant are of note, but when we write all the novelties are included, no good purpose is served by making a list of names.

In the collection also the so-called decorative kinds are grown well, and are to us more pleasing than the typical show kinds. For amateurs and others who cannot or do not wish to cultivate the show varieties, this class is of great value. Such kinds as the yellow Mlle. Lacroix or Charles E. Shea are exquisite for colour and very free. O. J. Quintus, a lovely mauve-pink, is a gem, and the plants are smothered with bloom. Comtesse Foucher de Careil, a bright orange-coloured Japanese kind, is one of the most beautiful of this class. The plant is dwarf and very free, and Comet is worthy of note, the flowers chestnut-orange.

It is evidence of the usefulness of the Chrysanthemum in smoky suburbs when such very fine plants are grown at Chelsea. The flowers perhaps do not last so long as those in the purer country air, but they are true and bright in colour.

Chrysanthemum Charles Davis.—This sport from Vivand Morel, which in the spring was at times spoken of as a golden-flowered form, is, at least in most cases, a kind of rosy bronze, though occasionally individual blooms may be met with in which the yellow tint predominates. In any case it is a good and distinct Chrysanthemum, which we shall doubtless see grown for some years, as in habit of growth it is a counterpart of the universally popular Vivand Morel. Among the numerous flowers of this last shown at the Aquarium show its variable character was very noticeable, for I observed several blooms which in the dim light appeared to be pure white (at all events they were almost so), while others were to be seen in which the flowers were of a much deeper tint than usual. There is certainly a greater difference between some forms of Vivand Morel than there is between many varieties that bear distinct names.—T.

Staging pompon Chrysanthemums.—The plan of putting these up in a given number of varieties of three blooms of each is an excellent one; some exhibitors, however, I have noted when competing in such a class seem, as it were, bound down too much to uniformity of height. At a recent show I noted that this was the case in a singular degree. In one exhibit each flower as well as each row scarcely varied in any perceptible degree; this made the entire stand look far too formal. Quite in contrast thereto was another exhibit in the same class; these were slightly varied in each case, thus adding greatly to the general effect. This latter stand of flowers won the first prize, and I must candidly confess I was glad to see it so, irrespective of the quality one with the other. I should not be at all surprised if the judges were not, although unconsciously perhaps, drawn to the more informal exhibit, as each flower was seen to better advantage. Those who exhibit should take note of these matters (trifling perhaps), and use them to their own advantage another time.—G.

Cut blooms with long stems.—At the recent Brixton, Streatham, and Clapham show there was a keen competition for the special prizes offered for twelve Japanese varieties "to be exhibited as grown, stems not less than 15 inches in length, to be staged in glasses or bottles not exceeding 9 inches in height." This proved to be a most attractive class, the winning exhibits more particularly containing some very fine flowers equal to, if not better than those shown in the usual way on boards. In nearly every case the foliage was in the best possible condition, thus adding greatly to the effect. The varieties shown in the first prize exhibit by Mr. Howe, Park Hill Gardens, Streatham, were Mme. Laing, Mlle. Marie Hoste (extra

fine), Vivand Morel, Edwin Molyneux, Col. Smith, Florence Davis, Sunflower, W. Tricker, W. H. Lincoln, Etoile de Lyon, Primrose League, and Lord Brooke. These were all shown in the best possible condition, looking all the better for the greater length of stem with the foliage attached thereto. To make such an exhibit look well there should be, as in this case, gradations in height, 6 inches being none too much for the back row of three. Hyacinth glasses of the old erect shape are well suited for this mode of staging; these as regards colour should be green, whilst if any support be needed, the slender wires, as used for Hyacinths, would be sufficient in any case. This plan of staging is not, I know, a new one, it having been adopted by other societies with good results some few years back, but, nevertheless, it is worthy of greater extension than it has hitherto received.—H. G.

ARRANGING CUT BLOOMS OF CHRYSANTHEMUMS.

AT most Chrysanthemum exhibitions prizes are offered for bouquets, vases furnished with flowers and for table decorations, to be composed principally of Chrysanthemum blooms. A visit to a few of the larger shows reveals the fact that in many cases the great mistake of overcrowding is most noticeable, while another very common fault is that of associating with the blooms of the Chrysanthemums either foliage or other flowers that are totally out of place. Croton leaves seem to be especial favourites for this purpose, and what is often regarded as a bouquet is a dense mass of the bright coloured leaves of these stove plants and Chrysanthemum flowers all wedged tightly together. While examples of this style were to be seen at the recent Aquarium show, there were on the other hand many arranged very differently, but it was left for Mr. Jones, of Lewisham, to show the grand effect produced by the very largest flowers disposed in a simple manner. The blooms in this case were cut with long stems, which were furnished with their own leaves and nothing more. One large and very striking vase was filled with nine grand blooms of Vivand Morel, showing a good deal of variation in tint as that variety does. Nothing, however, could be simpler or finer than the effect produced by these few loosely disposed flowers which could be arranged in a few minutes; whereas some of the crowded masses must have taken a long time. A dozen or so of fine incurved blooms were particularly noticeable in another vase, presenting as they did in their prim and formal shape a marked contrast to the preceding. The peculiar rosy bronze coloured sport from Vivand Morel, known as Charles Davis, associated with the pure white Florence Davis, also formed a pretty combination, while a large vase of the hirsute section, comprising W. A. Manda, yellow, Louis Boehmer, pink, and the White Louis Boehmer, also known as *Enfant des Deux Mondes*, was very interesting. The simple manner in which the flowers were arranged in these vases was infinitely more pleasing than the laboured overcrowding to be seen in another part of the building, where in some cases the object seemed to be to cram as many flowers as possible into a given space. With regard to Chrysanthemum blooms displayed in this manner, one fact that particularly strikes an onlooker is that in making selections of new varieties those with good stiff flower-stalks should be given the preference. T.

TRAINED SPECIMEN PLANTS.

WHEN making a close inspection of an exhibit of these, one cannot but be led to think of the amount of time that has been spent on what are termed trained specimens. True, they do just whilst they are in flower make a show, but the severely formal style adopted by some of the chief growers is really too much of an extreme. It cannot in any sense be termed natural; it is rather a perversion of Nature to an excessive degree. There does not seem to be any tendency to remedy this, the pre-

vailing style of specimen bush plants being that of width rather than height, so as to have a nearly flat surface of bloom. Furthermore, some adopt the plan of tying down each shoot with a bloom upon it close to the foliage; this is a still further perversion. What should be aimed at so as to have a proportionate specimen is that of the height, the width being at least nearly equal, letting the shape be more globular than flat. By following this plan the training or tying would not be so markedly out of all character with the Chrysanthemum in its more natural state. Standards again more often than not represent just half a sphere, a very formal shape; these would be greatly improved by an increase in height with the flowers standing free from, not tied down to the foliage. As far as standards go, I fail to see of what real use they are save just for the purpose of exhibiting. They do not, it is quite certain, adapt themselves to home decorative uses save in the largest of houses, where each one stands out distinctly by itself. Pyramids do not appear to be grown so much as a few years back; these, like standards, are not to be recommended except for exhibition. It is better to let both of these styles die a quiet death, which they would undoubtedly do in nearly every garden if no encouragement were given in prize schedules. If standards, which of the two are the least objectionable, are to be encouraged, let us have them merely supported and tied informally. As it is now, it is equally, if not more, a point of mere skill in tying than of cultivation; the skill in tying may well be diverted to other channels from which more profit can be derived, not to say more pleasure also save in the case of the man of patience who does the tying. There is no comparison, for instance, as far as real effect is concerned, between the twisted and contorted examples seen in shows and early struck cuttings which have been stopped two or three times so as to form a good base for a naturally grown plant. If looked at from the point of the room occupied, there is nothing to be said in favour of large trained plants.

GROWER.

Chrysanthemums, premier blooms.—I should like to see all societies adopt the plan of offering prizes for the best bloom in the two important sections—incurved and Japanese. All exhibitors of my acquaintance prize the award for the best bloom in the show. At one of the Portsmouth exhibitions a few years since this honour was conferred in the incurved section upon a well-developed bloom of Lord Alcester in a stand belonging to an amateur, the Rev. R. Wells, Havant, beating all others, myself amongst the number. The educational value consists in showing to the public what the judges regard as typical blooms in the sections that are mostly favoured—incurved and Japanese. Seldom indeed does the largest example obtain the coveted award in either section, the honour usually falling to one approaching it in size, but possessing qualities which the larger bloom lacks. For instance, in the incurved section mere width is not the acme of perfection. If a bloom measures 5 inches in diameter and 4 inches or even 3½ inches in depth, that bloom possesses much more merit than one wider, but less in depth. The former bloom will have solidity of petal, the latter will not, and will lack the globular shape so desirable in a perfectly incurved bloom. No bloom should be selected for this honour the petals at the base of which are fading, neither should it if the colour is bad; for instance, Queen of England, almost white, would be out of character. The colour of the variety chosen should be good. The petals ought to incurve properly and meet quite close in the centre. Lord Alcester has taken the position of premier bloom as an incurved variety oftener than all other sorts put together, I might safely say. Mme.ARRIER has had that distinction accorded it numerously of late at the earlier shows on account of the perfect symmetry which it possesses when in its true form. In the case of the Japanese section the same rule applies in nearly all cases; breadth of petal is important, perhaps more so than in the case of the incurved section, because

blooms with extra broad petals are not, as a rule, so solid in their "build." Depth consistent with diameter is important in the Japanese section; brightness of colour and strict formation of their florets in conformity with the variety are most important in choosing the premier bloom in this section.—E. MOLYNEUX.

Fimbriated Chrysanthemums.—What a pity more attention is not paid to this type of Chrysanthemum, presumably because more encouragement is not given in the shape of prizes offered at the shows. If this were the case we should quickly see an influx of new varieties; as it is their number is limited to about half-a-dozen. For decoration this section is charming, the fimbriated edges rendering the bloom at once novel as well as pleasing. All the varieties belonging to this section are free-flowering, a point desirable in all Chrysanthemums, especially where intended for decoration. The advantage of this section for exhibition is that the blooms can be staged in bunches of three or more with a good length of foliage attached. At but one autumn exhibition I know are prizes offered for these varieties—Portsmouth. No stand of blooms throughout the whole show is more attractive than that composed of fimbriated flowers. The back row of blooms is cut with 15 inches of stem, which enables a good quantity of foliage to be displayed, the front row being about 10 inches high. The blooms are arranged loosely, so that all are displayed and not in any way cramped and muddled together. Scapin, amaranth and maroon, the centre lilac, tipped yellow; Cræsus, golden-yellow, marked with dull red; Chardonnet, bright purple; and Massange, bluish-pink, are the best of the large-flowered varieties in the fimbriated list.—E. MOLYNEUX.

Grafted Chrysanthemums.—Some little interest was excited last season by an experiment which M. Alexis Callier, of Ghent, had undertaken, viz., the grafting of Chrysanthemum sinense on the Anthemis. The Comte de Kerchove states in a Belgian contemporary that that gentleman has now a large number of such grafted plants, one of which has made extraordinary progress. The variety grafted is Val d'Andorre, and it has assumed very large proportions, being about 7 feet in diameter. At the time of writing the plant had 790 buds on it, most of which have no doubt by this time expanded.—C. H. P.

Chrysanthemums at the Crystal Palace.—An immense number of the queen of autumn is grown annually at this favourite place of resort by Mr. W. G. Head. This year Mr. Head has of early, mid-season and late varieties some 8000 plants. This number of course extends the season considerably at both ends. When inspected a few days back on the occasion of the annual Chrysanthemum show the mid-season varieties were in their full beauty. The chief or most prominent group had been arranged at the southern end of the building next to the large Lily tank, over which are grown the noble Tree Ferns, finer than which are rarely ever seen. This group was so arranged as to face towards the centre of the building; thus it made a most brilliant display even from the distance, but when viewed more closely it could be seen that it was composed of the best standard varieties, these bearing very superior blooms. The colours were judiciously blended throughout the entire group. There was an entire absence of overcrowding in every part, each flower showing to good advantage. In form the group partook of about the half of an ellipse or oval; this afforded more scope than if it were the half of a circle, and this advantage had been duly taken advantage of by Mr. Head in carrying out the arrangement. There was also an easy gradation each way from the centre downwards. Taken as a whole it was a beautiful arrangement, which if in competition would be a bad one to beat. The Japanese varieties of course entered largely into its composition; none of the other sections lend themselves so well to artistic grouping. Forming flanks on either side were smaller groups, so arranged as to have backgrounds of fine-foliaged plants, being in a measure

associated with them. Of these there were several each comprising more material than one often sees in competitive groups. The whole formed a beautiful display of this popular autumn flower.

Staging Chrysanthemums in vases.—There have been some advocates for staging Chrysanthemums in vases with long stems in imitation of the American plan. For the big heavy flowers grown by English growers this method seems to be a faulty one, for they seem to require the aid of wire supports. Mr. Jones adopted the plan for some of his flowers at the Aquarium show. This could scarcely be considered a success, as towards the close of the first day many of the blooms had completely collapsed, and the foliage was hanging down in a faded condition. The blooms staged on show boards exhibited no such signs.

SOME NEW CHRYSANTHEMUMS.

THE present season has been so prolific in novelties, and many of them have been staged in such excellent condition, that it seems an opportune moment to indicate the names and brief descriptions of some of the best submitted to the floral committee of the N.C.S., whether certificated or not.

PRESIDENT BORREL (Jap.).—Long petals, rose-purple and gold reverse. First-class certificate.

MRS. C. B. MYERS (Jap.).—White, shaded greenish-white. First-class certificate.

CHARLES DAVIS (Jap.).—A warm rosy-bronze and yellow sport from Vivand Morel. First-class certificate.

Mlle. THÉRÈSE REY (Jap.).—Pure white, long drooping florets. First-class certificate.

LOUISE (Jap.).—Colour white, incurving petals, shaded pale pink. First-class certificate.

EDA PRASS (Jap.).—Incurved petals, soft salmon-rose. First-class certificate.

MME. EDOUARD (Jap.).—Light purple-amaranth, rosy reverse, incurving petals. First-class certificate.

MRS. P. BLAIR (Jap.).—Pale purple, reverse silvery, incurving petals. First-class certificate.

VIOLETTA (Jap.).—A deep flower, soft rosy violet. First-class certificate.

TRIBUNE (Jap.).—Pale lemon-yellow, centre darker. First-class certificate.

MME. CAMBON (Jap. inc.).—A massive flower, reverse of petal straw-yellow, crimson inside, which is scarcely visible. First-class certificate.

L'ISÈRE (Jap.).—White, long florets of the Dragon type.

SNOW (Jap.).—Long drooping florets, white, centre creamy.

MME. OCTAVIE MIRBEAU (Jap.).—White, streaked purple, something in the style of Belle Paule.

MME. M. RICOUD (Jap.).—Very deep rosy blush, good form.

MISS M. SIMPKINS (Jap.).—Globular incurved flower, creamy white, sharp-pointed petals.

VICE-PRESIDENT BARIGNY (Inc.).—Deep crimson, golden reverse.

FLORENCE CARR (Pom.).—A compact deep orange-bronze. Commended National Chrysanthemum Society.

MRS. COX (Jap.).—A crimson sport from M. Bernard.

PEARL BEAUTY (Jap.).—Broad, grooved, incurved florets, white.

ELSIE NEVILL (Siag. Jap.).—A pretty crimson long-petalled variety.

LADY SAUNDERS (Jap.).—Long drooping florets, colour delicate pale yellow.

COLONEL CHASE (Jap.).—A deep flower, long narrow florets, colour pale blush and yellow. First-class certificate.

ROSE WYNNE (Jap.).—Rosy white, incurving florets.

W. H. FOWLER (Jap.).—Rich golden yellow, a fine effective flower of good form.

E. L. JAMIESON (Jap.).—A charming shade of deep crimson, reverse bronzy gold, petals rather short.

JAMES MYERS (Jap.).—Thin fluted florets, deep rosy salmon.

SIR W. RALEIGH (Jap. Anemone).—Pale blush, guard florets flat.

Mlle. NATHALIE BRUN (Anemone).—Guard florets quilled, colour white, good high disc pale yellow. First-class certificate.

ERNEST CAILLE (Anemone).—A good flower, soft rosy buff, centre yellow.

MRS. C. J. SALTER (Anemone).—A medium-sized flower, rosy golden buff. First-class certificate.

W. W. ASTOR (Jap. Anemone).—Long flat guard petals tinted blush, high disc rosy yellow. First-class certificate.

JOHN BUNYAN (Jap. Anemone).—Thin fluted guard florets, high disc, light yellow self. First-class certificate.

HIBERNIA (Anemone).—Ochre-yellow, rosy buff disc.

CALEDONIA (Jap. Anemone).—White guard florets, disc tipped yellow. C. H. P.

CHRYSANTHEMUMS AT BROADOAKS, BYFLEET.

CHRYSANTHEMUM growers of the present generation have probably never experienced such a trying season as the past one. In this part of Surrey we did not get 1 inch of rain during the time the plants were making their growth, the heat of the sun at times being almost unbearable. Looking, however, at the collection of Chrysanthemums at Broadoaks, the residence of Major Collis-Browne, one would hardly imagine that it had passed through such a fiery ordeal. As many readers of THE GARDEN are aware, Mr. Carpenter, the gardener there, has for some years past been a successful exhibitor, and this season his plants are again in fine condition, carrying blooms of the highest quality. The Japanese are arranged in a small lean-to structure, but every plant is a model of vigour, and every bloom is fit for the show-board. Where only the very finest kinds are grown, and each flower is of high development, it is difficult to select any for special mention. Tastes vary much, but I think that all would be attracted by the fine blooms of Mons. A. Carrière. This variety, I think, realises the *beau idéal* of a Japanese Chrysanthemum. The huge plume-like mass of drooping petals so grandly effective are nevertheless quite free from the coarseness that unusual size frequently brings with it. C. Shrimpton, a glorified Cullingfordi, is in grand form, and is a variety that on account of its colour cannot be left out from the smallest and most select collection. The popular Viviani Morel is in fine condition, showing in one bloom only, and that apparently the oldest, the sportive tendency that characterises this Chrysanthemum. All the other blooms have the beautiful warm rose-purple shade that should distinguish this sort. The rich orange-yellow of Edwin Beckett, intensified by high culture, renders it very striking when in association with other colours. To my mind these four Japanese should find a place wherever Chrysanthemums are grown for decoration. The purest white is the well-known Avalanche, the largest, Mlle. Thérèse Rey, with broad petals, rather coarser, but certainly impressive. Mrs. H. Payne is carrying enormous blooms, and Edwin Molyneux, President Borel, C. W. Smith, W. Seward, and Excelsior, all in the finest form, are certainly of the aristocracy of the family.

Coming from these huge Japanese to the incurved ones, one can realise how it is that the former have become so popular of late. With the exception of some gain in colour, I see but little difference in the incurved section now and twenty years ago; the flowers were as perfect in form then as at the present time. Some of the varieties in favour at that time are still in repute; but where are the Japanese of those days? Completely driven out of culture by the ever-increasing size, brilliancy, purity, and form of those that come to us from France and America. From a decorative point of view they are overshadowed by their more showy relatives. I must confess, however, to an affection born of past days for the incurved varieties, and was glad to see them so well represented at Broad-

oaks. Jeanne d'Arc is very pure and good in bloom; Miss A. Haggas, golden yellow, in fine condition, and one that strikes the eye at once; and Alfred Lyne, of a pleasing lilac shade, are among the best of the more recent additions to the section. Refulgens is very good, with little or none of the defect that many fail to overcome. M. Bahuant, very big and finely formed; Princess of Wales, a handsome and telling variety as grown by Mr. Carpenter; Lord Alcester, the yellow sport from Empress of India, and Florence Davis were very conspicuous. Baron Hirsch and Mr. P. Clarke, both in grand condition, are certainly among the best of the incurved. The Teck family is represented, but I fancy Mr. Carpenter does not attach so much importance to this group as was the case several years ago. The incurved more acutely feel the effects of fierce sun heat and parching winds than the Japanese varieties, but it is surprising to see how green their foliage is. Mr. Carpenter apparently has a high opinion of soot as a manurial and restorative agent, and to its free use may be attributed the rich green of the foliage. Some plants the leaves of which were going yellow in the hot weather were watered daily with soot water, and its value was apparent in their bright green colour. J. C. B.

NOTES ON NEW VARIETIES.

CONTINUING my list on p. 386,

THOMAS HEWITT is deserving of notice. This Japanese variety has broad incurving florets, which give to it a massive appearance. The colour is pleasing—white, flushed and striped with rose, the inside being deeper in tint. Altogether a promising variety.

YELLOW LADY SELBORNE.—Its parent has long been regarded as one of the very best for producing blooms in quantity, the new yellow sport having all the characteristics of its parent in that respect will be welcomed as a great acquisition. The colour is a rich golden yellow, the reverse primrose.

MME. ADOLPHUS CHATIN also belongs to the incurved Japanese section; the florets are broad, pure white. With age they become tinged, which adds a pleasing tint to their appearance.

MIDDLETON CLARKE.—The reflexed florets are rose-crimson in colour. It is a full flower, in every way promising.

DUKE OF YORK.—The florets are of medium width, flat, the points inclined to incurve. The colour—magenta—is very showy, suffused as it is with silver. In habit of growth it is dwarf.

CHARLES CAPITANT.—Flesh-pink in colour, decidedly pleasing; the florets are notched or serrated.

MRS. A. J. PARKER, belonging to the Japanese section, has small flowers. It is very useful for decoration. The florets are long, narrow, and pointed, the colour chamois.

MRS. DREER.—An American raised Japanese, with narrow florets, brick-red, tipped with gold, full, and promising.

MME. ISAAC.—A pure white Japanese variety with flat, sword-like florets, which are numerous, making a full flower, promising.

W. FALCONER.—This belongs to the hirsute section, being a sport from Louis Boehmer, and is quite distinct from any other variety in this section. The colour, light pink or deep blush, is most pleasing.

H. HAMMOND SPENCER is a full-flowered Japanese, large, rose-lilac in colour.

SAUTEL 1893.—This is one of Sautel's favourite flowers; he thinking highly of it added the year to the name. In colour it is lilac, rose inside of the florets, which resemble those of Comte de Germiny in formation.

PEARL BEAUTY is an American seedling Japanese, raised by Pitcher and Manda in 1892. The florets are ivory-white in colour and massive in build. This is a most promising variety belonging to the incurved Japanese section.

SILVER CLOUD.—This American Japanese is unique in point of colouring, which reminds one of the outer covering of a pale-coloured Mushroom.

The florets are broad, late flowers reflex in exactly the same way as late blooms of Mlle. Marie Hoste.

NIVEUM is in growth just what is required—dwarf. The flowers are large, composed of pure white strap-shaped florets.

MRS. HILLIER.—The tips of the florets of this Japanese variety show an inclination to incurve slightly. The colour is primrose-yellow with a deep yellow centre, a massive flower.

MRS. J. HAMMILL.—This, belonging to the incurved Japanese type, has broad massive florets; the colour is pleasing—creamy white, suffused with rose, deeper towards the outer florets.

E. MOLYNEUX.

SHORT NOTES.—CHRYSANTHEMUMS.

Chrysanthemum Dolly Varden.—As a single variety this is remarkably free flowering. In colour the florets are rose-magenta, the disc yellow, and exceptionally high for a single-flowered kind.—E. M.

Chrysanthemum Pattie Penford.—This is a distinct and pleasing addition to the single-flowered section; the florets are of medium length, semi-drooping, pure white. The disc is high, pale green in colour.—E. M.

Anemone Chrysanthemums.—Some excellent additions were made to this class by Mr. Owen at the Aquarium show. W. W. Astor, John Bunyan, Sir Walter Raleigh, Queen Elizabeth, Hibernia, and Caledonia, varieties not yet in commerce, were the chief.

Chrysanthemum Elsie.—Those persons who require a free-flowering variety, pale lemon in colour, should add this to their collection, no matter how small that may be. It is certainly one of the very best, flowering so freely, while the colour is all that can be desired.

Japanese incurved Chrysanthemums.—Many of these so-called Japanese incurved varieties are only properly so in the early stages of development. With age they seem to throw back their petals and assume the appearance of the blooms of the ordinary Japanese type.

Chrysanthemum Mrs. Alpheus Hardy.—This white hairy Japanese Chrysanthemum, which attracted so much attention a few years since, and which it was thought would soon be discarded entirely because of its weak growth, was staged in very good form in several collections at the Aquarium show.

Chrysanthemum Ernest Caille is the only seedling of M. Délaux's we have seen this year. It was staged by Mr. Ives, gardeur to Mr. E. C. Jukes, at the last meeting of the floral committee. It is a very attractive Anemone-flowered variety with a capital centre, and is of a soft rosy yellow-buff colour.

Chrysanthemum Mlle. Martignac.—Any creditable addition to the incurved section is always appreciated, especially when, as in this variety, the colour is a rich yellow. The incurved section lacks this colour, which renders any addition all the more valuable. The petals are rather short, but promise to incurve nicely.

M. Calvat's seedlings.—At the floral meetings and at the trade displays, M. Calvat's new seedlings have been not only interesting, but a leading feature. From a note in the current number of the *Revue Horticole* it would appear that M. Calvat will have still more novelties of a high class to distribute next spring.—C. H. P.

November Roses.—Of course it is all the result of this remarkable year that the Tea Roses, having more than made amends in autumn for their fleeting display in the great heat of summer, are still full of flower. As I write this note on November 5 there is before me a bowl filled with sweet and beautiful blooms. Two of the chief kinds are Mme. Hoste and Anna Ollivier, the buds as fresh and perfect as at any time. Marie d'Orleans too is conspicuous, with full, fine flowers, whilst Bouquet d'Or, Gloire de Dijon, Emile Dupuy, Safrano, Pauline Labonte and Lamarque are also present. Many more might be culled, not forgetting Dr. Grill, whose many-tinted blossoms

vie in richness with the glorious colour that is now everywhere to be seen in wood, copses and hedges.—A. H.

STOVE AND GREENHOUSE.

URCEOCHARIS CLIBRANI.

This plant is of special interest botanically as well as horticulturally. To gardeners it is valuable as an addition to easily grown free-flowering stove plants of the character of *Eucharis*, whilst botanists are specially interested in it because of its so-called bigeneric origin. In July, 1892, Messrs. Clibran, of Altrincham, exhibited at one of the meetings of the R.H.S. an inflorescence of a *Eucharis*-like plant, which was labelled *Eucharis amazonica* × *Urceolina aurea*. Shortly afterwards Dr. Masters described it under the name it now bears, and it has since been distributed by Messrs. Clibran. The form and pose of the flowers certainly indicate the relationship with *Urceolina*, whilst the *Eucharis*, which was the seed-

8½-inch pots, and very well do such plants repay for the moderate amount of labour and attention they need. Like most of the *Salvias*, this variety is readily raised from cuttings, and it can be either planted out during the early summer and subsequently lifted for placing under glass, or it can be grown on in pots in a cool position, strict care being exercised to ensure a liberal supply of water. As the flowering period approaches it is necessary to give a top-dressing of old manure, or to supply liquid manure freely. This is especially requisite when the plants have been confined to pots which they have filled with roots.—OBSERVER.

Abutilons.—"T." says "the range of colour amongst *Abutilons* is not great." Scarlet, crimson, rose, pink, lilac, purple, yellow, white, with many intermediate shades are here. Surely this is range enough for the most fastidious. The *Abutilon* is everybody's flower, as easily grown as a Willow, while the shade and markings are as various as the colours. The foliage, too, partakes of the diversity. Under good management they are as graceful as *Fuchsias*. Most of them if left to themselves will push upwards and become bare below. To see them at their best they should be planted out in a conservatory. Two thus treated here are gay six months of the year. The border is 2 feet deep of loam, with a layer of bones (un-crushed) underneath, and their vigorous growth

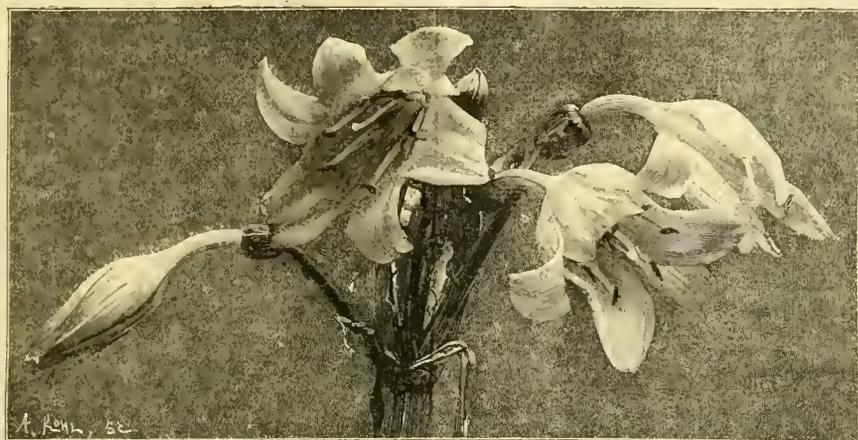

appearance, and suggesting the specific name of *rubro-cœrulea*. Given liberal root room it will soon cover a considerable space, while it can also be flowered freely in pots from 6 inches in diameter upwards. Seeds of this *Ipomœa* can be obtained at a cheap rate, and if sown in the spring will form fine flowering plants by the autumn.—T.

Anthurium crystallinum.—A few years ago, when fine-foliated plants were all the rage, this *Anthurium* was very frequently seen. This *Anthurium* grows freely under much the same conditions as most of the other members of the genus, that is potted in an open compost consisting principally of fibrous peat. As copious supplies of water are essential to its well-doing, the pots used must be thoroughly well drained, and the plant should be kept in a moist part of the stove where it can be shaded from bright sunshine. It is easily increased by offsets, which are sometimes borne freely. While the marking of the foliage depends to a certain extent upon the conditions under which the plants have been grown, some individuals are decidedly superior to others. Neat plants of this *Anthurium*, which are very useful for grouping in many ways, may be grown in pots 6 inches in diameter, and half a dozen or so form a bright and telling feature in the stove at the present time.—H. P.

Erica hyemalis alba.—Though *Erica hyemalis* varies a good deal in colour according to the conditions under which it has been grown, yet there is more than one form, and to the variety *alba* as long ago as 1883 a good deal of attention was directed, but nothing more was seen of it for three or four years. After that time, however, it became better known, and is a really pretty variety, especially valuable where white flowers are in demand. *Erica hyemalis* is one of the most popular Heaths, and great numbers are brought into Covent Garden Market during the autumn and winter months. Two other Heaths just now in full flower are the little white-flowered *Erica caffra* and the equally small-blossomed *Erica gracilis*, which is in some instances very richly coloured. Both of these remain in beauty for a considerable time.—T.

Agathœa cœlestis.—No particular season of the year can be assigned for the blooming of this pretty blue-flowered composite, upon which by some the name of the blue *Marguerite* is bestowed. Planted out of doors at the same time as the various bedding plants it will flower throughout the summer; whereas if struck in the spring or early summer, and grown in the open air in a position fully exposed to the sun, it will if stopped freely during its earlier stages form neat little bushes, which by the end of the summer are bristling with flower-buds, and taken then into the greenhouse they will maintain a succession of bloom for a long time. The pretty blue flowers are very useful for cutting, their straight wiry stems being a great point in their favour.—H. P.

Rhododendron retusum.—Mr. Otto Forster might well ask the question, why is this fine plant so rarely met with? The reason, I think, is that the flowers are too small to please many people, for the tendency now-a-days is towards huge blooms, it matters not in whatever class of plants. Habit and freedom of flowering are in many cases sacrificed to obtain large blooms, and this is especially noticeable in the case of some subjects, such as *Chrysanthemums* and *Fuchsias*. Many of the new *Fuchsias* that are now sent out are long-jointed and produce comparatively few flowers, but they are large ones, and to some this more than compensates for their other faults. With regard to *Chrysanthemums* much the same may be said, the pretty little pompon class being almost ignored. *Rhododendron retusum* is a very neat growing evergreen shrub, whose young leaves are prettily tinged with red. The small tubular-shaped flowers are borne in clusters, and from their shape and drooping character they remind one of a *Fuchsia*, the nearest being *F. triphylla*, for in this the colour of the blossoms is much the same as in the

Flowers of *Urceocharis Clibrani*.

bearing parent, predominates in size and colour. The plants have flowered freely, every period of growth having been followed or accompanied by a flower-spike. The flowers are borne with the young leaves, and the plant is evergreen like the *Eucharis*; whereas *Urceolina* is deciduous. The flowers are pure white when fully open, but there is a tinge of yellow on the buds. The flowers are borne in loose umbels on erect scapes about 18 inches long, strong scapes bearing about six. The leaves are as large as those of the *Eucharis*, and not unlike them in texture and shade of green. Whether it be a true hybrid or a seedling sport from *Eucharis amazonica*, there can be but one opinion as to the merits of this plant.

W. W.

Salvia splendens var. compacta.—The old *Salvia splendens* is well known and valued as a brilliant decorative plant. The variety *compacta* possesses a character, however, that is suitably expressed in the name, namely, its dwarf, compact habit, which renders it particularly useful where space is limited or where small shelves unfitted for large specimens have to be rendered gay. Plants can be grown as fine little bushy specimens 2 feet high and as much in diameter, covered with brilliant scarlet flowers and bracts, in 6-inch or

and profusion of bloom are surprising. I remember a few years ago seeing a collection of standards in 9-inch pots. The stems were about 3 feet high and the size of one's finger; the heads were globular, dense, and full of bloom. I suppose this was effected by repeated pinching back, sacrificing the flowers for a year or two, and well feeding with liquid manure. They were, however, very attractive specimens, and well repaid the trouble bestowed on them.—J. M., *Charmouth, Dorset*.

The Pelargonium house.—Among other inmates of the structure devoted at this season more particularly to zonal *Pelargoniums* may be mentioned *Salvia splendens*, *Bruantia*, *coccinea*, and *rutilans*, two varieties of *Eupatorium*, *Libonia penrhosiensis* and *Primula obconica*. With the exception of the last named, all the others are struck, potted on, and grown through the summer under the same conditions as the *Pelargoniums*, and make capital companions for them at this season.—E. B.

Ipomœa rubro-cœrulea.—This tropical Bindweed is well worth attention as a climber for the stove or intermediate house, as it flowers with great freedom in autumn, and, like many of its allies, the blossoms are wonderfully pretty, while, though the individual blooms do not last long, a succession is kept up for a considerable time. The flower is when first expanded of a beautiful pale blue, but afterwards it becomes suffused with a peculiar reddish tinge, giving it a very distinct

Rhododendron. This last is a native of Java, but it will succeed in a lower winter temperature than *R. javanicum*, whose massive heads of orange-coloured flowers are so beautiful. The various tube-flowered or Javan hybrids, too, require a warmer structure than *R. retusum*. This last has been but little employed by the hybridist, the only varieties claiming parentage from it as far as I know being Prince of Wales, sent out about thirty years ago and now almost dropped out of cultivation, and *Daviesi*, the result of intercrossing *R. retusum* and *R. javanicum*. In shape the flowers of *Daviesi* are about midway between their parents, and their colour—a glowing orange-red—renders them very showy.—T.

Begonia Gloire de Lorraine.—This beautiful Begonia, to which a first-class certificate was awarded at the last meeting of the Royal Horticultural Society, is, as surmised in the notice thereof, a hybrid with some affinity to the tuberous-rooted section. It was raised by that veteran hybridist, M. Lemoine, of Nancy, and announced by him as a hybrid between *B. socotrana* and *B. Dregei*. In his catalogue M. Lemoine gives some very interesting particulars regarding this Begonia, from which it appears that the cross was effected in January, 1891, and that the young plants obtained therefrom were already in full flower by November 15 of the same year. In February, 1892, it was awarded a first-class certificate by the National Horticultural Society of France, and now it has received a similar award in this country. Messrs. Lemoine say that the length of its flowering season is shown by the fact that the same plants shown in February were again exhibited in November of the same year.—H. P.

SOME RARE PALMS AND OTHER FINE-FOLIAGED PLANTS.

ALTHOUGH the Victoria house at Kew is for the present year losing its central attraction—the Victoria Regia declining in vigour and ceasing to flower as the days grow shorter—the house still remains extremely interesting by reason of a number of remarkably fine-foliaged plants which it contains. There are, indeed, over a dozen plants stood round the tank whose rarity and striking character make the collection quite unique, and one which no other garden in Europe could produce. Some of them are here and there to be met with in stoves; others, perhaps, may become not uncommon garden plants in course of time, but the majority are only known to horticulturists by having figured in many a traveller's tale. Some, such as the double Cocoa-nut and Palmyra Palms, we can scarcely ever hope to possess in large quantities in this country, owing to the difficulty of raising the plants. It may, therefore, be of interest to those who have tried to grow or raise these plants to know the conditions under which they have been found to so far succeed here and to learn the dimensions to which they have already attained.

LODOICEA SEYCHELLARUM.—This Palm is, as the specific name implies, a native of the Seychelles Islands. This is the only region in which it is found in a wild state, and even here it is confined to three small islets. In its adult state the Palm is 70 feet to 100 feet high, with a perfectly erect, straight stem about a foot in diameter. Ever since the discovery of the Seychelles in 1743 it has been regarded as a Palm of exceptional interest, not only because of its extremely limited distribution, but also from the fact that prior to that date the fruits were frequently found floating on the sea and were picked up by mariners. On the surmise that they were the fruit of some ocean plant, the name of *Coco de Mer* was given them, and their reputed medicinal properties gave them an enormous money value. Many attempts have of late years been made to get the plant under cultivation from seed, and some years ago a young plant was

raised at the Liverpool Botanic Garden, which, however, died shortly after germination. In the summer of 1890 two germinating nuts were sent to Kew from the Seychelles, and after growing successfully in a warm pit for two years, the stronger one was removed to the Victoria house, where it has since made extraordinary progress and is now to all appearance in perfect health. The plant is placed over the warm water of the tank, the bottom of the pot being for a few inches immersed. It now carries four leaves, and the youngest one gives evidence already of the remarkable dimensions they ultimately attain in this Palm. This leaf is undivided, the blade 5 feet long, each side of the midrib measuring 3 feet 6 inches across, but gathered up into numerous half-expanded folds. The seed, which is still attached to the plant and supported on a special stand, is a nut 1 foot long by 1 foot 8 inches across and consists of two immense lobes, hence the common name of double Cocoa-nut. It is the largest seed that exists in the vegetable kingdom.

BORASSUS FLABELLIFORMIS (the Palmyra Palm).—This Palm—a native of Tropical Africa—is of great importance as an economic plant in India, where it has evidently been introduced for a long period. It is especially valuable because it flourishes in dry, arid plains where scarcely anything else will grow. It has hitherto proved very difficult to cultivate in this country; nevertheless, a plant in the Victoria house is succeeding admirably under the same conditions as the double Cocoa-nut, notwithstanding the difference between the conditions here and those which are described as pertaining to the dry regions of India. It is a fan-leaved Palm with foliage of a slightly glaucous hue. It carries ten or twelve leaves, and is about 3 feet high. I believe this is the largest, perhaps the only specimen in Britain.

MAURITIA FLEXUOSA (Ita Palm).—Quite distinct is this Palm from any one generally known in cultivation. The Kew plant has not yet formed a stem above the soil, the leaves being borne on erect petioles 5 feet high. The central part of each leaf is circular, but the rest of the leaf consists of strips an inch wide at the base, narrowing to a long fine point, which hang straight downwards from the centre to a length of 2½ feet. The effect is not only strikingly distinct, but is also very graceful. The Ita Palm is found in British Guiana and other contiguous parts of tropical South America, occupying the margins of rivers and swampy ground. It is interesting to recall that fifty-seven years ago Sir Robert Schomburgk first discovered the remarkable Orchid *Catasetum longifolium*, a species that grows head downwards, on the stems of the Ita Palms.

VERSCHAFFELTIA SPLENDIDA.—Like the double Cocoa-nut already referred to, this Palm is a native of the Seychelles Islands. It has huge undivided leaves of somewhat the same character as *Stenersonia grandifolia*. The stem is quite erect, 3 inches in diameter, marked with the ring-like scars of the fallen leaves, and armed with long black spines. This Palm is not only a particularly ornamental one, but is interesting on account of the manner in which it is held aloft on its roots. As the plant grows in height roots are successively developed one above the other from the lower part of the stem. Each one is stronger than the preceding, and the older lower ones finally dying away along with the stem, the plant becomes at length elevated on so many legs. The plant here is only 7 feet high, but its latest roots have already to grow 1 foot before they can take hold of the soil. The growing point of each is guarded by a cap formed of effete scales, which, by retaining some of the water trickling down the root, provide for its being kept moist. The *Iriartea*s are other instances of this peculiar mode of root growth; in large specimens a man may pass upright between the bottom of the stem and the ground.

HYPHENE THEBAICA (Doom Palm).—The Doom or Gingerbread Palm is a native of Egypt and Abyssinia. It is of great interest botanically, being one of the very few Palms that branch naturally. Under cultivation it has always proved a difficult subject. The plant here is small, but

quite healthy. It has slightly glaucous fan-shaped leaves, the petioles of which are armed with a few stout black spines. It is the husk of the fruit which tastes like gingerbread, and although dry and unpalatable to Europeans is eaten by the poorer natives.

BISMARCKIA NOBILIS is a very rare Palm, and has the reputation of being a difficult one to grow. Whatever it may be under ordinary methods of cultivation it thrives exceedingly well in the Victoria house with its pot partly immersed in the tepid water, and is, in fact, in the rudest health. The plant is 4 feet to 5 feet high, its somewhat glaucous fan-shaped leaves measuring 3 feet across, the margins of the segments being furnished with a few white filaments. The species is a native of Madagascar.

MANICARIA SACCIFERA.—The Troolie or Bussu Palm of British Guiana is an important economic plant in that region. The stem, which is frequently very crooked, grows to a height of 20 feet, and bears channelled, entire leaves that are 30 feet long by 5 feet wide and quite erect. The seed contains a palatable milk, the leaves are used for thatch, and other parts of the Palm are put to various uses. The specimen at Kew is 6 feet high, no stem as yet being formed; the leaves, unlike those of adult plants, are irregularly pinnate. This Palm in its native state occupies tidal swamps, and therefore belongs to a class of plants which has always proved difficult to cultivate, owing no doubt to the lack of salt water natural to them.

STANGERIA SCHIZODON.—Strictly speaking, there is only one species of *Stangeria*—*S. paradoxa*—but it varies considerably in habit and foliage. Although a Cycad, its leaves are more like those of a Fern (*Lomaria chilensis* for instance) than any other Cycad. They are pinnate, quite glabrous, traversed by parallel forked veins, and of a deep green. *S. schizodon* is the finest and most robust form of the species; the plant here is 8 feet through, the leaves 4 feet to 5 feet long; the margins of the broad pinnae are toothed, as the name suggests, and more deeply than in the typical *S. paradoxa*. The variety was originally introduced about twenty years ago, but like the type is very scarce. The plant under notice carries several cones and has altogether a very noble appearance.

VRIESIA GLAZIOVIANA and *V. imperialis* are two imposing Bromeliads among the giants of their tribe. A plant of each is grown in the Victoria house, and being practically alike in foliage make a striking pair. The leaves, each 4 feet long, shaped like a rounded trough, and narrowing gradually to a point, are of a shining glaucous green, bronzy at the base.

MACARANGA PORTEANA.—This is one of the most striking fine-foliaged plants introduced in recent years. It was sent to the Jardin des Plantes at Paris from the Philippine Islands five years ago, and thence reached Kew. The leaves, of a rich olive-green (purplish when young), each measure 2 feet 9 inches in length and 2 feet 6 inches in width, being supported by long petioles which are attached to the centre of the blade. The leaf is supported like a shield, and is of the same outline. It is only in a large house that the noble proportions of the plant can be properly shown. The *Macaranga*s are euphorbiaceous plants, and are allied to the better-known *Acalyphas*.

Amongst other plants the following should be mentioned:—

PRIONIUM PALMITA (the South African "Palmitite").—A noteworthy plant that belongs to the family of the Rushes. In habit and general appearance, however, it is far removed from them and is more like a smooth-leaved *Pandanus*, destitute of prickles or spines. The tapering, channelled leaves are 3 feet long and of a glaucous colour. The plant is common in South African rivers and is quite easy to grow when treated as an aquatic. The leaves are valued for the fibre they yield, and the heart of the plant is used as a vegetable.

THE MANGOSTEEN (*Garcinia mangostana*) is represented by a healthy young plant. Although

known chiefly for the fruit it produces, it has some pretensions to beauty as a fine-foliaged plant, its large, oblong, deep green leaves being very handsome.

THE TEAK (*Tectona grandis*) also is distinguished by its large rhomboidal leaves.

GYNERIUM SACCHAROIDES (the Brazilian Uva Grass) is a curious and striking plant. Its crowded slender stems are 12 feet high and bear long grey-green leaves. It is a semi-aquatic and is here kept with the pot almost entirely immersed.

Although one might expect such things as the Ita Palm, which is naturally a swamp-loving plant, to thrive under the conditions that here obtain, it is something of an anomaly to find the Doum and Palmyra Palms (both of which grow so frequently in semi-desert country) succeeding equally as well, for not only are the bases of the pots in the water, but there must also be a continuously high state of humidity in the atmosphere. They are, however, simply so many more instances of the uselessness of attempting to reproduce in our glass-houses the conditions under which such plants naturally exist. These natural conditions, too, are often more apparent than real. The Doum Palm, for instance, has often been found to send its long roots deep through the sand and to have tapped underground springs. We must also bear in mind Darwin's dictum, that plants have often to live where they can and not where they would, and their existence on dry, poverty-stricken land is more a matter of necessity than of preference. One might, in fact, mention dozens of instances where plants that have been introduced from dry, torrid regions succeed under cultivation far better when treated like others from regions where absolutely diverse conditions prevail than they do under the most elaborate imitations of their native soil and atmosphere. W. J. B.

Cordyline indivisa.—I noticed your correspondent's note on this plant in your issue for Oct. 21 (p. 381), and can well imagine what a noble example it would be at the unusual dimensions given, and it may be of interest to others as well as myself if "H." would kindly say if he has any idea what age the plants are. I have been acquainted with a pair of plants growing in a greenhouse for twelve years, and although they appear to enjoy fair health, are very little larger now than when first I saw them. I am quite at a loss to make out why this plant should be confounded with the variety *C. australis* sold in London and elsewhere as *C. indivisa*, as there is no comparison between the two.—C. TURNER, *Willowfield, Halifax.*

Manettia bicolor.—There is now in flower in the stove at Kew an extremely pretty specimen of this small climber. It was introduced from the Organ Mountains, of Brazil, by Messrs. Veitch just about fifty years ago, and was, perhaps, better known to a past generation of gardeners than it is to the present. The plant under notice is trained upon a support 1½ feet high, and its slender leafy stems are so numerous as to make a perfect covering, which is thickly studded with the small, brightly coloured, jewel-like flowers. The leaves are small, lanceolate, and of a deep shining green, the flowers being tubular, the narrow tube scarlet at the base, whilst the upper part is yellow. It is easily propagated by cuttings, and is worth neting as a plant that flowers at a season when the stove is not plentifully supplied with bloom. Three or four other species of *Manettia* have been at various times introduced, but none of them is generally grown in gardens.

Clerodendron nutans.—Although there are in commerce other species of more gorgeous colours, this stove shrub of hardly scandent habit is well deserving of more extensive cultivation. It is a native of Sylhet, on the east side of Bengal,

whence it was introduced about 1830, and its inflorescence, as its specific name *nutans* indicates, is of a drooping habit. As is the case in several other species, the flowers show two very distinct colours. They are disposed in loose, pendulous, oblong panicles, long and slender, hanging down gracefully and vibrating with the least breath of air, situated at the extremity of the lateral growths. The flowers of which these panicles are composed are devoid of perfume, slightly ascending, with a calyx of a beautiful reddish purple colour, which forms a most pleasing contrast with the waxy pure white nature of the petals. These are somewhat egg-shaped, blunt, almost equal and flat, and the stamens being longer than the corolla and curved upwards are very ornamental. The leaves in this handsome species are either ternate (arranged in threes) or in pairs. Although not a climber, this species, which requires a minimum temperature of 60° in winter, is well adapted for growing as a pillar plant, as it is of robust habit, and whoever sees it in flower, as it now is in Messrs. J. Veitch and Sons' nursery, cannot fail to appreciate its merits as a decorative plant. *C. nutans* is readily propagated from cuttings struck in heat, and usually flowers from October to December. A very good illustration of it is given in the *Botanical Magazine* for 1831, t. 3019, where it is stated that it flowered for the first time in England in December, 1830, at Bretton Hall, and that the drawing was prepared from materials sent from that place by Dr. Wallich. A coloured plate of it was also given in THE GARDEN, Vol. XXXIII. (p. 412).—S. G.

Macrozamia Frazeri.—Many of the Cycads are so large and unwieldy, that they can only be grown to advantage in large stoves and where a permanent position can be given them. There are a few exceptions, however, most noteworthy of which is *Cycas revoluta*. But other species also might well be included, and amongst them more valuable than any, perhaps, in combining beauty and convenient form of growth is *Macrozamia Frazeri*. Most of the Cycads owe their decorative value to imposing regularity of outline and to the stiff, rigid pose of the fronds. *Macrozamia Frazeri*, on the other hand, owes its great attractiveness to the grace and beauty of its arching or pendent fronds. These in full grown specimens are 6 feet long, the pinnæ 1 foot long, narrow linear, tapering to a long fine point and of a peculiar, almost black-green colour. Another recommendation of this species is that it keeps on growing and is continually pushing up young fronds; whereas the Cycases and *Encephalartos* send up their fronds in whorls at long intervals, the old ones sometimes becoming very shabby before the young ones appear, especially after the plants have produced cones. The *Macrozamia*s are all natives of Australia, and some nine or ten species are included in the genus.

Winter-flowering Begonias are commencing to bloom freely, and where grown are quite a relief from the surfeit of Chrysanthemums. When in Messrs. Veitch's, Chelsea, a few days ago, B. John Heal was commencing to bloom freely, and in Messrs. Cannell's nursery at Swanley a large collection is in beauty through the winter months. We think that there is a great future before this interesting class, and the plants are of much value for flowering during a very dull season of the year, when Chrysanthemums are the chief things in bloom. One of the finest of all the Begonias is *Gloire de Sceaux*, which has a pyramidal habit of growth, the leaves large, bronzy-green, and the flowers pink—a fine contrast. An excellent group of it was shown last January by Mr. Jennings, of Ascot Gardens, Leighton Buzzard. Another fine kind is *President Boureuilles*, which is vigorous in growth, the leaves bronzy-crimson, and the flowers bright pink. *B. corallina*, *B. semper florens gigantea rosea*, *B. Bijou de Gand*, the free-flowering *B. Carrière*, and *B. odoratissima* are all worth cultivation.

Acacia platyptera.—This remarkable species, which may be said to herald in the flowering season of the Australian Acacias, is unusually

fine this year. No doubt the reason of this is to be found in the phenomenal amount of sunshine experienced during the past summer, coming nearer to what it enjoys under its native Australian skies than occurs very often in this country. In any season, however, if given a few weeks' exposure to full sunlight out of doors during late summer, it may always be relied on to produce an abundance of bloom from October to December. It is one of a small group of Acacias which (except in a rudimentary state) possess neither leaves nor the leaf-like phyllodes so common in Australian Acacias, the functions performed by these foliar organs being relegated in this instance to the curious wings attached continuously up each side of the stems and branches. These wings are green and, varying from a quarter of an inch to half an inch in width, are also cut up into forked lobes. The flowers are arranged in balls half an inch across, and are of the brightest yellow. The plant grows to a height of about 4 feet, and should be tied loosely to stakes rather than trained on balloons or other formal shapes.

Salvia azurea.—If we except the Chrysanthemums, there are no more useful flowering plants for the last three months of the year in the greenhouse than the *Salvias*. Amongst the scarlet species, *S. splendens* and its varieties are the best, but equally fine is the blue-flowered *S. azurea*, several groups of which now make a most delightful display in the conservatory at Kew. Unlike the dwarf varieties of *S. splendens*, which when well grown make handsome individual specimens, this species is of tall, somewhat sparse habit, and to obtain the best effect should be arranged in groups when in flower. It grows from 3 feet to 5 feet high, and has narrow, linear leaves 2 inches to 3 inches long, the flowers being borne on spikes 8 inches to 1 foot long. The lower whorls of flowers open first, and as they die away others higher up are developed, and by this means a continuation of bloom is kept up for many weeks. The main feature of the flower is its lower lip, which is half an inch wide and of a clear blue, relieved only by a patch of blue-tinted white in the centre. It is a native of West North America, the best form in cultivation being that known as the variety *grandiflora*.

PALMS UNHEALTHY.

I HAVE a quantity of large Palms, which are much valued by my employer for house decoration. The leaves of these began to turn yellow last year. I reported them when I saw them going wrong, and have taken every care of them since, but they are getting worse; although they are all throwing up plenty of new leaves, these are yellow. They are kept in a cool house, no fire-heat except in frosty weather.—PALMS TURNED YELLOW.

** The condition into which the Palms have got may be ascribed to quite different causes, but from the information given I am disposed to think that the chief cause of their present unhealthy state is to be traced to using them for house decoration too freely. Palms, at least a number of kinds, are very long-suffering, but they will ultimately rebel against excessive use in unfavourable ways, as in the case of nearly all other decorative plants. Information as to the size of pots or of plants either being supplied only in an indefinite manner, it is not possible to trace the origin exactly of this failing. If the plants were whilst in a healthy state in moderately small pots as compared with the size of the plants themselves, they would become unhealthy or turn yellow if sufficient water was not given them. When Palms are pot-bound they may almost be likened unto semi-aquatics as to the amount of water they will take, and if this be denied them, the effects would soon be as described by the inquirer. Another source of unhealthiness is that of using them too soon after they have been freshly potted; to do this is a great mistake, as can be

shown in a few words. Assuming that an average shift has been given, and the plants taken out of their growing quarters into a less congenial sphere soon afterwards, a check is at once given to fresh root action through the soil becoming cooler. Hence not nearly so much water is needed as it relates to the fresh soil, whilst the old ball may be dry. To water freely means that the young and tender roots in the new soil will suffer a check. This would also cause the plants to turn yellow. No plant should be used for decoration in the house until it is well established and is rather on the side of being pot-bound than otherwise. Such plants are altogether of a hardier constitution, and when well watered are much safer in every way from a decorative point of view.

Another source to which the same failing might be ascribed is that of too great extremes in temperature, but in this particular instance this does not appear to be the cause. A high temperature and atmospheric moisture in abundance will encourage a most luxuriant growth, the plants being for the time in the picture of health, but to transfer such plants to a dwelling-house would be folly in the extreme. Too much sunlight during bright and warm weather would also tend greatly towards a yellow appearance in the foliage. A moderate amount of shading is most essential for Palms under glass unless it be in the case of houses of immense size where there is a large volume of air always in motion. This would not, however, cause the roots to be unhealthy save as a secondary cause, this being accelerated by an insufficient supply of water. Insects would likewise largely aid in turning the leaves yellow, but as these are not mentioned, it is assumed that they are not the cause. It might, however, be added that red spider is a decided enemy to the *Thrinax* family and also at times to the *Latania*s, but not so much so to the *Kentias*. Unsuitable soil and inefficient potting are two important factors that should be carefully considered. To use soil of a close description, with an absence (to a large extent) of fibre, would only be to encourage failure. The soil should be quite fresh and full of fibre, two-thirds of loam to one of peat being a good proportion, with a liberal use of sand. Firm potting must be attended to, as upon this depends to a large extent the future well-being of the plants. Over-potting is, lastly, another cause, and it is one to which more attention should be given by those who grow Palms. It is quite true that many of the Palms are gross feeders, but it does not therefore follow that large pots are essential, for they are decidedly not when a liberal supply of water is given them. I have proved this over and over again both in the case of small, medium-sized, and large plants.

In the case now under consideration no mention is made by the informant as to the actual treatment given when the plants were fresh potted. It is stated that they were potted after they were seen to be turning yellow, but if in doing this they were given larger pots a mistake was made. The roots would no doubt be to some extent unhealthy; such should be looked over and the worst ones removed, as well as any sour soil prior to potting. Then in nearly every case it should be possible to put them back into the same sized pot again. To repot into larger pots in such cases would only end in aggravating the mischief, more particularly if the plants are at the same time being continuously used for house decoration. I have seen plants used thus that have at last had hardly a good leaf on them. When they arrive at this condition they take a deal of bringing round again, and their use should not again be entertained until their health is quite re-established. I note also that in this case the plants are being grown cool. This will to a moderate degree suit *Latania borbonica*, which it is assumed is the species grown. The *Kentias* will also withstand a cool treatment, but not so either of the true species of the *Thrinax* with impunity. This cannot be classed as a reliable plant for either a cool house or for house decoration save in the height of summer. Taking into consideration the state of the plants, the lowest temperature for the coming

winter should not in either case be less than 50°, but 55° would be better, 10° or 15° being added by day.—Cocos.

GARDEN FLORA.

PLATE 936.

TRITONIA AUREA.

(WITH A COLOURED PLATE OF *T. A. IMPERIALIS* AND *T. A. MACULATA*.)

TRITONIA, or *Crocoshia*, *aurea* is one of the most useful of South African bulbous plants. It is an old garden favourite, having been introduced to Kew in 1846, when it was figured in the *Botanical Magazine*. It appears to be common in South Africa and to grow under the most varied conditions. Under cultivation its requirements are of the simplest character, and it grows and flowers most freely and continuously under pretty much the same treatment as a bedding *Geranium*. In the warmer parts of England it may be left in the border all winter if protected with a layer of leaves or if under the shelter of a south wall. It spreads as rapidly as Couch Grass, becoming almost a weed in warm borders. For beds on lawns or as a plant for the flower border it is really valuable, and it is also worth growing in pots for the conservatory. Planted in loose sandy soil in a sunny position in spring, the corms will take care of themselves, and during the summer will develop numbers of stoloniferous corms which will flower the year following. If they have to be lifted for the winter, it should be done in October and the corms dried in the sun. They may be stored in a dry shed from which frost is excluded.

Typical *T. aurea* grows about 2 feet high, and has spikes of flame-yellow flowers 2 inches across. The variety *maculata* was introduced into cultivation by Mr. James O'Brien, of Harrow, in 1888, when it was named by Mr. Baker on account of the dark eye-like blotches at the base of the flower segments. So far as our experience goes, this character has almost disappeared under cultivation, the Kew plants having now only faint indications of the brown marks which were quite conspicuous in the flowers in 1889. But the spots are no loss, the true beauty of this variety being in the rich deep fulvous orange of its flowers and their exceptional width and length of flower-segment. Last year at Kew the spikes were fully 4 feet high (they were not quite so high this year) and the flowers were at least 3 inches across. A clump of the plant when at its best in a south border against one of the houses was greatly admired. In the same position and growing by its side was a clump of the variety *imperialis*, which is quite as tall in spike and broad in flower as *maculata*, but its colour is of a brighter shade of orange and the segments are narrower. This *Tritonia* was imported to Kew amongst some plants of *Lissochilus Krebsi*, which were planted in a border in the succulent house, where the *Tritonia* soon grew and flowered. It was also imported by Herr Max Leichtlin about the same time. Both the varieties as well as the type ripen seeds freely under cultivation.

About ten years ago a hybrid between *T. aurea* and *Montbretia Pottsi* was raised on the Continent, I believe by M. Lemoine, and named *Montbretia crocosmiæflora*. It is now fairly well known in English gardens, being easily

grown, free-flowering and the colour of the segments two distinct shades of orange, due, no doubt, to the presence of a tinge of red in the flowers of *M. Pottsi*, the seed-bearing parent. Following this success came a batch of seedlings and crosses raised by M. Lemoine, and which have all the excellent qualities of the *Tritonia*, with, in addition, variety of colour, ranging from pale lemon-yellow to flame-red. M. Lemoine distinguishes about twenty of them with such names as *Drap d'Or*, *Etoile de Feu*, *Gerbe d'Or*, &c. Still another addition to these plants, also of M. Lemoine's raising, is a double-flowered variety of *Montbretia crocosmiæflora*. This plant flowered at Kew this year; is in flower now in fact, and unless it improves upon its present appearance, it is not likely to find much favour except on account of its doubleness.

As an instance of how rapidly these plants increase under cultivation, I may mention a case recorded a few years ago from Sydney, where in less than five years six corms of *T. aurea* obtained from England and planted in a bed in one of the parks filled a space 4 feet in diameter and was a thick sheaf of spikes 3 feet high. It increases almost as rapidly here if planted in a good position in light rich soil.—W. W.

— *Tritonias* are amongst the most brilliant of late summer and autumn border subjects, and they are worthily fast coming to the front because of their long duration and desirable colours. I am now speaking, of course, of the large class of hybrids, so distinctly superior to the types whence they sprung, and which have so long had the special and intelligent care of the firm of V. Lemoine et fils and others. As a matter of fact, there is considerable variety, and the variety is widening every year. It may perhaps be useful to point out that whereas these flowers are more properly, or at least better authorised under the generic name *Tritonia*, which now includes *Crocoshia* and *Montbretia*, many of these richly coloured hybrid Irids may be better recognised by the name *Montbretia*. It may be well also on another score to recall these facts of nomenclature because, as I believe, they have most directly to do with the employment of the flowers in the open garden. I believe it is true that the want of hardiness of the bulbs has been the chief cause of the slow introduction, at least of the older sorts, but under the more familiar name *Montbretia* we have come to see that they are really hardier than we supposed, and it is really the case that the hybrids are hardier than, say, the typical *Tritonia aurea* (syn., *Crocoshia aurea*). It is doubtless inconvenient that so many names should surround the same class of flowers. Let me say, however, that these good things should not longer be neglected for open garden purposes, as with very little care indeed they are safe in the coldest winters in my Yorkshire climate. The care implied means that the bulbs should be set in light, but rich soil in March at a depth of 8 inches. I have kept some of the older sorts going for years with no extra trouble, but a further precaution might be advisable, that of a mulching of cocoa-nut fibre as soon as the plants have received their first cut by early frost. The two varieties shown on coloured plate are new and remarkable for their larger-sized flowers, otherwise they are representative of the large number of kinds. To my mind the bright colours of these flowers can never have justice done to them on paper compared with their living richness as seen in the garden with verdant surroundings.—J. WOOD, *Kirkstall*.

Veronica Jardin Fleuriste.—Some years ago I had, on the late Mr. Downie's recommendation, a few plants of a dark rose-coloured *Veronica* named *Jardin Fleuriste*. About that time I was replanting the climbers on the front of the resident agent's house, which is situated on a higher level than the gardens here. One of the *Veronicas*

* Drawn for THE GARDEN by Champion Jones in the Royal Gardens, Kew, August 8, 1892. Lithographed and printed by Guillaume Severeys.

ORCHIDOPSIS ... *ORCHIDOPSIS* ... *ORCHIDOPSIS* ... *ORCHIDOPSIS* ... *ORCHIDOPSIS* ...

was planted there at the time, the others were kept in pots. The Veronica planted out has bloomed in the late autumn of each year since planting, and at the present time it is in great beauty, being a mass of dark rose-coloured spikes of flower. Where Veronicas do well this is a valuable acquisition, and well worth a good position. The plants left in pots bloomed well the first year or two, but have got leggy. I will plant them out and increase the stock. I send you a flower or two of it. I do not see the name in any trade lists of Veronicas; probably it may be grown under some other name.—D. M., *Dunrobin*.

* * * A richly coloured, fine variety.—ED.

THE WEEK'S WORK.

THE KITCHEN GARDEN.

SOWING PEAS.—Although to a certain extent the sowing of Peas in November for the earliest crop has been abandoned, on account of the ready manner in which they may be forwarded under glass at the turn of the year, yet it is a system which still finds many advocates. Where they succeed generally is where the soil is of a sandy or gravelly description. The site chosen must also be well open to the sun. Before sowing fork the soil well over, adding also burned refuse and well-rotted manure. In the case of those soils where Peas do not succeed very well, the addition of some steamed bone flour will assist the growth considerably. It will also be necessary to sow the seeds rather thickly at this season, but previous to sowing it is advisable either to dress them over with a coating of red lead or even petroleum as a safeguard against the attacks of mice. The drills should be drawn with a flat bottom, and directly the points of the young plants appear, keep a sharp look out so that they do not receive injury, especially from birds. If slugs are troublesome, it is a good method to sprinkle a thin layer of sawdust along the lines, as on this material these marauders do not care to travel. The best varieties for sowing now are William I. and Veitch's Selected Early. The early dwarfs are not so well adapted for sowing at this season, but they will succeed on a warm and well-drained border. The rows of the former varieties should be 4 feet apart, and in the case of dwarfs 30 inches.

BROAD BEANS.—The best variety for sowing at this season of the year is Beck's Dwarf Green Gem. This should be sown in drills 30 inches apart. As long as the site is open and sunny Broad Beans will succeed, so space need not be taken up on a south border. But it is advisable to sow a row or two extra as a safeguard against injury, for as the Broad Bean may be readily transplanted, these extra rows will prove useful for filling up any gaps in the spring.

FORCING ASPARAGUS.—This is very readily forced, as with plenty of strong roots available, there need be but little fear that a supply will not be forthcoming as long as the requisite heat and moisture can be afforded. Asparagus may be forced readily on a hotbed, but it is more convenient to force it in a heated pit with a bottom-heat afforded by a body of fermenting material, this causing a genial heat about the roots. Asparagus may also be forced in any low and heated span-roofed structure as long as there is a bed for placing the roots into. In the case of forcing by the aid of a hotbed, see that the bed is efficiently made so that the heat may be regularly maintained. Tree leaves being abundant at this season should form quite one-half, the whole being well prepared by turning. The bed should be at the least 4 feet in depth and be made 6 inches larger than the frame all round. If good strong roots are not very plentiful, it is not good policy to commence forcing too early, the produce perhaps proving more valuable at the turn of the day. But in any case a layer of soil to the depth of 2 inches should be first placed over the bed, the roots being packed closely together and covered

over with the same depth of soil. A bottom-heat of 80° and a top-heat of 55° or 60° in pits where the temperature can be regulated is sufficiently high. Whether blanched produce should be provided is a matter of individual taste. If this is needed it is easily secured by excluding light. With a plentiful supply of strong roots, a batch put in to force at intervals of three weeks will result in an almost regular supply. Even if not required it will keep for three or four days if the ends are placed in water and kept in a cool place.

FORCING RHUBARB.—After a rest Rhubarb forces readily enough if given a position where a genial heat can be maintained with sufficient moisture about the roots. I have not yet found any better than Hawke's Champagne and the Early Red. Strong two-year-old roots can be forced as easily as roots of older growth, so there need not be any scruples about the roots not being strong enough if of the age stated. Where Rhubarb may be forced is often a matter of convenience. At this early date the temperature of the Mushroom house is not high enough to ensure a quick growth. The crowns will soon start if placed under a stage in a warm plant house, surrounding them so as to exclude light and allowing sufficient head room so that the stalks may rise. The roots should also be well surrounded with soil, as they will give treble the amount of produce than if left exposed or the roots merely stood on the surface. Rhubarb may also be forced quickly by packing the roots in deep pits in which have been placed leaves and litter for bottom heat.

FORCING SEAKALE.—To secure good Seakale early in the season two things are very necessary, viz., strong roots and a thorough rest. Therefore, for this latter reason do not be in too great a hurry to take up more than is requisite for a batch, as the rest is more thorough by the roots being left in the ground, a supply of course being anticipated by taking up sufficient to keep up the supply in case of frost. In this latter case lay the roots in a cool shed, merely covering with an old mat. As in the case of Rhubarb, the temperature of the Mushroom house is not sufficiently high enough to ensure the crowns starting readily into growth, but this can be obviated by forming a pit within this structure or any other shed, the heat being maintained with the aid of fermenting material. This method of forcing I have previously alluded to, so I need not further refer to it. What is wanted is a temperature high enough to force growth, but not so high as to cause a very rapid growth, or the produce will be tough when cooked. Light must also be quite excluded and the soil about the roots kept moist. For a small supply the roots are often packed in conveniently-sized pots, light being excluded by placing another over the top, the holes also being closed, and these placed in warm corners under the stage of plant houses. The only fault I find with this method is that the pot used for covering is apt to cramp the growth. A better system is to pack the pots or even the roots in soil in a kind of cupboard placed beneath the stage.

A. YOUNG.

ORCHIDS.

As I write the wind from the north-east, bitterly cold, is blowing upon our cool Orchid house. As I have previously hinted, I do not mind a little frost if unaccompanied by wind, but these cold east winds when the house is fully exposed to them find out every cranny. After growing cool Orchids in a span-roofed house exposed to all quarters but the east, and also in a lean-to exposed to the north and east, I would now recommend the span-roofed form; exposure to continued east winds certainly does not suit them. I consider the Masdevallias from the high mountains of South America, such as *M. Veitchiana*, *M. Harryana*, *M. Lindenii*, *M. ignea*, and *M. Davisii*, as amongst the most beautiful of the inmates of this house, and yet they have fallen into comparative neglect. When the beautiful varieties of *M. Harryana*, first imported by Messrs. Veitch, of Chelsea, flowered, very high prices indeed were paid for the best

varieties. The Bull's Blood variety, which I believe first flowered in the then famous Meadowbank collection, was sold at a very high price—ten and fifteen guineas for very small plants. This and the variety *M. H. sanguinea* were the best of the dark coloured forms. *M. H. cœrulea* and varieties of that type added a distinct feature to the paler coloured varieties. *M. Veitchiana* is in itself a remarkably fine species and in every respect distinct. There is a well-marked form grown in gardens under the name of *M. Veitchiana grandiflora*. The ordinary forms of *M. ignea* are of no great beauty, but the varieties *M. ignea Massangeana* and *M. ignea superba* are very handsome, and, as a rule, they flower before the others in the spring. *M. Lindenii* is next, closely followed by *M. Harryana* and *M. Veitchii*. I am aware that *M. Harryana* and *M. Lindenii* are now stated to be synonymous with *M. coccinea*, but for garden purposes Dr. Reichenbach's name will always be used. All the above require similar treatment, and should be placed at the warm end of the cool house. *Masdevallias* in many collections become disfigured by the leaves becoming marked with blackish blotches. This, I find, takes place much more in the houses with a northern aspect than it does in the span-roofed form of house. The plants require considerable supplies of water, even in winter; the Sphagnum Moss should not be allowed to become discoloured by being dried up. I grow the pretty little *M. Wagneriana* in pans and baskets near the glass roof of the cool house. This is easily grown and a plant or two should be in every collection. *M. polysticta* is also one that every amateur should grow a plant or two of. The flowers are whitish, distinctly spotted, and produced on a many-flowered inflorescence. *M. Davisii*, a high mountain species, is distinct and pretty, its flowers being yellow of various shades. I advise growing them in a minimum temperature of 50°. In our cool house, 60 feet long, the temperature ranges between this and 40° at the coolest end, and here I may add that the plants may be arranged with the *Masdevallias* at the warmest end, the *Odontoglossums* of the *O. triumphans*, *O. crispum*, *O. Pescatorei*, &c., in the middle, and the *Oncidiums* of the *O. macranthum* type at the coolest end. *Maxillaria grandiflora* will also do well in the coolest part of the house.

The plants had been thoroughly rearranged and cleaned a month ago, and this winter I am placing them upon the shell gravel stage instead of on the inverted flower-pots arranged upon it. This may be contrary to the usual practice, and I only advise it when the house is, as ours is, quite exposed to the east and north. In a sheltered house I would recommend a chink of air to be left on all night in fine weather. When the house is exposed it will be better to shut it close up. I do not care to do any potting in the cool house after the middle of November; indeed it may not be desirable to do much now in any of the houses. The potting has been delayed owing to pressure of other work in another direction, but it is yet time to repot the *Cymbidium Lowianum*. I have a few large specimens which it takes two men to move which will be repotted this week. I have generally repotted these plants in November, and they have done very well indeed. The usual Orchid peat and Sphagnum mixture is too light for them, but a little may be used with yellow loam, sand, and decayed manure.

Even now with our greatly increased knowledge many growers cannot believe that all Orchids must not be treated alike. Some very choice and beautiful Orchids are terrestrial and grow in loam, sometimes in very moist loam. Most of the *Cymbidiums* will do best with a liberal proportion of loam in the soil, amongst them the beautiful variety referred to above; also *C. eburneum*, which does best in quite moist loam. This beautiful species, once so rare, is now quite plentiful, but it is not yet, and probably never will be, a cheap plant when grown into good specimens, for it takes a long time to grow large. I have seen a moderate specimen sold at Stevens' sale rooms for seventy guineas. This, of course, was before the modern importations. The spotted variety *Dayi*

and the more freely spotted and exceedingly rare Parishii are of greater value. We have also now in flower *C. Mastersi*, or *Cyperorchis Mastersi* of Hooker's "Flora of British India." The drooping racemes of ivory-white flowers are very pretty, and, blooming as it usually does in November, the flowers are doubly welcome. I generally repot this plant when it passes out of bloom, using a compost of loam. All these *Cymbidiums* seem to do best on the shady side of the Cattleya house. When repotting them great care must be taken not to injure the thick fleshy roots. Generally they soon take to the fresh compost, and the roots may be seen running freely near the surface, and if that is covered with fresh Sphagnum the roots will push up out of the loam. The temperatures should be now at their lowest winter mean. Over-heating may do much harm.

J. DOUGLAS.

PLANT HOUSES.

STOVES.—In all probability the stove will now be fully occupied with plants which in some instances have been out of it for a time during the summer. It requires some amount of scheming and management to make the most of the room at disposal, for if the plants be crowded together indiscriminately, they will in nearly every case suffer before many weeks are past.

Under the supposition that some few specimens at least are being grown, it will be advisable to look these through and see what can be done in their case to make more room. If these happen to be *Crotons* which it is needful to retain, now is a good and suitable time to prune them, having first allowed them to become dry at the roots. The shoots taken off can be struck for a young stock, selecting only the best and cleanest growths, weakly or stunted wood not being in any sense desirable. After the pruning, the plants can be tied so as to regulate the growth; it is better to do this at once than to leave it until young shoots again appear. Any fresh potting, however, may advantageously be left until the spring unless the soil be absolutely in a bad state. Should a pit be at liberty where these cut-back plants can be placed for a time (provided, of course, that the temperature can be maintained as high as that of the stove), it would be all the better as far as appearance goes. In any case they should be kept close up to the glass. The first few leaves that are made may be of a greenish colour, but soon the proper tints will be assumed by the rest. Cutting back *Crotons* at this season is a good way of obtaining well-coloured specimens for exhibition another year. It also saves labour in cleaning to a large extent where insect pests are troublesome. Of other plants, the *Allamandas*, *Clerodendrons*, *Vincas* and *Bougainvilleas* will now all be capable of considerable reduction in their dimensions. Semi-pruning will not in either case do any harm, provided the plants be dry at the roots. After this has been attended to, such as the *Allamandas* can be twisted around stakes so as to take but little more space than the pots occupy. If the plants happen to be trained on the roof, then it will be advisable to thin out the wood, taking away the weakest so as to admit more light. Take particular care, however, that no plants are crowded out of the stove into cooler houses or pits. This has been the ruin of many a *Clerodendron* or *Allamanda* in the winter; a temperature of 55° should be considered the minimum, and this had better not be touched too frequently.

In dealing with plants of evergreen character, as *Ixoras*, the use of the knife at this season should be avoided except to thin out weakly wood. The *Stephanotis* should not be touched save for the same purpose in a moderate way. Some of the fine-leaved plants will possibly bear some reduction. These frequently take up a lot of room that cannot well be afforded all the winter through. Where Palms show signs of casting a leaf or two these can be removed without any trouble. *Marantas* often take too much room; so do *Anthuriums* and *Alocasias*. These should be treated in the same way as far as is consistent; then the

remaining leaves can often be drawn more together as a further assistance. *Dracenas* are more difficult to treat in this way, but if any of the larger sorts are growing too tall, the present is a suitable time to make a start in rooting the tops off. This process has been described, but it will bear repetition. Some growers depend merely on Moss as a rooting medium around where the incision of the stem has been made, but personally I much prefer soil and Moss combined, this being packed firmly into a small pot which has previously been sawn asunder and then bound together again, with the stem in the centre, the hole in the pot having been made larger to fit it. In such a case the incision should be just below the pot for further convenience in gradual separation. This process takes a little longer to do, but the rooting will be facilitated afterwards and the safety of the top made all the more certain. Large plants of *Pandanus Veitchi* are oftentimes an encumbrance than otherwise. If any such be not needed and the stock is short, let them go for propagation only; in that case all the strong leaves may be cut off and the crown of the plant stopped from making further growth by thrusting a red hot iron into its centre; this is done by those who propagate largely.

A caution against letting *Caladiums* become checked, or, for that, killed outright, is at this season opportune. Now that they have lost their foliage they must not in any sense be trifled with; nothing less than the temperature of a stove will be safe for them during their resting period, and there, even a warm corner is the most secure. Guard against excessive drought by an occasional watering, otherwise dry rot may be induced. *Gloxinias*, *Gesneras* and *Achimenes* will, on the other hand, be safe enough where the temperature does not often drop below 50°. Where *Gloriosa superba* is grown see to it that a label is in the pot, otherwise by mere accident the tubers may be lost. In the arrangement of the stove contrive to find the most suitable place for each class of plant. There are those which will do best in a dry, hot corner, as the variegated Pine-apple, the *Pandanads*, the *Vriesias*, and other bromeliaceous plants, whilst others, as *Crotons*, &c., will be more at home at the moister end. In this way each may be accommodated to its peculiar liking. Another good plan is to frequently re-arrange the plants; it is all the better for them, whilst it also affords a change at a season when every additional attraction is of essential service. In lean-to houses this is even more desirable than in span-roofed ones in order to keep the plants from becoming too much one-sided.

JAMES HUDSON.

FRUIT HOUSES.

PREPARING FIGS FOR FORCING.—Trees in pots will start all the more strongly and quickly if first exposed to moderately severe frosts, and there need not, therefore, be any hurry in getting these housed. Those permanently planted, and which are also to be forced somewhat early, ought now to be thinned out, foreshortening being freely resorted to in all cases where they are becoming too large for the space allotted them. Any infested with scale, mealy bug, and such like should be given a scrubbing with hot soapy water and be further dressed with Gishurst compound or other insecticide used as advised by the vendors. The petroleum remedy recommended for Peach trees is not suitable for Figs, the wood of the latter being softer, more porous, and therefore more susceptible of injury from strong penetrating insecticides. Trained trees should be taken down to admit of the glass and woodwork being thoroughly cleaned and the walls dressed with hot lime water, after which they can be re-tied. It should be remembered that the first crop next season will be borne at the points of all well-ripened young shoots, and good care should, therefore, be taken of these throughout. Trees trained against back walls are not, as a rule, very fruitful, a few of the leading branches trained 3 feet or so down the roof producing more fruit than the whole of the wood against the wall. Old trees

rooting in borders not recently renewed after the manner Vine borders are frequently treated ought to have the surface roots hared and then be given a rich top-dressing, a mixture of fresh loam, mortar rubbish, and fresh horse manure being given when the borders are not badly exhausted. Trees that are disposed to grow too strongly, this meaning light crops of fruit, should be partially lifted and freely root-pruned, fresh loam with mortar rubbish or chalk being substituted for the old soil and rammed down rather firmly. From the middle to the end of November is a good time to start Figs in pots that are to produce ripe fruit in April and May, the first week in January being quite soon enough to start trees permanently planted. In the meantime give the latter a thorough rest, not troubling to exclude a moderately severe frost.

PROTECTING VINE BORDERS.—Where the Vines carrying the latest bunches are rooting principally in outside borders, these latter ought to be covered with either shutters, strips of galvanised iron, spare lights, or other material that will ward off heavy rains. Grapes not keeping well when the borders are badly saturated. Vines that are to be started rather early ought to have their roots solely or principally inside the house, but if the front walls are arched or the roots have access to an outside border, that is where they will mostly be found. Till such time, therefore, as mild hot-beds are formed on these outside borders, they ought to be rather heavily covered with fresh leaves kept in position by either a straw thatching, boards, or shutters, this being done to prevent an undue lowering of the temperature. In the case of Vines that will not be started much before the end of February there is no necessity for covering these with either manure, leaves, or other material, as they would be all the better exposed to the sweetening influences of frosts, winds, sunshine, and rain. If a thin summer mulch of manure has been left on the borders, surface this over with newly-slaked lime and lightly fork it up. What few roots are damaged by this or are injured by frosts will be more than compensated for by the improved fertility of the border. All exposed stems, whether or not forcing is to be resorted to, should be carefully protected with hay bands, or else be enclosed in boxes large enough to hold a good packing of dry sawdust. Frosts do not injure the stems while the Vines are completely at rest, but would quickly rupture the sap vessels directly the sap commences to liquefy. If done now there will then be no risks run. It ought, perhaps, to be added that quite new borders or newly-added widths being liable to become badly saturated should be covered with a view to warding off heavy rainfall as much as possible.

STRAWBERRIES IN POTS.—It need hardly be pointed out that both the roots and plants are perfectly hardy, and the protection of glazed lights, pits or frames is quite uncalled for. Moreover, if Strawberry plants are so protected, they are very liable to become infested with green-fly and red spider and not unfrequently are kept too much on the dry side at the roots. Instead of being injured by frosts, the plants usually flower more quickly and strongly after being well frosted, this being especially apparent in the case of those started extra early. Nor do heavy rains have any marked prejudicial effect upon the plants, always provided worms are kept out of the pots and the drainage is good. At the same time if glazed lights can be spared, these may well be placed over the plants when heavy rains are imminent. But if the plants are hardy, the pots are not, or at any rate they crack badly if the soil they contain expands considerably by the action of frosts, and all ought, therefore, to be plunged up to the top of the rims in either ashes or fresh Oak leaves, packing them as closely together as possible, all being enclosed by rough frames. Vicomtesse Héricart de Thury is the best for extra early forcing, but it is not advisable to start a batch before December, the first week in January being quite early enough to commence forcing in most establishments. Any that have been lifted from the open ground well furnished with fruit in various sizes ought now to have the benefit of gentle heat, the shelves at the

back of well-ventilated forcing houses suiting them well. The fruit presents a more attractive appearance and ripens the more surely when the clusters are raised well clear of the rim of the pots by the aid of Birch or Hazel crutches, or they may be lightly staked up.

FRUIT TREES IN POTS.—These, in addition to being in the way if housed, are also all the better for the more thorough rest brought about by keeping them outside till the time arrives for starting them. Stand them on a good bed of fresh ashes and heavily bank over the pots with either fresh strawy litter, Bracken or leaves faced over with strawy litter. In the neighbourhood of towns sparrows are apt to help themselves to fruit-buds, but will not touch them if they are kept well coated with soot and lime-water applied through a garden syringe.

PRACTICAL.

ORCHIDS.

ONCIDIUM VARICOSUM ROGERSI.

I AM asked by Joseph Holmes to say a few words about this variety, so that he may form some idea of what it is like, as so many people find that what they send is nothing but the species. This fact I do not doubt. If "J.H." has a good plant of the species now in flower, I should say that he has reason to be proud of it, for it is a very gay and showy kind, producing a strong spike bearing many flowers of a fair size and of a rich golden yellow colour. The flowers last a very long time in full perfection, but in size the individual blooms cannot be compared with those of the variety *Rogersi*. Messrs. Rollisson, of Tooting, imported a great number of this species from San Paulo, and there were many fine forms amongst the plants, but none of the variety *Rogersi*. The plant was known to Lindley nearly fifty years ago, but not in a living state. It first flowered some long time after its discovery in the Horticultural Society's garden at Chiswick, and it was long after this occurred that I first saw the plant blooming. The variety originated amongst some imported plants in the garden of Dr. Rogers, then living at East Grinstead, in Sussex, in 1868, but I did not see it until two years later, when Dr. Rogers' plant was in the possession of the Messrs. Veitch, of Chelsea, where I saw it flowering in a hanging basket. The plant carried a large branching spike, which bore 170 flowers. This magnificent spike made quite an impression upon my mind, and I have only seen the true plant once since, and that was in the possession of Mr. Woodall, of Scarborough, who had a very fine form of it which he told me was brought from the garden of the Emperor of Brazil. I hope the plant is still in his keeping. It is a stout, robust-growing Orchid, with intense deep green pseudo-bulbs, which are deeply furrowed towards the top, where they are stained with flakes of black. The leaves, in pairs from the apex and about 1 foot in length, are strap-shaped, of a deep green colour on the upper side, paler beneath. The spike springs from the side of the pseudo-bulb at its base and becomes much branched. Each flower measures nearly 2½ in. across, the sepals and petals being small, the lip large and flat, having three deep clefts or notches in front. The colour is bright clear yellow, with, at the base, a few cross bars of reddish brown, which in this variety are very small. The plant enjoys a tolerably warm temperature and should be grown in the *Cattleya* house, which in the winter months will fall to about 55° at night, rising to 60° and 65° in the daytime. In the summer season it may be re-

moved to the warm end of the cool house. At this time it enjoys plenty of moisture in the atmosphere, but even when at rest, in spite of its stout bulbs, which might lead one to infer that it would withstand drought unharmed, it likes to be kept fairly moist. After flowering, if the growths have not made a start, I would advise its removal to the cool house. If, however, the shoots have begun to push, allow it to remain in the *Cattleya* house. Drain well and pot in a mixture of good brown peat fibre and Sphagnum Moss, pressing it down firmly so as to make a good hold for the roots, for I think many Orchids are lost through bad potting.

WM. HUGH GOWER.

Dendrobium Phalænopsis Broomeanum.

—Flowers of this beautiful variety come to hand from Mr. Broome, of Llandudno. They are of large size, measuring some 4 inches across, with broad sepals and petals. The ground colour is white, the petals tipped with crimson-lake; lip large. The front lobe has a ground colour of rosy carmine, streaked with crimson-lake. It is a superb flower. Another form marked B appears to me to be only the typical form of the species. W. G.

Orchids at autumn shows.—Although *Chrysanthemums* are the chief features at this season, a few good Orchids afford a charming variety. I have been struck with this just recently both at a suburban and a country exhibition. At both of these gatherings there were some excellent examples of Orchids in season. These were in the one case shown as individual specimens, whilst in the other they were arranged in groups. The latter was certainly the most commendable method, but of course it took a few more plants, whilst small ones could be used to good advantage. In the other the various competing exhibits were rather too uneven in size, although in each case excellent. The groups also possessed a finish that the others did not by reason of the addition of small Ferns and other suitable decorative material. Another fact which should be borne in mind, and one which is favourable to the grouping, is that small plants can be carried securely in boxes, which is far better than letting them be exposed during transit in a covered van. Not only as plants were Orchids shown in these instances, but they also entered into floral arrangements, as for bouquets, stands for the table, &c., and with good effect. Fortunately for those who reside within the fog radius, there has not yet been a visitation this autumn of any material consequence. Orchid growers can congratulate themselves on this fact.—H.

Cattleya labiata.—Mr. Broome sends me three excellent forms of this from recently imported plants. The flowers are of good size and excellent colour, especially those marked 1 and 2. I think No. 1 is the best in colour, but it is not the best shaped flower, having somewhat small petals. The front lobe of the lip is remarkably rich in colour.—H. G.

— I have a great number of blooms of this fine old species for an opinion, and I am not surprised that everyone is proud of having such beautiful flowers so near the end of the year. Even poor forms are valuable at this season. Those who prefer pale forms having much similarity to the *Gaskelliana* type would be well satisfied with the flowers sent by Thos. Malcomb. The Hon. Miss Winn, however, sends the second bloom of a beautiful dark coloured variety, the front lobe being very rich and heavily coloured, which is the part that J. Barclay's flowers appear most deficient in. In the flower received from J. Meston the sepals and petals have a rather deep shading of rosy lilac, and the lip is poorly marked. It is a somewhat poor form, certainly very inferior to the variety *Sandere*, and not at all like it. J. Cheesman sends three flowers, of which one only, marked No. 2, is worthy of notice. This has large and broad sepals and petals of a dark rosy purple,

and a very deep coloured lip, but not so rich as in the flower sent by the Hon. Miss Winn.—W. H. G.

Cattleya aurea Statteriana.—From Mr. Wheatly, of Ringmore, Devon, comes a flower of this chaste and lovely variety, which is figured in the "Orchid Album," t. 468. It has pure white sepals and petals, and the large lip intense deep crimson-magenta, having a velvety appearance. Mr. Rolfe says in the "Orchid Review" that this plant is figured in the "Lindenia" as *C. Hardyana Statteriana*, and suggests that it is a natural cross between that plant and *C. aurea*. From this opinion I differ, as the plant now under consideration does not appear to have any of the characters of *C. Hardyana*, which again is a supposed natural hybrid. The flowers are very fragrant, and it is one of the most beautiful of the autumn-blooming *Cattleyas*. Mr. Wheatly bought it for *C. Dowiana*.—G.

Cattleya aurea and others.—A flower of this kind comes from Mr. Wheatly; it was past its best upon arrival. Some people complain that it is a shy bloomer, but Mr. Wheatly says his plant made four bulbs from its two leading growths, and all produced flowers within a month, so that no one can say that it is shy flowering. The same person also sends me a flower of *C. maxima*, which appears to have been a very good variety, but it was too far gone for me to form an opinion. A very nice flower of *C. labiata* was also sent. The colour of this was very good, but it is the form which I recognise as *C. labiata Warocqueana*. A very fine form of *C. gigas* was also sent.—W.

SHORT NOTES.—ORCHIDS.

Laelias from Down House.—Mr. Denny sends me two varieties of a *Laelia* which he says were bought for *L. majalis*, but which do not resemble that species in the least. They appear to be quite new, but I should much like to see them again.—H.

Dendrobium Phalænopsis Schroederianum.—The more one sees of this variety the more one must admire it. A very nice lot of blooms came to hand the other day from Mr. Harris, Bowden House, Calne. They were principally light coloured forms with richly coloured lips. There was also included a fine broad-petalled form of *Cattleya Bowringiana*, which is about the brightest and darkest variety that I have ever noted.—C.

Saccolabium Blumei majus.—J. Harding sends me a fine spike of this plant under the name of *S. guttatum*. The spike sent measures 18 inches in length, the flowers waxy and thickly set, sepals and petals creamy white, faintly dotted with pale rose, the recurved lip being rosy magenta. It forms a beautiful pendent spike.—G.

FLOWER GARDEN.

THE ANDROSACES.

THE genus *Androsace* (of Linnæus), which belongs to the family of the *Primulacæ*, is the most alpine and the most characteristic of the genera of plants that are found growing on mountains. It comprises a number of plants which may be considered as typical of the alpine flora, properly so called, and represents the character of the vegetation of the lofty summits, at least so far as the perennial species, the only ones to which I am now referring, are concerned. It is the true "Flowering Moss"—the quintessence of everything brilliant and beautiful that is found in the flora of the high mountain ranges. It is, indeed, essentially a mountain genus, and more especially a European one, notwithstanding the fact that the mountains of Central Asia are the native home of a much larger number of species of

Androsace than that which is found on our Alps; but as the number of those Asiatic species which have been introduced into cultivation is very limited, it is true to say, from a horticultural point of view (from which I am now writing), that this genus is chiefly a European one. The chain of the Alps and that of the Jura present to us twenty endemic species, that is, species which are peculiar to the soil which produces them, and are the true daughters of these mountains. The Pyrenees afford four species which are exclusively confined to that chain. In the Caucasus also four species are found and the same number in Siberia. Lastly, nearly thirty species have their habitat in the Himalayas, the province of Yun-nan and the mountains of other parts of China.

From a cultural point of view, the genus may be divided into two classes, viz. (1) the open-soil kinds, which grow naturally in the pastures or on turf or rocky declivities, and (2) the rock species, which are found only in clefts of rocks. Of the first-named of these two classes, the following species are in cultivation:—

ANDROSACE CARNEA, L. (A. Halleri, Gmel.; Aretia Halleri, L.).—A native of the alpine region of the granitic Alps, the Vosges, the mountains of Auvergne and the Pyrenees at an altitude of 2000 mètres to 2500 mètres. A dwarf and caespitose plant, composed of a greater or less number of loosely-formed rosettes of linear-acute leaves, which are slightly glaucous and fringed with very short hairs; stems erect, from 2 inches to over 3 inches in height, each bearing at its extremity a small umbel of flesh-pink flowers in the months of April and May. It likes a siliceous soil and should be planted in heath-soil or peat, to which has been added a little sand that has no lime in it, on rockwork in a position half exposed to the sun. Multiplied by sowing the seed.

A. CHAMÆJASME (Willd.).—A native of the pastures of the calcareous Alps at an altitude between 1500 mètres and 2500 mètres, and also of the Atlas range, Siberia, the Caucasus, and the arctic regions of the northern hemisphere. In Eastern Thibet it has been found on lofty mountain summits at an altitude of 4000 mètres to 4500 mètres. A small plant with a branching root-stock and ciliated leaves disposed in spreading rosettes. The flowers are white with a light yellow disc at the throat, which changes to a bright pink colour and increases in width after the fertilisation of the flower has taken place. They are borne in a small umbel of three to six flowers on stems from 2 inches to over 3 inches high in the months of April and May. This plant does well under the same culture as the preceding one, except that it requires some lime in the soil in which it is planted. Multiplied by offsets or by sowing the seed.

A. FOLIOSA (Duby.).—A native of the rocky pastures of the Western Himalayas at an altitude of 3000 mètres to 4000 mètres. Leaves large, ciliated at the margin, and somewhat resembling the leaves of Daisies; in autumn they turn red, like the leaves of the wild Vine. Flowers large, of a light pink or lilac colour, and borne in an umbel on stems from 4 inches to 8 inches high in May and August. Rockwork, in deep soil, composed of leaf-soil, loam, and sand, in a position half shaded from the sun. Multiplied by division of the tufts, or from cuttings, or seed, when any is produced, which rarely occurs with us.

A. LACTEA, L. (A. pauciflora, Vill.).—A native of the calcareous Alps, the Cevennes, Jura, and the Carpathian Mountains at an altitude of 1000 mètres to 1500 mètres. Leaves deep green, glistening, disposed in pleasing rosettes. Flowers large, pure white, with a yellow disc at the throat, and borne in a broad, loose umbel of five or six flowers in April and May. This is one of the species that are easily grown. Rockwork, in light calcareous soil, and either fully or half exposed to the sun. Multiplied by sowing the seed.

A. LAGGERI (Huet.).—A native of the Pyrenees, at an altitude of 1800 mètres to 2400 mètres. The

prettiest of early spring plants, this is of a tufty caespitose habit of growth, with very narrow (almost aciculate) lanceolate leaves, arranged very closely together, and forming a very fine turf-like clump of a cheerful green colour. Flowers of a bright pink colour, borne in a small umbel of three to five flowers, which are sessile before fertilisation takes place, after which the flower-stalks commence to grow and increase in length as the flowers advance in age. In the months of February, March, and April the tuft is literally covered with flowers. Rockwork, in the full sun. Soil, the same as for *A. carnea*. Multiplied by sowing the seed.

A. LANUGINOSA (Wall.).—A native of the Western Himalayas, at an altitude of 2000 mètres to 3000 mètres, where it covers large areas of rocks. A trailing plant with branching, creeping stems, prostrate on the ground, and furnished with alternate sessile leaves disposed in rosettes at every branch of the stem. The whole plant is covered with long silky hairs, which impart to it a very singular satiny aspect. Flowers of a violet colour with a bright pink disc in the centre, disposed in closely-set umbels of twelve to twenty flowers in each umbel, and borne on a stalk 4 inches to 4½ inches high. The plant flowers from May to November, and forms broad silvery tufts which have a very fine effect. Rockwork or in the open ground, and fully exposed to the sun. Multiplied from cuttings struck in a cool frame in August. *A. oculata* (Hort.) is a variety of this species, with a more slender habit and pale lilac, almost white flowers. Same treatment.

A. OBTUSIFOLIA, All. (A. brevifolia, Vill.).—A native of dry, rocky pastures on the Alps and the Carpathian Mountains, at an altitude of 1700 mètres to 2500 mètres. Leaves lanceolate-oblong, fringed with very short hairs. Flowers white, with a light pink disc in the centre, disposed in a small corymb of four to six flowers, and borne on a slender stem 2 inches to 4 inches high in the months of May and June. Rockwork, in heath-soil, and fully exposed to the sun. Multiplied by sowing the seed.

A. ROTUNDIFOLIA, Hardw. (A. incisa, Wall.).—A native of the alpine regions of Nepal, and a curious species, forming a dwarf caespitose tuft with orbicular, incised leaves resembling those of *Saxifraga rotundifolia*, but of smaller size. Flowers small, of a lilac-pink colour, and disposed in a dense umbel of no great size. This species is grown at Kew and by some amateurs in England. I have never succeeded in growing it here, and I have never seen it grown anywhere else on the Continent.

A. SARMENTOSA (Wall.).—A native of the sub-alpine districts of Cashmere, Sikkim, and Nepal. A stoloniferous, creeping plant, distinguishable from *A. lanuginosa* by its very slender, bare stems and its velvety-tomentose leaves, which are disposed in broad rosettes at the divisional parts of the stems. Flowers lilac, in handsome umbels, and blooming from May to August. Rockwork, fully exposed to the sun. Multiplied by offsets. We cultivate in our alpine garden here, under the name of *Androsace Chumbyi*, a superb variety of this species, which might well be considered a distinct type. This is not a creeping plant, or, more correctly speaking, it is very slightly so. Its foliage is much more velvety, and its flowers are of larger size and of a fine carmine colour. Rockwork, fully exposed to the sun. It flowers in May and June.

A. SEMPERVIVOIDES (Jacquemont).—A native of Western Thibet at an altitude of 2000 mètres to 3000 mètres. This is a remarkable species, coming very close to *A. sarmentosa*, but distinguished from it by the resemblance to dry cones which is presented by its rosettes, the leaves of which curl up, much like those of *Sempervivum arachnoideum*. The flowers are of a bright purple colour, and bloom in May and June. Culture and propagation the same as for *A. sarmentosa*.

A. STRIGILLOSA (Franchet).—A native of Yun-nan. A singular-looking plant recently introduced into cultivation, with narrow, rigid, spinescent leaves, forming a closely-set rosette, from which is

produced a fine umbel of pink flowers in the month of May. It is not a stoloniferous species and is multiplied by offsets (when it affords any) or by sowing the seed. Rockwork, fully exposed to the sun. The soil should be rich in humus, but well drained.

A. VILLOSA, L. (A. capitata, Willd.).—A native of the rocky and calcareous declivities of the Western and Eastern Alps at an altitude of 1000 mètres to 2000 mètres; also found on the Jura, Pyrenees, Apennines, Carpathian Mountains, the Caucasus and in the East and Siberia. A plant with a branching root-stock, bearing almost globular rosettes formed of velvety silky leaves, from which spring the flower-stalks, 2 inches or less in height, each bearing three to five flowers, which are of a soft pink colour on the outside and pure white within, with a pink disc at the throat. Blooms in April and May. Rockwork, fully exposed to the sun. Requires lime in the soil, like *A. Chamæjasme*. Multiplied by sowing the seed. *A. arachnoidea* (Della Torre) is a variety that is still more velvety than *A. villosa*.

Of the second class (that of the rock species), the following are in cultivation:—

A. CHARPENTIERI, Heer (Aretia brevis, Hegeh.).—A native of the bare and arid summits of the granitic Alps which tower above Lake Como. It appears to be peculiar to the flora of Italy, as it has never been found in any other part of the world. It presents a well-marked type, being of caespitose and thick-set habit of growth, with small, imbricated, obtuse, pubescent leaves, forming small, closely-set rosettes. Flowers almost sessile, of a very bright carmine pink colour and borne on short, slender, dark brown stalks. Blooms in April. In the clefts of a rockwork (not limestone), half exposed to the sun and in a perpendicular position. Multiplied by sowing the seed.

A. CILIATA, D.C.—A native of the Upper Pyrenees, of caespitose habit, forming small dense tufts. Leaves of a dull deep green colour, fringed at the margin and disposed in rosettes. Flowers large, white, absolutely sessile. Blooms in April and May. Culture, the same as for *A. Charpentieri*.

A. CYLINDRICA, D.C. (A. frutescens, Lap.).—A native of calcareous rocks in Oule de Marboré, Upper Pyrenees. A caespitose plant, forming a small, closely-set tuft, with small leaves, which are covered densely with hairs and are imbricated and pressed closely together, so as to form small cylinders, from the top of which are produced in April and May the white and sessile flowers. It should be planted, fully exposed to the sun, in the clefts of calcareous rockwork. Multiplied by sowing the seed.

A. GLACIALIS, Hoppe (A. pennina, Gand.).—A native of the high granitic Alps at an altitude of 2000 mètres to 3000 mètres. This is one of the handsomest alpine flowers, and no one who has seen it in bloom in the sunshine on the heights, where it glows with an unequalled lustre, can ever forget it. The plant forms a loose, flat, spreading tuft, with branches short or elongated, bearing small, ciliated, pubescent leaves. In spring the tuft is so completely covered with flowers of the brightest pink (changing afterwards to pure white), that nothing can be seen of the foliage. Rockwork, fully exposed to the sun, in a porous cleft where some small fragments of granite can be introduced into the soil and which will be thoroughly drained. Blooms in March and April. Multiplied by sowing the seed.

A. HAUSMANNI (Leyb.).—A native of the Dolomites and the Alps of the Tyrol, at an altitude of 2000 mètres to 2500 mètres. This species is distinguished from *A. helvetica* by its soft pink-coloured flowers, and by its habit of growth being not so thick-set. Same culture.

A. HEBERI (Hegehch.).—A native of the Martin-stosh, at an altitude of 2300 mètres to 2600 mètres. This should be set down as a hybrid between *A. helvetica* and *A. glacialis*. The flowers are of a bright red colour, and the habit of the plant is intermediate between that of *A. helvetica* and that of *A. glacialis*.

A. HELVETICA, Gaud. (A. bryoides, D.C.).—A native of the calcareous districts of the Alps, at an

FLOWER GARDEN NOTES.

altitude of 2000 mètres to 3000 mètres. It is also found on the Carpathian Mountains. A plant with a very branching root-stock, forming a dense compact tuft like a hemispherical pin-cushion or pad, 2 inches or less in height. Leaves small, white, downy, imbricated, and pressed closely together. In April and May the tuft is entirely covered with the white sessile flowers, which are often set so closely together that the foliage is quite hidden from view. Rockwork, fully or half exposed to the sun, in clefts of calcareous rocks. Multiplied by sowing the seed.

A. IMBRICATA, Lam. (*A. argentea*, Gærtn.).—A native of the Western Alps, at an altitude of 2000 mètres to 3000 mètres; also found on the Pyrenees and the Spanish Sierras. This differs from the preceding species in having narrower leaves, which are covered with starry silvery-white hairs, in having a bright pink centre in its white flowers, and in forming denser or more closely-set tufts of foliage. Rockwork, fully exposed to the sun, in clefts of granitic rocks. Multiplied by sowing the seed.

A. PUBESCENS, D.C. (*A. alpina*, Lam.).—A native of the calcareous Alps, at an altitude of 2000 mètres to 3000 mètres; it is also found on the Pyrenees. Forms a small dense tuft of pubescent leaves, which are larger than those of *A. helvetica*, but are similarly arranged in closely-set rosettes, and turn brown or red in autumn. Flowers pure white, sessile. Blooms in April and May. Rockwork, in clefts of calcareous rocks. Multiplied by sowing the seed.

A. PYRENAICA, Lam. (*Aretia pyrenaica*, Leyé).—A charming species found on the Central Pyrenees, and in its white flowers and pubescent, glaucous foliage resembling *A. imbricata*, from which, however, it is very distinct. Same culture.

A. VITALIANA, Wild. (*Primula vitaliana*, L.; *Gregoria vitaliana*, Duby.).—A native of the Upper Alps, Pyrenees, and Spanish Sierras. A handsome, caespitose, stoloniferous plant with silvery-grey foliage composed of narrow-acute leaves, which are covered with a whitish meal or powder. Flowers solitary, sessile, tubular, and of a bright yellow colour. Blooms in March and April. Rockwork, fully exposed to the sun, in soil composed of heath-soil mixed with small pieces of broken flints. Multiplied by sowing the seed or by dividing the tufts.

A. WULFENIANA, Sieb. (*Primula Pacheri*, Leyb.).—A rare species, found on the granitic Alps of the Tyrol and of Carinthia, at an altitude of 2300 mètres to 2600 mètres. The tuft which it forms is not so dense as that of either *A. helvetica* or *A. pubescens* (both of which, however, it resembles), but is loosely set. The flowers are of a bright pink colour, have very short stalks, but are not sessile, and the leaves are covered with divided hairs. It blooms in April and May. Rockwork, half exposed to the sun. Multiplied by sowing the seed.

All the *Androsaces* of this second section, the prevailing characteristics of which are the closely-set and constricted habit of growth of their tufts and their sessile or almost stemless flowers, belong to the flora of the Upper Alps or that of the Pyrenees, and are found nowhere else except on the Spanish and Carpathian Mountains. Nearly all of them should be planted in a vertical or perpendicular position on a rockwork and should be carefully protected from an excess of moisture. In the wild state they are never found on declivities which have a northern aspect nor in open grassy ground, but invariably in the clefts of rocks (often very hard ones) or in rocky debris. This must be remembered when any attempt is made to acclimatise them. In our alpine garden here we raise them from seed, but we have never succeeded in propagating them by dividing the tufts, so that we are of necessity obliged to confine ourselves to Nature's one and only mode of increasing the number of these plants.—HENRI CORREYON, in *Revue Horticole*.

If any alterations are contemplated in the flower garden necessitating a certain amount of ground-work, it is well to put this in hand at once, so that not much remains to be done after the new year. Taking an average of the seasons for some years past, it will be found that most of the hard weather is experienced after the new year, and given four or five weeks' hard frost from that date, it is easy to realise that ground work left entirely until the break up of the severe weather has a great chance of being still in hand, when, owing to the pressure of ordinary work, it becomes a decided nuisance. If there is on any lawns either large or small too great a number of beds, that is, in proportion to the breadth of Grass, a great improvement can be made by the turving up of and the enlargement of others, an improvement which will be the more noticeable when the beds are planted, as so much better an effect can be produced from a limited number of beds on a fairly large scale than from a multitude of tiny ones. Again, the character of a flower garden can often be wonderfully improved by the judicious weeding out of ornamental conifers where these were planted somewhat thickly and are now assuming rather large proportions, blocking out views that would greatly add to the beauty of the garden and giving a heavy tone to the surroundings. This style was greatly in vogue some quarter of a century ago, and although the majority of trees planted may have been of fairly graceful habit and immeasurably superior to the formal hedges and clipped monstrosities dating much further back, yet their density of foliage where they were used to excess has imparted a sameness and a heaviness that are the reverse of pleasing. Thin them out by all means, leaving just one here and there in a suitable position, and give variety and brightness by the substitution of the best of the flowering shrubs.

STARWORTS.—On heavy holding land where they had a firm grip of the soil and the growth was well sustained, these favourite autumn flowers are perhaps still in their beauty, but in the majority of places they have had a short life. Several late flowering varieties have on more than one occasion furnished us with a nice lot of cut blooms at the end of the present month, but I am very doubtful if a single sort will be left this year at that date. The early decay will at least afford opportunity for a correspondingly early lifting, division and replanting where necessary—another piece of flower garden work that may be seen to as soon as possible. The stalks of the tallest Starworts and hardy *Fuchsias* make excellent little sticks not only for the summer laying in of Peach, Nectarine, and Morello Cherry shoots, but also for staking a number of small things requiring a minimum of support, such as Roman Hyacinths, Tulips, *Freelias*, *Anomathecas*, some of the more weakly *Achimenes* and *Gloxinias*, and may be saved for that purpose. Stored away in a dry place they afford work for wet weather in trimming and tying them up into different lengths and sizes. Dahlias came abruptly to an end. They were hardly better at any time through the season than on Sunday, Oct. 29, but the following morning found them blackened and destroyed. Care should be taken in lifting to see that the labels are securely fastened to stem or tuber, so that there should be no mistake another season if a special effect is required at a given spot with any particular colour.

WALL PLANTS.—Mention made in a recent note of *Ceanothus Gloire de Versailles* reminds me that it was included in a short list of wall plants recommended the other day, the others being *Cydonia japonica* var. *rosea* and var. *alba*, *Spiræa prunifolia* fl.-pl., *Chimonanthus fragrans* and the silver variegated Buckthorn (*Rhamnus Alaternus*). With the strong demand for flowers at all times and seasons, I think we might with advantage utilise every available bit of wall for some of our best plants. They are in their respective seasons a most beautiful and attractive feature of the garden. The double-flowering *Deutzia scabra* or *cretica*, as it is sometimes called, accommodates itself very well to a wall, and is as good for button-

hole purposes as the above-named double *Spiræa* is for sprays. This *Spiræa*, too, is very beautiful in wreaths and crosses introduced thinly among bright-coloured foliage. In buying *Chimonanthus fragrans* an endeavour should be made to secure the large-flowered variety. The variegated form of *Rhamnus Alaternus* is seldom met with except in old gardens, and yet it is about the best wall plant of its kind we have. Very bright and with the variegation well defined on every leaf, especially when growing in a warm light soil, it makes a nice break in the many different shades of green furnished by other wall plants, and is also available for cutting at all seasons if foliage of that kind is required.

Where one of the objects in the acquisition of more herbaceous plants is a largely increased and continued supply of cut flowers, it may be well to advise those who have to cater for special times and purposes that now is the time to plant for that purpose. If white flowers are in great request, one cannot well have too many; Aimée Vibert, Anna Maria de Montravel and Paquerette Roses, white *Pyrethrums Aphrodite* and *Mont Blanc* are especially good, the white Everlasting Pea, the lovely new variety of *Achillea ptarmica*, the old white Clove Carnations and the gem of the *Spiræas*—*palmeta alba*. Again, if there is a great demand for Easter (and that festival falls somewhat early in the year), the gardener is often at a loss which way to turn for flowers unless he has anticipated the demand by filling nooks and corners of lawns and many likely places in the pleasure ground with Daffodils. Given a fair variety in the trumpet and star sections, one is never at a loss to find a basket of outdoor flowers from early in February onwards through March and April. So far as the herbaceous borders are concerned, the aim in planting should be to always have something to look at and, if necessary, to cut, and with judicious planting there is, fortunately, but a very brief season when these borders are quite destitute of flower. Those who were early with their *Viola* cuttings and shifted them so soon as struck into required sites are now getting quite a nice display of flower, and very fine autumnal blooms these early cuttings will give, far better than were obtainable through the hot summer months. A group consisting of *Connarus* of *Hopetoun*, *Crimson King* and *William Niel* is just now quite a bright feature of the garden.

Claremont.

E. BURRELL.

Dahlia Glare of the Garden.—This is sometimes called *Fire King*, but whatever its name, it is a very brilliant variety for massing in the garden. It is quite dwarf, exceptionally free, and the small, neat flowers are brilliant scarlet in colour.

Gypsophila muralis.—This is a very graceful annual for rockwork, edgings, or any place where slender growth is desired. It grows about 9 inches high, has a spreading habit, and bears in quantity flowers of a soft pink colour. The flowers might be found very useful for cutting to arrange with other things in the same way as those of the perennial kind *G. paniculata*. It is quite as elegant, but has much larger flowers.

Martynia fragrans and **M. lutea.**—These Brazilian annuals are so much like *Gloxinias*, that anyone seeing them for the first time is apt to think they look rather out of place in the open ground. They are fine things, however, for sunny borders with warm soil, large in leaf, showy and striking in blossom, and the flowers are followed by curious horned fruits or seed-pods. *M. fragrans* has been blooming lately upon plants the seed of which was sown in the open ground. The flowers are large and showy, of a deep crimson-purple colour and possessed of a slight scent. It grows about 18 inches high. *M. lutea* is very similar, but has yellow flowers.—A. H.

Salvia splendens outdoors.—This is generally seen grown in pots or planted out and potted up in autumn and placed in the greenhouse. It is a most useful autumn plant for the open garden when it can be given a sheltered position, or in gardens near the sea where frosts do not come

early in autumn. I planted this season this *Salvia* with other plants in a narrow border facing south under the abbey. Here it has bloomed splendidly during October, and the last few days in the month I was able to obtain enough of its brilliant sprays to furnish a good-sized dinner-table. If the weather continues open the plants will go on blooming a long time yet.—J. CROOK.

Callistemma crachiatum.—Is this an annual, biennial, or perennial? A group of plants from seed sown in the open ground has been flowering throughout the autumn, and even now the recent sharp frosts have not hurt the plants. The habit of growth is bushy, but spreading, the leaves rather ovate and downy, whilst the flowers, borne on long slender stalks, exactly resemble those of *Scabiosa caucasica*, but are about half the size and of a pretty pale mauve colour, with a brown centre before the disc florets expand. Probably it is only an annual, but, at any rate, it is an interesting plant.—A. H.

WAYS OF USING HARDY BULBS.

THE charming illustration and article in THE GARDEN, October 28 (p. 387), reminded me that the hardy bulbs are used in too formal a way in gardens, and many beautiful things only dotted on the rockery or border may be planted in bold clumps and masses in positions usually left bare. A well planted garden of spring bulbous flowers is as pretty as anything one can get in the summer and autumn, and the illustration shows the beauty of the Poet's Narcissus in a field. It is only in large gardens that hundreds of thousands of bulbs can be planted, but we want to get away from the set pattern style, not confining the selection merely to a few Hyacinths or Tulips, each variety repeated until one tires of the colour. In the parks we notice that the finest kinds for colour are boldly massed, and this is necessary to get an effect in a large place, but even here the arrangement could be more varied by planting the bulbs in beds with other things, as Forget-me-nots or rising from a carpet of mossy Saxifrage. Trumpet, Poet's, or other forms of Narcissus make delightful pictures used in this way, or in small beds filled with distinct kinds. In my visits to gardens I have made note of effects that if carried out more largely would alter the place for the better. It is a good thing to plant, for instance, at the foot of standard Rhododendrons and other shrubs, the blue *Scilla bifolia*, *S. sibirica*, *Muscari* in variety, getting the more richly coloured kinds, *Chionodoxa*, the Star-flower, *Triteleia uniflora*, and *Bulbocodium vernum*. A charming association of colour I saw last year was the *Bulbocodium* planted thickly in a bed filled with a deciduous shrub the name of which I unfortunately forget, the flowers covering every bare portion of soil in the bed. Such a bed as this early in the year is welcome, and good association of colour is got by making freer use of the little Winter Aconite. It is strange that this common bulb is so little planted in gardens, although few things are prettier on a bright winter or early spring day than a colony of the yellow flowers in their quaint collar of green leaves. If *Eranthis cilicica* proves later in blooming, as it appears to be so far, one can get a succession to prolong the display.

In every suitable spot, bare corners, surfaces of beds, and wherever bulbs are likely to succeed they should be planted, and it is this phase of spring gardening that is delightful to all; neither is it beyond the reach of those who have unfortunately no broad acres in which to plant the Daffodil. The little Tenby Daffodil, the most exquisite in shape of the family, looks charming planted amongst the shrubby *Poten-*

tilla fruticosa, and some may easily extend this form of spring gardening by planting the margins of beds filled with *Kalmias*, *Rhododendrons*, hardy *Azaleas* and similar shrubs, and the yellow colour of the flowers would be in fine contrast. It is really in a way extending the idea of boldly massing Lilies amongst shrubs, and by treating the humbler bulbs in the same style, the year is fairly encircled with bloom. In the wilder spots naturalise Daffodils, Crocuses, Snowdrops, *Leucojums*, *Anemones*, and both the article already referred to and some interesting notes by "Jay-Aye" in THE GARDEN April 8, 1893 (p. 278), will help greatly.

The bedding-out system of treating bulbs is well enough under certain conditions, but it may be carried too far, even if the various kinds are selected carefully as to colour. Nothing is prettier than some old-fashioned border of bulbs, and notes have appeared from time to time recording fine examples of such features. Many an English garden might be beautified cheaply if the broad border that skirts many a high red-bricked wall were taken advantage of. Almost every old English garden possesses such a border, wherein the Daffodil in particular is at home. It is in perfect agreement with the surroundings, and one may get a good collection of varieties without displaying any trace of botanical arrangement by planting a bold clump or clumps of each kind, keeping the sections distinct. This reminds me of the border at Kew, which is backed with a high red-bricked wall, and in the spring this is gay with colour for many weeks with the succession of Daffodils, the sulphur-yellow *N. pallidus* precox being amongst the first to expand. This border is sown with annuals in a free, bold way in spring, and these make broad masses of colour during the summer, the growth spreading on to the Grass. This year annuals have failed, but many kinds, however, succeeded well here, the bulbs receiving no injury whatever from such plants. If fewer Daffodils were planted, hardy perennials could be cautiously interposed to prevent disturbing the bulbs.

A very pleasing edging of bulbs I saw last spring made an appropriate finish to a broad bed, and the edging was made up of the dwarfed *Narcissi*, *N. minimus* and *N. nanus* mixed with *Chionodoxa Lucilæ* and Snowdrops, as *N. nanus* blooms a little later than the other and provides a succession. Taken separately, these miniature *Narcissi*, so to speak, are not of much account for effect, but massed together with other bulbs for contrast they are bright and effective. When in the garden of Mr. Kingsmill at Harrow Weald recently, note was made of bulbs planted against the frames, a few inches broad of soil being reserved for them. In such sunny spots they succeed well, the bulbs comprising *Ixias*, the smaller-flowered *Irises* and *Narcissi*, whilst the carpet plant, so to say, was the little *Arenaria balearica*. Even now it is pleasing from the rich felt-like mass of green, intensified greatly by the flowers of spring. The *Scilla bifolia* looks well mixed with the spring Snowflake, and many other happy ways of associating bulbs could be named. One soon learns how to get pretty effects either by seeking suggestions in other gardens, or trying experiments. By doing this many very suitable spots for bulb growing may be made use of, such as the base of frames or plant houses, as indicated. One of the finest masses of colour I saw early in the autumn was the *Belladonna Lily* in a narrow, sunny, light border skirting a hot house. But in the majority of gardens such a position would have been either left bare or filled with unsuitable things. One can extend this kind of planting

to almost any degree, filling small beds on the turf with various bulbs. In one can be planted, for instance, the Snake's-head *Fritillary* (*F. Meleagris*), a delightful flower, and very elegant. There is quite a series of colours in the drooping flowers, ranging from creamy white to purple, with finely tessellated and mottled forms, quaint and interesting. It can be planted on the Grass if this is mown late, but it is as a flower for use in the garden proper I recommend it, just as the showy *Tulipa Greigi* may be treated.

Writing of Tulips reminds me also of the beauty of the species, which it is a pleasure to see are getting more popular in gardens. They are more expensive than the ordinary Dutch kinds, but it is worth the extra outlay to get the finer kinds for colour. *T. macrospeila* is a glorious form, the flowers crimson or deep carmine in colour, bold, large, and borne on sturdy scapes. *T. elegans* is superb, either planted in a small bed or massed together in larger quantities. The flowers are intense crimson, the segments tapering gradually to a point, where they reflex in a characteristic way. Rather later than this is *T. fulgens*, the flowers rich crimson, especially in the sun, when they seem to glow with colour. *T. retroflexa*, yellow, has reflexed segments. *T. spatulata*, *T. acuminata*, *T. Golden Eagle*, yellow margined with crimson, and *T. Picotee* are all fine kinds. The last-mentioned is exquisite, the flowers white, with a margin of carmine-rose to the segments.

One class of bulbous plants not made enough of in gardens is the *Erythronium*, the Dog's-tooth Violet. It is delightful planted thickly at the base of standard Roses or *Rhododendrons* and by the margins of beds filled with shrubs. Here it is quite at home, and colonies may be established on the rockery. The soil should be moist and peaty, hence in the case of the American shrubs suitable conditions are already provided. There are many beautiful varieties, the petals broader than in the type, and the colours range from pure white to deep purple, the names as a rule indicating the distinctive shades. The *Erythronium* is not difficult to grow if exposed to the sun and in the soil mentioned, but, judging by its comparative scarcity, one would suppose it a delicate exotic. C.

HARDY GLADIOLI.

I AM not at all surprised that "Delta" finds reason to complain of the want of hardiness in the varieties of *Gladiolus Lemoinei*. Some months ago I ventured to predict that the newer kinds at least would be found wanting in the very characteristic that should distinguish them from the fine *gandavensis* varieties. The original cross gave what one might reasonably expect to be thoroughly hardy varieties, and seedlings from them would be equally hardy. But if, as I suppose was the case, the *gandavensis* hybrids were again and again used, in the progeny there would be a slow, but sure deterioration in hardiness, culminating in the almost entire obliteration of the quite hardy ancestor. Probably in the first instance there was no thought of infusing more of the *gandavensis* blood into these hardy hybrids, but the temptation to gain in size, form and colour by so doing was too great to be resisted. If this sort of work is continued, it will not be long ere the term hardy as applied to the race of *Gladiolus* will be a misnomer. "Delta" does not say whether his experience has been confined to the varieties that have been raised in recent years. Has he grown the original hybrids and their immediate descendants? Some years ago I had a quantity of bulbs raised from seeds kindly sent me by Mr. Gumbleton. They passed several very hard winters quite unprotected and increased. These gave me the impression of their being perfectly reliable for the open ground.

I lost them in the course of time, but entirely through my own fault. Now I am sorry, because had I raised seedlings from them I believe that I should have possessed some thoroughly hardy varieties. I would do so now could I get some of the second or third generation from the original hybrids.

It would be well if someone having the time would take in hand these hardy Gladioli, only employing the varieties that were distributed some years ago, and resisting all temptation to make use of the tenderer kinds. Improvement would as surely come as it has done with the gandavensis section, and we should then have a race of really hardy Gladioli. This section of a fine family is valuable as preceding the gandavensis hybrids, thus filling up a blank between them and the early-blooming kinds, and giving us a succession of lovely flowers unapproachable in their particular style of growth by any other open-air flower. Putting the question of ability to resist hard winters on one side, it must be borne in mind that these so-called hardy Gladioli are not so capricious in their behaviour as their more handsome relatives. I have never heard that they are attacked by the dread disease, or dwindle away in the mysterious manner which is a characteristic of the gandavensis family. They appear to be, so far as regards the amount of cultural care required, as suitable for the cottager's garden as for that of the rich man. The past three winters have been very trying for any bulbous flower not quite as hardy as a Daffodil, and the last one of them was, I think, the most destructive. Four years ago I crossed some of the hardy varieties with brenchleyensis; some of the seedlings were very handsome, and they stood in the open ground quite unprotected and unharmed until last winter, which, I am sorry to say, was too much for them. They were probably killed just when a very severe frost came as the snow melted, the combination of cold and wet rotting the corms. A couple of inches of some protecting material would doubtless have saved them. J. C.

Blyect.

SHADING HARDY PLANTS.

THERE are some kinds of hardy perennials, such as Primroses, especially the double-flowered kinds, Polyanthus, Christmas Roses, &c., that dislike hot sunshine. Young seedlings, too, certainly grow more freely if screened from the burning sun in July and August. The difficulty I have experienced is in finding a way of giving the required shelter in an easy and inexpensive manner. If mats or canvas are used, a framework of some sort is indispensable, and the construction of this involves more labour than one can in a general way afford. The best thing I have found for this purpose is sprays of Birch. In the spring I lay in a store of Birch faggots and select the twiggy parts of them. Should a period of very hot, dry weather set in, it is an easy matter to lay some of this material on anything that may need a little shade, and on the return of moist, dull weather there is no need to remove it, as sufficient light will be admitted to keep the foliage from becoming weakly. It is surprising how well many hardy things do with this slight shelter. In the case of Hellebores and the hardy Primulas it seems to be just what they need. In a very hot, dry summer one cannot give everything that needs it a constant supply of moisture at the roots, and many hardy things do not require a great amount of it if they do not get the very hot sun on them. They thrive just as well in partial shade with the soil in a semi-dry condition as when in full exposure and constantly watered in a parching time. Violet culture in some places is troublesome and often unsatisfactory by reason of red spider attacking the plants, but a little shade will do more to keep it off than a great amount of attention with the watering-pot. It is curious how this troublesome insect abandons plants when the conditions under which they have existed are changed. A bed of Strawberries was badly infested, much of the foliage having turned quite yellow. I laid some

boughs rather thickly over them early in August, and although we had two months' hot, dry weather afterwards, by the end of September the leaves had again become quite green with hardly a trace of spider left on them. Young seedlings raised early in summer make much more rapid growth if the great heat of the sun is warded off. J. C. B.

Sternbergia lutea.—Recently I noticed some notes on this fine yellow-blooming autumn bulb. In this garden it has bloomed freely this year. This is the first time it has bloomed during the last five years, but this may arise from the bulbs having been small when first planted. I have it growing in a south border in a somewhat open soil. I do not think it is necessary to have it in a very open site. In a garden near Dorchester some five years ago I saw it growing under some pyramid Pear trees, where it had but little sun and none too much moisture.—J. CROOK, *Forde Abbey*.

Verbena venosa.—Some twenty or more years ago this was far more grown than now. I have used it in the mixed border during the last two or three years in large masses with the best results. It goes on blooming far into the autumn and is most useful for cutting from. Some plants of it have stood out safely where the roots had run under some stones. I find it best to take up a portion of the old plants, wintering them in boxes in a cold pit.—J. C. F.

Planting Narcissi.—I transplanted the greater portion of my stock of Daffodils about the middle of September, and I was only just in time. Many of the bulbs, had already formed roots and some were beginning to shoot. Some that I could not deal with then I have lately moved, and they had made roots 2 inches long. This shows how wrong it must be to defer the planting of this class of hardy flowers until the present time. With many, November is the bulb-planting month, and in some instances I will admit it is not very practicable to get the bulbs into the soil at a much earlier date. Where tender plants or annuals are set out among hardy bulbous flowers to fill up the spaces later on, or in the case of mixed borders it is not, of course, possible to plant in early autumn; but where the ground is unoccupied, the latest date for planting should be the second week in September. Every day that a bulb remains out of the ground after that date must affect its blooming powers. There will be little if any difference in the flowering time of bulbs planted in September and two months later, but the difference in the amount of roots that they will have when the flower-spikes appear will be so great as to have a marked effect on the quality of the blooms. The necessity for transplanting Narcissi at certain intervals depends on the kinds grown and the adaptability of soil and climate for this flower. With me even such kinds as cernuus in the course of three or four years need replanting. The bulbs increase to such an extent that they get too thick to allow of their blooming satisfactorily. In some soils and where the rainfall is heavy, the only way to succeed with the more delicate kinds is to lift them as soon as the foliage dies off and replant in August.—J. C. B.

Frost and flowers in Scotland.—After the longest and most congenial season within my recollection, frost has come and ruthlessly cleared off many tender flowers. Dahlias never were finer. Up to October 27 Roses also were blooming almost as freely as they did in July. Gloire de Dijon where it can extend itself well was as fine as one could desire. This grand old favourite, which also is one of the first to flower, should be planted largely; we have it on arches, on pillars, and on walls, and on all it does well, but it requires good soil and room to extend its roots in proportion to its branches. Pentstemons should be propagated largely or sown from good stock. They are fine at present, and have been so for months. The dwarf white Antirrhinum still flowers profusely, and has been gay since June. East Lothian Stocks are fine and have flowered freely this season. The white Wallflower-leaved is very useful where white

flowers are much in request. Tufted Pansies are yet blooming freely. Now is a good time to sow show and fancy Pansies on ground well trenched and manured. When plants are well prepared during growth there is little fear of drought destroying them. While transplanting shrubs I notice that the soil at a depth of 2 feet is as dry as dust and hard, almost like rock. Most trees and shrubs do well with mulching when planted. I find that where Rhododendrons have been planted in poor gravel soil and liberally mulched, they are doing well and are loaded with buds. It is pleasing to see in gardens everywhere that the cultivation of hardy plants is increasing, and that carpeting has decreased proportionately.—STIRLINGSHIRE.

White Clove Carnations.—In reply to Mr. Engleheart's challenge, I would say that I wrote respecting the double white Clove Carnation only what has long been regarded as correct in the locality referred to. All the same, the old white Clove may be other than Gloire de Nancy, or it may be identical. I assert neither, but the similarity is great. It would be interesting to learn how long Gloire de Nancy has been grown here under that name, and how long the old white Clove, which has also been long regarded as a sport. It may be that this latter assumption is based on the great similarity that exists between it and the old crimson Clove in habit, character of flowering, and leafage. That the flowers of the white variety seem to have better form is, I think, the case. As to whether Carnations do really sport, except in flaking or to self, that may be matter for inquiry. Looking over the report of the Carnation conference held at Chiswick a few years since, I anticipated that some information would on such an occasion have been afforded not only in relation to these matters, but also in respect to the origin or time of introduction here of the old crimson Clove, but none is furnished. Who gave to us Gloire de Nancy, and when was it first introduced?—A. D.

BEDDING BEGONIAS.

In a general way I can follow E. Burrell in his notes on flower gardening, but I cannot agree with him in his remarks anent bedding Begonias, at least as far as my experience and observation go. I have been a grower of these for bedding more or less for the last twelve or fifteen years, and I never had them so good as they have been this year. Nor do I think my case is a singular one, as a neighbour of mine remarked to me this autumn when I was looking over his garden, how well Begonias had done with him. Again I have had an opportunity of seeing these used somewhat extensively in a garden in North Hants, and here they were making a splendid show. The same holds good, too, in a garden I recently saw in Norfolk. According to my experience, Begonias need the soil to be rich with plenty of moisture. I find they are greatly benefited by a good soaking of manure water when in full growth; after this I mulch them with spent Mushroom manure and keep them moist. Treated in this way the plants this season have made very sturdy growth, and at the end of October they are still blooming freely, so much so that I am loth to remove them with other things. During this season I have found the same treatment answer perfectly with the shrubby type of the semperflorens section.

One of the evils in Begonia culture is that of growing the bulbs in pots in spring, and allowing them to get into a starved condition before planting them into their summer quarters. I never pot mine, simply planting them out from the frames where the bulbs are placed to start into growth.

With me Begonias are far superior to Pelargoniums, that is in the average of seasons. This may well have been called a Geranium season, but Begonias have surpassed the Geraniums in this garden. J. CROOK.

Forde Abbey.

TREES AND SHRUBS.

MAGNOLIA CANDOLLEI.

THIS *Magnolia* I received some years back from the late Louis van Houtte, Ghent. It has evidently been raised from *M. conspicua*; the flowers are larger, with broader petals, more cupped, of the purest white, in every case a larger and superior flower to that of the parent. It does not come into a flowering state so early, its time of blooming in spring being a week or ten days later.

JOHN SAUL.

OSMANTHUS.

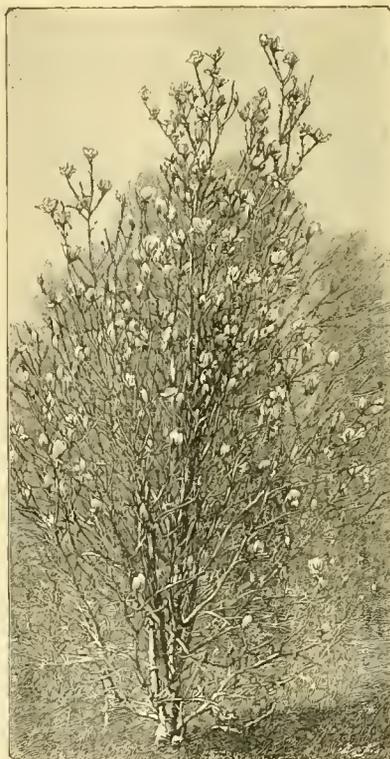

As indicated by the note on p. 426, the different forms of *Osmanthus* are in many cases flowering with unusual freedom, in all probability owing to the exceptional summer through which we have passed. There are several distinct forms in cultivation, and the nomenclature of some of them is in a rather confused state. By far the best as an evergreen shrub is what I regard as *O. aquilifolius*, which is a free-growing bush, and forms, if placed under favourable conditions, a well-proportioned specimen, clothed with dark, almost olive-green foliage, deeply cleft, and with the bark of the young shoots almost black. The second form, known usually as *O. ilicifolius*, is far more commonly met with than the other, but it is not so ornamental a plant. In this the leaves are of a much paler tint and not so deeply cut, while the young bark is altogether wanting in the deep hue of the preceding. The plant is of slower growth and it is decidedly less ornamental than the first named. There are at least three variegated varieties of *Osmanthus*, one in which the Holly-like leaves are edged more or less irregularly with white, and another in which they are yellowish. Besides these, a third form—*latifolius marginatus*—is in cultivation. This is altogether a larger and bolder growing bush than the others. Two green-leaved varieties, sports from the commoner kinds, are to be met with, and are certainly ornamental little shrubs. The best of the two is *myrtifolius*. The second, *rotundifolius*, has small roundish leaves, and is not unlike that form of *Ilex crenata* usually known as *Fortunei*. Though some forms of *Osmanthus* are so much like a Holly, there is really no relationship between them—in fact, they are more nearly related to the Olives. It may be pointed out that the plant alluded to on p. 426 as *Osmanthus fragrans* is really the same thing as that occasionally met with in old-fashioned gardens under the name of *Olea fragrans*. This is not thoroughly hardy, though it is admired by many as a cool greenhouse shrub on account of the delicious fragrance of its inconspicuous blossoms. A well-timed caution is given in the above-mentioned article to avoid plants that are grafted on the Privet, and there is really no necessity to increase them in this way, as they strike root readily from cuttings put into a cold frame. Still, for all this, among the most flourishing examples of the greenhouse *O. fragrans* that I have seen were some grafted on the Privet, but for increasing the outdoor kinds it is a great nuisance.

T.

A pretty permanent bed.—In working out some arrangements recently it was necessary to place some object or feature at a point where the walks diverged. I made a circular bed about 14 feet in diameter, in the centre of which I planted a nice specimen of the small-leaved Weeping Ash (*Fraxinus lentiscifolia pendula*); around this I put seven or eight plants of the common white Broom, around this again a belt of *Cassinia fulvida* (*Diplopappus chrysophyllus*?), then a bold margin of *Megasea crassifolia* resting on the Grass; the effect is very good.—T. SMITH, *Nevry*.

Phyllocladus rhomboidalis.—Only one representative of this genus was exhibited at the conifer conference two years ago—*P. asplenifolius*.

It was sent from Kew where, along with two other species—*P. trichomanoides* and *P. rhomboidalis*—it is grown in the large temperate house. No statistics in respect to any of these species were given in the conference report, and I do not think it can be generally known that one species at any rate will thrive out of doors in such localities as South Cornwall; probably all three would grow there if tried. Last month, when visiting the delightful garden of Colonel Tremayne at Carclew, near Falmouth, I was much surprised to find a specimen of *P. rhomboidalis* growing on one of the lawns. This was not only because of its great rarity, but also on account of the size of this particular specimen, which is about 15 feet high, well furnished with branches, the stem about 2 inches in diameter at the base. I think it is probable no larger example of this *Taxad* exists in Britain. The three species above-mentioned are natives of Tasmania and New Zealand. The genus is remarkable on account of the branches being flattened out into the form and performing the functions of leaves. In *P. rhomboidalis* these branchlets are

Magnolia Candollei in flower in Mr. John Saul's nursery at Washington, D.C.

1 inch to 2 inches long, rhomboidal or cuneate in outline, with the margin cut into blunt lobes or teeth.—W. J. B.

Autumn tints.—*Pourthia villosa* will have to take a front place in the autumn gardens of the future as a brilliantly beautiful small tree. Just now it has no rival; the tints of orange and scarlet are difficult to describe. *Pyrus arbutifolia* is also very bright, the habit, however, very different. It forms stolons and grows into a spreading clump; as a front row plant it is excellent. *Pyrus erythrocarpa* grows into a small tree of 10 feet or so high. The foliage is glossy and handsome in the summer, deep olive-green, crimson and scarlet now; the fruit is black. *Audromeda Mariana* as a front row plant is excellent, the colour rich and beautiful. *A. arborea* for some reason (perhaps want of moisture) is not so rich this season as it usually is here; still it is very good. This is a vigorous-growing and distinct small tree of 10 feet or so. *Vaccinium pennsylvanicum* is just now very beautiful, the colour ranging from

pale green to yellow, orange and rich carmine. Where autumnal colouring is required this could not well be left out. *Itea virginica* is a tall-growing shrub, ultimately perhaps reaching 5 feet or 6 feet; it is now very striking.—T. SMITH, *Nevry*.

HARDY CEANOTHUSES.

ON last September 14, MM. Simon-Louis, nurserymen, of Plantières, near Metz (Alsace-Lorraine), exhibited at a meeting of the National Horticultural Society of France a collection of cut flowers of *Ceanothuses*, which appeared to us sufficiently interesting to form the subject of the following article. In a general way it may be said that the *Ceanothuses* are in autumn what the *Forsythias* are in spring; but while the charming yellow bells of the latter always herald the approach of summer weather, the former, on the other hand, display their delicate flowers from the end of June until they are cut off by frost, thus ranking amongst the summer and autumn-flowering shrubs, the species of which are comparatively few in number.

The *Ceanothuses* belong to the family of the *Rhamnaceae*, and are small shrubs whose native home is in N. America, and especially in that part of it which comprises the United States and Mexico. In our climate they are commonly considered to be not very hardy, and are, consequently, very rarely seen in our landscapes and pleasure-grounds. This estimate of their hardiness, which is correctly applicable to the varieties of *C. azureus*, does not hold good in the case of the varieties which have been raised from *C. americanus*, and these hardy varieties are the subjects to which MM. Simon-Louis have given their attention and devoted their efforts. We can now state that these efforts have been crowned with success, as the fine series of flowers exhibited on last Sept. 14 belongs to this interesting group. Without being actual novelties, some of these *Ceanothuses* are as yet not very widely known; others of them have never been put into commerce and are still under observation and study. In addition to their hardiness, they are valuable for their free-flowering character, their handsome appearance, and especially for the delicate colouring of their flower-clusters, which are generally light and graceful in form, and range in colour from pure white to rosy-white and bright carmine-pink, and from sky blue to dark blue. The flowers, disposed in compound clusters, are borne on branches which are mostly of a reddish hue and are furnished at their axils with caducous, lanceolate-oval, regularly toothed and shortly-stalked leaves. These leaves, which are of a shining deep green colour on the upper surface and paler underneath, are very slightly pubescent, and diminish in size as they are placed nearer to the flowers. They are also characterised by having two lateral veins or ribs, which are almost as prominent as the midrib, and, like it, they traverse the blade of the leaf from the base to the point. The flowers of these small shrubs are very small; the sepals are elongated and coloured, while the petals are bunched together so as to form a sort of small hood. The stamens are slight, projecting, and showing the trifid style in the centre. The flowers are borne on rather long flower-stalks, which in some instances are coloured more deeply than the sepals, and thus impart a two-coloured appearance to the flower-clusters. The fruit, which is about the size of a pea, is a slightly-winged, triangular capsule, somewhat resembling a clerical cap in shape. As the fruit-clusters ripen, they become blackish-brown in colour, and are in some degree ornamental.

The species and varieties, the flowers of which were exhibited at the meeting of the National Horticultural Society, are as follows:—

I.—PALE BLUE, RANGING TO DARK BLUE.

CEANOTHUS DELILIANUS.—Regarded as a distinct species, this form, already well known, has thin furnished clusters of pale blue flowers, borne on reddish branches. It is also distinguished by its largish leaves, which are slightly downy on the under surface.

C. AMERICANUS VAR. BLEU CELESTE (Simon-Louis frères).—This variety is characterised by its compact, corymb-like, broad rather than elongated flower-clusters, which assume a fine azure-blue colour, and by its large leaves, which are downy underneath.

C. A. VAR. BIJOU (Simon-Louis frères).—This variety is chiefly remarkable for its light flower-clusters, blooming in fine succession on the branches. The flowers are of a pale blue colour and are borne on purplish-red stalks. Leaves much smaller than those of the two preceding varieties.

C. A. VAR. LEON SIMON (Simon-Louis frères).—A superb variety, with very long flower-clusters of a fine light blue colour, and leaves which are very downy underneath.

C. A. VAR. THEODORE FRÉBEL.—A very distinct form, with light flower-clusters of a blue colour, with reddish reflections. Leaves large.

C. A. VAR. GLOIRE DE PLANTIERES (Simon-Louis frères).—An unequalled variety, with long well-furnished flower-clusters of a rich dark blue colour. Leaves roundish rather than lanceolate in shape.

II.—LIGHT PINK, RANGING TO BRIGHT CARMINE-PINK.

CEANOTHUS AMERICANUS VAR. LE GEANT (Simon-Louis frères).—Flower-clusters extremely long, of a handsome double colour produced by the white flowers and the carmine flower-stalks. Quite a remarkable variety, with very large leaves.

C. A. VAR. PRESIDENT REVEIL.—A superb variety with long, well-furnished flower-clusters of a fine, very soft pink colour. Leaves very large.

C. A. VAR. MARIE SIMON (Simon-Louis frères).—Flower-clusters of no great length, borne on long branches, and forming small roundish bouquets of a splendid bright carmine colour. Leaves very large. This variety has a slight and very elegant habit of growth.

C. A. VAR. ROSE - CARMIN.—Flower-clusters branching, in the form of corymbs, and of a very bright and handsome carmine colour, which is mainly produced by the flower-stalks. Leaves rather large.

C. A. VAR., not yet named; a very hardy variety (Simon-Louis frères).—A magnificent novelty with long, branching, light, graduated flower-clusters of a beautiful pink colour with bluish reflections. Leaves very large.

III.—WHITE OR WHITISH.

CEANOTHUS AMERICANUS VAR. CORYMBOSUS (Simon-Louis frères).—Flower-clusters borne on long branches and at the same level, of a whitish colour with bluish reflections produced chiefly by the sepals. Leaves large and handsome.

C. A. VAR. ALBIDUS (Simon-Louis frères).—A distinct variety, with branching flower-clusters, which are more compact than elongated, and of a white colour with a faint tinge of bluish. Leaves very large.

C. A. VAR. FLORE-ALBO-PLENO (Simon-Louis frères).—A splendid and absolutely unparalleled variety with somewhat compact flower-clusters, well graduated and of an entrancing, remarkably soft pink colour, which is chiefly produced by the sepals and flower-stalks, the interior of the flowers being white. Leaves rather large.

The foregoing are the floral varieties of *Ceanothus* which we had the opportunity of estimating last September 14, and which, in our opinion, are worthy of being recorded. Although in France these small shrubs thrive best of all

when planted close to the sea-shore, and especially in the neighbourhood of Nantes, Brest, and Cherbourg, they might, if the above-named varieties were employed, be advantageously grown in more rigorous climates, since it has been proved that they are quite hardy at Motz. In planting them it is especially important that the soil should be a sandy loam and somewhat moist rather than of the opposite character. In northern districts they should be protected in winter with a simple covering of fallen leaves, or the branches might be frost-bitten. If cut down to the ground, they will produce shoots which will flower in the following autumn with a copiousness proportionate to the vigorous growth of the shoots. In the neighbourhood of Paris good results are obtained by treating these small shrubs in this way. The *Ceanothuses* are readily multiplied by means of cuttings of the soft wood, struck under a cloche or bell-glass in a cool house, in July and August. They may also be layered at the same season. Raising them from seed need not be resorted to unless for the purpose of obtaining new varieties. They will always produce a fine effect when planted here and there on the margins of shrubberies or groups of trees along with *Chenomeles* (*Cydonia*) *japonica*, *Deutzia gracilis*, and *Diervilla japonica rosea*, which display their handsome flowers throughout the entire period of spring. Lastly, I may add that, for supplying cut flowers for vases in dwelling-houses, these *Ceanothuses* are very serviceable, as the cut flower branches will remain in excellent condition for nearly a week.—CH. GROSDÉMANGE, in *Revue Horticole*.

Magnolia stellata.—Such a specimen as that illustrated in THE GARDEN (page 426) must be a very beautiful object, as even the small plants usually met with in this country are charming in early spring before the expansion of the foliage. Very sharp spring frosts are sometimes apt to injure the expanded blossoms, but, as a rule, they are not much damaged in this way; indeed, heavy rains during the blooming period are generally worse than frosts, as from the low stature of the plant and the consequent proximity of the pure unspotted blossoms to the ground, they are especially liable to be splashed during wet weather. As the rate of growth is slow, this *Magnolia* is more often grouped than planted singly, and if in a small bed, the surface of the soil may be carpeted with some low-growing subject to obviate as far as possible the splashing of the flowers. For this purpose the pretty little Wintergreen (*Gaultheria procumbens*) is well suited, being bright and cheerful at all seasons. On March 28 last Messrs. Veitch showed at a meeting of the Royal Horticultural Society a variety of this *Magnolia* in which the flowers, instead of being white, as in the type, were of a decided pink tint. An award of merit was bestowed upon it, and when distributed, this pink variety will no doubt be much sought after.—T.

Magnolias at Melbourne.—We have had a most magnificent display of *Magnolias*, both evergreen and deciduous, this month (September), which is about the beginning of our spring. The photographs I send represent a large bed of the deciduous kinds in bloom on a lawn in front of our Museum of Economic Botany, which was opened to the public in the beginning of this year by our worthy governor, his Excellency the Earl of Hopetoun. Some of these *Magnolias* are very fine specimens, notably *M. conspicua* (the Yulan) and a variety of it, *M. Soulangeana*, with whitish flowers. These, together with *M. purpurea*, *M. superba* and many hybrids from them, vary in height from 6 feet to 18 feet or more, and the flowers are so profuse that the masses of fallen petals, which literally carpet the ground for a considerable distance beneath the trees, might be likened to snow splashed with purple. One variety

called *spectabilis*, a sport from *M. conspicua*, is a noble object in the foreground, and the flowers of this are almost pure white. The species *glauca*, *stellata* and *Campbelli* are comparatively new introductions here and are only a few feet high, but, judging from their rapid growth during the past two years, they give promise of attaining a great size. *M. Campbelli* has never bloomed in this country. The evergreen species *grandiflora*, *annonæfolia* and *fuscata* are dotted about in the grass close by, as also other representatives of the order including *Liriodendron tulipifera*, *Drimys*, *Illicium*, and *Michelia Champaca*.—WILLIAM R. GUILFOYLE, *Director Botanic Gardens, Melbourne*.

* * The photos show some charming groups of these *Magnolias*.—ED.

Pinus leucodermis (Antoine).—In the year 1864 this Pine was introduced from Dalmatia by Maly, at that time head gardener of the Imperial Gardens, Belvedere, and described by Antoine, director of the Imperial Gardens, Vienna. For a long time only a few specimens of this Pine were to be seen in gardens. In the Imperial Gardens, Belvedere, Vienna, there are at present several beds with seedlings of it. M. Vesely, the head gardener, collected seeds of it about three years ago in the mountains of Herzegovina. He says that at elevations of about 1500 metres it is to be found amongst Beeches; at 1600 metres, where the Beeches cease to grow, it is more abundant; at 1700 metres the trees are small and very slow in growth. Old trees with stems 20 metres to 30 metres in height, with a diameter of about 1 metre, have the form of a topped pyramid on account of the upright-growing side branches. The bark is of a white-grey colour. Dr. Günther Ritter Beck von Managetta writes in the *Wienna Gartenzeitung* that it never has the flat-topped head like the Austrian Pine when this grows on rocks. It is very hardy and thrives in places where the common Spruce and Austrian Pine will not pay to be planted.—LOUIS KROPATSCH.

Ampelopsis Hoggi.—I recently saw this mentioned in THE GARDEN and I have also seen various examples of it during the past summer, but have failed to detect any relationship to an *Ampelopsis*; in fact, it is without doubt a *Rhus*, and if not identically the same as the North American Poison Ivy (*Rhus toxicodendron*), it is at all events very nearly related thereto. This fact should be borne in mind, for whereas the *Ampelopsis* is (as might be expected from its near relationship to the Grape family) quite harmless, the *Rhus*, on the other hand, is very poisonous, and with the transposing of names an accident might easily happen.—T.

Populus Van Geerti.—With a dull damp summer and autumn this scarcely merits the title of a golden-leaved Poplar, for the foliage has only a slight yellowish tinge; but this season, and especially for the last month, it has been very bright and stands out conspicuous from most of our trees and shrubs. Various as are the different tints assumed by our trees and shrubs before the leaves drop, the soft yellow of the Poplar in question is quite distinct from that of any others. At no time and under any conditions is this Poplar so rich in colour as the Golden Elder and some other subjects, but still when at its best the soft tints are very pleasing. A small group of young thrifty trees is especially noticeable against a background of sombre-hued conifers. This Poplar strikes readily from cuttings of good stout, well-ripened wood put into the open ground where the soil is of a somewhat sandy nature and not liable to be parched up during the summer.—T.

Weeds.—It is certain that if one wishes to keep weeds down the hoe must be constantly used. A very free use of it through the spring months will bring its own reward in lessened labour during the remainder of the growing season. I make it a practice to set out Strawberries for giving a supply of young plants in September or early in October. Last year I happened to put them out rather earlier than usual, and the weather being moist afterwards and the ground between not

being stirred before winter set in, the weeds had time to come up. In spring several hoeings were necessary to clean them, as the ground got so wet in February, and as soon as the dry weather set in I had the surface well stirred several times in the course of a month, so as to get the surface right for the runners to root into. Weeds gave but little trouble this summer, but the late rains have brought them up in quantity. I never remember to have seen them grow so fast at this time of year. Several hoeings have been necessary except among the above-mentioned Strawberries, where very few weeds have come up. Hoeing among them has not been necessary, scarcely a weed having come up. This seemed strange until I remembered how frequently the soil was stirred there in spring. Apparently nearly all the seeds in the top inch of ground sprouted and were killed, and until the soil is again worked there will not be another crop of weeds there. The easiest way to keep ground clean is never to wait until weeds appear, but to make a practice of running the hoe through all growing crops at regular intervals whether there are signs of weeds coming through or not. In many gardens I know this is the rule, but in too many instances there is disinclination to use the hoe until a crop of weeds appears.—J. C. B.

KITCHEN GARDEN.

PREPARATION OF SEED POTATOES.

How often do we see the prospects of the Potato crop ruined by badly-prepared seed tubers, and I cannot too strongly urge the importance of attending well to the tubers, so that they should be in a perfectly satisfactory state by the time the planting season comes round, be this early or late. Although to a certain extent cultivation is mainly responsible for the future state of the crop, yet with two plots planted side by side, one with the seed tubers well prepared and the other with weakened sets, through the primary sprouts being lost and the tubers otherwise weakened by being allowed to lie huddled up together in a heap in a close and darkened structure, there would be a vast difference in the condition of the crops as they are dug. Not only is this the case in both the number and size of the tubers, but it affects earliness as well, and this to no small extent. With the early crops this is a matter of great importance. It is astonishing the difference this apparently small matter makes. With the sets well prepared, each having the primary sprout about an inch in length and also stout in proportion, the planting may be delayed until a safe period, the grower in the meantime knowing that, although planting is being delayed for a week or two, these well-prepared sets when they are planted soon make up any supposed lost time; in fact, with these well-prepared sets it is positively dangerous to be in too great a hurry in planting, as with a short spell of fine and bright weather directly afterwards, the growths are not long in making an appearance. Having set forth the advantages that will accrue to the grower upon having well-prepared sets, it now remains to explain the best methods of retarding so that the primary sprout shall be stout and intact at planting time.

This season more than ordinary care is needed to prevent the sprouts growing too much. Very often it is owing to insufficient space that the preparation has to be delayed, and makeshift methods have to be resorted to to meet the desired end as much as possible. The two evils that have to be guarded against are darkness and allowing the tubers to lie huddled up together in a heap, both of which quickly cause a forced growth. Frost has also to be guarded against, but beyond this the cooler the sets are kept the better. The best sets are secured where the tubers can be laid out thinly, be well exposed to the light, and receive a free circulation of air. Much may be done to economise space by placing the tubers in cutting boxes, arranging them on end, the thick end uppermost.

I have packed these boxes one above the other, with pieces of wood between to let in light, and then as space can be spared laid the boxes out thinly. The convenience of this method is, that in case of frost the boxes can be packed up together in a small space and be covered up effectually to prevent the tubers receiving injury. Light, it must be remembered, is indispensable, and likely positions will suggest themselves according to the convenience at command. The best sets are those which can be wintered in a structure where the temperature ranges at about 40°, this ensuring a thorough rest. Cellars are the worst possible places for seed tubers, as these besides being dark are also unduly warm, conditions which will quickly cause a blanched and attenuated growth. Sets for forcing may be quickly advanced by laying the tubers on leaf soil in boxes and keeping this moist in a warm structure. A. Y. A.

Potting Cauliflower plants.—This is an old method and one often thought out of date. If seed of Cauliflowers had been sown in August, there are good plants now for potting. The sturdiest should be selected for the work. I prefer to use $\frac{1}{2}$ -inch pots, as these allow of more root space, as if the plants are too much cramped at the root or suffer from want of moisture, they button in the early spring and are useless. Firm potting tends to sturdy growth, and it is a mistake to use rich soil; a compost of loam with some mortar rubble suits well, as this allows of free, but firm growth. The plants never require heat, and the cooler they are kept now, the more likely are they to winter well. It is necessary to pot in October so as to get sufficient roots to support the plants in severe weather. There is no better system than plunging the pots in ashes up to the rim, taking care to fill in the cavity round the pots, as the ashes preserve the roots. I winter in cold frames near the glass, and in severe weather bank up the sides of the frames with ashes and cover the glass with litter, not exposing after severe frost till the soil is thawed. Very little water is required through the winter months, and an occasional sprinkling of dry wood ashes will keep mildew off. The great advantage with these plants is that they so soon go ahead when planted out in March or early in April, as being in cold frames they can be freely exposed; whereas plants raised in heat require pricking off, carefully protecting, and even then are at times caught by frost. It often happens we have a succession of east winds in the spring that soon wither up tender plants raised in heat, but the sturdy winter plants pass through safely, there is no flagging at planting, and only a very slight check, as the plants come direct out of the plunging material and are a mass of roots. On the whole, I consider the old plan the best and safest.—G. WYTHES.

Shantung Cabbage.—Being specially fond of vegetables, I tried a few years since some seed of Shantung Cabbage, for which I was indebted to Kew. For two years I thought it worthless, its open heartless heads running up to seed very quickly. But this year I sowed the remains of my seed, and yesterday a dish of what appeared to be beautifully white Cos Lettuce was brought to me. Boiled, at dinner, I found it most insipid and worthless, simply so much tender green vegetable between the tongue and teeth, with absolutely no flavour to the palate. To-day I have tried it as a salad, and I find it excellent, white, crisp and sharp as the best summer Cos Lettuce. Worthless as a vegetable, but of great value as supplying an excellent late autumn salad.—R. MILNE-REDHEAD, *Holden Clough.*

State of the vegetable crops.—As far as this district is concerned, green vegetables never were more plentiful than at the present time. Unfortunately, the majority of the winter crops, notably Savoys, Cabbage generally, Brussels Sprouts, Chou de Burghley, and early Broccoli are far too forward, and there is every likelihood of many of them being spoilt. Owing to the absence of frosts and comparatively warm state of the ground, the growth of these vegetables, and also Broccoli,

Cauliflowers, Spinach, and Turnips, has been both rapid and strong up to November 1, though it is to be hoped the late severe frosts will have checked further rapid progress. Not only are the vegetables far too tender and succulent to stand much frost, but the bulk is much too coarse to be generally satisfactory. Autumn Giant Cauliflowers could hardly be got into a bushel basket, Veitch's Autumn Protecting Broccoli being nearly as large. In some instances, where the ground is rather rich, these two kinds have been so large that a single plant could scarcely be got through a door, the hearts being of very little value indeed. Savoys have arrived at a stage when they are very easily spoilt by frosts, not a few having already split open. Those who grow for the markets have a great difficulty in getting rid of their produce at any price, and for some time to come low prices must prevail. Most probably it will be a case of a great glut this side of Christmas and a scarcity afterwards. The latter will of a certainty be brought about if we experience a severe frost at all similar to what took place last January, very few winter vegetables being in a fit condition to withstand much cold.—I., *Somerset.*

All-the-Year-Round Cabbage Lettuce.—No Lettuce has during this past phenomenally hot and excessively dry season given us greater satisfaction than this old, but thoroughly well-proven variety. Others have been introduced since the advent of All-the-Year-Round, but not one of them will surpass it now. When other kinds of Cabbage Lettuce, as New York, a form of the well-known Neapolitan, gave out during the long period of drought and was of inferior quality at the best, this fine kind was excellent, the hearts large and firm, standing well after they were fit for use. Such Cos Lettuce as Hicks' Hardy White even did not behave well during the hottest weather; it was most fortunate, therefore, in our case that we had our old friend to fall back upon, with which a constant supply has been maintained up to the present time with a good stock still in hand. All-the-Year-Round is during its earlier stages of growth somewhat spreading in its habit, the outer and spreading leaves are also large, the ground being fairly well covered where the plants had been put out a foot apart each way. Thus with water frequently given, the ground retained the moisture. After making a few of the large leaves the hearts quickly turn in, there being but few varieties which come into use earlier from the time of sowing the seed. As regards the colour no fault can, I think, be found with it; the pale green colour is in my opinion preferable to a dark green, at least in the Cabbage Lettuces. If sown early in the spring it will prove a first-rate succession to Veitch's Golden Queen, which as an early kind either for framework or the open ground is not to be excelled. In this locality large quantities of Lettuce are grown for the market mainly of the Cos section, but these succumbed to the hot and dry weather even where the ground was heavily manured. For private use the Cabbage varieties find considerably more favour than in the market where mere size counts for a good deal.—J. H.

A RUNNING KIDNEY BEAN.

ONE of the reasons why kidney or dwarf French Beans are not so much grown as the Scarlet Runners, or runner Beans as now most generally termed, is the fact of their not being sufficiently continuous bearing. They bear a quick heavy crop of pods, but these soon become too old and stringy to be used, and in order to have a long succession of tender young pods, several successional sowings have to be made. Several forms of running kidney Beans have been raised or selected. One that I once had, but lost owing to not being able to ripen seed, grew to a great height and also produced a long succession of small, delicately-flavoured pods. At Longford Castle I once saw a long row of kidney Beans that had been supported by stakes about 3 feet high. The plants had attained fully that height and were producing an extra heavy crop of long straight pods that could not be

distinguished from the Canadian Wonder. From Mr. Ward I learnt that this running kidney Bean was actually a selection from Canadian Wonder, the seeds being of the same colour. This was five or six years ago, but I was forcibly reminded of it by seeing a form very much resembling Mr. Ward's shown by Messrs. R. Veitch and Son, Exeter, at several of the leading west of England shows. For the purpose of transit the plants were placed in 10-inch pots and coiled round stakes. All were bearing extra heavy crops of fine straight pods of the Canadian Wonder type, and which were said to fully equal that old favourite in quality. Messrs. Veitch's variety, it is to be hoped, will have been sufficiently well fixed and the stock fit for distribution soon, as it is very certain it is a novelty that will be in great demand among gardeners generally, and those in particular who cannot devote time and space to grow more than a few early kidney Beans. It should be welcome also to those exhibitors of vegetables who may desire several late dishes of extra fine straight pods, those planted and supported by stakes producing these more surely than dwarfs. There is also the likelihood of this running form of kidney Bean being grown in borders or boxes under glass and forced. It ought to be possible to take a much longer succession of young pods from these running plants than from the older forms, a considerable amount of labour being saved accordingly.

W. IGGULDEN.

PUBLIC GARDENS.

CHRYSANTHEMUMS IN THE PARKS.

EACH year an exhibition of Chrysanthemums takes place in the majority of the London parks. This season the displays are of the usual high standard, and this form of attraction, so to speak, has increased greatly of recent years, in a few instances very fine houses being built especially for their accommodation. We made notes of the fine displays, and may mention that every district almost in or near the metropolis is well provided for in this respect, the Inner Temple Gardens, Finsbury, Waterlow, Battersea, Victoria, and Southwark Parks in particular. Finsbury Park was until recently ill-provided for as regards accommodation, but a splendid house has been built for the plants and the best varieties are represented, including the more recent additions. The position of the parks varies so much, that it is unfair to criticise. Plants can be grown easily to far greater perfection in Finsbury Park than in smoky Southwark, surrounded with evil-smelling chemical works, but even under such conditions the plants are excellent. From time to time through the present season we shall make notes of the finer varieties in the parks, as one display in the matter of effect is much like another. We refer to two of the more important exhibitions, and the varieties mentioned are also worthy of note in the collections in other parks.

One of the recent additions to the open spaces of the metropolis is

WATERLOW PARK,

and the Chrysanthemums here are remarkably fine. This open space was formerly, it will be remembered, a private garden, and the original vineries and plant houses remain. In these the Chrysanthemums are grouped, and the plants are well grown, attracting thousands of visitors every day from the populous surrounding district. A well-built conservatory is filled with plants in full bloom, and the more recent kinds are grown as well as old favourites. In every display we have seen this season Vivian Morel is superb. It is so here, and the

of various shades colour in the flowers from different buds are interesting. That fine Japanese variety Mons. Tarin is quite a feature, and even against the many newer kinds its flowers are in a way unrivalled; they are large, and the drooping petals silvery rose in colour. Edwin Molyneux is another kind grown largely, and amongst novelties or comparatively so were several that deserve mention. John Shrimpton and William Seward were two of the more important. Both bear large flowers of superb colour—deep purple-crimson—and the plants are evidently very free, whilst easy to manage. Alberic Lunden is a fine Japanese variety for colour, the flowers crimson-amaranth. That beautiful early-flowering variety Avalanche is the backbone, so to say, of the displays in late October, and many specimens were in perfection here at the time of our visit. This is one of the most exquisite kinds of recent years, and as yet unrivalled for purity and grace. It is a set-off to Sunflower, another good early variety, the flowers not stiff and of an intense yellow shade, making a rich effect. A rather scarce kind is Mrs. F. A. Spaulding, well grown at Waterlow Park. It is one of the finest Chrysanthemums ever raised in America, the flowers nankeen-yellow in colour and the petals broad. Beauty of Exmouth is worth a note, but we do not think it is a variety that will hold its own long as an exhibition flower. It is an English-raised seedling, the flowers when in perfection measuring about 8 inches across and ivory white in colour. Miss Anna Hartshorn is now well known, and many good blooms may be seen here, whilst also of note are Florence Davis and J. Stanborough Dibbens. We are not writing of Waterlow Park in particular as regards the names of the plants, as they are correct as far as possible, but in other places the nomenclature is faulty. This is scarcely pardonable, as in all good nurserymen's lists the names are fairly correct, and in public parks care should certainly be taken in this matter. Some French names undergo amusing alteration. Besides the foregoing Japanese varieties, such kinds as Condor, Mons. Astorg, Gorgeous, Mlle. Lacroix, Elaine, Margot and Peter the Great fill the spacious houses with colour. In comparing the older varieties with the more modern kinds, it is interesting to note the great advance in size, but some of the smaller Chrysanthemums are the more beautiful. The rich bronzy orange Source d'Or, more grown for market than perhaps any other, is very charming. Incurved kinds as a rule are not made much of in the parks, but here one sees several well-known varieties in true character. The fact is the Japanese are better for effect than the prim incurved. M. R. Bahuant of the latter section is conspicuous. It is an early-blooming kind, the flowers not very bright in colour, a somewhat dull carmine-rose, the petals smooth and well incurved—a fine seedling unquestionably of the Queen family, similar in growth, and with the same bold style of flower. Robert Cannell is in full bloom. On its first appearance we thought this fine variety of Mr. Cannell's raising would be too rough, but it has proved otherwise, the flowers large, rich bronzy red, and the reverse of the florets old gold colour. Amongst what are called decorative kinds, the variety Mr. C. E. Shea was conspicuous. This is a sport from Mlle. Lacroix, and a charming flower, rich in colour, a soft golden yellow, and useful for cutting. The Chrysanthemums in

FINSBURY PARK

are well arranged, and the new house affords scope for effect. It is almost too elaborate,

but fortunately is not obtrusive, like the big refreshment place that disfigures what should be the finest position in this park. The plants here are later than at other places, the position being cold and breezy. The Japanese varieties are grown largely, and Vivian Morel is one of the chief kinds. On one plant the flowers are of two distinct colours, the purple-lilac of the later buds and pure white. A very fine kind we made note of is Col. W. B. Smith, which is a splendid exhibition flower. Fully-developed blooms measure 8 inches across and quite 5 inches in depth, the colour golden bronze, shaded with a terra-cotta tint. Although so large, they are not coarse. We lay stress upon this, as size, as a rule, means coarseness. A well-grown plant of W. A. Manda is in bloom, and this variety belongs to the hirsute or Alpheus Hardy section. We care little for the "hairy" character if the colour is good, which it is in this case—a pure golden yellow. Eynsford White was superb, and it is a lovely flower, pure white, distinct and free; whilst we noted also Beauty of Exmouth, Louis Boehmer and those mentioned above. Amongst Anemone-flowered kinds, two were of note, one, Delaware, the other M. Charles Lebocqz. The former is very pleasing, the centre yellow, very full and the guard florets pure white; whilst the latter is citron-yellow, with a shade of carmine, the centre full.

It would serve no good purpose to individualise each park more than we have done. It is sufficient to know that the growers in every case deserve praise for their year's work to provide during November a gay mass of flowers for inspection. In many places attention might be given also to the outdoor varieties more so than is at present the case; but in Southwark and very smoky, low-lying districts they should, perhaps, be left alone, except two or three varieties that resist such unpleasant surroundings. The object to provide a large house of indoor plants is distinctly praiseworthy, encouraging the dwellers in surrounding populous districts to also grow and love flowers, but the majority of people have no accommodation for a greenhouse. A few beds of the best outdoor kinds, arranged in distinct colours or several shades of one colour, would provide a fine picture in late October and November. One of the gayest masses of flower we remember seeing in the open in November was a wall of Chrysanthemums in Hammersmith. The garden was small, quite of the suburban type and surrounded with houses, but the plants were a sheet of bloom, this, too, in quite full exposure.

Martinmas term.—The 11th of November is a time which is often fraught with great anxiety to young gardeners (foremen and journeymen) who have to leave their situations and go at such an untoward season of the year to find new appointments, or get into nurseries, if they are even so fortunate as to find employment there. Why the system of frequent migration in the north is so common it is difficult to conceive. In some districts the practice seems to be contagious. If the young men were leaving to better their condition or to gain superior knowledge every sympathy with their action would be given, but often by this migratory system they leave gardening and seek employment at anything which comes first to supply them with means of subsistence. Nurserymen are sadly taxed with the eager applicants' appeals for situations when there are not openings for a third of them. If those who are well placed and have no direct prospect for the future could remain in their situations two or three years instead of changing every six or twelve months, they would learn much more of their business and

be better off financially, as well as be more eligible for an opening when such occurred. The most of the young men who have been employed under me have pursued the course I advise, and all have done well when they have left, which is generally between terms, as is so general in England. The worst evil in the north is the continual raising of apprentices in many places, often where they can learn little gardening, and at the end of three or four years they are thrust out into the cold world to fight for themselves.—KENT.

Epilobium latifolium.—I think "E." would be almost certain to obtain *Epilobium latifolium*, the equally fine, perhaps finer, dwarf species *E. obcordatum*, and other choice kinds of *Epilobium* from Messrs. Backhouse and Son, Holgate Nurseries, York. They had a nice collection of these plants, including the above-named species, some time ago.—W. M.

—In reply to "E." (p. 428), I think this plant is likely to remain in cultivation, because it is both a pretty and useful species, and also a plant with a free habit of self-propagation; anyhow it has been here for many years and is much appreciated, and even were it intended to root it out, it could be done only with some difficulty. It is but a few inches high, the foliage is almost blue-green, and for the size of the plant the flowers are large and effective. It is a capital plant for the rockery, where it should have plenty of room, and in the same ground early spring or autumn-flowering bulbs might be set without injury to the plant or themselves, so as to relieve the deadness of the space at those periods. It is a native of the colder regions of North America, and hardy beyond all question.—J. WOOD, *Woodville, Kirkstall.*

SOCIETIES AND EXHIBITIONS.

ROYAL HORTICULTURAL SOCIETY.

NOVEMBER 14.

COMPARED with the last meeting, which was a most exceptional one, this was not so extensive, nor could it be reasonably expected that it would be, considering the foggy day. We do not, however, remember to have seen a better display at any time in the middle of November. There were several good groups, prominent amongst which were some fine forms of *Cattleya labiata* and several of *Cypripediums*. Amongst the latter the most noteworthy were the best varieties of *Cypripedium Leeanum* that have been seen. This hybrid is certainly one of the best, whilst it has a still further recommendation in its favour, that of flowering at a season when there is a comparative scarcity of really good and distinct species or other hybrids. Of the old *C. insigne* there were also several fine varieties, notably *Sanderæ* and *Ernesti*, two lovely pale forms. Other good hybrids of *Cypripediums* and *Cattleyas* were also shown.

Orchid Committee.

First class certificates were awarded to—

LÆLIO-CATTELEYA STATTEMANA (*Cattleya labiata* × *Lælia Perrini*).—A decided acquisition with fine, large and bold flowers, the sepals and petals of a soft mauve-pink, the latter much the broader, both being of extra substance, and in no way reflexed or twisted, the lip being of a bright velvety crimson, with a light bar across it at the throat, almost white; the growth is very free and compact. From Messrs. J. Veitch and Sons.

CYPRIPEDIUM SOUTHGATENSE SUPERBUM (*C. bellatulum* × *C. Harrisianum*).—A remarkably fine hybrid with the characteristics of the first named parent, into which have been infused the deeper colour and increased vigour of the latter; the markings of the flowers are of a deep vinous purple as profuse as in *C. bellatulum*, the ground colour a soft suffused shade of pale purple; a very distinct addition to an already numerous class. From Mr. Thos. Statter, Stand Hall, Manchester.

Awards of merit were given to—

CYPRIPEDIUM LEEANUM VAR. JAMES HAMILTON.—An excellent variety, with the fine dorsal sepal of the parent increased in size, pure white in colour, with the characteristic stripe through the centre and green base, but no spots; the petals are broad, and the labellum of a deep bronzy shade. From Messrs. Sander and Co.

STANHOPEA LOWI.—A new species, which comes near to *S. Amesiana* in form, but instead of being pure white the colour in this instance of the sepals and petals is of a creamy yellow, the central portion of an ivory-white. The usual perfume pervades the flowers, reminding one of *Stanhopea tigrina*. From Messrs. H. Low and Co.

CYPRIPEDIUM SWINBURNEI (Stand Hall var.), which has extra large and bold flowers supported on tall footstalks, the petals distinctly spotted, the dorsal sepal white, with greenish stripes and small dark markings—a good plant. From Mr. Thos. Statter.

PLEIONE MACULATA ALBA.—A white form, with delicately beautiful flowers rather smaller than those of the type, the lip having a faint trace of pale yellow; the plant bore several good blooms. From Mr. G. W. L. Schofield, Manchester.

CYPRIPEDIUM ASHWORTHÆ (*C. Leeanum superbum* × *C. selligerum majus*) has the prominent dorsal sepal of the former, but of finer proportions, pure white in colour, with minute chocolate spots radiating in lines from the greenish base, the labellum being of a dark bronzy brown.

Medals were awarded as follows: A silver Flora medal to Mr. Measures, Cambridge Lodge, Camberwell, for a choice collection containing some unique kinds. Amongst these was a plant of *Cypripedium insigne Sanderæ*, a gem in its way with its soft pale (almost self-coloured) greenish yellow flowers, the upper portion of the dorsal sepal being pure white. *C. insigne Ernesti* may be termed a fitting companion to the foregoing, with nearly self-coloured flowers, but of a pale yellow without the green shading, having a faint, almost indistinct spotting on the dorsal sepal, in both cases the blooms were very lustrous as if burnished. *C. Celeus* (*insigne Chantini* × *villosum*), a light spotted hybrid, very pretty; *C. Exul* and the Cambridge Lodge var.; *C. T. B. Haywood*, a grand hybrid; *C. Mrs. C. Canham*, with extra fine flowers; *C. Argus*, with its distinct spotting; *C. Leeanum*, a good form; *C. Arthurianum*, a distinct hybrid; and *C. Spicerianum* were also included. Other good things consisted of *Cattleya labiata vera*, with the usual fine labellum of an intense dark crimson shade, and a good piece of *Oncidium tigrinum*.

Messrs. B. S. Williams and Son, Upper Holloway, contributed an interesting group of choice things, the plants well grown and healthy, comprising several *Cypripediums*, the best of which were *C. Pitcherianum* (Williams' var.), with dark lustrous flowers of large size; *C. tonsum*, *C. Harrisianum superbum* in good form; *C. Dauthieri superbum*, *C. insigne Mrs. Wilson*, after *Chantini*, but darker; *C. selligerum nrbum*, *C. enfieldense*, *C. Arthurianum*, *C. Huybrechtianum*, *C. insigne punctatum violaceum*, one of the best; and *C. Ashburtonæ expansum*. *Cattleya Bowringiana lilacina* is quite a distinct form, its colour denoted by its name. *Cattleya labiata* and *Compæretia macroplectron*, a singular, but pretty species, with a curious motion of the flowers when shaken, were also shown. A silver Flora medal was awarded.

Messrs. Sander and Co., St. Albans, had a variety of good things, prominent amongst which were fine forms of *Cypripedium Leeanum*, one of the best being a very good form called *virginale*, which has the dorsal sepal void of spots or stripes, being large, pure white in colour, with green base, the other parts of the flower pale in colour. *C. Leeanum excellens*, a large and fine form of *C. Leeanum superbum*, one of the best; *C. Chamberlainianum* with two flowers and *C. Burberryanum* were also shown. Of other Orchids there were *Calanthe rosea*, with pale bluish flowers, *C. Cooksoni*, *C. Sandhurstiana*, with deep rose-coloured flowers, after *C. Veitchi*, but with a darker labellum, and *Odontoglossum sceptrum*, with flowers of a dull brick-red colour. *Barkeria Lind-*

leyana, seldom seen, *Lycaste Skinneri alba* and *Odontoglossum Humeanum*, as well as the curious *Restrepia antennifera* and *Masdevallia polysticha* were also shown here, with one example of *Oncidium sceptrum*. A silver Flora medal was awarded. Messrs. H. Low and Co., Upper Clapton, had a very pleasing group, amongst which there were several nice plants, freely flowered, of *Miltonia Roeziana* and the white variety; these were very good for the season. Several good forms of *Cattleya labiata* were shown here, and an excellent example of *C. Massaiana* with mottled sepals and petals, the lip of a deep velvety crimson shade, with two distinct pale yellow blotches on the side lobes. *Lælia Russelliana*, very distinct and beautiful; *Cypripedium Stonei*, seldom seen now; and *C. bellatulum*, usually shown by this firm, were also included. Awarded silver Banksian medal. Messrs. Lewis and Co. also had a pretty group, in which were staged three capital specimens of *Cypripedium insigne*, freely flowered. *Cattleya labiata*, in the best form; *C. maxima Lewis's var.*, with a distinctly marked lip; *Cynorchis grandiflora*, *Trichosma suavis*, and *Cypripedium insigne punctatum violaceum* (too long a name), were also sent, the award being a silver Banksian medal. Minor exhibits included *Cypripedium rubescens* (*anatum superbum* × *Boxalli*), a dark-coloured hybrid, and *C. Ariadne* (*Spicerianum* × *selligerum majus*), the resemblance to the former parent being very marked. Mr. Foster Alcock, North Church, Berkhamsted, sent a pretty variety of *Odontoglossum Wilckeanum*, and Mr. Holmes, Pickering Lodge, Timperley, Cheshire, sent cut examples of fine varieties of *Cattleya labiata vera* and a distinct variety of *C. Bowringiana* with the labellum of a deep crimson.

Messrs. J. Veitch and Sons staged a grand hybrid, *Lælio-Cattleya Pallas* (*C. Dowiana* × *L. crispata*), with the sepals and petals of a pale blush and prettily undulated, the lip beautifully fringed, of extra depth and of a deep purplish crimson shade, both of the parents being harmoniously blended in the offspring. *Cypripedium* (*Enone*, *C. T. B. Haywood*, *C. Euryades*, and the singular-looking hybrid *C. microchilum*, with quite a minute lip, were also included.

Floral Committee.

The exhibits before this committee consisted chiefly of *Chrysanthemums*. First-class certificates were awarded as follows:—

DRACENA JAMESI.—This is a very pleasing *Dracena*, distinct and with richly coloured leafage, deep chocolate-green, margined with crimson. It would be very handsome as a specimen, and when young for table decoration. Exhibited by Messrs. J. Veitch and Sons, Chelsea.

PRIMULA FORBESI.—A beautiful mass of this interesting Chinese species was shown by Sir Trevor Lawrence, Bart. It reminds one at once of *P. obconica*, but the flowers individually are smaller and produced in profusion on slender stems about 12 inches or so in height. It is also very free-flowering, the flower-stems rising from a thick mat, so to say, of deep green slightly lobed leaves. It is certainly a most interesting species, and the clear rosy colour of the flowers set off with a small deep orange eye is delightful. We presume it is a greenhouse species, thriving under the same treatment as *P. obconica*, and is likely to prove a valuable plant, especially if it can be easily grown. It appears unusually vigorous, and is far more graceful than *P. obconica*.

CROTON RUSSELLI.—This is a fine form of the Queen Victoria type. It has bold foliage of distinct and rich colouring, deep green, barred with crimson, the mid-rib of a very bright shade. It is quite an acquisition to the long list of good *Crotons*. From Messrs. H. Low and Co., Upper Clapton.

Awards of merit were given to the following *Chrysanthemums*:—

CHRYSANTHEMUM Mlle. THERESE REY.—This is unquestionably the most beautiful new variety exhibited anywhere this year. The flower is very large, massive, and with fine, broad, pure white florets. It is a splendid exhibition variety, and

not in the least coarse, which is more than can be said of some recent novelties. Shown by Mr. C. E. Shea, The Elms, Foot's Cray, Kent, and Messrs. J. Veitch and Sons.

CHRYSANTHEMUM JOHN BUNYAN.—This is a lovely Japanese Anemone-flowered variety. It is beautiful both in form and colour, the disc centre full and bright yellow, with the neat guard florets of a paler shade. It is an English-raised seedling. From Mr. Owen.

CHRYSANTHEMUM LORD ROSEBERY.—An English-raised incurved kind, very distinct and of exhibition character. The flowers are of fine form, the petals neat and bright purple-rose in colour. A most welcome addition to this class. Exhibited by Mr. Owen.

CHRYSANTHEMUM ROBERT PETFIELD.—This is another valuable incurved variety, English raised, and with well-shaped, full massive flowers of a rosy-purple shade of colour. Shown by Mr. Owen.

CHRYSANTHEMUM WILFRED MARSHALL.—An incurved Japanese kind, the flowers of striking aspect and intense golden-yellow colour. A highly promising and effective exhibition kind. From Mr. Owen.

CHRYSANTHEMUM NIVEUM.—This is a Japanese variety of American origin, and a delightful flower. It is full, massive, and the broad petals are bluish-white in colour, which seemed almost pure white in the murky atmosphere of the Drill Hall. Exhibited by Mr. Owen.

CHRYSANTHEMUM GOLDEN WEDDING.—One of the best novelties of the present year. The colour is clear golden and the petals incurve. It is what we should class as an incurved Japanese kind. This was shown by no less than four exhibitors—Messrs. J. Veitch and Sons, R. Owen, G. Stevens, Patney, and H. Cannell, Swanley.

CHRYSANTHEMUM ROSE WYNNE.—A fine Japanese variety, the petals broad and delicate blush in colour. From Mr. Owen.

CHRYSANTHEMUM CHARLES DAVIS.—This is now well known, as it has been fully described in recent numbers. Shown by Messrs. J. Veitch and Sons and G. Stevens.

CHRYSANTHEMUM MRS. C. J. SALTER.—This is a charming Anemone variety, the flowers neat and pleasing. It is interesting to know it was raised from Scarlet Gem, a single scarlet variety crossed with Nelson, a crimson-purple Japanese Anemone kind. The result is a neat bloom, the centre reddish-bronze tipped with yellow, and the guard florets reddish-buff. From Mr. W. Wells, Earlswood, near Redhill.

CHRYSANTHEMUM DUKE OF YORK.—A Japanese incurved variety, the flowers broad, large and massive, of full exhibition standard. The florets are deep crimson with silvery reverse. Shown by Messrs. H. Cannell and Sons.

The largest group of Chrysanthemums came from Messrs. H. Cannell and Sons. A splendid collection of zonal Pelargoniums was also shown by Messrs. Cannell, comprising such beautiful single varieties as Galatea, rich salmon-rose; Mill's Favourite, deep crimson; Radba, crimson; White Lady; Mme. Melba, white, flushed with salmon-pink; an improved Lady Brooke; Etoile de Lyon, the florets red, white in the lower portion, a finer kind than Souvenir de Mirande, of which it is possibly a seedling; Lady Tennyson, rich salmon; Mme. de Bondeville, rose, deeper margin to the petals; Blue Peter, magenta; the Double Improved Raspail and Double New Life (silver medal). Messrs. J. Veitch and Sons sent a fine group of Chrysanthemums, comprising splendid individual blooms, especially of the Japanese varieties J. Stanborough Dibbens, Val d'Andorre, Mlle. Marie Hoste, Sunflower, Florence Davis, and Mrs. C. W. Wheeler (silver medal). A large and well staged collection of cut blooms came from Mr. Wythes, gardener to the Duke of Northumberland, Syon House, Isleworth. The flowers individually were of much merit, especially the incurved, as Mabel Ward, Mrs. Norman Davis, and Jeanne d'Arc; whilst of the Japanese kinds, Eynsford White, Louis Boehmer, Mme. C. Audiguier, Florence Davis, and Sunflower were of note; and of the reflexed, the bright yellow Chevalier

Domage (silver medal). Mr. R. Parker, Impney Gardens, Droitwich, had a very creditable collection, comprising leading kinds (silver medal). In each of the following cases a bronze Banksian medal was given. Mr. W. Wells, Earlswood, Redhill, had a large assortment, comprising many seedlings and novelties, as Golden Wedding, Emily Wells, rose, single; and Mme. Albani, a deep crimson-purple flower, more strongly scented of Violets than Progné. Mr. C. E. Shea had a delightful collection, and shown on small stands, being sections of the ordinary 6-inch board. His flowers of Mlle. Thérèse Rey, Silver King, a fine silvery rose-coloured Japanese seedling; Sunflower, and Sarah Owen were worthy of note. Mr. W. Salmon, West Norwood, had a group of cut Chrysanthemums. Amongst the finest flowers were those from Mr. Slowgrove, gardener to Mrs. Crawford, Gatton Cottage, Reigate. These deserved a silver medal. We have never seen six finer blooms of Thunberg, a variety not easy to get to such perfection, and a cultural commendation was worthily awarded. He also had superb blooms of Sunflower, Boule d'Or, Mlle. Lacroix, W. Seward, and Viviani Morel. Messrs. J. Carter and Co., High Holborn, showed some promising varieties, and a large collection of novelties was staged by Mr. Owen; the finer types are described above. Pride of Maidenhead, a white Japanese variety, is highly promising. An important exhibit was the fine mass of Begonia John Heal from Messrs. J. Veitch and Sons, and a new acquisition named Mrs. John Heal. This is an addition to the valuable class of winter-flowering Begonias raised by Mr. Heal, and in the present instance the same parents were used as in John Heal, namely, a tuberous variety and B. socotrana. The flowers of Mrs. Heal are larger than those of the other hybrid, deep crimson, with small white centre, showy, and produced with comparative freedom. It is rather early to judge of it as yet, but it seems to be a vigorous, free, and bright winter flower, with far more of the B. socotrana character than John Heal, which is a splendid kind for winter, bright, and fog-resisting.

Prizes for Chrysanthemums.

Classes were provided for Chrysanthemums, and there was good competition. The most important was for a collection, distinct kinds, in which Mr. Wythes was first, showing a large assortment of fine flowers tastefully set up. The incurved varieties were remarkably good, also the Japanese, as Mr. A. H. Neve, Col. B. Smith, Stanstead Surprise, Sunflower and the reflexed Cullingfordi. We could mention more, but may say that all the leading kinds were represented. A good second was Mr. Thos. Osman, Ottershaw Park, Chertsey, Surrey, with the chief varieties; and Miss R. Debenham, St. Peter's, St. Albans, third, this exhibit comprising many single kinds. A very fine exhibit from Mr. J. McLeod, Dover House Gardens, Roehampton, was disqualified, as not in compliance with the schedule. Another class was for eight new Chrysanthemums, and the first prize went to Mr. W. Slowgrove for eight of the finest blooms we have seen this season. They were superb for form and colour, and comprised Lord Brooke, a noble bloom; G. C. Schwabe, Excelsior, Chas. Davis, R. Flowerday, deep crimson, silvery reverse; Mrs. Libbie Allen, W. Seward and Mrs. Harman Payne, all shown in the finest form. Mr. Wythes was an excellent second, his collection including more incurved kinds, as M. R. Bahuant and Baron Hirsch.

Fruit Committee.

The exhibits before this committee were not so numerous as usual, though most interesting. Seedling Potatoes and new Apples were shown in quantity. Messrs. H. Cannell and Sons, Swanley, staged seventy dishes of Potatoes, having well-known kinds and a few of recent introduction, the best dishes being Colonel Long, Edgocote Purple, Peach Blow, The Dean, Our Boy, very large, several seedlings, and Eynsford Mammoth, rather coarse, but stated to be of excellent flavour (silver Banksian medal). From the society's gardens came a large collection of Celery, most of

the kinds in cultivation being staged. The best were the well-known Sandringham White, Giant White, Veitch's new Dwarf Red and Early Rose, the latter an excellent form of pink Celery for early use; Carter's Solid Red, Dobbie's Select Red, a solid good variety; Henderson's White Plume and Golden Dwarf, novelties, but not valuable where size is required; Major Clarke's, an old variety, and still one of the very best; and Standard-bearer, the last one of the best for its good late-keeping qualities. Mr. Leach, Albury Park Gardens, Guildford, sent some nicely curled Parsley named Leach's All the Year Round. This should be shown next spring to show its keeping qualities. Mr. E. W. Howard, Canterbury, sent two dishes of seedling Potatoes The Field King, specially suitable for field culture, and Lord Wolseley. Mr. J. H. Ridgewell, Histon, Cambridge, also sent four dishes of new seedling Potatoes named Earl's Court Champion and New International; these seedlings the committee desired to be tried at Chiswick, as then their cropping qualities could be ascertained. Mr. W. Roupell, Harvey Lodge, Roupell Park, N., sent good Newtown Wonder Apple grown in the open in the London radius. Mr. Divers, Ketton Hall Gardens, Stamford, sent a good dish of Barnack Beauty Apple, and Mr. W. Jenkins, Abergavenny, sent a nice-looking fruit named Monmouthshire Beauty, but not superior to existing and well-known kinds. Mr. J. Godfrey, Rolle Street, Exmouth, had a small collection of Apples of second growth, small fruits in clusters at the points of the shoots. Mr. T. Edmunds, Uckfield, contributed two dishes of seedling Apples. From Mr. Crook, Forde Abbey, Chard, came a good dish of Coe's Golden Drop Plum, showing its value for late keeping. Mr. J. Pitt, Panshanger Gardens, Hertford, sent a dish of the recently certificated Banana named Lady's Finger, a small fruit, but of excellent quality.

Mr. R. Parker, in the course of his remarks on the Chrysanthemum, stated that he first became interested in the flower by visiting the Stoke Newington show some twenty years ago. There had, however, been a great advance both as regards size of bloom and number of varieties. A great deal had been done of late years towards raising new varieties, but this was not all that was wanted to bring these flowers into notice and to retain them in favour. What he wanted specially to see was varieties that would flower freely and so be useful for cutting. A great number of people were in favour of striking their cuttings in December or early in January, but he did not consider it at all advisable to do so unless the plants were grown solely for exhibition, when more time was required. For decoration he would prefer striking in February or March, and then potting on or planting out. If potted, he advised 9-inch pots, which were large enough for most purposes. The plants should be stopped three times after they were rooted, and if planted out he did not consider it wise to make the ground too rich, as by so doing many failures in the culture of Chrysanthemums took place. He considered good loam with a little leaf mould was quite sufficient when first potted, and after the plants had set their buds he considered manure was more beneficial than at any other time. A great many people in potting up Chrysanthemums were in favour of placing bones at the bottom of the pots, but he considered it a very bad plan; he could not in any way imagine how the plants could reap any benefit; indeed, the contrary. A good material at the bottom of the pots was shell gravel, putting it through a sieve, mixing the fine with the potting compost, and using the coarse as drainage. One thing he was in favour of was top-dressing, which he thought most beneficial, as Chrysanthemums had most roots on the surface of the soil. With regard to planting out, he considered it one of the best and the readiest way for the production of a large quantity of blooms. If planted out in the early summer and lifted in autumn, Chrysanthemum culture was simple. Those who could spare a vinery or Peach house would be able to have a large quantity of blooms for cutting. He

would advise anyone growing Chrysanthemums on this principle to cut round the plants several days before lifting. For the destruction of insect pests, syringing with soft soap for green or black-fly was most beneficial. He was not an advocate of patent manures for the plants. Other modes of culture were not touched upon, such as the production of large blooms, &c.

Paraffin.—What is the paraffin so many of your writers talk about? I have seen paraffin recommended for this and that in connection with plants and have tried what we call paraffin as advised, and have failed with it in every case. In THE GARDEN for Oct. 7, 1893, "Ridgewood" advises its use for Rose mildew—a disease our Roses are much subjected to and for which no efficient remedy is known here. Believing that your paraffin is not the substance we here know by the name, I ask as above before trying it on Rose mildew. Our paraffin is a residuum from the distillation of wood, coal, oils, crude petroleum, &c., and is an oily, waxy substance; in fact, so waxy that we make millions of boxes of candles from it. I suspect your writer's paraffin is kerosene, benzine, benzole or some other distillation of petroleum, and not a residuum from said distillation.—JOHN ADAMS, *Chicago*.

** When I have been writing upon paraffin as an insecticide, what is more correctly known as paraffin oil has been meant. John Adams evidently confuses the two. The oil I use is the ordinary paraffin utilised for lighting purposes at about 10d. a gallon. It makes a very safe, cheap and reliable insecticide when used in the proportions I have frequently recommended, and especially as a further ingredient to many insecticides. I find it leaves the foliage particularly clean and also much less subject to the attack of mildew; indeed, it is so deadly to this blight, that, if used with due care, mildew fails to gain a hold upon any leaves that have been washed with the solution I advised in THE GARDEN of Oct. 7.—RIDGEWOOD.

Old stems of trees.—An old Walnut tree, the inside more or less soft and rotten, has been blown down and I have had it sawn up into 4-foot lengths. My idea was to make a sort of rockery with the pieces at the end of a bed that faces the north, and is partly shaded by trees. Can you tell me what (if anything) would grow in the tree? As a last resource I must plant creepers in the ground.—H. J. S.

** We think it always a mistake to make rock-work of any kind of wood. It is never artistic, enduring or pretty. It is often best to leave the old stem where it dies and clothe it with some beautiful species of Clematis or other climber that one may care for. Another way of dealing with old stems is to saw them in pieces and use them as rustic vases.—ED.

Anthracite coal.—In answer to your correspondent "G. H. B." on p. 450 of last week's issue, I would like to state that I have used anthracite coal now for some years, and it has always given every satisfaction. I find a considerable saving in labour as compared with other fuel, inasmuch as there is not so much stoking required—in fact anthracite coal resents being meddled with too much. The heating power I consider is far in excess of either coke or nuts, and a great advantage is that there are very few clinkers. As to price, I am sure that weight for weight it is much cheaper; at all events since using it my fuel bill has been £10 per year less than hitherto.—W. J. BRIGHT, *The Gardens, Plas Isob, Ruthin, N. Wales*.

— If "G. H. B." can get a ton of best cobbles delivered at 20s. compared with coke at 15s. per ton he would never use the latter again, that is if draught is good. After a lengthened trial I prefer cobbles, as being more economical in every way, less dust, no time lost in breaking, and a lasting fire. There being anthracite of very inferior quality in the market, I would advise "G. H. B." to obtain the best direct from the colliery in trucks holding from 8 to 10 tons. In using anthracite there are less dust and ashes and very few clinkers,

and no fear of the fire being out after twelve hours, while there will be no difference in the heat in the pipes at the end of the time stated. Poking between the bars from underneath is preferable to stirring up the coal. There is no smoke, and since I have used anthracite the flues are cleaned out every third week instead of weekly.—STEPHEN CASTLE.

IRON ROOFS.

WITH reference to your correspondent's complaint about his iron roofing, I fear the fault lies in his own ignorance of the material he is using. A slate or tile roof may be put up, and if left to itself it will wear as long as the wood of the laths will last; but it is not so with an iron roof. This requires a certain amount of looking after; but given this small amount of attention I think that everyone who has tried them will agree with me that iron is by far the cheapest both as to first cost and also in the long run. Now as to the proper way to go to work. The iron should have been galvanised, and if possible tarred on both sides before it was put up, and once a year during the fine weather it should be brushed over with tar as hot as can be managed. Hot tar is to be preferred to the much-advertised black varnish, as it is not so brittle and liable to chip off. No doubt paint would do equally well if price were no object. There seems to be a general feeling in favour of corrugated sheets for roofing, and as I have always used these I cannot claim to speak with any authority on the point, but I am strongly of opinion that flat sheets would be better. Given equal weights per unit of surface covered, the flat iron would be nearly twice the thickness of the corrugated, and would only have half the surface to tar and to rust. Nor should the flat sheets require any more spars to support them. Spouting is a much more difficult matter, and here I admit iron is not satisfactory. Hardly a winter passes without some of the cast-iron downrights being ripped to pieces by the frost. Up to the present wood has given most satisfaction both for the spouting and the downrights, but it soon comes to naught if it is not kept well painted. I can call to mind some chemical works near this place where the air is frequently thick with acid vapours, and yet the iron roofs appear to be as sound as when they were put up ten years ago, owing to the annual treatment with tar they receive.—H. J. S.

** A good comment on modern ignorance of the art of building! A roof—which originally meant a thing like a rock to shelter man from sun and frost—must be doped with tar once a year! The slightest experience should convince that an iron roof in the end is more expensive than one which will last, such as that formed of tiles, or stone, or concrete. There are plenty of tiled roofs in England that have existed for several generations and have never had annual attention, and there are roofs that have existed now for two thousand years to our certain knowledge. The whole of the iron roofing business is an ugly and impudent makeshift, and, as regards effect, the greatest misfortune that ever befell the home landscape in England. Even a wooden roof is far better in every way than iron, as the following paragraph in a recent issue of Garden and Forest will show:—

Wooden roofs.—A shingle roof which had been put on fifty-three years ago was lately removed from a house in Nashville, Tennessee. Four kinds of shingles were used indiscriminately—Poplar, Oak, Chestnut and Walnut. The Poplar shingles led in soundness, followed in order by the Chestnut, Walnut and Oak. The Chestnut had simply worn away, the Walnut had a dry rot on the under side of the exposed portion, and the Oak had rotted. The shingles were rived and hand-drawn. It is not probable that a modern sawed shingle of either wood would have lasted half as long. Besides cutting across the open ducts of the wood, and affording inlets for moisture, the saw leaves a fuzz on the surface of the shingle which causes it to dry off more slowly after rain.—ED.

The weather in West Herts.—The most noteworthy feature of the weather of the past

week has been the persistence of north-easterly winds; in fact, during the eight days ending Monday for only three hours did the wind come from any other point of the compass than those between north and east. With the exception of Saturday, the last eleven days have been all unseasonably cold, and on two nights the exposed thermometer indicated from 11° to 12° of frost. Since the 4th the temperature of the ground at 2 feet deep has fallen 5° and at 1 foot deep as much as 8°. Until Tuesday the weather had been fairly dry, but on that day over half an inch of rain fell. Previous to this fall no measurable quantity of rain water had come through the percolation gauge containing heavy soil for eight days. Small quantities were, however, measured each morning from the light soil gauge. On Thursday in last week and also on Sunday and Monday last the sun shone brightly for six or more hours.—E. M., *Berkhamsted*.

Book on Ferns.—Will you kindly inform me in next issue of THE GARDEN (if possible) what you consider the best work on exotic Ferns?—INQUIRER.

** The best work on exotic Ferns is undoubtedly the "Book of Choice Ferns," giving the descriptions of the best and most striking Ferns and Selaginellas, and giving also explicit directions for their cultivation and propagation, the formation of rockeries, the arrangement of ferneries, &c. This important work, which is the most practical and complete ever published on the subject, is written in a popular style and is particularly accurate. It is illustrated with numerous coloured and monochrome plates and engravings prepared from drawings, photographs and sketches made especially for the work. All the generic names have their derivations given, and every specific name has also its equivalent in English, which greatly assists in remembering them. The geographical distribution and the culture of each genus are separately and extensively given, and the illustrations, as also the letterpress, are all that can be desired. This handsome work may be had, either in parts or in bound volumes (twenty-one of the former or three of the latter completing the work), of the author, Mr. G. Schneider, 17, Ifield Road, West Brompton, London

Names of plants.—*Thos. Stansfeld*.—A poor variety of *Cattleya labiata*.—*E. Gurney*.—1, *Cypripedium Arthurianum*; 2, *Cattleya Loddigesii*; 3, *Cattleya Bowringiana*; 4, *Dendrobium Phalanopsis Statterianum*.—*Thos. Robinson*.—1, *Hymenophyllum asplenoides*; 2, *Gymnopteris nicotianifolia*; 3, *Odontosoria auleata*; 4, *Asplenium cuneatum*; 5, *Adiantum macrophyllum*.—*W. A. Gunner*.—*Liparis spathulata*.—*T. J. M.*—*Laelia anceps*; 2, *Laelia autumnalis*.—*W. Woodward*.—1, *Polystichum lobatum*; this is found in many varieties at Clova, and this is one of them; 2, *Asplenium Adiantum-nigrum*.—*J. B.*—Please send better specimen with leaves.

Names of fruit.—*G. Warrington*.—1, *Uvedale's St. Germain*; 2, *Catillac*; 3, *Baroune de Mello*; 4 and 5, *Fondante d'Automne*.

"The Garden" Monthly Parts.—This journal is published in neatly bound Monthly Parts. In this form the coloured plates are best preserved, and it is most suitable for reference previous to the issue of the half-yearly volumes. Price 1s. 6d.; post free, 1s. 9d. Complete set of volumes of THE GARDEN from its commencement to end of 1892, forty-two vols., price, cloth, £30 12s.

"Gardening Illustrated" Monthly Parts.—This journal is published in neatly bound Monthly Parts, in which form it is most suitable for reference previous to the issue of the yearly volumes. Price 5d.; post free, 8d.

"Farm and Home" Monthly Parts.—This journal is published in neatly bound Monthly Parts, in which form it is most suitable for reference previous to the issue of the yearly volumes. Price 5d.; post free, 8d.

"Hardy Flowers."—Giving descriptions of upwards of thirteen hundred of the most ornamental species, with directions for their arrangement, culture, &c. Fifth and Popular Edition 1s.; post free, 1s. 3d.

"The Garden Annual" for 1893.—Contains Alphabetical Lists of all Branches of the Horticultural Trade. The Lists of Gardens and Country Seats (containing over 9000) have been very carefully and extensively revised, and are admitted to be the most complete ever published. Price 1s.; by post, 1s. 3d.

All of our readers who are interested in the improvement of cottage homes are invited to help us to make Cottage Gardening known. It is published at the very lowest price to meet the wants of those for whom it is intended, and copies will be sent for distribution, free, by the publishers, Messrs. Cassell and Company, La Belle Sauvage Ludgate Hill, E.C.

No. 1149. SATURDAY, November 25, 1893. Vol. XLIV.

"This is an Art
Which does mend Nature: change it rather; but
THE ART ITSELF IS NATURE."—*Shakespeare.*

CHRYSANTHEMUMS.

CHRYSANTHEMUMS FOR COLOUR.

MANY much-praised Chrysanthemums are of poor colour. The flowers are beautiful in form perhaps, but of a dingy purple, magenta, rose, or similar shade, which looks fairly well on the show board, but not in a mass. Such kinds one does not want to grow for cutting, and the rage for size in the individual bloom has led to the rejection of many charming varieties for colour which we have mentioned in these notes.

The large collection of Chrysanthemums in the Chiswick Gardens is interesting, as many old varieties are grown, and the plants have been little disbudbed. I went carefully through the large array in the vineries and old Palm house to select a few of the finer simply for colour, taking no account whether they were new or old. Others may be able to add a few more kinds not mentioned here, free-growing, vigorous varieties with flowers of a decided shade. One notices the large number of white-flowered Chrysanthemums, and the prettiest of all is Jane, or Snowflake, a single kind, the flowers individually large and of the purest white. Two or three specimens are smothered with bloom, and the graceful sprays are delightful to cut for the house. If only one white Chrysanthemum were required for cutting, my selection would be this, so free, graceful, and informal. Mons. Astorg, Fair Maid of Guernsey, Eynsford White, Avalanche, and amongst the earlier kinds Elaine, Lady Selborne, and Mlle. Lacroix are invaluable. Of course, very few comparatively of the large number of white Japanese varieties are mentioned, but sufficient for ordinary collections. Of this number I prefer Avalanche and Eynsford White to the others. There is a charming curve, so to say, in the florets of the last-mentioned. In the other classes white-flowered varieties are numerous. Amongst the pompons Miss Talfourd is of note, the flowers of the purest white, and of the large flowering Anemones Fleur de Marie is very beautiful. Mention must also be made of *Sœur Melanie*, one of the freest of Chrysanthemums, a gem for cutting.

A large section of Chrysanthemums comprises those with flowers of chestnut-orange and allied shades. The most popular of all is *Source d'Or*, a variety, like many of the others mentioned, seldom seen at an exhibition. It is remarkably free, the colour orange and gold, and the flowers produced in profusion. No kind is grown more for the market, and I remember some time ago when in the nursery of Messrs. Balchin and Sons at Hassock's Gate, near Brighton, a large houseful of it, the rich colour giving as much pleasure apparently as the purest white. Another fine variety at Chiswick is *William Stevens*, the flowers rich chestnut-red in colour, with the petals margined with orange. A plant in full bloom is superb, the colouring being so rich and decided. Such kinds as these are very different to the dull reds, purples, and yellows which unfortunately abound. *L'Île des Plaisirs* must also be mentioned, a very old variety, it is true, but rich and beautiful in its bronzy red colouring.

Rozain-Boucharlat, *Le Nigre*, very free, and *William Robinson* all deserve a place. The last of the trio is still one of the best Chrysanthemums in cultivation for cutting, and at the recent Aquarium show there were several fine flowers of it. Of yellows there is a very large selection. The best single is unquestionably *Yellow Jane*, the counterpart of the white form, the flowers of a very rich self-yellow colour inclining more to orange. It is very free, and in every way a fine Chrysanthemum for cutting. *Sunflower*, a well-known exhibition kind, is charming when grown in a natural way, the shade of yellow in the flowers being as fine as in any Chrysanthemum in cultivation. *Buttercup*, *Golden Mlle. Marthe* amongst the pompons, the thin-petalled Japanese kind *E. G. Henderson*, a perfect mass of bloom; the golden yellow reflexed *Cloth of Gold*, and *Elsie* are all of merit, the flowers of varying shades. Thus *Elsie* is more of a primrose tint, a lovely colour, and I think this is the most beautiful Chrysanthemum almost in cultivation. There are several plants in the Chiswick collection, and all of the same free habit in growth and bloom.

A class I think too little grown for cutting is the *Anemone pompon*. At Chiswick a very fine deep crimson-purple kind is *La Marguerite*, not a dingy colour, but bright and distinct. It is very free and well worth a place in even small collections. *Purple Pompon* is a good rose-purple shade, and amongst others with purplish-coloured flowers is *Progue*, which has quite a Violet-like fragrance. *William Holmes* is, of course, one of the best of the crimson-coloured flowers, and others I especially singled out were *La Charmeuse*, *Brilliant*, *deep crimson-purple*, an intense shade, and *Eynsford Gem*, a pompon one does not often see, but a neat, pretty flower of a rich crimson-purple colour. *La Triomphante*, white, shaded with rose; *Mlle. Cabrol*, a beautiful Japanese *Anemone* variety, white and with a rose-coloured centre; *Maiden's Blush*, rose; *St. Leonard*, bright rose, a fine reflexed flower; *Beauté de Jardin*, rose-purple; *Jas. Salter* and *Margot* are all of fine colour, especially the last-mentioned, which is one of the most charming Chrysanthemums grown. The flowers are of rather flat form, but delightful colour, a kind of rose-lilac, very soft and delicate. A few others of great merit and grown naturally, so to say, as at Chiswick, gain in interest. The large *Anemone*-flowered *Nouvelle Alvéole*, the flowers carmine-rose in colour, is very pleasing, so also is the Japanese variety *Hamlet*, the colour dull red, with buff reverse to the florets. *Miss Rose*, single and of a rosy colour; *Mary Anderson*, single, white, touched with pink; the pompon rose-coloured *Mlle. Elise Dordan*; *Triomphe du Nord*, light red; and *Mr. Charles E. Shea*, the yellow-flowered sport of *Mlle. Lacroix*, a very free and pleasing variety, are also noteworthy.

Such kinds as those mentioned are of use for amateurs in particular and all who do not want exhibition blooms. As will be seen, many that are prized by exhibitors are included, these when grown more naturally being very beautiful. It is time one saw a group of such plants at exhibitions. At the Royal Aquarium show a special prize was offered for naturally-trained specimens, but not for a group, although such a feature would prove of much interest. The group need not be confined to Chrysanthemums alone, but *Ferns* and *Palms* might be intermixed to get a varied effect.

C.

Old certificated Chrysanthemums.—I recollect not long ago somebody complaining that

many varieties which had received first-class certificates were no longer grown, and, therefore, that the awards were improperly made. The explanation seems very simple, and anyone who has attended the meetings of either the R.H.S. or the N.C.S. must readily admit that many flowers which a few years ago would have been sure to get this coveted award would now-a-days stand not the slightest chance. The standard of excellence has been raised enormously, but particularly so during the past three years, and it is only right that as cultivation advances the societies should be more exacting. Among Chrysanthemums that once occupied a prominent position as certificated varieties may be mentioned *Agnes Flight*, *Alpha*, *Brise du Matin*, *Buttercup*, *Duchess of Albany*, *Duke of Berwick*, *Emma Stevens*, *Hamlet*, *Jupiter*, *L'Ebouriffée*, *La Triomphante*, *Macaulay*, *Mlle. Panle Dutour*, *Maiden's Blush*, *Margot*, *Martha Harding*, *M. Astorg*, *Moonlight*, *Mrs. J. Wright*, *Othello*, *Phœbus*, *Roi des Japonais*, *Fernand Feral*, *George Stevens*, and many others. Where are they now? So far as the show-boards at our leading exhibitions are concerned, they may be said to have been practically swept out of existence, a remark that applies with equal force to the list of the best twenty show Japanese of a decade ago. The varieties most in favour in those days, and still remembered by many of us, were such standard sorts as *Fair Maid of Guernsey*, *Mme. C. Audignier*, *Peter the Great*, *Comte de Germiny*, *Elaine*, *Meg Merrilies*, *M. Ardène*, *Baronne de Prailly*, *Criterion*, *Hiver Fleuri*, *Album Plenum*, *Sarnia*, *Fanny Boucharlat*, *Soleil Levant*, *Boule d'Or*, *Triomphe de la Rue des Châlets*, *Bertier Rendatler*, *Père Délaux*, *The Sultan*, and *Thunberg*. It is a striking contrast to the duration of a modern favourite that many of these old varieties remained in cultivation from ten to fifteen years.—CHRYSANTH.

Certificated Chrysanthemums.—Last season at the floral committee meetings of the N.C.S. there were thirty-four varieties certificated. These were staged by eighteen different exhibitors, being a trifle under the rate of two certificates to each exhibitor. Up to the 8th inst. the same society had awarded twenty-six first-class certificates to twelve exhibitors, which, as will be seen, is just a little over the same rate. These figures, to my mind, seem to point conclusively to the impartiality that is displayed by the committee in making its awards. Considering the enormous number of novelties staged at some of the meetings, the committee can scarcely be charged with being prodigal with these distinctions.—C. H. P.

Chrysanthemum Source d'Or.—This is one of the most popular of market varieties, and it will be long before we get another kind of its colour that will yield such profitable returns. It grows very freely, and the flowers are, when not thinned, of just the size that suits the florist. What is needed is a late blooming variety having the same characteristics. *Golden Gem* is very good, but it has not enough of the much admired bronzy colour that distinguishes *Source d'Or*. By stopping the latter at intervals from the middle of June till the end of July one may have good blooms up to mid-December, but I have not found it practicable to get them at the new year.—J. C. B.

SINGLE CHRYSANTHEMUMS.

THESE are certainly very pretty, and will probably become popular. It is to be hoped, however, that raisers will direct their efforts to improvement in form and colour other than to an increase in size. The flowers of such varieties as *Jane* and *Mary Anderson* are very lovely, and have an excellent appearance when used in the house with some kind of foliage that will show them off to advantage. One of, if not the smallest flowered of the singles is *Miss Rose*. To my mind this is one of the most charming flowers in cultivation. It is so small, that at first sight one might easily mistake it for one of the annual varieties. It is quite a charming little Chrysanthemum, and one that would satisfy the most refined taste. Purity is

very good, and is interesting as showing how the present race of incurved varieties originated. The petals have a marked tendency to turn inwards, and it was probably a single kind like this, perhaps identical with it, from which descended the show varieties of the present day. Jane and its yellow variety are among the best known of this section, and Guernsey Sunset, Miss Ellen Terry, Exquisite, Coquette, Mozart and Miss A. Bates are among the best. The Virgin and King of the Yellows are late bloomers. As regards beauty of form, I doubt if any variety can surpass Mary Anderson, and if I had to choose one only, this would be my sole choice. Some of the recent additions to this section of the family may, however, be as good, my experience of single Chrysanthemums being limited to those that have become more or less popular. As they seed so freely, there is a danger of our having too many too much alike varieties.—J. C. B.

—These were shown remarkably well recently at the Royal Aquarium, but we missed the bunches of recent years. These were very pleasing when no attempt was made to make all the flowers point one way. It is quite a mistake, as on this occasion, to cram the blooms on a small board, or to cut them with short stalks and little or no leafage. Why cannot there be a class for Chrysanthemums of this type, pompons, Anemone pompons and allied sections, in which the flowers shall be shown in graceful bunches? Throughout the whole exhibition, large as it was, there was not a bunch of single or any other Chrysanthemums in the competitive classes that one would care to see in such a form on the table. Plants, groups and blooms are stiff and unreal at these exhibitions.

CHRYSANTHEMUM GROUPS.

I HAVE observed with very great satisfaction that the once favoured trained plants at the Chrysanthemum shows are gradually becoming extinct. It is one of the things which no one will mourn over, for they have long been plant abominations. They never would have existed but for the encouragement given them in the shape of prizes, and they have been grown only to win prizes. As gardening is not dependent for its existence as a profession upon prize-winning, and still further, as so far as trained plants are concerned, has it rarely been found that their production has helped horticulture, so does it seem folly to sustain the growing and showing of what is neither desirable nor pleasing. There still remain, however, these objectionable features at show Chrysanthemum groups. At our summer shows we very often see of miscellaneous productions some very lovely combinations, that by their lightness, grace, beauty of arrangement in form and colouring command the warmest admiration of everyone. Everyone has felt that the farther in these summer groups we get away from the lumpy and formal, the more pleasing are they. We have at some of the winter shows attempted to copy these through similar agency, but generally with indifferent success. The result was usually a poor copy made in bad light and with indifferent surroundings. Even these groups are now becoming fewer, and the field at the winter shows is being still more left to the Chrysanthemum groups. Now of these it may be said with entire truth that the farther they are removed from the lightness and elegance which characterise the summer groups and the nearer they come to dull, heavy stiffness and formality, the more are they held in esteem. It would almost seem as if Chrysanthemum growing for exhibition did conduce to the killing in growers of all sense of grace and of appreciation for natural beauty. Apart from the fact that the groups are huge masses of large mop-headed flowers on tall plants, it would be difficult to find anything in plants that gives so much that is stiff, solid and unattractive as does a modern Chrysanthemum group. There is about the arrangement from top to bottom, from back to front, such an attempt to bring every flower into face and line, just as if each one had been clipped,

that not a petal should project one hair's breadth above or below the level. How can it be otherwise than that this sort of thing should tire? The half-dozen competitors for the prizes regard the groups with passing interest until after the awards are made, but no one else cares. If the prizes were offered to the gardener who could succeed in packing into a given space of so many square feet the greatest number of plants and mass of bloom, we could then understand the crowding now seen. But that any sensible man should suppose that cramming means beauty or effect is hard to believe. In not a few cases how wretched an appearance around their lower fronts do these groups often present—a collection of pots in various sizes, too often dirty, smaller ones stuck upon larger ones, or the reverse, sticks like to a wood, leafless stems, ragged foliage. How often does this present a true picture, and it would be a kindness did someone, considerate for the feelings of the spectators, but draw a cover of green baize round the whole and shut it out from view. Why should all this be endured? Groups of some description must be continued; why in such miserable form? It is constantly pleaded that, mixed with fine-foliaged plants, the groups would be far lighter and more graceful. Of course they would. No one wants to see groups in which there are twenty plants of a white or a yellow or pink repeated *ad nauseam*. A. D.

Chrysanthemum flowers in vases.—A new and fine feature at the recent exhibition of the National Chrysanthemum Society was the bold arrangement of blooms from Mr. H. J. Jones, Rye-croft Nursery, Lewisham. The flowers were of the usual show type and loosely and tastefully arranged in very tall vases of good design, appropriate to the colours of the Chrysanthemums. Fern fronds and Asparagus were trained over the sides and at the base, the whole forming one of the most effective exhibits we have ever seen at a Chrysanthemum show. We used to be told that it was impossible to get pleasing displays in this style, but have always urged that such a bold flower as this could be used to the greatest advantage at exhibitions, and features like these are a relief to the single cut blooms and stiffly-trained plants.

Late Chrysanthemums.—The exceptional season we have had, with many kinds of flowers a month or more in advance of their ordinary season of blooming, does not appear to have affected Chrysanthemums to the extent one might have expected. In fact the ordinary dates of Chrysanthemum shows have even in the south of England found the flowers just at their best, and little difficulty has been experienced in either hastening or retarding the blooms, at least of the majority of kinds. In the case of those varieties that are grown expressly for late bloom, I do not find them at all in advance of ordinary seasons. I grow a quantity, principally white varieties, for cutting at Christmas and onwards, and they have just been placed under glass. The buds are just bursting out, so that there will be no difficulty in keeping them until required. I find old plants cut down once are excellent for producing a quantity of bloom. They are kept in cold frames after they cease flowering in January until danger of severe frost is over, when they are set out in the open, shaken out of their pots, repotted in extra large pots or tubs, and in May topped to ensure a good head of flowering branches. They are then allowed to grow quite naturally, getting abundance of water every day and liquid manure three times a week. Very little disbudding is done, the result being some hundreds of good useful blooms on the largest plants.—J. GROOM, *Gosport*.

Japanese Anemone Chrysanthemums.—One of the most interesting features of the National Chrysanthemum Society's show was the Japanese Anemone type. We have seldom seen better flowers, and this class is difficult to produce in perfection. The exhibits from Mr. Ives, gardener to Mr. E. C. Jukes, Hadley Lodge, Barnet, are always good, and we should like a note from

him as to their culture, as he succeeds remarkably well with the plants. Those shown comprised the best now in cultivation. A novelty is named Rodolpho Ragioniere, which is a beautiful addition to the list, the name, unfortunately, a drawback. The guard petals, as in all the true Japanese type, are long, broad and silvery white, touched with rose, the centre gold, but the tubes delicate rose with silvery white tips. Jeanne Marty is one of the older forms and well known; whilst also worthy of mention are the following: Le Deuil is a new kind, given a first-class certificate by the society last year. The flowers are of true character, the centre good, and the colour is self crimson-purple, a distinct and attractive shade. Minnie Chate, rose-lilac, with rose disc; M. Pankoncke, described not inaptly as claret-brown, the florets tipped with a bronzy yellow colour; Mme. Cabrol, rose-pink, a very pleasing flower; Sabine, one of the most distinct for its primrose-coloured flowers; James Weston, the guard florets white, centre very delicate primrose or sulphur colour; Nelson, purple-crimson; and Fabias de Maderanaz, which has remarkably long guard florets, are the best of this section. Two of the best novelties we have noticed this season are Mme. Lawton and Mme. Natalie Brun. The former has broad and flat guard florets, pure white, tipped with delicate rose, the disc pale pink and full. The other is delicate pink, except the disc, which is white.

FREELY-GROWN CHRYSANTHEMUMS.

ONE might go into scores of gardens at this season of the year and find only specimen blooms. These are all very well in their way, and I have nothing to say against them; but those people who devote their energies to the production of these only, lose a great deal of the charm of a Chrysanthemum. These large Chrysanthemums are only of short duration, but not so those freely-grown little bushes, which, if a good selection is grown, will gladden the eyes of the grower or owner for at least four or five months. For cutting for room or table decoration they are hard to rival. One might even cut basketfuls for friends without their hardly being missed. Varieties adapted for this form of culture I am always on the look-out for, and which may be cultivated well in 6-inch, 7-inch or 8-inch pots, according to the variety. Singles as well as the ordinary varieties I grow under this form, although as regards the singles there is not that advancement in the habit of the plants that one would like, and which, perhaps, is one cause why these have not become so popular as their admirers expected they would; in fact, some of them have quite a wretched habit, being tall and weak-growing as well, the flowers hanging their heads instead of holding them erect. Cut and placed in vases this defect may not be so noticeable, but a variety to become popular should have a good habit when grown as a pot plant for conservatory decoration. Such, for instance, as Mary Anderson, Jane, Miss Rose (the latter perhaps the most compact-habited Chrysanthemum in cultivation), Gus Harris, and last, but not least, Mme. Edouard Crousse, a most charming variety, silvery white, shaded with rose, very free-flowering. It is the best single variety since Jane and Mary Anderson were sent out and does well in pots.

M. Gustave Grunerwald is certainly a very fine introduction as an early decorative variety. It has a good habit and a very pleasing colour. My stock of two plants will be increased considerably, as nice plants may be grown in 6-inch pots. Mme. Greard is a capital early white of good habit. Alexandre Dufour, described as Bishop's Purple, is one of the most perfect habited varieties for growing in small pots; so also is the crimson *Roi des Précoces*. As an accompanying white to the above two excellent varieties we have the pure *Sœur Melanie* and *L'île des Plaisirs*, deep crimson, tipped with gold. A variety that I am particularly pleased with is *Margot*. The plant in itself is certainly rather loose, but the quantity of flowers a plant will produce is wonderful, and the colour is pleasing. Those who have not grown this variety as a

freely grown bush, I would advise them to do so. Although described as an early variety, it is not so when grown as described. Of course, James Salter and Lady Selborne are two well-known varieties, and now that we have a yellow sport, we have a charming trio. Then there are the pretty Florence Piercy, Mlle. Lacroix, and its sport Annie Clibran. Source d'Or is also a well-known beautiful kind for cutting, and just now I have a distinct sport, being a lovely shade of old gold, and which I hope to fix. Elsie, a reflexed straw-yellow, is of a distinct shade which we have not got in any other Chrysanthemum. A variety I have named Garon is another very pretty Chrysanthemum, the colour a silvery rose. Mme. de Dubois, creamy white, shading off to a violet-rose, is most effective; so also is Coral Queen. La Charmense, a shade of purple, suffused with white, is very showy grouped along with the more sober toned colours. Peter the Great and W. H. Lincoln, two distinct shades of yellow, are very free grown in a bush form, but must be given in the larger sized pot. Then there are La Nympe, Bouquet Fait, Mme. Louise Leroy, and some others. Coming to later varieties, what could be better for Christmas decoration than Boule de Neige and Golden Gem. In pompons there are the pretty Mlle. Elise Dordan and the little Snowdrop. Other newer varieties I have on trial to note their adaptability for this form of culture. A. Y.

AMERICAN CHRYSANTHEMUMS.

IN some respects it seems to be an unfortunate thing for American seedling Chrysanthemums that Messrs. Pitcher and Manda, of Hextable, relinquished their business there almost on the eve of the Chrysanthemum season. During the past two or three years the meetings of the floral committee of the National Chrysanthemum Society have been exceptionally interesting by reason of the new American varieties exhibited by that firm, to say nothing of those which have been introduced by our own growers from such raisers as Mr. Spaulding, Peter-Henderson and Co., Mr. Thorpe and others of like renown. The competition between the French-raised and the American Chrysanthemums was becoming very keen, and if matters had gone on in the usual way, I believe from past experience we should have this season found that the best of the new introductions would have been varieties raised in the States. Fortunately for the credit of the French, M. Ernest Calvat just stepped into the ranks in time, but if we except the new flowers sent out by him, the really genuine novelties of American growers far surpass those of all the other French growers put together. One feature, however, in connection with the American sorts must be borne in mind. Not all the Chrysanthemums received from the other side of the Atlantic can be fairly termed American, because large numbers of those cultivated there have been imported from Japan, and there is much difficulty in ascertaining definitely which they are. Being catalogued in American lists often leads our introducers to assume that the new flowers they purchase are the product of those American firms who sell them, but this is often not the case, as previously mentioned.

In looking over the reports of some of our leading exhibitions, it will be noticed that Chrysanthemums from America form an important feature on the winning show-boards, although they have not done so at the meetings of the floral committee. English raisers, too, are now beginning to compete very successfully with their foreign *confrères*, and it is possible that if an audit of the best 50 or 100 show flowers were now taken, it would be made up of almost an equal number of French, American and English-raised varieties. This, however, is a work that must be left to other hands, but it may be useful to mention the names of such American Chrysanthemums as have been shown in the best form during the past few weeks, and as they are mostly well known to the average Chrysanthemum grower, descriptions may be usefully dispensed with. They are Col. W. B. Smith, Mrs. E. W. Clarke, Mrs. E. D. Adams, Wm. Tricker,

Violet Rose, W. W. Coles, Puritan, W. H. Lincoln, Eda Prass, Waban, Lord Brooke, Mrs. C. W. Wheeler, Julius Roehrs, R. C. Kingston, Potter Palmer, Miss A. Hartshorn, E. G. Hill, Wm. Falconer, Mrs. Alpheus Hardy, Louis Boehmer, G. W. Childs, John Dyer and Mr. A. G. Ramsey. Those which have been certificated are Eda Prass, Tribune, Golden Wedding and G. W. Childs.

CHRYSANTH.

SPOILING THE CHRYSANTHEMUM.

SOME years back you published some remarks from me under this heading, and since then there has been a great improvement in the method of showing the Chrysanthemum. The flowers are often shown on long stems, either with the natural foliage or with Ferns or other feathery leaves. There was a very pretty stand at the Drill Hall on Tuesday, November 14, where the blooms were resting among the branches of a Ficus or some similar trailer. At the Aquarium there were some fine vases filled with Chrysanthemums on long branches on Mr. Jones' stand, and these had a splendid effect. As a contrast, and not far off, were a series of hideous "trained" plants, all elaborately tied out on sticks in a balloon form, with stiff flowers at equal distances, with the general artistic appearance of an "ornament for yer foire stove," or of the pink wooden imitation flowers sold to Seven Dials children for a halfpenny. It is a horticultural scandal that prizes should still be given by any leading society for such tasteless monstrosities. If they still must be given to please important supporters who stick to the "florist" standards of their youth, an encouragement should be given to more natural and tasteful habits of growth. Prizes should be offered for naturally grown plants, lightly staked and with all the buds left on as Nature places them. True, the flowers would not have the size of a Sunflower, a Dahlia, or a Cauliflower, but they would be infinitely more in accordance with the grace and, so to speak, the natural standard of the Chrysanthemum.

While it is very satisfactory to notice more artistic ways of showing the flower gradually making their way, I fear that the flower itself is continuously and rapidly losing all its natural grace and beauty. It is true that the odious incurved section is fast losing its hold on the favour of private growers. But the stiff regularity of that Cauliflower among indoor blooms is still the ideal of the so-called florist. As the incurved flowers go out an excellent imitation takes its place in the newer so-called Japanese varieties. They have already reached the standard of beauty of a double African Marigold, coupled with the size of a Sunflower, and with perseverance they may yet be turned into the roundness of the cricket-ball, and may even vie with the grace and careless abandon of the double Dahlia. This seems ten thousand pities. Where are the old thread-like or tangled tresses of the native Japanese sorts? Where are the flowers that the artists of Japan depict on their countless varieties of vases and fans with such infinite skill and artistic effect? Would any artist take a prize Japanese of our shows of to-day and put it anywhere in a picture? why he would as soon take the kitchen mop, handle and top included, as his emblem of floral perfection!

Again, who wants Chrysanthemums as big as soup plates, and what can be done with such floral monstrosities? Such flowers are simply impossible in a nosegay or for any decorative purpose. For cutting, outdoor plants while they last are infinitely superior, and this year the semi-early Japanese left alone to grow as they pleased out of doors, but planted in rich

soil, have made a splendid display. The half opened buds round the central flower have quite trebled the beautiful effect of the plant growing as Nature meant it to grow. It is no doubt true that in many years such flowers would fail out of doors, and we do not seem, therefore, to be advancing much with the hardy kinds. We want a race of Japanese that shall flower all through October out of doors. Then we want a hardy break of singles for late October and November blooming in our borders. Singles would be less affected by the frost and damp of our miserable autumns.

These remarks were suggested to me by Mr. Parker's expression of opinion at the Drill Hall, that the Chrysanthemum had greatly advanced as a flower in the last twenty years. So far as size goes he is perfectly right, but when beauty and grace are considered, I think the double flowers have distinctly retrograded. The Horticultural Society is eminently fitted to bring us back to a more natural state of things, by forbidding curling tongs and similar abominations, by insisting on flowers being shown on long stems, by giving encouragement to plants that are not disbudded, and to single plants grown naturally in pots as Nature meant them to grow. J. I. R.

CHRYSANTHEMUMS AT MAIDENHEAD.

MR. ROBERT OWEN, of the Floral Nurseries, Castle Hill, Maidenhead, is so well known to cultivators of the Chrysanthemum as a raiser and importer of many excellent varieties, that a few notes concerning the novelties now on view there will be welcome. Besides a complete collection of all the newest and best of the American and French introductions, Mr. Owen has a large number of new seedlings of his own. He does not confine himself to any one section, but seems to be equally skilful in the obtaining of pompons, Anemones and incurved, besides of course the latter day favourites, the Japanese. There are six or seven glass-houses containing the plants in bloom, and there are few trade displays in or near London where a more interesting collection of novelties can be seen, although there may be several of more extensive dimensions. The plants are well grown and the blooms very fully developed, except those in one house, which are reserved specially for fertilisation. High exhibition cultivation for this purpose would be useless, as most growers of seedlings are aware, and those who desire to obtain seed in any quantity must resort to other methods than those adopted by the winners of prizes at the leading shows. A large number of the seedlings are as yet unnamed, many of them are being tried for the second and third season, and doubtless a large proportion of the best will in due time be announced for distribution. The principal seedlings which attracted attention were a rosy mauve counterpart of Colonel W. B. Smith; a large rosy mauve globular Japanese; a fine orange-bronze Japanese with a yellow centre and long florets; a deep rosy amaranth long-petalled Japanese with a silvery reverse raised in 1891; another of the same season of a peculiar shade of light lemon-yellow, and many others of the same section. I also noticed some promising seedlings raised from Mrs. Falconer Jameson; a few interesting incurved varieties of a very deep crimson colour obtained from seed from M. R. Bahuant, and a goodly assortment of Anemone-flowered novelties, chiefly of light lilac and deep yellow colours.

Of varieties which have already been noticed in these columns and to which I need not append descriptions, the best are H. W. Fowler, W. H. Atkinson, E. L. Jamieson, Pride of Maidenhead, Wm. Mease, Golden Wedding, Thomas Wilkins, Rose Wynne, Niveum, Miss M. Simpkins, Lord Brooke, Charles Blick, John Shrimpton, Wm. Seward, Gettysburgh, all belonging to the Japanese section and exceedingly well done. Others not so well known are Marion Dingle, a very large

white Japanese, with a pale greenish centre; Prince du Bois, a deep golden yellow Japanese with narrow curly florets, a fine globular bloom; Mrs. Denne, a massive long-petalled Japanese, deep silvery mauve; and Richard Dean, an enormous crimson and gold Japanese with long drooping florets. Fascination also belongs to the same class, having long florets of a pale primrose hue. Dr. Masters is another, but a globular flower of deep chestnut-crimson and golden bronze reverse. Robert Owen, a large Japanese incurved, is a big solid bloom of deep golden bronze. President W. R. Smith is also a finely incurved Japanese of a deep rosy blush. Close at hand are Walter Surmar, a globular flower with pointed florets, a deep orange-yellow Japanese, and Golden Gate, with long fluted twisted florets of the colour indicated by its name.

The incurved are represented by Mrs. John Gardener, a very regularly built flower of deep golden yellow, slightly lined with reddish bronze; Wm. Tunnington, a large perfectly formed flower of the class, crimson inside the petals with reverse of bronzy yellow. A pale straw-yellow sport from Lucy Kendall is promising, and Brookleigh Gem, a sport from Jeanne d'Arc, sent out last season, is also good. Lord Rosebery has rather narrow pointed florets, but it is a massive incurved bloom of rosy purple, and a true example of the type. Most of the novelties in this section, such as C. B. Whittall, Robert Petfield, and the like, are in fine form.

There are two or three of the Italian seedlings sent out last year, but most of them have had to be discarded. French seedlings comprise Mme. Thérèse Pankoncke, a real Japanese of the old type, a spreading flower with snow-white flat petals; Soleil de France, an incurved Japanese of crimson and gold; Souvenir du Jambon, a short-petalled Japanese also of crimson and gold; Mme. Rozain, a very fine large Japanese bloom with long incurved petals, colour rosy mauve; M. de Mortillet, a big flower, rather broad, but flat, colour crimson with tips of gold. These are principally from M. Ernest Calvat and M. Boucharlat, but one, a small Anemone called Lumière d'Argent, a pretty shade of pale silvery blush, was one of the few seedlings we have seen this year from M. Simon Délaux.

American-raised varieties are also numerous. Etna has long pointed petals of reddish-bronze with a yellow centre; Golden Wedding, shown at the Aquarium show, is also good in colour, but rather thin; Matchless, as round as a ball, but a Japanese flower of rich yellow, were the most attractive. Lilian Russell, a Japanese with very narrow florets, is a big golden yellow flower; so, too, is Mrs. E. D. Adams, but the colour is a deep pink, and not almost white, as we have seen it elsewhere. Niveum, pure snow white and very large, is remarkably delicate in appearance. Rosslyn, also a Japanese of pale shrimp-pink colour not fully out, and others for which space cannot be spared, were also promising. Since the advent of Mrs. Alpheus Hardy and Louis Boehmer, much attention seems to have been paid to the raising of new varieties of the hairy section both on this and on the other side of the Atlantic. Zambesi, a fine yellow flower sent out from America as one of these, is quite destitute of hairs at Maidenhead, and unworthy of the name. L'Enfant des deux Mondes, a white Louis Boehmer, is well deserving of the appellation. Chrysanthémiste Délaux is also a hairy sort; the colour is a dull unattractive crimson, quite distinct in its class, but not a pretty flower in any respect. Mireille is of a pale shade of lilac, a Japanese variety of the hirsute section; so is Souvenir de l'Ami Coye, a pure white incurved Japanese with narrow, grooved, pointed florets, the backs of which are well covered. Belle Arlésienne has the peculiarity less marked than the one preceding; it is a pure white flower with a centre of yellow. Others in this class are Miss Baldwin, a tall grower, light mauve, bloom rather flat. Mrs. Dietrich, deep silvery mauve, with incurved florets, which are twisted and curly; and Sautel 1893, which is, perhaps, the best of all. This is a Japanese incurved variety with deeply grooved florets, the colour inside being light rose-amaranth, and the reverse a silvery-pink.

The new Anemones and a few new pompons are interesting, but we have said enough to show that we may yet expect to have some important additions to the lists from the Castle Hill nursery, as we have already done in the past. VISITOR.

DWARF GROWING CHRYSANTHEMUMS.

Now that so many new varieties are being raised from seed, we are in possession of many kinds of dwarf habit which give blooms equally as good as the tallest growers. This is important, as it will tend to popularise the Chrysanthemum more than anything else. Few persons, apart from those with unlimited convenience for housing plants, can find room for varieties that run up to 10 feet and 12 feet high. The point for raisers to consider is to utilise the already numerous comparatively dwarf growing sorts as seed-bearers. No better type of plant could be imagined than Avalanche; this favourite white-flowered Japanese possesses all the points alluded to to render it valuable for this purpose.

It is not everyone who cultivates Chrysanthemums purely for cut blooms. Many never think of destroying the beauty of the flowers by cutting them the moment they arrive at their best. Dwarf varieties are a boon to such cultivators, and any addition to this class is sure to find a warm welcome. It is possible now out of the material obtainable to form a really good collection of Chrysanthemums that do not, under the orthodox method of cultivation for the production of large blooms, grow above 5 feet high. Many varieties produce many fine blooms at a foot less, and indeed many grow but a yard high.

It is in the Japanese section that we look for and find so much improvement in the height of growth, for the reason that varieties in this section are so easily raised from seed. Not so in the incurved and other sections; we are in a great measure dependent upon sports, which cannot be controlled. So few really deserving incurved blooms according to the florist's standard are obtained from seed, that the business is a slow one. Blooms from seedlings are not of the character consistent with the present-day necessities of perfect flowers of the incurved section. Hence the slight advance made in bringing out new kinds of dwarf habit. Seldom indeed do the Queens, Alfreds, or the Princess family give us perfect examples from dwarf plants—those under 5 feet high for instance. Amongst the newer introductions in the Japanese section none shows a greater advance than Viviani Morel in this respect. The finest blooms of this variety that I have ever seen were growing upon a plant 3 feet 6 inches high. Its golden bronze sport—Charles Davis—is identical in growth with its parent. This appears to be a capital variety for giving blooms singly on plants 2 feet high in 6-inch pots. Apparently we shall have a white-flowered variety directly from Viviani Morel, if there is not already one in existence. White flowers are always appreciated, especially when obtained from plants of low growth. Comte F. Lurani, G. W. Childs, John Shrimpton, William Seward, Mrs. F. A. Spaulding (syn., J. S. Dibbens), Edwin Beckett, G. C. Schwabe, Mrs. E. D. Adams, Mrs. Nisbet, Countess of Hambleton, W. K. Woodcock, Mme. Octavie Mirbean, Mrs. Falconer Jameson, Mrs. C. Wheeler, Mlle. Thérèse Rey, Mrs. J. S. Fogg, Val d'Andorre, Colonel B. Smith, and M. Bernard are dwarf growing Japanese kinds that should be found in every good collection.

E. MOLYNEUX.

Good Chrysanthemums.—That the good qualities of plants may be viewed from different standpoints was well illustrated in a conversation overheard the other day at an exhibition of these beautiful flowers, in which the terms good and bad varieties cropped up pretty frequently. Their merits were in this case, I found, based neither on the value of the flowers for exhibition nor for decoration, but from the readiness with which they could be propagated—that is to say, those that produced suckers in quantity were good

varieties, and when the reverse was the case they were then bad. There is certainly a very great difference in this respect to be found among the various Chrysanthemums, for some will produce an almost unlimited number of suckers, while others are very sparing in this respect—so much so, indeed, that in nurseries where large quantities of any particular variety are often required it is a difficult matter to get sufficient stock—at all events till the return of spring. Several of the newer varieties are very prolific in this respect, for such as Beauty of Exmouth, J. Shrimpton, William Seward, C. Shrimpton, Princess Victoria, Viscountess Hambleton, Edwin Beckett, Charles Davis, Baron Hirsch, and many others yield quite a wealth of cuttings, while Robert Owen, Golden Wedding, Lord Brooke, and other strong growers are not nearly so free in pushing up their young shoots. Some varieties will often stand a long time without producing any good cuttings, the Princess of Wales group of incurved being very backward in this respect, while of Japanese a few that may be mentioned are Critteron, Eynsford White, Mrs. C. W. Wheeler, Mrs. Falconer Jameson, Christmas Eve or Mrs. H. Cannell, Anna Hartshorn, and Sunset. Many others show various peculiarities of especial interest to the propagator, notably the huge-flowered Etoile de Lyon, cuttings of which take longer time to root than those of any other variety of Chrysanthemum that I have tried. This is especially noticeable if cuttings of a great number of varieties are put in together, for some will be growing freely before those of Etoile de Lyon have made a single root.—T.

Chrysanthemum Col. Chase.—In your issue of THE GARDEN, November 11, 1893, it is stated in the report of the N.C.S.'s show at Westminster that Chrysanthemum Col. Chase, which received a first-class certificate, was raised and exhibited by Mr. E. Beckett. Allow me to correct this. It was grown by Mr. Beckett for a friend of mine, Mr. Kelly, gardener to Mrs. B. Dobree, Beauregard, Guernsey, who raised it with many other fine varieties, notably Violetta, for which Mr. Beckett also received a first-class certificate, October 25, 1893.—THOS. H. LE LIEVRE, *St. Martins, Guernsey.*

SHORT NOTES.—CHRYSANTHEMUMS.

Chrysanthemum Pearl Beauty is one of the most promising of recent new varieties. The flowers are of the Japanese incurved class and blush-white in colour.

Chrysanthemum Beaute de Toulousaine.—This is a good Japanese variety for colour. It is new, and therefore not common as yet. The florets are of a deep red shade.

Chrysanthemum Pride of Maidenhead, a seedling raised by Mr. Owen, of Maidenhead, and shown by him at the recent meeting of the Royal Horticultural Society, is very charming, the flowers of beautiful form and white.

Chrysanthemum Primrose League is a very promising Japanese variety, and we have seen good blooms of it at recent exhibitions. The colour of the flower is distinct and pleasing—soft primrose passing to creamy white in the centre.

Chrysanthemum Waban is a good new kind of the Japanese incurved section. The flowers are full, and pink in colour. We do not care greatly for this class generally as we seem to lose all the charming freedom of the typical Japanese kinds.

Chrysanthemum Mrs. Robinson King, the new incurved variety, was well shown at the recent Aquarium show, although this class was not in perfection as a rule. The flowers were very rough. This variety is of a deep orange-red colour.

Chrysanthemum G. W. Childs is a variety we have not seen remarkably fine this year, but it will undoubtedly come to the front. It is a seedling possibly from Edwin Molyneux, and very fine in colour—deep crimson with old gold reverse to the florets.

Chrysanthemum Mme. Darrier was one of the best incurved varieties at the recent Aquarium show. It is a remarkably neat and compact flower, the petals small, and of a nautkeen-yellow colour with purple stripes or suffusion, rather dull, but not objectionably so.

ROSE GARDEN.

WILD ROSES.

WE all allow the Roses of the florist to be without rival among flowers of the garden, and we can but admit that wild Roses are perhaps the most lovely flowers of the field. What can be more beautiful than *Rosa arvensis*,

and now attains to a height of about 20 feet, making wreaths of rosy blossom in summer. The Spruce is now dead, but the Rose still clings to the old stem, which forms just the right kind of support. Such an object as this or *Rosa arvensis*, in the collection, makes us wonder why these single Roses have not received more attention. They are usually so robust, just what is wanted for pleasure grounds and the wild garden, and then in

have doubles of *Rosa spinosissima*, but just now we are far more interested in single varieties, for which there should be a considerable future. We do not by any means despise the doubles, for of all flowers the Rose doubles with best effect in point of real beauty and loveliness, but we cannot do without the type of flower that Nature gives us. We remember the suggestive paper on "Modern Roses and Hybridisation" communicated by Lord Penzance to the Rose conference in 1889, and published in the eleventh volume of the "Journal of the Royal Horticultural Society," and also the exhibits of Sweet Brier hybrids by that raiser, who has, we believe, some singles, and thus has taken a lead in the direction that seems to us so desirable for raisers to follow. There may be fine exotic single Roses yet to introduce, for Mr. Christy has told us of Sweet Briars growing in the neighbourhood of Constantinople with flowers of various shades and some 3 inches across. No doubt our own Sweet Briars are capable of immense improvement; indeed, the common Sweet Brier as it is, like *R. rugosa*, makes a line, which serves as a hedge, of great beauty. It would be a good work to get our native Roses together, to select the best kinds and raise from them with a view to improvement. No doubt, too, they might be crossed with exotics with good results. We should endeavour to secure the natural elegance of habit that marks some of the kinds, and to have Roses that need not the hard pruning by which certain garden Roses are often so ugly when not in flower. Our attention may be devoted to the truss, the individual flower, the colour, form and size, and to the almost essential attribute of perfume. It were a pity, however, to lay down laws, if we can only get raisers to work, for by rigid rule many fine flowers have been lost by the florist. It would be safe to say that numbers of handsome single Roses have been thrown away as useless.

To show what material there is, we may mention that the seventy or so distinguished forms of Britain fall under seven distinct aggregate species according to "The Student's Flora."

We have first the well-known Scotch or Burnet Rose (*R. spinosissima*), lovely with white or pink flowers; next, *R. villosa*, which in various forms makes a large bush, with erect or arching branches, very hairy leaves and densely glandular sepals. It is distinguished from the last-mentioned by its larger size and equal prickles, and from *R. canina* by its straight prickles. Under it we have *R. tomentosa*, with a large pale pink flower, and *R. mollissima*, with a smaller, deeper-coloured flower. The succeeding species is *R. involuta*, under which are numerous kinds, small and erect, with short branches and crowded prickles, passing into bristles. Among them we may note *R. Wilsoni*, with bright red flowers, and *R. Sabini*, with ample foliage and pale pink flowers. Next is our fragrant *R. rubiginosa*, which, however, is less fragrant, as it approaches *R. canina* and *R.*

The Field Rose (*R. arvensis*). Engraved for THE GARDEN from a picture in the possession of Mrs. L. Marse.

the subject of the accompanying illustration? It portrays a lovely wealth of white blossom, but there are numbers of these untamed wildings, if we may use the expression, all beautiful, and some of surpassing charm. We want to see them more often grown in our gardens, for which they are so well suited. Sometimes we admire a chance seedling, as, for instance, in the Cambridge Botanic Garden, where some years ago *R. dumalis* (*R. canina* var.) took possession of a Spruce Fir,

in autumn we frequently have a brilliant display of red fruit. At this moment in some of the hedges of the neighbourhood are shrubs with quantities of fruit, which in a garden would help considerably in colour effect.

The attention of the raiser might well be given, we think, to British Roses—the Roses of our own climate. Certainly we have doubles in the Ayrshire Rose, from *Rosa arvensis*, which lately in its single wild form has greatly excited our admiration, and we

villosa. It is one that has already given good results in hybridising and is certainly one to work with. Belonging to this species we may mention *R. macrantha* and *R. sepium*, both of which have rather pretty flowers, though they are somewhat small. The common Sweet Brier is equal to either and might be the best form to work with. *R. hibernica* is the next species to refer to, and it is intermediate between *R. spinosissima* and *R. canina*, though most like the latter. It is small and erect, with short, sometimes arching branches and erect globose naked fruit. It is figured with pale pink flowers. *Rosa canina* is the familiar Dog Rose, of which the varieties are very numerous. It has long arching branches, with stout hooked prickles, having a thickened base, and in the common form is the strongest growing of British Roses. It is often very beautiful, and, all things considered, some of the best results may no doubt be got from this species. *R. cesia* and *R. incana*, belonging to this species, have glaucous leaves. The foliage of *R. Bakeri* is very pretty, and we have already referred to *R. dumalis* as a fine tall-growing kind, but the varieties of this species are so numerous, that it is difficult to specify. Our last species is *R. arvensis*, the typical form of which is the subject of our illustration. It is known from *R. canina* by the union of the styles into a long slender column, that species having the styles free. There are two sub-species, *R. arvensis* proper (*R. repens*) having the leaflets glabrous, glaucous beneath, and *R. stylosa* with leaflets pubescent beneath. This last connects *R. arvensis* with *R. canina*, and under it the several varieties occur. The variety *Monsonie*, found in a hedge at Watford, has very large red flowers and sub-globose, orange red fruit. It is our present *R. arvensis* proper to which the Ayrshire Rose must be referred. The flowers are more cup-shaped than those of any other British Rose, and Lindley says that Sabine had a variety with pink flowers. No illustration has before appeared in any journal, but a figure in "English Botany" shows to some extent what a fine thing it is. The plant has long, trailing shoots, with small, scattered prickles, oval leaflets, glabrous on both surfaces, and glaucous or whitish green beneath. The flowers are of elegant outline, with pure white corolla, except the throat, which is yellow, and have a purple calyx. The fruit is scarlet when ripe. It is a common plant in the south of England. This same form, probably, is very charming in the Cambridge Botanic Garden, where it grows over and over itself, making a great round hummock of flowers and foliage.

The raiser may probably obtain the best results from *R. rubiginosa*, *R. canina*, and *R. arvensis*, and as well, no doubt, from *R. spinosissima*, which in some single forms is very lovely. We should like to see crosses of at least the three first with the Austrian Copper and Yellow Briers, which might be possible. It is not alone our

British Roses that might be worked with for single forms, but such kinds as *R. lucida*, the foliage of which is often so finely coloured in autumn, and *R. rubrifolia*, which early in the year is remarkably charming with red-grey leaves. It comes near *R. canina*, and with it might give some curious results. *Rosa rugosa*, again, may be improved, for in the Cambridge Botanic Garden we have a very fine form with splendid flowers, and much more elegant in habit than the common *rugosa*, to which species it is referred by the Kew authorities. Rose hedges are now plentiful, and the best way is perhaps to sow the seeds when quite ripe in pans and place them in a cold frame.

R. IRWIN LYNCH.

STAYING POWER OF ROSES UNDER GLASS.

WHEN one first begins selecting Roses for cultivating under glass he does not always realise the importance of choosing those varieties that possess staying powers, or that are amenable to a moderate degree of heat. I know I did not, or I should not have included in my first selection of Hybrid Perpetuals such as *La Reine* and *Mme. Rivers*, which require at least 10° more heat in the month of March to get the flowers to open properly than those varieties which have a less number of petals, like *General Jacqueminot*. Since that time I have avoided such varieties as *La France* and *Queen of Queens* for early forcing, not only because it is more difficult to get the flowers to expand, but because they do not last any longer than those developed in a lower temperature. This is not the only objection I have to these full-petalled flowers. I dislike them because the blooms have a tendency to hang down their heads owing to their weight. With regard to the staying powers of the different flowers, whether they are Teas or Hybrid Perpetuals, my experience leads me to prefer those flowers that are not too double.

Niphetos I regard as all that is good in this respect, and the more varieties we can get with the same useful qualities the better. Flowers of a semi-double character like *W. A. Richardson* are not always the best, as under a bright March sun the buds expand so quickly, that those which show no signs of opening in the morning are useless by mid-day. *General Jacqueminot* is a good type of a Hybrid Perpetual, possessing good staying powers, and so are also the *Duke of Teck* and *Dupuy Jamain*. To these I may add *Mrs. J. Laing*, *Ulrich Brunner*, *Alfred Colomb*, and *Perle des Blanches*. It is amongst the Teas, however, that we must look for Roses possessing the greatest staying powers, and we shall find them in varieties like *Catherine Mermet* and *Anna Ollivier*. The flowers of these are not so full of petals but what they can expand in a moderate temperature, and there is sufficient space between the individual petals of an expanded flower to allow the air to circulate and prevent damping; whereas in very full flowers the centre prematurely decays under the influence of damp and a low temperature. *Perle des Jardins* possesses wonderful staying powers, as does also *Marie van Houtte*, but *The Bride* and *Grace Darling* are not remarkable in this respect. I do not think anyone would regret growing the single Roses in pots for early forcing when the flower-buds are required for personal adornment, and surely none can be prettier in the bud state than *Fortune's Yel-*

low, which is semi-double. Of course, the plants would have to be removed to a lower temperature before the buds had time to expand.

J. C. C.

REPOTTING ROSES FOR FORCING.

I do not think "*Ridgewood*" will find many private gardeners support him in his views on this subject (see *THE GARDEN* for October 21, p. 361), for the reason that the private grower cannot secure a fresh stock of plants every three years, as "*Ridgewood*" says he does. Both Hybrid Perpetual and Tea-scented Roses can be kept in good condition in 8-inch and 10-inch pots for many years, provided they get a change of two-thirds of fresh soil. "*D. T. F.*" says that no pot Roses should be shifted previous to being forced. I quite agree with this. I have always found that the proper time to repot Roses that are to be forced is the early part of the month of August. By that time the growth the plants made in the forcing house and afterwards has got well hardened and the eyes on the lower part of the branches prominent. If properly treated they are at that time resting, so to speak. They have exhausted the soil in which they are growing and require the assistance of a fresh root medium to support the young growth and blossoms which they are sure to produce when introduced into a higher temperature. If the plants are dealt with at the time I suggest and two thirds of the old soil removed and the stock given cool treatment without being exposed to severe frost, the roots will have taken well hold of the new soil by the beginning of November and be in just the right condition to respond quickly to an increase of temperature.

The private grower has to keep his stock of pot Roses for forcing in good condition for many years. Nor is it difficult to do so, a little judicious root-pruning, by which I mean the removal of the large ones, and a change of compost once a year being all that are required in the case of those which are restricted to 8-inch pots. When 12-inch and larger sizes are used, a change of soil once in two or three years is sufficient if the plants are otherwise skilfully treated. When good growing Hybrid Perpetuals are selected for pots, which are worked on the *Manetti* stock, they can be kept in a fairly vigorous condition for many years, and will produce blooms of sufficient merit to be appreciated. As a matter of fact plants of this character give less anxiety in the forcing house than those more recently potted, for unless a plant is well established, the newly-made growth has a tendency to extend instead of forming flower-buds. It may be that "*Ridgewood's*" remarks were intended chiefly for the Tea-scented Roses. On that point he is not very clear. If so, I admit that there is less fear of that class of Roses producing flowerless wood under his treatment than the Hybrid Perpetuals. Still, as a private grower who has never had the advantage of a separate house for the production of early forced Roses, I have found that the less root-disturbance the plants had just before forcing the more flowers I got.

J. C. CLARKE.

Pot Roses.—These need careful attention as regards water. If allowed to suffer at all, there will be a corresponding check in the rise of sap. At the same time an equal amount of mischief may easily be done by keeping the soil over-moist. The roots must not be flooded simply because the plants are making new growth freely. If my previous notes upon pot Roses have been followed up, it will be well to take a batch of plants under cover now, choosing those most forward from among the earliest pruned. By the end or middle of November I would advise that all pot Roses be pruned, and those intended for the latest batches placed in a cool pit, care being taken to give all the air possible without admitting frost. Where young growth is attacked with aphid, no time should be lost in cleansing the plants. A very slight attack at this period of the year is far more injurious than in the spring, as the plants are by

no means so quick growing and robust during the sunless days so often experienced from now onwards. Take full advantage of this splendid weather to thoroughly cleanse the plants by frequent syringing with a weak solution; this will not be so easily done a little later on, and the mild weather seems to have brought almost a spring crop of insect pests. I find my own plants need much more attention than usual in this respect.—A. P.

Red Roses under glass.—I do not find any Rose so good in this colour as *Reine Marie Henriette*. Many red Roses have been tried, but none possess so intense a scarlet, combined with good foliage and long flower-stalks, as the one under notice. I have previously remarked upon its good qualities under glass, but would like to call attention to this fact again. It is only during favourable seasons that we see it bright out of doors, while under glass its brilliancy is most remarkable. It grows exceptionally strong and clean, while few, if any, Roses are so free-flowering. I have cut away large quantities of wood and yet been able to leave many long and well-ripened rods upon my plants. Early in the season and under glass the flowers are almost as deep and bright as those of *General Jacqueminot*.—A. P.

THE EARLY FORCING OF CLIMBING ROSES.

WHETHER grown in pots or in the border these need steady treatment far more than any other class of Roses. If too much heat be afforded only the forwardest eyes will carry satisfactory flowers. Even with other varieties I find that the few forwardest eyes grow away and practically monopolise the whole of the plant's energies; but this is far more noticeable with climbers. Under steady treatment I secure a fine crop of bloom, and this is made much more certain when the shoots are brought into a horizontal position. Of all Roses for early forcing I consider these the most certain to produce a good crop of bloom provided they are carrying a shoot or two of thoroughly matured growth. By introducing one or two plants to a slightly raised temperature at an interval of a week or so, we can be tolerably certain of successional crops. Let almost all of the plants stand in a house with a temperature of about 40°; a late vinery will answer well. As the plants break into growth, choose out the forwardest of them for placing in a slightly warmer temperature. After the young growth has attained a length of 2 inches to 3 inches, a further increase may be afforded with safety. The grand secrets are well ripened wood and very steady forcing at first; in fact, the first few weeks scarcely come under the name forcing, being rather more like keeping them exempt from cold nights than anything else. I have a large batch of these climbers which were repotted early in September immediately after the wood was ripe. These have now almost filled the pots with healthy and vigorous roots, while the wood itself is almost as much at a standstill as when they were first shifted. My own experience has proved that it is much better to pot this section directly the wood has become sufficiently ripe. The batch I am writing of was grown in 6-inch pots, and is now in 8-inch and 10-inch pots. On no account should this repotting be done until the plants have finished growing, and provided they are well done and afforded a sufficient amount of liquid stimulants, there is little difficulty in securing growths ranging from 6 feet to 12 feet in length. Once get the wood matured, a steady rooting into fresh soil must be a great support to early forcing. One cannot follow Nature too closely, and I contend that the above treatment approaches Nature far more closely than the immediate forcing of Roses without first securing a considerable amount of new roots. We find that Roses in the open ground make a large quantity of root growth fully four to six weeks previous to the eyes showing any signs of bursting into leaf.

When Roses are hurried too much at first, they produce a large quantity of blind growths, and I am sure a large proportion of these are caused by the check resulting from the roots not being sufficiently forward to provide enough nourishment, and so prevent any check when once the Roses have started. The plan I have recommended prevents this, but if we introduce plants that are pot-bound, we do not get so early and efficient a batch of new roots; in fact, a pot-bound plant requires much more starting than one in the stage I have endeavoured to describe above. R.

Cutting Roses for decoration.—How often do we find cut flowers of all kinds removed from the plant with so short a stem as to preclude the possibility of using them to full advantage in decoration. Roses are not exempt from this ridiculous practice; indeed, I sometimes think they are worse treated in this respect, considering how very easy it is to obtain sufficient stem and also the great advantage of retaining an improved shape in the plant at the same time. A Rose cut with a long stem, having a few buds around the bloom and being possessed of a few clean grown leaves, is one of the few things it would be difficult to place wrongly when decorating. It also possesses greater boldness and has a far grander appearance than the same flower cut with so short a stem as often seen. If one-tenth of the flowers usually employed when these short stems are in use could consist of good blooms upon stalks of from 1 foot to 2 feet in length, a much prettier effect would be secured. There is also a considerable saving in time by using the bolder spikes, while the buds and foliage enhance the beauty of the whole so much, that it is strange we do not more often see Roses so used. Roses which have a drooping tendency, such as *Mme. Bravy*, are not so well fitted for cutting as those with a bold, upright growth like *Anna Ollivier*. A second consideration in Roses for cutting is to secure those producing a good centre flower among a quantity of buds in various stages. I also grow a few plants of *Perle de Lyon*, not for the blooms, but on account of its most handsome foliage. This variety is well worth growing for the above purpose. I do not know of any Rose that has foliage of a more handsome appearance. It is the deepest coloured of any, and the shoots carry very prettily shaped buds. As these seldom open well, there is less reluctance to cut them in order to further enhance the beauty and value of such varieties as produce good showy blossoms. The young shoots of such rampant growers as the *Boursault*, *Ayrshire* and other climbers which make an over-abundance of wood may also be used to great advantage; but, as a general rule, it will be found that the foliage of each class is best suited for its own blooms. Given long stems, formality and stiffness are easily avoided, and the whole effect can be more natural.—A. P.

Winter Roses.—Never in my recollection have there been better prospects of full crops of Roses during the winter months, say December to end of February. The wood upon all plants, whether growing in pots or planted out under glass, has matured so well that little excuse can be found for failure among winter Roses. Owing to their early and efficient ripening it has been possible to start plants with safety rather sooner than usual. In addition to this, the splendid weather of October has been far more like early spring than usual, with the result that the sap in ripened wood is already moving freely. Many of our earliest plants are carrying growths which already show the flower-buds. Others are breaking strongly and satisfactorily, and those still in the pits are swelling rapidly. Such charming weather as the present will afford all of the plants a most excellent and natural start. This is of considerable importance, it being by no means easy to secure stout breaks sufficiently early to produce good winter blooms during a dull November. This season, owing to so welcome a start, the plants will probably pull through well even if we get a dull time during the few weeks before Christmas. Up to the time of writing, my plants have had no fire-heat, shutting

up the house about 4 o'clock being quite sufficient at present. The secret of having good Roses during winter is thoroughly ripened wood and very steady treatment until new growths have reached some 3 inches to 5 inches in length, after which they may safely be hurried on as required.—R.

Rose William Allen Richardson.—On October 21 I cut a good bunch of this beautiful Rose, which was introduced by *Veuve Ducher* in 1878. The majority of our strong climbing Roses are by no means perpetual, but this variety and *L'Idéal* produce a full crop of bloom more than once during the year and also afford a few stray blossoms between the larger displays. This year, probably owing to the dry summer causing the growth to ripen better and earlier than usual, many of the long maiden shoots are clothed with fairly good blooms. A batch of maidens growing upon the seedling *Brier* in an open field with a northern aspect is now carrying a most serviceable crop of bloom. This will by no means injure the plants for another season, as the wood now blooming would be of little or no service next season, owing to the whole of the plants having to be shifted to new quarters. Even upon established plants of considerable size the earliest of the shoots are carrying a fair crop of flowers. Not far from me there is a cottage by the roadside, over which a plant of this variety has grown so luxuriantly as to almost completely cover the front. I have passed this perhaps a dozen times during the summer, and not once was the plant without several good flowers, while early in June it was a perfect picture.—A. P.

Rose The Pet.—This miniature Rose is one of the most profuse bloomers grown. All through the spring and summer a batch of plants in pots has been a mass of bloom. The flowers are about the size of a shilling, very double, almost pure white, and produced in large trusses. These plants are some four years old, and do not average more than a foot high. They produce a series of shoots from the bottom which carry immense trusses of blooms for their size. I know of no Roses better suited for conservatory culture or a suitable window than than the following half a dozen: *The Pet*, *White Fairy*, *Perle d'Or*, *Mignonette*, *Lawrenceana rubra*, and *Lucida*.—R.

Rose Margaret Dickson is a splendid grower, and will probably make a good white Rose for pegging down. As a maiden it seldom blooms; at any rate, my plants have been almost flowerless. The growths reach a length of 6 feet to 8 feet, are short-jointed and well matured. If it turns out as good under pegged-down treatment as it promises from a couple of plants so treated during the past summer, it will without doubt rank as the best white Rose of any size for this system of cultivation.—N. S.

CANKER IN ROSES.

THAT this disease is first caused by a sudden check to vigorous growth or by the unequal production of sap is more impressed upon me than ever. Lately I have been pruning several Roses that are turned out in a border under glass. I find canker upon plants growing on the *De la Grefferaie*, the *Brier*, and upon the *Manetti* stocks. Taking the requirements of each variety grown upon them and the amount of sap each stock would generally produce, I do not find much to choose between the three. Among these Roses are some *Jean Ducher* that were 8 feet to 10 feet high, and splendid bushes. These were grafted upon the *Manetti*, and up to this season have done well. Even now they are carrying remarkably clean and healthy wood, but this cannot possibly do itself justice during the coming season owing to canker having set in very strongly. Two plants of *Reine Marie Henriette*, also grafted upon the *Manetti*, are developing canker, and will probably be of little use after next spring. Each plant was carrying about twenty shoots of this summer's growth before I put the knife into them a few days ago, and as they would average a length of 10 feet, it will be seen how strongly the plants grew. The same variety

on the seedling Brier has not grown quite so strong, and does not show signs of canker. On examination I find that the Rose has swelled more rapidly than the stock at the point of union. The roots must perforce have grown in proportion to the Rose wood, but the swelling at the union not being uniform seems to me the real cause of canker in these plants. Many of my readers have doubtless noticed a number of warty protuberances upon Rose wood when the tying material has been too tight and the swelling wood has been restricted. I fail to see the least difference between this and canker at the base. We do not find canker upon own-root plants unless under a state of constriction, nor upon worked plants when the stock and Rose seem to be equally balanced.

There is something not fully understood in regard to this disease among Roses. For instance, we find some varieties in each class or section which refuse to do well upon one or other of the stocks which their companions delight in. Among the Hybrid Perpetuals we may instance Horace Vernet, Marie Verdier and Her Majesty—three Roses of most distinct habit and representing weak, medium and extra strong growth. Neither of these takes kindly to the Manetti. In the first variety the Manetti evidently overpowers the Rose, while in the last we have so strong a grower as to seemingly overpower the Manetti, and yet all three of these good Roses refuse to do well upon this stock. Further than this, we find that almost all of the strong-growing Teas and Noisettes will prosper upon the Manetti, but there are notable exceptions in Rêve d'Or and Bouquet d'Or. I have also frequently noticed a strong, healthy-growing Rose first show signs of canker after a large quantity of growing wood or roots had suddenly been removed. This would seem an additional point in favour of undue balance of root and wood having a great influence upon this disease. Over-feeding with liquid manure will have similar results, and which are evidently brought about in the same way. Too strong a stimulant will kill the points of growing roots and also render the soil distasteful for a time to new rootlets. When this is the case it is evident that the supply of sap is considerably reduced, and at the very period when a fall flow is absolutely necessary if vigorous growth is to be sustained. RIDGEWOOD.

STOVE AND GREENHOUSE.

BOUVARDIAS.

To flower Bouvardias well at this season of the year it is necessary that the plants should be treated a little different to those for summer and early autumn blooming. For early flowering the cooler they can be kept, provided they are well exposed to the sun, the better they will do; but plants to bloom well now must have plenty of warmth, all the light that can be given and plenty of air. I find early-struck or cut-back plants are most reliable, but they should be stopped from time to time, the last time of stopping being about the end of August or beginning of September.

The plants may be potted on according to their size, never allowing them to get stunted through want of pot room. All liquid or artificial manures should be withheld until the plants begin to flower, when either liquid manure made from cow manure and soot, or any reliable artificial fertiliser may be used frequently. At the commencement it should be used sparingly, gradually increasing the strength. The plants must be kept free from insects. A small dark-coloured aphid is often very troublesome, and when once it makes its appearance it is only by frequent fumigation that the plants can be kept clean. Before the flowers begin to open, clear soot water may be used for syringing and will go a long way towards keeping off insect pests. The syringing, however, must be discontinued after the plants begin to come into bloom. Those grown for cut bloom may be syringed occasionally after the bloom has been cut.

In the neighbourhood of London it is difficult to flower Bouvardias well at midwinter, but in more favoured localities many of the sorts will keep up a succession through the winter, or at least up to the time that forced spring flowers begin to be plentiful. For winter flowering it is not desirable to go in for a great number of varieties; the only varieties I would recommend are President Cleveland, scarlet; Mrs. Robert Green, pink. The most reliable white is Vreelandi, though other whites might be grown. Jasminoides is a good one, also candidissima, the latter named more particularly as a pot plant, being dwarf in habit and very free. It does not, however, keep up a succession of bloom. I am not an admirer of the double-flowered sorts, but where they are preferred the three best sorts are Alfred Neuner, President Garfield, and Hogarth flore-pleno. The single yellow flavescens has flowered well with me this autumn, and the colour does not fade so quickly as when we get more sunshine. It is a great pity we cannot get a really good yellow variety. I have tried the double and single varieties, but cannot say much in favour of any of them; flavescens and flavescens flore-pleno are the two best.

Few classes of plants are more useful for cut bloom than Bouvardias, and they are much easier to cultivate than is generally supposed. The most important point is to avoid starving the plants. Planting out is often recommended, but my experience is that the plants make good growth, and flower freely for a time after they have been taken up and potted, but do not keep up a succession of bloom like those grown in pots. F. H.

Rhododendrons, Javanese.—The fine bright weather, of which we have had so large a share this autumn, would appear to have been very favourable to the Javanese Rhododendrons, for they are flowering with unusual freedom, and have been very beautiful for the last month, while, judging by the number of unopened buds, they bid fair to continue for some time. Where a structure is kept at a temperature above that of an ordinary greenhouse these Rhododendrons are just the things to brighten it, not only at this season, but to a certain extent nearly throughout the year. These Rhododendrons succeed within the baneful influence of the London fogs better than many other classes of plants, certainly far better than their allies, the Indian Azaleas, many of which will after a few days' fog lose nearly the whole of their leaves. A light warm structure with a free circulation of air is just the place for these Javanese Rhododendrons during the autumn and winter, as if too cold and damp the young leaves are very liable to be attacked by mildew, which especially in the case of the weaker growers is somewhat difficult to eradicate. There are now a great many varieties of these Rhododendrons, but two of the oldest, viz., Duchess of Edinburgh and Prince Leopold, are about the most continuous blooming of any. The first-named will often flower itself into a bad state of health unless given an occasional rest. Its blossoms are of a glowing crimson tint, which causes it to stand out conspicuous among paler tinted varieties. In the case of all these Rhododendrons over-potting must be especially guarded against, as their roots are by no means particularly vigorous.—H. P.

Iris alata in pots.—This beautiful autumn-flowering Iris is sent here from the southern part of Europe in the shape of fine bulbs, which are all ready to flower if placed under favourable conditions. I have seen numerous examples this season of bulbs that reached here about the end of August in a thoroughly ripened state and were then potted and placed in a cold frame. About half a dozen bulbs were put into a pot and were soon in full flower. These little masses of Iris flowers formed a very pretty and most uncommon autumn feature in the greenhouse. There is no reason why Iris alata should not be more often grown for flowering under glass, and in the spring several other kinds of the bulbous Iris are very useful in this way. Iris reticulata has been so employed in a very limited fashion for years, and last

spring I saw the strikingly marked Iris persica in fine condition in a greenhouse.—H. P.

The Spanish Jasmine (*Jasminum grandiflorum*).—This Jasmine, so widely cultivated throughout the warmer parts of the globe, is not much known in this country, yet in a warm greenhouse it will often flower for a long time during the winter, and the delicious fragrance of its blossoms causes it to be much appreciated. The flowers of this Jasmine are white, sometimes slightly tinged on the exterior with red, and altogether they bear a general resemblance to those of the common *Jasminum officinale*. According to the "Dictionary of Gardening," *J. grandiflorum* occurs wild at 2000 feet to 5000 feet elevation in sub-tropical North-western Himalayas and was introduced into this country in 1629. It is of a somewhat rambling style of growth and may be trained to a rafter in the greenhouse, or in some similar position, while little specimens flowering well as bushes may be occasionally met with.—H. P.

A TRIO OF USEFUL DECORATIVE CROTONS.

CROTON WARRENI.—This fine variety is without doubt one of the very best, if not the best of all long-leaved Crotons of pendulous growth. I can at least say I have not seen one yet to equal it when it is grown in good form and well coloured. It is of most robust and vigorous growth, and well calculated for cultivation on single stems, or at least without stopping the leader, a few lateral growths may be thrown out, but these are immaterial to the general effect of the plant. I have it now in capital condition, and every succeeding leaf even at this season of the year assumes its variegation as well as in the summer-time. The foliage in its earlier stages is irregularly mottled and suffused with orange-yellow on a pale green ground, changing as the leaves become fully developed to a rich crimson and dark green. A plant of this variety, when well coloured and clothed to the pot with healthy foliage, has a beautiful effect when allowed to be the central plant of a large dinner table arrangement. I used it thus a few months back, and was particularly struck with the beautiful effect produced by its elegant and richly coloured leaves when under artificial light. It was perhaps rather venturesome of me on that occasion, and I would not advise anyone to follow the practice if he had not a strong heat at command for after treatment. Finding the plant to be about a foot too tall for my purpose, I cut the top off at the required height, thus securing fine foliage to the point of separation from the parent stem. This top was then stood into a glass receptacle, and afterwards made to appear as if it were growing in a mound of Selaginella. Later in the same evening the same top was inserted into a small pot, then transferred to the propagating frame, and is now a well-balanced plant. When this variety is grown as a trained specimen, each shoot being persistently tied in, the graceful effect of the plant is lost. By far the better way is to grow it even if of large size in the free pyramidal style.

CROTON BARONESS JAMES DE ROTHSCHILD.—This is another excellent decorative variety of the broad-leaved section, which for home uses is best grown on a single stem, just as one sees *Ficus elastica* presented. The habit in fact of this variety predisposes it to this style of growth, and when seen in good condition, from 1 foot to 2 feet or more in height, and the foliage retained down to the pot, it is all that can be desired as a vase plant. Its foliage in shape is after the old, but still useful *C. pictus*, rather broader perhaps, having one decided advantage, however, over that well-known kind in possessing leaves of far greater substance, and consequently endowed with more persistency in withstanding the changes of temperature, &c., concurrent to a plant that is required for other uses than being displayed in its growing quarters. The richly coloured markings of its leaves are seen to great advantage either by daylight or by artificial light. The ground colour in the well-matured foliage is a dark olive-green with veins of a

rich crimson, the latter colour being frequently extended around a portion of the margin of the leaf. In the younger leaves an excellent contrast is afforded by the light green ground, veined with a pale golden colour.

CROTON ANDREANUS.—This, like the foregoing variety, is, I believe, of continental introduction, and in many respects resembles that fine kind, in habit in particular. Its leaves are possibly one-third longer and a trifle broader. The leaves, too, are thick and leathery, denoting persistency when used for decoration. Its growth is vigorous, whilst if at all shaded the foliage oftentimes takes on too much of a green colour. GROWER.

CRINUM MOOREI ALBUM.

THERE are good and bad Crinums from the cultivator's point of view, and *C. Moorei* belongs to the good ones. It is easily grown in a greenhouse, or it may be grown out of doors for summer effect and wintered in a shed as we do with *Agapanthus*. In the warmer parts of these islands it is grown successfully in the open border out of doors. In addition to all this it is a really good stove bulb. Since it was first introduced by the late Dr. David Moore and grown by him with marked success at Glasnevin some twenty years ago it has become a common plant in gardens. Like many good garden plants, it has numerous names, having been called *C. Makoyanum*, *C. Mackeni*, *C. natalense*, *C. Colensoi*, *C. ornatum*, &c. But its correct name is that given to it by Sir Joseph Hooker in compliment to the man who first grew it and flowered it at Glasnevin. In the gardens of colonists in South Africa it is one of the commonest plants, and is generally known as the Natal Lily, being, I believe, found wild only in Natal and Caffraria. It was first made known to botanists by Bishop Coleuso, who sent a drawing of it to Kew in 1858.

There are several varieties of *C. Moorei*; the ordinary form or type, a second improved form with broader segments and richer colour, and a third with pure white flowers, which is the one represented in the accompanying woodcut prepared from a plant flowered at Kew. The late Dr. Regel looked upon this as a distinct species and figured it under the name of *C. Schmidtii* in his "Gartenflora," t. 1072. It is, however, nothing more than an albino form of *C. Moorei*. For the introduction of this variety we (in England) are indebted to Mr. Woodall, of Scarborough, who sent a bulb of it to Kew, where it flowered in 1891, when Mr. Woodall wrote :—

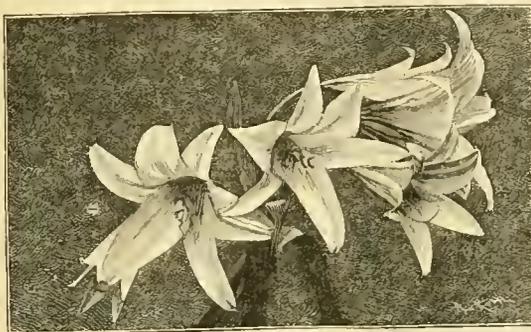

I read with pleasure that the bulb of a *Crinum* which was given me in Madeira four years ago under the name of *C. giganteum* has bloomed in the cold frame at Kew, and is now rightly named *C. Moorei album*. . . . A grand clump of this fine *Crinum* in a Madeira garden, with thirty spikes of its snow-white blossoms on long stalks above the bright green foliage, was so beautiful a sight that I asked for a bulb, never dreaming it could be possible for such a magnificent Lily to be hardy, or nearly so, in England, and I am consequently equally surprised and pleased to know it is a white form of the hardy *C. Moorei*, which will grow and flower wherever the *Amaryllis Belladonna* thrives.

The Kew plant has since yielded a good number of offsets, and to show how quickly this *Crinum* grows I may mention that an offset planted in 1892 flowered in spring this year in a cold greenhouse. The picture described by Mr. Woodall of the Madeira speci-

men is enough to make all who succeed with *Crinums* out of doors long for the "trimmings" of that grand mass. The flowers of *C. Moorei album* are as large and substantial as those of the best forms of the pink-flowered type and of the purest dazzling snow-white.

We have now available a nice little group of hardy *Crinums*, namely, the above *C. Moorei* and its varieties, *C. longiflorum* (capense) and its several varieties, all of them quite hardy at Kew, and the hybrid *C. Powellii*, raised nearly twenty years ago by Mr. Powell, of Tunbridge Wells, from *C. Moorei* and *C. longiflorum*. The hybrid is represented by three distinct forms: 1, *rubrum*, with deep rose-coloured tubular flowers not unlike those of the *Belladonna*; 2, *roseum*, a pale pink form, slightly smaller and still more tubular; 3, *album*, with pure white flowers. Mr. Gumbleton, who grows these plants well, says of the white *Powellii* that it is "quite one of the most beautiful hardy bulbs with which I am acquainted," which is saying a great deal, but not a whit more than it deserves. All these *Crinums* grow and flower to perfection planted out in the borders in the large temperate house at Kew. W. W.

Impatiens Sultani.—The fact that there are several distinct forms of *Impatiens Sultani*, as

Crinum Moorei album.

mentioned on page 421, does not appear to be generally known, although a very interesting series of them may often be seen at Kew, where they form a very striking feature. I cannot say if they are flowering there just now, but I have noted them often within the last two or three years, and have been very much struck with the variation in tint. I see in the catalogue of one of our prominent nurserymen, that besides the typical *I. Sultani* the varietal names of *carminata*, *salmonca* and *variegata* also occur. This last has the foliage variegated with creamy white, but it can scarcely be considered a desirable form, for the pale green of the foliage does not contrast so markedly with the variegated portion as in the case of many other plants.—H. P.

Thibaudia acuminata.—This has been flowering with unusual freedom with me for the last two months; indeed, the blossoms have been almost as numerous as they generally are during the spring. It is certainly a very pretty evergreen for the greenhouse at all seasons, as the deep-tinted shining leaves are very ornamental, and being in the young state tinged with pink they are then very noticeable. The tubular flowers, which are borne in clusters at the points of the shoots, are about 1½ inches long and of a bright red, tipped with greenish white. They are of a thick wax-like texture. The colour of the blossoms varies a good deal according to the conditions under which the plants are grown, as in a clear atmosphere the flowers are more richly tinted than when it is dull and heavy. With regard to this feature, I have been given to understand that the flowers are never so attractive with us as they are in their

South American home. Messrs. Low have before now showed us how to grow this *Thibaudia* in the shape of neat little bushes studded with flowers, but its usual habit is to form a leese-growing shrub, very suitable for a pillar plant or for some similar purpose. This *Thibaudia*, in common with most other members of the genus, is a native of the mountainous regions of South America.—H. P.

Rhapis flabelliformis.—In any selection of Palms that can be depended upon to keep in health for a lengthened period in the house a prominent place must be assigned this *Rhapis*, which, given ordinary care and attention, may be kept in health for an almost indefinite period. Being a native of Japan it requires only the protection of a greenhouse, and consequently it resists draughts much better than those subjects that are grown in a higher temperature. It must at no time be allowed to suffer from want of water, and the leaves should be well sponged at least once a week, as they are not so smooth as those of the *Kentias* and *Aspidistras* (two subjects commonly employed for the same purpose), and consequently the dust adheres more readily to them. A good specimen of this *Rhapis* forms a very graceful object, and for dropping into single vases it is in many situations just the thing. This Palm in its earlier stages should be grown as a stove plant, but, of course, it should be thoroughly hardened off to a greenhouse temperature before it is brought into the dwelling house. It would doubtless be much more commonly met with if seeds were sent to this country in large quantities, as in the case of some Palms. As matters stand, the principal means of increasing this *Rhapis* is by division, which must be carefully done, and the plants encouraged to grow away quickly afterwards, as if allowed to get stunted they often take a long time to start into growth. There is a form with variegated leaves, but it is not often seen.—H. P.

TREE CARNATIONS.

THE season generally has been very favourable for these. The early autumn blooms suffered from the attacks of thrips, but this troublesome pest has now pretty well disappeared and blooms open well. In the management of winter-flowering Carnations it is most important that the plants should be started at the proper time. There are some varieties which flower only once during the season, while others will branch out freely, and the lateral growths will flower a month or so after the main shoots have bloomed. Where large quantities are grown, it is not difficult to keep up a succession of bloom throughout the year of such sorts as *Winter Cheer*, *Miss Jelliffe*, and those of similar habit. Yet many of these grown for winter flowering require to be started at intervals to keep up a succession. The plants should be stopped about the end of April; this applies to old plants or those propagated during the winter, and then others propagated later and stopped a few weeks after the first batch will come on in succession. Those propagated from short side shoots, say about April, will not require any stopping. As so much depends upon the sorts and the condition of the cuttings, it is impossible to give any definite instructions, but it is only by growing plants on in batches that a succession of bloom can be kept up, and it is quite useless to attempt to force them into bloom. A little extra warmth may be given when the buds are well developed, and they will open better for it. Light and air are the most important factors in the culture of Carnations. Sufficient fire heat may be given to keep out frost or to dry the atmosphere in damp weather. See that the plants are kept quite free from insects and not over-watered, and there will be little risk of failure.

Lists of the best sorts have been frequently given; to these I may add *La Neige*, one of the best whites for winter work; it is remarkably free, though the flowers are rather small. The improved variety of *Miss Jolliffe* should always be grown in preference to the older form. *Winter Cheer* is a distinct advance on all other scarlets

and will be likely to hold its place for years to come. In crimsons Mrs. Hemsley is likely to find a rival in Duke of York; the flowers of the latter are larger and of more substance. We are still badly off for yellows. *Andalsia*, which used to grow so vigorously, seems to have quite lost its character. *Pride of Penhurst* and *Germania*, though belonging to the border sorts, may be grown with the Tree varieties, and will bloom well in the autumn or early spring, but do not flower well except from the main shoots; consequently they should never be stopped. The plants grown indoors for early spring blooming will make good stock for autumn if layered as soon as flowers are over, or they may be propagated from cuttings, but layers make the strongest plants, and cuttings are uncertain, especially after we get bright warm weather. All of the border section lose vigour if grown under glass, and where it is desirable to grow them for early flowering new stock should be procured from time to time. *Gloire de Nancy* is useful for early flowering, but though a vigorous grower, it soon becomes weak when confined to pots. F. H.

Amaryllis formosissima.—This beautiful bulbous plant is more generally known by the above name than that of *Sprekelia formosissima*, though this latter is now regarded as the correct one. It is quite distinct from anything else grown in our gardens, and its rich crimson flowers are about April and May very attractive. It is grown in considerable quantities by some of the Dutch bulb growers, and grand thoroughly ripened bulbs that can be depended upon to flower well are readily obtained at this season at quite a cheap rate. They should be potted as soon as received and placed in the greenhouse, but little water being given till the roots are active. The pots should be well drained, and the soil best suited for the *Amaryllis* is an open sandy loam. After flowering, the plants should be encouraged to complete their growth by keeping them in a light position in a warm structure, and as they go to rest water must be gradually withheld.—H. P.

Ixias.—As I had a grand show of these early last spring and am about to pot up bulbs for next season's display, a few notes upon their treatment may be welcome. A variety of chaste colours is found in these. The bulbs are very cheap, and for a frame or cool greenhouse must rank among the most pleasing plants we have. If grown outdoors they must have a warm and sheltered border either at the foot of a wall or hedge. I prefer the latter, as being much drier in winter. The best bed of outdoor *Ixias* I have had was at the foot of an old Yew hedge and in rich, but light soil. Here the bulbs were quite hardy, and with *Sparaxis*, *Calochortus* and *Babianas* afforded a charming lot of cut blooms all through the late spring. But it was not upon their outdoor culture that I wished to dwell, but on their value in the unheated greenhouse. If this structure is to look well, great care is needed in selecting the various occupants, and a batch of *Ixias* is certain to please all who will carry out the following instructions: In the early part of November put six or eight of the bulbs into a 5-inch pot, using a compost of loam, sand, leaf soil and manure. I use these in about equal proportions. Make it firm and cover the bulbs with about 1½ inches of soil. Plunge in a cool pit or frame. They need no water through the winter, but early in March, when they will be showing their flower-spikes, more moisture will be needed. The temperature found in unheated greenhouses at this time is much more suitable to these pretty bulbs than a heated house.—R.

Adhatoda cydoniæfolia.—In reference to your request for specimens of new or old plants not generally cultivated with a view to their being described in THE GARDEN, I herewith enclose some sprays cut from the above-named stove shrubby flowering plant. Our plant is growing up the roof of a stove containing a mixed collection of stove-flowering and fine-foliaged plants. It is trained to three wires fixed under one of the rafters, in the same way as Vines are often grown.

It is planted in a brick pit about 18 inches square and 12 inches deep, built under the hot-water pipes that run round the house under the stages. The pit is raised some few inches above the level of the floor to prevent its getting water-logged. The soil used is a mixture of two parts sandy loam, one part peat, and one leaf soil, plenty of drainage being used. Blooming, as it does, during the month of November, it is a very useful addition to any collection, especially as stove plants having blue or purplish-coloured flowers are not plentiful at that season. We use it occasionally for mixing with other flowers for the decoration of vases in rooms, though it does not stand so long when cut as some flowers do. For those who have convenience to do so, it would be better adapted for training up pillars than up the roof. Another year, all being well, I intend trying it in baskets, striking the cuttings in spring, and planting them in the baskets in the same way as Ivy-leaved *Geraniums*, *Petunias*, &c. I have no doubt it will have a charming effect when thus grown. It is a very free-growing plant; ours has made fully 10 feet of growth this year. I find cuttings strike freely in spring by taking small side shoots some 4 inches in length and inserting them in a sandy compost round the sides of small pots, which are plunged in a brisk bottom heat either in a hotbed or propagating case in the stove.—H. J. CLAYTON, *Grimston, Tadcaster.*

KITCHEN GARDEN.

WHITE TURNIPS.

WHILST all admit that we have just now a wealth of winter crops almost beyond precedent, the white Turnip crop has been found unusually plentiful, and the roots are very clean, fresh, tender, and sweet. That very unlooked-for result—for not so long since does it seem when it was thought impossible to secure a plant—is most due to the persistent sowings made in repeated succession so soon as others failed, so that not a day was lost. Had growers but waited a week or two longer, the season might have been absolutely lost. But all who had experience of the ground recognised that it was as warm and capable of promoting quick seed growth in September this season as is usually the case in August, and what with this warmth, the thoroughly fertile condition of the soil through lack of summer exhaustion, and continued ample light, realised that these presented unusually favourable conditions for late-sown Turnip breadths, which has since proved to be right. To these advantages has been added one of the best and most extended growing autumns ever remembered, so that it is no wonder we have now such a wealth of fine, clean, white Turnips in the market, whilst we cannot hope always to have such fine opportunities for late-sown breadths. The fact that we have had them so exceptionally plentiful this year may at least encourage the making of some late and, indeed, frequent sowings ordinarily, for there seems to be no knowing what good results may arise. Sometimes the bulbs are but half grown. They are considered very small, yet how delicious are they and how much more soft and refined is the flesh than is that of larger bulbs. Sometimes no bulbs result, but there is a good breadth of plants that will carry a heavy crop of the most delicious tops in the spring, and, indeed, if even so much as that be not realised, the resultant growth more than repays the small trouble involved in the sowing if dug in as a green manure crop. Oddly enough, we very seldom in gardens utilise green crops as manures. Some portions probably must be left vacant to undergo

the annual operation of trenching, one far too important to be neglected, but still some breadths can always be thus manured, and a very excellent manure, as well as a cheap one, is a good green Turnip crop when thus buried in the soil in the spring, especially if there be no bulbs on which grubs or wireworms can subsist. As to summer Turnips, we have long since realised that these are but very secondary crops, seldom being then needed as a distinct dish, and chiefly required for flavouring purposes. A very small breadth sown every ten or fourteen days keeps all the Turnip needs of the summer fully supplied. Even this season, late as it is, we have found the immense abundance of Cauliflowers everywhere to militate appreciably against the use of the Turnip, because the soft succulent flesh of the root of one and the flower of the other have close identity when cooked. The great demand for Turnips comes more fully when at the end of November Cauliflowers are past and other roots have largely lost their freshness, even Brussels Sprouts becoming under the influence of the greater cold rather strong; then it is that Turnips, if still young, fresh and juicy, are so highly appreciated. But if hard weather sets in, the Turnips soon suffer also, unless something be done to afford them protection, and that is too seldom found. Even in gardens it is still far too much the rule to sow seed broadcast. When, however, sown in drills 12 inches apart, and that is perhaps rather close together, it is easy then to pull up to the end of November every intervening row, finally clearing them absolutely away, so that soil from the cleared spaces can in gardens with a hoe or fork, and in fields by the aid of the moulding plough, be drawn up to the remaining rows, and thus give them capital protection through severe weather. In such case the roots keep much fresher and juicier than if pulled and stored in any other way for winter use. A. D.

Field Mushrooms.—I should think readers of THE GARDEN would note with surprise 1s. 2d. being paid per pound for Mushrooms, and this field one, too, in this abnormal season of plenty. As I am credited with this statement, I can only say that it must be a printer's error. What I stated was ½d. (one halfpenny).—A. YOUNG.

Vegetable Marrows outside.—It is not often one can send these to the table the first week in November, but this I was able to do so from the open ground, and not a single fruit, but five good useful ones. These were grown in a sheltered spot, and when the early frost in September came on the plants had an old mat put over them and this preserved them. We had no frost again to speak of till the first week in November.—DORSET.

Kales and drought.—It is wonderful how the Kales and Broccoli have recovered from the drought, especially the late varieties of the former. The various kinds of Broccoli are most luxuriant; whereas some of the Kales present a patchy appearance and had a hard time; indeed at one time despite all watering they refused to grow, the excessive heat on our dry, gravelly soil being most injurious. I never saw the sprouting Broccoli so good. Veitch's Protecting Broccoli is very fine this season; indeed, with so many drawbacks, there is a wealth of green vegetables. Celery I have never had better. Certainly it was a little tough a few weeks ago, but it is all that can be desired now, and out of many heads I have not seen one that has bolted. On examining the quarters in which the Kales are growing I find that those which stand the severe weather the best have suffered most from the heat of the past summer. The Buda or Asparagus Kale suffered

badly; indeed, this was our worst variety, although it is one of the hardiest Kales grown, as in the severest weather the stem of the plant rarely suffers. Another kind—the Cottager's—suffered similarly; this also is one of the best and hardiest varieties grown. The variety known as Ragged Jack is also badly affected by the heat. On the other hand, the Curled Green or Scotch Kales suffered very little; indeed, they are as good as usual, very finely curled, and somewhat dwarfed. The purple Kales seem to thrive in hot weather, as there are no blanks and the colours are deeper than usual. I prefer the Scotch to the Purple, as I consider it better flavoured and equally hardy. The effect of the past season on the hardier kinds shows that these varieties require a heavier soil to be able to resist drought and make headway, so that in light soils deep cultivation is imperative, selecting the heaviest soil for those kinds. Though Kales thrive in poor soil in ordinary seasons, it pays to give those kinds richer food which are required to prolong the supply till spring Cabbage turns in.—G. WYTHES.

The London or Rosette Colewort.—I am pleased to find Mr. Iggulden recommending this delicious winter vegetable, and am surprised that it should be met with so seldom. It is essentially a winter vegetable, but I have sometimes seen it fit for cutting during August and September, the seed having been sown in spring with the ordinary winter stuff. If seed be sown about the second week in July and the seedlings transplanted as soon as ready, they will form good solid hearts by the beginning of November. The smaller seedlings should be allowed to grow for another fortnight and then be planted. These will arrive at maturity in December. For hardiness nothing can equal this Colewort. I have known all the Broccoli, Brussels Sprouts, and even the old hardy Scotch Kale succumb to severe frosts, and the little Colewort pass through the ordeal unharmed. Their small size allows them to be planted from a foot to 15 inches apart all ways, and any plot from which Peas, Beans, or Potatoes have been cleared may be used for Coleworts without any further preparation. Another point in its favour is the non-liability to split when fully hearted, while the flavour will please even the most fastidious. Taken from all points, I know of no winter green vegetable of greater merit.—JOHN CRAWFORD, *Cod-dington Hall*.

Coarse vegetables.—In whatever is grown for eating flavour should be the first consideration. If this be so, will anyone venture to say that a big half Cabbage-like Brussels Sprout is as good in flavour as one of the small bullet-like close sprouts? Again, is the flavour of a Drumhead Savoy equal to that of a Tom Thumb? I quite agree with "A. Y. A." that the large Cauliflower is inferior to the small type as regards flavour. Let anyone cook a dish of both kinds in July and then compare them. The same holds good in the case of all green vegetables. Regarding Onions, it will take stronger proof than "W. I. R." has advanced to make me believe that those large growing soft kinds will keep as well as the good old James' Long Keeping. A short time ago I called on a friend who is an expert in growing large Onions, and who has gained several prizes for them on the exhibition table. When looking at some bulbs from 2 lbs. to 3 lbs. each, I asked him where his stock was for supplying his family. When he showed them to me I remarked, "Then you do not believe in these big soft kinds for keeping." He shook his head and said, "None of those for me." The remarks made by "A. D." at p. 378 are to the point. I fail to see where the educational point comes in in any committee giving prizes to produce that has nothing but mere size to recommend it. I think judges are equally to blame in this matter, and a reform is badly needed.—J. C. F.

Carrot Early Gem.—This is a distinct variety, oval in shape, from 4 inches to 6 inches long, and of excellent quality. It differs from many varieties by the small amount of core; indeed, some of the smaller roots have scarcely any core. This

is a distinct gain, as the roots are more succulent and of better flavour. I am induced to send this note on account of its value for shallow soils or places where Carrots canker. This is one of Messrs. Sutton's recent introductions, and one that will hold its own when it becomes well known. It possesses several advantages over the earlier or Stump-rooted kinds, being more fleshy and equally early, thus giving more weight for the room occupied. It is also an excellent keeper, retaining its good flavour for a long period. For early sowing it should become a special favourite on account of its good quality and quick growth, and, what is so desirable in early roots, increased size.—G. W. S.

WHOLE OR CUT POTATO SEED.

FOR several years back opinion has been a good deal divided regarding the question of cutting the tubers of Potatoes used for seed. Many farmers still firmly adhere to the practice of cutting the seed once or twice according to the size of the Potato and its stock of "eyes." I have even known them slice a bit off the "blind" side rather than plant the tuber whole. The great advantage claimed for the cutting is the economy effected in seeding. As it generally requires from 14 cwt. to 16 cwt. of seed to plant an acre, it will readily be seen that the cost entailed for seed is considerable. It is only natural, therefore, that means of economising should be adopted, especially in seasons when big prices are obtainable in the market; but the saving policy can be overdone, and, in the light of recent investigations and experiences, it might be worth while for those who have hitherto held firmly by the system of planting cut Potato seed to weigh carefully all the facts of the case, and ask themselves whether, in the long run, the method is in reality an economical one. In nearly all the celebrated Potato-growing districts seed-cutting has been finally abandoned. Whole seed, although a little more costly, has been found to produce very much better results in every way. Not only is a heavier crop produced from the entire tubers, but the crop while on the field is found more vigorous and robust in growth, and therefore less liable to yield to the attacks of blight or disease. It is not claimed that the use of whole seed is an absolute preventive of disease. But crops grown from whole seed have been found to resist the scourge more effectively than those produced from cut sets. Therefore, although not in itself a complete preventive, the system appreciably assists any other preventive or curative means that might be employed. It is also maintained by experienced farmers that a more uniform crop, and therefore a larger percentage of marketable or profitable tubers, is obtained by planting the seed uncut. The seconds, or medium-sized tubers, are best adapted, and are generally used, for seeding purposes. The largest-sized Potatoes are not any better growers than the seconds if the latter are wholesome and sound, while they invariably command a more ready and more remunerative market.

A striking instance of the superiority of whole tubers over cut ones for seeding purposes came under my notice a few weeks ago. When inspecting the crops on a well-known farm in the county of Bedford, my attention was attracted to a curious mixture of crops in a few drills on one side of the Potato break. There were a few bunches of Potato haulm visible here and there, but what at first sight appeared to be weeds, and what a closer inspection revealed to be Oats and Vetches, held the upper hand. Upon inquiring of the farmer the meaning of that strange conglomeration—Potatoes, Oats and Vetches—growing alongside such a level and magnificent crop of tubers, I learned the cause. As is his custom, the farmer selected and retained the seconds of the preceding Potato crop for seed. But he found that he had not sufficient to cover the ground allotted to this year's crop. Accordingly he fell back upon the firsts, which he considered, on account of their size, should be cut. This was done, and the result was the utter failure referred to.

I would not urge those who still plant cut Potato seed to at once abandon their old and well-tried method in order to adopt the one I recommend—the planting of whole tubers. I have every confidence that the latter practice would in time commend itself strongly to them; therefore I invite those who have never given it a fair trial to do so on a small scale before finally and exclusively accepting it. Let them begin to experiment next year with a few drills, giving of course both kinds of seed similar treatment and opportunities in every respect. The following year, or for a few years, the trial might be repeated until the results are sufficiently conclusive to decide which is the better system.—B. M., in *Field*.

Rosette Coleworts.—These, like other vegetables, differ much in quality and shape. There are good and bad forms even in Coleworts, and those who have a good one have at this date a choice vegetable equal to the early spring Cabbage. The Rosette Colewort is a most useful autumn vegetable, easily grown, but one often sees in a quarter plants of various heights and not at all like Rosettes. Out of many hundreds of plants I have scarcely a rogue, and the quality is all that can be desired. I have seen the hardy green mixed with the Rosette. This is annoying, as it spoils the quarter and gives the kitchen garden an untidy appearance. The hardy green Colewort is equally useful, but should be grown for spring use, as it stands severe weather. The Rosette is more tender, having more heart and is soon injured by frost. To prolong the supply well into the winter it may be lifted and placed in a cool place.—G. W.

Veitch's Self-protecting Broccoli.—Often in the autumn after the Cauliflowers are over there is a gap before the winter Broccoli are in. This variety will furnish the supply for at least six weeks at a period of the year choice vegetables are on the wane. There is no better vegetable than this if cut in a small state. The heads are beautifully white, free of caterpillars and of a mild flavour. I have for years taken care to have a good quarter of this variety, and I do not know of a better for late autumn use, as it possesses peculiar advantages, having a perfect covering of leaves over the flower. Where there is a demand for choice vegetables, the Cauliflower and Broccoli are always appreciated, and by planting at the end of June, there will be no lack of good heads at this date. If small heads are desired, plants may readily be lifted and placed under a north wall to prevent their getting too large and to prolong the supply till such varieties as Snow's Winter White come in. By having a good breadth, the latest plants may be placed in cold frames or even Peach cases, and, with free exposure, will eke out the supply.—S. H.

Late-sown Carrots.—The present season has taught us some useful lessons, among others that of sowing a good supply of Carrots at midsummer, as this year, owing to the intense drought, the first crop was nearly a failure. Directly I had lifted some early Potatoes I dug the ground and sowed Early Nantes, French Horn and James' Intermediate Scarlet. Heavy rain having fallen directly afterwards, the crop grew away rapidly. Lately I have pulled an abundant supply, and certainly for quality they are far superior to the early-sown. I feel sure that even in ordinary seasons it would be better to have two distinct crops than to rely on the early sowing for a full supply.—J. G. H.

Cool storage for Salsify.—This is not appreciated as it deserves, and in some instances the flavour is much impaired by storing in unsuitable places. The value of the above is as a spring vegetable at a time there is a dearth of other things. Those who can store in cool cellars have a great advantage over those who store in warmer buildings, as in the latter the roots grow out badly, and by the early spring have lost that plumpness all roots should possess. Even such roots as Beetroot, Carrots, Turnips, and winter Radishes require cool storage, and many shifts have to be made if flavour is considered. I have used disused ice

wells and stoke-holes in preference to dry, airy sheds, which are useful for such roots as Onions. Even Cauliflowers and Broccoli often require shelter at this season, but those who wish to preserve the above vegetables will do well to store as cool as possible just free of frost, and when placing in the store to use plenty of soil or ashes between the layers, this keeping the roots firm, preventing shrivelling, and also warding off frost.—S. H. B.

FERNS.

TINTS IN FERNS.

In addition to the variegated Ferns referred to in a previous note, a variety of distinct shades is found in the normal forms. Under favourable conditions many Ferns, especially the *Adiantums*, assume very bright tints in the young fronds. These brightly tinted fronds gradually fade until they assume the normal green colour, but while they do retain the bright colour they add considerably to the effect of the fernery. The old system of growing Ferns under heavy shading was not favourable to the development of colour, besides which the plants were too tender to be used for decoration outside the fernery. Most of the *Adiantums* may be grown fully exposed to the light, and will only require a slight shade during the summer-time; in fact I have seen *Adiantum Farleyense* growing luxuriantly when fully exposed to the sun. Of course, it is necessary to be careful that the plants do not get dry. I find, too, that the brightest tints are produced when the plants are potted in a good loamy compost. It may be advisable to use some peat for a few of the more delicate sorts, but good fibrous loam, leaf-mould, a little well-rotted manure, and good drainage will suit most of the *Adiantums*. I have often heard complaints about *A. Farleyense* damping off, and find the cause has generally been through letting the plants get too dry. There may be no outward appearance of damage, but on examination some of the under fronds will be found to have shrivelled up. As soon as the damp settles on these they will begin to decay and the fungus, which almost invariably makes its appearance on the decayed parts, will spread and cause further damage. The mischief is generally put down to too much moisture, while the primary cause is just the opposite. Although *Adiantums* do sometimes suffer from drought, it more often happens that they are over-watered.

Among those with tinted fronds, *A. tetraphyllum gracile* is one of the most remarkable. It is a delicate variety and should be confined to rather small pots. The young fronds have quite a crimson hue. *A. Veitchi* is a free-growing variety with equally bright fronds. This can only be propagated by division, and consequently is not very common. *A. rubellum* is another deep crimson-tinted variety, of which there are several slight variations; in fact, most of the tinted varieties vary somewhat when raised from spores. *A. tenerum* may be found in all shades, from a pale fawn with just a slight tinge of pink to a deep, almost purple tint. Those with the deep shade change to a deep green, while those with a lighter shade of colouring in the young fronds are of a paler shade of green when matured. Of this lighter shade *A. Collisi* is one of the finest. *A. Farleyense* must be included in this list, for when well exposed the young fronds have a lovely rosy-pink shade. It is remarkable that those of the *cuneatum* type have no colour, though when well exposed they are of a lighter shade

of green than when grown under heavy shading. Those of the *Capillus-veneris* type, too, are destitute of colouring, and almost invariably retain the deep green. *A. C.-v. Mariesi* may be given as an example, the peculiar deep green shade of its fronds forming a distinct contrast to such as *A. Williamsi*, which has a very pale soft green shade. It is remarkable that those destitute of any colouring in their fronds almost invariably like a more shady position than those with the bright tints. None of the *Aspleniums* have the slightest tinge of colour, and these all delight in a shady position. The *Nephrolepis* may also be quoted as having no colour, and all flourish in a shady position. To return to the tinted varieties, *Lomarias* contribute very distinct and beautifully coloured varieties, of which *L. l'Herminieri* is the most remarkable, the young fronds being quite as bright as a well-coloured *Dracena*; it is a delicate Fern, however, and is not often seen in good condition. It should be grown in the cool fernery, but must not be exposed to a dry atmosphere or a draught. *L. attenuata* is another. Though the tint is of a paler shade it is equally attractive, and the plant is not quite so delicate, though by no means vigorous-growing. *L. Pattersoni* is a very distinct Fern of dwarf habit; the young fronds have a bronzy tint, which gradually changes to deep olive-green. In the *Doodias* we have some bright colour, *D. aspera* and its variety *multifida* being the brightest. I have seen the latter very bright indeed. It is best when grown on freely from seedlings. Though it may be grown with the greenhouse Ferns, it succeeds better when grown in the stove.

Of *Blechnums*, *B. occidentale* is one of the prettiest tinted forms. *B. longifolium* also gives a distinct shade, the young fronds being of a deep bronzy purple. *B. corcovadense*, the tinted variety of *B. brasiliense*, when well exposed has a very bright rosy crimson tint.

Davallias contribute only one tinted variety, as far as I am aware; this is *D. polyantha*, which has large recurved fronds, deep bronzy purple when young, and changing to deep green with almost black rachises. Although there is no colour in the other species, there are various shades of green from pale pea-green, as in *D. pallida*, to deep olive-green, as in *D. bullata*. I should not omit the beautiful *D. immersa*, usually known as *Leucostegia immersa*; this has a deep bronzy tint in the young fronds, and changes to a pale almost straw colour.

In *Lastreas*, *L. erythrosora* is the brightest coloured; *L. prolifera* also has a deep bronzy tint, and *L. opaca* has a pale bronzy brown tint. These hardy varieties colour well when grown in warmth in the spring. In the *Pteris* family we have several good variegated varieties, but few with the tinted fronds. *P. aspericaulis* is the only striking variety with coloured fronds; it has deep bronzy brown fronds with a slight reddish tint when well exposed. It is nearly allied to *P. tricolor* and almost as beautiful, with the advantage of being much easier to manage. It should be grown in the stove, and in an elevated position where the damp will not settle on the fronds. *Woodwardia orientalis* may be included in the list of tinted Ferns; the bulbils, each of which has a tiny frondlet of a rosy tint, do not always develop the rosy tint, but I have seen them beautifully coloured. Most of the *Osmundas* are remarkable for the pale shade of green. *O. palustris* is an exception; it is one of our most beautiful greenhouse Ferns, graceful in habit, beautifully tinted with rosy red, and does not lose its fronds in winter.

Others might be added to this list of tinted Ferns. There are also those which have per-

manent colours, as in the *Gymnogrammas*, &c., to which I will refer in a future note.

A. HEMSLEY.

SEEDLING FERNS.

FREQUENTLY at this season of the year there may be found a considerable quantity of small seedling Ferns in the pots of other plants, or even on borders where the Ferns may have stood. If the stock of any kind is short, advantage should be taken of these young ones to replenish it, and it will be found far better to attend to this item of work now than defer it till the spring comes round. The young plants may not make much progress, but they will at any rate become established, starting away in the spring much more readily. Where the plants are large enough, they should be potted singly into small pots straight away, and if somewhat small they can be pricked off in seed-pans for a time. By looking after young plants in this way it is always possible to keep up the stock for decoration as plants or for cutting. It is also far better to do so than to depend upon the same plants from year to year. Some will decline under the best of culture in course of time, and it does not pay to attempt the restoration to health again of any kind that can be grown on from the seedling state in a short time. Some sorts, it is true, are not so easily obtained from spores; to these the foregoing remarks do not apply. When seedlings are not obtainable under natural conditions, then the well-ripened and fertile fronds should be searched out for the purpose. Some prefer to let these fronds lie on paper for a time after they are taken from the plant, but I cannot see any actual advantage in this. The idea is no doubt to ripen the spores, but this is not in any degree necessary. The better way is to prepare at once some pans (shallow ones by all possible means) and distribute the fronds over the surface fertile side downwards, and leave the rest to Nature for the time being. Later on, as the fronds decay and the spores are distributed on the surface, a covering of glass will be found desirable to prevent rapid evaporation, as well as to encourage a more speedy growth. The soil should consist chiefly of peat, and that not very fine, silver sand or rough sandstone being also good additions; a smooth, even surface even is not essential. Two or more species of one genus may be raised in the same pan without any trouble. By thus intermixing them there is always the possibility of obtaining something distinct, the fertilisation taking place, as most are aware, after the spores have made a further advance in the pans. It is in this way that new varieties are obtained by those who make it their special study. For raising a young stock it is better to start at once, it being a waste of time to leave it until the turn of the day.

FILICES.

GARDEN FLORA.

PLATE 937.

DIPLADENIA ATROPURPUREA.

(WITH A COLOURED PLATE.*)

THIS is an exceptionally good stove plant, which was first introduced from Brazil by Messrs. Veitch, of Exeter, and flowered by them in 1842, when they exhibited it before the Royal Horticultural Society, who awarded it the Banksian medal as a new plant of exceptional garden value. It was figured in several periodicals at that time, notably by Dr. Lindley in his *Botanical Register*, 1843, t. 29, where it is called *Echites atropurpurea*. It does not appear to have remained long in cultivation, notwithstanding the figures, medal, and its undoubted

* Drawn for THE GARDEN by H. G. Moon in Mr. Sauer's nursery at St. Albans, June 8, 1893. Lithographed and printed by Guillaume Severeys.

DIPLADENIA ATROPURPUREA

beauty, for we find no record of its having been in gardens for the last thirty years until it was re-introduced in 1889 by Mr. Russell Clarke, of Croydon, in whose garden it appeared as a waif upon a mass of imported Cattleyas. Mr. Clarke sent flowers of it to Kew, where it was identified with the plant figured by Lindley, and referred to its proper position under *Dipladenia*. A plant of it raised from a cutting received from Mr. Clarke flowered at Kew in 1890. The stock afterwards passed into the hands of Messrs. F. Sander and Co., St. Albans, who have exhibited beautifully flowered specimens of it during the last two years, and in whose nursery there is a large number of plants which have flowered profusely, even small plants blooming freely. A first-class certificate was awarded to it by the Royal Horticultural Society in June, 1892. It also received an award when exhibited under the name of *D. Marie Henriette* at one of the shows held at Earl's Court last year. It has also been called *D. atropurpurea* var. *Clarkei*, without, however, any good reason.

Most cultivators who have grown *Dipladenias* know how freely *D. boliviensis* grows and flowers compared with the other larger-flowered species, such as *D. Brearleyana*, which, whilst ranking with the most beautiful of all stove plants, are not good-natured under what may be called ordinary treatment. Luckily, *D. atropurpurea* is as well behaved in this respect as *D. boliviensis*, growing as freely and flowering as profusely as that species under the same treatment.

The size, form and rich colour of the flowers are well shown in Mr. Moon's drawing, and when it is understood that flowers such as these are produced by plants grown in 5-inch pots the value of this species will be readily seen. Cuttings of the shoots will root at any time. The first bit of the plant received at Kew was grafted on to *D. boliviensis*, and it formed a nice specimen by the following year, when it flowered. The shoots may be trained on to a balloon trellis or up a pillar, or they may be stopped freely so as to induce the plant to form a bushy, self-supporting little pot shrub. Sir Joseph Paxton grew it along with *Stephanotis*, a happy idea, the deep crimson of the *Dipladenia* and waxy white of the *Stephanotis* going well together.

Messrs. Sander and Co. have lately introduced two other new garden *Dipladenias*, viz., *D. illustris*, a handsome stove climber with a woody root-stock, annual climbing stems, leathery ovate leaves, and large rosy red flowers. This species flowered at Kew in 1891, and was figured in the *Botanical Magazine*, t. 7156. It was also offered in the same year among the new plants sent out by Mr. Bull. The second is an exceptionally beautiful species which is likely to become a favourite with growers of stove plants. It is a small-leaved, free-growing plant, bearing bunches of rich rosy red flowers, nearly as large as those of *D. atropurpurea*. It was recently named *D. eximea* by Mr. Hemsley, of Kew.

Whilst upon *Dipladenias* I might call attention to the excellent results I lately saw obtained from sowing the seeds of *Dipladenias* in a garden in Cornwall. I forget the name of the species, probably *D. Brearleyana*, but a pod of seeds produced by the plant had been sown, and from them a batch of seedlings of beautiful character had been raised. They were in vigorous health and flowering freely, the flowers showing considerable variation in size, form and colour. Evidently the seeds of garden *Dipladenias* are worth looking after. The other species of *Dipladenia* already figured

in THE GARDEN are *D. Brearleyana*, 1875, *D. profusa*, 1881, and *D. boliviensis* this year. There are some twenty-five species of *Dipladenia* known, and they are all natives of tropical South America. The genus *Mandevilla* is very closely related, a relationship which hybridisers might profitably take advantage of.

W. W.

THE WEEK'S WORK.

THE KITCHEN GARDEN.

FORCING CARROTS.—There are few establishments where a supply of young and tender Carrots is not expected to be forthcoming as early as possible, and as at this season of the year there is generally an abundance of leaves, a bed may well be started at once. Where there are deep brick pits at disposal, these form the best places, as in these the heat is retained longer, that is when a depth of not less than 4 feet of well-trodden leaves can be provided. Failing brick pits for holding the leaves together, wattled hurdles may be used, using a little fresh stable litter so as to bind the bed together. It is also advisable to use a little stable litter in any case where leaves by themselves are not likely to generate warmth. The soil for surfacing should be fairly rich and friable, and to bring it to this state use sifted leaf-soil or old potting soil. A depth of 6 inches or 8 inches will be sufficient. The seeds should be sown in drills drawn 5 inches apart in preference to broadcast, and as the drills are drawn in, firm them with the back of a rake. The best variety for early forcing is the kind known as the French Forcing.

HORSE RADISH.—Although this is generally left undisturbed for years, with the result that there is a difficulty in securing a decent sized stick, yet with a little systematic management this may be overcome and a supply be at hand when needed. On some soils it may take two seasons to secure good-sized sticks, whilst in others this may be done in one season. In the case of a neglected bed a trench should be taken out to the depth of at least 2 feet, and then the whole be carefully forked over, taking care to break the roots as little as possible. The roots should now be sorted over, those of a usable size being laid in by themselves for immediate use, the others being reserved for planting. The best sets for planting are those thin roots a foot or so in length with a crown. The preparation of these can be done on a wet day. This will consist in rubbing off any side roots to within an inch of the bottom, either with a blunt knife or even with a piece of sacking. The site for the reception of the sets should be worked well over to the depth of 18 inches, mixing in some burnt refuse. If any rotten manure is added, this must not be placed nearer the surface than 15 inches, or forked roots will be the result. The roots should be inserted their full length, the crown being an inch or so below the surface. They are also best arranged in rows a foot or 18 inches apart, and 9 inches between the sets.

HORSE RADISH ON RAISED BEDS.—On cold or shallow soils excellent produce may be secured on raised beds. In this case a bed is thrown up, similar to a raised Asparagus bed, using plenty of decayed manure and burned garden refuse, especially the latter.

CARDOONS AND CHARDS.—After these become fully blanched they are apt to decay if left in the soil, but if this process is not yet fully completed, leave them a little longer, protecting the tops with a little long litter in case of severe frost. Those that are ready should as they are taken up have the hay-bands removed, also any decaying portions. Take them to a cool shed or cellar, standing them upright with some sand laid about the base of the stems or roots.

PROTECTING CELERY.—Celery is in fine condition this season, the weather having been most favourable for earthing up. Whether protection from frost will be needed will depend upon cir-

cumstances, for where the rows were set out at the distance apart as I advised in a former calendar, there would be ample soil for earthing up well. Celery highly fed is apt to decay rapidly. Celery which is well earthed will only require protection in case of a sharp and prolonged frost. In this case a layer of dry litter or Bracken may be laid along on each side of the row, a little of the longest being sprinkled lightly along the top, removing it again directly the frost has passed away. In low-lying districts where wet often causes injury from decay, a good plan is to lay a cap along the tops of the rows formed by having two thin boards fixed together thus \wedge . They must be so fixed that light and air may circulate freely.

GREEN MINT AND TARRAGON.—Both of these useful herbs may be forced readily enough in an intermediate temperature, and as they are always in demand a few clumps of Mint should be taken up and laid in boxes with a surfacing of rich soil. The growth will be more satisfactory if the roots are placed near the glass. Tarragon forces best if established in pots, but if no provision has been made, some roots must be taken up and placed in boxes.

A. YOUNG.

ORCHIDS.

THE Orchid grower has time now to give more attention to the details of the work, such as cleaning the plants, the glass and woodwork; this I have generally impressed upon cultivators as being of more importance than many growers care to admit. As there is not much to be done in the way of repotting plants, we may well discuss the question why certain Orchids after a time have such a tendency to degenerate in most collections, and occasionally by mere chance, as it were, they will thrive well year after year when no particular care has been taken of them. One lovely and particular Orchid I would allude to because it is in flower now, *Vanda cœrulea*. For a few years after its introduction it grows freely either in the *Cattleya* house or the East India house, and produces its splendid spikes of large delicate blue flowers abundantly, with a score of blooms upon each, and two spikes on small plants. Why do the plants decline after producing these spikes pretty freely for a few years? I fancy because the *Cattleya* house is not the right place for them, and because the spikes of blooms, large indeed for the size of the plants, take too much out of them if the flowers are allowed to remain until they fade. I was proud of a batch of these plants some ten years ago, which were pictures of health in the *Cattleya* house, but which declined after the fourth and fifth years of their flowering. They were removed to the East India house temperature and placed at the coolest end of the house, and in a light position near the glass roof; they are again in good condition and flower well, but I cut the spikes off when the flowers have been open a week or less, and they are used as cut flowers in the house. The *V. suavis* and *V. tricolor* types have not this tendency to deteriorate in quality, but they have a tendency to go wrong in another direction, which is a considerable annoyance to cultivators, that is to lose several pairs of leaves sometimes every year or every alternate season. I think it is annoying to a degree to see the leaves gradually change from deep green to paler green, and at last lose their greenness altogether. The leaves generally go one, two or three pairs of them all at once, and when they are removed the plants go on all right again for another year or two, when the same disturbance in the life of the plants occurs. Doubtless every grower who has passed through this experience has felt greatly annoyed at it, and has asked himself the question, how is it? What is the reason? I have known the leaves go wrong after the spikes of flowers have been upon the plants for six weeks or more, and have felt inclined to blame the flowers for exhausting the plants, but here again is the fact that *Vandas* in some collections flower twice in a year, and retain their leaves well. I fancy the cause is probably owing to the plants being grown in an atmosphere that is too dry and a temperature higher than it

ought to be. Being East Indian plants, some growers have come to the conclusion that the warmest house is best for them, and also that they will do if very lightly shaded from the sun in summer; and herein are two grave errors made. One in keeping the plants too warm, and the other in not sufficiently shading them, two causes which might easily by themselves be the medium whereby the lower leaves fail to retain their vitality. I have tried them in various ways, and find the shady side of the Cattleya house suits them best, and even if the temperature falls below 50° the plants are not injured in the least, and never at any time should they be exposed to the sun so much as most of the Cattleyas and Lælias. At this season they are in a state of comparative rest, and should not be too freely watered. Let them rest until signs of growth appear early in the year; this is apparent by the tips of the roots assuming a green tint, while they are almost as brittle as glass, and the ends snap off at a touch. I ought to add that when the plants get bare at the lower parts of the stems to such an extent that they are really an eyesore, it may be better to cut them over, being careful to see that there are plenty of stem roots above where the cut is made. Sometimes growths will be made from the bare stems, which will in time cover them again, but cutting the top off causes the growths to start more freely. When it is time to repot the plants, which is in the early spring, the pots should be filled three parts of their depth with clean potsherds, large pieces at the bottom, smaller pieces at the top; put a layer of Sphagnum over the drainage, place the plants on it, and fill up amongst the roots with a compost of equal parts clean washed live Sphagnum and potsherds, with a few pieces of charcoal mixed with them, finishing off the top in the form of a mound like a molehill. After repotting, keep the surface always fairly moist, so that the Moss will grow, and it should be thus kept in a growing condition all through the summer without giving the plants too much water. The deciduous Calanthes are now pushing up their flower-spikes very freely; we allow them to remain in the warmest house until a few of the lower flowers upon the spikes are developed, when they are arranged in the Cattleya house amongst Ferns, which are useful to hide the bulbs and perhaps a few leaves which may be in a half-decayed state. They do not require a great deal of water—enough merely to keep the soil fairly moist. No manure water should be used now; this should only be used when the plants are in healthy, vigorous growth. The Pleione are also in flower and are very pretty when they are arranged with Maiden-hair Ferns. The showy Cattleya labiata makes a fine display, and C. Bowringiana, although not so showy, lasts a long time in good condition.

It is pleasant, too, to see the long spikes of Lælia anceps rapidly rising up. See that the points of the spikes do not come into contact with the glass roof, as they may get injured in that way. As I write these lines the plants are being exposed to very damp, raw weather with fogs, which make things very unpleasant, and cultivators are fearful lest both their Orchid flowers and those yet in the bud state will be destroyed. The Phalaenopsis seem to be more easily injured than most others when in bud, and we can do nothing but look on and see the mischief done. Orchid cultivators who are within the radius of dense fogs do not take kindly to the patent ventilating apparatus which Mr. Toope has invented to save the blooms in the densest fogs—at least I have not yet heard of their doing so. It is a matter certainly deserving the attention of cultivators, as I believe Mr. Toope grows Orchids and preserves their flowers from injury by his method of filtering the air through charcoal and some other preparation, and this in an East-end district, where, to say the least of it, the conditions are not nearly so favourable as they are at the more open West-end. If anyone has had this ventilating arrangement fitted to his houses, he would certainly confer a boon by giving an account of it in the gardening press. Meantime we must do our best by keeping the houses shut up when dense fogs are on and ven-

tilate carefully at all seasons, being very careful in the dispersion of water by evaporation. The temperature of the cool house may now be 45° to 50° at night, with a rise of about 5° in the daytime; Cattleya house about 55° as a minimum, and the warmest house need not be more, especially on cold nights, than 60° to 65°. J. DOUGLAS.

PLANT HOUSES.

PREPARING PLANTS FOR CHRISTMAS.—Between now and the end of the year we have to deal with the most unpropitious part of the season. If forcing in any form is attempted it has to be done cautiously, otherwise the results will not be of a satisfactory character. To delay forwarding any particular class of plant for another week or two means that an undue amount of forcing will have to be attempted. I make use of the word "attempted," for failure may ensue where irrational methods are adopted. There should be at least a few days' interval between the time of a plant being forced into flower in heat and its use in a cooler house, otherwise it cannot be expected that it will last for any length of time in good condition. The probable demand, with a slight margin in advance thereof, should be anticipated, and steps be taken at once to meet it. In almost every establishment the needful supply at the coming season is above the average, and it will be a rare occurrence to find any excess therein. In some cases it may be found necessary to delay rather than to hasten on the stock of any given kind. Roman Hyacinths are in our case an instance of this; these, when potted or boxed early, are now showing their flower-spikes in cold frames. To have these either as a regular succession, which is our object, or *en masse* is only a question of comparative simple management. The mistake of deferring potting in the case of this useful and quite indispensable article is very palpable when the bulbs thus treated have to be afterwards forced into flower. In such cases it is absurd to lay the blame on the bulbs themselves. The Snowflake, Paper-white and Roman Narcissi will, if potted early, need but little inducement to flower at the right time, nor will the Duc Van Thol Tulips.

With Carnations also it is more a question of keeping in than of forcing into flower. Cold chills and winds ought to be guarded against, and aphides must be watched for; a gentle warmth in the pipes with ventilation to preserve a genial buoyant condition of the atmosphere will suit them. Bouvardias should have at least 5° more warmth (or a little more even than the Carnations); they will flower in less heat, but the secondary or lateral shoots will not be so freely produced. Poinsettias will require tact to keep them fresh until Christmas, a dry atmosphere, plenty of light, and a moderate stove temperature suiting them best. The old form and the double (*P. plenissima*) are the best sorts for the season now coming on. Euphorbia jacquiniæflora, where the growth has been well ripened, should come in about right under ordinary stove treatment. So also will *Aphelandra aurantiaca* Roezli, which is a beautiful plant for the time of year, well worthy of extended culture. *Eranthemum pulchellum* (invaluable in the winter) may if struck somewhat late, so as to have dwarf plants, require some little hastening to get it into bloom. A moist and warm house will suit this plant admirably; the spikes produced in heat and moisture are much finer than those from a cooler stove. *Gesnera cinnabarina* and *G. exoniensis* are extremely showy and valuable plants both in foliage and flower, but to cultivate them within the fog radius is only to court failure. *Epiphyllum truncatum* Russellianum vars. are the best for the end of the year. These should now be advancing into flower; a stove temperature is too much for them, but an intermediate house will suit them admirably. *Plumbago coccinea* and *P. rosea* look well enough on the plant, but in a cut state or in a cooler house whilst in flower they are comparatively useless. The shrubby winter-flowering Begonias are, however, invaluable; a cool stove fairly

dry will be the best place for them. The old kinds, as *B. insignis* and *B. Knowsleyana*, with the newer sorts, as *B. Gloire de Sceaux* and *B. Gloire de Lorraine*, are amongst the best of these. One advantage which these Begonias possess is that they light up well, at the same time putting up with exposure to other than a congenial atmosphere as well as most plants.

In the cool house the *Epacris* will be found at their best where managed as advised by the end of the year, and *Erica hyemalis* will also be then in full flower, if not so already. Look to it that in neither case the plants suffer from want of water. Both double and single forms of the Chinese Primrose will also come in useful in a month's time. Keep the plants now in as dry an atmosphere as possible, and close up to the glass to prevent the flower-spikes from lengthening out too much. *Cyclamen persicum* now in cool houses may require a little hastening to get them well into flower in time, but it must be done gently. Late *Chrysanthemums* are rather earlier this year than usual; these will require to be kept as cool as is possible, otherwise they will not keep fresh. *Jasminum grandiflorum* is one of the best cool house species for the winter; it flowers well as small bush plants, but better when allowed a free run to the roof. In a cut state it is an excellent substitute for the *Stephanotis*, being delightfully fragrant. *Lasiandra macrantha floribunda*, although classed as a cool house plant, does better with slightly more warmth and moisture; a fernery suits it well for flowering.

In the forcing house or pit Lilies of the Valley claim our first attention; these should be crowns, not clumps for this season; about twenty crowns in a 6-inch pot will make a good show. These should be brought on in a brisk heat with moisture, it being a good plan to cover the pots with cocoa fibre or Sphagnum Moss to keep the crowns constantly moist, otherwise they will not start all at once or in a kindly way. By putting in a good few pots at short intervals, it should not be any trouble to get a batch at the right time. Early Azaleas will be found useful for cutting, the white varieties being most in demand; of these the old white (*A. indica*) and *A. Deutsche Perle* are two of the best. The latter will often flower almost without any forcing. *A. amoena*, *A. obtusa*, and *A. vitata elegans* are the best early coloured sorts still. Lilac can be got into flower by Christmas if started in heat and moisture at once. A steady bottom-heat from a bed of leaves cannot be surpassed as an incentive to growth at this season of the year, Oak or Beech leaves being preferable.

From the open ground the Christmas Roses should now be lifted with good balls, and then be transferred to a cold frame from which the frost can just be excluded when desirable. Potting, &c., will not be requisite unless the plants are wanted in the conservatory or house when in flower; in fact they will be all the better if not so treated. JAMES HUDSON.

HARDY FRUITS.

APPLES.—Heavy crops of fine well-coloured fruit have been the order of the day, but unfortunately all have kept or are keeping badly. Getting rid of the bulk of the fruit of what should have been late in ripening may have been advisable in the case of market growers, though not so in private gardens, especially if a steady, light demand for ripe fruit is the rule. It will have been found that of the whole of the fruit, not more than one half in fact early became spotted or diseased, the rest keeping fairly well. Those, therefore, who have good-sized heaps of late varieties ought to carefully sort these over occasionally, turning out all that are diseased or decaying and keeping the rest as cool and dark as possible, short of exposing them to frosts. Thus treated, Cox's Orange Pippin, Blenheim Pippin, King of the Pippins, Margil, Adams' Pearmain, Beauty of Kent, and such like are keeping better than at one time thought probable. So many bushels of early and second early Apples have been

spoil this season, that many growers will have wished ere this that fewer of them and more of the later varieties had been grown, and if this experience tends to promote the more extensive planting of good later sorts than formerly, then this must be reckoned as a result of the unusually hot summer of 1893.

WALL CULTURE OF APPLES.—The specimens of Peasgood's Nonsuch that attracted so much attention at west of England shows, and were also awarded medals at different metropolitan meetings, were gathered from a tree trained against a high sunny wall. In this position the tree rarely ever fails to bear a crop of fine fruit, and other Apples succeed equally well under wall culture, the fruit invariably being large, of good form and well coloured. Those, therefore, who have wall space to spare and are anxious to grow prize-winning fruit, should cover it with Apple trees. They may be trained exactly the same as Pears, or as cordons, palmette verriers, horizontal, or fan shaped. The informal fan really appears to best meet the case, branches being simply laid in wherever there is good room for them. If no clear wall space can be given up to Apples, it might yet be possible to plant single cordons on the broad-leaved Paradise stock midway between Pear and Apple trees that do not fully occupy their allotted space. Peasgood's Nonsuch is much the finest Apple in cultivation, Warner's King for size, and other good qualities being the nearest approach to it—Belle Dubois or Gloria Mundi, Belle de Pontoise, Bismarck, Emperor Alexander, Golden Noble, King of Tompkins Co., Mère de Ménage, Potts' Seedling, The Queen, and New Hawthornden all likewise attaining a great size and perfection when the trees are given the benefit of wall culture. Lady Sudeley, an early dessert variety, is particularly handsome when grown against a wall, and so also are Beauty of Bath, Worcester Pearmain, Red Astrachan, Baumann's Winter Reinette, and other popular Apples.

ESPALIER FENCES, ARCHWAYS AND CORDON TRAINING.—In some parts of the country the good old plan of training Apple trees to espaliers is still in vogue, and, properly managed, they are remarkably productive. Fences, as advised for Pears on page 440, are suitable, the trees being horizontally trained. If grafted on the Pear stock the trees should be planted about 18 feet apart, those on the Paradise stock being arranged 10 feet apart. Apples are also well adapted for training over either small or continuous archways, and for these, single or two-branched cordons and palmette verriers, or what may be roughly termed six-branched cordons, are the best. Plant them so as to bring the branches not less than 1 foot apart. Horizontally-trained cordons are not gaining ground in fruit growers' estimation, these requiring to be frequently partially lifted and root-pruned to keep them in a productive state. These should be on a dwarfing stock, single cordons being planted 6 feet apart, and doubles, or those with branches for training right and left, 12 feet apart, all being trained to a single strong wire strained from 18 inches to 30 inches from the ground. A single line may fringe a walk, and sometimes three lines of trees are planted in these positions, a distance of 18 inches dividing the rows, the back row being the highest and the front the lowest. When these low cordons are properly managed, this including protection from frosts when in bloom, very heavy crops of fine fruit are frequently obtained from them.

BUSHES AND PYRAMIDS.—Apples can be grown in a pyramidal form, but not so readily as Pears, and bushes are the least trouble and the most profitable in the end. The majority received from nurserymen are of pyramidal form, but they can easily be converted into bushes by simply cutting out the centre. Trees on dwarfing stocks are naturally the first to produce crops of fruit, but for real service those on the Crab stock are greatly to be preferred. The former may be planted 6 feet apart, but if the latter are to be allowed to grow freely with a view to eventually taking bushels of fruit at one time from them, they ought to be disposed 16 feet apart, and half that distance from

the walks. Good cooking varieties for either espaliers, cordon training, pyramids, or bushes will be found in Manks Codlin, Lord Suffield, Ecklinville, Duchess of Oldenburg, Lord Grosvenor, Lord Derby, Stirling Castle, Frogmore Prolific, Beauty of Kent, Peasgood's Nonsuch, Tower of Glamis, Warner's King, Domino, Cox's Pomona, Bramley's Seedling, Prince Albert, Wellington, and Northern Greening. Dessert varieties suitable for similar purposes are Beauty of Bath, Red Astrachan, Lady Sudeley, Worcester Pearmain, King of Pippins, Cox's Orange Pippin, Margil, Ross Nonpareil, Adams' Pearmain, Braddick's Nonpareil, Scarlet Nonpareil, Court Pendu Plat, Claygate Pearmain, Lord Burghley, Sturmer Pippin, Duke of Devonshire, Cockle Pippin, and Cornish Gilliflower.

ORCHARD TREES.—These have been most extensively planted of late years, and a few standards ought to be found room for in most places, as these sometimes produce extra heavy crops of serviceable fruit. In orchards devoted entirely to standards the trees are usually disposed 20 feet apart each way, but if there is to be an undergrowth of pyramids, bushes, and small fruits generally, then ought the standards to be arranged about 25 feet apart. Not many comparatively large trees of popular varieties are to be found in nurseries nowadays, and this is a matter for congratulation rather than regret, young trees really being the first to arrive at a large and serviceable size. Cooking varieties for orchard culture are as follows: Early July or Duchess of Oldenburg, Ecklinville Seedling, Golden Noble, Pott's Seedling, Cox's Pomona, Emperor Alexander, Hambleton Deux Ans, Hoary Morning, Lemon Pippin, Loddington, Lord Grosvenor, Reinette du Canada, Bramley's Seedling, Prince Albert, Wellington, Beauty of Kent, and French Crab; while suitable dessert varieties will be found in Lady Sudeley, King of Pippins, Cox's Orange Pippin, d'Arcy Spice, London Pippin, Claygate Pearmain, Gascogne's Scarlet, Wyken Pippin, Baumann's Reinette, Winter Queening, Sturmer Pippin, and Blenheim Pippin.

W. IGGULDEN.

FLOWER GARDEN.

NELUMBIUMS HARDY IN ENGLAND.

WHATEVER "W. W." may write is always suggestive and well worthy of attention, but has he himself seen, heard of, or grown any species of Nelumbium in the open air in a cold water pond in this country? Having seen Nelumbium speciosum grown in tanks, tubs, ponds, canals, and even in swamps and ditches in the tropics, I know something of its grace of habit and of form, and much admire its superb colouring, and I should be extremely glad to see the plant established in a pond or tank in either England or Ireland. In the late Mr. Whampoa's celebrated garden at Singapore a canal 100 yards long or more was full of Nelumbiums, Nymphæas, and Victoria regia, and to see their flowers at sunrise was a sight long to be remembered. The success achieved in several of the Northern States of America is very encouraging so far as it goes, and that these plants will withstand cold equalling that of our most severe winters seems beyond a doubt. The main point in the struggle, however, is summer heat and sunlight rather than the winter's severity, and if we compare our average or mean summer temperature and sunlight with that of Paris or New Jersey, I am afraid we shall find that these factors will be against our doing likewise with Nelumbiums in this country. Could we make sure of a succession of such sub-tropical summers as that through which we have just passed, I should feel much more sanguine of success,

but such seasons in a continual sequence are too much to hope for, nor would they be altogether desirable for us generally speaking, however good they might be for these and other beautiful aquatic plants. One of the most successful attempts at growing Nelumbiums in the open air I know of was that of N. luteum in the round tank in the Jardin des Plantes at Paris. For years the plant flowered every summer, but in winter a glass roof was placed over it, and this protection was augmented by other coverings during frosty weather. This is the only species of Nelumbium I ever heard of as blooming "in the open air" at any time and enduring a northern winter in a cold water tank, but there are other instances, and I should be very pleased to hear of many more of them. In the "Transactions of the Royal Horticultural Society," vol. vi., p. 535, there is a very interesting paper read in 1826 relating to the culture of N. speciosum and N. luteum in Northern Italy, and this paper deserves the notice of all interested in these plants. The author, Mr. Joseph Clare, is very sanguine, and his experiments taught him the futility of trying to grow Nelumbiums from seeds in tubs or other small vessels in which the water is apt to stagnate and become infested with confervæ, and so the plants eventually dwindle away. By putting seeds in a large pot of earth, however, and plunging this into a small stone basin in which there was a fountain always playing, the water from which supplied another garden, and thus was always running, under these conditions the seedlings "flourished very much, throwing up leaves 2 feet wide, with abundance of flowers, and they ripened a great quantity of seeds. These plants, though left every winter in the open air, have since (1822 to 1826) continued to bear abundantly." This success, however, was obtained under an Italian sky, the summer temperature being for some weeks during the year 1822 at 93° in the shade. In the following winter the thermometer was at 25° Fahr. below the freezing point for above a month. Now all that this experiment really proves is that Nelumbiums will thrive in N. Italy in a cold water tank, as assisted by a splendid summer climate of 93° in the shade, and that as so cultivated their rhizomes will live through a month's frost or more with the thermometer at 25° below freezing point. We are not told if any snow lies over the ice in Italy, but in the United States this is the rule; hence, the aquatics as grown there are practically protected during winter by Nature in America as they are by man in Paris, *i.e.*, isolated from external fluctuations of light, and heat or cold. Mr. Clare seems disposed to attach much importance to a constant inflow of fresh water wherever these plants are grown, at least during the summer months, and as an example he mentions that N. luteum as grown in a tub in the Pavia Botanic Garden never flowered until the tub leaked, and to replenish it a tap of running water was turned on to it, when "the plant sent up flowers and ripened seeds in that same year." Mr. Clare distinctly tells us that "all Nelumbiums require is fresh water and a long and warm summer; they are not affected by the severest frost of winter." In Northern China we are told the Nelumbium is cultivated in every available wet ditch, or marsh and swamp, its seeds and fleshy rhizomes being edible and highly esteemed in Chinese cookery, its deliciously fragrant flowers are in great demand for decorative and votive uses, while its petioles and leaves are devoted to medicine. The moats and ditches under the walls of Peking are full

of these flowers during the warm months, but in winter the ice is so thick and firm that carts can cross.

The seeds of *Nelumbiums* are said by Mr. Lee to grow after being kept for forty years, but I should prefer fresh ones, and plenty of them in order to make experiments as suggested by "W. W." Seeing that many good cultivators of these flowers have failed with them from seed and otherwise, even in hot houses expressly fitted with every convenience for their reception, it may be that a lack of a sufficiently copious supply of fresh or running water is one of the causes of such failure. It is well known that water, if at first quite free apparently from aquatic vegetation, soon becomes infested with chara, confervæ, &c., or otherwise it becomes vitiated and stagnant, both results or either result being mimical, and hence we may thank Mr. Clare for his experience and records in this direction as likely to lead us to better practical success. In endeavouring to naturalise *Nelumbiums* it would be well to begin with the very hardiest varieties or forms, and these are not always easy to procure. In Northern China, as also in Japan, where hard winters occur, we are told that there are numerous hardier kinds than those familiar in most tropical countries nearer to the line, and we should welcome any information as to whence and how these kinds may best be obtainable say in April or May of next year. Our American friends could doubtless send us seeds in quantity of *N. luteum* from its coldest limits in the Northern States. This species was introduced in 1810, and was flowered first in England by Mr. Miller, of the Durdham Down nursery at Bristol, who grew it in a warm plant house or stove.

N. luteum inhabits, we are told, the swamps, lakes, and slow rivers from New Jersey to Eastern Florida, extending inland to Louisiana. Michaux met with it in Illinois, and it was at one time introduced into the Brobston meadows near Philadelphia. A coloured figure and description of *N. luteum* as flowered at Bristol in 1839 are given in Maund's "The Botanist," vol. i., for that year. It has more recently been flowered in a tub by Mr. Lynch, of the Cambridge Botanic Gardens, and possibly elsewhere.

There is a hardy form of *Nelumbium* mentioned as having been seen by Pallas growing in great abundance near Astrakan and at the mouth of the Volga, and he says that a very fragrant water or perfume is made from its flowers. This plant has been called *N. caspicum*, but it is now regarded as a European or hardy variety of the eastern *N. speciosum*.

The open question still remains: Is it possible to establish any species or variety of *Nelumbium* in an open-air cold-water pond anywhere in the British Isles?

If I can obtain seeds in quantity, I shall begin the experiment next April or May, by cutting the hard testæ a little, enclosing the seeds themselves in lumps of adhesive earth or clay, and then boldly flinging them into the rich mud of our little Water Lily pond. Others I may try in tubs near to a tap or pump spout, as suggested by the extracts given above. Baron Von Mueller tells us that the ancient Egyptian method of sowing was to enclose the seeds in balls of muddy clay and chaff, which were then sunk in the water where the plants were desired to grow.

So far I have spoken of water under its natural climatic conditions, but wherever tanks or ponds are heated either by hot water running into them, or by hot water or steam-pipes running through them, then I should say *Nelumbium* and half hardy *Nymphaea* culture

ought to be a comparatively easy matter. Even a brick or concrete tank 2 feet deep and well sheltered from wind in the hottest and sunniest corner of a yard would be warmer and so better for this kind of experiment than a deeper pond in more exposed positions. A good deal has been said from time to time in THE GARDEN on cold, i.e., unheated, greenhouses for the culture of choice half-hardy things, such as Sikkim Rhododendrons, Magnolias, rare Lilies, Bamboos, Australian Tree Ferns, Fan Palms, &c., but there also seems a future looming upwards for cold houses for the growth of half-hardy aquatics such as the choicest of hybrid *Nymphaeas* and these exquisite *Nelumbiums*. When at Newry lately I saw such a house built expressly for Water Lilies by Mr. T. Smith, and in which *Nymphaeas*, *Sarracenias*, *Sagittarias*, &c., were growing well. One great advantage possessed by such glass-roofed and wall-sheltered tanks is that the plants are more immediately under the eyes and hands of the cultivator than when in a deep open-air pond exposed to all natural vicissitudes of climate and other, as it may be, adverse conditions.

"W. W." deserves the thanks of all who are interested in rare and choice aquatics for his able and persistent advocacy of their claims. My own views on naturalising *Nelumbiums* would be more sanguine if our mean summer records of temperature and sunshine were some few degrees higher than they generally are. But the greater the difficulties, the greater will be the satisfaction of whoever first establishes these beautiful flowers in our ponds or streams.

F. W. B.

NOTES ON HARDY PLANTS.

Aster puniceus.—I believe there are more varieties of this very beautiful species than have as yet found their way into the Chiswick Gardens, or, in other words, to the notice of the members of the Aster conference. I have seen flowers from more than one garden where they have been grown without a knowledge of the name of the plant, and in one case especially the flowers were really beautiful. I have them now standing in a vase with a few Catherine Mermet Roses, and I never saw a vase of flowers more beautiful. The conspicuous red stems of the Aster, the feathery effect of the heads sustained by bract-like leaves of a pale green, and the manner in which the panicles are set up render this Aster invaluable for cutting. I believe all the varieties of *puniceus* are useful, whilst a few are among the best of the Michaelmas Daisies. To call all the best varieties by name is as yet, I believe, impossible, but, thanks to the Aster committee, we know two by name that are worth securing, namely, *A. puniceus* var. *lucidulus*, the habit branching, stems purple, very leafy, flowers 1½ inches in diameter, pale lilac, height 5½ feet; also *A. puniceus* var. *pulcherrimus*, bushy, spreading habit, stems dark purple, flowers white, tinged with lilac, rays reflexed, height 5 feet. Some of the *Asters* are over-praised, but the best varieties of this species are not so. As I have often said before, the scientific names are useful, but very often the varieties of a species are superior to the type, and to one seeking flowers for their floral worth, all will depend on making the selection.

Solidago californica.—Personally I do not know this plant, but a friend having sent me seed with the note, "Saved from a plant raised from seed collected at Banff Springs, Canadian Rocky Mountains," I take it in hand with great pleasure, and the reason why I do so when given may possibly be useful. The seeds sent me are unpicked, that is in the form of the growing panicle, and, judging from this, the plant must be worth growing for its autumn effect alone. The fluffy clusters of seeds are, to my mind, a garden ornament equal

to white flowers. I mention this because I know few people care to grow the Golden Rods, and often the genus is passed by without a thought, but for garden purposes some of the *Solidagos* are useful.

Synthyris reniforme.—This somewhat uncommon plant is quite green, pushing fresh flowers when others are going down. With a little protection I have had it in bloom all winter. True, its flowers are small, but they are of a pretty blue, and the short spikes have a delicate effect. The whole plant is characterised by neatness, and its hardiness is well proved.

Plumbago Larpentæ.—It is quite clear that the flowering of this plant is entirely a question of suitable weather or climate. Since my last note about it, the weather has kept exceptionally fine and favourable, and the result is that the flowers have come out well, and just now among the dwarfier subjects it is the belle of the garden.

Aster diffusus var. *horizontalis*.—It seems that there are two distinct varieties or sub-varieties of this, not reckoning the variety *pendulus*—syn. *Nondescript*. Both have the same twiggy, rigid, densely bushy and horizontal habit, but one has much redder or, more strictly speaking, brown-red flowers than the other. I merely draw attention to this because, though the distinction is very clear, both the plants cannot yet have received notice, as one may judge from the report of the Aster committee.

Lychnis vespertina plena.—My oldest and largest plant of this, in the latter end of October, is a mass of big white, sweetly-scented double flowers. On the same plant there has been a profuse succession of blossom ever since June. It is supposed to be a well-known plant, and if so, why is it not more cultivated? Each flower resembles a double white *Primula sinensis*, but nearly twice the size. So double are the flowers, that none of the seminal organs or rudiments of them can be seen. The plant has a straggling habit, but if set in an out-of-the-way corner sheltered from wind, it would prove a most useful thing for those who like table and button-hole flowers.

Veronica epacridea.—I thought I had in this one of the freer-flowering, dwarf, conifer-like species, and because of that I was inclined to forgive it for being a little more tender than other kinds. Patience, however, must have an end even with plants. After watching it for blossom all the sunny season of 1893 I give it up as hopeless. No flowers have appeared, and as it cannot take care of itself in winter, I for one shall let it go.

Senecio pulcher.—Notwithstanding the fine season and a good position in the garden, plants of this are only yet showing their flowering stems, and the heads might open and dazzle our eyes with their rich colour if we could have another month of fine weather, an almost unreasonable thing to expect after what we have had. Doubtless this plant requires to be brought on under glass in early summer, at least for these northern parts.

Romneya Coulteri.—No plant so well exemplifies the varied climatic conditions of our little isle as this. In some of the more favoured spots in the south, on the west coast, and on the chalk formations, it may be grown year after year without winter protection, but in my own district it is very far indeed from hardy, so that possibly the more favoured districts referred to may be just about the maximum extent of its hardiness, or the conditions under which it may be left out of doors in winter. Still, we should not forget that very often the climate which is warmer, drier, and otherwise more favourable for a plant in winter is the climate that would better ripen or mature the plant and fortify it against the winter season. I fear there is another drawback in connection with this plant than its want of hardiness for general use, that of being a spare bloomer under some circumstances, and such circumstances as many of us would not imagine would be fatal to flowering. The finest plant I ever saw was in the sunny garden of Mrs. Acton, of Wrexham, where the soil is light and rich, and where the position afforded for the

plant one would have thought should have exactly suited it; anyhow the position was where the plant had thriven for two years, and attained a diameter of 3 feet to 4 feet, and still even in this sunny year of 1893 it had failed to produce a single flower. Possibly the points might have been sunburnt. Many, I know, would imagine this at once, but as I have some idea of the great care with which plants are tended in the garden in question, and especially the Romneya Coulteri plant, I do not think that drought would be the cause of no flowers. In other gardens, too, I have heard complaints of no flowers, though the plants have been strong and woody at the base, so, as I take it, indicating a state of maturity in regard to age. The plant is becoming more common now, but, so far as I have seen, mistakes are made in planting it now, and it will only be with great care that it will keep alive through the winter. It would certainly be unnecessary risk to set out young plants, however strong in the autumn. I should not do so until April or May; in no sense would there be any loss of time by so doing, but a gain if kept in a cool greenhouse near the glass.

Androsæce sarmentosa.—I saw this splendidly grown in the gardens of Mr. F. A. Sturge, Coed Efa, and it struck me as being well adapted for the wall garden, where, by means of its stolons, it draped the face of the stones with its soft grey rosettes in masses. The wall in question was not a mere dry structure, but a retaining wall, on the higher side of which it was filled up level with earth. This sort of wall, as I have before pointed out, is a very different medium for plant culture to the common narrow and dry fence wall. The former gets by capillary attraction nearly as much natural moisture as the soil itself; whilst the latter practically gets none, especially if more than 3 feet high. On a wall of the character indicated, this plant is highly decorative when not in flower. I was much struck with the way in which it grows in the climate of North Wales. The patches are not long in growing to a diameter of 2 feet or 3 feet. It is distinctly a lime lover. It may be grown without lime, but it is infinitely better with it and plenty of it in the form of limestone chips.

Spigelia marilandica.—I should consider this a plant certainly needing some special treatment about this time in the way of protection. It is never a vigorous grower and it certainly does not endure very severe frosts without injury. To plants in pots I would afford the protection of a cold frame, plunging the pots in such frame until spring and keeping them a good distance down from the glass. To plants in the open I would give a mulching of 2 inches or 3 inches of cocoa-nut fibre, and in addition a small armful of Bracken lightly disposed and secured against the wind by a peg or two. It is very much with this plant to-day as it was in Miller's time—a scarce thing, and scarcely kept in this country but by frequent importations. J. WOOD.

Woodville, Kirkstall.

Hardy bedding Fuchsias.—Absence from home has prevented my replying to Mr. Burrell's inquiry about these at p. 255. The Fuchsia I referred to is a kind that used to be grown in pots many years ago. It has a long red flower, foliage reddish green, the habit drooping and very dwarf. It makes a good bed, and has occupied the same place for several years. I grow both the Tobacco and Hyacinthus candicans amongst it, and find the same treatment answers for all. The bed is on a raised site, thus rendering it comparatively dry.—R. CROOK, Forde Abbey.

Notes on Violets.—The remarks of "M. H. F." as to Violets suffering from red spider this season are applicable to this district also. Of course, the single varieties are not grown hereabouts for market, but the double varieties, now found in all gardens of any pretension, are much affected by this pest, several batches I have seen being fit for nothing but the rubbish heap. Where the plants are grown on open quarters fully exposed to the

summer sun, it is next to impossible to deal with this enemy, especially if the subsoil is of a gravelly or porous nature. My plants occupy an east corner of the garden, and are surrounded by tolerably high walls; this allows the sun to play upon them for a few hours in the morning, which strengthens without distressing them. After the rooted runners are pricked out in May they are screened by small Spruce twigs, placed at intervals throughout the beds until established, afterwards well mulched with spent Mushroom manure and thoroughly watered on alternate evenings. At intervals of a fortnight a handful of flowers of sulphur is mixed with the water. This further aids in warding off red spider. As I have no other plot so suitable for Violets, I biennially renew the border with rough leaf-mould, the edgings of

and simply a mass of various coloured flowers, ranging from rose to pure white. This variety would make a charming edging to a large bed, or even a group by itself would be pleasing in late autumn. It is as free in bloom as the taller growing *A. cordifolius*, now smothered with the small white flowers.

SINGLE CACTUS DAHLIAS.

The single Cactus Dahlia, which is well represented in the accompanying engraving, the electro having been kindly sent us by Messrs. Dobbie, of Rothesay, we understand originated with Mr. E. J. Lowe, Shirenewton Hall, Chepstow, and is the result of much careful selection.

For the last two seasons single Cactus Dahlias have been grown largely by Messrs. Dobbie, of Rothesay, and Messrs. Keynes, Williams and Co., of Salisbury. The former firm has on several occasions set up beautiful groups of them before the committee of the Royal Horticultural Society. The single Cactus Dahlia will be sure to command favour with those whose notions are not too conventional, and if care is taken not to send out inferior varieties it will to some extent displace the circular type of singles. Already there are several really good varieties of the new type in the market. Guy Mannerling is a creamy white, valuable either for cutting or garden decoration; the blooms stand 9 inches clear of the plant; Ivanhoe, pink, of a fine incurved form, the plants not more than 30 inches high; Meg Merrilies, an exquisite yellow flower, very attractive and beautiful.

One of the most beautiful features of these varieties is that they are not flat, but are rather incurved in form, the points of the petals being twisted. The most desirable qualities would seem to be good substance, bright distinct colours and a stiff foot-stalk, which would serve the double purpose of keeping the flower erect after it is cut and of holding it well above the foliage when growing. These qualities we hope raisers will keep in view. Dwarfness of habit is also another point which would be a decided advantage. We do not mean like the Tom Thumb varieties, but somewhere between 30 inches and 3 feet. During next season these new Dahlias are certain to obtain an extensive trial, and by this time next year growers will be able to speak of their merits.

Single Cactus Dahlias.

FLOWER GARDEN NOTES.

ONE special piece of work in connection with the flower garden for the present season

is the re-arrangement and partial replanting of a long herbaceous border, and this, already in hand, will be pushed forward rapidly in order to complete it if possible before the advent of severe frosts. The border in question has been the receptacle for all sorts of herbaceous subjects, odds and ends, and bits of special favourites that have come to hand from time to time, and as a consequence is somewhat mixed; the aim, therefore, in the re-arrangement is to plant all subjects in sufficient quantity to get a good display from each. I noted above partial replanting, and this is so, so far as the present time is concerned, because several things, notably Pentstemons, Snapdragons, and early-flowering Chrysanthemums, will not be planted until the spring of 1894. The border is about 400 feet long by 8 feet wide, the width being sufficient to allow a depth of three clumps, if these are worked at an angle behind the front row. The annual

walks and drives, and horse manure, incorporating these thoroughly with the staple soil. This is as good as changing the site. I would draw the attention of growers to that most excellent variety Lady Hume Campbell. It has a large pale blue flower, similar to the old Neapolitan, but is a better doer than that variety. The plant is most vigorous, standing the worst fogs with impunity, which cannot be said of Marie Louise. The flowers are very fragrant, and although not usually produced until early spring, are none the less valuable on that account. It is quite useless taking stock from plants infested with spider; such are better consigned to the rubbish heap, and fresh runners secured from another source.—JOHN CRAWFORD, Coddington Hall, Newark.

A dwarf Aster.—A very dwarf Aster worth a note now is *A. versicolor nanus*. It is one of the dwarfiest of the family, only a few inches in height,

A dwarf Aster.—A very dwarf Aster worth a note now is *A. versicolor nanus*. It is one of the dwarfiest of the family, only a few inches in height,

mulching this border has received from a heap of rough manure has given us 2 inches of nice soil that will work in well with the natural soil of the border, and this being rather on the light side, a compost of a rather heavier nature will be added as the work progresses for the benefit of those plants that may require it. I find the batch of cuttings of new tufted Pansies that were put in early in August come in admirably for occasional front row clumps; they are so managed in their respective colours as to contrast well with other things, preference being given to decided colours, whether in the light or dark shades, and to varieties of dwarf, compact habit. With the tufted Pansies will be associated such things as Ernest Ladhams, Her Majesty, and Pheasant-eyed Pinks, and an occasional clump of a good border Carnation, Iris pumila in variety, and some of the dwarfed Veronicas and Campanulas. In noting a few things that will be used either in the front, centre or back of border it may be added that they are not supposed to represent all that will be utilised, or that they are so much superior to other things, only that they are typical of the several heights of the different clumps in their respective positions. A few clumps of a good Star Daffodil that was planted three years ago so that a good batch of these flowers would be close at hand for quick cutting will not be disturbed, as so soon as the foliage dies down the ground can be covered with some summer-flowering tender plant that will harmonise well with its surroundings. The spaces required for those things at present in the cutting stage alluded to above will be required chiefly in the central portion of the border, and the necessary room will therefore be reserved. Other things, however, adapted for present planting will be Spiræas, Irises, Funkias, Hemerocallis, Pyrethrums in variety, specialities such as Gypsophila paniculata, two varieties of Sea Lavender, and such Starworts of medium height as acris, Amellus major, and ericoides. Any varieties possessing decided rambling tendencies in the matter of root action will be excluded, as also nearly all plants with similar characteristics, such, for instance, as the Japanese Anemone. Their proper place is in sites where they can have a wide range without trespassing on other things. There is not such a choice of subjects for the back clumps of the border, that is, to ensure a variety of colour, although a judicious selection of the taller Starworts, with a few Helianthus, will furnish a good display. It will be advisable to alternate these things with earlier-flowering subjects, as Delphiniums, and then there will be no large bare gaps for any length of time starting from the first display of flower. This, indeed, is a matter for consideration in all planting of herbaceous things where the general effect of the border and a long-sustained display of flowers are to be special features. A mulching from a heap of rough manure, breaking this well to pieces with the fork for the benefit of the smaller plants, will complete the work.

BORDER CARNATIONS.—That the good work already performed in the way of popularising these flowers has resulted in a much improved race is well known, and yet intending planters to whom they are a comparative novelty may well be warned against accepting many varieties that are put forward in some catalogues as specially good things, instead of holding fast by tried sorts that have been certified to in THE GARDEN pages as possessing all the necessary qualifications of good border varieties. For instance, chatting the other day with an acquaintance who had recently made a Carnation planting I said, "You have of course included such representative sorts as Countess of Paris, Mrs. Reynolds Hole, Ketton Rose and Murillo that cannot be beaten in their respective colours?" "No," was the answer; "so far as Countess is concerned, I was informed it would not do out of doors, and for the others I have decided improvements on them." Now the vendor in this case could not possibly have tried Countess of Paris outside or he would not have made such an assertion, and as for the improvements on my old favourites, all I can say is when they are at their best next

year, may I be there to see and note. Besides Ferns in variety, the indispensable Asparagus plumosus and the trailing Smilax, anything in the way of greenery is acceptable through the winter months where a lot of cut flowers is required, and a batch of scented-leaf Pelargoniums in pots is just now very useful. The varieties denticulatum majus and the small quercifolium were growing with others in the open, and were carefully lifted and potted before the appearance of frost. With an eye to increased material in this way for another summer, an occasional plant of Tamarix gallica may fill up an odd corner in the shrubbery; also one or two pieces of Taxodium distichum. This latter may be kept to the required height by the use of the knife, and makes a handsome shrub-like tree with plenty of its very delicate foliage always available. E. BURRELL.

Claremont.

Dictamnus giganteus.—I have read with interest Mr. J. Wood's note on this plant. I believe the Dictamnus which passes under this name is

unhappy one, as it usually is when applied to flowers, giving generally the idea of un-gainliness, but the plant is certainly much more robust and has finer flowers than D. Fraxinella. Grown under the same conditions as D. Fraxinella, D. giganteus is considerably taller and the leaves are much broader; the flowers are also a little lighter in colour than those of D. Fraxinella. Even in the seedling stage young plants of D. giganteus are more robust than are those of the ordinary Dittany. They require good treatment, however, to bring them to a flowering size.—S. ARNOTT, *Rosedene, Carsethorn, Dumfries.*

A SELECTION OF MICHAELMAS DAISIES.

I SUBMIT a brief descriptive list of choice Michaelmas Daisies as verified by the recent Royal Horticultural Society Aster Conference. I employ their nomenclature, and it may be seen that this short enumeration embraces the cream of those marked by the committee XXX. Of course the more distinct types or species are not

NAMES.	COLOUR.	SIZE.	DATE OF BLOOMING.	HABIT AND STATURE.	REMARKS.
Aster acris draunculoides	sheeny dark purple	small	Sep.	bushy panicles, 3 to 4 ft.	effective.
nanus	"	"	Sep. to Oct.	bushy panicles, 1 to 1½ ft.	fine.
Amellus amelloides	dark purple	2 to 2½ in.	Sep.	bushy, 2 ft.	one of the best blues.
hessarabicus	lilac-purple	"	"	"	"
amethystinus	amethystine-blue	1 in.	Oct.	3 to 4 ft.	effective.
cordifolius Diaua	pale, but sheeny lilac	small	"	erect, very bushy, 4 ft.	exceedingly beautiful, new.
elegans	bright lilac	"	Sep.	erect, very bushy heads, 4 ft.	most useful.
diffusus horizontalis	brownish-red	"	Oct.	horizontally and densely bushy, 2 ft.	neat and pleasing.
ericoides	white	"	"	bushy panicles, 2½ ft.	pretty.
grandiflorus	blue-purple	2 in.	"	branching, 2 ft.	very good.
levis Apollo	deep lilac	1½ in.	Aug.	sparingly branched, 5 ft.	"
Arcturus	rosy-lilac	"	Aug. and Sep.	sparingly branched, 4 ft.	fine.
decorus	pinky-lilac	"	Sep.	dense, 3½ ft.	effective.
Flora	rich lilac	"	Oct.	free, 5 ft.	"
floribundus	rosy-purple	1 to 1½ in.	Sep.	sparingly branched, 4½ ft.	"
formosissimus	rosy-lilac	1½ in.	"	slender, 4½ ft.	"
Juno	rich purple	1 to 1½ in.	"	bushy, 5 ft.	"
Pygmalion	bright lilac	"	Aug. and Sep.	dense, 2 ft.	"
multiflorus	white	small	Sep.	one-sided, branched, 3 ft.	"
Novæ Angliæ pulchellus	deep violet	1½ to 2 in.	Oct.	robust, 4½ ft.	splendid.
præcox	rich purple	2 in.	Aug. and Sep.	" 3½ ft.	most desirable.
rosæus	pale rose	"	Sep. and Oct.	" 5 ft.	"
ruber	deep rich rose	1½ to 2 in.	"	" 4½ ft.	one of the best.
Novi-Belgii der sus	lilac-purple	1 to 1½ in.	"	very bushy, 3 ft.	extr. mely effective.
Harpur Crewe	white, rose-tinted	1 to 2 in.	Sep.	slender, branched, 4 ft.	very desirable.
Janus	white to rosy-purple	1 to 1½ in.	Aug. and Sep.	slender, branched, 5 ft.	"
John Wood	white	"	Sep. and Oct.	fine shrubby habit, 3 ft.	splendid bouquet material.
levigatus	deep rose	1 in.	Aug. and Sep.	densely bushy, flowers crowded, 2 ft.	most pleasing.
ranus (syn., hybridus)	rose	small	Sep.	branching, 1 ft.	a charming rock plant.
Purity	white	1 to 2 in.	Aug. and Sep.	robust, 5 ft.	"
Robert Parker	lilac-purple	1½ to 2 in.	Sep. and Oct.	bushy, 5 ft.	fine.
paniculatus W. J. Grant	pale mauve	medium	Sep.	free branching, 3½ ft.	a graceful variety.
ptarmicoides	white	small	Aug. to Oct.	slender, bushy, 1½ ft.	"
punicæus pulcherrimus	lilac, tinged white	1½ in.	Sep. and Oct.	robust and bushy, 5 ft.	a silvery beauty.
spectabilis	dark blue-purple	1½ to 2 in.	Aug. to Oct.	spreading, 2 ft.	notable for deep rich colour of heads.
Thomsoni	silvery-mauve	2 to 2½ in.	Aug. to Nov.	branching, 1½ ft.	a gem.
Tradescanti	white	small	Aug. to Oct.	profusely branched, 3 ft.	"
umbellatus	creamy white	"	Aug. to Sep.	Willow-like, 5 to 7 ft.	beautiful when established by ditch or pond-side.
versicolor (syn., discolor minor)	white, changing to rose and further deepening to purple	1 in.	Sep.	twiggy, 6 to 18 in.	a dainty rockery subject.
versicolor Antigone (syn., discolor major)	"	"	"	robust, 3½ ft.	dressy.
versicolor Themis (syn., discolor)	"	"	"	erect, 2 to 2½ ft.	showy.
vinosus	white	small	"	bushy, 2½ ft.	"

also known as D. davuricus, but, so far as I can discover, neither name appears in any of our British books of reference. There can be no doubt whatever that the true D. giganteus, or whatever may be its correct name, is distinct from the ordinary D. Fraxinella. The name of giganteus is an

so designated by the committee, but yet amongst them are some of the more beautiful varieties of the genus, notably acris, grandiflorus, pyrenæus, sibiricus, spectabilis, and Thomsoni. I have slightly varied the size of flowers, stature of plants, and period of blooming according to my ex-

perience of the plants in my more northern Yorkshire climate compared with Chiswick. I have overlooked the inclusion of the fine variety Archer Hind.

I believe it will be found that there are many other beautiful varieties of Michaelmas Daisies that, so far as the Chiswick committee's publications are concerned, have not yet been dealt with, and evidently it must be so, for there are not only old varieties that have long been hidden in old gardens that have not yet been brought into general notice, but in many places where the species or otherwise in fairly large collections of Asters are grown, new forms are constantly appearing as seedlings. These we must have whether we would or no, and however much we might desire finality of nomenclature, I cannot see that it is possible under the circumstances, *i.e.*, if we are to go on selecting improved forms and applying to such forms some designation by which they may be commonly recognised.

J. WOOD.

Woodville, Kirkstall.

LILIES IN 1893.

THE present year has, generally speaking, not been a favourable one for Lilies, for though some kinds have done fairly well, there has, on the other hand, been many failures, especially where the soil is light and dry. One of the most affected by the abnormal weather through which we have passed is the golden-rayed Lily (*Lilium auratum*), which in many gardens has failed to flower in a satisfactory manner. Its troubles commenced early, especially where fully exposed to the sun, as several of the plants seemed to suffer from a kind of sun-stroke. Many of them were attacked quite early in June, at which time the sun was unusually powerful, and in all cases it was the upper portion of the stem which was affected. This was at once shown by the leaves becoming yellower than usual, by the growth being arrested and the top portion of the stem commencing to bend over. In a few days some of the leaves would drop, and frequently a discoloured stripe would make its appearance up the stem, which soon commenced to decay. Very frequently the upper portion would show all signs of being stricken with this disease, while the roots at the base of the stem would be fresh and active, thus showing that the malady originated at the top and did not travel upwards from the bulb. The golden-rayed Lily is every season liable to be attacked in this manner, but, as a rule, only a limited number are affected; whereas, this year I have seen large quantities and under different conditions, in all of which the percentage of flowers was very small indeed. The vigorous variety *platyphyllum*, which is more robust in constitution than the ordinary *L. auratum*, also suffered terribly in many cases; while those two choice forms—*rubro-vittatum* and *Wittei* or *virginale*—whose bulbs are as sent here from Japan usually a good deal smaller than the type, have both suffered very much, especially the white one. The hard dry weather experienced during the spring affected the early-flowering Lilies very much, and the erect, cup-shaped ones, which compose the bulk of the very earliest, in many cases did not open kindly. Most of these are varieties either of *L. davuricum* or *umbellatum* and *L. elegans* or *Thunbergianum*, this last being less in stature than the other. Again, when the blooms were expanded the weather was so excessively hot, that they quickly changed colour and the petals dropped. *L. umbellatum* was so much affected by the excessive heat, that even in a few hours the petals lost their freshness and became dull. The smaller *L. elegans* was not quite so much affected, except the variety *lateritum* or *biligulatum*, which lost colour directly after expansion. Some specimens of *Lilium odorum* flowered grandly with me; whereas, on the other hand, two or three appeared to be diseased like *L. auratum*, but the flower-stem did not totally decay, and after a time a secondary stem was pushed up, which in each case flowered about the middle of August. The blooms, however, were not so massive as those that flowered at

the proper season. *L. Browni* in most cases bloomed well, but the chocolate coloured exterior was less dark than usual, hence the contrast between the ivory white of the inside and the dark-tinted exterior was less pronounced than it mostly is. The Turk's-cap Lilies all flowered well, especially the very dark-coloured *L. dalmaticum*. The flowers of this last remain in perfection a long time, and do not pale when exposed to the full rays of the summer's sun. Of what may be regarded as hardy border Lilies, two of the oldest are *L. bulbiferum* and the old Orange Lily (*L. croceum*). They are both great favourites of mine and are especially valuable from the fact that the blooms of these two remain in perfection for a very much longer period than those of their immediate allies. *L. bulbiferum* blooms about the same time as *L. umbellatum*, but instead of the flowers being gathered together in a crowded cluster, as they are in this last, those of *L. bulbiferum* are disposed in more of a pyramidal-shaped head. The flowers, too, are of a bright orange-red, and a clump of it forms a showy feature in the garden for quite double the time that a corresponding mass of *L. umbellatum* does, though this last is very effective when first expanded. The second to mention for the persistence of its blossoms is the old Orange Lily (*L. croceum*), which is one of the cheapest of all Lilies, and for blooming out of doors one of the very best. A clump of this with me flowered from the middle of June to the end of July despite the trying season. I have never had so poor a display of *L. Szovitzianum*, even established bulbs failing to flower in a satisfactory manner. The best examples of this Lily that have come under my observation during the present year were grown in a stiff loamy soil in a rather moist spot. Of *L. testaceum*, which follows closely on the early-flowering Lilies, I have seen many fine examples, though in nearly every case the plants were dwarfer than usual; indeed, this seems characteristic of all Lilies, owing to the hot, dry weather. *L. longiflorum* in its different forms is undoubtedly grown to a greater extent than any other Lily, and its flowering season also extends over a very lengthened period, for I saw some beautifully flowered examples of the variety *Harrisii* quite early in February, and cut half-a-dozen good flowers from secondary stems in the open ground as late as October 5. *L. Harrisii* is so generally grown in pots for flowering under glass, that its great beauty when planted out of doors is apt to be overlooked. Still, for such a purpose I do not consider it the best of the *longiflorum* group, as my choice would be the Japanese form, which by some is called *L. longiflorum grandiflorum*. Large quantities of this section are sent here from Japan, but the forms are not always of equal merit, though the majority consist of the superior type indicated above. As a rule the flowers of this differ from those of *Harrisii* from Bermuda in the tube being somewhat broader and the segments not so much reflexed, but these are only geographical variations, and grown under the same conditions for a year or two it is impossible to distinguish the one from the other. When grown out of doors the varieties of *L. longiflorum* are very dwarf compared with their height under glass, and this season they have been shorter than usual, while another noticeable feature is that the blooms in most cases opened perfectly; they are apt if the weather is wet during the flowering season to split in the tube, and this, of course, destroys a good deal of their beauty. This feature I have noticed most pronounced when heavy rains alternate with hot sunshine. The importations of the Bermuda Lily have this season been very large, and they reached here in good condition.

THE TIGER LILIES mostly flowered beautifully, but as might be expected they were about three weeks earlier than usual. Another season's experience of them has only confirmed the opinion that by far the best form is the variety *splendens* or *Leonoldi*. Treading closely on the heels of the Tiger Lilies, we have the different members of the *speciosum* group, the first of which to bloom was the variety *punctatum*, after that the forms *album*, *rubrum*, and *roseum*, both from English grown

bulbs, and those imported from Holland. The very dark coloured forms that we get from Japan flower earlier after a season in this country than they do the first year. In this latter case a good deal depends upon the time the bulbs reach here and the condition they are in on arrival. These two points certainly play an important part in the flowering season, regarding which I will have a few more words to say in dealing with *L. Henryi* and *L. sulphureum*. This year has been especially favourable for the development of the blossoms of *L. speciosum* in the open ground, as the fine bright weather experienced during the flowering period caused the blooms to open cleanly and regularly, which is by no means the case when the weather is cold and wet. This Lily has a very good constitution, and owing principally to the numbers sent here from Japan every year it is now much commoner than was the case a few years ago. So generally grown is it, that I saw good flowering examples of it on a costermonger's barrow in the streets of London as early as the middle of July. These were, however, the produce of Dutch bulbs, and not the Japanese ones. The different varieties of *L. speciosum* have also been very fine at Kew and at the Earl's Court exhibition, while, associated with *L. longiflorum* and *L. auratum*, they formed a very showy feature at the large show of the Royal Horticultural Society held at the Agricultural Hall. In no Lily has the earliness of the season been more noticeable than in the Neilgherry Lily (*L. neilgherrense*), of which grown in a greenhouse we had flowering examples on the 1st of August, and whereas the latest blooms are in some seasons nearly as late as Christmas, they are this year just opening now (October 9).

NEW LILIES.—Of Lilies that must be regarded as strictly new, that is, flowered for the first time in this country, there is, I think, but one to mention, though there are several rare or uncommon kinds that have increased their reputation during the present year. The one that has proved to be quite new is that first shown at a meeting of the Royal Horticultural Society, held at Chiswick on July 11. It was shown by Messrs. Veitch under the name of *L. Ukeyuri*, and by Messrs. Wallace, of Colchester, as *L. Alexandrae*. Some bulbs of this Lily were disposed of at one of the auction sales last spring, and were then spoken of as a hybrid between *L. longiflorum* and *L. auratum*, but Mr. Baker, of Kew, to whom the flowering examples were submitted, regarded it as a variety of *L. japonicum*, to which he applied the varietal name of *Alexandrae*. For my own part, however, I am inclined to accept the hybrid origin, as the different examples of this Lily that I have seen are about midway between its reputed parents, though some individuals show a greater leaning to one and some to the other. The Lily in question reaches a height of about 18 inches, the stem being stout, erect and clothed with rather pale green leaves, which are about 5 inches or 6 inches long and three-quarters of an inch or so in width, but they widen out just at the upper part of the stem. The flowers are shorter than those of *L. longiflorum*, and less shallow than in *L. auratum*, though, as indicated above, they vary somewhat. The colour is a clear white shaded at the base of the flower both inside and out with green. The fragrance resembles that of *L. longiflorum*. Though the height of most of the specimens seen was about 1½ feet, it is probable that with increased strength it will grow taller. This Lily is now I see offered for sale by most of our leading nurserymen, and it is more than probable that a good many will be sent here from Japan during the coming winter.

Lilies of recent introduction, though not exactly new, are a very interesting class, and some of them are doubtless come to stay. A very promising one is *L. Henryi*. This Lily, which was illustrated by a coloured plate in THE GARDEN, November 7, 1891, first flowered under glass at Kew in the autumn of 1889, and the following year some bulbs of it were there planted in the open ground. They have proved to be quite hardy, and continue to gain vigour each succeeding year, so that this season's display of bloom has been a very fine one. On one of the strongest I counted

no less than thirty flowers and unopened buds, which shows at least that the conditions under which it is growing at Kew suit it well. On March 22 of the present year some bulbs of this Lily were offered for sale by Messrs. Protheroe and Morris. The bulbs, which were firm and in good condition, were of a mahogany colour, and not much unlike those of two other eastern Lilies—*L. nepalense* and *L. sulphureum*. The bulbs of *L. Henryi*, though potted directly and kept in the greenhouse, were some time before they started into growth, and the first flower did not open till two or three weeks after the last bloom on the Kew plants was over. This Lily was shown in pots at the Royal Horticultural Society's show about the end of August, and a week later Mr. Ware showed quite a group at the Westminster Aquarium on the occasion of the Dahlia and early Chrysanthemum exhibition. It is I see for the present winter season quoted at from one and a half guineas to two guineas each.

L. sulphureum is another Lily of recent introduction and a very beautiful one, but is, I think, more adapted for culture under glass than in the open ground. It was first named by Mr. Baker *L. Wallichianum superbum*, but that gentleman afterwards reconsidered his decision and bestowed upon it the specific title of *sulphureum*. The large funnel-shaped flowers of this are of a beautiful rich cream tint in the interior on expansion, but become somewhat paler afterwards. Judging by some specimens of this Lily that we have here it should take rank with the latest blooming kinds, but this feature is of course influenced by the mode of culture. Thus, the first time it was exhibited by Messrs. Low, its introducers, was on June 25, 1889, then a couple of established specimens we have here were this year out of bloom by the end of August, but a dozen plants above referred to are as yet, October 9, only in the bud state, and will in all probability not open for another ten days or a fortnight. They are from a late importation, having been sold on April 21, so that the late blooming is thus accounted for. At this season, however, they will be even more useful than if they flowered during the month of August. *Lilium nepalense*, another of Messrs. Low's introductions and one of the most distinct Lilies of recent years, was shown by them at the Royal Horticultural Society's meeting on September 26 and again on October 10. This is a difficult Lily to cultivate, and one that is always likely to remain scarce. Freshly imported bulbs if of sufficient strength flower without difficulty, but, as far as my experience extends, there are not many of them that bloom the second year, and still fewer the third. It is such a beautiful and distinct Lily, that a little additional pains may well be taken with it. *L. Lowi*, which was shown once or twice last season, was this year awarded a first-class certificate on July 11. It is a very distinct Lily, but is not likely to turn out so good a garden plant as some of the others. It is rather a slender growing species with narrow leaves, while the blossoms are bell-shaped, with a somewhat spreading mouth. They are about 3 inches in diameter, and the colour is white with just a suspicion of green. The three inner segments, especially on the basal half, are densely spotted with crimson. This is a very scarce Lily, as the price at which it is quoted in Mr. Ware's catalogue (twelve guineas) will show. *L. Grayi* continues to gain in vigour, but it is certainly very nearly related to *L. canadense*. *L. Dalhousii*, a very pretty and extremely interesting hybrid between *L. dalmaticum* and *L. Hansonii*, was figured in THE GARDEN as recently as September 16, and accompanying the plant was a valuable article by Mr. Powell, of Southborough, Tunbridge Wells, the raiser not only of this Lily, but also of the justly popular *Crinum Powellii*. H. P.

Magnolia pumila.—This and *Magnolia fuscata* are two of the least showy of all the *Magnolias*, yet as a set off their blossoms are very fragrant—so much so indeed, that a single bloom is sufficient to make its presence noticeable throughout a good-sized structure. Small plants of both are producing a few blossoms at the present time, though *M. fuscata* rarely flowers at this

season. On the other hand, *M. pumila* often bears a bloom or two during the winter. It is quite a dwarf-growing species, reaching a height of 1 foot to 18 inches, but the ovate leaves are rather large, being as much as 6 inches in length, and of a dark glossy green on the upper surface and slightly glaucous beneath. The flowers are 2 inches or more in diameter, and of an ivory-white tinged with green. The flowers do not last more than a couple of days. This *Magnolia* is said to be a native of Java, but it will succeed well in a greenhouse temperature.—H. P.

ORCHARD AND FRUIT GARDEN.

CULTIVATION OF THE BANANA.

MANY grow a few *Musas* for the sub-tropical garden, but only a very few are grown for fruit-

those of *M. Cavendishi*, but the bunch large and somewhat like that of the last-named variety in shape. I have on several occasions tasted this variety, and the flavour is excellent. As regards its habit of growth, I am unable to speak, not having seen plants growing, but I should strongly advise its culture for its good flavour. I would also draw attention to the flavour of a home-grown Banana, which is rich, juicy and refreshing; whereas many of the imported fruits are mealy and dry, especially those cut before the fruit is full sized. I am well aware there are serious objections to the cultivation of *Musas*, owing to their large size and the time the fruits take to ripen, but this objection does not hold good when the plants are also used for conservatory decoration. When a house is devoted to their culture, much space and a certain amount of patience are required. Considerable cost as regards fuel

A fruiting plant of *Musa Cavendishi*.

ing. Having of late been questioned as to the value of these plants for fruiting, I would state that from a market point of view they are about the last fruits which would pay the cultivator. We must not, however, look at it from a monetary point of view, but as a means of providing a varied dessert for those who can afford the luxury. One of the best for fruiting is *M. Cavendishi*, though I have several others on trial. There are many varieties of *Musas*, and they differ much in size of fruit, leaf, and bunch. Some of the largest growers produce small fruits. I will not go at length into varieties, but I would name one that appears to be first class. This is of recent introduction, and is grown by Mr. Fitt at Panshanger Gardens, Herts. It is called the Ladies' Fingers, the pods being smaller than

has to be incurred, as to get the best results, heat is one of the chief factors. It is important to have a drip-proof roof and plenty of piping. I do not mean that Bananas cannot be grown in an ordinary house, but to get the best results heat is indispensable. When grown in a high temperature abundance of moisture must be given, and if there is a constant dripping on to the leaves, the moisture is conveyed down the midrib into the centre of the plant, causing decay and total loss of plants and fruits.

Few plants thrive under the dense foliage of the *Musa*. I have been asked the best form of house to grow these plants in. I would advise a span roof, growing a tall kind, such as *Paradisica* or *sapientum*, down the centre and

Cavendish at each side, with a walk round the two sides and end of house; if a lean-to, the height of house will determine the variety to plant, as *Paradisiaca* and *sapientum* grow 20 feet high, thus requiring a lot of head room, and Cavendish only 6 feet to 7 feet. A walk around the sides of the house allows of head room for the foliage, and a side staging in front of the lights is useful for such crops as Beans, Melons, and Cucumbers. Beds raised, say, 2 feet above the ground level are best, as this allows of better drainage and checks the roots. The latter is necessary to get early fruit and to rest the plants. When beds are above the ground level they should be built in sections, allowing a certain space to each plant. I would also prefer the hot-water pipes running between the beds and covered over, not directly under the roots. A space of 18 inches may be allowed between the beds for the hot-water pipes, and in addition to these, two flow and return pipes will be required along the front of the house. This will give ample heat for a large house and prevent driving the fires too hard, as it is false economy to spare the piping. We cannot give our plants a house as described above, as our structures are not modern. We have a front row of the dwarf sorts and a back row of taller kinds, devoting two large houses to the fruiting plants, growing several varieties for ornamental purposes in the conservatories. Musas may be fruited in twelve months if done well and large suckers planted. They like good stout loam and abundance of food. As soon as the fruit is formed we surface-dress with cow manure and mix Thomson's Vine manure in the compost. Fish manure is also excellent. Musas are equally useful for pot or tub culture if fed and well cared for. For conservatory decoration *M. Paradisiaca* and *M. sapientum* are noble plants if sufficient head-room can be given them, but there are none equal to Cavendish for fruiting in a short time. This last variety requires careful management in winter, as if full grown and the house too moist, the fruit decays in the stem and does not push up in the spring. It also requires to be closer to the light. I do not think the flavour of this variety can be compared to that of some, but it is one of the best for general use and a long way ahead of imported fruit. The temperature during growth is from 70° to 80°, the minimum at night and at this season when the plants are just kept moving, 60° to 70° during the day and 60° to 65° at night, keeping the plants as dry as possible, but not to check slight growth. Moisture in the house is essential, as thrips and red spider soon cripple the plants if a dry atmosphere is maintained. I prefer planting in the early spring, as often late-planted Musas are sickly growers and fail to fruit satisfactorily. Rapid growth is essential to success. Suckers of those kinds named are produced in abundance, and to get early fruit these must be removed as they appear, leaving one or two to produce plants as soon as the fruits begin to swell. If left too long they often prevent the fruit forming. After fruiting the old stem should be removed and the sucker detached, the border cleared out and filled with new soil, as the old soil will not be good enough for the young plants. Time is often saved by potting up suckers, as they appear to take the place of the fruiting plants as soon as the fruit is cut.

G. WYTHES.

The Fairy Crab.—The fruit of this is somewhat larger than that of other kinds. In shape and colour it resembles a Duchess of Gloucester Apple, being nearly as large, of a beautiful glowing red, and the flavour is very good. The trees this season were loaded with fruit. This is one of the

best varieties for bush culture, as it fruits so freely in a small state, and is also of neat growth. For shrubberies it is one of the very best; its only drawback is that birds soon pounce upon the fruits. The fruit remains on the tree a long time after it is ripe.—G. W.

PEACH BUDS DROPPING.

Two years ago I built a small Peach house, not heated, and planted in it three young trees and one some years older which I transplanted. All were planted in new soil from a pasture field without manure. The old tree gave a crop both last year and this. The other trees bloomed splendidly this spring, and appeared to be in perfect health, growing strongly and covered with leaves all the season. Some of the flowers at first appeared to set, but the fruits fell off one by one till only five remained. What can be the cause, and what remedy would you advise me to adopt?—JAMES SWEENEY.

** When Peach and Nectarine trees grow very vigorously, as in this case, the majority of the flower buds are either malformed or drop off prematurely. Unless root-lifting and pruning are resorted to, this in some respects very unsatisfactory state of affairs may go on for four years or longer, especially if the top-growth is at all restricted. Allowing the young growths to spread considerably, the best placed of the side shoots from these being also laid in for fruiting, is sometimes a sufficient outlet for the exuberance of the tree, but even this is of no avail when the roots have free access to a mass of good fresh soil. In the case now before me I should advise root-lifting and pruning being carried out at once, and if this does not actually make the trees much more productive next season, it will of a certainty have this desired result in the following year. The undermining and root-pruning ought not to be overdone, or to the extent of badly crippling the trees, but should be sufficiently thorough to admit of all deep running roots being reached and cut through by way of a preventive of injuriously deep root-action. A trench 15 inches wide and to the full depth of the made border should be opened about 4 feet from the stem of each tree, the soil being then gradually and carefully forked away from the roots to within 15 inches or rather less of the stem, this reserved ball of soil being further undermined till only a pedestal capable of supporting, with the assistance of the trees fastened to the wires overhead, the mass of soil and roots. All deep running roots, as before hinted, should be shortened and eventually brought nearer the surface, or if too stiff for that, be cut cleanly back. If it is found that the trees have sunk considerably since being planted, or to the extent of burying the collars 3 inches or more below the surface, take this opportunity of raising them to slightly above the level, thereby anticipating evils that would otherwise have to be contended with sooner or later. In any case go over all the roots found, cutting out all that are badly bruised and lightly shortening the rest, making an upward cut in all cases, cleanly-made wounds healing much more surely and quickly than do those that are jagged and broken. Seeing that the soil is comparatively fresh and good, this may well be used again, a fairly liberal addition of burn-bake and old mortar rubbish being made with very probable advantage. Relay the roots thinly and evenly in the soil, keeping them well up to the surface, as they will not be long before they strike downwards again. The soil should be made moderately firm by trampling, and should the old ball of soil and roots be at all dry, give it a good watering prior to finally levelling over the surface. The older tree that has done well should not be interfered with at present, but in the course of another year or two may be all the better for having its roots lifted, lightly pruned, and a little fresh loamy compost given.—W. I.

The weather in West Herts.—Another cold week. There was, however, one day of unseason-

able warmth—Friday, when the shade temperature rose to 56°. On the coldest night the exposed thermometer showed 8° of frost. Since the early part of the month the temperature of the ground at 2 feet deep has fallen 6°, and at 1 foot deep 8°. During the six days ending Sunday rather more than 1½ inches of rain and melted snow were measured. On Sunday morning the ground was covered with snow to the average depth of 2 inches, but before the evening of that day the greater part had been melted by rain. Throughout Saturday evening and night the wind continued very high, the average velocity for the twelve hours ending 5 a.m. on Sunday amounting to twenty miles an hour, direction N.W. At times the individual gusts reached the force of a gale. During the last nine days only about five hours of clear sunshine have been altogether recorded.—E. M., *Berkhamsted*.

ORCHIDS.

ANGRÆCUM CAUDATUM AND A. CHAILLUNUM.

I RECENTLY received a flower of *A. caudatum* from a friend in Scotland. I think it is the only time that I ever had a bloom of this species sent to me. I used to grow it some forty years ago. The same friend also sent me some months ago *A. Chaillunum* for a name, and I then promised I would make a few remarks upon this, and as the plants are both natives of Western Africa, I will refer to both. *A. caudatum* was introduced by the Messrs. Loddiges from Sierra Leone, in West Africa, in 1832, and for some years afterwards it was grown in many collections, but at the present time it is rather rare. I hope when the West Coast of Africa becomes more opened up this plant may again be introduced, and that it may become more generally grown. Bate, when attached to Dr. Barker's Niger expedition, sent home many species, but all small and inconspicuous kinds. Gustav Mann found the fine plant known as *A. Chaillunum* on the Nun River. The plants sent by M. Chaillu from the river Gaboon flowered first in the country, and were named in compliment to their finder. This proves that we have two very fine species from the West Coast of Africa, so that we may yet hope to find some others. Whether the species with coloured flowers which rumour records is to be found in this district exists or not remains to be seen. This last-named plant was called *A. arcuatum* by Lindley from Mann's dried specimens, but when the plant flowered in this country it was found to be abundantly distinct from the South African plant *A. arcuatum*.

A. CAUDATUM is a plant with an erect stem, having numerous distichous leaves, each about 9 inches long and about 1 inch broad. The spike is axillary and pendent, bearing from three to eight or more large flowers, having a spur measuring about 9 inches in length. The sepals and petals, which are spreading and nearly equal, are olive-green, and the large clawed lip is pure white, serrated at the edges.

A. CHAILLUNUM is a far prettier plant, having a similar habit of growth, the leaves being of a rich deep green. The spike is drooping, bearing many flowers of the purest white, having a spur to the lip, which is straight and about 6 inches in length.

These two fine plants, coming from one of the hottest parts of the world and one of the very dampest, require to be grown in the warmest house we have. They also like abundance of moisture in the air all the year round, although much less is necessary through the dull

months of winter than in the summer months. The pots or baskets in which they are grown should be well drained, for the plants like a good supply of water to their roots through the growing season; but care should be taken that none is allowed to lie about them in a stagnant condition. Sweet and clean Sphagnum Moss is all they require to be potted in, and it should not be allowed to get stale or rotten. These plants do not like full sunshine, so that if they are grown in hanging baskets with a good exposure to the light, a thin shading should always be in readiness to put over them during the hottest and brightest part of the day. During the winter season I have found them thrive well with the temperature never below 65°, but in the summer the glass may rise to any height, provided there is ample moisture in the atmosphere.

WM. HUGH GOWER.

Cattleya labiata.—Some very fine coloured flowers of this species come to hand from Mr. R. B. White, of Arddarrach, and he tells me that he has about 130 blooms now open. Among the Cattleyas sent is a light coloured variety, which is white saving the front lobe of the lip, which is rosy purple. This is the form known as *C. labiata Sanderae*. This, although rare, appears to be cropping up in sundry places, and I congratulate Mr. White in having one among his fine lot of Cattleyas.—W. H. G.

Angræcum eburneum.—"J. D." sends me a flower asking if it is not *A. superbum*. All the plants I have seen in cultivation under the name of *superbum* have proved to be *A. eburneum*, and I cannot see the slightest difference in your flower. The plant is a very bold grower—in fact quite a giant among Orchids. *A. eburneum virens*, which I used to grow, but have not now seen for a long time, is nearly as large in its growth; the foliage is of a deep green, but the flowers are, however, much smaller, and the ivory-white lip is tinted with pale green.—W. H. G.

Orchid flowers from Cheltenham.—Mr. Cypher, of the Queen's Road Nursery, sends me some choice flowers. First is a fine bloom of *Cattleya aurea*, the sepals and petals of which are of a pleasing shade of lemon, the lip marked in front with deep crimson-magenta, the side lobes heavily streaked with the same rich colour upon a yellow ground. A flower of the splendid form of *Cypripedium insigne* called *punctatum violaceum*, with its massive dorsal sepal broadly bordered with pearly white, and which was figured in THE GARDEN, XXI., t. 444; a distinct form of *C. insigne*, very prettily marked, but far inferior in beauty to the one already named; a twin-flowered peduncle of *C. Spicerianum*; a magnificent form of that fine old hybrid *C. Arthurianum*, large, and well coloured, and also a very good form of *C. polystigmaticum*, a cross between *C. venustum* and *C. Spicerianum*, and which has the dorsal sepal quite like the last named, the petals broad, tipped with purple with numerous dotted lines of black, and the lip as in *C. venustum*, were also included. Nice forms of *C. Sedeni candidulum*, *C. cardinale*, and flowers of *Dendrobium album*, the finest that I have seen, were also sent.—W. H. G.

Calanthe Veitchi.—This hybrid, raised by the Messrs. Veitch close upon forty years ago, is one of the very best winter-blooming Orchids we have at the present time. A fine spike of this in full beauty is now to hand from "T. H." The spike bears thirty-eight flowers; some of the upper ones are buds only yet and not open, whilst some of the lower ones have dropped off. The flowers are of a rich rosy carmine with a pure white eye. These plants are usually deciduous, but sometimes some of the leaves do remain until after the flowers are past; this, however, does not add by any means to the beauty of the plants. It is by far the best plan to dry the bulbs before flowering sufficiently to cause all the leaves to fall away, and if they have not all fallen they should be cut away. The plants like a short rest after flowering, and may be stored away upon a shelf in

a cooler house. As soon as potted, water must be applied cautiously for some little time. Some people give them liquid manure once or twice a week for the last half of the growing season, but I do not like this, and if it is practised for several years the bulbs will be weakened, and in the end probably die.—W. H.

ORCHIDS AT EAST SHEEN.

ONE of the finest collections of Orchids in the west of London is at Clare Lawn, East Sheen, the residence of Mr. Wigan. The plants comprise many rare species and varieties. When there a few days ago we made note of several interesting things in flower, but, as in other places near the metropolis, fogs are injurious, especially to the *Phalænopsis*, which are quickly spoilt.

In various houses *Cypripedium* were blooming freely, and a fine mass of *C. insigne* in variety was brightening a grotto-like ferry, quite cool, the large specimens arranged with Ferns and other fine-foliaged plants. *C. insigne* varies greatly and pleasingly in colour, some of the better forms we noticed being *albo-marginatum*, *Chantini*, *Maulei*, and *punctatum violaceum*, but really the difference between many of them is one of degree only. *Cymbidium Lowianum* and *C. giganteum* were also showing many sturdy spikes. They are in the same cool structure, heated just sufficiently, we should say, to keep out frost, but under such conditions they thrive to perfection. The most interesting Orchid in beauty now is *Barkeria Lindleyana*, a lovely thing, which many seem to find difficult to grow well. A small space between two houses is allotted a group of specimens, providing a warm moist corner. The plants are in small pans, suspended not far from the glass, and are a mass of roots, tall slender spikes being produced in profusion. It is one of the most elegant of Orchids, and the flowers are varied and rich in colour, but usually of a warm rose-purple, deepening in the lip. This position is very warm, and all through the last hot summer, with the exception of a very light shading, no protection whatever from the sun's rays has been afforded. The result is examples furnished with an abundance of the long white roots, and we may say to those who have found some difficulty in growing it that plenty of water is given during the growing season, but from now to March only sufficient to keep the bulbs from shrivelling. That troublesome genus to grow well, the *Phalænopsis*, is in excellent condition, and one house is practically devoted to it. *Phalænopsis amabilis*, *P. Schilleriana*, represented by many fine plants pushing up sturdy spikes, *P. Stuartiana*, *P. Aphrodite* var. *casta*, *P. A. leucorrhoda*, and *P. speciosa Imperatrix*, besides many others, were of note. Of the last mentioned, one of the best plants in the country, is here, and when at Clare Lawn last year it was in full bloom. We remember that at a meeting of the Royal Horticultural Society on May 21, 1891, Mr. Young showed it, the plant bearing a spike of eight flowers. *P. casta* is an interesting supposed hybrid between *P. Aphrodite* and *P. Schilleriana*. As regards leafage, one sees a resemblance to *Aphrodite*, whilst the flowers are white, crimson dots appearing at the base of the lip, set off with a suffusion of yellow.

In this house is blooming one of the most charming of all *Cypripedium*s, whether hybrid or otherwise. This is *C. Niobe*, of which a coloured plate was given in THE GARDEN, May 23, 1891. It is no exaggeration to say that this is the most beautiful hybrid *Lady's Slipper* that has appeared, having first flowered in the year 1889, when it was exhibited and at once given a first-class certificate at the Royal Horticultural Society's meeting. A very good form of *C. Harrisianum*,—and there are few finer kinds,—also *C. Haynaldianum*, a species from the Philippine Islands, and very attractive when represented by a good variety, as here, were in flower. A batch of *C. barbatum*, a very useful species, was planted out and succeeding remarkably well. We noticed the beauty of splendid masses of *C. Lawrenceanum*. Even when out of bloom this is very beautiful for the fine and distinct variegation of the foliage.

The *Cattleya* and *Lælia* house is a large structure and crowded with good species and varieties. *L. anceps* was in bloom, and in a large collection one gets fine shades of colour, the flowers of one form being remarkably rich, especially the lip—intense crimson-purple, with rose-purple sepals and petals. *L. autumnalis* was of note, and its beautiful variety *alba* pushing up spikes. Amongst *Cattleyas*, *C. Warocqueana* was noteworthy, and very bright in this house were masses of *Pleione Wallichiana*, a lovely species at this time of year and grown here very successfully, the plants, it may be useful to mention, being potted every year. This *Pleione* should be grown largely, and nothing is brighter in the Orchid house at this season and the flowers do not lose much by the absence of leaves, as they smother the pan. They are individually of good size, useful to cut for a button-hole or decoration and rose in colour. It is strange that the *Pleiones* are not made more of in gardens, being free, showy and not difficult to grow. *Sophranitis grandiflora* was bright, the flowers varying from intense scarlet to paler shades.

In another house the fine old *Phaius grandifolius* is sending up several of its strong spikes. It is a splendid evergreen species and is in beauty in the winter and spring. It is one of the few Orchids that do not suffer greatly when used for decoration, and the bold brown and white flowers last long in beauty. Hard by *Cypripedium Spicerianum* was flowering freely, and in spite of many new hybrids and species, this vigorous and free-blooming kind remains one of the most useful. A very interesting Orchid is *Arundinæ bambusæfolia*, a native of India and Burmah and a *Sobralia*-like plant of much interest. The flowers are pleasing in colour, the sepals and petals soft rose-pink and the lip rich purple, whilst the habit of growth is exceedingly graceful. It is worth growing almost for this alone.

Much interest is taken in the *Masdevallias*, of which there is a very good collection, *Restrepias*, *Cirrhopetalums*, and similar genera. If not so useful as *Cattleyas* and such like, they are quaint and in many cases beautiful. Amongst the *Masdevallias* most conspicuous was *M. tovarensis*, a remarkably useful Orchid, the plants when in full bloom being of great use in choice decorations, and the flowers individually pleasing when cut. It should be grown by all amateurs, and is not difficult to manage. *M. bella* and *M. rosea* were flowering freely. An interesting Orchid is *Restrepia antennifera*, an elegant species none too often seen. The flowers are curious in form and beautifully coloured. Amongst *Cælogynes*, splendid masses of *C. cristata* in variety promise well, and a pleasing species in bloom is *C. barbata*, the flowers very attractive in colour, sepals and petals white, the lip rich brown. Lycastes of many kinds will soon be in beauty, *L. Skinneri* and its variety *alba* showing sturdy spikes, and *L. plana* is in bloom. Its flowers are quiet in colour, but pleasing.

A very pretty and sweetly-scented *Oncidium* in bloom was *O. cheiroporum*. It is very free, and the small yellow flowers make a bright show, lasting a considerable time in perfection. Later on *Dendrobiums* will be a feature of interest, *D. Wardianum* in particular. C.

SHORT NOTES.—ORCHIDS.

Oncidium cucullatum (W. W.).—The flowers you send are all varieties of this species. Many people confound this and *O. Phalænopsis*. No. 3 is a very fine variety, the lip of a rich deep plum colour. It is quite an alpine plant.—W. H. G.

Cælogyne cristata.—"Anon" says that "nearly every year some of the flower-spikes damp off." I suppose this is brought about through too great an amount of moisture in the air. Try them in a house with less moisture, but do not subject them to a dry atmosphere or the spikes may shrivel up.—W. G.

Lælia Dormaniana (H. W.).—This is about the first time I have ever seen any difference in the colour of the flowers of this. In the flowers sent the front lobe of the lip is of a rich rose colour instead of the usual purplish crimson, which gives it a quite

different appearance. It is worth preserving, and you should mark it to see if it comes of the same colour next season.—W.

Sophrontis grandiflora.—I have a fine lot of varieties of this flower sent me with no sender's name. They are exceedingly bright and of good size, but they are not so large as those of the variety that I saw upon several occasions in the late Mr. Southgate's collection when it was under the charge of Mr. Salter. They have the same round appearance, only varying in colour.—H. G.

Miltonia vexillaria rubella (G. T. S.).—This appears to be the variety you send. I do not remember having seen it bloom so late, nor do I recollect seeing such a small flower. I should think it was from a very small plant and one that had been starved. It is about the brightest coloured form that has come under my notice, being of a deep rich rose colour.—G.

Masdevallia macrura.—John Edden asks if "he should put this plant into warmer quarters for the winter months." To this I should answer no. You may move it to the warm end of the Odontoglossum house, but warmer than this I should not keep it. This plant grows at 6000 feet and 7000 feet elevation in the same country as the Odontoglossums and succeeds well under the same treatment.—W. G.

Maxillaria venusta (J. Hill).—This appears to be your plant. It may be distinguished from *M. grandiflora*, with which you have confounded it, by having always a nodding flower instead of an erect one; the segments are also more pointed. This is a plant that succeeds well grown in the cold house with the Odontoglossums, and I have had it bloom twice a year in such a place. It likes plenty of shade.—W.

Spathoglottis (C. Hearn).—These plants now should have lost their leaves and be dormant. During this time the soil should be kept nearly dry and the plants be removed to quite a cool house and the soil kept in a nice friable condition, which will have the effect of resting the corus better than keeping them dry and in the heat of the East Indian house, into which they may be moved when they again start into growth.—W. H. G.

Dendrobium nobile (J. S.).—Your flowers represent ordinary varieties of this old species, and I should have thought they had been produced by newly-imported plants if you had not told me otherwise. You say these four or five plants have for several years produced their flowers at this season. The flowers now will be a great acquisition, making a nice variety whether for cutting or for general purposes of decoration. I should value the plants much and try to work up a stock of them.—W. H. G.

SOCIETIES AND EXHIBITIONS.

NATIONAL CHRYSANTHEMUM SOCIETY.

A LARGELY attended and very interesting meeting of the floral committee of this society was held at the Royal Aquarium on Wednesday last, Mr. G. Gordon occupying the chair. The November floral meetings are usually busy ones, but this year the number and character of the exhibits have been beyond all precedent, and it is a question whether the committee should not meet weekly in the height of the season instead of fortnightly, as hitherto. Mr. Robert Owen, of Maidenhead, was awarded the society's silver medal for a collection of new varieties, which contained some very meritorious flowers of his own raising, besides some high-class American novelties. M. Ernest Calvat, of Grenoble, staged twenty-four of his new seedling varieties of the present year, and a remarkably fine lot they were. He certainly seems determined to maintain the high position amongst Chrysanthemum raisers which he has already attained, and the committee thought so highly of his exhibit, as to award him a silver medal for the collection. M. Calvat may be congratulated on being the recipient of an award which no other French exhibitor at this society has yet succeeded in gaining, and which is a far more difficult one to obtain than in his own country, where medals are usually distributed in the same way as money prizes are in this country.

Messrs. Cannell and Sons, of Swanley, sent some fine examples of cultural skill, but many of the

flowers were already known to the committee; a bronze medal was therefore deemed a suitable recompense in their case. Before referring to the certificates and commendations granted, it is needful to point out to intending exhibitors that a certain standard of excellence must be arrived at before any new varieties are sent to the committee for certificates. A variety must not only be new, but must be staged in presentable form; otherwise it is sure to be passed over, and the time of the committee, which can ill be spared, is wasted. Several remarks were made on this subject by men whose time is valuable in the middle of the day.

The following were awarded first-class certificates:—

WILLIAM TUNNINGTON.—A very large, perfectly formed incurved variety of the true type; the florets are very regularly disposed and are of a deep golden bronze, with crimson interior. Shown by Mr. R. Owen.

MRS. T. DENNE.—A strikingly effective large Japanese incurved bloom, with very long rosy purple florets; the reverse is very little lighter in colour than the inside of the florets. This, too, was shown by Mr. R. Owen.

PRINCE DU BOIS.—A big yellow Japanese. It has narrow curly florets, the bloom is heavily built and of very globular form. Also from Mr. R. Owen.

GOLDEN GATE.—This is a Japanese of American origin. It is a large spreading flower of a deep rich bronze-yellow, with very long florets. Shown by Mr. R. Owen.

CECIL RAY.—An English-raised flower of the Japanese type; long, flat florets of good width, colour a clear rich yellow. Mr. E. Beckett was the exhibitor of this.

MME. CARNOT.—One of the largest Japanese in existence, a very full flower of the purest white with fine curly florets slightly grooved. Raised by M. Ernest Calvat, who also exhibited it.

PROFESSOR LACKMAN.—Another French seedling of the Japanese section. The petals incurve rather boldly and are of good breadth, the colour inside being purple-amaranth with a rosy reverse. M. Calvat was the exhibitor.

Several good blooms were commended, and chief among them were Deuil de Jules Ferry, a Japanese of a beautiful tone of rosy amaranth, with large incurved florets, and President Leon Say, a large Japanese of chestnut-bronze with a golden reverse, both of which also came from M. Calvat. Niveum, an American white Japanese, C. L. Jamieson, a bright crimson one, both from Mr. Owen, also received commendations. M. P. Martignac, a pretty yellow incurved, staged by Mr. E. Beckett, was treated in the same way. There were some other good flowers worthy of mention, such as Richard Dean, a large Japanese, crimson and gold; Celtic, an Anemone of very fine shape, a self-coloured chocolate-rose which the committee desired to see again. Colonel J. C. Bourne, a deep rosy wine-coloured Japanese with fine spreading florets, was well received, as was Mr. E. Whittle, a large, pale blush flower of the same type.

An ingenious tube for staging three exhibition pompons was shown by Mr. Rowbottom, and highly commended. The meeting was held in the organ gallery, and, as is only too often unfortunately the case, the light was so bad during the latter part of the meeting, that it was a most difficult matter to distinguish the colours.

— On Monday evening last the general committee of this society met at Anderson's Hotel. Mr. R. Ballantine, who occupied the chair, announced that the recent show had proved to be an unqualified success in every respect, and that the quality of the blooms staged and the attendance of the public during the three days were all that could be desired. The arbitration committee having awarded to certain exhibitors at that show silver-gilt, silver, and bronze medals, the same were confirmed. Mr. R. Dean, the secretary, reported on the financial position, by which it appears that income to the extent of £525 has been received to date, the principal items being members' subscriptions, donations, and affiliated societies' fees. During the ensuing year it is proposed to hold four shows corresponding with those held in 1893.

Some remarks were made concerning a new home for the society, but the chairman pointed out that the Aquarium Company, besides providing £275 towards the prize list this year, also supplied all the tables, the bills and bill posting, and advertised the shows in the daily press, and he thought it was not possible to obtain better terms anywhere else, and he did not know of any building in London more suitable for the purpose. Mr. Cannell referred to a show held over thirty years ago in the Agricultural Hall, and deprecated any attempt to imitate that. The Guildhall was suggested, but as the civic authorities would allow no gate money to be taken, that place was consequently out of the question. The matter, therefore, fell through. New members and Fellows were elected, making a large addition to the roll for the year. In the unavoidable absence of Mr. C. E. Shea from ill-health, it was resolved that the paper which he was to have read should stand over until he could attend. The paper, which was stated to be a remarkably interesting one on "Judging," could not be fairly discussed in the absence of the writer, and therefore was deferred so as to give Mr. Shea an opportunity of replying to any criticism that might arise. A vote of sympathy was accorded to Mr. Shea on account of his indisposition. Several suggestions having reference to alterations in the new schedule were read from members and exhibitors, all of which were referred to the schedule sub-committee to deal with later on.

Royal Horticultural Society.—The next fruit and floral meeting of the society will take place in the Drill Hall, James Street, Victoria Street, Westminster, on Tuesday, November 28, when special prizes will be offered for groups of Chrysanthemums naturally grown. At 3 o'clock Mr. T. Crasp, F.R.H.S., will deliver a lecture on "Late-keeping Grapes."

NOTES OF THE WEEK.

Carnation Duke of York.—Mr. May, Edmonton, sends us some blooms of this rich, boldly-formed Carnation, which is certainly a very fine variety. He also sends us other kinds, but the Duke of York is by far the best, although the flowers are not so double as those of some of the others.

Single Chrysanthemums out of doors.—It is worth recording that even now (November 22) several plants of the following single varieties are very fine at Kew in the open: Le Mout, rose-purple, yellow centre; Gus Harris, rose-lilac, a very free kind; and Miss Rose, rose; also the pompon Golden St. Thais, which makes a bright mass of colour.

Zygopetalum Gautieri is one of the most interesting species in bloom at Kew. It is an exquisite flower, not often seen, but worth a place in the choicest collections. The flowers are rich in colour, the sepals and petals green, barred with deep chocolate-brown, and the lip pale blue in front, but of an intense violet-blue at the base. *Z. Gautieri* is more elegant than the other species, and is a native of Brazil.

Statice puberula.—This fine *Statice* is in bloom in the temperate house at Kew, and it is worth growing more in private gardens. It was introduced in 1830, and is a useful plant for a cool house. The leaves are bold, of a glaucous shade of colour, and have quite a satiny sheen, whilst the rich violet-blue flowers are crowded together on the sturdy stems. It remains in bloom over a long season, and is welcome at this time of year.

Reinwardtia tetragyna.—This is a very bright, showy plant during the dull months of the year. It wants a warm greenhouse or stove, and should be more seen in private gardens, succeeding well in a lower temperature than is required by *Reinwardtia trigyna*, known also as *Linum trigynum*. The flowers of *R. tetragyna* are of a yellow or pale orange shade, and the plant is

of neat growth. Both are well worth growing in gardens, and may be readily propagated by cuttings in the spring months. If grown on freely in the summer, a bright show of bloom will be the result in winter.

Notes from Baden-Baden.—*Morina Coulteriana*, not Coulteri, has narrower leaves than *longifolia* and the flowers are yellow. *M. Wallichiana* is distinct from *longifolia* by its considerably longer flower-tubes and more spiny leaves. *Aster alpinus speciosus* is a native of Russian Central Asia and has been named by Dr. von Regel. It is not botanically distinct from *Aster alpinus*, but it has much larger flowers. Seedlings vary a little, but as yet I have not been able to produce a marked variety.—MAX LEICHTLIN, *Baden-Baden*.

Destruction of ornamental timber in Scotland.—The parks of noblemen's seats in Scotland have suffered greatly from the recent storm. A two-mile avenue at Drummond Castle, which belongs to the Earl of Ancaster, has been virtually destroyed, Oaks and Beeches, centuries old, being either broken or uprooted. At Dunrobin Castle, Kennet House, Banff House, Alloa Park, and Langholm Lodge the parks have been wrecked. Throughout Scotland plantations have suffered greatly.

Two good Chrysanthemums for the greenhouse are *La Nympe* and *Mrs. James Carter*. The former belongs to the Japanese class, and we recently saw two fine specimens bearing a splendid lot of flowers of very distinct expression, the florets narrower than is usually the case, and delicate rose and white in colour. The other is not much to look at, but the flowers are very useful for cutting. They remind one of a *Centaurea*, the narrow thread-like florets pale yellow in colour. They are very pretty by gaslight arranged with Fern or similar foliage.

Ipomœa ternata is a stove climber one does not often see in gardens. A specimen in the stove at Kew is now very attractive. The flowers, unfortunately, last only about a day in beauty, and are at their best early in the morning, but a succession is produced, so that a continuous display is maintained. They are quite waxy in texture, very pure, and like a beautiful white *Convolvulus*, whilst the plant is of robust, free growth, the leaves leathery and deep green. We should like to see such a climber in other than botanic gardens, and there is certainly need of a little variety in most places.

Saxifraga Mertensiana.—J. Wood, Kirkstall, in his notes of November 11, p. 436, appears to be very unfortunate with the lovely *Saxifraga Mertensiana*, which has flowered annually in the frames at Kew since 1886. He has changed it about, but gives no indication of the treatment he has adopted. Let Mr. Wood try a moist, shady spot, and I have no doubt he will succeed. It has always done well at Kew, and was greatly admired in the alpine house on account of its pretty, though small flowers, and the abundance of bulbils formed in the axils of the branches. It is a native of America.—D. DEWAR, *Bot. Gardens, Glasgow*.

Orchids at Kew.—The Orchid house at Kew is of much interest just now, many rare species and varieties being in bloom. *Cypripediums* are a feature, especially a mass of the old but still useful *C. insigne* and its forms. *C. Spicerianum*, unlike the majority of the genus, is not proof against fogs, the flowers being much injured, whilst those of *C. Meirax*, *C. Sedeni*, and *C. venustum* are untouched. Quite a number of *Oncidium*s are in beauty, including *O. ornithorrhynchum*, a delightful sweet-scented free-blooming species, the yellow-flowered *O. cheiroporum*, *O. Jonesianum*, *O. varicosum*, *O. tigrinum*, *O. Forbesi*, and *O. Gravesianum*. One of the most beautiful of the *Lælias* is *L. furfuracea*, recently described in THE GARDEN, one variety in particular having very deep-coloured flowers. Angreemns are numerous, comprising *A. O'Brienianum*, producing a pendent raceme of white long-spurred flowers, reminding one of *A. Sanderianum*, the greenish-flowered *A. Hildebrandti* and *A. pellucidum*. A wealth of colour is produced by the fine plants of *Calanthe Veitchi* and *C. vestita rubra oculata*, also *Cattleya labiata*, *C. Bowringiana*, and *Odonto-*

glossum grande. Note may also be made of the beautiful *Cyperorchis Mastersi*, *Platyclinis Cobbiana*, producing graceful pendent racemes of yellowish-white flowers, *Epidendrum æmulum*, and *Scuticaria Steeli*.

Morina Coulteriana.—In reply to Mr. Wood, this species, as Mr. Wood indicates, is distinct from *M. longifolia* even in the leaves, which are always longer, narrower, and with longer spines. The flowers are yellow instead of being deep rose-coloured, as in *M. longifolia*. The bracts are narrower, and the calyx is mucronate instead of being obtuse, as in the other species. It is not such a handsome plant as *M. longifolia*, but it is very distinct, and well worth growing in addition to that species. It was first cultivated by Mr. Anderson-Henry, who flowered it in 1880. It was also raised at Kew from seeds sent home by Dr. Aitchison from Afghanistan, and flowered on the rockery there in August, 1883. Another species of nearly equal importance is *M. betonicoides*, which was raised from seeds sent from the Calcutta Botanic Gardens. Both these species flowered annually at Kew, *M. Coulteriana* in the herbaceous grounds and *M. betonicoides* in a peat bed in the rock garden.—D. DEWAR, *Bot. Gardens, Glasgow*.

FUEL AND BOILERS.

THE relative merits of anthracite coal and coke have been so often discussed in THE GARDEN, that it seems almost superfluous to again refer to the matter were it not that the present condition of the market renders anything pertaining to the consumption of fuel a very pertinent and opportune question. It may be clearly stated at the outset in reply to "G. H. B." (p. 450) that, weight for weight, at a fairly level price anthracite coal is decidedly the cheaper fuel, given suitable boilers and a careful and economical stoker. Also it may be added that the coal, if possible, should be purchased in cobbles form; if received in very large lumps the loss of time spent in breaking it up adds materially to the cost. On the other hand, while recognising from a stoking standpoint the superiority of the coal both in cleanliness and in amount of labour required, if good coke (and there is considerable difference in the quality) can be purchased at a much lower figure per ton, there is certainly nothing to be gained economically by the substitution of coal. In ordinary seasons, for instance, if coke can be delivered from the nearest gas-works at say 17s. per ton, and the anthracite, including cost of transit from station, will be nearly 24s., the difference of 7s. would be more than the superior heating and lasting properties of the coal would cover. I should be prepared to give 3s. per ton more for anthracite; beyond that, to say 5s., there would be little to choose between them in the matter of economy, whilst a wider margin would be decidedly in favour of coke. The qualifying statement in connection with anthracite is made above—"given suitable boilers and an economical stoker," and these are very important factors. It cannot be too strongly impressed upon the stoker that a much less body of fire of anthracite is required to keep up a given heat, also that it must be left to do its work without poking or raking, to replenish at rare intervals being about the only operation necessary. Again, arising indirectly from one of the points under consideration, "that in the case of the anthracite a smaller body of fire will do an equal amount of work," it is obvious, reasoning from this, that a smaller boiler will be desirable; or, to put it more plainly, that whereas with coke as the sole heating power for, say, 1500 feet of 4-inch pipe, a 60-inch plain saddle would be as useful as a 48-inch Chatsworth or Cornish boiler, with anthracite the smaller-sized boiler would be decidedly preferable. Another matter worth careful consideration in any large scheme of heating apparatus is the desirability of working all or nearly all from a given centre. I know this is generally deemed advisable, but it does not always lead to satisfactory results, especially if there is a considerable amount of space between the different structures and the pipes employed in the connections cannot be utilised for any practical purpose.

Here we have a considerable amount of piping serving no useful end, a large amount of heat in an underground trench, much longer time is requisite to get the warmth into the respective houses, and it is no new experience to find that the sockets in such places have not been properly packed. If a socket happens to go wrong, the chances are that it is in the underground trench. Great improvements have been made in boilers of late years, but yet some few of a bygone generation that remain testify to the fact that they were well and truly made. We have one of Sylvester's cog boilers heating 600 feet of 3-inch pipes in a *Camellia* house that was put in its present place over forty years ago and is still doing its work remarkably well, everything pertaining to boiler and pipes being to all appearance as firm and sound as it was when the work was finished. It is a decidedly economical boiler, requiring for its size but a small amount of fuel. In this case small cobbles anthracite is a great boon, it being fed from the bottom, and in the original setting not much space was allowed between the lower rim of the boiler and the furnace bars. E. BURRELL.

Claremont.

Death of Mr. John Waterer.—Just as we are going to press we learn with regret of the death, at the age of 67, of Mr. John Waterer, which took place at Bagshot on the 21st inst.

Orchid Grower's Manual.—Messrs. B. S. Williams and Son, Holloway, inform us that they have now in the press a new and much enlarged edition of this work, containing many additional illustrations. It will be issued early in the new year.

BOOKS RECEIVED.

"Chapters in Modern Botany," by Patrick Geddes, Professor of Botany, University College, Dundee. London: John Murray.

"Bulbs and Tuberous-rooted Plants: their history, description, propagation, &c." Illustrated. By C. L. Allen. London: Kegan Paul, Trench, Trübner and Co., Limited.

Names of plants.—*J. Henley*.—1, *Lepicystis squamata*; 2, *Adiantum Wilesianum*; 3, *Asplenium præmorsum*; 4, *Doryopteris palmata*.—*W. Diddam*.—1, *Doodia caudata*; 2, *Blechnum occidentale*; 3, *Doodia aspera*; 4, send again when fertile; 5, *Doodia media*; the others next week.—*G. Oldham*.—1, *Lycaste Skinneri*, light form; 2, *Sophrontis violacea*; 3, *Pilumna fragrans*.—*J. M. B.*—1, *Phymatodes vulgaris*; 2, *Phymatodes pustulata*; 3, *Asplenium canariense*; 4, *Blechnum lævigatum*; 5, *Doodia lunulata*.—*Eustace F. Clarke*.—1, send in flower; 2, *Enothera odorata*.—*J. T. C. I.*—*Bucklandia populnea*.—*R. Macleod*.—Impossible to name from one leaf only.

Names of fruit.—*J. C. Tallack*.—1, *Colmar d'Areberg*; 2, *Aromatic Russet*; 3, *Court Pendu Plat*; 4, *Baldwin* (?); 5, *Rosemary Russet*; 6, *Flower of Kent*.—*T. A. Selway*.—1, *Pear rotten*; 2, *Bergamote d'Esperen*; 3, *Beurré Rance*; 4, *Easter Beurré*; 5, *Beurré Rance*; 6, *Apple Beauty of Kent*.

"The Garden" Monthly Parts.—This journal is published in neatly bound Monthly Parts. In this form the coloured plates are best preserved, and it is most suitable for reference previous to the issue of the half-yearly volumes. Price 1s. 6d.; post free, 1s. 9d. Complete set of volumes of THE GARDEN from its commencement to end of 1892, forty-two vols., price, cloth, £30 12s.

"Gardening Illustrated" Monthly Parts.—This journal is published in neatly bound Monthly Parts, in which form it is most suitable for reference previous to the issue of the yearly volumes. Price 5d.; post free, 8d.

"Farm and Home" Monthly Parts.—This journal is published in neatly bound Monthly Parts, in which form it is most suitable for reference previous to the issue of the yearly volumes. Price 5d.; post free, 8d.

"Hardy Flowers."—Giving descriptions of upwards of thirteen hundred of the most ornamental species, with directions for their arrangement, culture, &c. Fifth and Popular Edition, 1s.; post free, 1s. 3d.

"The Garden Annual" for 1893.—Contains Alphabetical Lists of all Branches of the Horticultural Trade. The Lists of Gardens and Country Seats (containing over 9000) have been very carefully and extensively revised, and are admitted to be the most complete ever published. Price 1s.; by post, 1s. 3d.

All of our readers who are interested in the improvement of cottage homes are invited to help us to make **Cottage Gardening** known. It is published at the very lowest price to meet the wants of those for whom it is intended, and copies will be sent for distribution, free, by the publishers, Messrs. Cassell and Company, La Belle Sauvage, Ludgate Hill, E.C.

No. 1150. SATURDAY, December 2, 1893. Vol. XLIV.

"This is an Art
Which does mend Nature: change it rather; but
THE ART ITSELF IS NATURE."—*Shakespeare.*

ORCHARD AND FRUIT GARDEN.

GRAPES KEEPING BADLY.

From various quarters the report comes that Grapes are keeping very badly indeed, and there is every likelihood of their being comparatively scarce by mid-winter, at any rate as far as many private and some few market growers are concerned. Towards the end of October so many Grapes were rushed into the markets, that fruiterers in provincial towns lost a lot, and had to wire to senders to hold back their supplies. Unfortunately, holding back the Grapes meant a heavy loss to the growers, in many cases decay being very rapid after once it sets in. Owing to the great heat of the past summer, Grapes, in common with all other fruits, ripened earlier and more rapidly than often happens, but this in the case of late Grapes would presumably have been in favour of long keeping rather than otherwise. The advice to have late Grapes well coloured and ripened in September is frequently given, and is sound enough. Unless they are ripened largely by the aid of sunshine, assisted by artificial heat during the nights generally, and in the daytime when there is little or no sunshine registered, late black Grapes may colour well, and yet be mere bags of sugar and water. In some cases the water may be plentiful enough and the sugar be conspicuous by its absence, too, little heat being responsible for the want of solidity and richness of flavour. Imperfectly ripened Grapes are very difficult to keep for any length of time, but I cannot believe that the other extreme or over-ripeness is the cause of the early decay of many Grapes this season. It is far more likely that economising fuel has been responsible for numerous failures, and very doubtful economy it has proved accordingly.

During October, and again once or twice in November, we had very changeable weather, but it was during the very warm muggy weather when the mischief was done among hanging Grapes in variety. Everything seemed to be dripping with water, and in vineries where the hot-water pipes were not well heated, and both front and top ventilators opened a few inches, the berries became heavily dewed over for hours together. If the house could have been closely shut, being also well glazed and also heavily shaded, then the atmosphere might have remained fairly dry and no harm been done. Or, again, if the bunches had been cut and placed in bottles of water suspended in a cool, closely-shut dark room, they would have escaped the moisture and kept better accordingly. I tried the experiment of keeping a house with a few bunches hanging in it shut close, but a short partial burst of sunshine so quickly raised the temperature of the house, that moisture collected badly on the berries before air could be given. Unless the berries can be kept dry they will not keep long. If drip reaches them, or they are allowed to remain dewed over for an hour or two, the bloom is destroyed, the skins are softened, and wholesale decay is the sure consequence. Once the skins have been softened, and they are very susceptible of injury, no amount of fire-heat will long stave off decay.

Cracking of berries also took place in some cases, Gros Colman, Alicante, and Lady Downe's all behaving badly in this respect. Too little air, not necessarily quite dry, was the cause of this. Some that I had nearly opposite end ventilators that were kept constantly open did not crack in the least, yet no fire-heat was turned on. It would also appear that the bunches on Vines partially or wholly rooting in outside borders behaved the worst, this being attributed to the heavy rainfall following upon a long spell of very dry weather, but may have been prevented by a freer use of fire-heat. My contention is that the pipes in a house of Grapes should be kept moderately hot during the night-time, or sufficiently so to keep up a good circulation of air, this entering the front ventilators and passing out at the top of the house, the ventilators being set open about 6 inches in each instance. If the atmosphere is dry in the daytime, little or no fire-heat is needed, but it must be turned on freely if at all damp, while during cold frosty nights a good heat should be kept up in the pipes, not, however, because low night temperatures are actually injurious to ripe Grapes, but rather with a view to preventing the berries and house generally from becoming very cold. This may at first sight seem a little contradictory, and I will endeavour, therefore, to make my meaning clearer. When the berries, leaves, and walls become very cold during the night, or, as not unfrequently happens during a spell of very wintry weather, a sudden change to muggy weather often takes place, and moisture condenses on everything cold accordingly, nothing short of hard firing with front and top ventilators open will prevent this in most cases, and prevention would have been safer and better in every way.

When the bunches are cut and placed in bottles of water suspended in properly constructed Grape rooms, it is a comparatively easy matter to keep them perfectly dry and never much above or much below 45°, and no great difficulty is experienced in keeping such varieties as Alicante, Lady Downe's, Mrs. Pince's Muscat, Gros Colman, Mrs. Pearson, Golden Queen, Muscat of Alexandria, Gros Guillaume and West's St. Peter's. The case, however, is very different in makeshift storing places. It has never fallen to my lot to have a Grape room, but few gardeners, probably, have tried to keep Grapes in a greater variety of makeshift places. Fruit rooms, packing sheds, offices, lofts, and spare bedrooms have all been tried with varying success. All things considered, a spare bedroom facing north and with a fire place in it answered better than any place I have yet tried. Fire-heat was kept up only during the prevalence of very sharp frosts, injurious fluctuations of temperature being prevented by the aid of shutters for the window and fire-place and by keeping the door constantly closed. If we allow the surroundings and the berries to become very cold and then set the doors and windows wide open directly the change to warmer weather takes place and before the walls become warmer, we must not be surprised to find the moisture running down the walls and a heavy dew on the berries. It is a state of affairs we wish to avoid, but go the right way to bring about.—M. H. F.

—Grapes may be coloured perfectly and yet not be ripened up sufficiently to ensure their keeping well through the winter. But why some varieties of Grapes should shrivel more than others under apparently the same conditions is, I must admit, rather a puzzle, and it is principally with Muscat of Alexandria and to a lesser degree Mrs.

Pince. Whether there is anything in "Vitis's" theory of shortening the fruit-bearing laterals, time alone will tell. It is, however, not surprising that "Northern's" Grapes should shrivel, seeing that he turned off the heat at the time stated, and their subsequent treatment. At the present time I have perfectly coloured bunches of Mrs. Pince, also Alicante and Lady Downe's without blemish of any kind, and yet a little warmth was kept continually in the pipes during the night, but always with a little ventilation both at the front and top of the house. One bunch of Mrs. Pince has shrivelled. This had the least colour, and was not ripened so well as the others. In another house wholly devoted to Muscats and which were fit for cutting the first week in September, there are bunches now hanging perfectly plump and fresh, and others shrivelled on the same vine. At an exhibition I attended last week three perfectly coloured bunches of Mrs. Pince were exhibited. I have known the Vines now for some years that these Grapes were cut from, and the Grapes are always the same. These Vines are also subjected to a little warmth continually in the pipes during the night. Why some bunches of Muscat of Alexandria should shrivel and others not, though growing on the same Vine, is a mystery. On some other bunches a berry is shrivelled here and there. Upon examining these I find the stones are not so perfect as in those not shrivelled. It may be that the stoning is not perfect on those bunches which shrivel generally. It is also observed that the berries of Muscats that are fully exposed to the sun through having the leaves removed—a very questionable practice, however—are often the first to shrivel.

When living in Herefordshire I had a vinery wholly devoted to Muscats, and shrivelling never caused any anxiety. I daresay that the cause of the Muscats shrivelling in many vineries this season has been solely on account of their not being ripened up satisfactorily. This, it must be understood, I do not put forward as the sole cause of shrivelling, for as I have previously pointed out this sometimes takes place with Grapes that are apparently well ripened in every respect. The ripening may be arrested from other causes than the want of warmth, such as scalded leaves and also perhaps on account of red spider and thrips. Partially coloured berries will also shrivel more quickly than others perfectly coloured. To the keeping of any kind of Grape in good condition after being fully ripe, or until cut or bottled, I am certain that the practice of turning off the heat during the night is not conducive. Fixed temperatures I do not believe in, but the slightest warmth should be maintained in the pipes continually with a little air both on the top and bottom ventilators during the night and on dull days, increasing it more or less on fine days.—A. YOUNG
Abberley Hall Gardens, Stourport.

Strawberry Stirling Castle.—Seasons have always more or less effect on the Strawberry crop; still some varieties are less influenced than others, and Stirling Castle is one of the best of that class. In wet or dry seasons it always proves satisfactory, and as a fruit for jam-making it is second to none. A large grower informed me that he had marketed 130 tons of it this year, and for its general excellence he found no other variety to equal it.—W.

Raspberry Norwich Wonder.—This is one of the best varieties that can be grown for market, as the canes are strong, healthy and less affected by drought than those of any other kind that I am acquainted with. Its cropping qualities are also first-class. During the past season, which has been a most trying one for Raspberries, it has produced by far the heaviest crop of any, and also made the finest canes for next year. A variety named Victoria so much resembles Norwich Wonder in every point, that I fail to see any difference.—W.

Home versus foreign fruit.—If any doubt existed about the home-grown Apples being inferior to any received from abroad, the doubter

has only got to visit some of our leading hardy fruit exhibitions to see that we can hold our own and surpass the best importations. This season has been remarkable for fruit keeping badly, yet in spite of that there was held at Hereford on the 15th, 16th, and 17th of last month a magnificent show of Apples, Pears, &c. The fruit was larger, of better colour, and in far greater quantities than last year at the same place, and the farmers' classes particularly indicated a most decided improvement. The Kent fruit exhibited by Mr. Bunyard was very fine, but there was a very close competitor to him in Mr. J. Watkins in the 100 dish class; in fact many thought the latter had the finest fruit and I think it only a question of time when the Herefordshire Apples will be second to none. Amongst other large exhibitors Mr. C. Lee Campbell, Glewston Court, Ross, Mrs. Evans, Moreton Court, Hereford, Sir J. Pulley, Lower Eaton, and Lady Emily Foley, Stoke Edith, put up splendid fruit that would compare favourably with any from any quarter of the globe. Last year I requested one of the largest Apple importers to send me samples of the best Canadian and American Apples to compare with some of the finest home-grown ones; he kindly sent me about a dozen samples, six fruits of each, but they were inferior in both size and quality to our own. If growers would only produce in bulk such fruit as shown at Hereford, the foreigner would soon be excluded from our markets.—W. G. C.

FRUIT GROWING.

I GRATEFULLY acknowledge the compliment of "Stirling" (p. 452), and quite agree with what he says on fruit growing. He truly says, "there is much yet to be accomplished both in Kent and Worcestershire." He also infers that progress is more nominal than real, which is true to a certain extent only, for, notwithstanding such discouraging views, there are many distinct signs of real progress and work rightly done. In the first place, it is an acknowledged fact that we are producing better quality fruit year by year, and it has, moreover, been publicly stated repeatedly this season by experienced salesmen that English grown fruit is well able to hold its own against that of foreign importation. That I take to mean as long as the English-grown Apple crop holds out. This information from such a source is at least encouraging, but, however, in common fairness, on the other hand, it should be mentioned that the foreign crops this year are by some means somewhat inferior. At all events, there is at the present time a demand for good home-grown fruit at fair prices, viz., 12s. per cwt. and upwards, a demand which I do not think can be met and sustained. As a rule one sees the best results obtained by men with small holdings, and I have repeatedly seen these men place on the exhibition tables of small local shows better samples of home-grown fruit grown under ordinary, but diligent cultivation than those seen at metropolitan or provincial shows of greater pretensions. This, too, is evidence that the soil is suitable, the climate favourable, and that only intelligence and enterprise are required to bring about the success we are striving to secure for the depressed British farmer in suitable districts. Unfortunately, there is no class of men individually so prejudiced against new methods of utilising the land, nor any so slow to put modern safe principles into practice as the average British farmer, and I believe it will take him a generation to learn the practical lesson of fruit growing and to properly market the same, for although corn and cattle farming are at a very low ebb, he yet waits and hopes on, "Micawber-like," that something will turn up. It is pretty certain he has already sunk a

large proportion of his available capital with little chance of realising; therefore, if willing, he finds he cannot stand the first few years of light returns from fruit farming, which is possibly the greatest drawback. Anyhow, whatever planting he does, he only does in a half-hearted sort of way, lacking the necessary enthusiasm to command success, although in our case the very best kinds and well-rooted trees are supplied him free of cost, but for which some are not particularly grateful; on the contrary, ask to have them planted, staked, fenced or pruned for them. In some cases this even has been done, but there are many notable exceptions; in fact, personally, I think under the circumstances it would be well to plant and take the trees in hand for the first few years, for the reason that the foundation of well-furnished permanent trees would be secured. Probably this would lead to the proper thinning of the fruit, when possibly friction would arise. The average farmer is so conservative in his notions, that he prefers replacing with young trees the old ones blown down or decayed, instead of the infinitely better plan of breaking fresh ground and planting an entirely new orchard. The greatest success is found where the farmer happens to be planting a new hop yard and where he can be persuaded to plant trees to succeed the Hops. The cultivation and manures thought necessary for the Hops are available for the trees, and good permanent growth is secured. There has hitherto been a general desire to plant Ecklinville Seedling on account of its early and precocious bearing qualities, but now it is found to be one of the worst Apples for travelling on account of its thin skin and soft flesh coming out damaged and discoloured. On this estate experiments have been carried on so as to find out the best kinds for tenant farmers' market purposes, and upwards of 200 kinds are under trial, whilst stocks of those kinds are annually worked up according to their respective merits. We think very highly of Newton Wonder, Bramley's Seedling, Bismarck and Gascoigne's Scarlet Seedling for standard orchard trees; Lane's Prince Albert, Lord Grosvenor and Pott's Seedling for bush trees. American Mother, Lady Sudeley, Beauty of Bath and May Queen have been added to the dessert section and will be grafted in quantity.

Undoubtedly the best Apples for market are those having fairly thick skins and plenty of colour, preference being given to those which remain dry if slightly bruised. The most promising young orchards we have are to be found on farms that have fallen into the owners' hands during the past ten years and where the trees have been properly attended to. Some are planted with all choice Apples, others with Pears, and some with Plums, both on turf and on arable or Hop land. W. CRUMP.

Madresfield Court.

Forcing Peaches.—The early houses will in many gardens be now started, and the buds will be carefully inspected daily to see if that dreaded evil "falling buds" is likely to take place. While not attempting to give any of the numerous causes of bud-dropping, I believe that the lack of potash on light soils has much to answer for in that respect. Nearly all light land is deficient in potash, and when we consider how much of that element is extracted from the soil annually by the fruit alone, containing, as it does, so large a percentage of potash, it will at once be apparent how necessary to good health and production of fine fruit is the return of potash to the soil in rather a copious manner, otherwise the annual loss will become greater, until the trees, crops, &c., are all in a stunted and unsatisfactory state, and the trees

and borders have to be cleared out and a fresh start made. I know that many gardeners are heavily handicapped in the way of manures, particularly chemical manures, but if employers would only give this matter some consideration, they would at once see how much it is to their own interests to supply their gardeners with means to produce fruit in quantity and of the highest quality. Having to deal with a very light sandy soil, I have found chemical manures of immense value in fruit growing, especially Peaches, for which I use muriate of potash, applying 1 oz. to the square yard just before starting the trees, a similar dressing at the stoning period, and again as soon as all the fruit is gathered. The earliest house is always started about the middle of November, and though planted principally with a variety (Early Alexander) noted for casting its buds, I have had very little to complain of in that respect, and I would suggest a trial of the above-named manure to those who have been troubled with bud-falling on a light soil. I may add that before I used the muriate of potash, neither trees nor fruit was satisfactory; now, after six years' use, both have kept on improving.—W.

Apple Byford Wonder.—At the recent fruit and root show held at Gloucester a grand dish of the above was exhibited in the class for any cooking variety not named in the schedule. The competition was keen, and many good dishes of Apples were staged, but the variety mentioned was an easy first, owing to its immense size, heavy weight and attractive appearance. The fruit, I understand, will keep sound and plump until March, and as a cooking variety it is unequalled. In addition to these good points the tree is a most abundant bearer, and should prove a valuable acquisition to the list of late Apples, not only for amateurs, but also for market work. I would suggest that a dish be sent to one of the Royal Horticultural Society's meetings, as I believe it to be quite distinct and well worth distributing.—W. G. C.

Pear Josephine de Malines.—This is certainly one of the grandest winter Pears in cultivation, being of most delicious flavour. This latter characteristic, however, is developed according to the soil and position in which it is grown. Given a warm soil and favourable aspect, then fine flavour is assured. The late Mr. A. Barker, when gardener at Hindlip in this county, used to have it in perfection; in fact, nowhere have I seen it so good. Instead of being of a dull green when gathered, it had quite a pale yellow cast with a tinge of colour on the sunny side, the fruits also being large for the variety. Possibly there may be instances of its having ripened satisfactorily on trees growing in the open in favourable soils and districts during the past season, but the proper position for it is a south or west wall, preferably the former, as then success is more assured. I have had it excellent both from cordons and fan-trained trees on the Quince, and from this latter form also on the Pear. I have also noticed that those fruits which ripen the quickest are from trees on the Quince. As a cordon or even under other forms Josephine de Malines is rather slow in coming into bearing, but this to some extent may be remedied by lifting the trees after they have reached a fair size. During some seasons again the flavour is improved and ripening hastened by placing the fruits in a warm house for a few days. In this case the process is more perfect and the colour more pleasing if the fruits are placed in a single layer in a shallow box with a layer of wadding above and below the fruit.—Y. A. II.

Fish heads for Vine borders.—Fish heads are doubtless a good manure for Vines provided they are well prepared by incorporation with turfy loam and allowed to remain unused for some time. If mixed in the proportion of 2 cwt. of fish heads to one load of soil in the autumn, and allowed to stand unmoved all winter, then in spring turned over several times, adding thereto a goodly portion of old mortar or lime rubbish, it will form a good top-dressing, over which should be placed a shallow covering of sweet horse droppings. The

most luxuriant and fruitful lot of Vines in the midlands had a large percentage of fish manure mixed up with the compost when the borders were made, but evidently there was a lack of preparation previously, as the Vines for several years did not progress satisfactorily; after this date, however, they made headway. I once remarked to Mr. William Thomson, of Clovenfords, that Mr. Dowding, of Oak Hill, near London, many years ago formed his Vine borders, which grew such celebrated Grapes, partly of carrion, and asked how it was if this article was so injurious to the roots of Vines, as many contended, that such good results followed Mr. Dowding's use of it. He replied, and, I think, rightly too, "that the Vines grew splendid Grapes, not on account of the presence of carrion, but in spite of it, adding that no doubt when once it was reduced to its kindred dust it would add to the richness of the border, but until then the roots were better without it. Doubtless all flesh manures are better for being mixed with some absorbing material, or much harm may follow their use.—J. CRAWFORD, *Cod-dington Hall.*

MARKET FRUIT GROWING.

It is many years since such a crop of fruit has been gathered in this country, for all parts of the kingdom appear to have been equally favoured. As the land under fruit crops has of late years increased at a rapid rate, the quantity grown has been very great in the aggregate. Whether such heavy crops are an advantage from a market grower's point of view I very much question, as I think many will find by the end of the season that, although their crops have been much heavier than usual, their profits have not been equal to those from much more moderate crops, as the extra expenses of gathering, marketing, &c., combined with the very low prices, have left but little for the grower. It is very difficult to arrive at a correct estimate of what the average prices have been, and, as far as I can gather, the growers who have found a market for their produce within a few miles of their homestead have little to complain of, while those who have to send their goods by rail have fared badly, and it is not surprising that we hear of many despairing of fruit culture and talking of grubbing up their trees. A little sober reflection will, I think, make them think twice before they act on such a hasty resolution. Grubbing up is the right course to adopt, I do not deny, in the case of a good many of the fruit trees grown, but only the inferior sorts the fruit of which fails to meet a ready sale even in years of scarcity, and which in a year like the present can hardly be given away, ought to be destroyed.

When I speak of good market kinds of fruit, I mean a kind that catches the salesman's eye, and is not shunned by fruiterers. Some of the very best fruits for private use are not to be recommended for market. For instance, Ecklinville Apple is a really fine variety, but I hear from many that it is condemned as a market sort. I would advise those who are in doubt about what to do with their fruit gardens to weed out all the varieties that they find do not find favour with buyers and to fill up with those that do.

Fruit, like all other perishable goods that must be sold at once, will always be liable to glut the market, and the prices realised then do not pay working expenses. The demand for fruit increases enormously, but the means of getting it conveyed to where it is wanted is one of the greatest drawbacks to its being sold at a price within the reach of all; consequently growers at long distances from market have a real difficulty in disposing of their goods to ad-

vantage. Railway rates are excessive, and local rates appear levied on land as if it were the only thing in the country that yielded any profit at all. Much could be done to aid the fruit grower by a readjustment of taxation, and much more can be done by the growers themselves learning how to dispose of as well as how to grow their fruit. We are yet very much behind the foreigner in the art of packing and grading our fruit; all the improvement has been in growing fruit.

I suppose there never was a finer crop of Pears than this year, not only as regards quantity, but also size and quality. Although our home-grown fruit was so good and cheap, many fruiterers have given a higher price for French or Channel Island Pears, for the simple reason that the boxes contained so many fruits all of equal size, while the home-grown mostly came to hand in sieves or bushels with several sizes mixed together. This is only one of the things that tend to keep down the price of the home-grown fruit.

In storing fruit there is also much room for improvement. Apples like Blenheim Orange, Wellington, &c., have been gathered and rushed on the market and sold for about half what they would be worth in December. Surely if it is worth growing good fruit it is worth taking a little trouble to store it and sell in the best market.

The present outlook as regards planting fruit trees may possibly have received a slight check, owing to the low market prices, but I think if more care in selection of varieties were taken by those who know not only that the varieties are suited for market, but suited to their own locality, they would still find fruit tree planting by no means a poor investment. Beware of very soft or light Apples that look very well on an exhibition table, as, for instance, a good dish of Emperor Alexander. Pears are even more capricious, and the list of varieties suited to a market grower is not at all large, although there are hundreds of sorts to select from.

Happily, there is one thing that ought to cheer any that are inclined to despond, viz., the splendid rains and mild weather that have filled up the buds and invigorated trees and bushes after the heavy strain they have borne for months. Where trees have been carefully cultivated, there is no reason why a good crop should not be borne next year.

Gosport.

JAMES GROOM.

THREE GOOD NEW STRAWBERRIES.

A CONSIDERABLE number of new varieties of Strawberries has been raised and distributed of late years, but it is to those raised by Mr. Allan, Gunton Park, that I would particularly draw attention. If some of our old favourites are ever displaced it will be by the Gunton trio, these possessing every requisite that goes to make a Strawberry popular. Varieties that require extra good culture to keep them in a profitable state, and those in particular that are somewhat fickle as to soils and localities, inevitably die out, no matter how good the quality of the fruit. In this category I must include both British Queen and Sir Charles Napier, both of which are considered by connoisseurs to be of exceptionally good flavour, though perhaps the latter is somewhat too acid for all palates. In this neighbourhood both quickly die out, the foliage not being proof against a moisture laden atmosphere accompanied by severe frosts at times. The nearest approach to Sir C. Napier in productiveness, size, rich colour, and brisk flavour that I have yet tried is to be found in Countess, and the latter is also robust and hardy. When, therefore, Mr. Allan commenced experimenting with a view to raising varieties of

superior flavour without the concomitant of a weakly habit of growth, he could not possibly have selected anything better than British Queen and Countess for the purpose of effecting valuable crosses. Other crosses in which British Queen figured prominently did not prove at all satisfactory, the whole of the seedlings thus raised by Mr. Allan being discarded in favour of those resulting from British Queen and Countess crosses. Of these latter there are three very distinct varieties now being generally distributed, large numbers of plants being already well established in numerous private gardens. The first to be described, because most favoured by those who have tasted fruit of all the trio, is named

LORD SUFFIELD. Each time I had an opportunity of tasting this excellent Strawberry its superior quality was unmistakable. The fruits are long, comparatively thin, and tapering, reminding me somewhat of the old Rivers' Eliza grown to its full size, but the colour is quite distinct, being of a dark glossy crimson, or nearly as much so as Waterloo, the flesh being firm, rich and sweet in flavour, without, however, cloying the palate, while the seeds are well on the surface. In

EMPRESS OF INDIA we have a variety possessing the full rich flavour of British Queen and none of the latter's weak points. The fruits are fairly large, of good conical form, bright glossy scarlet in colour, the flesh being firm and the seeds well on the surface, this constituting it a good traveller Of

GUNTON PARK, the other variety to be noticed, it is said by those who ought to be good authorities that it is likely to become the "market Strawberry of Strawberries," and, according to my experience, this prophecy bids fair to become realised before very long. In this instance the fruits more nearly approach the shape of Countess, being flat or cockscomb-shaped, but of greater depth near the stalk. Personally I have formed a high opinion of the quality of Gunton Park, the flavour being a happy mixture of British Queen and Countess, and no fault can be found with either the colour, firmness of flesh or good travelling and keeping properties of this fine Strawberry.

The first time I tasted fruit of these three varieties it had been gathered from forced plants, and though nearly two days travelling before it reached me, yet in each case it was in excellent condition. Others gathered from the open ground were equally good and travelled remarkably well.

Those who have procured plants of these Strawberries will bear me out in the assertion that there are no signs of a weak constitution about them—quite the contrary, in fact. We have also had very good proof that all succeed well under pot culture, and, seeing that Mr. Allan has frequently pitted them against all other varieties in open competition, both collectively and in single dishes, winning premier honours in each instance—including those where the flavour test was applied—there is every probability of their becoming popular among exhibitors as well as those who rightly place rich flavour before great size. All, apparently, are main-crop varieties. It is very much to the credit of Mr. Allan that he should be able to raise three varieties of Strawberries each deemed worthy of receiving a first-class certificate from the Royal Horticultural Society. W. IGGULDEN.

Raspberries in Norfolk.—Mr. English, a farmer at Garboldisham, near East Harling, Thetford, picked the enclosed Raspberries from his garden this afternoon, and gave them to me as I was walking past his garden. I send them to you, as it may be of interest.—G. J. COOKSON, Nov. 17.

Amsden June Peach for open walls.—Probably after the hot summer of 1893 many will be inclined to replant, at least to some extent, their Peach walls in the open air, and surely the stout well-matured wood visible in all trees occupying such positions this autumn will warrant such a course. To all intending planters I would strongly recommend the variety Amsden June. Several years ago it was favourably mentioned in THE GARDEN by Mr. Coleman, Eastnor Castle, and, acting upon his advice, I immediately planted it in the half

standard form, which I prefer to all others, as the union with the stock, always a more or less tender part, is thus elevated beyond the chilling effects of frost and damp, and the bottom portion of the wall can always be furnished by training the branches downwards. The tree bore heavily the second season after planting, and has never failed since. The fruit is large, carries a fine colour, and is, moreover, of good flavour. Although this is, I believe, an American variety, I am inclined to try it under glass, as if it would retain its flower-buds in spring it would prove a worthy substitute for the capricious Alexander and Waterloo.—J. CRAWFORD.

Pear Triomphe de Jodoigne.—I cannot agree with Mr. E. Burrell as to the above variety of Pear being at all a satisfactory one to recommend for planting. True, it makes a fine looking tree, is prolific, and the fruits grow to a large size, but the flavour is coarse in the extreme. It certainly might have come of better quality this past season, but I discarded it long ago. My opinion is not singular, as I have heard several people speak of it in the same terms as myself.—Y. A. H.

KITCHEN GARDEN.

SEED PEAS.

It would be folly after the past season's experience not to anticipate an enhanced price for Peas during the coming year. The drought of the past summer simply prevented the development of the crops, so that in many places there was either a miserable crop or literally none to harvest. Of course we are not entirely dependent on home-grown Peas; if we were, it would go very hard with us often, and especially now. Still with all the world to find us seed, there were such universal losses from drought, that crops are almost as short on the Continent as here, and seedsmen have found it very difficult to get their requirements supplied. All the same, it must be expected that some old seeds will be sent out in the spring, and some that, if new, will be hard and imperfectly matured. So much is inevitable, especially among wrinkled Peas, because these seem to have suffered everywhere, the shrinkage in seed-produce being almost without precedent. Under these circumstances it will be well if gardeners or others using seed Peas should try and meet the seedsmen half way. Almost everybody sows Peas too thickly. There is no feature in gardening more common than this, and whilst no gardener could afford to have fewer Peas to gather, it does seem as if all that is needed could be furnished with one-half the usual quantity of seed. It may be pleaded, however, that it is just when seed is of doubtful germinating quality that thicker sowing is needful. That may be true in some cases, although it is not an absolute necessity. But in the case of Peas, and especially of the later or wrinkled varieties, how much might be done to counteract the evil arising from immature or old seed if the plants be raised singly in small pots for once, and being helped by the warmer temperature of a frame, there is far better prospect of inducing imperfect seeds to make pretty good growth than is likely to follow when the seed is sown in the open ground. If two hundred, or even double that number of small pots be sown with the best selected seed Peas, it is pretty certain that 80 per cent. would grow, and some 160 single plants only turned out of pots when but 4 inches in height would make at but 3 inches apart a grand row 40 feet long. Plants so raised and put out would, if the ground had been previously well prepared, make

fine growth. The distance apart might be increased with advantage. But just such sowings made once every ten days during the summer would give a considerable saving of seed, and it would ensure that the plants throughout the row were perfectly equal. Even were raising in this way thought to be too much trouble, hard selection of the best seeds and dibbling them out thinly into the drills would prove a saving method. Then it will be very wise, not merely in the case of Peas, but in relation to some other seeds, not to sow too early. A week or so later when the ground is warmer may make a great difference in favour of germination. There are few garden seeds in fact with respect to which it may not be assumed that because of the untoward drought of last summer they may lack much of the ordinary vitality. Market growers will probably feel the pinch most, for a few shillings more per bushel is never recouped by a higher price for their pod produce, as that is governed by other considerations. A. D.

Flavour in Brussels Sprouts.—I am well aware a great deal depends upon the cooking, more especially at certain seasons. In a season with abundant rainfall there should be no complaints as to vegetables being strongly flavoured. Some may say that such weather does not add to flavour, but promotes size. I object to size, and do not plant those kinds which are noted for mere size. In vegetables quality should be first, and there is no loss, as more plants can be grown in the same space as the coarser varieties take up. Of late I have noticed a decided leaning to quality in judging vegetables. This is a step in the right direction, and one that should be encouraged, as anyone who grows vegetables in quantity and studies their quality knows that in nine cases out of ten those vegetables which are not coarse are the best flavoured and also resist changes of weather. The flavour of a good type of Rosette Colewort at this season cannot well be improved upon. This shows that quick growth tends to good flavour. I prefer a dwarf early Brussels Sprout for various reasons. The sprouts can be boiled and served whole. When cut they are not yellow inside like an overgrown Cabbage; the green portion is always the best flavoured. This is retained in a medium-sized sprout, whereas in a larger one a great portion of the green leaves is cut away in preparation. It may be said that even dwarf kinds get large if planted early, but the sprouts do not if the strain is good, and those who have to provide a long succession would do well to make two sowings, one in frames early in the year, and the second in the open early in April. From these two sowings three plantings are obtained, and firm, green, bullet-like sprouts from the end of September till March. After making a trial of many varieties I prefer the Paris Market. I would add just one note as to cooking. Abundance of water is necessary, and, with strong vegetables, two lots of water, boiling water being used to put the sprouts into the second time. The sprouts should be boiled gently, then drained through a sieve and dished up whole.—G. WYTHES.

Protecting Globe Artichokes.—It is now high time the stools of this somewhat tender vegetable were mulched as a protection against severe frosts, should such occur. During the last two or three years rows of these have perished either through being left to take care of themselves, or from being surrounded by half-rotten manure. I think of these two evils the latter is the worst, as the material holds the moisture and is afterwards frozen into a solid mass, frequently destroying the roots altogether, or weakening the plants beyond recovery. The best way is to surround the stools with a good quantity of stable litter, working it well in amongst the crowns with the hand. This, while excluding frost, allows all superfluous moisture to pass away. Where it is found necessary to renew the stock, obtain offsets from a good

strain, as seedlings are generally worthless, producing small and, in many cases, useless heads. Of the green and purple-headed varieties, perhaps the former is the more popular.—JOHN CRAWFORD.

THE TOMATO SEASON.

THIS has been an ideal season for Tomatoes in the open air, the growth being hardy, fruitful, and free from disease of any kind. If we could depend upon Tomatoes succeeding generally as they have done this year, we should soon see an increase of cultivators, especially amongst amateurs, and in small gardens where they cannot be grown under glass. Although the season has been so favourable, yet the success which has followed must not be wholly attributed to the weather, as even in a season like the present success has been much more apparent when close attention has been given to all important details connected with open-air culture. Not the least is the importance of putting out good strong plants as early in the season as possible, that is compatible with safety. Weakly plants lead to failure, as the greater part of the most favourable weather is past before a satisfactory growth is formed, and by the time this gains strength to produce fruit, it is too late for this to become ripened. With strong well-furnished plants there is no loss of time, as they keep on making satisfactory growth, which in its turn produces fertile trusses of bloom, to be followed quickly by fruit. When fruit is formed late in the season, the short and moister days of autumn are upon us before the ripening process is finished.

It must be generally admitted that we have secured within the past two or three years varieties which are more amenable to outside culture, being altogether more fruitful and not so gross in growth. It is the gross growing varieties which produce large and ugly fruits, and very few of these to a plant. The variety which I have proved to be the best for open-air culture is

EARLY RUBY.—This is an excellent Tomato for early fruiting, but it is not one that I should select to depend upon exclusively throughout the season, as it does not possess sufficient stamina, and the fruit also comes too much corrugated. But earliness and free fruiting are great points in its favour, and these must be considered. I also notice that the fruits are not so corrugated earlier in the season. It is not at all a strong grower, but ripe fruit, and this of good quality, was produced much earlier than on others growing alongside. I have also formed a good opinion of

LADYBIRD as being a variety well adapted for open-air culture. In growth it is only moderately strong, but very fruitful, several fruits to a truss, these ripening up continuously and well. These small-fruited sorts will be found to ripen up much quicker than larger varieties. Other two varieties which I am especially pleased with are Challenger and Conference.

Planted against a low wall, all the above varieties have produced an abundance of fruit.

A. Y. A.

A running kidney Bean.—On page 472 of THE GARDEN of November 11 we notice Mr. W. Iggulden's remarks concerning a running kidney Bean. We think that Mr. Iggulden cannot be acquainted with our climbing Bean, Sutton's Tender and True, which we introduced in the year 1892. It is exactly what he describes as having seen at Longford Castle, a climbing Bean about 4 feet high, with long, straight pods that cannot be distinguished from those of Canadian Wonder. The seeds are also exactly alike; in fact it was selected from this variety. Our Tender and True was awarded a first-class certificate by the Royal Horticultural Society, and nearly all the horticultural papers have spoken in its praise. During the two years that we have distributed it to our customers, we have had an immense number of testimonials from them saying what a great acquisition it is, having all the advantages of a large-cropping, continuous-bearing runner Bean with the delicate flavour of the dwarf.—SUTTON AND SONS.

FERNS.

POLYPODIUMS.

Among the Ferns most valuable for decoration, Polypodiums occupy a prominent position. The genus is very extensive and comprises plants of small, medium and large dimensions, adapted either for growing in suspended baskets, for pot culture, for planting out in the open-air fernery, or as edgings for the rock garden. The geographical distribution of the genus is such that it may safely be said that Polypodiums of one section or another are found in nearly every part of the globe. Besides the common Polypody (*P. vulgare*), which makes for itself a congenial home in the mossy bark of old trees or on the tops and in the crevices of old walls, or which we find clothing the sloping sides of our hedge-banks, where it frequently forms a dense mass of undergrowth among the roots of the hedges themselves, the most remarkable species

which are distinguished from each other by their mode of venation or of fructification. These are *Campyloneuron*, *Cyrtomiphlebium*, *Dictyopteris*, *Dipteris*, *Drynaria*, *Goniophlebium*, *Goniopteris*, *Grammitis*, *Niphobolus*, *Phegopteris*, *Phlebodium* and *Phymatodes*. All the foregoing, and more than forty other names which have now become obsolete, are Polypodiums, inasmuch as they have round or roundish sori (spore masses), which are naked or without indusium or covering and composed of sporangia (spore cases) with an incomplete vertical ring. With few exceptions Polypodiums are provided with rhizomes or decumbent stems from which their fronds are produced. In some species the fronds have their stalk adhering to and continuous with the rhizome, and are of an evergreen nature; but by far the greater number of Polypodiums have their frond-stalks articulated to the rhizomes and are either wholly deciduous, like our own Oak and Beech Ferns, or partly so like our common Polypody, the beautifully purple-

plenty of height to allow the fronds space to hang, a specimen with numerous fronds each 10 feet to 12 feet long is a sight not easily forgotten." The same author also indicates another use for this plant when he says: "This Fern can with great advantage be utilised for covering dead trunks of Tree Ferns; in such positions it makes a very beautiful object and grows apace, as it delights in sending its roots and rhizomes into partly decayed vegetable matter."

Among the strong-growing kinds of either erect or semi-drooping habit which show themselves to greater advantage by being planted out in the rockery I may mention the glaucous *P. aureum* and its variety *sporadocarpum*, *Billardieri*, *fraxinifolium*, *heracleum*, *irioides*, *mussefolium*, *ornatum*, *Phyllitidis*, *subpetiolatum*, &c. Among the species of medium growth particularly attractive through either the singular shape or the pleasing nature of their foliage, the most distinct are *P. angustatum*, *appendiculatum*, *chnoodes*, *drepanum*, *fossium*, *heteractis*, *lingua* and its crested and contorted form *corymbiferum*, *Meyenianum*, *platyphyllum*, *vulgare cambriacum*, *elegantissimum* and *pulecherrimum*, and also the very singular *P. xiphias*. Of the dwarf-growing Polypodiums best known in gardens, the most useful and attractive are *P. accedens*, *acrostichoides*, *adnescens*, *alpestre flexile*, *Dryopteris*, *hexagonopterum*, *glaucophyllum*, *lycopodioides* and its variety *salicifolium*, *piloselloides*, *Phegopteris*, *reptans*, *rupestris*, *tricuspe*, *stigmaticum* *vaccinifolium*, and the beautifully marked *venosum*, most of which make very handsome objects when grown on a pyramid of turfy peat.

A small number of Polypodiums, such as our Oak and Beech Ferns, are provided with rhizomes of a slender nature, which delight in running underground in partly decayed vegetable matter, but in the majority of cases the rhizomes of either a fleshy or of a woody nature prefer being kept above or close to the ground to which they have the faculty of adhering very firmly. The Polypodiums best adapted for pot culture are those in which the fronds are produced from a central crown, although those provided with underground rhizomes may be managed equally well in pots or planted, according to their native habitats, either in the stove, cool rockery or outdoor fernery. The soil which suits these best is a compost of one part leaf-mould or fibrous peat, two parts fibrous loam and one part silver sand. For those species which are provided with rhizomes of a more or less woody nature, which keep near, or even on the surface of the soil, a material of a different nature is required, and they have been observed to grow more luxuriantly in a mixture in which good fibrous peat or half-decayed leaf-mould predominates and with a small portion of fibrous loam. In their case no silver sand is required. The propagation of the species provided with rhizomes may take place almost at any time of the year by division, while the others are most rapidly increased by means of spores, which in the majority of cases germinate freely when sown in heat and soon after they are ripe. It is worthy of notice that the plants raised from seed are usually of better shape than those of the same species produced by division of the rhizomes.

A FERN LOVER.

Polypodium nigrescens. Engraved for THE GARDEN from a photograph sent by Mr. G. J. Anson, Clapton.

native of Great Britain are the Oak Fern (*P. Dryopteris*), the Beech Fern (*P. Phegopteris*) and the Limestone Polypody (*P. calcareum* or *Robertianum*), all well known to Fern lovers. But even these species, although indigenous to this country, are of a very cosmopolitan character, the range of their habitat extending to North America and Japan. There are a few species native of Australia and a few native of Japan, while a certain number of very distinct species are found throughout India, and a few others are native of the United States of North America and Canada. It is in Central and South America, however, that Polypodiums are most abundant and also most varied in form and in the texture of their fronds. An idea of the importance of the genus may be gathered from the fact that Nicholson, in his "Dictionary of Gardening," vol. iii., p. 186, states that "the genus Polypodium comprises upwards of 460 species," and also from the numerous sub-divisions to which it has been subjected by various authors. There are still a dozen of these sub-genera retained by Hooker and Baker in their "Synopsis Filicum," all of

which are distinguished from each other by their mode of venation or of fructification. These are *Campyloneuron*, *Cyrtomiphlebium*, *Dictyopteris*, *Dipteris*, *Drynaria*, *Goniophlebium*, *Goniopteris*, *Grammitis*, *Niphobolus*, *Phegopteris*, *Phlebodium* and *Phymatodes*. All the foregoing, and more than forty other names which have now become obsolete, are Polypodiums, inasmuch as they have round or roundish sori (spore masses), which are naked or without indusium or covering and composed of sporangia (spore cases) with an incomplete vertical ring. With few exceptions Polypodiums are provided with rhizomes or decumbent stems from which their fronds are produced. In some species the fronds have their stalk adhering to and continuous with the rhizome, and are of an evergreen nature; but by far the greater number of Polypodiums have their frond-stalks articulated to the rhizomes and are either wholly deciduous, like our own Oak and Beech Ferns, or partly so like our common Polypody, the beautifully purple-

Primula capitata (Roylei).—I am sending you a bloom of this fine species and a photograph of the plant from which it is taken. The plant is growing in a little alpine house in my nursery here, and the bloom is one of eleven on the same plant all out together. I suppose there is scarcely

a month in the year in which I have not bloomed this plant, notably in the winter months, and with the shelter of an unbeated house or frame it has been a fine spot of colour. The plant is so far more commonly seen of a quality in many respects inferior to this, that I have the impression that I may have become possessed of a distinct and superior strain worthy a distinct name. The superb character of the purple will be noted, and I believe I am right in stating that the individual blooms (and not merely the blooming season) endure for many months if sheltered from the worst weather. The strain, too, is here quite hardy and long-lived. From all accounts this latter quality is not a common one with this species.—H. SELFE-LEONARD, *Guildford*.

FLOWER GARDEN.

CAMPANULA GARGANICA.

ON page 454 of THE GARDEN there is a note headed "Campanula muralis (Bavarian variety)." Before speaking of any particular species or variety I should like to say a few words about the nomenclature, and especially the nursery nomenclature, of the genus Campanula. The best botanical catalogues enumerate nearly 100 European species of Campanula, besides at least as many more synonyms and varietal names, giving rise to endless cross naming. About half the species have a very limited area, many being confined to Greece or its islands, some to Crete, or to a single island in the Greek Archipelago. A large proportion of these have never been, and are never likely to be in general cultivation in England, and if we include the annuals and biennials of the genus, I cannot count more than about thirty good perennial species known to English gardens. I am aware that a collation of nursery catalogues would supply many more names than this. Some years ago I collected a Campanula of every name I could find offered. Then came the difficult process of verification. With the help of the Kew herbarium I reduced nearly a dozen names to the two species *C. garganica* and *C. Portenschlagiana*, and at least as many more to the one variable species *C. rotundifolia*. I was warned at Kew to exclude the name *C. muralis* of Portenschlag, which has been eliminated from authentic botanical catalogues for at least half a century. If anyone asks why the name survives, I can tell them one reason which I discovered whilst trying during several years to improve the very confused nomenclature of hardy plants in nursery catalogues. Some of the nurserymen readily adopted my corrections, but one eminent firm in the north replied that they knew many of their names were wrong, but if they changed them to right, they might be accused of the (unpardonable?) offence of selling an old plant under a new name. I presume that this is one of the few nurseries at which, as we are told, *C. muralis* may be bought true.

Now for *C. Portenschlagiana*. The botanist Portenschlag published a "Flora of Dalmatia" at Vienna in 1824. Amongst the plants he described was a Campanula, to which he gave the name of muralis. When his plants were examined by other experts it was found that he had included two species under this name, one new to botany, the other already known as *C. garganica*. Therefore the name muralis was dropped, and the new species was called Portenschlagiana in honour of the discoverer. This name first occurs in the botanical work of Reimer and Schultes, which was completed in

1835, so that the amended name is nearly sixty years old. The obvious distinctions for gardeners to notice between *C. Portenschlagiana* and *C. garganica* consist in the form of the flower and in the habit of growth. The former has reflexed divisions, which if cut off would be almost equilateral triangles, the cutting descending less than half the length of the corolla, which retains the form of a bell, whilst the flower of *C. garganica* is split up into five narrow lanceolate segments, the division reaching nearly to its base. The habit of *C. Portenschlagiana* is to spread fast, forming rooted tufts as it extends, with short upright stems, whilst the stems of *C. garganica* are prostrate and long, and all proceed from one central tuft, which increases slowly. Now for a few words about the Bavarian variety. I know the plant so called, and had it from Mr. Paul's nursery at Broxbourne several years ago. I consider it a great advance on the older and smaller type, of which it has all the virtues, and is twice as large in all respects; but I do not know what claim it has to be called Bavarian. It is perhaps a large development of the type raised from garden seed in the same way as those large forms of *Aster alpinus* we are now getting from Continental nurseries. It may have come from M. Sundermann's nursery at Lindau, in Bavaria, from which many good alpine—not Bavarian—have been distributed, but I can find no record of the species as a Bavarian plant. Its native area beyond Dalmatia is very limited, not extending to the north beyond the coast of the Adriatic.

Little room is left to speak of *C. garganica*. It was named by the botanist Tenore from the famous Italian mountain on which it was first discovered. Gargano is a huge mass of limestone mountain covering several hundred square miles and rising to a greater height than anything in Britain. It forms the only conspicuous projection from the Italian coast into the Adriatic, and is celebrated in Latin poetry for the roaring of its Oak forests in the north winds, as well as for the myriads of bees which were attracted by the fragrant flowers of its slopes. This was the only known home of the very pretty Bellflower which bears its name until Portenschlag found it on the opposite coast of the Adriatic. It is a charming plant for rockeries, creeping amongst the crevices with its long slender branches and not rising more than an inch above the stones. I have had several varieties, one of them with flowers pretending to be white; another—the most robust, but not the prettiest—with soft hairy leaves. The form generally sold as muralis is more compact and has a more upright growth, but it is certainly no improvement on the type. Perhaps it is a Dalmatian form of the plant. The species in general is not nearly so robust as *C. Portenschlagiana*, which may at any time be divided and transplanted with a trowel. *C. garganica* requires more care in division and takes longer to form a new plant. I have never tried to raise either species from seed.

Edge Hall, Malpas.

C. WOLLEY DOD.

P.S.—Since writing the above I observe under "Notes from Baden-Baden" on p. 500 of THE GARDEN that M. Max Leichtlin mentions the history of *Aster alpinus speciosus*, about which I was mistaken. I have heard, however, that there are more than one large-flowered variety, and two or three bearing different varietal names have come to me from continental nurseries, but I have not yet been able to compare the flowers. I hope some reader may be able to tell us the history of the double-sized *C. Portenschlagiana*, which I have tried in vain to learn.

AQUATIC PLANTS AND THEIR CULTURE.

THE following interesting article by Mr. L. W. Goodell, Pausy Park, Dwight, appeared in Part I., 1893, of The Transactions of the Massachusetts Horticultural Society.

No class of plants is attracting more attention at the present time than the aquatics. The great interest that has been awakened in them is chiefly due to the fine displays that have been made in the public parks and at the shows of our own and other horticultural societies during the past few years. They are now grown in the parks of nearly all the large and many of the smaller cities of the country, and always attract the attention of crowds of people. Boston seems to be the only large city without aquatic plants in its parks. I am informed by Superintendent Doogue that the conditions here are unfavourable for their culture. It would be interesting to know what there is in the water or soil of Boston injurious to them. No more attractive feature can be added to any public park or private place than a water garden. There are thousands of natural ponds scattered all over the country in which the many beautiful hardy Water Lilies would grow to perfection, and take care of themselves if once introduced. Nearly all kinds can be grown with success in large tubs, or cemented tanks of any size desired; and that large class of flower lovers who cannot afford a large and expensive water garden, can cultivate and enjoy them in this way with little expense. On many places there are small streams of water running through rich meadows where an artificial pond can easily be made. The earth for the bottom of such a pond, if not already rich, must be made so by the addition of thoroughly decayed manure. One of the most important points in the cultivation of aquatic plants, especially the tender varieties, is warm water, and in selecting a site for an artificial pond, whether it is to be large or small, it should be where it will get as much sun as possible, at least for six or eight hours during the day, and, if possible, where it will be sheltered from the cold north winds by trees or buildings. If the water garden is to be of small size, it is best to make it in some regular form, like a circle, oval, or parallelogram; but if large, an irregular outline, like a natural pond, is more pleasing. If the water supply comes through pipes and is limited, it is necessary to cover the bottom and sides with a coating of cement. The soil should be excavated to a depth of 2½ feet, and the bottom, after being shaped, should be pounded down as hard as possible. It should be gradually sloped to the top, from a line within 4 feet or 5 feet of the edge, or it can be made of the full depth to the edge, and an 8-inch brick wall laid for the sides. This is the most common way, but it adds considerably to the expense and is not necessary, except in soils that heave badly with frost in winter. But if the edge is well protected with leaves or straw and boards—as the edge of all cemented ponds ought to be—there is not much danger of injury in any soil. A small pipe should be laid upon the bottom to some lower part of the grounds for the purpose of drawing off the water when necessary for planting or cleaning the pond. A fountain can be added if desired, but if the tender aquatics are cultivated, it should not be allowed to play except on special occasions, or when necessary to keep the pond full; otherwise the cool water would lower the temperature too much. Aquatic plants are hearty feeders, and the soil for them should be of the richest

possible nature. Good turfy loam and at least one-third part of thoroughly decayed stable manure should be used, and the addition of some good, high-grade, commercial manure, at the rate of three or four pounds to each cubic yard of soil, will cause a more rapid growth. The soil should be spread to the depth of a foot over the bottom and pounded down as hard as possible; then spread on 2 inches of sand or fine gravel to hold the soil down and prevent it from mixing with the water. To ensure success in growing the tender *Nymphaeas* without artificial heat, shallow water is one of the most important points, as the sun heats it up much better than deep water. During the early part of the season 4 inches or 5 inches is enough, which may be increased to 1 foot as the season advances. The best season for planting all kinds of aquatics is the spring, and the 1st of June is early enough, in this latitude, for the tender varieties. When ready to plant, draw off nearly all the water, set stakes where the plants are to grow, and set them out just as you would set plants on dry land. The large, tender *Nymphaeas* should be set from 8 feet to 15 feet apart, and the hardy varieties from 4 feet to 8 feet. In planting large artificial or natural ponds, do not, above all things, set the *Nymphaeas* in regular rows at equal distances apart, as though it was an agricultural crop needing cultivation with a horse hoe. This I once saw done in a pretentious public park. Conceal the artificial, and imitate Nature as closely as possible. Let the planting be done in irregular groups around the margin. Give some of the plants plenty of room for full development, with here and there a scattered plant to partially connect some of the groups, but leave plenty of open water between and in the middle of the pond. The attractiveness of a water garden is greatly increased by harmonious surroundings, and there is no more appropriate place for the cultivation of sub-tropical plants, such as *Cannas*, *Musas*, *Caladiums*, *Castor Beans*, and the like, than in a border on the north or back side. To grow the large, tender Water Lilies to full size and perfection, artificial heating of the water is necessary. This is usually done by running over the bottom of the pond coils of pipes from a conveniently located greenhouse boiler. Instead of covering the entire bottom of the pond or tank with soil, it is better to put it in boxes a foot deep and 3 feet or 4 feet square, and a depth of at least 2 feet of water over the crowns of the plants is best. In beginning a list of aquatics, the grandest of all, that truly royal plant,

VICTORIA REGIA, should stand at the head. To grow this magnificent plant in the open air to full size, with flowers from 12 inches to 15 inches across and leaves from 6 feet to 8 feet, requires a tank 30 feet or more across and artificial heat, all of which involves considerable expense. But it can be grown and flowered without artificial heat with good success even in cold New England with little expense. I have flowered it in this way for three years. The most important point to ensure success is to get a strong growth early in the season. To accomplish this, I set out a good plant about the 1st of June, and then made a frame around it of planks 10 feet or 12 feet square and wide enough to come 5 inches or 6 inches above the surface of the water and covered it with hot-bed sash; this gave nearly all the advantages of artificial heat; the temperature of the water and soil often rose to 100°, which caused very rapid growth, soon filling the frame with leaves. Both sash and frame were then removed to give the plant more room. My plants made leaves 5 feet across and were in flower for a month. The variety experimented with was the crimson-flowered *Victoria Randi*. This differs from the typical

Victoria in having the vertical rims of the leaves much higher, and the flowers turn to a deeper red when they fade. It also flowers earlier, and the plants do not grow so large.

EURYALE FEROX is an East Indian Water Lily resembling the *Victoria regia* in its general appearance, but its leaves are only 2 feet across, and they do not turn up at the edge; its flowers are small and of a deep violet colour. It is much hardier and more easily grown.

The most attractive and popular of all aquatic plants are the *Nymphaeas*, and there is nothing in the floral world more gorgeous than some of the tropical varieties. These are divided for the sake of convenience into day-blooming and night-blooming species. The day-bloomers open their flowers early in the morning and close about the middle of the afternoon. The night-blooming varieties open after sunset and do not close until nearly noon of the next day if the weather is cool or cloudy. Each flower opens four times. The following are day-blooming varieties:—

NYPHLEA ZANZIBARENSIS is one of the most beautiful and the most easily grown of the tropical Water Lilies. Its flowers are of a rich deep blue, and when well grown will measure fully 10 inches in diameter.

N. ZANZIBARENSIS AZUREA is like the preceding in everything except colour, which is of a lighter shade.

N. ZANZIBARENSIS ROSEA varies in colour from a pale rose to deep rose, almost crimson in some specimens. All of the above varieties are very free-blooming, beginning when the plants are quite small and continuing until frozen up in the autumn. They are so hardy, that they will stand a good deal of cold weather without material injury.

N. SCUTIFOLIA is also very easily grown, and bears an abundance of flowers all summer. These are from 4 inches to 6 inches across and of a light blue, shading to white in the centre. It is a native of the Cape of Good Hope, and is hardy south of Washington, D.C.

N. STELLATA, from tropical Africa, is a free-blooming and desirable species, with large, bright blue flowers.

N. GIGANTEA is a native of Australia, and is considered by many to be the finest of all. Its flowers are of the largest size, with numerous petals of a beautiful purplish blue, shading to white at the base, and it has a mass of golden stamens. This species when well started grows freely and produces flowers in abundance, but is one of the most difficult of all to manage in the younger stages of its growth. The young plants have a disagreeable habit of losing their foliage, and the tubers then go to rest for an indefinite length of time. I have had tubers remain dormant two years, in spite of all efforts to start them into growth.

N. ELEGANS is a pretty species from New Mexico and Texas, with small white flowers tinted with pale blue.

N. GRACILIS, from Mexico, has large white flowers resembling those of *N. dentata*, but the plant is of smaller growth.

N. FLAVA, from Florida, has small, golden yellow flowers, but is of little value for northern culture in the open air, as it seldom blooms here.

N. MEXICANA is a new species from Mexico, which was thought at first to be identical with *N. flava*, but it is quite distinct. The plant is of stronger growth, the foliage larger, and it also flowers quite freely in the open air here. Both of these species must be kept during winter in a greenhouse in growing condition.

The following are night-blooming varieties:—

N. DEVONIENSIS, a hybrid between *N. Lotus* and *N. rubra*, raised many years ago by the Duke of Devonshire, is one of the most gorgeous varieties in cultivation. The flowers are of a brilliant rosy red, from 10 inches to 12 inches across, and borne in abundance, a dozen or more often being open on a plant at one time.

N. RUBRA is a native of the East Indies; it resembles *N. Devoniensis*, but the flowers are more cup-shaped and of a lighter colour.

N. STURTEVANTI is a hybrid of American origin and a magnificent variety, but a poor bloomer. It resembles *N. rubra* in colour, but the petals are broader and the foliage is quite distinct.

N. LOTUS is a native of the tropics of the Old World. It grows in abundance in lower Egypt, and is the true Sacred Lotus of the ancient Egyptians and was sometimes engraved on their coins. The seeds and roots when dried and ground were made into bread by them. The flowers are 6 inches to 8 inches across, with broad, white petals.

N. DENTATA is the largest of all white Water Lilies, the flowers being from 10 inches to 14 inches across and of a pure paper-white. It blooms very freely through the season, and is one of the easiest of the tropical *Nymphaeas* to grow.

HARDY NYMPHAEAS.

Water Lilies that will endure the winter in the Northern States are called hardy. The books tell us, and it is generally believed, that no Water Lily will bear actual freezing of the roots, and that they must be planted in water deep enough to be below the reach of frost. But my experience during the past winter has convinced me that this is an error, which, while easily disproved, nobody seems to have hitherto detected. One of my artificial ponds is supplied with water by a small stream which was frozen up during the severe weather of January, and the pond dried up, freezing to the bottom. This pond contained my stock of *Nymphaea odorata rosea*, *N. alba candidissima*, and *N. Marliacea Chromatella*. Being very anxious as to their condition, I had large blocks of ice cut out. The roots were frozen solid in the soil to a depth of 6 inches and had to be cut out with an axe. Several of each variety were thrown under a greenhouse bench to thaw out, when it was found that not a single bud on them was injured in the least, and they are now making good growth in a tank of water. It is very likely that other varieties will also stand freezing of the roots, but this can only be determined by actual tests, as some varieties may be more susceptible than others.

NYPHLEA ODORATA is our own well-known fragrant Water Lily, and is considered by many the most beautiful of hardy varieties.

N. ODORATA ROSEA has beautiful rose-coloured flowers, and is known as the Cape Cod Pink Water Lily, because it was first discovered there many years ago. It is now extensively cultivated and is generally considered the most lovely of hardy varieties.

N. ODORATA SUPERA is a fine variety with larger flowers than the type.

N. ODORATA MINOR is a variety having flowers only about one-half the size of the common one, and is very pretty. It grows in abundance in the ponds of New Jersey.

N. ODORATA SULPHUREA is a new variety with yellow flowers and will no doubt become a great favourite. Its foliage is mottled with reddish purple and brown spots.

N. ODORATA EXQUISITA is a new variety with rosy carmine flowers of a deeper shade than those of *N. odorata rosea*.

N. ODORATA GIGANTEA is a native of Florida, where it was discovered two or three years ago. Both flowers and foliage are larger than in the type. The flowers are more cup-shaped and are produced later in the season and it is a freer bloomer. The leaves are very large and thick, often measuring over 1 foot in diameter, and sometimes nearly 2 feet; their edges are ruffled and sometimes turned up, forming a slight rim after the manner of the *Victoria regia*.

N. ODORATA CAROLINIANA is the largest and finest of all the *odorata* varieties. It is supposed to be a cross between *N. odorata rosea* and *N. alba candidissima*, and was raised by Dr. H. T.

Bahnsen, of North Carolina. It has the vigorous habit and free-flowering qualities of the latter variety. The flowers are quite fragrant, from 4 inches to 6 inches across, and of a delicate salmon-rose colour, deeper in some specimens than in others.

N. ALBA is the common white Water Lily of Europe, the flowers larger and more freely produced than those of our common variety, but without fragrance.

N. ALBA ROSEA is a pretty pink variety of the preceding, but neither so deep in colour as our Cape Cod pink variety nor so desirable, as it is a poor bloomer.

N. ALBA CANDIDISSIMA is the largest and best of all hardy white Water Lilies. The flowers are pure white, the petals very broad, and much more waxy than those of *N. odorata*. It begins to bloom in May, and continues to bear its superb flowers in abundance until frozen up in autumn. With good treatment the flowers measure from 5 inches to 7 inches across, and I have counted as many as twenty-two open at one time on a strong plant.

N. TUBEROSA is the common native species of the Western States. It has large white flowers, but does not bloom well in cultivation.

N. PYGMÆA is the smallest Water Lily known, and is a little gem. It is a native of China and Siberia. Its flowers are white and about the size of a silver half-dollar, opening at noon and closing at night. It is a free bloomer, being the first to flower in the spring and the last in autumn.

N. PYGMÆA HELVEOLA is a good variety with light yellow flowers about 2 inches in diameter.

N. MARLIACEA CHROMATELLA is one of the very choicest and best of the hardy varieties. The plant has the vigorous habit of *N. alba candidissima*, and it flowers freely from May to October. The flowers are from 4 inches to 6 inches across, with broad petals of a beautiful light yellow and bright orange stamens. This variety should be grown in water 2 feet or more deep. If grown in shallow water its abundant foliage grows in a bunch so thickly as to hide the flowers, while in deep water its leaves spread out and float on the surface.

N. MARLIACEA ALBIDA has medium-sized flowers of a pure paper-white, resembling those of *N. alba*.

N. MARLIACEA CARNEA is of a delicate blush or flesh colour, and a charming variety that will become popular.

N. MARLIACEA ROSEA is of a delicate rose colour, deeper than the preceding, and a great acquisition.

N. LAYDEKERI ROSEA is the newest and one of the finest of the small varieties. Its flowers, which are freely produced and about 2 inches across, are of a peculiar rosy purple colour in the centre, shading to white at the tips of the petals.

Nymphæas cross with each other very readily, but the raising of new varieties in this way is yet in its infancy, and the possibilities in this direction have only just begun to be realised. The time is not far distant when varieties will be much more numerous than now. *M. Marliac*, the French grower to whom we are already indebted for some of the choicest varieties, has two superb novelties which will be flowered for the first time in this country at the Chicago Columbian Exposition. One of these has been named *N. Laydekeri rubra punctata*, and has large flowers variegated with brilliant red. The other, named *N. Marliacea flammea*, has flowers of an amaranth-red with orange-red stamens. Several American growers are also doing good work in this line. Benjamin Grey has a beautiful new variety which has been named *N. Greyæ*, it is a cross between *N. gracilis* and *scutifolia*. In habit it resembles the latter, but the flowers are of a bright rose-pink, are larger than those of *N. zanzibarensis*, and borne on stout stems from 15 inches to 18 inches above the water. It is a great acquisition. William Tricker, of Staten Island, has a new variety, not yet named. It is a seedling of *N.*

dentata, supposed to be crossed with *N. zanzibarensis rosea*. The petals are wider than those of *N. rubra*, and more like those of *N. Sturtevantii*. They are white at the base, shaded to rosy carmine at the tips. Some varieties of Water Lilies are easily grown from seeds, and it is exceedingly interesting to watch their development from the seeds to flowering plants. The easiest to raise from seeds are the *Nymphæa zanzibarensis* varieties, *N. scutifolia*, *N. cœrulea*, and *N. dentata*. The seeds should be sown in February or March in small pots of good soil well firmed down. Scatter the seeds on the surface and cover with an eighth of an inch of fine sand. Then they should be immersed in a pan of water deep enough to cover the tops an inch or two. The water should be kept at a temperature of from 75° to 80° until they germinate, which will be in from six to ten days. If the temperature is much less than that named they will not germinate at all, or only after a long time. The seeds of *N. dentata* require about three weeks. Before the plants get crowded they should be transplanted to 3-inch pots, and be shifted to 4-inch, if necessary, before the time to plant them out in June. Those who have no greenhouse can start the seeds near a stove in the dwelling-house where the water will keep at the right temperature, moving them to a hotbed, cold frame, or a warm, sunny window when up. The little plants grow with astonishing rapidity under proper conditions, and begin to bloom in about 100 days. I have had the Zanzibar varieties begin to flower in sixty-five days from seeds started in June. These varieties are particularly well adapted to tub culture. The *Victoria regia* is always propagated from seeds, which should have the little caps or shells that cover the germs carefully removed before sowing. Plant in 5 inch pots in February, covering them with an inch of soil. The water should be kept at a temperature of about 90°. They germinate in from fifteen to twenty days, but are always more or less uncertain about coming up even with the best of care. The Nymphæas are interesting plants, resembling the *Nymphæas*. They have yellow flowers borne on stems above the surface of the water. *N. advena* is our common native species. *N. pumilum* is a pretty species of smaller growth. *N. japonicum* is a new species from Japan. *N. luteum* is a European species. The

LOTUS, OR NELUMBUM,

is one of the most magnificent of aquatic plants. Its grand circular foliage (sometimes 2 feet or more in diameter) and gorgeous flowers rise 4 feet or 5 feet above the surface of the water. Its flowers are produced freely from June to September, each flower opening four times. At first they are cup-shaped, but on the last day they expand to a diameter of from 6 inches to 12 inches. There are two species and several varieties, all of which are hardy here, having endured four or five winters where ice formed a foot or more thick over the roots. They can be grown in any warm pond with a rich, muddy bottom, in water not more than 2 feet or 3 feet deep. There is no reason why Lotus ponds should not become as common in this country as they are in Japan. The plants spread rapidly by means of runners beneath the surface of the mud, these runners often travelling several rods in a season. Thick tubers are formed deep in the pond during the latter part of summer, which live over winter. The best time to move and plant them is in the spring, when they are just starting into growth, which is the latter part of May in this latitude. The tubers should be covered 6 inches or more with soil. The Lotus can be easily grown in large

tubs, which should be moved to a cellar in winter, or cemented basins can be made in the lawn, where it would do still better. If grown in a water garden with other aquatics the roots must be confined in compartments to prevent them from injuring other things. Make partitions of bricks, set on edge in cement, and high enough to come a little above the surface of the soil. The soil should be very rich and not less than a foot deep.

NELUMBUM LUTEUM is the American Lotus, a native of the Southern and some of the Western States. Its flowers are of a sulphur-yellow colour.

N. SPECIOSUM is commonly called the Ezyptian Lotus, and is the Sacred Lotus of the Hindoos. Its flowers are creamy white, shading to pink at the tips of the petals. This does best in a rich clay soil.

N. SPECIOSUM ROSEUM has flowers of a bright pink, shading to bright rose at the tips of the petals. This variety makes a stronger growth with me than *N. speciosum*, and is in every way superior to it.

N. SPECIOSUM ALBUM GRANDIFLORUM has large, pure white flowers.

N. SPECIOSUM ALBUM STRIATUM is white, splashed and marked with crimson on the edges of the petals, and is a superb variety.

LIMNOCHARIS HUMBOLDTI is a showy plant bearing an abundance of lemon-yellow flowers all summer. It is commonly called the Water Poppy, from the resemblance of the flowers to those of the California Poppy. It has oval floating leaves, and multiplies by means of runners which creep about in shallow water. It succeeds best in water not more than 6 inches or 8 inches deep. It is half-hardy, but must be wintered in a house.

L. PLUMERI is a fine, tender species 1 foot or more tall, with rich, velvety green leaves and spikes of small lemon-yellow flowers.

EICHORNIA CRASSIPES MAJOR, which has been given the appropriate common name of Water Hyacinth, is of very easy culture and great beauty. Its glossy, dark green leaves have thick, bulb-like leaf-stalks filled with air, causing the plants to float on the water. It bears large spikes of delicately coloured flowers resembling in form a spike of Hyacinth blooms. Each flower is 2 inches in diameter and of a soft lilac-rose colour, with a blue blotch near the centre, enclosing a golden yellow spot. It will grow and flower if left floating on the surface of the water, but grows and flowers much better if set on the edge of a pond, where it can grow in the soil. Here it will soon spread and form a large mass of plants, and bloom freely for several months. It can be grown in the house in winter in a tub, pan, or anything that will hold a little rich soil and water. It makes a very interesting window plant, and would be well worth growing even if it had no flowers.

E. AZUREA is a very choice and beautiful species from Brazil. Its flowers resemble those of *E. crassipes major*, but they are light blue with a deep indigo-blue centre. Its manner of growth is entirely different; it branches freely and creeps about on the surface of the water very much like a Verbena on dry land, each plant covering a space from 3 feet to 5 feet in diameter, and it keeps in bloom all summer.

PONTEDERIA CORDATA, our native Pickerel Weed, has spikes of blue flowers, and is well worth growing on the margin of an aquatic garden. There is a fine white variety of this species which was sent me from New Hampshire last year.

LIMNANTHEMUM INDICUM—the East Indian Water Snowflake—is an exceedingly pretty and interesting aquatic recently introduced. The plant throws up leaves to the surface like a Water Lily, and the flowers are borne in clusters on the petioles near the blade; roots are also emitted at the same place, forming a new plant. The flowers are pure white, an inch or more across, and thickly covered with a growth of hairs, like the *Mrs. Alpheus Hardy Chrysanthemum*, but much more numerous. In a tub or shallow pond it will flower all summer, and all winter in a warm room or greenhouse. It

will stand considerable freezing without injury, but must be wintered in a house.

L. NYMPHEOIDES is the European Floating Heart, with pretty golden yellow flowers. It is perfectly hardy, and should be introduced with caution in an aquatic garden, as it spreads very rapidly and is liable to become a nuisance unless care is taken to keep it in check.

L. LACUNOSUM, the native species, is pretty and interesting with its clusters of white flowers.

L. TRACHYSPERMUM is a native of the Southern States, and resembles *L. indicum*, but does not have the hairy growth.

MYRIOPHYLLUM PROSERPINACOIDES is a native of Brazil, and has been given the common name of Parrot's Feather, on account of its beautiful pinnate leaves. It grows in shallow water, and is one of the prettiest plants that can be imagined for a water-tight hanging basket, vase, or tub, containing some rich soil, and kept filled with water. Several plants should be set around the edge, and they will soon trail over the edge several feet in the most graceful manner, completely covering the vase or basket with the most beautiful foliage. It is not quite hardy.

SAGITTARIA JAPONICA FLORE PLENO is a very choice double-flowered Arrowhead from Japan, and is perfectly hardy. The flowers are white, nearly as large and double as a Balsam. It grows best in water not more than 6 inches deep.

S. MONTEVIDIENSIS is a very large tender species, growing 3 feet or 4 feet high, bearing spikes of large white flowers with a crimson spot at the base of each petal. It is easily grown from seeds, and should be treated as an annual.

OUVIRANDIA FENESTRALIS, the Lace-leaf Plant, is one of the curiosities of the vegetable kingdom. It is a native of Madagascar, and has long, narrow leaves, which spread out horizontally beneath the surface of the water. They are of a dark green colour, and are merely a network resembling a skeletonised leaf or a piece of lace. It can be grown in a warm house in pots of rich soil immersed in a pan or tub of water kept at a temperature of about 70°.

CYPERUS PAPYRUS is the Egyptian Paper Plant, and should be in all collections of aquatics. It has triangular stalks from 5 feet to 8 feet tall, supporting at the top an umbel of long narrow leaves. It grows best in rich soil and shallow water, and is tender.

C. ALTERNIFOLIUS resembles the preceding, but is of smaller growth with wider leaves.

C. STRICTUS is also a desirable species. It grows 6 feet or 7 feet high.

ZIZANIA AQUATICA is a highly ornamental annual Grass from 6 feet to 10 feet tall, which grows in abundance in the lakes and rivers of the Western States, where it is known as Indian Rice. It has been introduced, and is now naturalised in some places in the Eastern States, growing in shallow water. Care should be taken not to allow the seeds to scatter about, or it may become a nuisance in a water garden.

AZOLLA CAROLINIANA is a pretty Moss-like plant which floats on the surface of water, covering it like a carpet. When grown in the shade it is of a beautiful green, but is tinged with red in the sun. Patches of it here and there have a very pretty effect. It increases very rapidly, and soon becomes so abundant, as to be unsightly if too freely introduced.

PISTIA STRATIOTES, or Water Lettuce, is a native of Florida. It forms a rosette of beautiful velvety yellowish green leaves, and floats on the surface of the water, or takes root in the mud in shallow places. It needs a warm, shady place in the house.

SALVINIA NATANS is a little floating plant with soft, green, hairy leaves.

APONOGETON DISTACHYON from South Africa—sometimes called Cape Pond Weed—is a very fine tuberous-rooted plant, with oval floating leaves and forked spikes of very fragrant white flowers. It is hardy if planted below the reach of frost, or it may be grown in a tub in a greenhouse in good rich soil.

There are many other species and varieties of aquatics, some of them natives of this country, which are interesting and could be easily introduced into a water garden, but the above list contains the most valuable of those in cultivation at the present time.

THE VENICE MALLOW.

(*HIBISCUS TRIONUM*.)

WHEN seen at its best, few annuals are more admired or more worthy of careful cultivation than that represented in the accompanying engraving. Those who are well acquainted with the typical *H. Trionum* as commonly found in old-established mixed borders, beds, &c., and rarely absent from good collections, will at once see the immense improvement in the present

The Venice Mallow (*Hibiscus Trionum*).

plant. *H. Trionum* appears to be an extremely variable species, and little wonder, seeing the length of time it has been cultivated in gardens, and also the fact of its being so widely scattered over all the warm regions of the Old World. It is usually described as a common sub-tropical weed, found plentifully in cultivated fields in Afghanistan. Specimens of it, which, however, were very small-flowered—indeed, not so large as what we look upon as those of the type in gardens—were collected near Khorassan by Dr. Aitchison, of the Afghan Delimitation Commission. It is found in several places in China, and is a very common weed in waste garden ground and rich damp soil throughout the Cape Colony. It has given rise to almost innumerable varieties, a few of which are so distinct as to have at one time been considered species.

The present plant was introduced by the Royal Gardens, Kew, seeds having been re-

ceived in 1888 from the Orange Free State and Zululand, but chiefly from the Spitzkop Mountain, 11,000 feet high, and Drakensberg, 8000 feet high. It is probably a cultivated form, as none of the dried specimens from any other part of the Cape quite agree with it in size of flowers, &c. The great objection to the type (figured in the *Botanical Magazine*, tab. 209) is the short-lived flowers, which Gerard says open at eight in the morning and close at nine, and which supposed fact gave rise to the curious appellations, "Flower of an hour," "Good night at noon," or "Good night at nine."

In the plant figured, however, this objection is quite done away with, the flowers opening in the morning, and, on bright days, remaining so until late in the afternoon. Individual flowers do not last very long, but there is such a succession on a well-grown plant as to always ensure plenty of blooms open at one time, and these are so large and beautiful as to entitle the plant to a place in the greenhouse, its effectiveness in pots having been already proved. It is for open-air culture I would, however, most strongly recommend the above variety. It is quite as hardy as the one usually grown, seeds as freely, and withal is so much more striking and beautiful, that the effect of large clumps of it would certainly not fail to attract admirers. Like other hardy annuals, it needs no care in sowing in spring—simply scattering the seeds in the open on the spots where they are intended to grow, thinning, where too close together, to 6 inches or 1 foot apart, and leaving the sun, &c., to do the rest. It will even sow itself, the seeds coming up in plenty the following spring if the winter has not been unusually severe, but sowings should be made at different periods to ensure bloom all through the summer and autumn. There are, I believe, several annual species of *Hibiscus* found at the Cape, but this is the only one, I think, in cultivation, although the others are said to be equally beautiful. D. K.

Hardy Cyclamens.—I am glad to see the attention of your readers called to these beautiful plants. They are charming things for the wild garden. By far the best is *Cyclamen hederæfolium*. I have grown this species in a wood for a long time. It thrives anywhere under trees, even where nothing else flourishes, although it is, like everything else, much finer in good soil. The ornments increase in size year by year; some of those I have must bear at least twenty-five or thirty flowers at a time. *C. hederæfolium* blooms late in the year, but the leaves, which are most beautiful, remain until summer comes round again. It produces seed in abundance, but the seeds do not ripen with me before the winter, and then the birds get them. It is very easy, however, to ripen the seeds artificially, and there is no difficulty in raising young plants in a cool house. I remember seeing this plant in a garden at Caen, in Normandy, and it was there seeding about all over the place, but I have never known it to seed naturally at Cringleford. Some years ago I brought some roots from Algeria of a plant which the Algerian botanists call *C. africanum*. It seemed to me the same as *C. hederæfolium*, but none of my specimens sur-

vived the following winter, so that I could not compare the two forms. Plants which are called *C. græcum* and *C. neapolitanum* are nearly allied to *C. hederæfolium*, but I do not know much about them. I brought some roots of the *C. neapolitanum* from Italy some years ago, but they did not grow. *Cyclamen europæum* is quite a different plant and not nearly so pretty. It is not uncommon in some parts of Switzerland, and where it does grow it is very abundant. Near Ragatz there is a large forest as full of it as a Norfolk wood often is of Primroses. *Cyclamen coum*, which resembles *C. europæum*, is very charming in the early spring, and should be largely grown by those who enjoy wild gardening. I do not know any hardy plants which give less trouble or more pleasure than do these hardy *Cyclamens*.—F. W. HARMER, *Oakland House, Cringleford, Norwich.*

FLOWER GARDEN NOTES.

WORK in connection with the flower garden for the past week has been the final clearing of all mixed borders, the late visitation of rather severe frost having settled almost everything in the way of flowers, except occasional blooms of *Violas*. This removal of dead and dying vegetation requires a considerable amount of care this year, as many bulbs are already pushing through. As the work progresses, any herbaceous plants that may be in a weakly state should be removed and their places filled either at once by division of other things, or later with young plants that have been wintered in frames. If the invalids are special favourites and the stock is rather limited, they may be placed on a border to be, if possible, nursed back to health. It sometimes happens that things are placed in the hurry of planting in unsuitable soil, and a change to a more congenial compost is all that may be required to bring them into a healthy state. It may be well to remind those who contemplate the introduction of herbaceous plants into their flower gardens that the selection of these things in variety should depend greatly on the purpose for which they are required; thus many things that would commend themselves to the plant lover as rare and choice specimens in their different species would be of little use where two principal requirements are, general effect on the several borders and plenty of cut blooms. Accuracy of judgment in such matters is not gained in one or two seasons, but has to be acquired by careful study, first of the species, then of the many varieties that are often available, their heights, time, and duration of flowering season. Any time from now until the end of the year before work presses heavily in the houses may be devoted to the preparation of several plants that may be required for special flower garden work another year.

Cuttings of *Francoa ramosa* if not already in should be inserted at once singly in 2½-inch pots in a good open compost, and, in common with old plants that can be shaken out and repotted if they are likely to be required, will stand well on the back shelf of a vinery or Peach house. Good large bulbs of *Galtonia candicans* may be potted singly in 8-inch pots and stood in a cold frame from which frost can just be excluded, and nice clumps of *Funkia grandiflora* in pots, pans, or small tubs may occupy a similar position. There are few things that cover more quickly or effectually as summer climbers than *Cobæa scandens* and the variegated variety, and if there is a supply of old plants, they can be cut back and potted up from their outdoor quarters. Seed of the *Cobæa* does not always come away kindly in the early year, and if a number of plants are required, the old stuff is likely to be very handy. Specimen plants of such things as *Aloysia*, *Heliotropes*, scented *Pelargoniums*, &c., that are now inside may have all dead and decaying matter in the way of flowers and leaves promptly removed and be lightly tied in to render them presentable in their winter quarters.

BEDDING BEGONIAS—I am sorry if any remark in these notes conveyed the impression of an altogether unfavourable opinion of the above as sum-

mer bedders; on the contrary, I have always regarded them as among the very best plants for the purpose, with, it must be understood, certain reservations. So far as the past summer was concerned, for instance, in all gardens with a naturally dry light soil and possessing no facilities for watering thoroughly and repeatedly, they have certainly not done well. True, the showers early in September and a short spell of dull cloudy weather set them up for the remainder of the season, but that hardly made up for the indifferent display earlier in the summer. Again, I cannot admire in the flower garden those varieties with heavy drooping flowers; even when planted very thinly on a dwarf carpet one can see little of their true character, whilst for a mass of glowing colour they cannot compare with Henry Jacoby, King of Bedders, or Beckwith's pink *Pelargoniums*. The erect and semi-erect flowering section is, however, a different matter; they may take rank in the majority of seasons with the best things in the flower garden. Among later things in *Begonias* for a similar purpose is the fibrous-rooted *semperflorens atropurpurea*, and those readers who have not already given it a trial should not fail to order a packet of seed. Sow with the tuberous-rooted section at the end of January or early in February, and grow on quickly. Mistakes in planting this charming novelty are not easily made; it looks well mixed with silvery *Centaureas* and *Cinerarias* on a carpet of *Mangiesi Pelargonium* or *Koniga variegata*, or associated with other things in ribbon borders, although this last is the least satisfactory. It would also make a fine vase plant, especially for large vases where a good mass of flower and foliage is required with an edging of a light-flowered Ivy-leaf or *Gnaphalium lanatum*.

Claremont.

E. BURRELL.

NOTES ON HARDY PLANTS.

Lithospermum fruticosum.—Latterly we have been told that this is identical with *L. prostratum*. Is it really so? *L. fruticosum* of Linnæus is a very different plant to *L. prostratum* (Lois.). The latter plant is much more herbaceous, so to speak, and has longer stems, with leaves more distant, and these stems are prostrate all their length; in other words, the growth has more the tendency to spring from the ground line or plant collar. *L. fruticosum*, as I grow it, and which agrees perfectly with the Linnean description, has at first a more erect habit and then the growth is short and twiggy, always so, and the young twigs soon assume a woody texture; in fact, in harmony with its specific name it is much the more shrubby form. With all these distinctions it is not impossible that one may be a variety of the other, for have we not the authority of Lehmann that Linnæus' *fruticosum* is a variable species. I would not have troubled the reader about this matter only that it becomes important that we should recognise the different forms for practical gardening purposes. *Lithospermum prostratum* as generally recognised is a favourite plant. It is also a fact that in many places it fails to survive a cold winter, and it is precisely because I believe (indeed, have proved) that the Linnean plant *fruticosum* is much hardier than the true *prostratum*, that I draw attention to the point; and as the two forms indiscriminately go under the one name *prostratum*, it may be worth our while to try to get the true Linnean form *fruticosum*. Some plants of this have almost the habit of miniature standards, but apart from that feature the plant could be readily recognised when side by side with *prostratum* by its shorter and stiffer twigs and shorter and more bristly leaves, which have also a slightly incurved habit. Besides being the hardier plant, it is of closer growth and does not make an inconveniently large patch in one season of 2 feet to 3 feet, like the more sprawling and true *prostratum*.

Salix amplexicaulis.—I have had but very slight experience of this Willow, yet for two reasons I pen this short note. One is to say that it is as beautiful as other bright-barked varieties, but its effect is most distinct by reason of the habit of

the beautiful glaucous foliage. In the common acceptance of the term *amplexicaulis* the leaves are not so, but being almost erect with the stems and incurved in relation to the midrib of each leaf, the leaves have the effect of enfolding the stem, especially as seen at a short distance. When the leaves fall the bark is of a shining reddish yellow. The other reason for this note is that I wish to inquire of anyone who had tried it for one or two years to what stature it attains. I care say that the best information that I can expect must be imperfect on this point, as I think the plant is quite new. I have somehow got an impression that it will be a lively and charming object for the rock garden, but I may be wrong if it grows too strongly, only there is no plant or shrub that can be beheaded or pollarded with more impunity than Willows.

Galanthus robustus (Baker).—It is evident already that this Snowdrop is distinct. It is already bursting into flower, which is anything but desirable; still it shows at least some of its distinct qualities. On the matter of earliness it may not be much to say that the flowers are already appearing, because I believe all the bulbs as yet in this country are newly-imported ones, and we know that bulbs from certain warm climates often prove abnormally early (for us) the first and even the second year.

Gentiana acaulis.—I believe in most gardens the *Gentianella* is fitful in its blooming habit, and it is no uncommon thing to see a sprinkling of flowers all the summer after the main crop, and even in winter, but it is not given to us every year to see the flowers so fresh and fair and large as we see them now in mid-November. Whilst speaking of a *Gentian*, and especially of the species most noted for going to extremes as regards flowering in different gardens, I may say I have given Dr. Clark's theory of counter irritation at the roots by means of sharp edged particles a good trial, and in the second year I must say that I have experienced a welcome difference and improvement where this plant used formerly to scarcely ever flower at all. I do not think that there is much in the theory of very cold water drenchings in summer—at any rate, in the case of this species—because it is well known that the buds are nearly a whole year in forming, and I know of a garden where the *Gentianella* flowered with greater freedom than ever I saw it anywhere else, and it was exposed fully to the south, the long, broad edging of it fronted by stones standing at least 1 foot above the walk surface on the south side, so that, so to speak, the sunshine could play on the surface of two sides of the square.

Sweet Violets.—I am induced to pen this note because a variety of Sweet Violet which has been grown here for the past eight years, and nameless, as it reached me from a German nobleman, never fails to yield an abundance of flowers without either special protection or special culture. It simply grows in a broad dense mass, and at all reasonable seasons it is full of leaf, and scarcely ever, except in the direst winter season, flowerless. I am sure it is not because of any peculiarity of position, as it came to me specially recommended as a perpetual bloomer, and others who have taken a few roots into their gardens have a similar experience of it to my own. Indeed, it was in a friend's garden the other day that I saw his plants (set last summer) almost blue with bloom. I have no doubt that with liberal treatment it would do even better, because the outer runners taking possession of the fresher soil are always the most liberally flowered. I can see no difference in the plant or the flowers from the ordinary sweet, single, dark blue kind, and my reasons for believing it to be a distinct variety are based on what I was told, and which I find to be correct, that it blooms with a persistency and freedom found in no other Violet.

Aster grandiflorus.—Several plants pass under this name. That is not saying much for an Aster, as many species have had fictitious representatives. But the wonder in this case is that it could be so, the true form having several

peculiarities. All this, however, would not matter much were not the true plant worth possessing. It is a stately Aster, and produces heads of great beauty and richness. It is perhaps one of, if not the bluest of all the Michaelmas Daisies. It has a bold and pleasing habit, with foliage of a distinct type. I am not going to try to describe it; it should be seen, and seen in flower. In ordinary summers it might not flower in the open garden. This is a drawback, but for all that it should be grown. It is worth growing for stock and potting in the spring, to be flowered in the cool conservatory in the Chrysanthemum season. It has, however, flowered well in the open air this year, but we do not get many summers like 1893.

Gentiana Saponaria.—There are three authorized plants under this name, but though the Linnean plant is what we may term the true and certainly the more fully authenticated one, the other plants bother us. For instance, *G. Saponaria* (Fries) is the well known Andrews, and *G. Saponaria* (Walt.) is identical with *G. ochroleuca*, odd as that may seem. *G. Saponaria* (L.) is also the *G. Saponaria virginiana* foils of Moris, and *Pneumonanthe Saponaria* of Schm.

Campanula muralis (Bavarian variety).—Mr. Arnott (p. 454) does me the honour to read and take exception to what I have said about this beautiful variety, and his remarks may possibly deter some growers of the dwarf or alpine *Campanula* from taking this in hand. That would be an injustice to the plant. May I ask if he grows the plant, or has he watched its summer-long habit? If he has, I can only express my surprise that he has had anything but praise for the plant; and if he has not grown it for at least a summer, if he will excuse me saying so, he has insufficient ground for the opinion he has given. My remarks about the plant were very brief (p. 436), and all embraced in six lines. I sought to emphasise more the showier flowers and their remarkable succession, and I may add to what I then said, that even yet, after three severe nips of frost, it affords one of the best bits of blue in the garden. I agree with Mr. Arnott that it would not be desirable to increase the vigour of many plants, but I scarcely think this is one of them, being naturally a small species with flowers scarcely in proportion to its herbage, so that in this case, if the little extra vigour yields more blossom in size, quantity, and succession, I think it is a case in which most people would consider these features a gain.

Chelone Lyoni.—It is true that this and other species of Tortoise Flower, or what our American friends know by the name of Snake's-head, are rarely seen perfectly happy. If I may make such a bold statement, I believe that the general cultivation of this genus has never yet been what it should be. The usual stature of this species of about 2 feet to 3 feet, the crowded spikes of bloom, and the brown pointed foliage occurring before the plants have arrived at maturity, are all proofs that the plants are not cultivated up to their capabilities. It is all explained in a word. *Chelone* is naturally a bog plant. Grown as such, it attains a stature of 4 feet. The flower-spikes are then longer, the flowers bigger and brighter, and the whole plant has a more verdant aspect. As we are used to seeing it, it is not worth having, but well grown in boggy vegetable soil, it is a noble plant, keeping bright for many weeks. The root habit of the plant indicates a want of annual mulch, such as we may reasonably conclude that it receives in its boggy habitat in a natural way. We often see it in borders with its roots in matted form visible on the surface, and consequently soon dried up. Its new roots spring from a higher part of the stem every year.

The German Iris.—Many would not think it possible to kill this Iris by untimely transplanting, but it is if you divide it in winter and do not have behind the leading growths of the old rhizome. From spring to mid-autumn the roots are very active, but in very cold weather the more sappy exes of rhizome are apt to rot after rupture by frost in the damp soil. You may plant either shall

low or 3 inches to 4 inches deep, but as a rule you will find that the flowers will be scarce until the plants have developed the root-stock or rhizome on the surface. A mulch in spring will be useful, but there should be nothing like a permanent top-dressing attempted that would keep the rhizomes covered; their function is to receive the light and sunshine.

Woodville, Kirkstall.

Campanula muralis.—In answer to Mr. S. Arnott's note in THE GARDEN of November 18, will you allow me to state that *Campanula muralis* (Portensch.) and *Campanula Portenschlagiana* (Roem. and Schult.) are synonymous. Portenschlag found it in 1830 in the mountains of Dalmatia, and labelled it in his herbarium as *C. muralis*; but meanwhile Roemer and Schult. published the same plant under the name of the founder, so that that name, according to de Candolle's "Lois de la Nomenclature Botanique," must be considered as the right one. However, as the name *muralis* is much more correct and able to give the character of the plant, I, in the *Jardin Alpin d'Acclimation* in Geneva, as well as in the botanic garden of the Linnaea, give that name to this *Campanula*, and we sell under the name of *muralis* the *C. Portenschlagiana*. I cannot understand, as the plant does not grow at all in Bavaria, why it is spoken of as a Bavarian variety. Is the quite different, although nearly allied, and Italian *C. garganica* confused with it?—H. CORREVON, Geneva.

Carnations and Roses at Farnham Castle.—The keep around the castle was till recently a fruit garden, and as such not at all in keeping with the surroundings. It is now devoted to Roses and Carnations—a happy combination. The beds are in keeping with the surrounding building. A grand old vase and fountains occupy the centre or round bed, and around this is a series of square and round beds, the latter being small and filled with choice Carnations, which do splendidly. This garden has only been recently formed by Mr. Dowding, and it is a great addition to the castle. The work was carried out under great difficulties, as being so high above the other portions of the garden, every bit of turf, gravel, and soil had to be wound up by a pulley. Creepers clothe the banks in all directions, trailing gracefully round the few low vases dotted here and there. These vases, which are of great age, are quite covered with Moss and Lichens. The approach to this beautiful spot is formed of rough steps.—G. WYTHES.

Eschscholtzias.—The late Mr. Charles Perry, when an amateur Rose cultivator at Birmingham, used to adopt the practice of growing *Eschscholtzias* among his standard Roses, and, as he always said, to his entire satisfaction. That he obtained brilliant effects was patent to all who saw his Rose garden when his favourite annuals were in bloom, and one saw large bushes with deep orange, yellow and lemon-coloured tulip-shaped flowers rising above the graceful foliage in thousands, growing high enough to hide a good portion of the naked stems of the Rose trees. Mr. Perry always held no harm was done to his plants or the bloom they carried; indeed, he considered that in summer on dry land the *Eschscholtzias* were beneficial, keeping the soil cool; and, as he said with some truth, if it is necessary to have such a covering, let it be something beautiful to look upon. Since Mr. Perry grew his *Eschscholtzias* several fine new varieties have been raised. In his day he had the lemon coloured *E. tenuifolia*, the yellow *E. californica* and the golden *E. crocea*. The varieties have since been extended by the introduction of the white form of *E. californica*, the rich, the pretty and distinct rosy carmine *Rose Cardinal*, which is regarded as a variety of *E. grandiflora*, and the rich deep orange *E. Mandarin*, which, though placed in seed lists as a variety of *E. crocea*, actually came from *Rose Cardinal*. Doubtless other annuals would serve the purpose of carpeting beds of standard Roses, but perhaps nothing more lasting, brilliant and graceful than the *Eschscholtzia*. Mr. Perry made a practice of sowing seeds in

his Rose beds in December, and by so doing he had the plants at their greatest beauty at the time the Roses were in bloom, and they continued to flower in good condition until September, when the plants were all pulled up in order that the soil should not be made sour for the autumn. Originally grown as a biennial, the *Eschscholtzia* blooms much better as an annual, and never, perhaps, so finely as when autumn-sown. I have seen in Mr. Waterer's nursery at Knap Hill plants of *Eschscholtzias* raised from seeds sown in late autumn that were marvellously fine, and it is not too much to say that the *Eschscholtzia* is among the hardiest of annuals. When the seeds are sown broadcast the plants come up thickly, and it is necessary they be thinned out 12 inches to 15 inches from each other, so as to afford ample room. They are much better sown in the open than when transplanted.—R. D.

THE HOLLYHOCK.

I LOOKED over a garden well furnished with hardy plants the other day. Amongst them was a number of Hollyhocks raised from seed, all of which were smothered with the deadly disease. The most remarkable part of the story is that they were raised from seed during the present year, and no other Hollyhocks of any kind were near them. Mallows carry the disease on the leaves, and Mallows are everywhere, but no diseased Mallows were known. Some seasons it does much mischief, destroying every green leaf before the flowers are developed. I have thought that soft soap and sulphur would kill it; Condy's fluid and other things have been tried, but they do not make a thorough clearance of the disease.

I grew about 150 plants this year in the garden at Great Gearies, and the disease appeared in the summer, but it did not in any way cripple the plants so that their flowering was prevented, and now they are growing clean and healthy from the base. The Hollyhock is a comparatively hardy plant, and established seedlings that have not flowered brave the severest winters unscathed. Not so the old plants that have flowered; they may be killed, and it is not safe to depend upon them passing through severe frosts. The gardener has, therefore, to do two things at this time of the year (November); he has to look to the safety of his old plants and prepare the ground for another year.

The Hollyhock needs a plentiful supply of rich food and deep soil to grow in, and it is well to trench the ground in time to allow of its being well exposed to the frosts of winter. Give a good dressing of rich manure, and if the ground has grown Hollyhocks previously, it should be freshened up by the addition of some good loam. When I was a young gardener in Scotland some thirty-five or forty years ago, the Hollyhock was one of the most popular of garden favourites, and the late Mr. William Thorn, of Newtonton, near Kelso, was one of the best growers. He grew the plants year after year on the same ground. In those days the Hollyhock disease was unknown in this country. Mr. Thorn used to trench the ground about 2 feet deep in November or December; a layer of manure was placed in the bottom of the trench and another layer 9 inches or a foot below the surface, but with the top layer was placed a good thick layer of loam from decayed turves, and at planting time in the spring some of this loam with the addition of a little manure was placed around the ball of roots and gave the plants a good start.

There are two classes of plants, *i.e.*, those raised from eyes or cuttings taken from the growing plants in the summer even before the flowers are expanded, and cuttings taken from the old plants in the early spring. An old stool will produce from three or four to a dozen growths or even more, and these if taken off with a heel attached in the spring will usually root well if planted in small flower-pots singly, the pots to be plunged in a gentle bottom-heat in the forcing house. The summer

propagated plants are usually wintered in cold frames and they are always well ahead of the spring-struck ones. The latter also flower later; there are two or three weeks between their time of flowering. This is important when the object is to obtain good single blooms or spikes for exhibition, for if the lower flowers are gone, they cannot do much good on the exhibition table. In order to obtain good cuttings in spring, the old stools must now be taken up and potted. I use 8-inch and 9 inch flower-pots and find these quite large enough. We are now taking them up to be potted, and the plants are placed on a shelf not far removed from the glass roof of a vinery or Peach house. The frost is merely excluded by a fire during sharp frosts. The disease if it is amongst the leaves does not spread much in winter, not until the cuttings are placed in heat, when it spreads rapidly. The single-flowered Hollyhock is not much admired, but I saw some fine tall plants lately in a cottage garden which seemed to be a perfect paradise for the humble-bees; the spikes were very tall and well flowered and had an excellent effect. The florist goes in for the largest, fullest flowers he can get and would not grow the single-flowered varieties. The single-flowered Dahlia is now very popular, so also are Roses with single flowers. One day single-flowered Hollyhocks may become popular, but we may admire both without favouring too much the one or the other.

J. DOUGLAS.

TRITONIA AUREA.

TO THE EDITOR OF THE GARDEN.

SIR,—It is, I fear, somewhat presumptuous in me to question advice over the initials "W. W.," but surely there is some mistake in that given at p. 462 to dry off the corms of *Tritonia aurea*. When lifted in October new growths of 6 inches or more in length, and looking like very strong Couch Grass, will already have started. These will soon perish in any process of drying, and though the corms will no doubt start again, yet the finest growths should be preserved as in every way the best. In North Notts, at any rate, *T. aurea* will not succeed altogether in the open. It is not the cold of winter (that may be met by covering), but our late spring which stands in the way; the plants making a late start find autumn upon them before they have completed their summer growth, and by degrees dwindle away. *Montbretia crocosmiæflora* seems better able to stand our climate, and *M. Pottsi* is, I think, quite hardy. Neither of these, however, is to my mind equal to *Tritonia aurea* when at its best. I am without it now for want of proper winter and more especially spring quarters, but for some years I grew it very well under the following routine: The corms when lifted in October were at once potted in light sandy soil, the new growths being coiled (a little care is needed to prevent breakage) so as to bring the growing points just under the surface of the soil. During the winter the pots stood on the floor of an orchard house from which frost was barely excluded, and remained there until genial weather in April or May suggested their transference to summer quarters. These were a partially shaded spot in a light soil enriched with leaf-mould. During winter little or no water was given, just enough to prevent the soil becoming dust-dry, but when growth is active the plants like plenty of moisture with good drainage. A hot, dry position is not suitable, and soon shows its evil effects in red spider.

JAMES SNOW WHALL.

Worksop.

Crocospia v. Tritonia.—The plants represented in the plate in THE GARDEN last week are *Crocospias*, and not *Tritonias*. *Crocospia* (not *Crocospia*, as it is sometimes spelt) is a monocotyledonous genus founded in 1851 by Planchon, a French botanist, on *C. aurea*. This plant is figured in the *Botanical Magazine*, t. 4235, as *Tritonia aurea*. It is, of course, very near *Tritonia* proper, as is proved by the hybrids raised by M. Lemoine between *C.*

aurea and *T. Pottsi*. The genus *Montbretia* is still kept up, but it does not now include the plant generally known as *M. Pottsi*, which is a *Tritonia*. Mr. Wood and others interested in these plants will find their correct nomenclature in Mr. Baker's "Handbook of Iridæe," 1892 (Bell and Sons). The plants figured in THE GARDEN last week are grown at Kew as *Crocospia aurea maculata* and *C. aurea imperialis*.—W. W.

—There is evidently an error—perhaps change of labels—in the description and figure of the varieties of this plant in THE GARDEN of November 18. The flowers of *C. aurea imperialis* are of a reddish fulvous orange, and have broad, imbricated massive segments, much broader and fuller than those of *maculata*. No. 2 of the figures might agree with this. No. 1 scarcely agrees with Mr. O'Brien's *maculata*, which on the average is better, but, of course, it is difficult to reproduce exactly. I have not imported *aurea imperialis*, but have raised it from seed saved after twelve years of careful selection. I sold the stock of it to M. W. Hans Herrnhut in 1887, under the name of *C. aurea macrantha*, which he thought proper to change into *imperialis*. I had for some years preserved a series of flowers to show the gradual development and increase of the size of the flowers during my experiment which would have convinced everyone of the truth of my statements, but ultimately have thrown them away. I have been so ill treated and the origin of the plant so much disputed, that this shall be my last word about it.—MAX LEICHTLIN, *Baden-Baden*.

Dictamnus giganteus.—I obtained this from Holland a few years ago, and, like J. Wood, I could see no difference from the type until I compared the flowers and leaves; those of *giganteus* were about twice the size of those of the old *D. Fraxinella*. The height of the two varieties was about the same.—J. W. THOMAS, *Belmont, Carlisle*.

Nicotiana affinis in Ireland.—When well grown this is a beautiful plant, and possesses the additional charm of having an exquisite perfume. This perfume is only to be distinguished in the evening. The flowers close up during the day, and the whole plant seems drowsy while the sun is shining, but the moment that the shades of evening steal on, *Nicotiana affinis* opens wide its flowers and pours forth its fragrance far and near. I had a large number of plants this year. They were grown in the herbaceous border not only for their beauty and fragrance, but also on account of the attractive power that the flowers have for insects. In former years I have captured a number of the handsome *Sphinx convolvuli* on its blossoms. This is one of the largest of our hawk moths—indeed the largest, with the exception of *Acherontia atropis*, the death's-head. No *Sphinx convolvuli* appeared this year. My object, however, in writing this note is to mention that I have never seen finer specimens of *Nicotiana affinis* than I had in my garden this year. They were all, in fact, quite exceptional in their growth and the vast number of flowers they produced. One plant I measured was 4 feet 6 inches in height. It had seventeen flowering stems. One of these measured from the junction with the main stem 3 feet 8 inches. There were 328 flowers.—WILLIAM W. FLEMING, *Coolfin, Portlaoine, Co. Waterford*.

Primula Forbesi.—This, raised from seed in March, has been in bloom during the whole summer in my greenhouse. It may be considered an interesting rather than a showy plant, as the individual flowers are small, but growing in a mass, the slender intertwining silvery stems and lilac flowers attract attention. The crows were repotted a short time since and all flower-stalks and buds removed; but flowers are being produced nearly as fast now with only the shelter of glass, as in the heat of summer. It is a decided shade lover. Some plants in pans placed under a stage and overlooked were found to have flowers fully half as large again as those produced in full light, though carefully shaded from the hottest sunshine. A few seedlings put out in a sheltered border have also flowered continuously throughout the season and stood the first frosts very well, but the severer test

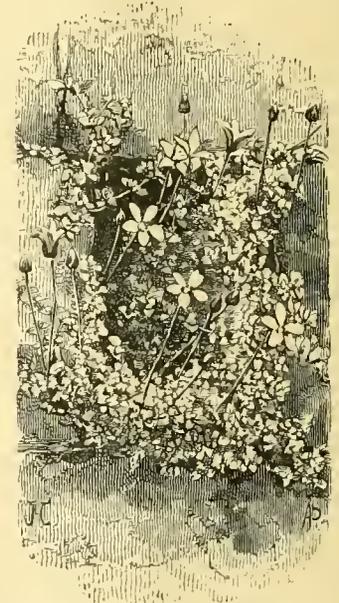

of the biting wind and frost of November 18 and 19 raises doubts of complete hardiness in our climate (Amman Valley, South Wales). It may be that the crows will remain dormant throughout winter and start again in spring, in which case *P. Forbesi* will be a valuable addition to the plants suitable for a shady alpine garden. In spite of its exceptionally free-flowering habit, it has not ripened seed, to my knowledge, during the past season, perhaps owing to over-flowering; but it is very possible that seedlings may spring up, self-sown, as in other *Primulas*, e.g., *P. floribunda*.—K. L. D.

GARDEN FLORA.

PLATE 938.

THE MOUNTAIN SANDWORT.
(WITH A COLOURED PLATE OF *ARENARIA MONTANA*.)

THE *Arenarias* are delightful rock plants in suitable positions in the garden. Mr. Moon made the coloured illustration from a dangling tuft of this species as growing in an elevated

The Balearic Sandwort (*Arenaria balearica*).

wall pocket in the College Gardens at Dublin in May of this year. As thus grown on the top of a low, half-shaded wall or on elevated rocks, the plant assumes quite a free and elegant habit, the masses of pure white blossoms drooping most gracefully, as shown in the plate. The plant is not so often seen as its freedom of growth and beauty would lead one to desire. It is readily increased by cuttings or by seed, which is very freely produced. The seed may be sown as soon as ripe in boxes of any light sandy soil to which old lime rubbish, in which these Sandworts generally delight, may be added with advantage. Cuttings taken off in April or May root quite freely, and by covering some of them with nodules of sandstone or other rock refuse, rooted plants can soon be obtained. Old straggling tufts and masses may be divided from time to time. As grown on the border or in ordinary low rockwork or amongst stones, the plant forms a

* Drawn for THE GARDEN by H. G. Moor in the College Gardens, Dublin, May 16, 1893. Lithographed and printed by Guillaume Severeus.

cushion-like mass, often so thickly covered with flowers that scarcely a leaf can be seen—in fact the plant has many phases of habit, according to the aspect and position in which it is grown. So far as I am aware, the best forms of *A. montana* are quite superior to all other Sandworts at present met with in our gardens, although nothing can well be daintier and more fairy-like than its relative *A. balearica*, which forms a dense Moss-like covering over moist sandstone, and is very lovely as seen thick set with its long-stalked pearl buds and white flowers. *A. montana* is a native of mountains in France and Spain, and is said to have been introduced as long ago as the year 1800. It is sometimes known in gardens under the name of *A. grandiflora*, which has, however, a shorter and more tufted habit of growth.

A. montana has appeared in lists of choice alpine and rock plants for the past ten years at least, along with other species and varieties, amongst which I need only mention *A. biflora*, *A. cæspitosa*, *A. purpurascens*, *A. triquetra*, and *A. verna*. F. W. B.

THE WEEK'S WORK.

THE KITCHEN GARDEN.

WINTER TOMATOES.—The ripening of winter Tomatoes will not be regular unless a warm, airy and buoyant atmosphere is maintained, and unless this is also regular the flavour also will be wanting. A minimum temperature of 58° or 60° is what must be aimed at, with a rise by day from sun-heat, this, of course, coupled with a little ventilation so as to keep the air moving. Anything approaching a close and moist atmosphere must be avoided. The soil will have to be kept fairly moist, this requiring more attention where the roots are wholly confined to pots than where these latter are stood so that the roots may work through into richer and warmer soil. Plants which are supporting good crops of fruit and also confined at the roots may have an occasional dose of tepid diluted liquid manure. In the case of plants in small pots a surface-dressing of richer material would be an advantage, using plenty of wood ashes in the compost. Keep all useless growths pinched out.

PROTECTING VEGETABLES FROM FROST.—Care will now have to be taken that Lettuce and Endive which are being preserved in frames are not injured by frost, as where these are of fairly large size decay sets in very rapidly if frost is allowed to reach them. In the case of severe weather the lights should have a thick covering of litter or Bracken placed upon them, and if the frost continues, allow it to remain on until this has passed away. The sides of the frames will also have to have some litter placed around. On the other hand, ventilation will have to be attended to on all fine days. Cauliflowers will also need protecting, but these must not be unduly coddled. Parsley will also require attention. This may be easily done if the plan I have frequently advised has been carried out. Once let Parsley become injured by a severe frost or beaten down by snow, decay will rapidly set in. Parsley must not upon any account be coddled, a free circulation of air being essential during damp or mild weather. Protection from frost and snow and a free circulation of air at other times are what is needed.

MANURE.—The preparation of manure goes a long way towards securing the best results from its use. The past season showed that what is termed solid manure obtained either from the stables, or, better still, from the cow-sheds, produces better crops when used in conjunction with artificial manure than where the latter only is used. Tree leaves form an excellent manure where they can be placed in yards to be trodden down by cattle, and this is what we are doing this season, straw being none too plentiful. Very often

the greater part of that which is obtained from stables is required for hotbeds, but, however this may be, it is necessary to well prepare the manure as it is obtained. Instead of carting it or wheeling it into a heap, it must be turned as often as necessary to ensure a regular decay, and be moistened with water if wholly composed of stable manure, that is, if at all dry. If it can be so stacked as to have a pit to catch the drainings which may be thrown over it, all the better.

SALADING.—The salading it is possible to maintain will to a certain extent depend upon the provision which has already been made. Where Endive is growing on the floors of vicereries and Peach houses, care will have to be taken that the soil about the roots does not become too dry, or the quality will be poor. To prevent this, water must be applied, pouring it through a small-spouted watering-can between the plants. Even where transplanted into frames, Lettuces as well as Endive will also have to be treated likewise if at all dry. Round-leaved Batavian is the best Endive, and with well-grown plants very little aid to secure blanching has been necessary, merely covering or drawing the outer leaves up together and tying being all that have been needed. As long as Endive will blanch in this manner it need not be removed to darkened structures. Witloof may be taken up as required, cutting off the old foliage to within an inch of the crown and forcing similarly to Seakale. Take care that the soil about the roots is moist. Smaller succession Cabbage Lettuce must have the lights kept over them, when almost every leaf of the growth that is made will be fit for use. A. YOUNG.

FRUIT HOUSES.

FORCING POT VINES.—There is less need than formerly to resort to hard forcing with a view to having ripe Grapes in April, Lady Downe's and Mrs Pince's Muscat keeping well till May and even later. At the same time, if fresh Grapes are wanted extra early, a start ought to be made at once. In some instances forcing has already commenced, but it is a very doubtful gain starting much before December. Hard-forced Vines are of little further value after the crops are taken from them, and that and also because they can be more conveniently forced is why pot Vines are most generally preferred. The canes of the latter ought to be strong, short-jointed, well ripened and strongly rooted in 12-inch pots or rather less. If they have been exposed to the severe frosts already experienced, they will start all the more quickly and strongly and probably overtake others that were started earlier. There should be no pruning at this late date, and the greatest care should be taken not to break or damage the canes, or excessive bleeding will most probably result. No cleaning or dressing with insecticides ought to be necessary. They must have the benefit of a gentle heat and moist ammonia-charged atmosphere, and this ought to be largely created by means of a hotbed of stable manure, previously prepared, and fresh Oak or other leaves. Set the pots on piers formed with loose bricks and build the hotbed up sufficiently high to well cover the pots. At first, or till it is seen the heating material will not become dangerously hot, make it only moderately firm, packing it more solidly about the pots later on. Add fresh heating material occasionally. At the commencement and for some time afterwards water should be given somewhat sparingly, anything approaching saturation being most injurious, and the better to be able to judge when the water is needed, defer top-dressing till the roots are on the move, the canes at first being coiled round so as to bring their points well back to the pots, a more even break being brought about accordingly. Supposing the Vines are being forced in low, well-heated structures, the canes can be trained up the roof directly a good break has taken place. Syringe as often as needful to keep up a moisture-laden atmosphere, taking care that too much of the water does not trickle down into the pots. Commence with a night temperature of from 50°

to 55°, increasing from 5° to 10° in the daytime, and if even still higher figures are reached during bright days there will be no necessity to open the house.

FORCING PLANTED-OUT AND PERMANENT VINES.—Where two compartments in low forcing houses can be principally devoted to the growth of early Grapes, much better crops can be had than from pot Vines. In one the young Vines would have to be prepared for forcing the following season, one good crop being all that hard forced Vines are capable, as a rule, of producing. Planted in narrow borders with hot-water pipes underneath for affording bottom-heat, little or no difficulty ought to be experienced in securing heavy and early crops. Prior to starting, probe the border to a good depth and give a soaking of warm water if at all dry, liquid manure being substituted if the soil is well filled with roots. Treat the canes as advised in the case of pot Vines, the temperatures and other cultural details being also much the same. Vines permanently planted in inside borders may also be started at the present time, and may do well provided hard forcing is not resorted to. If they have been forced and have had a good rest since, they will start far more readily. At the same time, if there are any permanent Vines of Black Hamburg, Madresfield Court, Foster's Seedling, and Buckland Sweetwater that are becoming less profitable than formerly, and it is thought desirable to replace them with a fresh set of Vines, these latter being given the benefit of a new border, a good early crop might be had from the condemned Vines in time for their being cleared out and others planted in May or very early in June. To be plain, by hard forcing old Vines and closely replacing these with young canes of the current year's growth, a loss of one season will be prevented. In all cases where permanent Vines are forced, these ought to be subjected to the softening, growth-promoting effects of a moist and ammonia-charged atmosphere. Not only should hotbeds of stable manure and leaves be formed in the house, but these ought to be partly turned every morning and frequently renewed so as to keep up the heat and vapour. Use the syringe rather freely about the well-coiled or bent-back rods and the house generally on bright days, the heating material giving off enough moisture in dull weather. Start with rather low figures, or say about 5° lower all round than in the case of any given the benefit of bottom heat. When the buds are bursting strongly increase the heat to 50° to 55° by night and 60° to 65° by day, and if sunshine raises the heat beyond these figures, so much the better. Not till the back buds are pushing strongly should the rods be straightened out, and the ends may well be depressed for some time longer. Stop the most forward shoots in all cases two leaves beyond the bunches directly the points can be got at, this greatly strengthening the later shoots.

FORCING PEACHES AND NECTARINES.—Trees in pots given the benefit of a moist bottom heat, and not forced too hard at the outset, are usually the first to produce ripe fruit. In most gardens, however, permanently planted trees are principally relied upon to produce ripe fruit in quantity in April and May, and in all such cases the start should be made not later than the first week in December, a still earlier commencement being desirable if such extra quick ripening varieties as Waterloo, Early Alexander, Hale's Early and Princess Beatrice Peaches are not grown. The trees have had a good rest and should start well. Examine them closely to see if there are any traces of scale left, and if necessary once more freely syringe the trees with the mixture of petroleum or paraffin and hot water. The latter should be heated to a temperature of 112°, and in every 3 gallons of this dissolve a lump of soft soap near the size of a hen's egg, and then add 6 oz. or three wineglassfuls of the oil. Syringing the trees freely with this should also destroy the eggs or progeny of black and green aphides, and thereby obviate the necessity for fumigating just before the flower-buds expand. If the borders are at all dry give a soaking of tepid water, liquid manure being substituted where the soil has not

been renewed for some time past. Commence with a night temperature of from 45° to 50°, increasing from 5° to 10° in the daytime. Syringe the trees every morning and again at mid-day, a generally moist atmosphere being maintained.

EARLY STRAWBERRIES.—Very early dishes of Strawberries are always appreciated, but it is doubtful if they pay for the trouble taken in producing them, especially seeing how many of the plants when hard forced fail to form fruit. If a commencement is made now, it ought to be possible to have fairly good fruit in February or the first week in March at the latest. All things considered, the best variety for early forcing is *Vicomtesse Héricart de Thury*. It is possible to have *Noble*, *Princess of Prussia*, *John Ruskin* and such like quite as early, but compared with *Vicomtesse* the quality is very poor indeed. A strong, dry heat, or say such as the plants would be subjected to on shelves in forcing houses, is not suitable. Strawberries in pots push up their flower-trusses more surely and strongly when plunged in a mild hotbed formed in a heated brick pit, the top-heat not often exceeding 60°. If the bottom-heat ranges from 70° to 75°, the top-heat ought to be quite 15° lower. Under these conditions the leaf growth is retarded and the root action accelerated, and there is also less likelihood of the foliage being infested by red spider and green fly; the pits to be made use of for starting the plants, shelves in forcing houses being the best place for them when coming into flower. If there is no choice in the matter, start the first batches in Peach houses and vineries being forced.

PRACTICAL.

PLANT HOUSES.

PLANT TYING.—What there is of this to be done should be attended to between row and the turn of the days. For home use I am no advocate for the formal training of plants, nor is it any special recommendation even for those grown for exhibition. Some amount of training is, however, necessary, otherwise in some instances really well balanced plants cannot be grown. Too free a use of sticks makes a plant look extremely unsightly, these being oftentimes more prominent than the plant itself. By using a smaller quantity and adopting the slinging process the work is really more effectually done. An expert at tying will do a lot of this instead of using so many sticks. To thrust sticks promiscuously into the roots of a hard-wooded plant will often be fatal to it if a number be used. None should be put into the inner part of the ball next the stem, unless it is into the holes out of which others have been taken. Tapering points are far better than blunt ones, and for choice plants sharp edges ought to be guarded against. For special purposes I prefer to buy what are termed double laths and make my own sticks therefrom. In splitting up the wood and making the sticks there will be various sizes; the slighter ones will do best for slender or thin growing plants, the stouter ones for those of dense and heavy growth. To add fresh sticks without removing the old ones is a mistake, being only a slovenly way of doing the work. No definite rule can be laid down for tying, but oftentimes a ring of sticks around the sides will suffice, with probably a central one as well. Some plants have a tendency to grow erect and close whilst still small. The *Epacris* is an example of this; the shoots thus become much crowded, but by using a few small sticks the sides may be brought out, and in a season or two the old wood left after pruning will become set. In this way a better groundwork is made to build up a shapely plant. *Ericas* in some cases have the same tendency; thus the plants become leggy and unsightly instead of dwarf and bushy. *Azaleas* under good management require but little staking. When the form of plant is determined on the treatment should accord with it; a dwarf bushy plant only needs the sides to be drawn out, a pyramidal one should be taken in hand whilst still of medium size with a central stick, and the outer shoots tied down with string

to the rim of the pot, around which a wire should have been previously fixed for the purpose.

A deal may be done by the regulation of the shoots in many kinds of greenhouse hard-wooded plants, so that shoots of extra vigour do not weaken other parts of the same plant. This can be effected by drawing the shoots downwards to a horizontal (or nearly so) position as well as by stopping. To allow a plant under pot culture to grow in quite a natural manner would shorten its existence; its treatment has to be modified to suit the case. Sometimes the sticks become rotten and a plant looks like falling to pieces, then perhaps a string is run round to bunch it up together again, the remedy being as bad or worse than the complaint. It is not by any means necessary to spend a lot of time on tying, but in any case sufficient attention should be given to it to keep the plants in a respectable condition. When tying these plants a permanent material should be used. Raffia is next to useless; the best things are either small green string about the size of carpet thread, this latter material being also very good, but I prefer the string. Small Bamboo sticks will do for some plants, but their use for the purposes now under consideration should not be countenanced. When the sticks are painted, which of course they should be, see that the paint is of nearly the same colour as the plants. A stick painted light green and used afterwards in a plant with dark green foliage makes a sort of display that is not desirable; on the whole a dark green stick is to be preferred.

WATERING, &c.—The watering in this department should now be proceeded with in a cautious manner. So far we have not had to use much fire-heat, thereby causing the plants to dry up somewhat more quickly. The weather on the whole has been favourable to hard-wooded plants, hence they will take rather more water than when it is dull, damp and sunless. The ventilation also has been maintained, this also tending to the good of the plants. But little water is needed when we are going through a spell of gloomy weather. It should be looked to early in the day with no useless stopping in the work. Plants that have been newly potted will take much less than those which are pot-bound, whilst if a plant be somewhat out of health additional caution is essential. Those which take the most water are small *Heaths* and *Epacris* that have been grown on quickly and are still in relatively small pots. Large specimens will, on the other hand, go for a week or a fortnight even without any. *Azaleas* should now be kept fairly on the dry side, not being allowed to suffer of course; if they have too much water during the winter the young growths come away too soon, being thus in advance of the flowers as well as weak. When the watering is done let it be thorough; just a little at a time is worse than none at all. See also that all the plants are kept upright, which in specimens is a most important matter. Use rain water or that which has been exposed in a tank in preference to drawing it straight from a tap or other source not congenial to plant culture.

JAMES HUDSON.

ORCHIDS.

It is of the utmost importance at this season that as much time as possible should be devoted to thoroughly cleaning the plants and woodwork of the houses. I noted also the tendency of many species of Orchids to do badly in some collections, while in others the plants will make good strong growth and flower well. Recently, too, I pointed out how important it is that no drip should be allowed to fall upon the plants or even in the compost wherein the plants are growing. Drip may get upon the plants in two ways, either by rain or snow water getting through the roof glass or by condensed water, which gathers inside the glass and runs down the rafters, dripping as it goes. One can well imagine the disastrous effects of drip upon Orchids at rest, such as *Dendrobiums*, *Cattleyas*, *Vanda teres*, *Chysis*, &c. They might start to grow before their time and all the calcula-

tions of the grower may be upset, besides the injury that may accrue to some plants by wet getting into the centre or damaging the young growths. It is easy to avoid it, and every good hot-house builder knows how to plan the sash-bars and rafters so that the water may be carried down to their base and outside into the gutters.

Many Orchids may already have passed through their period of rest and should now be started into growth again. In starting the plants into growth care must be taken not to place them too suddenly out of a quite cool house into an East Indian temperature. This may be the means of the growths starting away rapidly—too rapidly in fact, and some of the bloom-buds dying off instead of producing perfect flowers. A sufficient number of *Dendrobiums* of all the free-growing free-flowering deciduous species should be placed in heat. During recent years many of our plants have not been placed in the warmest house at all, as I found they flowered better in the *Cattleya* house; the intermediate temperature is brisk enough to cause the expansion of the flowers, but not enough to produce good strong growths. By not watching the plants carefully when at rest and treating them well, we weaken the constitution of many species and rare varieties, so that they do not retain their vigour. Of the *Dendrobiums* which I would recommend to start into growth in the *Cattleya* house at this season, none can be placed before *D. Wardianum*. The plants are easy to import, and every one will grow, and grow strongly, the first year, and stronger still the second, but in a few years the native vigour of the plants becomes exhausted, and the growths are year by year weaker and weaker until the plants are not worth growing. The same remarks apply to that beautiful species *D. Bensoniæ*. They are quite different in growth and require to be placed under different cultural conditions, yet they are the same when we come to take stock of the plants after six or eight years. The plants have hitherto been sold so cheaply that it has not been a great expense to renew the stock every two or three years, but all the same it is a sorrowful experience for an amateur who cares for his plants to see them gradually decline. In many collections a serious fault is the way in which the plants are crowded upon the stages and overshadowed with other plants hanging above them. Growth made under such conditions seldom produce flowers freely. Referring again to *Dendrobium Wardianum*, I bought a dozen plants from a collection of them that had been crowded. The growths they had made were much longer than some in our own collection, but when flowering time came a few blooms only were produced near the ends of these long rods; while our own with short-jointed growths produced on plants near the roof-glass were well furnished with flowers almost from end to end. It does not matter much where the plants are placed before they come into flower and while they are in flower, but as soon as the blossoms pass away the plants should be placed where they are to make their growth at once, for in the case of *D. Wardianum* and some others, the young breaks have made considerable progress before the flowers are removed, and if repotting or rebasketing is required, see to it at once. I believe *D. Wardianum* does best in baskets, and it should have new baskets every third year. It would not be the time to do this at present, but we have our earliest *Dendrobiums* in flower about the new year, and as soon as these pass out of bloom they will either be repotted or surface-dressed.

Pleiones should also be repotted as soon as the flowers fade. Some persons repot them annually—I have done this and approve of it—others once in two years. They have also done well in our collection with that treatment. I grow them in flower-pots in good peat and Sphagnum Moss. The method of potting, &c., has been described in previous numbers. I observe at this present moment two classes of *Odontoglossums* in the *Cattleya* house requiring quite different treatment for the winter—*O. vexillarium* and *O. citrosimum*. The latter are placed in the lightest part of the house, where they get all the sunlight available, and the

plants receive no water unless the pseudo-bulbs show a tendency to shrivel up too much, when a little is given. On the shady side of the house are the plants of *O. vexillarium* (Miltonia) and they are kept growing all through the winter. We keep them clean by dipping or the use of fumigating material, but it is easy to injure the growths of *O. vexillarium* with bad tobacco or bad tobacco paper. Yellow thrips, which are the desperate enemies of this *Miltonia*, can be destroyed by dipping the plants overhead in a solution of tobacco water and soft soapy water, 2 oz. to the gallon. Any other Orchids requiring dipping should be done at the same time. The water should be warm to dissolve the soap; add to it a gill of tobacco liquor. This mixture kills aphides easily, but even thrips cannot live after two dippings. Lay the plants on their sides after dipping them and sponge over the leaves with clean water. *Odontoglossum Roezli* in the warmest house should also be dipped at this time. Neither of the two can stand strong tobacco.

J. DOUGLAS.

CHRYSANTHEMUMS.

SHOWING CHRYSANTHEMUMS.

ONCE more the Chrysanthemum shows have come and gone, or at any rate they are all over as far as the midland and southern districts are concerned, and once more the recollections are not altogether of a satisfactory character. Each year we hear the same complaint of monotonous arrangements, more especially among the cut bloom classes, and if something is not done soon to vary the display, there is every likelihood of a serious falling off in the attendance of visitors to the shows. Enthusiasts or those conversant with the majority of the varieties can, provided they have an opportunity of getting near enough to the stands, see much to admire in the individual blooms, novelties serving to well sustain the interest. The case, however, is very different with the majority who attend these shows. They see little besides a solid mass of blooms extending probably down two or more long tables, and finish up their inspection not greatly gratified, and little, if any, the better or wiser for their trouble. Even if they wished to discover the names of the varieties it is scarcely possible for them to do so, not one exhibitor in a hundred displaying the names in a legible manner and where they can be seen. Introducing or tolerating larger boards has certainly improved the appearance of the larger varieties, but, as was prognosticated, it has also had the effect of excluding very many good varieties whose only fault is that they do not cover the boards sufficiently. The larger-sized boards make the medium sized to small blooms appear very small by comparison, and when none of the varieties shown are up to the standard set by leading exhibitors, full-sized stands are a glaring mistake. Owing to the necessity for carrying a considerable number of blooms in rather close quarters, any innovation in the direction of increasing the difficulties of what I may term travelling exhibitors will be strenuously opposed by these latter, but something ought to be done to break the monotony that prevails. The question is, ought the travelling cupboards to be remodelled in order to meet the demand for an improved method of exhibiting Chrysanthemums, or must the owners of these unsightly, but indispensable accessories be studied at the expense of the reputation of show Chrysanthemums generally? My contention is that something must be done to obviate the present monotonous methods of showing cut blooms

even if this does touch the pockets of the exhibitors. The latter may grumble at the altered conditions, but will not hesitate to meet them directly this becomes necessary.

What greatly detracts from the beauty of cut Chrysanthemums is the absence of live greenery of some kind. We, however, get rather too much of the green paint on the boards in the case of incurred varieties, this not obviating the painful neatness of the blooms in the least. What would greatly improve their appearance, viz., some of their own leaves, is supposed to be impossible of use, generally, owing to the necessity for cupping up the blooms. Where fine blooms perfectly filled up in the centre are cut and shown before they are in the least bit stale, it is surprising how well they will keep without any extraneous aid other than the easing and regulating of the florets according as they expand, but they open considerably after they have passed their prime. I shall, perhaps, be told that it is not possible to show incurred blooms in a condition fit to be seen without resorting to the old cupping-up tactics, but let me ask, has the attempt ever been fairly made other than on a small scale in isolated cases? Personally, I would rather see a few more "eyes" and more greenery than the stiff, unnatural lines of blooms that have found a place in so many exhibitions this autumn. Owing to the great length of peduncle in the case of the Princess of Wales family in particular, I would not insist that these or any other varieties should be shown exactly as grown, but would admit of a portion of their own wood and leaves being attached to each. This plan has been tried at Devizes, and in one instance a perfect lot of blooms, equal to what are usually shown in the orthodox manner, and which certainly were far more attractive in appearance, were put up. All that is necessary is to stipulate that not less than 4 inches of clear stem, accompanied by foliage of each variety, be shown, and the rest may be left to the exhibitor. The middle and back rows may be either cut with longer stems or raised slightly higher than the front row, and be improved in appearance accordingly.

Reflexed and Anemone-flowered varieties, again, frequently look quite lost on the show boards, being flatter, though scarcely so firm and formal as the incurred section, and these therefore should also be shown with their own foliage. Thanks to the efforts of innumerable raisers, extra large handsome Japanese varieties are being distributed wholesale, many of them being fully equal to covering their share of space on the enlarged boards; while on the older size (24 inches by 18 inches) they present quite a crowded appearance. But in order to see these at their best they ought to be accompanied by their own foliage, that is to say, be shown very much as I have advocated in the case of incurred varieties. This would necessitate allowing still more space for each bloom, though it does not follow that larger boards than those 28 inches by 21 inches need be made. Instead of twelve, twenty four and thirty-six blooms being asked for, the numbers should be reduced to eleven, twenty-two and thirty-three respectively. Why not? There is nothing but past procedure to warrant the framers of schedules in sticking to any particular numbers, and if odd numbers best meet the case, the innovation ought to be made. If my numbers were acceptable, there would be no real necessity to greatly disturb existing arrangements, the middle line of holes only in the boards being reduced to three in number, and angling the blooms would have the effect of allowing rather more room and displaying it both the blooms and the foliage

to better advantage. Alterations on these lines would not add greatly to the expense of the exhibitors, the old cupboards at any rate being still available, only they would not be deep enough for so many stands or boards as formerly. Personally, I fail to see why travelling boxes should not be used, Chrysanthemums not being so fragile as not to bear contact with each other. If triplets could be shown clear of stands and either with their own foliage or interspersed among small Ferns and Lycopods, backed by small Palms, this would be a very great improvement on the present fashion of exhibiting Chrysanthemums. This excellent plan has, I believe, been repeatedly adopted by Mr. Wythes, of Syon House, Messrs. Cannell, and others, but it does not become at all general. At least three different secretaries have distinctly stated to me they intend introducing fresh classes for cut blooms with a view to rendering them still more attractive, but when the time comes for making these alterations, they (secretaries generally) are apt to shirk the responsibility of suggesting innovations. Since writing the foregoing I have read the short note on "Staging Chrysanthemum Flowers," which appeared on p. 454, and would like to be able to verify the statement to the effect that there are any signs of a marked improvement in the matter of staging blooms at the west of England shows. At present the signs, with the exceptions noted, are all the other way, and if it is allowed to rest with the exhibitors, it is very certain there will be no breaking away from the old monotonous style. The change must be initiated by the framers of prize lists. Let the prizes be worthy of the occasion, and exhibitors will soon be found to compete for them.—W. IGGULDEN.

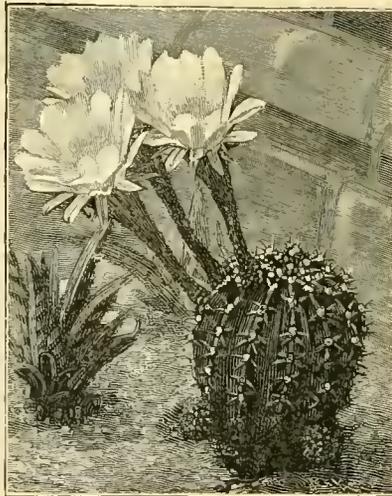

— Any new departure from or variation in the monotonous arrangement of cut blooms is worthy of every encouragement. What is invariably lacking is foliage to tone down in a measure the excessive brightness of the flowers. When any attempt in this direction is made it should be taken note of as being suggestive of further improvement in the general effect of the Chrysanthemum exhibitions. At the recent show at Hult a new class was provided, which had for its object the more tasteful arrangement of cut blooms. The class in question was worded as follows: "Twenty-four blooms Japanese, distinct, arranged for effect and set up in any manner the exhibitor desires, with or without Chrysanthemum or other foliage, on a table, space not exceeding 6 feet in length by 2 feet 6 inches in width. N.B.—The object of this class is to introduce a more tasteful system of staging highly developed flowers; therefore first quality blooms are indispensable, and their merits will be estimated by points in the usual manner. At the same time artistic arrangement is essential, and will be fully considered by the judges and receive due weight in the adjudication." The moving spirits of the Hult show are to be congratulated on the enterprise they displayed in making this new departure, and, considering it was the first time, the result with respect to the first and second prize awards must be considered very satisfactory. The prizes, it should be noted, were very liberal, amounting to about £10, divided into first, second and third, so that one could afford to go to a little extra expense in providing the additional decorative material. The first prize, be it noted, went to Mr. G. W. Musk, Haverland Hall Gardens, Norwich, so that no excuse could be made that such a class would only find competitors in the immediate locality. Each prize was taken, but it is with the first and second that I wish to deal more particularly. The judges did quite right in awarding the prizes as they did. The first prize exhibit was an excellent one. The flowers, which were of first-class quality, were arranged in an informal manner upon a groundwork of small fine-foliaged plants and Moss, amongst which were interspersed here and there a few light Palms, Crotons and other

plants, all of what may be termed "table size," the front being finished in a graceful style with Panicum, &c. The one improvement which suggested itself to my mind was that of using green Hyacinth glasses in lieu of other receptacles for holding the flowers. These would be deeper, thus with more water in them would aid in keeping the flowers all the fresher, providing at the same time a firmer base for holding the blooms in position. These were cut with from 1 foot to 18 inches of stem, being arranged with their own foliage also. It was in all respects a most suggestive exhibit, and which might be copied with decided advantage in home arrangements. Take, for instance, a side-board or hall table of nearly the same dimensions as that specified in the schedule; it could hardly be put to a better use than for the display of such an exhibit as this. It had all the necessary elements to make such an arrangement both effective and imposing. Such decorations as these are frequently called for during the present season of the year, and that in question may be taken as an excellent pattern. The grouping of the foliage plants, with some in flower also, as dwarf Chrysanthemums, may oftentimes have been performed, but in this case we have finely-developed cut flowers instead grouped in a suitable manner. A few of the varieties used were Vivand Morel, Avalanche, Edwin Molyneux, Florence Davis, Sunflower, and G. C. Schwabe, all useful for the purpose, but neither of them what could be termed formal flowers. I should like myself to have seen another bloom or two of Sunflower, one of the finest of all the Japanese, but as it said "distinct," this could not be. It would have been possible, I think, to have added half-a-dozen more flowers on the space allotted without overcrowding; thus thirty blooms in eighteen distinct varieties would be a good proportion; this would allow of a few duplicates of such as Sunflower, Vivand Morel, and other decided colours. The space really occupied would be for the twenty-four blooms under this arrangement about one-third more than when upon the regulation size boards—not a vast increase considering the greater attractiveness in the eyes of visitors generally. In the second prize exhibit the flowers were arranged informally in threes, the colours in a measure being grouped; this also had a very good effect. It would, however, have looked better with a few more light foliaged plants, but it was a suggestive arrangement all the same. The meaning of the schedule did not in the other case appear to have been fully grasped. I hope further encouragement will be given to this new departure another year; a smaller class even might be provided for those who cannot conveniently manage the larger one. The secretaries of other societies would do well to consider the matter for their schedules another season. The chairman, Mr. Falconer Jameson, and the hon. secs., Messrs. Edward Harland and James Dixon, are certainly to be congratulated on this additional feature in their show to which they devote so much time and energy.—J. H.

—The Chrysanthemum show season may now be said to be at an end, and to all who have had opportunities of seeing many of the exhibitions which have been held throughout the country during the last few weeks, it must be obvious that some new departure will have to be made from the stereotyped methods of arrangement observed by one and all if these shows are to retain their hold on the general public. The average visitor sees no difference year after year in the long monotonous rows of big blooms, and the (usually) stiffly arranged banks of plants. Not being a connoisseur, he does not take any interest in the numerous novelties which may be shown. From the point of view of the general public the shows are all very much alike, and in consequence it has recently been found necessary in many places to supplement the flower show with a concert, a dance, a fancy fair or something of interest to draw the public who care not who has the champion incurred, and are blind to the charms of the latest hirsute variety. This is an artificial method of making Chrysanthemum shows an apparent success, which cannot but prove in the long run to be disadvan-

tageous to the object with which I presume these exhibitions were primarily instituted, viz., the improvement and popularising of the Chrysanthemum. As years go on the supplement, that is to say the concert or whatever it may be, will become the principal instead of the accessory institution. The reason of this I fancy will be the absolute want of variety in the flower shows.

How then is this to be remedied?—a difficult question I confess. I will at once admit that the present system of showing cut Chrysanthemums, unpleasant as it is to the eye, is the best possible one for displaying the different points of the flowers. Cut blooms are occasionally set up with long stems and the foliage as grown, but how do they look on the second day of the show? The wood as a rule is hard, and the water in which the ends of the stems are placed has no refreshing effect on the leaves and flowers, the consequence being a pitiable array of drooping leaves and petals. This was very noticeable in some cases at the recent show at the Westminster Aquarium. A suggestion made recently that in a certain class each competitor should be allotted so many square feet of table or benching, the first prize going to the man who filled the space most artistically, no restrictions beyond measurement being made, struck me as an excellent one, and I hope it will be generally adopted in next year's

Echinopsis oxygona var. *Zuccariniana* in flower in the open air. Engraved for THE GARDEN from a photo sent by O. Overbeck, Chantry House, Grimsby.

schedules. Beyond this idea there is not, I think, any field for originality in cut-bloom showing. The groups, however, sadly need changing. The only beauty to be seen, artistically speaking, in the groups at the Aquarium, for instance, was in the varied colours of the flowers. Leave the colours out, photograph it, and where is the beauty? Certainly not of form, merely a uniform bank of lumpy flowers. Of course, the lover of Chrysanthemums delights in the cultural skill apparent in the stout dark foliage and magnificent sized blooms, but still one could pass a builder's straight-edge over the whole group within an inch of any particular point and not touch a flower.

Why not offer prizes for groups of Chrysanthemums of one colour, or say shades of a colour, yellow, for instance? Competitors might be limited to one colour (of which different shades may be admitted into the group), but might be allowed to select that colour. In this way a number of floral monochromes, so to speak, might be obtained. Much good may, I think, be done by the N.C.S. next year offering a good prize for the best original suggestion, practically demonstrated, of exhibiting either plants or cut blooms, and we may thus possibly escape from the terrible sameness in Chrysanthemum exhibitions which at present prevails.—F. C. SMALE, *Torquay*.

GOOD OUTDOOR CHRYSANTHEMUMS.

IT would be useful to get a complete list as far as possible of Chrysanthemums that bloom well in the open, and I have made notes of those of good distinct colours that are bright and free far into November. Whilst the indoor grown kinds are being shown at exhibitions throughout the length and breadth of England, a few varieties are flowering freely unprotected in the garden, and these are as important in their way as those produced at great labour and expense. The colours in the outdoor kinds are restricted, and one gets the same varieties repeated until the flowers become a little monotonous. It is astonishing what may be done towards brightening the garden in the autumn with Chrysanthemums, not the Mme. Desgrange type alone, but those that flower at this season. The great thing is to grow the plants entirely in the open, and not to let them remain from year to year until they get weakly and poor through want of a fresh place. I saw a few days ago a small garden in a suburban street one mass of Chrysanthemum flowers, and if such beautiful colours can be obtained in isolated instances, it can be by the majority. The large-flowered types are of little value, and the selection must be restricted to those bearing flowers that throw off the rains, such as the reflexed, the pompons, and some of the incurved. I give the names of a few of the best noticed, and it is to be hoped readers who have seen kinds doing well outdoors will record their names, so as to get a full and useful list.

COITAGE PINK, probably the same as Emperor of China, is one of the best. It seems to succeed everywhere in cold localities and in the south of England. The flowers are light purplish in colour, pretty in form, and produced with great freedom.

JULES LAGRAVERE is indispensable, and I see that it is planted largely in the parks. It is the hardiest of the lot, very free, and the flowers warm purple in colour, a little dead perhaps, but still welcome in November.

JARDIN DES PLANTES is a fine yellow. A plant smothered with the richly coloured flowers is as bright as anything we can get in November, and even after severe frosts its beauty is not materially diminished.

MRS. RUNDLE is a good white, but white flowers, except in very mild, dry seasons, are not satisfactory. The flowers get quickly sullied by the weather and are spoilt.

GOLDEN BEVERLEY is another good yellow kind very free, and bright in colour.

LA VIERGE, white, was very beautiful this season early in November. Bushes of it were laden with flowers, but it is not every season that suits it. The spotless white flowers are spoilt in wet autumns, but it is a variety that should be grown. It has proved one of the finest things in the garden this autumn, the plant of graceful habit, bushy, and vigorous.

In a recent issue of THE GARDEN some interesting notes appeared upon hardy Chrysanthemums, but these are of the earlier blooming kinds. I have given only those in beauty now, and hope to see the names of many more from those who have grown them. C.

Chrysanthemum Brookleigh Gem, one of the new incurved varieties, we do not care much for; its colour is not decided enough. The flowers are rose-purple, the petals tipped with white. The flowers we saw may not have been in true character, but the colour is not sufficiently clear.

Chrysanthemum Princess of Wales and its variations have this year been shown well on the whole. The finest of the variations that I have noted was Mrs. S. Coleman, which was uniformly good. On the other hand, Violet Tomlin was usually of a paler shade than in former years. What a beautiful exhibit the Princess family would make by itself. So also would the Queens and Empresses. I see no reason at all why this plan of grouping them together in separate exhibits should not be adopted. Three blooms of each form of these types would make a fine display of themselves. Perhaps the N.C.S. will take a hint as to this.—H. G.

Chrysanthemum Vivand Morel.—This lovely variety is oftentimes described in colour as

pink, which is most misleading. Personally I cannot see a trace of that colour in it. That given against it in the N.C.S. catalogue is an excellent description, viz., "silky mauve." This also seems to be of a sportive turn. I noted in one stand at the Crystal Palace the white, the yellow and the silky mauve, all fine flowers. The class there in which these were shown was not for distinct varieties; therefore, there was no quibble about the white form, nor do I think there should be provided the colour is pure white. I wonder how many blooms of Mrs. Heal have been cut from plants of the Princess of Wales. My own impression is that in process of time the white form will be sufficiently fixed to be shown in any stand with the others if the exhibitor wishes to do so.—G. H.

Prices of new Chrysanthemums.—Among the host of new Chrysanthemums distributed last spring, two—Robert Owen and Viscountess Hambledon—were quoted at half-a-guinea each, which was considered a very high price, but that has now been far left behind by one of the French nurserymen, who announces a new variety to be distributed next May at £1 each. The variety in question is Mme. Ferdinand Cayeux, which is alluded to in the following terms: "We have bought from M. Reydellet at the price of £20 the unique plant of this superb variety. It is a new type with downy petals, the enormous flowers being of a bright mahogany tint with a green centre." From the price and description this should certainly be a good and distinct Chrysanthemum, and one that will be looked forward to with interest next autumn.—T.

Chrysanthemum Mrs. W. R. Wells.—A fine flower of the white sport from Viviani Morel, named Mrs. W. R. Wells, was shown on a plant at Norwich. The plant, which was about 18 inches high, only bore the one flower. This sport has given rise to some discussion this year, many of the flowers having reverted to the original colour, but there could be no question as to the bloom in question being distinct.—J. C. T.

Cutting Chrysanthemums with long stems.—An interesting note appears in THE GARDEN, p. 456, on the above, and I quite agree with the same, but would point out that the cut blooms would be more attractive if the glasses could be covered in any way, such as in a bed of Moss or in boxes of Ferns. With glass bottles or jars exposed to view there are serious objections, as unless furnished by the society there will be a varied collection, differing in size, shape, and quality. If the stems are too long they do not absorb the water, the leaves flag badly and the effect is marred. If cut say from 6 inches to 18 inches long, there is no objection, and the habit of growth of each variety can be seen. The Royal Horticultural Society have of late encouraged this mode of staging, but hiding the glasses containing the water is, I think, an improvement, and one that Chrysanthemum societies should encourage.—H. S.

Dwarf Chrysanthemums.—I saw some splendid examples of these at Farnham, the plants being about 18 inches high and bearing very fine blooms considering the size of the pots. They were in 4½-inch pots, and furnished with leaves down to the top of the pot, the foliage being large and healthy. A few plants were in pots a size larger. These contained three plants, but those grown singly were the more effective. There is a ready sale for such plants, the grower and nurseryman informing me he could have disposed of a much larger number than he grew. Such plants are invaluable for the front of a group, and should be grown in larger numbers, as often the groups at shows are anything but well finished, the naked stems and pots looking most unsightly. Dwarf plants are easily grown by striking the strong points of the cut-back plants in June. If potted on into 4½-inch pots they make useful stuff by November.—G. WYTHES.

Chrysanthemums as bush plants.—At one time long stems and one flower on each were unknown, indeed would not have been tolerated. We are gradually going back to the old system. I

have observed in many groups five stems instead of three, and equally good blooms as from single stems. One great advantage with the flowers from bush plants is their long-lasting properties compared with large blooms, which are produced on very hard stems that cannot absorb moisture. When cut they soon flag and are worthless; whereas I have now flowers from bush plants that have been in vases ten days in a cool room, and are now quite fresh. I feel certain the old system with better culture will yet become a favourite one for decorative work, and I am pleased to see many of the newer kinds have a dwarf compact habit, rendering them suitable for bush culture.—G. W.S.

STOVE AND GREENHOUSE.

HANDSOME FLOWERED CACTI FOR THE GARDEN.

For a really choice, unique, and exceedingly neat and handsome class of plants for bordering small raised beds, I know of no more effective subject than plants of the Cactus family, known by the name of Echinopsis, and distinguished by

Echinopsis Fyriesii in bloom in the open air. Engraved for THE GARDEN from a photograph sent by O. Overbeck, Chantry House, Grimsby.

the large size of their delicately tinted blossoms and the lovely effect of their long-tubed Lotus-like flowers here and there expanded at eventide or by day.

I have now for many years grown these during the summer months, planted out here in the east-wind-swept cold sea-coast of Lincolnshire, where I have been rewarded with a wealth of blossom quite unknown to those who only understand and follow the ill-treatment system we see generally. These plants can stand when absolutely dry (soil and atmosphere), some 10° or 12° F. of frost, since in storing these plants away in a dry, sunny unused room I have had them frozen as hard as glass and become quite transparent. Upon throwing a blanket over them to keep off the light, they have slowly thawed and flowered the succeeding year as strongly as ever. The treatment they have undergone with me for the last twenty-five years has been the following, and small plants of various species which had been much admired by friends and made a gift of, and "greenhouse-coddled" after, have shown in after years the miserable weak growth so often seen in these plants. The hardy treat-

ment received by others of the same size with me have left them quite in the shade, and have been double as large. It is an error to think that such species as *Echinopsis Decaisneana*, *tubiflora*, *oxygona*, even *Eyriesii* and *Wilkinsii*, require heat in the summer. No, they require fresh air and wind about them to constantly dry their stomata and ripen their growth, so much the more important in our short summers (especially here in Lines).

I plant them out, after fear of frost is over, in a light rich bed of soil composed of plenty of old melon-bed soil, sand, peat, oyster shells, and good meadow loam, full of fibre and broken up into coarse pieces, as the whole bed should be of a lumpy character and very well drained, so that by no amount of continued rain in wet summers can the ground become sodden, which is fully analogous to their natural climate (except in point of a few degrees of temperature), where they undergo continual drenchings, accompanied with alternations of warm sunlight, during which time they swell up from their shrivelled, ripened state to a fresh green, grow rapidly and flower, to ripen when the drought follows, which ripening process is so severe, even with plants of such resistive capacity to heat as these plants are, as to give them a half-dead, shrivelled appearance.

Hence I water at first not at all (say they are planted here in the latter half of May), as the soil will be damp enough, then freely syringe in June and July, every other day in August, and twice a week in the first half of September. I then let them slowly dry out, dig them up and treat like *Echeveria* in the winter.

In this way it is simply astonishing how these plants grow and flourish, and how free they are from that insidious mealy bug at the roots, so often the ruin of these plants in pots, and recognised by the white fungoid-like woolly patches on the roots, every tip of which will be seen to have been attacked and destroyed. Since the root end protected by the root-cap is the only part of the root which can by its root-hairs absorb the vapours and liquids of the soil, we thus lose every means of renovating the plant's health except by cutting off all the roots, washing every trace of the bug off and repotting. Every time I do this I lose a season, and as all these plants (truly shrubs by their age and woody texture when matured) flower only after some years have elapsed, this is a loss to me. But at all times they are beautiful in their regularity of arrangement and the colouring of their thorns and stems. Unless required to increase the stock, the young plants produced at the base of the plant should be taken off by a sudden pressure with a blunt point upon them from above. Remember I never give them a single drop of water from October to April or May, since by planting together in boxes they retain the moisture for some time, and part with it but slowly. If stored in an empty room they should be raised from the floor, since the draught will do them no good. Let them here have during the winter every gleam of sunlight obtainable. The wonderful size, form and colour of the blooms, together with, in most species, their delicious scent, render them a wonder to those who have never seen them (and very few ever have), and a perfect sight when seen as their large Lotus-like blooms expand (always in the evening) and shine like large stars (6 inches to

9 inches long, and 3 inches to 6 inches across) glowing in the clear summer's moon with silvery white, cream colour or a bright rose shaded to pure white.

ECHINOPSIS EYRIESII (here figured), (especially the exquisite double-flowered species) the black sooty bud, compared with the open flower with its intoxicating scent, something between Lemons, Lilies, and vanilla, can only be realised by one who has seen it. In all these plants the bud first appears as a black, hairy, or woolly cone in the axil of a tileola (Thorn group), which grows at first very slowly indeed until about 2 inches long, then rapidly expands to its full length, in the latter stages an inch per day, being covered with patches of dark hairs and scales, which enlarge and grow paler farther up, and end in the long-pointed (narrow or broad and mucronate) petals of the flower. In *E. Eyriesii* the hairs are so black and dense that the bud looks as if covered with soot. The flower may be watched expanding, as it generally opens at nightfall. In their native country they are nocturnal bloomers, since with their delicate texture the morning sun would soon snivel them. *E. Eyriesii* seldom lasts more than the night, hanging over the plant like a limp rag the next day. In its native habitat the temperature may be 130° to 140° F. in the sun by day and nearly 32° F. at night. In *E. Decaisneana* and *E. oxygona* the flowers often last two nights and two days for the admiration of all. Among all our bedding plants, however choice, none can compare in blossom to the untold beauties of *Echinopsids*. Their habitat differs with the species (but all are very amenable to the same culture), those from Brazil and Bolivia being slightly more tender than those from Chili and Peru or parts of Mexico.

ECHINOPSIS OXYGONA VAR. ZUCCARINIANA.—Originally bought in one of those little scarlet pots in Covent Garden for 6d., now twelve years old. Here we have a brilliant flushed blossom of the purest rose shading to white, a magnificent flower with broad petals (mucronate), imposing sheaf of whitish stamens with yellow anthers forming a long tassel in the tube, and a white stigma with rayed style also white, the blossoms in this splendid season for Cacti measuring 9½ inches by 4 inches. To see three expanded simultaneously on one plant is very uncommon indeed. Just think of the juices required to be given up by the plant to produce these. At the base of the tube will be seen the ovary or seed-vessel—the flower being stalkless or sessile. If left on the plant it will grow into a fruit the size of a hen's egg, greenish yellow when ripe, covered with patches of hairs, and crowned with the remnants of the dead flower. It is very hardy and easily grown. Its thorns are under an inch long.

ECHINOPSIS DECAISNEANA.—This (in England rare) Cactus is the hardiest of all, and a sure bloomer within three years of separation from the parent plant; in its full grown state it equals *E. oxygona* in size, with more robust thorns. The blossom is generally constructed (as in the whole family) upon the lines given under *oxygona*, but the petals are narrower and not mucronate (with a short tip in the centre of an otherwise blunt end), and of a delicious cream colour shaded to rose, and with (as in *oxygona* too) at the upper external end brownish rose sepals, with a brown stripe down the middle of each. Hairy, as in *oxygona*, yet very distinct when seen side by side, being also a more open flower.

ECHINOPSIS TUBIFLORA is a short-thorned, very blue-green stemmed variety, with an absolutely pure white flower, opening at night only. It lasts for a couple of days as a rule. Its thorns are very dark, and expanded to a broad black base; hence easily recognised.

I have had hitherto three flowers this year on *oxygona*, and may, as a rule, take it that I get on *oxygona* per plant three to five flowers; *Decaisneana*, three to five; *tubiflora*, two to four; *Eyriesii*, one to two.

The above few notes will help, I hope, to make a lovely, yet neglected, family more popular, and since photographs are incapable of

exaggeration, I trust readers will not find the text in excess of the reality.

OTTO C. J. G. L. OVERBECK.

Chantry House, Grimsby.

Dwarf Cannas for autumn bloom.—How useful these are in the autumn, as they take up little room and give a large quantity of flower. I have just gathered some very fine heads of bloom from plants in what may be termed a warm greenhouse, these having been given a few degrees more warmth during the past month, thus inducing them to throw up a quantity of their richly coloured blooms at a time flowers other than *Chrysanthemums* are more plentiful. The new dwarf Cannas are beautiful not only on account of their free-blooming qualities, but for their handsome foliage. The flowers, which range from golden yellow to deep scarlet, are produced in abundance. For autumn decoration I find small plants in 6-inch pots most useful. These if potted in the summer and grown cool or even in the open, will give a lot of bloom when placed later in a warm greenhouse. They are so readily increased and may be divided almost at any stage, that there is no difficulty in securing plenty of plants in a short time. To keep the plants sturdy a light position is necessary, and in potting up for autumn bloom, do this in time to get the pots full of roots, this allowing the plants to be fed to produce strong flowers. The flowers last much longer at this season than in the summer.—G. WYTHES.

Celosias for autumn bloom.—I have for some years sown a pinch of seed of *Celosia pyramidalis* for autumn blooming, and find it valuable for this purpose, as the blooms last a long time after being cut. It may be said, why grow the *Celosia* when *Chrysanthemums* can be had in quantity? but the latter do not set up so gracefully as the *Celosia*, whose light feathery plumes are always charming for vase work, specially if a good strain is grown. I am aware the coarse kinds are anything but graceful. *Celosias* are also valuable when grown late for room decoration, and make nice heads in quite small pots. Good plants may be grown for autumn in 4½-inch pots. These require little heat; indeed the seed may be sown in cold frames in July and the plants be grown without heat of any kind. In the late autumn careful watering is necessary, as the flowers soon suffer in a damp house. The great advantage of these late plants is that they rarely get infested with red spider or thrips.—G. WYTHES.

Ixora macrothyrsa.—A plant of this 6 feet high and bearing two immense trusses of flowers has been a most conspicuous object in the Palm house at Kew for some weeks past. For such a structure the species is well adapted, but for smaller houses its tall straggling habit makes it inconvenient, and the dwarfier, more compact species and varieties are to be preferred. In the size of its trusses, however, no species approaches this, neither do any of the fine hybrids that have been raised in gardens. In *I. macrothyrsa* the trusses are sometimes 1½ feet across, the flowers being deep red, acquiring a crimson shade with age. The foliage is of proportionate vigour, leaves upwards of a foot long and of a rich deep green being produced. After being cut back in spring the shoots should not be stopped again if they are expected to flower that year. This plant requires abundant heat and moisture during the growing season, being a native of the Pacific Islands. It was figured in *THE GARDEN* (as *Ixora Duffii*), April 6, 1878.—B.

Well-grown Poinsettias.—At the late Cirencester *Chrysanthemum* show some remarkably well-grown *Poinsettias* were shown by Mr. T. Arnold, The Gardens, Cirencester House. There were only six plants, yet they made quite an imposing display. Only the early-flowering form was shown and all were old plants having one to four main growths. These latter divided and subdivided in a most extraordinary manner, or much

as I am assured *Poinsettias* do in tropical countries, and I counted as many as eighteen fairly large, well-formed, richly-coloured flower-heads that had come from a single stem of this year's growth. Mr. Arnold informed me these plants were grown in cold frames all the summer, the lights being raised as more head room was needed. Fine *Poinsettias* are numerous this season, but I have seen none to equal those at Cirencester.—I.

Urceocharis Clibrani.—The note on this plant which appeared in your issue for November 18 (p. 459) reminds me that I had intended sending a note on its value for cutting. On June 12 of this year Messrs. Clibran sent to me a scape which had on it four open flowers and six buds. They appeared quite fresh on arrival, though they must have had a very trying journey, having been two days in transit when the weather was exceptionally hot. I placed them in water, which remained unchanged, and the buds opened one by one, the last being perfectly fresh and of good size and colour thirty-one days after it was received by me. The flowers which were open on arrival also lasted many days. "W. W." mentions six flowers as the average for strong scapes, so the one I received must have been extra fine, although another, figured in the *Gardener's Chronicle* for August 20, 1892, shows eleven, and I should think it probable that ten would be about the average when the plants have had time to become thoroughly established.—J. C. TALLACK.

Bougainvillea glabra in cool houses.—What a lovely creeper this makes in a cool house in the late summer months when allowed to grow freely without much cutting or training. In such a position the flowers assume a deep rose colour, which is rarely seen when grown in a warm house. I recently saw a noble plant of this variety at Farnham Castle covering the back of a cool plant house or conservatory. This had filled its allotted space, and was allowed to ramble at will outside the house during the summer months. It was a beautiful object, the blooms being much finer and of a deeper shade than usual, the fine weather suiting it. There are also other advantages in growing this in a cool place, as the blooms last longer when cut. The flowers of *B. glabra* are lovely for vases if a few bracts are loosely placed together with a little foliage. In planting out it is necessary to restrict the roots to induce abundance of flower and to rest partially during the winter months, pruning or cutting out the weak wood before new growth commences, and giving plenty of water and liquid manure when growing freely.—G. WYTHES.

THE PALM LILIES, OR CORDYLINES.

It is to be regretted that there is so much confusion in gardens and in garden literature as to these highly ornamental decorative plants from New Zealand and Norfolk Island. The true *Cordylina* (*Dracena*) *indivisa* is a plant quite distinct and unmistakable if once seen. Its leaves vary from 2 feet to 5 feet in length and are 5 inches wide in the middle, glaucous green beneath, while their upper green surface is finely striated with red nerves or veins. The specimens alluded to in *THE GARDEN*, Oct. 21, p. 381, as growing in the open air at Menabilly, Cornwall, are very remarkable indeed, and it is, as there suggested, a misfortune that this noble species is not more frequently planted out in warm and sunny positions, especially near the sea. A specimen of *C. indivisa* 9 feet in height with leaves 6 inches wide is indeed worth going a long way to see. Now and then, but very rarely, this plant is met with as a greenhouse or conservatory plant, and in places where it is not hardy it well deserves culture indoors during winter and spring, as it is one of the showiest of all fine-foliaged plants for plunging outside on the Grass during the summer and autumn months of the year. There is a coloured figure

of a leaf in Lowe's "Beautiful Leaved Plants," p. 107, where it is called the "undivided or unbranched Club Palm," and it is further therein suggested that it might "probably prove hardy enough to bear the air in the south of England."

This noble plant was introduced by Messrs. J. and C. Lee, nurserymen, of Hammersmith, in 1852, and has been well grown and exhibited amongst stove and greenhouse fine-foliaged plants from time to time. It is a native of New Zealand, being found on the mountain ranges at a considerable altitude. Its undivided trunk attains a height of 20 feet. The leaves yield the so-called "Ti" or Toi fibre, and the old leaves do not fall, but remain persistent on the stem for many years after they die off and turn brown. The flowering panicle is at first erect and branched, afterwards it becomes pendulous, and is laden with white berries. We must ask some of our New Zealand friends to send us a consignment of the fresh ripe seed of this species, as it grows readily, and it was in this form that Messrs. Lee received their original stock forty years or so ago.

C. BAUERI of J. D. Hooker, from Norfolk Island, is very closely related to the last in botanical characters, but it is distinct in appearance, and attains a height of 40 feet, and the stem is branched. C. Baueri was named C. australis by Endlicher, a proceeding that has misled cultivators and others a good deal. I have not yet seen C. Baueri grown in the open air through an English winter. The third species I shall allude to is

C. SUPERBIENS of C. Koch, which is synonymous with the C. australis of J. D. Hooker, and the plant so often mis-called C. indivisa and C. australis in gardens. It would be best to drop the name C. australis and employ the correct name C. superbiens for this plant, as suggested by Baron von Mueller. This plant is perfectly hardy not only in the south of England and Wales and in Ireland, but at Mount Usher, Ashford, co. Wicklow, several fine branching specimens belonging to the Messrs. Walpole ripen an abundant crop of seed every year, and this year I believe the harvest is a more copious one than ever. The plant is hardy near the shore all the way from Dublin to Cork and Kerry, where it luxuriates, and the same is true in a slightly less degree of the coast line from Dublin to co. Down, Donegal and Galway. The plant is found wild in New Zealand, where it grows 40 feet in height, and has a branched trunk. It has numerous long and narrow, thin-textured leaves 3 feet to 4 feet long by 1 inch broad, the old dead leaves being readily separable from the stem, and, according to Baron von Mueller, the berries are blue, but the specimens at Ashford before mentioned produce white berries the size of small peats on panicles as big as a bee-hive. When in flower its starry blossoms are very sweet, and they are generally covered with numerous insect visitors, such as bees and flies, during warm, sunny days. Thanks to the generosity of Messrs. Walpole in the matter of seed, I have been enabled to raise hundreds of this species, and have them planted out in all sorts of positions. No amount of frost seems to injure them, but now and then plants damp off wherever they get too much moisture. My plan here is to cover the base of the stem just at the ground level with coal ashes or old lime rubbish so as to keep the collar dry and prevent moisture from collecting at that vulnerable point.

CORDYLINA BANKSI of Hooker is another New Zealand species, growing 10 feet to 12 feet in height, its stem being usually undivided. Nicholson, at p. 372, "Dictionary of Gardening," says the leaves are linear lanceolate, 5 feet to 6 feet in length, and $1\frac{1}{2}$ feet to 2 feet broad, the latter portion of the statement being presumably a misprint for inches. There are six to eight very prominent veins on either side of the very pronounced midrib.

All the above species vary within certain limits as raised from seed, the main differences

being in the length and breadth of the leaves and the colouring of the midrib or veins. Some forms flower more freely than others, and the natural result is that the flowering specimens branch more freely than do the others, for I have so far never observed a Cordylina to branch unless it had either produced a flower-spike from its centre, or had had its growing point injured by wet and frost or by wind. Seeds sown at once in boxes of well drained sandy soil will germinate in March or April next, and soon form plants of a useful size for pots or tubs, or for planting outside in sheltered places in woods or plantations, or in the dressed grounds. These plants are also even more quickly increased by cuttings of the thickened underground roots or stems, as dibbled into boxes or pans of soil and placed on a gentle bottom-heat fully exposed to light. In this way any desirable variety can be kept distinct and increased with facility. C. indivisa (true) is not quite a rarity in our gardens after all, since it is offered in several catalogues at a moderate rate, about 2s. 6d. a plant, but all the same we should welcome a few ounces or pounds of fresh seed.

F. W. BURBIDGE.

Increasing Malmaison Carnations.—I believe most cultivators will adhere to the old-fashioned plan of propagating this plant, viz., that of putting out the old plants in the open air, surrounding them with a light fibrous mixture and layering the shoots into it. This system is always attended with more or less risk, as should the early autumn prove wet and cold, many of the layers root indifferently, while others die off altogether. Moreover, when lifted most of the soil leaves the roots, and some time elapses before the young plants are established. A plan I have adopted for several years and which answers well is to move the old plants after flowering, say in July, to the north side of a span-roofed greenhouse, which is somewhat shaded by Azaleas and Camellias. Select the best of the shoots, stripping from them the lowest leaves, afterwards making an upward incision with a sharp knife from one joint through the other immediately above it. The incision is kept open by means of a small piece of Moss being wedged into it, and the whole is finally bound round with the same material. This is kept moist by regular syringings twice daily, and in a month young rootlets will appear through the Moss. The plants are then detached from the parent and potted, Moss and all, into 3-inch pots. Rapid growth follows and good strong specimens are obtained before winter. If the work is carefully performed, 90 per cent. of the layered shoots will root satisfactorily.—J. CRAWFORD.

Pelargonium F. P. Raspail Improved.—That this is a grand Pelargonium for flowering during the summer was well shown by a fine group at the last Temple show, and now a mass of it at the Aquarium Chrysanthemum exhibition shows that it is equally useful for blooming during the dull days of autumn and winter. It is a decided improvement upon that popular variety F. P. Raspail first sent out fifteen years ago. The improved kind is being distributed by Messrs. Cannell, who have been the exhibitors whenever it has been shown in quantity. The colour of the flower is a rich crimson-scarlet, while the individual blooms are very large. For cutting, the bold trusses and long stout stems stand it in good stead.—H. P.

Iris reticulata in pots.—This Iris is one of the best known of the bulbous kinds, but not often seen in gardens, although perfectly hardy, and the flowers are beautiful and as strongly fragrant as the Violet. I should like to see the bulbs grown more for the conservatory and greenhouse and they stand gentle forcing. Five or six bulbs may be put in each 5-inch pot and placed in a cold frame until early December, when they should be taken to the greenhouse, in which they

must remain. It is not wise to give too much heat, and the time at which they bloom will depend upon the temperature. I. r. reticulata is more beautiful than any of its forms. I. r. cyanea is, however, a little gem, the flowers bright blue in colour, and the plant is very dwarf. Krelagei is dull in colour—a reddish purple tint—and the flowers are almost scentless. The flowers of I. r. purpurea are of a decided purple, and those of sophonensis of a red-purple colour, set off with a yellow crest.

Pentas carnea.—Though this will bloom at almost any season of the year, the flowers are more useful during the autumn and winter than at any other time; hence the aim of the cultivator is usually to induce it to bloom about the present season. To effect this in the case of young plants the cuttings should be struck early in the year and grown on in the temperature of an intermediate house. If stopped a few times when young and shifted on as required, they will form neat bushy little plants, from which (if needed for the autumn and winter) it may be necessary to remove some of the earliest flower-buds. The compact clusters of flesh-coloured blossoms are not particularly showy, but for all this they are very neat and pleasing, and where cut flowers are in demand, a few specimens can always be depended upon for cutting. Pentas carnea is a native of the southern portion of tropical Africa, and in this country needs the cool part of the stove or intermediate house. A second form—kermesina—is regarded as a variety of carnea, but the flowers are much deeper in colour, being, in fact, more of a carmine-rose tint. It is, however, neither so neat nor so free a grower as the other, and probably for this reason it is less frequently seen than P. carnea. An open atmosphere during the winter is very necessary to their flowering, for where fogs are frequent at that season, as they are in the neighbourhood of London, both these forms of Pentas suffer severely.—H. P.

POINSETTIAS.

THESE appear to be much earlier than usual this season. Although I have given them less artificial heat than usual, I have them now (November 16) with well developed bracts. I grow two distinct varieties; in one the leaves are deeply lobed and the bracts nearly a regular oval, while in the other the bracts are lobed and the leaves oval, though they vary a little sometimes. I believe the early variety is sometimes called carminata. There is a slight difference in the shade of colour, but it is hardly a carmine. This early variety is hardier than the other, but more inclined to run up tall. Many people propagate Poinsettias much too early in the season. Strong cuttings in July or even August will make good heads of bracts and the plants keep their foliage better than those propagated earlier, besides which they do not get so tall. It is always advisable to take some cuttings early, as the old plants do not make vigorous growth if not cut back, and the early struck plants may be topped. The tops make fine cuttings, and the plants will break from two or three eyes, and each will make a good head of bracts if grown in, say, a 6-inch pot. Five inch pots are large enough for those with single stems. Poinsettias do well in a cold pit during the summer, or if grown indoors they should be kept close to the glass and have plenty of air, but no shading. As the autumn draws on and the nights get chilly, a little warmth should be given. When allowed to remain under cool treatment too late in the autumn they are sure to lose their foliage as soon as put into warmth. As soon as the coloured bracts begin to show, the plants may be supplied liberally with liquid manure, and extra warmth will help to increase their size. After they are well developed they will last longer if kept cooler again. They also keep their colour better if not fully exposed to the sun. When plants are required for cutting only, they may be planted out under glass, and will not require so much attention. I may here mention that few flowers last better when cut than Poinsettias. I have had them keep in fine condition for

fully three weeks after they have been cut. Care must be taken that they are not exposed to the cold or put into quite cold water; they last best when put into tepid water as soon as cut and kept from cold draughts. Among the great variety of winter flowering plants we have nothing to equal Poinsettias for brightness. F. H.

ORCHIDS.

DENDROBIUM STRATIOTES.

THE above named species was introduced by M. Linden, of Brussels, during the last decade from some part of New Guinea. I have received some flowers from "J. T." which he says are from a plant purchased for this species, and with which he is very much disappointed. The flowers sent are the same as those from a plant which I first saw in the collection of the late Mr. H. J. Buchan, of Wilton House, Southampton, and which he had from Thursday Island. As this island is only a port of call for vessels coming from Australia to England, it was only shipped from there, I should suppose. The plant resembles *D. stratiotes* very much in its growth, but here all similarity ceases; the flowers, instead of being large and white, are brownish green with a yellowish lip, and the sepals and petals are all twisted. This plant is *Dendrobium Strebloceras*, and I am not surprised at "J. T." being disgusted with it when he thought he had got the fine plant here named. Both plants belong to the *Stachyobium* section of the genus, which includes such kinds as *D. superbiens*, *D. taurinum*, and some others.

The finest form of *D. stratiotes* I have seen flowered with Mr. Jones, gardener to Mr. Sherwood, at Streatham Hill, Brixton. It bore several flowers on a raceme. These were some 3 inches across, pure white, the petals erect and twisted; lip large, three-lobed, the side lobes erect, prettily streaked with purple, the front lobe white, beautifully marked with lines of carmine and purple. This plant, too, flowers in the autumn months and lasts long in beauty. Like many of the section *Stachyobium* to which it belongs, it likes plenty of heat and moisture. Under these conditions it grows well and flowers profusely. In a letter, Mr. Cypher, who grows *D. Phalaenopsis* remarkably well, says he has had over 2000 flowers open for the past ten weeks, but they are fading fast now, and he further states that he has cut one hundred spikes this week. This letter was accompanied by a remarkable lot of fine varieties, which did not appear to have been open that length of time. Mr. Sander, of St. Albans, sends some fine blooms of the rare variety which he imported with it, *D. Leeanum*, and which proves to be another fine autumn bloomer of this section. Yet another one comes from Mr. Williams, of Holloway, in *D. superbiens*, a dwarf, free-flowering variety of the species which was introduced by the Messrs. Veitch. Capt. Broomfield, in speaking of it, says that he considers this superior to all his others, and that it is the only one absolutely always in flower, a raceme of this being obtainable at any time. Captain Broomfield also says that this plant grows upon the Prince of Wales group of islands, which lie about twenty miles from the mainland of Queensland and thirty miles from New Guinea, and he says it is also to be found, but somewhat sparingly, on the nearest mainland of Australia. Mr. Williams says Goldie, then collecting plants for him, found it on the northern extremity of Australia and the southern shores of New Guinea.

These plants are best grown in either pots or baskets, which must be well drained. They should be potted firmly in good brown peat fibre and chopped Sphagnum Moss and be well exposed to the sun and light, have a very high temperature, with abundance of moisture in the atmosphere and a free circulation of air. During the summer season they enjoy a liberal supply of water to their roots as well as overhead from the syringe, and the thermometer at night should never be allowed to fall lower than 68°. In the winter a temperature some few degrees lower is preferable, say from 60° to 65°, when also less water and less moisture in the air should be given.

WM. HUGH GOWER.

Lycaste plana Measuresiana.—J. Dale sends a fine flower of this very pretty variety, with broad spreading sepals of a bronzy green; the petals and lip white, profusely spotted with bright rosy purple, with a plain white border to the petals, the lip also clear white. The plant is a native of Bolivia and will thrive in the cool house through the summer months, but in the winter it requires a little more warmth, and at this time it should be placed at the cool end of the *Cattleya* house.—W. H. G.

Dendrobium tetragonum.—This plant, discovered by Allan Cunningham, was originally introduced from Australia by the Messrs. Rollisson, of Tooting. It has pendent quadrangular stems. The flowers, produced singly, are very distinct, having long narrow sepals and petals, the lateral ones slightly twisted, pale green, streaked with red; lip recurved at the point, white, with numerous transverse red streaks. I am in receipt of a growth with flower of this species from James Sheppard, asking if I can tell him of a figure of it. I only know of a very poor one compared with the flower sent, and that is in the *Botanical Magazine*, t. 5956.—H. G.

Lælia Gouldiana (*H. Goodheart*).—This, according to some, is a natural hybrid between *L. anceps* and *L. autumnalis*. The flower measures 4 inches across, with bright rose-purple sepals and petals, the side lobes erect, white at the base, tipped with rose-purple, and streaked on the inside with the same colour. The front lobe is of a deep rich purplish crimson, the crest yellow. The plants may be grown on blocks of wood or in hanging baskets with good drainage and in good peat fibre and Sphagnum Moss. Slight shade is necessary for these plants during the hottest and brightest part of the day.—W. H. G.

Cypripedium cardinale.—Joseph Thompson sends a very fine flower of this hybrid, which was raised by the Messrs. Veitch and Sons, of Chelsea, between *C. Sedeni* and *C. Schlimi albidiflorum*. "J. T." says it has been in bloom for the last eight months with several flowers open at a time. I remember to have seen a plant of this variety which flowered freely for thirteen consecutive months. It is a better plant than *C. Sedeni*, having a rounder pouch, which is of a much brighter colour, and the petals are broad, white, whilst the dorsal sepal is slightly tinged with green. The variety sent is a very good one, the flower being large and bright.—W.

Cypripedium insigne var. *Sanderæ*.—There are few more useful flowering plants for early winter than the old and well-known *Cypripedium insigne*. It is easily grown, flowers unfailingly, and in appearance compares favourably with many *Cypripediums* ten times as costly. Several varieties have in late years been introduced, the most distinct and beautiful of all being the variety *Sanderæ*. A flowering plant of this was shown by Messrs. Sander at the Drill Hall, Westminster, on Nov. 14. It has the same bright green, strap-shaped leaves as the typical form, but they appeared, if anything, to be shorter and stouter. The flowers, instead of having the yellow-green colour of the ordinary *C. insigne*, are of a beautiful shade of clear yellow and have an almost varnished appear-

ance. The upper margin of the standard sepal is of a perfectly pure white, the only other variation of colour in the flower being a few brown-purple spots on the standard sepal. This variety is at present very rare, but should it become plentiful, its immense value as a garden Orchid cannot fail to be recognised.—B.

Phalaenopsis Esmeralda.—G. Scott sends some very nice varieties of this plant, which vary considerably in their colours and markings. In the ordinary form the flowers are of a brilliant amethyst-purple. This species comes from Cochinchina, and grows freely in a temperature of about 70° to 75° in the daytime, and some 5° or 8° lower at night. In the winter the temperature should never be lower than 65°, and a nice moist atmosphere should be maintained, but it does not like water overhead. It should be potted in Sphagnum, and the pots be thoroughly well drained.—W. H. G.

Cypripedium Calceolus.—Doubtless this Lady's Slipper is fond of calcareous soil, but it is by no means the case that it will not flourish without lime. I wish you could see some plants that have been grown in nothing but boggy peat and sand. The fresh stringy roots have run out in numbers and to a considerable length, and the next best proof of the healthiness and vigour of the plants is to be seen in the crowns, almost as big as Cob nuts, which are just showing on the surface. Some might say that this is abnormal, and that I do not deny, but it is useful to know how we can get abnormal developments in regard to bulk and vigour with some things. The practical point is, can you grow this plant well with or without lime? and as it has long been proved that such is the case, it is a mere matter of choice with the cultivator as to how he plants it in this respect.—J. WOOD.

Cattleya aurea Statteriana.—A letter comes to hand from Mr. Johnson, Stand 1111, Manchester, complaining that I have misrepresented the flower known by this name which exists in the collection of Mr. T. Statter, of which he has the charge. I can only say that the flower received from Mr. Wheatley is exactly the same as that figured in the "Orchid Album," t. 468, and called by this name. The plate was drawn and coloured by Fitch, and described by myself in the accompanying letterpress to the figure above-mentioned, and I have not heard of any complaint being lodged against it.—W. HUGH GOWER.

Lælia elegans Morreniana.—Oswald, Rheims, sends some beautiful flowers of this variety. The flower now before me measures upwards of 5 inches across. The sepals and petals are of a rich rosy magenta, the petals much the broader and beautifully waved at the edges; the three-lobed lip is at the base china white, the reflexed tips rich crimson. The front lobe is large and flat and of a deep rich crimson, having a border of lilac with some deeper coloured veins. I know of but one finer variety, and that is *L. elegans Broomeana*.—W.

Oncidium Jonesianum.—Oswald, Rheims, also sends me four flowers of different varieties of this plant. All are very pretty, but the one marked No. 3 may be taken as the typical form. He tells me he has found this plant likes a great deal of heat and moisture in the atmosphere, and in the winter months it does not like drying. I used to see this plant done well in the late Mr. Buchan's collection at Southampton, where Mr. Osborne used to keep it in the East India house.—G.

SHORT NOTES.—ORCHIDS.

Lælia autumnalis alba.—"J. T. II." sends beautiful flowers of this albino. The flowers are of the purest white, with just a stain of yellow on the disc of the lip. This is the only colour which is admissible in a white flower.—G.

Lælia anceps.—A very good form of this plant comes from H. Brockner, of Hesse, East Yorkshire.

It is a fine flower, although somewhat spoilt by having been packed in cotton wool, which should never be used for Orchids. The front lobe of the lip is very dark and rich in colour.—W.

Cattleya pumila.—H. Broekner sends a flower of this species under the name of *Laelia præstans*. It is not that species, although a very nice form of the plant named above, being of good colour and shape. The lip is small and very different from that of *L. præstans*.—W.

Cypripedium Harrisianum.—H. Broekner also sends me a rather dark coloured form of this plant. He says he has been told it is the variety *vivicans*, but I do not see anything about it to warrant the name. It is a pretty variety, but there are now so many fine forms of this hybrid, that one can be easily misled.—W.

Cattleya Bowringiana.—I find this succeeds best in the warm Orchid house, and whilst in growth it takes a plentiful supply of water. During the winter months it must not be allowed to become dry or it will surely suffer. Being also a very free-rooting species, it must not be allowed to suffer from the want of pot room.—A. Y.

Cattleya labiata.—I am in receipt of flowers from Mr. Broome, of Llandudno, of a variety with a finely coloured lip. Mr. Broome also sends me a bloom from the same plant as that from which he sent me such a magnificent flower last year. The one now to hand is very inferior to it; indeed, the dried specimen is equal in colour to it.—W.

Bolbophyllum cupreum.—Mr. Cypher sends a spike of this plant. It is one of those plants which often are imported by mistake, for no one would gather this to send it home. The flowers, of a deep copper colour, are densely set on the spike. It is about thirty years ago since I had this species growing, and I have never seen it since. It is of no value.—G.

Peristeria elata.—Benjamin Jones sends me flowers of this, which is popularly known as the Dove Plant, and asks why it is that one of his plants never flowers. If the two plants are strong enough to flower and both are treated in the same manner, it simply confirms my previous remarks upon this species, that there are some varieties which are much freer blooming than others, and I suppose that "B. J." has one of each of them.—G.

Dendrobium Phalænopsis dellense.—"P. H. P." sends me flowers of this species, which are beautiful, and which represent the above-named variety. My friend tells me he has twelve flowers upon a spike. The flowers each measure about 3½ inches across, and have a ground colour of French white with a flush of violet in the lip. It is a charming form, the original plant being in the collection of Baron Schröder, of The Dell, Egham.—W. H. G.

Disa tripetaloides.—"G. H." sends me a spike of this very pretty terrestrial species. The flowers are of a creamy white nicely spotted with crimson. This is an old species that was first found by Thunberg many years ago. It is only within the last few years that it has been brought alive to this country. I have seen it in several places, but most frequently in the garden of Mr. Smee at Carshalton, where many of these little rarities can be met with.—W. H. G.

Dendrobium linguæforme (M. Harper).—This is the name of the flower you send. It was found by Mr. Brown at Port Jackson, in Australia. It has thick, fleshy leaves, which are ribbed on the upper surface and deep green; the flower-stalk is slender, bearing a number of pure white flowers; the small lip is pale yellow, and the side lobes slightly spotted with red. The lip is quite concealed from view, so that the flowers appear to be pure white. It will thrive well upon a block of wood in the cold house.—W. G.

Dendrobium infundibulum.—J. Wescott sends flowers for a name. The curved spur of the lip and the smooth side lobes all confirm me in the opinion that the above is its name. It is one of the nigro-hirsute or black-haired *Dendrobies*. It was introduced first by the Messrs. Veitch, but was afterwards sent home by the Rev. Mr. Parish to the Messrs. Low, who grow it in quite a cool house, where it does better, and flowers more freely than when placed in more warmth. The large white blooms last a long time in perfection.—W.

The weather in West Herts.—A week of changeable weather as regards temperature. For instance, on Thursday in last week the shade temperature at no time exceeded 38°, whereas on Tuesday last the highest reading was 53°. Again

on Sunday night the exposed thermometer showed 11° of frost, but on Tuesday night the same thermometer never fell lower than 46°. Both at 1 foot and 2 feet deep the ground is now warmer than at any time for ten days. November was the first unseasonably cold month that we have had since January, or for ten months. The total rainfall has already (Wednesday) exceeded the average for the month by about a quarter of an inch—making this the third wet month of the present extraordinary year—the other two being February and October.—E. M., *Berkhamsted*.

NOTES OF THE WEEK.

Flowers from Australia.—Acting on past experiments with *Chrysanthemum* flowers, we understand that a bouquet of Australian wild flowers is now on its way to England frozen in a solid block of ice, and intended as a present for the Queen.

Jasminum gracillimum is a stove climber of note for its clusters of pure white deliciously fragrant flowers. It is very pleasing trained against a pillar, and gives over a long season a display of bloom. Few flowers are more fragrant than those of *J. gracillimum*.

Veronica Andersoni variegata.—Several plants of this in the greenhouse at Kew are well worthy of note. This is a plant amateurs might grow more, as it is easy to cultivate and remarkably handsome, the leaves being well variegated, green, with a broad band of creamy white, whilst the flowers are purple-blue in colour and produced in dense spikes.

Sonerila maculata.—This was very pleasing a few days ago in the stove at Kew, where several plants were in full bloom. It was introduced by Mr. Ball, of Chelsea, about the year 1890, and was at first named *S. orientalis*. This *Sonerila* is well worth attention. It grows about 9 inches in height, is very compact, and has purplish coloured leaves, the flowers being produced in neat erect bunches, the colour pink, a bright contrast to the foliage.

November leaves.—Mr. Waterer sends us a charming bunch of his Pennsylvanian Wortleberry, which is delightful and of very good colour; also some of the bright American Oaks, to which is given the general name of *americana*, which, we think, does not belong to them. There are several species of American Oak remarkable for the beauty of their leaves.

Trichinium Manglesi is a very pleasing little plant in bloom in the Cape house at Kew. The flower heads are large and not unlike small balls of wool with pink skeins through them. The way to propagate it is by cuttings of the roots, the stouter ones being selected. If inserted in pots or shallow pans and stood on a shelf in a warm greenhouse they will root well. *T. Manglesi* is not a plant for ordinary gardens, but it is certainly interesting.

Pear Winter Nelis.—I am sending you by this post half-a-dozen Pears Winter Nelis. I remember you think highly of this kind, and rightly so, considering the high flavour and long keeping qualities. Another of its merits is that, according to my observations, it can be depended on. This is more than can be said of many of the big kinds. Even in this low situation it is the best Pear I have. It should be much more extensively cultivated, and would pay for any attention.—JOHN CROOK, *Forde Abbey*.

* * The finest examples we have seen in London of this Pear—large, very good in colour, and with the flavour this sort has when in a good state.—Ed.

Senecio macroglossus, a South African climber, has been mentioned more than once in THE GARDEN as a distinct and interesting species. A specimen in the Cactus house at Kew is in bloom, and the whole aspect of the plant is

quite unlike that of any other climber. The flowers are yellow, not unlike those of the yellow Marguerite in shape, and in contrast to the wealth of Ivy-like leaves, which are deep green and distinctly veined. At first glance it is difficult to see the difference between the leafage of the two climbers. It is of vigorous growth, and suitable for a house of considerable size.

Peristrophe speciosa, better known as *Justicia speciosa*, is one of the most charming of winter flowers for the warm greenhouse. It looks extremely well mixed with other things, as forced bulbs, and good effects may be got in the greenhouse in this way. The flowers are of a warm purple colour, and very distinct from the majority of things in beauty at this season.

The Phylloxera.—We learn that serious damage is being caused by the Phylloxera, especially in Sicily. In three or four years the ravages of the Phylloxera have reduced the Vine harvest to half its former yield. In the provinces of Syracuse and Catania the loss owing to this cause may be calculated at a milliard of francs, and, if not arrested, the evil will destroy the best kinds of Italian wines. The scarcity of means of curing the Vines is much felt in the province of Trapani, which is the principal sufferer.

Bomarea oligantha is not unlike *B. fröderi*, of which a coloured plate was given in THE GARDEN, May 11, 1892. A plant on a rafter in the Cactus house at Kew is in full bloom, and makes a pleasing feature at this dull season of the year. It is a native of Peru, and the flowers are produced in heads of about eight each, individually tubular in shape, the inner surface rich yellow, spotted with deep crimson, the outer portion reddish. When well established, the *Bomareas*, which are much neglected in English gardens, are very handsome, and give comparatively little trouble. At Kew they are planted out in a shallow raised bed on the south-west side of the succulent house, and are never shaded.

Thunbergia mysorensis, in bloom in the stove at Kew, is a remarkably interesting plant, and the flowers are finely, if quietly, coloured. It is a rare species, and not likely to get very popular, as it is not a showy climber. A specimen running over a rafter betokens robust growth, and the raceme of flowers is very much like the *Wistaria*, each raceme carrying about thirty flowers, which when fully expanded are pleasing. Individually, they are not unlike a magnified *Antirrhinum*, the upper segments broad, reddish brown or buff on the outside, the centre rich yellow, the outer segments reddish buff, and very charming for their particular shade of colour. The leaves are rich green and undulated at the margin. It is seldom one gets such a distinct colour, and this climber is valuable on that account.

Japanese Kakis.—We have received from M. Latour-Mariac an interesting box of the Japanese Kaki. He writes: "I have the pleasure to send you some specimens of the Japanese Kaki. If they have not the merit of novelty in your eyes, they have at least that of being my own growth. For eating they ought to be well bletted so as to be quite soft, or they will be tart and astringent as the Sorb. In a proper degree of maturity these Kakis are extremely juicy and full of sugar. Having carefully removed the skin, we generally moisten them by adding a little rum or brandy, as in the case of Pine-apples, adding sugar to taste, but many prefer them without these additions. The kind I send is known in Japan as *Ione Nashi*, signifying 'without seeds.' I hope you will like them."

Acidanthera æquinoctialis, a native of Sierra Leone, we noticed lately in bloom in the Royal Gardens, Kew. It reminds one of a *Gladiolus*, and the whole aspect of the plant is not unlike that of *G. sulphureus*, of which a plate was given in THE GARDEN, July 19, 1890. The flowers are of about the same size, produced in much the same way, but they are more beautiful even than the soft yellow blooms of *G. sulphureus*. They are pure white, not more than two, judging by the

Kew specimens, being borne on the rather slender stems, and at the base of the segments there is a arched dagger-shaped blotch, so to say, of colour, whilst the centre is yellow, and a slight suffusion of the same shade appears just around it. The plants are in comparatively small pots, and the growth with the flower-stems reaches a height of about 4 feet, the leaves Gladiolus-like, of a fine green colour, and by no means unattractive. The purity and beauty of the flowers are the chief charms of the *Acidanthera*.

Brownea Crawfordi.—Visitors to Kew during the winter months should notice this fine *Brownea* in the Palm house. It is commencing to bloom, and is one of the best of this remarkable genus. The late Mr. Crawford, after whom it is named, bequeathed his collection of *Brownias* partly to Kew and partly to Glasnevin. A plant is also in the latter collection. The Kew specimen is about 15 feet in height, and when in full beauty strikingly handsome. It is a hybrid between *B. macrophylla* and *B. grandiceps*, and shows affinity to both parents, agreeing with the former in general expression and foliage, and the latter in the flower. The heads of bloom are large, and composed of upwards of seventy flowers, individually from 2 inches to 3 inches in length, reddish salmon in colour, with numerous stamens standing out conspicuously. The leaves are pinnate, broad, and about 2 feet in length, the colour deep green, in fine contrast to the splendid clusters of flowers.

Hardy Crinums.—To "W. W.'s" list of hardy Crinums might be added *C. crassifolium*, a coloured plate and description of which may be found in Jacquin's "Hortus Schoenbrunnensis." Dean Herbert, in his invaluable work on "Amaryllidaceæ," pronounces this as the hardest known species. The flowers, of which in strong specimens about a dozen are produced in an umbel, are about 3 inches long, white on opening, turning to a deep rose when they have reached maturity. With me this species flowers very regularly every year in June and July, strong bulbs carrying many spikes; it produces but few offsets. The white Crinum Moorei, which, however, is not quite hardy here, is certainly one of the most magnificent greenhouse bulbs. The flowers, which are large, broad, and very fragrant, have the curious peculiarity of partially closing in the early part of the day, and they are seen at their best after about 4 o'clock p.m. The illustration given on page 483 is clearly that of *C. Powellii* album, and not of *C. Moorei* album, as stated.—C. G. VAN TUBERGEN, JR., *Haarlem*.

Staging Chrysanthemum blooms.—At the last Royal Horticultural Society's meeting in the Drill Hall, Messrs. H. Cannell and Sons staged some splendid cut blooms in such a manner as to immediately attract attention. There were several of the best varieties of the Japanese section, chiefly the newer ones, arranged in threes in vertical rows. True, there were a few other exhibitors who staged in somewhat similar fashion, but these being in larger numbers gave a much better effect. This system was advocated by me a year or two ago in these columns, and it is a method that ought not to be lost sight of. Whilst there is time and before the schedules are again drawn up, will the various societies take note of this kind of arrangement and give it a trial? Messrs. Cannell and Sons are to be congratulated upon the excellent style in which these flowers were staged and likewise upon the very plain and legibly written names. Twelve of the very best incurred or Japanese varieties, three blooms each, would make a fine display.—H. G.

Narcissus blooming twice a year.—The *Narcissus Tazetta* of Cornwall and of the Scilly Islands is just now in bloom for the second time during the present year, as the result in part no doubt of the recent hot, dry season. This is, however, often the case with bulbs of *N. Tazetta* vars. that have been forced for early bloom and then planted out in warm, dry sunny corners about May, such bulbs frequently bearing flowers and leaves in October, November, or December. There are, moreover, several varieties of bunch or cluster *Narcissi* from the south of France and

Italy that naturally flower at this season of the year. *N. Tazetta papyraceus*, the paper-white of the shops, often blooms here in November in the open air, as also do *N. Tazetta patulus* and *N. Tazetta chrysanthus*, or *N. T. Bertoloni*, and, as before indicated, this is often the case with several of the Dutch varieties, especially with *Soleil d'Or* and *Grand Monarque*. There is no reason why *Narcissi* should not bloom twice a year under certain conditions, just as early forced Strawberries often yield a second crop in the late summer or autumnal months of the year, but so far it seems that this habit is confined to *N. Tazetta* and its variations.—F. W. B.

Ugly names.—We regret to see that an American botanist, in attempting to give a new name to the well-known Snowdrop tree, cannot do better than invent the ugly one of *Mohrodendron*. First he tried to make it "*Mohria*," and in doing so fell into the mistake which he regrets in the following paragraph in *Garden and Forest*, November 8:—

THE GENERIC NAME OF THE SILVER BELL TREES.

In a note published in the issue of this journal of October 18, 1893 (pp. 433, 434), I called attention to the fact that the generic name *Halesia*, Ellis, was antedated by *Halesia*, P. Br., and should therefore be rejected. I proposed that it should be replaced by *Mohria*, in honour of Dr. Charles Mohr. My attention has since been called to the long previous publication of a genus *Mohria* (Swartz, *Syn. Fil.*, 159, 1806), a South African genus of *Ferns*, dedicated to D. M. H. Mohr, a distinguished cryptogamist, who died in 1898. Thus, in attempting to correct one homonym, I have inadvertently published another. This is unfortunate, but can easily be corrected. I here suggest for *Halesia*, Ellis, the generic name *Mohrodendron*=*Mohria*, Britton (*Garden and Forest*, vol. vi., p. 434), not Swartz, and for the species:

1. *Mohrodendron carolinum* (L.)=*Halesia carolina* (L.)=*Halesia tetraptera* (L.).
2. *Mohrodendron dipterum* (L.)=*Halesia diptera* (L.).
3. *Mohrodendron parviflorum* (Michx.)=*Halesia parviflora* (Michx.). N. L. BRITTON.
Columbia College, New York.

We hope our readers will always keep to the old name, and, happily, in any case there is a good English one. Surely from the vast number of beautiful Greek and Latin names it should be easy for a man of learning and wit to find a beautiful Latin name for so fair a tree.

SOCIETIES AND EXHIBITIONS.

ROYAL HORTICULTURAL SOCIETY.

NOVEMBER 28.

THIS meeting was one of the smallest of the whole year, being quite a contrast in this respect to the last October gathering. It was not devoid of interest, however, there being several good things shown both in Orchids and Chrysanthemums. Of the former the hybrid *Cypripediums* had the monopoly, whilst almost as a matter of course the Japanese section of the Chrysanthemums was by far the most conspicuous. Some excellent examples of Apples and Pears were staged from Sussex; finely developed fruit. The vanguard of the Daffodil family—*Narcissus monophyllus* (*Corbularia Clusii*), with its paper-white flowers was shown in good condition.

Orchid Committee.

A first-class certificate was awarded to—

LÆLIA ANCEPS AMESIANA—A very distinct and fine form. The flowers appeared to be only just expanded, but the colouring was excellent. The petals are broad, suffused with violet towards the extremities and white at the base, the sepals having less colour; the lip is somewhat small, but of an intensely deep velvety crimson shade, the inner portion being richly veined. From Mr. Thos. Statter, Stand Hall, Manchester.

Awards of merit were voted to the following—

CALANTHE VICTORIA REGINA.—Said to be a cross between *Limatodes rosea* and *C. Veitchi*. The growth and habit of the spikes are intermediate between those of these varieties, being sturdy and well clothed with flowers, the colour of the flowers a pale blush-pink, the lip of a lighter shade. Several plants were shown, forming a fine mass of flower of a most pleasing colour. From Messrs. Sander and Co.

CALANTHE MYLESI (*C. nivalis* × *C. Veitchi*).—A beautiful white hybrid pure in colour, save a faint trace of the palest yellow upon the labellum, a distinct variety, and quite an acquisition as well as a decided contrast to the richly coloured forms. The habit is much like that of *C. Veitchi*. From Messrs. B. S. Williams and Son.

CYPRIPEDIUM MARY LEE (*C. Leeanum* × *C. Arthurianum*), in which the latter parent is clearly to be traced in the drooping petals with their distinct markings; the dorsal sepal is particularly good and distinct, partaking of its other parent; it is pure white, with faint spots of a purplish shade and a green base. From Mr. W. R. Lee, Ardenshaw, Manchester.

CYPRIPEDIUM INSIGNE VAR. ILLUSTRE.—A fine form of the *Chantini* type, being profusely spotted in the dorsal sepal as that variety is, and upon a pale greenish yellow ground with a white margin, the petals freely spotted also. From Mr. R. J. Measnes, Cambridge Lodge, Camberwell.

CYPRIPEDIUM FARIANO-LAWRENCEANUM, best described as being possessed of the form of the former, with the characteristic colouring of the latter parent. It is in size intermediate between the two. From Mr. Thos. Statter.

CYPRIPEDIUM MINOS (*C. Arthurianum* × *C. Spicerianum*), which has the clearly defined character of the latter both in the fine dorsal sepal and in the bronzy-coloured pouch, the petals being much after *C. Arthurianum* in form and colouring—a very pleasing and distinct hybrid. From Messrs. J. Veitch and Sons.

CATASETUM DARWINIANUM, which very much resembles *C. Gnomus*, to which a botanical certificate was awarded on Sept. 26 (see issue for Sept. 30, p. 313). From Messrs. J. Veitch and Sons.

A botanical certificate was awarded to—

HABENARIA CILIARIS.—A very pretty species with pale orange flowers, the lip being beautifully fringed, the spike about 2 feet in height, a rare plant (North America). From Messrs. J. Veitch and Sons.

Of other miscellaneous exhibits, there was a beautiful display of *Cattleya labiata*, twelve cut spikes with nearly three dozen flowers. One variety was particularly fine, the lip being marked more after the manner of the best forms of *C. Mossiae*. These were tastefully set up, coming from Mr. Blandford, Moorhill, Southampton. Messrs. J. Veitch and Sons showed their hybrid Orchids, amongst which were *Cypripedium Cleola* (*C. Boissierianum* × *C. Seblimi albiflorum*), a beautiful hybrid with blush-white flowers, after *C. Sedeni*, but larger; *C. Aretè* (*C. Spicerianum* × *C. concolor*), with small flowers; *Lælio-Cattleya Cornelia* (*C. labiata* × *L. pumila*), with a purplish suffusion in the sepals and petals, the lip large in comparison, growth dwarf and compact. Mr. Lucas, Warham Court, had *Dendrobium d'Albertysi*, a small, but pretty species, with pale flowers. Messrs. H. Low and Co. showed a small, but rather leggy example of *Vanda Sanderiana*, bearing a small spike of flower; also *Cypripedium Pluto* (*C. Boxallii* × *C. calophyllum*), a very pretty hybrid, and *C. calurum Ainsworthi*, a fine variety in the way of *C. Schroederae*, but not so large. Messrs. Sander and Co. had *Calanthe Sandhurstiana*, rosy red, a rich colour; *Cypripedium Pryorinum* (*C. Lathamianum* × *C. Harrisianum*), which partakes much of the latter parent, having bold flowers; and *C. Lynchianum* (*C. Spicerianum* × *C. selligerum majus*), another very pretty hybrid. From Mr. Lee came the best variety of *C. Leeanum* called *superbum*, the dorsal sepal being particularly fine. Mr. Cobb, Dulcote, Tunbridge Wells, sent *Cypripedium Cobbianum* (*C. Law-*

renceanum × C. Sullieri), a vigorous-growing plant with dark lustrous flowers. *Cymbidium Mastersi* was shown by Mr. Tracey, Twickenham.

Floral Committee.

First-class certificates were awarded to—

AGLAOMORPHA (POLYPODIUM) MEYENIANA.—A noble looking Fern with a creeping rhizome after the manner of *Phlebodium aureum*, carrying a fine head of fronds, the lower part of each having the pinnae entire, the upper part (about half of the frond) which is the fertile portion being serrated after the manner of *Nephrolepis davallioides*; a fine variety and one that would be an acquisition in a fernery. From Mr. H. B. May, Dyson's Lane Nursery, Upper Edmonton.

ACALYPHA MACFEEANA.—A very showy plant, valuable for decoration, lighting up so well by reason of the rich colouring of its foliage, which is blotched with bronzy red and crimson in an irregular manner. The plants shown were dwarf and compact. From Mr. H. B. May.

Awards of merit were given to the following *Chrysanthemums*—

LE PRINCE DU BOIS (Japanese).—A deep bright yellow, large and full, shape and character of *Beauty of Exmouth*. From Mr. Owen, Maidenhead.

H. M. POLLETT (Japanese).—In style of flower much resembling *Vivand Morel*, but with the colouring of *Etoile de Lyon*, a distinct rosy purple. From Mr. Owen.

MRS. J. MITCHELL (incurved).—A sport from *Empress Eugénie*, with pale bronzy coloured flowers, a pleasing colour. From Mr. Owen.

MRS. J. GARDINER (English seedling incurved).—In form of flower much after *Princess of Wales*, but in colour a decided orange-yellow with deeper lines, much darker than *Mrs. S. Coleman*. Pure golden yellow flowers from later buds of the same variety were shown. From Mr. Owen.

ELSIE WALKER (pompon).—A distinctly beautiful variety with large bronzy red or chestnut coloured flowers tipped with gold and with serrated edges. From Mr. Owen.

LITTLE PET (miniature pompon), with deep bronzy red flowers, prettily imbricated, a very pleasing variety. From Mr. Owen.

JUDGE HOIT (Japanese Anemone-flowered).—A fine variety with extra large flowers of a pale blush-pink colour, a decided acquisition to its class. From Messrs. H. Cannell and Sons.

GOLDEN GATE (Japanese).—A deep golden yellow with broad petals. It might have been called *Golden Etoile de Lyon*, being much like that variety and nearly as large. From Messrs. H. Cannell and Sons.

ELMER D. SMITH (Japanese).—A very fine reflexed variety of large size, in colour a deep crimson suffused with purplish maroon, the petals having a lighter reverse. From Mr. T. B. Haywood.

Mr. G. Wythes set up a very effective group of Orchids and other decorative plants in season; of the former there were several well-grown examples of *Cypripedium insigne*, carrying from twelve to sixteen flowers each; also of *Calanthe Veitchi*, bearing long spikes of deeply coloured flowers (these are two of the best Orchids for this season). Other plants consisted of *Poinsettias*, *Crotons*, *Dracaenas*, and *Palms*, with dwarf Ferns as a finish (silver Flora medal).

Messrs. H. Cannell and Sons had a fine display of *Chrysanthemums* and zonal *Pelargoniums*. The former were staged in threes of each colour in lines similar to the plan advocated in *THE GARDEN* last year, and formed a most effective exhibit. The following were the best kinds staged: *Madame Thérèse Rey*, *Robert Owen* (extra fine flowers, the best we have seen this season), *Vivand Morel*, *Waban*, *Golden Wedding*, *Golden Gate*, *Mrs. C. H. Payne*, *Judge Hoyt*, *John Dyer* (a superior *l'Adorable*), and *Robert Flowerday* (dark maroon). Of the *Pelargoniums* which were staged in large bunches, the best were *Maud of Wales*, deep pink; *Mrs. Wildsmith*, a bright pink; *Mascagni*, cerise centre and white edges; *Etoile de Lyon*, white centre and cerise edges; *A. F. Wootton*, salmon;

Sunbeam, deep rosy salmon; *Album*, pure white; and *King of Purples*, a purplish-magenta (silver Banksian medal). Messrs. H. Low and Co. sent well grown *Cyclamens* of the best strains, the plants bearing large flowers with great variety of colour, also a small group of hard-wooded greenhouse plants, chiefly *Correas*, of which *C. cardinalis* was particularly well flowered. *Acacia platyptera*, a pretty variety, *Grevillea alpina* and *Crowea latifolia* were also shown (silver Banksian medal).

Miscellaneous exhibits comprised the following: Mr. Latham, Botanic Gardens, Birmingham, showed cut examples of *Callicarpa purpurea*, a stove species introduced from India in 1833, bearing an abundance of deep violet-coloured berries in dense cymes close to the leaf-stalks and in a continuous manner for a length of 3 feet or 4 feet; a most attractive plant for this season of the year. A cultural commendation was awarded to this exhibit. Mr. G. Wythes brought from Syon Gardens a cut example of *Sterculia nobilis* in a fruiting state, this being the first time of its fruiting there after a period of fifty years, the plant in question being of nearly the same height. The fruits are of a dark maroon colour and similar to a chestnut; the flowers are of a pale buff colour. Mr. H. B. May showed a fine-foliaged *Begonia* named *Mme. Lebourg*, of dwarf habit, with silvery foliage; useful as a decorative subject. Mr. T. S. Ware showed *Narcissus monophyllus*, to which allusion has already been made, also *Lachenalia pendula* (the true variety), with stout sturdy spikes of its Indian-red flowers, tipped with green. Mr. Owen had a few new *Chrysanthemums*, as *H. L. Sunderland (Jap.)*, which might be termed a *Golden Elaine*, and *Walter Surman (inc. Jap.)*, a bronzy yellow with serrated florets; also *E. L. Jamieson (Jap.)*, chestnut-bronze, of extra size. Mr. Blick, The Gardens, Hayes, showed *Helen Crawford (Jap.)*, a lilac-mauve, with silvery reverse, and Mr. Duncan brought from Warnham Court another called *Eric (Jap.)*, a light-coloured variety with long drooping florets. Mr. Salter, Woodhatch Lodge, Reigate, had large blooms of *Lord Brooke* and *Chas. Davis*. Mr. Seward, Hanwell, sent one called *George Seward*, a dark velvety crimson, after the style of *Mons. W. Holmes*. Mr. Stevens, of Putney, showed an incurved Japanese called *Pearl Beauty*, which is of much promise. This we hope to see again; it is of a creamy white colour. Long shoots of *Guernsey Nugget*, showing its peculiar character of flowering throughout the entire length, were shown by Mr. Blandford, who also had cut blooms of other varieties.

In the competing class for *Chrysanthemums*, Mr. Vince, Highgate Cemetery, was first with neatly grown plants of medium size, the best being *Florence Piercy*, *Mme. de Sevin*, *Source d'Or*, *Vivand Morel*, *Avalanche* and *Mons. Bernard*. Mr. Wythes was second in this class with plants informally trained.

Fruit Committee.

At this committee seedling Apples were numerous, but some were past their best.

An award of merit was given to—

APPLE BYFORD WONDER.—A very heavy solid kitchen variety, in shape and colour resembling *Warner's King*, but with dark spots. It was quite distinct in flavour. It is said to be a heavy cropper and good keeper. From the Hereford Fruit Co., Hereford.

Messrs. Bunyard and Co., Maidstone, showed two new seedling Apples, but somewhat over-ripe. One named *Foster's Scarlet Prolific* is very attractive, being highly coloured, the other *Christmas Pearmain*, a dessert variety, is somewhat like a *Blenheim*. Messrs. Peed and Son, Roupell Park Nurseries, sent a new seedling named *King of the Valley*, a light green medium-sized fruit. A new seedling named *Bartlett's Glory* was also staged, but past its best; this was given an award of merit earlier in the season. Some half-dozen fruits of *Diospyros Kaki* were staged by *MM. Chantrier frères*, France. These are of a deep yellow colour, in size resembling a small *Orange* and of a peculiar taste. A dozen very large *Uvedale's St. Germain Pears*

weighing in the aggregate 27 lbs. 6 ozs., one fruit alone weighing 3 lbs 8 ozs were staged by Mr. Arnall, Headington Hall, Oxford. Mere size, however, does not add to keeping qualities, as these large fruits were decaying rapidly; whereas in ordinary seasons this sort may be kept well into May (bronze Banksian medal). A cluster of *Musa Cavendishi* was shown by Mr. Quarterman, Silvermere Gardens, Cobham, Surrey; the fruits were large and the bunch of considerable weight (cultural commendation). The *Liverpool Horticultural Co.*, The Vineyard Nurseries, Garston, Liverpool, sent some bunches of *Colman Hamburg Grape*. This is stated to be a seedling, but it is much like *Gros Colman* both in berry and colour, and the committee considered it too much like the latter in flavour to merit a special award. Bunches from a Vine inarched on another variety were also staged; these were also very similar to *Gros Colman*. A very fine lot of Apples (thirty dishes) and a dozen dishes of Pears were shown by Mr. Goldsmith, Leonardale, Horsham. These were noticeable on account of their splendid finish and perfect shape. *Beurré Gendron*, *B. Alexandre Lucas*, *B. Bachelier*, *Duc de Nemours*, *Vicar of Winkfield*, *Maréchal Vaillant*, and *Duchesse de Mouchy* were especially good. Amongst the Apples, *Peasgood's Nonsuch* was very fine, while *Ribston*, *Cox's Orange*, *Blenheim*, *Adams' Pearmain*, *Hoary Morning*, *Lady Henniker*, *Newtown Wonder*, *Lane's Prince Albert*, *Bismarck*, *Beauty*, and *Warner's King* were also noticeable. A silver Koightian medal was awarded.

The lecture on late-keeping Grapes by Mr. Crasp, Swansea, was read by the secretary. This is unfortunate, as in the absence of the author any questions that may arise cannot be explained. At the outset Mr. Crasp stated many growers thought that late Grapes needed less care than early ones, hence the many causes of failure in private places. He said that late Grapes failed to keep well simply because they were badly finished and badly grown from the start. The border and the roots were the primary points, and to these too close attention could not be given. He did not advocate costly borders; indeed, they were not essential. What was specially required was efficient drainage. In private gardens the preparation of borders should not be haphazard, as where the canes are expected to last a long time, greater care was necessary. The site should not be low or damp, or there would be a difficulty in keeping the fruit. Vines like a warm, well-drained position and good soil, not too heavy, as clayey soil was cold and productive of great evil. The orthodox top spit of heavy soil was not always the best, and in cases where the natural soil was not suitable it was better to purchase than use such. A porous soil, but not loose, was essential to good culture. In some soils there was no lime, and this must be added. Rank manure was not required, this souring the soil and causing stagnation. When Vines required food, plenty of crushed bones and a top dressing of spent manure were beneficial, with frequent applications of warm liquid manure in the growing season. He advised a free use of the latter in preference to over-loading the soil with manure. Deep borders were not necessary, a depth of from 2 feet to 3 feet being quite sufficient. Planting too close was an evil, also too near the glass. The Vines should not be less than 2 feet from the glass, as if too near, the leaves had no room to develop, and in the case of late Grapes plenty of foliage was necessary. Such varieties as *Muscat of Alexandria* required plenty of space so that the berries could colour and be of good size.

When late Grapes were kept hanging too long there was not time to give sufficient rest or to expose the rods thoroughly before re-starting them. Vines required considerable moisture. The borders in which late Grapes are grown are often kept too dry, but one must not err in the opposite direction. If the roots are in outside borders, only sufficient protection to throw off heavy rains and snow should be given. Grapes started late colour late, and thus their keeping qualities are impaired.

There is no need to keep the fruit hanging too long on the Vines, as when cut it will keep well in bottles filled with water. He advised prompt attention to the stopping and disbudding, as there was great loss of power by large removals of foliage at one time. Muscats require more light to colour, and some kinds must be artificially fertilised. Many mistakes were made in thinning. Such varieties as Alicante and Lady Downe's needed severe thinning. As regarded temperatures, he gave 85° to 90° as a maximum day temperature, and advised span-roofed houses. In colder districts he had found that a lean-to house was the most suitable for growing late Grapes. He recommended that water should be given every month, allowing 10 to 15 gallons to the square yard, using it tepid and not drawn from underground tanks. Late Grapes take longer to mature than early ones. When the Grapes are hanging, the temperature may be from 45° to 50°, or even less in cold weather, and the Vines should be cleared in January to allow of their being pruned and given a rest. The best late varieties he considered were Lady Downe's, Muscat of Alexandria, Gros Colman, West's St. Peter's, Alicante, and Trebbiano.

The Royal Gardeners' Orphan Fund.—A meeting of the committee took place at the Horticultural Club, Hotel Windsor, on the 24th ult., Mr. William Marshall presiding, there being a full attendance. The following special contributions to the fund were announced: Proceeds of concert at Kingston, per Mr. W. Furze, £21 13s. 6d.; opening of Ketton Hall Gardens, Stamford, per Mr. W. H. Divers, £2 6s. 5d.; Reading and District Gardeners' Society, per Mr. J. Pound, secretary, £5 15s.; Mr. G. W. Cummings, admissions to see the Chrysanthemums at The Grange Gardens, Carshalton, £5; Mr. W. Bates, Twickenham flower show, £1 16s.; Mr. J. Wright, 171, Fleet Street, donation, £1 1s. Box and card collections: Mr. A. D. Christie, Ragley, Alcester, 8s. 9d.; Mr. W. H. Divers, Ketton Hall Gardens, 11s. 3d.; Mr. G. T. Cale, Charters Gardens, Berks, 11s.; Romford Chrysanthemum show, 5s.; Messrs. McDonald, Chichester, 10s. 6d.; Miss Holmes, Frampton Park Nursery, Hackney, £6 4s.; Mr. W. G. Head, Crystal Palace, Sydenham, £2 0s. 6d. On a review of the financial position of the society, it was resolved that five children be placed upon the fund at the next election, and the secretary was instructed to issue notices to that effect. Mr. Osman, Commercial Street, E., was elected a member of the committee in the place of Mr. H. Low. Mr. D. Sheahan, Hartfield Road, Wimbledon, was appointed local secretary for that district.

OBITUARY.

Mr. Isaac Dixon.—We are sorry to have to announce the death at the age of fifty-eight of Mr. Isaac Dixon, which took place on the 18th last after about a fortnight's illness. Mr. Dixon was manager of Messrs. Chas. Lee and Son's Feltham Nursery for twenty-five years; also traveller for the same firm, which he had represented as such for twenty years in all parts of England, and up to the time of his death. Having caught a severe chill, he was obliged to return home from Bath on November 3, and never recovered. He had been with Messrs. Lee and Son for upwards of thirty years, being at Hammersmith some few years before taking the management of the Feltham Nursery.

Mr. John Daniels, for forty-two years gardener and steward at Swyncombe Park, Henley-on-Thames, died near that place on November 1, at the age of seventy-seven years. About eighteen months ago he retired upon a pension. Born in the year 1816, at Kniveton, near Ashbourne, Derbyshire, he was placed with a nurseryman in the neighbourhood, and after a term of service he became second gardener at Smithland Hall, Leicestershire, from which he went to Elsenham Hall, Essex, where he remained until his employer's death. In 1850 he entered upon the duties of head gardener at Swyncombe Park, and eventu-

ally had charge of the estate as steward. While here he effected marked improvements in extending and beautifying the grounds. Taking up spring gardening when it was becoming popular, he was very successful at Swyncombe, and established a spring display second to none in the county, while in the woods he naturalised many charming subjects with marked success. His reputation as a successful gardener is more particularly associated with the culture of *Bougainvillea speciosa*, which he grew so well, that in the year 1860 he brought flowering sprays to one of the meetings of the Royal Horticultural Society and was awarded its silver medal. The plant when in bloom covered a space of 400 superficial feet on the roof of a large plant house, and hung down in handsome festoons. Planted by Mr. Daniels some years previously in a corner of the house near the boiler and abundantly supplied with moisture in the growing season, the plant grew with great rapidity, and the freedom with which it bloomed was considered by Mr. Daniels to be due to the wood being so well ripened by the proximity of the plant to the boiler.

Mr. Duncan Welsh.—All who knew the late Mr. Welsh will deeply regret to hear of his death, which took place at Lochend, Beith, Scotland, on November 19, in the sixty-fourth year of his age. Mr. Welsh's gardening career commenced in his native country, Scotland, and he went to Ireland nearly forty years ago as foreman in the then celebrated Vice-Regal Gardens under Mr. Geo. Smith. At the end of his engagement with Mr. Smith he was appointed gardener to the Earl of Pembroke, at Mount Merrion, Co. Dublin, a position he held with all honour and respect for thirty-six years; in fact, he only retired, with the good wishes of all who knew him, in the spring of the present year, as alluded to in THE GARDEN at the time. His management of Mount Merrion was a credit to himself and his employers, as also to the horticulture of Ireland, and plant-loving pilgrims were ever rewarded at seeing his pet Orchids, Pitcher Plants, such as *Nepenthes*, *Sarracenia*, *Darlingtonia*, and *Cephalotus*, and stove and greenhouse plants generally in splendid health and vigour. His specimen plant of *Darlingtonia californica*, photographed by Mr. Greenwood Pim, M.A., and engraved in THE GARDEN, was the finest example of cultivation in its way perhaps ever seen. He was a good all-round cultivator. Fruit and vegetables he took equal pride in bringing to perfection; so also hot-house Grapes and Peaches. Of late years he had curtailed somewhat his bedding plant displays, always beautiful in their way, and had extended the old-fashioned herbaceous plant and choice shrubby borders that suited so well the quaint Elizabethan house at Mount Merrion.

Francis Parkman died last week after a short illness at his home, on the banks of Jamaica Pond, in Boston. It is as a rosarian that Mr. Parkman is best known among horticulturists. He was one of the first Americans to cultivate a collection of Roses, and his example has done more, perhaps, than that of any other man to raise the standard of Rose-growing in America to its present excellence. "The Book of Roses," which he published in 1866, and which embodies sound cultural instruction with an account of the different races of his favourite flower, is still the best work within the limits of this field that has been written on the subject. In 1861, a small collection of plants, purchased from a nurseryman at Yokohama by Dr. George R. Hall, was placed in Mr. Parkman's hands to propagate. This was probably the first collection of plants sent directly to America from Japan; in it were several plants now well known in our gardens, including the double-flowered Apple, which bears Mr. Parkman's name and which is still standing in his garden, several *Retinosporas*, *Thuja dolabrata*, *Rhododendron brachycarpum*, *Andromeda japonica*, the double-flowered *Wistaria*, and bulbs of the familiar *Lilium auratum*, which Mr. Parkman flowered before anyone else in America or Europe. To the cultivation of Lilies, which were always favourites with him, he devoted much attention, trying to improve them by cross-breed-

ing; in this he had at least one conspicuous success with *Lilium Parkmaui*, which he raised by crossing *Lilium auratum* with *Lilium speciosum*. A paper from his pen, published in the "Bulletin of the Bussey Institution of Harvard College," records the results of his experiments in hybridising Lilies. In the improvement of plants by cross-breeding, Mr. Parkman was always interested, and many good varieties of Iris, Delphinium, Pæony and Poppy were raised in his garden. He was one of the first Americans to grow a collection of herbaceous plants; and his garden was always full of interesting shrubs, bulbs and hardy perennials. For a short time Mr. Parkman was professor of horticulture in Harvard University, which he served faithfully for many years as an Overseer and then as a Fellow, and for two years he was president of the Massachusetts Horticultural Society. In the development of horticulture in America, Mr. Parkman's influence has been considerable and always in the right direction, and of those Americans who have practised the gentle art, not one has brought it to a more sincere love or a keener intelligence.—*Garden and Forest*, Nov. 15.

PUBLIC GARDENS.

Thames Embankment at Greenwich.—The Greenwich District Board has received the consent of the Council to the proposed embankment of the Thames in front of Greenwich Hospital.

Kingston.—The First Commissioner of Works has consented to the towing-path above Kingston Bridge, on the Middlesex side of the river Thames, being laid out as a public promenade. The improvement is intended to commemorate the marriage of the Duke of York, and will probably be called York Parade.

A new open space.—A conference of delegates from the local authorities respectively of Bermondsey, St. Olave's, St. George-the-Martyr, and St. Saviour's has been convened with the object of seeking an interview with the London County Council, with which body to arrange the best terms for the acquisition of Guy's Burial Ground, Nelson Street, as an open space. The sum asked for the site is £2600, and the local authorities of St. George's, Southwark, have agreed to contribute £164.

Dipladenia atropurpurea.—In your issue of THE GARDEN, November 25 (page 489), it is stated that *Dipladenia atropurpurea* was re-introduced by Mr. Russell Clarke, of Croydon. It should have been the late Mr. Stephenson Clarke, of Croydon Lodge, Croydon. It was found by his gardener on a mass of *Lælia purpurata* bought at one of the sale rooms.—WM. CARR.

Destroying weeds on lawn.—Could some of your readers suggest an expeditious method of clearing a lawn of *Plantago* (black heads) which, being imported amongst Grass seed, has become such a pest as to almost exterminate the natural Grasses? Hand-weeding was tried, but the *Plantago* seeds so freely, that it is quite out of the question now. If there is any chemical that can be applied it might answer, as the colonial Grasses growing from rhizomes would not be affected by any poison on the surface.—J. D. C. L., *Belmont, Cape Town*.

A lawn mower for the Cape.—Will any reader tell me the best lawn mower for this colony, where the Grasses, being species of *Cynodon*, are very wiry, and in summer so harsh and twiggy that the knives would have to revolve rapidly to cut the tough stems and tall flower heads which grow so quickly in their season. Many makes have been tried, but they all leave something to be desired. An Archimedean tried some years ago gave the best results, but was hardly strong enough for continual use on a luxuriant sward.—J. D. C. L., *Belmont, Cape Town*.

Names of plants.—*Judy*.—*Sophronis grandiflora*.—*H. Goodheart*.—*Lælia autumnalis*; poor colour.—*Dortier*.—German Ivy (*Senecio mikanioides*).

Names of fruit.—*T. Bull*.—1, Blenheim Orange; 2, not recognised, so much bruised.

No. 1151. SATURDAY, December 9, 1893. Vol. XLIV.

"This is an Art
Which does mend Nature: change it rather; but
THE ART ITSELF IS NATURE."—Shakespeare.

ORCHARD AND FRUIT GARDEN.

DAMSONS.

At the present time, when many people are puzzled what crops to plant, and turning their attention to fruit culture, it may perhaps be useful to remind intending planters of the value of Damsons as a remunerative and almost certain crop. The Damson is suited for almost all soils, and will succeed admirably where the Plum, Apple, and Pear crops fail. Not only so, but as a shelter to other fruit crops Damsons are useful, breaking the force of the wind, and the crop pays far better than anything else that could be planted in such exposed positions. On waste land where the soil is fairly deep, Damsons will in a few years give handsome returns if the trees are liberally dressed with manure annually. Again, as hedgerow trees on farms they will hold their own and produce good crops, especially when the trees become large and able to afford shade to cattle, the droppings from which act as a good stimulant to the trees. Planted in hedgerows as described, I have known the fruit realise more than the crop of hay produced in the field. It would be unreasonable to expect good results annually, but, taking one season with another, Damson trees will do well either planted about the farm hedgerows or in a plantation by themselves. Many people have an idea that Damson trees are a long time in getting large enough to bear a paying crop. Such an idea is not borne out by facts, for if a Damson tree and an Apple tree are planted as standards at the same time, the former will be profitable several years before the latter. If planted on land of moderate quality, the trees staked, and an annual mulch of good manure applied, paying crops will be had in five years from the time of planting. The importance of heavy manuring is that a strong growth may be induced, and consequently a good head formed to the tree that will be able to carry a full crop of fruit without breaking the branches. Unless a good foundation is made at the start, a large well-formed head is almost an impossibility. While the standards are young it is a wise plan to cut away the small twiggy shoots formed in the centre, and thus cause the main branches to be stronger than they otherwise would be. Afterwards as the tree becomes larger little or no pruning is required.

To get quick returns the bush form of culture is the best, as the Damson answers to this system of culture quite as well as Apples and Pears, and it is astonishing the amount of fruit a good bush tree will carry. Another advantage of these dwarf trees is that they can be thoroughly washed in case insects attack them, and the crop thus rendered more certain, while as a shelter for bush Apples and Pears they are first-class. Small trees only planted two years will commence bearing freely, and unless the season is very unfavourable they will continue doing so for many years. King of the Damsons makes a fine tree in any form and is very prolific, producing fruit of large size. Cluster Damson, Mitchelson's, and the Shropshire Damson are heavy croppers, with fruit some-

what smaller than that of the first named, but excellent for market or private use. The question is frequently put, Will not fruit growing be over-done? I think the best answer to that is, Look at the Board of Trade figures. While they indicate such immense importations and vast sums of money paid to the foreigner, there can be no danger for many years to come of good fruit being too plentiful to be profitable. Even this season when prices have ruled low the inquiry for choice fruit has been good and prices satisfactory, and the demand for Damsons was heavy. One buyer asked me if I could get fifty tons or upwards for him. As stated, for sound fruit of good quality, attractive appearance, and well packed, the demand is practically unlimited, with every indication of its continuing. It is the bruised, badly packed, and unsuitable kinds that are a drug in the market. I think it only a question of time when such fruit will be almost, if not quite, unsaleable. W.

Apple Improved Bess Pool.—Judging from the number of times this variety has been exhibited this season, this excellent Apple is finding favour amongst planters. So far my experience of it is that it is too long in producing a remunerative crop to be profitable to plant for market, having the same failing as the ordinary Bess Pool in that respect. To those who can afford to wait or plant for future generations this Apple is extremely valuable, because as the tree acquires age it crops freely. The fruit is large, heavy, of a beautiful shape and lovely colour, and will keep sound until the end of May. As a cooking Apple it is excellent, and by no means a poor dessert variety—in fact, better than the old well-known variety in every respect, and worthy of a place in every collection. It is also valuable for exhibition, owing to its perfect shape, size, and deep red colour.—W.

Pear Clapp's Favourite.—This handsome Pear is finding much favour amongst a few planters for market, but I question the wisdom of selecting this variety for the purpose on a large scale. Unless the quality is much better in other places than here on our light soil, it is very poor indeed, for during the past eight years not a well-flavoured fruit has been produced. Its cropping powers are splendid, and so are the size and colour of the fruit, but I think that all planters for profit should combine quality as well in the fruits they plant. Buyers very soon detect any inferior flavoured fruit and are shy at purchasing more of the same description, and then the grower finds a difficulty in disposing of it, even at low rates. My own practice is to mark all poorly flavoured Pears as seconds, and then regular buyers know exactly what they purchase and have nothing to find fault with, because they have not been deceived.—Ross, *Hercford*.

Old fruit trees at Farnham Castle.—Having an hour to spare a short time ago when in the neighbourhood of Farnham, I visited the castle gardens, where there are some very old trees of Apricots, Pears, and Cherries. On a southern aspect one or two Apricot trees considerably over 100 years old are still giving good crops of fruit yearly, and at this date the trees look most promising, being covered with fruit buds. When the cultivation of the Apricot is taken into consideration, it will be seen at a glance that there is something that suits these trees at Farnham. Trees probably 50 years old are perfect in shape and free of decay. From close observation, no doubt they benefit from the soft sandstone found in the neighbourhood, and, what is better, these old trees are in elevated positions. The ground in which they are planted slopes away from the wall, and there is a hard walk in front of a narrow border. This drains away excessive moisture in the early part of the year, just when the sap is rising, and to a certain extent the trees are protected from the east and north by rising ground, and what may be of great service is the

solid walls, in many places from 6 feet to 8 feet in thickness. Here also may be seen grand examples of Figs, which bear not only abundance of fruit, but also of the very best quality, fully equal to fruit under glass. The variety is Brown Turkey. The oldest Apricots are of the Breda variety, a medium sized fruit, but highly flavoured. Morello Cherries are equally old, and give splendid crops. These are not trained against the walls, but have been planted many years ago at the foot of the castle or keep wall and allowed to form a head. These trees project out from the walls, the stems being enveloped in a dense covering of Cotoneasters, Ivies and other creepers, giving the fruit trees the appearance of springing out of the stonework, and when in fruit presenting a nice effect, the Cherries showing to advantage with a dense green background. In the courtyard, covering a part of the castle, are some very old Pear trees, the stems of these being as thick as a man's body. These cover a large extent of the oldest portion of the building, but are of no value as far as their bearing qualities are concerned.—G. WYTHES.

Rivers' Orange Nectarine for forcing.—The value of this variety for early forcing is not, I think, very generally known, or we should more often meet with it in early houses. Some three years ago a note in its praise appeared in THE GARDEN from the pen of Mr. Temple, of Carron House. I took the hint and planted it, and have been abundantly rewarded with fine fruit and plenty of it. When started early it retains its buds, sets its fruit freely, invariably passes safely through the stoning period and ripens a very little, if any later than Lord Napier. Unlike that variety, however, it is not liable to sunstroke, and although any fruits which happen to be placed on the under side of the trellis, and therefore more or less shaded, do not assume the elegant mahogany tint which do those on the upper surface, yet they are beautifully golden and of striking appearance. As to flavour it is irreproachable. Some of our so-called early forcing Nectarines are not at all reliable. Stanwick Elruge is liable to cast its buds and also its fruit when stoning, and Lord Napier is also capricious, although fine where it does well. Rivers' Orange will, I think, please all who care to give it a trial.—JOHN CRAWFORD.

WINTER PRUNING AND NAILING.

In large and small gardens alike pruning and nailing take up much time, especially in those where there is a number of Morello Cherry and Peach trees. With us a wall about 150 yards long and 16 feet high covered with Morello Cherries takes about a month. This wall is always the first to receive attention, for before the days are too cold the leaves have usually fallen, so that there is nothing to prevent the work being taken in hand. It is bitterly cold standing in sharp frosty weather against a wall having a northern aspect; therefore, we aim at completing the work before we get such weather. There are several advantages to be gained by so doing. In the first place, there is no fear of the buds pushing on a wall facing north in the case of bright weather occurring in February, as the sun has little effect on the northern side. Secondly, there is not so much danger of the young twigs being broken off when nailed as when left loose. It is not everyone who can nail a Morello tree, practice and a good eye being indispensable, so as to enable him to see at a glance where the shoots are to be laid in. It is my practice to take off portions of the trees each season to prevent the young twigs being overcrowded. If the trees receive proper attention during the summer it is seldom that any pruning is required in winter, so that nailing can be done with more facility. The main shoots should be spread out first, nailing these from bottom to tip, taking care to have them as straight as possible. The nail should always be on the opposite side of the shoot to the direction of its pressure, so that the shred, and not the nail, may perform the work of holding the shoot in position. The former must also have length

enough to permit the twigs to have plenty of play, for if too short they are apt to cut them before they can be replaced. Having laid in all the main shoots, the next thing is to see if they are evenly balanced, and if they are not, they must be altered so that the tree may present a symmetrical appearance. We must now begin at the top of these leading branches, to lay in the off-shoots, taking care that each has the same amount of space allotted to it. The tips of the shoots must also be parallel to those which have been previously nailed to the wall, so that by the time the bottom of the wall is reached each one is pointing to the same spot at the top of the wall. No shoot should be so nailed to the wall, that if allowed to grow for two or three years it would cross any other. Each one should be allowed the same amount of space, about 3 inches being a good distance, as with such room there is no fear of the leaves becoming overcrowded.

PLUMS are the next to receive attention, and as these are planted in different aspects, the work must be regulated according to the weather. Plums are peculiar trees to nail, as often spurs die off, and even branches several years old will sometimes go without warning. This, if not well looked to, will give the trees an unsightly appearance. To make up these losses is often extremely puzzling unless the person who has charge of the tree thoroughly understands his business. No attempt should be made to bend a shoot or branch out of its oblique line for the sake of filling up a gap; far better leave the place bare. But if two or more shoots can be altered, so that they can be brought to fill up the vacancy without altering their slanting direction, this should be done, even if it causes the whole of them to be a greater distance apart. Lateral shoots may be utilised to fill in the intervening spaces, so by this means the tree will be more evenly balanced and look more uniform.

PEARS should next receive attention, for their spurs being at a greater distance from the walls, the flowers are not so easily excited as those of trees whose bloom buds are in close proximity to the wall. Since the practice of training trees on the cordon system has come into vogue, horizontal palmettes, fans, and other modes have long gone out of fashion, so that training these is not now of such importance as formerly, but pruning is of the utmost consequence. The great object in such trees is to keep them from making too much wood, and at the same time to keep them in a healthy condition. To accomplish this, the "summer pinching" has to be resorted to, so that there is less need of it at the time of winter pruning. All that is needed is to see that the spurs are properly furnished with flower buds and that the shoots are kept at the same angle while nailing, always paying attention to the leaving of plenty of room in the shreds.

APRICOTS AND CHERRIES are best left till the last, as their buds are easily excited into growth by the first burst of genial weather in spring, so that if too early pruned they often suffer from the ravages of late frost.

PEACHES should also be left till the last, for their shoots when nailed close to the wall often start into growth through the absorption of the sun's heat by the bricks, and its consequent radiation at night. Therefore, those nailed too early are more liable to suffer owing to their forward condition than others that have been left loose, and are therefore further from the wall.

H. C. P.

Fruit notes from Scotland.—The Pear season is going to be a very short one. Here in Scotland the time of ripening is generally several weeks later than it is in the south of England; but this year it is different, as sorts like Winter Nelis and Knight's Monarch, which ripen slowly and sometimes last until February, appear unlikely to last the year. Marie Louise generally keeps until Christmas, but it is over by the third week of November; so also that delicious sort, Doyenné du Comice, is now past. I note that some growers incline to consider the latter as good in quality as

Marie Louise. This year it has certainly been better, but I do not think it keeps so well as the old favourite. A Pear that is seldom good here is this year high-class. I refer to Van Mons Leon Leclerc. Thomson's is always good, but this season it did not crop well. Some of the second-class sorts, e.g., Beurré Bachelier and Napoleon, are, curiously enough, of wretched flavour; whereas, in bad seasons when first-class sorts are scarce these come in fairly good. Beurré Clairgean, on the other hand, was good. Generally it is fit only for cooking. We have only a limited number of Ne Plus Meuris, Easter Beurré and Beurré Rance, none of the kinds having borne well; but I am hopeful that these will ripen much better than it is usual to have them. I have heard complaints about Pears keeping. Numbers, I believe, were gathered much too early, and doubtless many were kept in the fruit room too long; in fact, until they were so over-ripe as to rot. The same remark applies to Apples, which I have never had finer, and though some of the early kinds exhibited a slight tendency to rot, as a rule the Apple crop is keeping well. We have nothing here to come up to Warner's King as a valuable Apple. Unfortunately, during the past four or five years all our trees have exhibited a tendency to canker very badly. As a healthy free-fruiting Apple I like Keswick Codlin. It never fails, and with ordinary attention produces good fruit, which is of much value for cooking. Another noteworthy fact was a small second crop of Figs borne out of doors. The fruits were small and certainly did not contain seeds, but I am assured they were of good flavour.—R. P. BROTHERSTON, *East Lothian.*

FRUIT TREES AND THE LATE DROUGHT.

WHEN recently lifting some fairly large fruit-bearing trees of Peaches and Nectarines I was struck with the dry condition of the soil under them, and that in spite of such rains as most of us would consider ample to penetrate to the roots and beyond. Such, however, was certainly not the case in this instance; the soil, in fact, crumbled away in a semi-dusty state. This has given me quite sufficient indication as to the condition throughout the entire border (an extra long one), and I am fully persuaded that a good soaking of water will do good. Were I to leave it as it now stands, and provided there is not a heavy rainfall within a reasonable time, there need not be any surprise if bud-dropping became general in the spring. The aspect, I ought to say, is a westerly one, so that one might fairly have surmised that the ground would have been moist enough after the rainfall we have had. The borders were well mulched through the hot and dry weather, several waterings having been given; they are also nearly level, which I consider a most important point in the cultural detail save in the wettest localities and soils, or where the latter is of a tenacious character. Were they otherwise, they would have given us an incessant amount of trouble during the drought. Sloping borders may look very well and be found suitable for supplementary early crops, but the fruit trees should always have prior consideration. A deal depends, of course, upon the width of the fruit tree borders, but even then an almost level surface is far better than a sloping one, the latter being considerably drier at the back than the front as a natural sequence. I have not the slightest doubt that there are many fine trees which have been suffering for years through drought near to the stem where planted against walls on sloping borders. The result of this is that the roots have to penetrate further, to be disturbed probably every time the ground is dug deeply or trenched, or have pushed their way into the less congenial

subsoil; whereas if there were sufficient moisture nearer home with good mulchings such would not be the case. In some instances one sees narrow pathways on the soil next the trees; these if not broken up annually with the borders will become almost impenetrable to moisture, to the certain detriment of the trees. Personally, I am no advocate for these pathways of trodden down and impervious soil. Leave an open space by all means if it can be afforded, but mulch it well with manure; thus it will be kept in a much better condition, as the mulching can be trodden on without much harm being done.

Where there are pathways for the greater convenience of attending to the trees, they should be broken up immediately the fruit is gathered, using boards afterwards for treading upon during pruning and nailing. More than once when dealing with sloping borders I have raised the front where it was not possible at the time to lower the back. Not only will Peaches and Nectarines suffer from drought, but Pears and Plums are further instances, also Apricots, the last requiring far more water than they generally receive. Figs may be all the better if on the dry side rather than otherwise through the winter, so as in a measure to check their inherent tendency to make gross wood if given too generous a treatment. Cherries are another case in point; give them liberal supplies of water with manurial stimulants, not omitting lime or bone-meal, the constituents of which enter largely into the formation of the stones in these and other fruits. If I saw a tendency of decline in any tree, and had the slightest suspicion of the soil being impoverished, or drought existing, I would build up a ring of soil at a good distance therefrom and then give it a thorough good soaking with manure water. I often do this in the usual way when emptying a cesspool during the winter, the penetrating powers of a liquid exceeding those of a solid manure. A deal depends, I know, upon the character of the soil with which one has to deal, but I am fully persuaded that more harm is done by drought than many are aware of, or even suspect to be existing. It does not do to be led away with the idea that because the leaves have fallen no need of moisture then exists. If the fibrous roots suffer the tree suffers also, for upon these roots more than any others depends the fruitfulness of any tree of fruit-bearing character. In concluding these remarks, another fact might be drawn attention to, the time now being opportune for its observance. It is that of well watering in all newly-planted fruit trees. Not nearly enough importance is attached to this item of cultivation. In the majority of cases I venture to say it is never thought of. I have had a difficulty in fact to get it done without standing by whilst it was effected. Even if the roots be not dry, which will be a rare occurrence, the mere fact of settling the soil closely around them is of the utmost importance for their well-being. Even in wet ground I would adopt the plan for this latter reason alone.

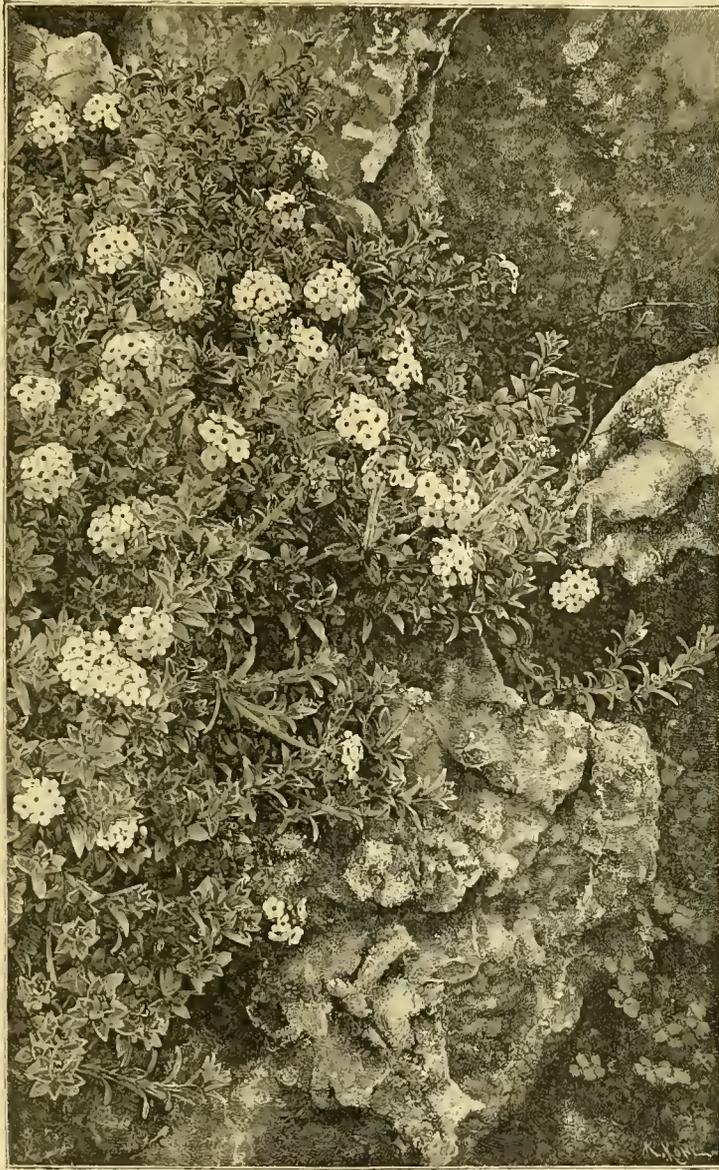

POMONA.

Pear Josephine de Malines.—I quite agree with all "Y. A. H." says in favour of this grand winter Pear. On the south coast it comes to great perfection on open bush or pyramid trees, which grow freely, and crop regularly. The fruit assumes a beautiful golden tint and the flavour is very good. If there is any difference, I think the fruit grown on open trees surpasses that grown on wall trees. This is one of the few Pears that market growers ought to grow in quantity, as during its extended season there is no fear about finding a ready sale.—J. G., *Gosport.*

FLOWER GARDEN.

ANDROSACE LANUGINOSA.

This beautiful alpine plant has been so recently and fully described by M. Correvon in THE GARDEN, page 466, that I will merely give the treatment adopted for the specimen represented in the annexed engraving. It was planted three years ago in a mixture of

Androsace lanuginosa in the garden at Chaddlewood, Plympton. Engraved for THE GARDEN from a photograph sent by Mr. G. Soltau-Symons.

peat, leaf mould and light loam, in a sloping position among lime rock, the surface covered with loose stone to keep the stems and leaves as dry as possible. Damp is fatal to it. It cannot have too much sun, and should be placed in a southern aspect. The specimen, part of which has been engraved, falls over a rock nearly 3 feet, and is 2 feet in width. It was in bloom from June to the beginning of November. *A. lanuginosa*

was first raised in Trinity College Gardens, Dublin, by Dr. Mackay, from seed sent from India, and first flowered in August, 1842. It is a native of the Western Himalayas, and is found at from 7000 feet to 10,000 feet elevation. There is no *Androsace* more easily grown and none more lovely for a rockery.

G. SOLTAU-SYMONS.

Campanula garganica.—Under this heading on p. 506 I am made to say that if we include the

the white Clove being of a dwarf spreading growth, with flower-stem upright and with the flowers boldly facing the sun. Gloire de Nancy, on the other hand, presents a more robust habit of growth, though the stem "wobbles" and the flowers hang down. The old crimson Clove is in habit much like the white Clove, but somewhat more dwarf, with foliage of a darker shade of green and much affected by disease, so much so that some growers cannot keep it. I got a bluish form of the white Clove from Cambridge several years ago, but this is not worth growing. There have been many Cloves put into commerce in past years, but no one has yet superseded the old form. I have got what is termed the old Scotch Clove under the name of P. Engleheart. This is not nearly so good as the old crimson. The finest white border Clove Carnation I have had is Niphotos. Aline Neuman, a red-coloured Clove, is also a most excellent variety. Another good variety is Jessica, with soft shining crimson flowers. Lady Nina Balfour appears to be a very useful variety.—R. P. BROTHERSTON, *Tynninghame*.

HARDY HERBACEOUS PLANTS.*

THE value of herbaceous plants seems to become more recognised every year. It is, however, only of late years that the cultivation of these plants has advanced with rapid strides and has found such universal favour with the public generally. It is not a mere craze or fashion, but a recognition of their undoubted merits that has brought these hardy plants to the front, and gained for them the appreciation of the rich as well as the poor. We are living in a progressive age, and by the development of a more artistic taste we have become susceptible to the charms of beauty of form in Nature, and we prefer graceful outlines and harmony of colour to the geometrical designs in the gardens of our ancestors. There exists no class of plants which offers such an unlimited number of graceful forms as the hardy herbaceous plants. Not a single shade of colour can be mentioned which is not in some way or other represented by this class of flowers. The variation in size, too, is simply enormous. We have flowers like *Gypsophila paniculata* (which are not much bigger than a Mustard seed), and we have flowers of the boldest type measuring 6 inches and 8 inches across. We have plants that never grow beyond a few inches in height, and we have plants that attain 6 feet, 7 feet, or even 8 feet. Such unlimited variation in every shape or form, I may boldly assert, cannot be equalled by any other class of plants.

But these hardy flowers have still other merits of greater importance. Many kinds will bloom continuously for several months, while others will bloom at a time of the year when flowers are scarce. Even in December and January we have Christmas Roses out of doors. In February we have *Anemone apennina*, *Arabis albida*, and *Hepaticas* of various shades, to say nothing of the many early bulbous plants. March brings us *Adonis vernalis*, *Iberis stylosa*, *Mertensia virginica*, several *Anemones*, *Doronicums*, *Omphalodes verna*, Lenten Roses, *Primulas*, and many others. In April we have *Dodecatheous*, *Gentiana acaulis*, many *Iris*es, dwarf *Phloxes*, *Trollius*, *Epimedium pinnatum*, *Corydalis lutea*, *Iberis*, *Aubrietias*, *Alyssum*, and a host of others. I need not mention the flowers of June, July and August. Their name is legion, and we may choose from hundreds of varieties of every shade of colour. But even in September, October and November, when

biennials and annuals, there are not thirty good perennial species of *Campanula* in English cultivation. It is obvious that the word include should be exclude. The context will show that I referred only to European species. If Asiatic (Caucasian and Siberian) species were added, the number would be much greater.—C. WOLLEY DOD.

Clove Carnations.—Gloire de Nancy is quite distinct from the white Clove, which I have known as long as I can remember. The flowers of the latter are smaller, of a better shape, but not so pure white. The habit of growth is quite distinct,

* A paper, illustrated by sketches, diagrams, and coloured plates, read at the Exeter Guildhall before the members of the Devon and Exeter Gardeners' Mutual Improvement Association on Wednesday, December 6, by Mr. F. W. Meyer, Exeter.

our Dahlias, our annuals and other flowers have vanished, we have still an abundance of hardy flowers out of doors. We have Rudbeckias and Achilleas of various sorts, Asters, *Physostegia virginica*, *Helenium Hoopesi*, and *Helenium grandiceps striatum*, *Stokesia cyanea*, *Zauschneria californica*, *Plumbago Larpentæ*, *Senecio pulcher*, *Anemone japonica*, *Pyrethrum uliginosum*, and many other excellent things. There is thus not a single month in the whole year in which hardy flowers of one sort or another are not available, and if we make a careful selection, our gardens need never be entirely without flowers. With regard to position, too, we have plants suitable for every conceivable situation, no matter whether it be dry or wet, sunny or shady, warm or cold; it is simply a matter of selecting the right thing for the right place. Even bare spots beneath the shade of trees, where not even Grass would grow, can be made bright and cheerful by such plants as hardy *Cyclamen*, *Hepatica*, *Anemone*, *Primula*, *Epimedium*, *Trillium* and many others, to say nothing of an admixture of such hardy bulbs as Dog's-tooth Violets, Snowdrops, Daffodils and Winter Aconite. If we have rough waste spots in a wood or shrubbery, we can turn them into a charming "wild garden" by dotting about irregular groups of plants of the blindest type, such as the Giant Cow Parsnip (*Heracleum giganteum*), *Telekia cordifolia*, or *Cephalaria alpina*. Here, too, we may have colonies of Foxgloves, *Verbascum*, *Anemone japonica*, and scores of others. If we have a wet or swampy place near a pond we may grow colonies of Iris, and such handsome leaved plants as *Saxifraga peltata*, *Rodgersia podophylla*, *Gunnera scabra* and *G. manicata*.

ARRANGING HERBACEOUS PLANTS WITH A VIEW TO SUCCESSION OF BLOOM.

Much depends of course on the purpose for which the flowers are to be grown. If cultivated for the exclusive purpose of supplying cut flowers for the house or for sending away, there is no need to have them in the flower garden at all. They might in this case be grown in a border in the kitchen garden, or some other spot set apart for them in a situation where disfigurement by constant cutting would be of little consequence. In such a case the arrangement would be more a matter of providing cut flowers of the most desirable colours, and at a season when they are most required, than of artistic grouping. But when herbaceous plants are used in the flower garden the grouping must naturally be of the utmost importance, so as to ensure a succession of effective displays. This, in my opinion, is the most essential part of all. The general cultivation of hardy plants is easy enough, but arranging them effectively is not so easy as it might appear, and requires not only a considerable amount of taste and forethought, but also an intimate knowledge of the plants to be used. Before we can hope to arrange them effectively we must know to what size they will grow; we must also be acquainted with the colour of the flowers, the time of blooming, and the behaviour of the plants after their flowering season is over. It is not enough to arrange the herbaceous plants themselves so as to give the best possible effect, but we have also to associate them with other suitable kinds of plants, such as bulbs, shrubs, or Ferns, and we have to blend the whole into one harmonious picture, or rather a succession of harmonious pictures, for the combinations will gradually change from week to week as the season advances. Thus we may have, for instance, a colony of blue flowers springing up from among

plants that bore white blossoms a week ago, and before the blue has quite faded from sight we may have sheets of pink or yellow appearing above the foliage.

BORDERS.

Years ago the orthodox style of border in the flower garden was the ribbon border, in which bedding plants were displayed in continuous lines with geometrical exactness. Of these it might well be said that if you had seen a yard you had seen the whole, because the same pattern ran through the whole length no matter how long the border might be. This kind of monotonous display, which moreover could not last longer than three or four months every year, is now, I am glad to say, almost a thing of the past, and has given way to the hardy plants, with the result that we have now not a monotonous and temporary, but a continuous and picturesque mode of display almost all the year round.

Borders in the flower garden may sometimes be in a straight line either quite open or bounded on one side by a wall or trellis covered with all kinds of creepers. But there can be no doubt that the most effective border is that which has an irregular outline, and is arranged against a background of ornamental trees and shrubs. As a rule such borders are not made nearly wide enough to allow all plants to develop their full beauty without becoming overcrowded. Now and then the choicest shrubs of the background should project into the border and mingle with the hardy flowers, while in other places the border itself should break the line of shrubs by forming here and there a deep recess among the taller plants. Such a border should never be dug over (unless in the course of years it should require to be altogether rearranged), and it should never show a single yard of bare soil either in winter or summer, and in this direction I think the borders of most gardens may be greatly improved. The worst fault of most borders is that they are generally arranged with far too much regularity. As a rule people are content to have their tall plants at the back and the small ones in the front, leaving the ground between perfectly bare. The result is a more or less regular bank during the summer months and a bare soil during winter. But there is just as much difference between this and the picturesque style of arranging borders as there is between a group of lovely Orchids and choice stove and greenhouse plants arranged for effect at one of our principal exhibitions, and another group forming a more regular bank of flowers and foliage arranged with such painful exactness, that its outline might be compared to the sloping roof of a house. In a well-arranged group, as now often exhibited for effect, we have short plants among taller ones, springing from a dense carpet of Maiden-hair Fern or other greenery, studded with flowers, but all plants are or should be so placed that the eye can penetrate and admire the full beauty of each individual flower or foliage plant, while the whole combination has a most pleasing and graceful effect. Why is it that plants grouped in this manner and offering, as it were, a series of vistas, through which the shorter plants are distinctly visible, are so pleasing to the eye? It is because this combination picture produces different effects of light and shade, and each visible short plant between the taller ones becomes in itself a picture viewed through the living frame of other plants.

This, then, is the style which should be our pattern when grouping plants out of doors; it is on the principle of the true style of Nature and will lend itself to an infinite number of

most effective variations. Instead of leaving the soil bare between the taller plants, let us carpet it with flowers and greenery, just as Nature clothes the bare soil of our woods with all kinds of dwarf vegetation, or as we would do in the case of a group of Orchids arranged for effect at an exhibition. We have an endless variety of hardy plants suitable for the purpose. What could be prettier than a colony of bright flowers springing from a carpet of the woolly Thyme (*Thymus lanuginosa*), or of such plants as *Herniaria glabra*, *Arenaria cæspitosa*, mossy Saxifrages, *Veronica repens*, &c. Or if we desire carpets of a lighter colour, we have Phloxes, Veronicas, *Erysimum*, *Alyssum*, *Arabis*, *Aubrietia*, *Iberis*, *Campanulas*, and scores of other varieties to choose from. Surely there is no excuse for bare spots when we have such delightful evergreens as these to cover the ground.

The larger herbaceous plants should be arranged not singly, but in groups, intermingling with each other. One or two large groups of the same variety, consisting, say, of from ten to twenty plants, kept sufficiently far apart to allow the plants which form the groundwork to be plainly seen, will be found much more effective than dotting the same number about in a sort of general mixture. Bulbs of all kinds are a valuable addition to borders intended for successive displays. Take, for instance, that charming early spring flower—*Chionodoxa*—growing from a carpet of *Veronica repens*. When the blue flowers of *Chionodoxa* have faded away, the white flowers of the *Veronica* would take their place, to be followed, perhaps, by the scarlet Windflower, and later on by *Platycodon*, which in its turn might be succeeded by the white *Physostegia virginica*, or late in autumn by the purple flowers of *Senecio pulcher*, which often will last till November. In an adjoining group we may have a bright pink carpet of Phloxes (setacea varieties), to be followed by *Narcissus*, which will look all the brighter for the dwarf carpet covering the ground beneath them. When the *Narcissus* have had their turn, we may have Carnations or blue *Campanulas*, to be followed in autumn by the scarlet *Lobelia* or white *Anemone japonica*. Another good combination is a group of Lilies with an undergrowth of *Iberis* and *Epimedium* and mixed with *Pæonies*. The *Iberis* would be the first to flower, the *Pæonies* coming next, and by the time these have died away the Lilies would come out in all their glory, and the now flowerless *Iberis* would form a dark green carpet mixed with the bronzy tint of the *Epimedium*, thus giving by way of contrast a bold relief to the Lilies. As an example of a pretty group without bulbs, I would mention a combination which I have used with great success, and consisting of *Primula Sieboldi*, *Spiræa filipendula* and *Plumbago Larpentæ*. When in early spring the *Primulas* were in full bloom, the *Plumbago* plants scarcely showed a leaf above the ground, while the Fern-like foliage of the *Spiræa filipendula* formed an exquisite setting for the bright-coloured blooms of the *Primulas*. No sooner had the latter died away than the handsome trusses of white *Spiræa* flowers appeared, followed later by the brilliant blue of *Plumbago Larpentæ*, lasting till late in October. I could quote other examples by the score, but I think I have said enough to show the enormous advantage of this system of arranging plants as compared with the old-fashioned style of mixed borders.

FLOWER BEDS.

Beds of all shapes and sizes can be satisfactorily and permanently decorated by using

hardy herbaceous plants instead of bedding plants. Take, for instance, a bed of yellow or orange Carnations in a setting of purple Violas, or a bed of red Roses springing from a carpet of mossy Saxifrages, which in spring would be covered with charming white flowers before the Roses appear, and in winter would clothe the ground with luxuriant verdure when the stems of the Roses are bare.

Or take a bed of delicately coloured Tea Roses on a carpet of crimson Thrift or the bright blue Veronica prostrata, or yellow Roses among purple Aubrietias.

Small beds in the flower garden we might fill with Crocuses, to be succeeded by Campanula carpathica or turbinata, which in its turn might be followed by that grand yellow autumn flower, *Helenium pumilum*. Large beds of shrubs might also be fittingly relieved by hardy flowers, as, for example, the large Rhododendron bed in the gardens of Baron Rothschild, which is relieved by an exquisite display of tall Delphiniums when the Rhododendron flowers are over. In a like manner will the effect of a bed of dwarf Veronicas (*V. carnosula* and *V. buxifolia*) be enhanced by scarlet *Lobelia* or other autumn flowers.

Equally striking effects may be produced by other combinations, but time forbids my dwelling longer on this subject, and I conclude by expressing the earnest hope that I may have been successful in convincing at least some of my audience of the fact that a class of plants so capable of further development, and so admirably suited for the permanent embellishment of our flower gardens, offers one of the richest fields for horticultural research, and is well worthy the attention of every gardener and every lover of flowers throughout the land.

NOTES FROM OAKWOOD.

WHILE about at Oakwood taking advantage of the good weather, looking to the moving of plants and making alterations, I was struck by how much there is to be found in gardens pretty even in mid-November, and think that what I saw may be worth a note. The glories of the autumn tints of the Liquidambar tree have departed. Some of the deep red leaves of *Vaccinium pennsylvanicum* and of *Andromeda arborea* still held on. There are not many flowers out; most are on mounds, for which I have a weakness, thinking that plants show themselves better on them than on level ground. Where precautions have been taken against soil washing down, plants thrive well. There are some Primroses of many colours; hardy Cyclamens with their prettily marked leaves, some with flowers. One of the prettiest is *Cyclamen cypricum*, which I had from M. Max Leichtlin; the flowers, though small, are very pretty; it is a free flowerer, and the leaves have rich and distinct markings. *Cyclamen macrophyllum* has fine leaves, and stands the winter with us; one plant has held its flowers well in a sheltered situation, notwithstanding some sharp frosts. *Cheiranthus mutabilis* was a favourite of the late Rev. Harpur Crewe, who gave it to me. It is well to take cuttings of this, as hard winters kill it. A few *Gentianellas* are out, and one or two *Hepaticas*. *Helleborus maximus* is still very pretty. A very fine form of *Harebell* keeps throwing up flowers; this was given me by a gardening friend, who has made all forms of *Campanula rotundifolia* a study. The Cornish Heaths have a few flowers. *Andromeda floribunda* always well deserves its name, and is now loaded with buds.

What show well are the many shades of green in some plants, and dark and light brown of faded leaves, stalks, and flowers in others. The large bunches of dead flowers of *Hydrangea grandiflora* look very well in the distance, and *Polygonum compactum* holds its leaves and seeds, both of a very pale shade of brown. Many of the glaucous and pale grey-leaved plants are pretty; *Meconopsis*

nepalensis, with its hairy leaves studded with rain or dewdrops, one of the prettiest. French Lavender (*Santolina incana*) and *Agrostemmas* are pretty greys. In one of the ponds, *Myriophyllum proserpinacoides*, given me by the late Sir Wm. Bowman, is still green with its prettily cut leaves. *Diplopappus chrysophyllus* is cheerful looking. *Arenaria tetraquetra* has pretty compact foliage; mossy Saxifrages and white Thyme rich green.

The part of the garden where the view is now the prettiest is in the middle of the wood looking west. In a recess under the trees, Oaks and Birches with their autumn tints come first; Camellias with rich glossy green leaves; these are well set with buds; then *Retinospora squarrosa*, *Cryptomeria elegans*, Blue Spruce (small), *Retinospora pisifera aurea*, *Cupressus Lawsoniana lutea*, *C. L. viridis erecta*, blue Cedar (especially pretty), *Veronica Colensoi glauca*, *Hydrangea paniculata grandiflora*, with large bunches of faded flowers; *Andromeda japonica*, covered with red buds; *Polygonum compactum*, with pale brown leaves and seeds; *Kalmia angustifolia variegata*, *Berberis Fortunei*, with its small bright red leaves; *Eulalia gracillima*, still holding green (both this *Eulalia* and *E. zebrina* have flowered well this season); *Veronica verrucosa*, *Skimmia oblata*, a bank of *Rhododendrons*, *R. Wilsonianum*, *Ledums* with their buds, *Sciadopitys verticillata*, New Zealand Flax flourishing alongside a great plant of Bog Myrtle; all these together make a pretty picture. I have no doubt that many other pretty plants might be found, but fear the note is already too long.

G. F. WILSON.

PULMONARIA DAHURICA.

It always seems to me such a pity when a particularly desirable plant which used to be common enough drops out of sight and is in danger of being forgotten. Such now is certainly the case with one of the prettiest of all spring flowers. I refer to *Pulmonaria dahurica*, a most dainty and lovely little thing. It is sometimes called *Lithospermum davuricum*, as in Sweet's "British Flower Garden," and was much better known in his time than is the case now. The flowers are in panicles of a bright azure-blue when expanded; before expansion they are of a rather light purple, and no one could see it on an April day without being struck by it at once. It is a special favourite of mine, and year by year for nearly twelve years I should say I have hailed its appearance above ground in the spring with very great delight. I first of all met with it in the garden of the late Rev. Harpur Crewe, where it seemed to be flourishing, and I have always been told that the late Mr. Atkins, of Painswick, grew it in great abundance and that it did well in his hands. From him the main stock of this precious little flower passed, I believe, into the possession of Mr. George Paul at Broxbourne, and I have seen it quite happy in his interesting collection; but that was a long time ago, and Mr. Paul has since then had to lament that a cruel frost deprived him of one of his greatest treasures. My deprivation came about in a different way. The plant certainly is what is called "miffy" in our English climate if it be left to itself, but it was easy to provide against this by putting one of Mr. Wood's excellent glass protectors over its head before the autumn rains set in. With this small measure of help it has not troubled me at all for quite a long time. But this year the case has been different. I was away from home in early autumn, when the little bit of glass should have been used, and on my return, when I did think about it, I found, alas! that it was too late; the plant had rotted away. I have just a little side bit, which I took off in the spring, which may or may not be alive, but with this

possible exception I am now no better off about this delightful little flower than Mr. George Paul is. The reverses which he and I have met with in this sort of way do not daunt me in the least, for I think I know exactly where the trouble arose, and I should take more care to guard against it in the future. I believe that the ground was unusually hot from the baking summer we have had, and when the autumn rains came they set up a difficulty at once against which many delicate plants could not stand at all unless they had been safeguarded; they simply rotted away.

But now my anxiety is lest *Pulmonaria dahurica* should be lost to cultivation altogether. I have written several letters about it, so as if possible to get it again for another long spell, I hope, in my garden. But I can hear of it nowhere, and one good gardener goes so far as to say this: "I fear it is now extinct in England." I must say I join in his fear unless the very little bit I have referred to above should come up well in the spring. Now and then I think Herr Max Leichtlin has had *Pulmonaria dahurica* in his hands, but I do not know how it is at present, and at any rate I should be much obliged to anyone who could put me on the proper scent and help me to recover this gem. I imagine that it must be found somewhere on the Continent, if it be found at all. But it would be a great thing to have it once more amongst us, for it is so very pretty, and if it is found, then those who are so fortunate as to get it should take greater precautions against frost than Mr. G. Paul thought it needful to take, and earlier precaution against the deluge of autumn than occurred to me this year. But neither of these two things is difficult to manage, and if they are managed in light rich soil, *Pulmonaria dahurica* is sure to do well.

HENRY EWBANK.

St. John's, Ryde.

FLOWER GARDEN NOTES.

WITH the approach of December and the possibility of the commencement at any time of a spell of protracted frost, any plants in the flower garden above ground or beneath the same in the shape of bulb, corm, or tuber that may require protection should at once receive attention. At the same time, if even with protection the chance of any such plants coming safely through the winter is very slight, it is hardly advisable to trouble about them if a young stock can be easily raised to take their place. This would apply to such garden favourites as the Sweet Tobacco and *Galtonia candicans*, which can only be safely wintered outside in comparatively mild winters and under favourable circumstances. Individual plants of *Yucca filamentosa* (which makes a charming bed in summer) should be staked and tied up, or frost and wet will rot the heart of the plant. The same remark applies to the graceful *Arundo conspicua*, not nearly so hardy as the true Pampas Grass. Plants of *Aloysia citriodora* on walls must be matted up if they are to be saved through the winter, and as established plants of this furnish such splendid material for cutting, they are well worth the trouble. Beds of semi-hardy bulbs, as *Montbretias* and *Ixias*, should be heavily mulched with leaves and a little Fern be sprinkled over the leaves to prevent the same being blown about with the first high wind.

THE HARDY FERNERY.—This is an almost indispensable adjunct to all flower gardens, sometimes on a large scale, where natural ravines, slopes, or glens can be planted, or on a small scale, where some nook or shady walk can be utilised for a few varieties. In many gardens of small and average size there is a shrubby walk connecting the flower and kitchen gardens, and either side of this for a portion of the way is very well adapted for the culture of hardy Ferns, that is if a sufficient

width of space is available between the walk and shrubs. Occasional clumps of rough stones at intervals at the back and partially across the border will enable the soil to be raised here and there, and then to slope away to the front and in irregular hollows also the width of the border. Smaller groups of stones will be wanted occasionally more towards the front for the planting of any dwarf subjects requiring comparatively little soil, as the small *Aspleniums*, *Ceterach officinarum*, and *Cystopteris fragilis*. For the centre and back of border a capital variety can be secured, the aim in planting being to so distribute the many good things that a fairly even balance of heavy and light, graceful fronds is preserved. Some years ago if the planting of a hardy fernery was contemplated, a very pleasant day could be spent in a Fern district in a diligent hunt for specimens, but the hedge-rows, at any rate except in very remote districts, have now been so thoroughly and indiscriminately rifled, that time, labour, and expense would be saved by repairing to a nurseryman who makes a speciality of hardy Ferns and purchasing the sorts required. If the latter course is adopted, and the purchaser is not thoroughly well versed in the conditions under which the several varieties exist naturally, recourse should be had to a friend or to a good work on British Ferns. There are many things which it would be useless to plant, but, on the other hand, the list will be very much strengthened by a knowledge of individual wants. When the necessary number of Ferns has been planted, it may be well to dot in occasionally a few bulbs or any small spring-flowering plants that would make the fernery bright pending the full development of fronds. Among the many varieties of *Narcissus*, for instance, that can be tried are the trumpet forms *minimus*, *minor* and *nanus*, the small *Hoop-petticoat* and *Tazetta*, also such things as little clumps of *Scillas* and *Hepaticas*.

In the dull period that will intervene before the arrival of catalogues and the selection of subjects therefrom, a definite decision must be made as to flower garden arrangements for another season, also, if the weather continue open and the ground workable, some beds may possibly be partly planted that are to be a combination of hardy and tender or hardy and half-hardy plants. In the first category may be placed *Violas*, to be summer dotted with specimen *Fuchsias* or *Ivy-leaved Pelargoniums*, and in the latter such a mixture as *Pinks*, with scarlet *Lobelias* or the silvery *Veronica incana*, with the new fibrous *Begonia semperflorens atropurpurea*, recommended in last week's notes. Also before the order for seeds is given, the stock of bedding plants may be overhauled with the view of the substitution of seedlings if any particular colour is likely to be scarce, and if the colour cannot well be supplied, beds of mixed shades as can be furnished by *Verbenas*, *Petunias* and *Phlox Drummondii* may perhaps answer the purpose. In some cases, however, the required shade is easily procurable in seedlings, as, for example, in white, yellow and purple.

E. BURRELL.

Claremont.

Tritonia imperialis.—I do not find this grand variety of *Tritonia* increase so rapidly as the typical *Tritonia aurea* or the many garden forms so widely distributed under the generic name of *Montbretia*. As far as it has been tried here it is somewhat less hardy than M. Lemoine's numerous hybrids, but it forms such a fine, bold specimen, that a place must be found for it in all gardens where this beautiful class of plants is grown.—H. P.

Foliage and flowers.—It was recently remarked in THE GARDEN that the foliage of the *Mahonia* associated remarkably well with the flowers of the *Chrysanthemum*, its rich bronzy-green colour showing up in particular the shades of orange and chestnut that abound. The leafage of the *Blackberry* is of great value for mixing with the *Chrysanthemum* flowers, especially on the table, and its use makes a distinct and pleasant change. The leaves are long retained, not falling

so quickly as those of many things. Placed around dishes, they are pleasing and assist to create variety, not relying alone upon the beautiful foliage of the *Virginian Creeper* or *Ferns*. Too little use is, as a rule, made of *Vine* leaves, and we have seen the most charming effects produced with them.

ORCHIDS.

LÆLIOPSIS DOMINGENSIS.

THIS is now a very rare plant in cultivation. I used to have some four or five plants of it when with the Messrs. Jackson, of Kingston, nearly forty years ago, but I have very seldom seen the plant since until this summer, when some flowers of it came to hand from Thos. Galloway, asking for a name. This plant, as far as I know, is only found growing in the island of St. Domingo. It has somewhat the habit of a *Lælia*, but yet it differs from this genus, inasmuch as I could find but four pollen masses, although it is said eight are to be found. The plant when it flowered with me at Kingston used to make erect spikes from between the leaves. The spikes, about 1 foot or 15 inches long, bore five or six flowers, each measuring about 2 inches across. The flowers from Mr. Galloway are larger, being nearly 3 inches across. The sepals and petals are of a bright rosy lilac, the petals as broad again as the sepals, the lip sessile and three-lobed, the side lobes rolled round the column, the anterior lobe undulated, the front portion and the side lobes of a bright rosy lilac, the throat of a pale yellow, the veins all bearded with short hairs. The plant has somewhat stout pseudo-bulbs about 2 inches long, being somewhat compressed, and bearing a pair of coriaceous leaves which are from 3 inches to 5 inches in length. It grows well upon a good-sized block of wood or in well-drained earthenware baskets or pans hung from the roof. During the growing season the plant likes an abundant supply of water, and during the resting season it should be removed to a cooler place and kept fairly dry. We are told that in a state of nature the plant is subjected to a severe drought, but I found the above was the best system of resting it, and it flowered every season. It was grown in the East India house and exposed to the full sun during the whole day.

W. HUGH GOWER.

Pleione Wallichiana.—John Jones says: "I have nearly a hundred flowers of this plant open and opening on different plants. I send you a few blooms as a sample." These are superb in colour and of large size, which shows that the plants have been grown well and rested properly. This plant is found at great elevations in Northern India, and grows well in a cool house. It likes a fair amount of sun during the growing season.—W.

Oncidium Lanceanum (B. W.).—This beautifully fragrant species comes to me in two varieties. The one marked No. 1 is the variety known as *Louvrexianum*, which has a paler lip and the other parts of the flower not so rich and dark as in the flower marked No. 2, which is the typical form of the plant, and has a lip of the richest and deepest purple. "B. W." tells me these plants are growing well with him amongst his *Marantas*, with plenty of moisture and shade all the year round. Those who find the species difficult to grow should bear this in mind.—W.

Cyperorchis Mastersi.—This is none other than the beautiful *Cymbidium Mastersi*, but the name given is that under which it is known at Kew, the genus *Cyperorchis* being that to which

authorities have now removed it. *C. Mastersi* is one of the loveliest of *Orchids*, introduced by Messrs. Loddiges, of Hackney, in 1811. The habit of growth is elegant, like that of *C. eburneum* in this respect, the leaves narrow, arched gracefully, and varying in length from 1 foot to 2 feet. The flowers are very beautiful, and appreciated at this season of the year, several being borne on the scape. The sepals and petals are pure white. The lip also is white, but blotched with yellow in the centre.

Lælia Schilleriana.—A gentleman signing himself "Avalanche" sends me flowers of a very fine form of this species or variety, and says his friends tell him that it is *L. elegans*, but he has never seen such a fine form, and he asks me to give him the right name. It is a very fine form of the variety known as *Lælia Schilleriana*, and has, I think, been figured under the name of *L. Warneri*. It is well worth taking great care of. It is not so much like *L. purpurata* as *L. Wolstenholmie*, which is, I think, the most beautiful form of all the plants that are put down as varieties of *L. elegans*. All of these plants require a slightly warmer house than the *Cattleyas* and *Lælias*, which are usually grown together.—W.

Orchids at Gunnersbury Park.—The *Orchid* house here is bright with colour, varieties of *Cattleya labiata* in particular. This is a charming type, and was one of the finest things at the meeting of the R.H.S. recently. The plants are free, and the bold flowers display considerable variety in colour, the lip varying from pale to intense crimson. *Lælia anceps* was throwing up a fine mass of spikes, and *Masdevallias* of many kinds were commencing to bloom. *Orchid* growing near London, however, is beset with difficulties, and the worst enemy is fog, which plays great havoc with not only expanded flowers, but buds.

Zygopetalum Burkei (S. S.).—This is a rare species, introduced by the Messrs. Veitch & Sons from Demerara. It was known for a long time before it was brought home in a living state. The flowers are produced on an erect spike, and measure about 2 inches across; the sepals and petals are about equal, having a ground colour of green, margined and streaked with dull brown; lip and column white, furnished with a frill at the base, and streaked with crimson. It is a very pretty plant, and although somewhat small in its growth, it, like the larger growing kinds, will thrive well with a mixed lot of stove plants. My friend says the specimen from which the flowers sent were taken was brought home from Georgetown, in British Guiana, by himself a year or two ago.—W.

Cypripedium insigne albo-marginatum.—Flowers of this plant come from "H. S." for a name. He also wishes to know if it is one of the *montanum* varieties. I do not know if this plant is cropping up amongst these plants, but I should imagine it to be very likely, and I have seen some varieties very near to it. The true *albo-marginatum* was found in our collections before anyone had thought of the *montanum* forms. The flower now before me is of ordinary size, the whole having a rich yellow hue, saving the pouch, which, however, is yellow with a tinge of reddish brown. The upper half of the dorsal sepal is pure white without spot or blemish, and this white border is continued down the sides of the sepal to the bottom. It is a very charming flower and somewhat rare.—W. H. G.

Cypripedium macropteron (C. Durdan).—The flower sent may be a seedling of your own, but it has the same parents as the kind named above, which was originally obtained by Mr. Seden at the Messrs. Veitch's between *C. Lowi* and *C. superbium*. In the flower sent the dorsal sepal is light green suffused with brown, ribbed with a darker green, and broadly bordered with white, in which it differs somewhat from the original form, which is narrowly bordered with white; the petals, however, appear to be less brightly coloured, and the pouch is also of a duller colour. I do not think the flower sent by "C. D." is such a good one as I have seen produced by Messrs. Veitch's plants in several collections, but

he may take it for granted it is this variety. As it gains strength, two or more flowers will be produced on the scape.—W.

Odontoglossum cirrhosum.—S. Butler sends me a densely flowered spike of this. This is a rather curious time to see this Orchid blooming. It is a small free-growing kind of great beauty, especially when seen so fine as this is. The plant was sent out originally by Mr. W. Bull, and it soon became common, so much so that nurserymen that had secured a large quantity of it found they could scarcely give it away. The time came, however, when it could not be obtained, and at the present time it is again highly thought of. It comes from a good altitude, and thrives well in as low a temperature as does *O. Alexandra*, or even cooler.—W.

SHORT NOTES.—ORCHIDS.

Cypripedium insigne Wellsianum.—This is a magnificent variety and very distinct. It is one of the largest forms of this fine old species now known. I noted it recently in the Melbourne Nurseries of Messrs. Gutzow & Co., of Bexley Heath.—W. H. G.

Lælia xanthina.—E. Jessop sends me flowers of this plant under the name of *L. grandis*. It was introduced by the Messrs. Backhouse, of York, upwards of thirty years ago, and is a very desirable species. I have never seen such a fine variety as that figured in the "Orchid Album," i. e. t. 23.—W.

Cattleya gigas Sanderiana.—A very large and fine variety of this plant was flowering in the Messrs. Gutzow & Co.'s nursery upon a recent visit. The lip was remarkably dark, and stood out in fine contrast to the many fine forms of the old labiata which were flowering close to it.—G.

Lælia autumnalis Arnoldiana.—T. Dickson sends this variety for autumnalis alba, but there is a stain of colour on the lip which takes away from the flower the character of alba. Nevertheless, it is a very pretty form, and does well under the same treatment as does the typical plant.—W. H. G.

Lælia grandis tenebrosa.—T. Dickson sends for my opinion a remarkably fine coloured and large form, with broad sepals and petals 8 inches across; these are of a rich bronzy brown and the large lip is deep maroon-purple, shading towards the front to soft bright rose colour, white at the extreme point. It is a magnificent variety.—W. H. G.

Cattleya speciosissima Carrieri.—"J. S." sends me a very pretty form of this variety of the labiata section, having sepals and petals of a rich rose colour, but somewhat narrow. The lip is deep rose in the side lobes where rounded over the column, the front lobe rich magenta-purple, having two rich yellow eye-like spots near the throat.—W.

Cattleya labiata Percivaliana.—G. Hunter sends me a very fine form of this plant. He says the plant from which it was taken is now carrying fourteen more equally large blooms. The flower sent is certainly very fine, measuring $5\frac{1}{2}$ inches across, with broad sepals and petals of a soft rosy hue; the front lobe of the lip has the edge beautifully serrated and the margin soft rose, whilst the whole of the other surface is of a deep velvety crimson; the throat is prettily streaked with old gold.—W. H. G.

PLANTS FROM AMERICA.

LAST spring I had some plants from America—things not mentioned in English catalogues. I have no doubt some of your readers have done the same. It would be interesting if they would give their experience. In the meantime I will give mine.

DWARF EVER BLOOMING CALLA.—Grew well, but has not bloomed.

IPOMÆA PANDURA (Hardy Moon Flower).—Started in a frame well; turned out in June in a rather sheltered corner, after which it scarcely moved.

GLADIOLUS CHILDSI.—Had three; one had blossoms 5 inches across; another was a poor thing; the third did not blossom. I grow the finest English Gladioli.

HIBISCUS CHRYSANTHUS.—Showed blossoms out of doors in September. After being taken up it bloomed indoors in November.

HIBISCUS (Childs' new hybrids).—I had a plant, which dwindled and died. Seedlings which I raised grew from 4 inches to 6 inches in about five months. Looked unhealthy. My soil is a first-rate light loam. This Hibiscus ought to be a fine thing if it will do in England. It is said to be quite hardy.

A. A.

STOVE AND GREENHOUSE.

BEGONIA ERFORDIA.

This is a hybrid between *B. Schmidtii* and *B. semperflorens* Vernon. The growth and the graceful habit are similar to those of the former species, while the colouring of the leaves resembles that of *B. semperflorens* Vernon. The flowers, of a lovely rosy carmine, are freely produced in loose clusters and form a beautiful contrast to the dark foliage. The plants attain a height of about 12 inches to 15 inches, and are literally covered with flowers during the whole season without suffering in the least from cool and damp weather. It is useful for the flower garden and is also a good winter-blooming va-

Begonia Erfordia.

riety. The electro and the description of the plant were kindly sent us by Messrs. Haage and Schmidt, of Erfurt.

Azalea linearifolia.—This is a very distinct winter-flowering Azalea, and seldom seen outside botanic collections, as at Kew, where several fine plants are in the temperate house. It first flowered in England with Messrs. Standish at Ascot, and is a Japanese species, introduced about the year 1867. It is remarkably distinct, quite unlike the Indian Azaleas, the leaves linear and usually about 4 inches in length. The flowers are starchy in expression, the sepals narrow, and the colour is soft rosy lilac, whilst the stamens are long, with the filaments rose colour. It is scarcely a species to grow largely, but is worth a place in all good collections for its delicate colour and freedom.

Double Poinsettia (P. pulcherrima plenissima).—This variety, which has in addition to the whorl of bracts round the terminal cluster of flowers a separate whorl of smaller bracts round each individual flower, is most effective, and it has the advantage of lasting on later in the season than the ordinary form. It is, however, rather a delicate subject, and to bring the heads of bracts to perfection, it requires careful attention. Early in the season the plants will grow nearly as well as those of the old form, but later on when they begin to show the coloured bracts they require more care. Careful attention to watering is one

essential, and a regular temperature is another important point. If not carefully treated, the flowers are apt to fall off while they are developing the bracts. A low temperature is almost sure to bring about the loss of flowers.—F. H.

The white Poinsettia is worthy of attention. This does not usually carry quite such large heads as the scarlet variety, but it forms a good contrast. Like the double form, it requires some care to grow it well. The stock plants should be started earlier in the spring than is recommended for the ordinary form. Strong cuttings being most desirable, the old plants should be potted in some good open compost, and grown on until they have gained some strength before the first cuttings are taken. The cuttings made from the long shoots must be cut off quite close below a joint, otherwise they will not callus properly. If the first cuttings do not succeed, the later ones will be all the stronger if the plants are allowed to get a good start.—F. H.

Tree Carnations.—In my notes on these I omitted to mention the new pink variety Mrs. Leopold de Rothschild. This appears to be a really good thing, the flowers being larger and a little deeper in colour than those of Miss Joliffe. Mlle. Thérèse Franco is another good pink variety of which I lately saw a nice batch in Messrs. Veitch's nursery. This has been awarded a certificate of merit by the Royal Horticultural Society. Mrs. H. Cannell is another variety worthy of mention. I have not seen this growing, but, judging from cut blooms, it is a fine winter-flowering variety.—F. H.

THE GIANT ARAD.

(AMORPHOPHALLUS TITANUM.)

A GOOD deal of interest was excited a year or two ago when this plant developed its evil-smelling spathe for the first time at Kew. As a fine-foliaged plant of large proportions and of some elegance of habit it will always be welcome wherever there is hothouse space for its development, but after the Kew experience perhaps the less often it flowers the better, seeing that the plant is almost unapproachable at that period of its existence. Another very interesting giant Arad is the Dracontium (*Godwinia*) *gigas*, a native of Nicaragua, this being in all probability the Giant Arum of South America, just as is the *Amorphophallus* of the Eastern Archipelago. The last named plant was discovered in Sumatra, and I recently came across a very interesting account of the plant as it exists in its native forests in Carl Bock's work on the "Head Hunters of Borneo" (pp. 189-190) that may be of interest to those who have grown or heard of this vegetable prodigy. The explorer Bock thus writes of it:—

In the damp and shaded places in the forest, where the sun's rays never penetrated, the giant flower, *Amorphophallus Titanum*, which Dr. Beccari had found at Ajer Mantjoer, grew in fair abundance. The natives here called it sikaribut, while at Ajer Mantjoer it was known as grubuc. The first specimen I saw was pointed out to me by a native, who carefully dug it up; it was a young plant, the bulb measuring 11 inches in diameter. The next was a mature specimen, but almost dead, with a straight stem 5 feet 10 inches high, and measuring $3\frac{1}{2}$ inches in diameter at the base, with a fruit resembling the ear or head of Maize, 25 inches long and 4 inches in diameter at the base, tapering somewhat towards the top; the stem was 1 foot in the ground, and the bulb measured 10 inches in diameter. Since then I have frequently seen the plant in different parts of the highlands of Sumatra, but the flower and fruit are rare. Of the former I have seen only three, and of the latter only five specimens. It quite puts the great Rafflesia in the shade. It grows to a height of from 5 feet to 6 feet, when it throws out three large leaves, which may almost be called branches from their size

and from the fact that they are covered with small subsidiary offshoots, which may be called leaves. The stem, which is cellular and contains a large quantity of water, is of a beautiful bright green colour, mottled with spots of yellowish white. Its growth is remarkably rapid. I have watched the young plant, and found it grow no less than 1 foot in two days, so that it attains its maximum height in about twelve days, when it stops growing, and the leaves or "branches" are formed. The flower, which always appears before the leaves, grows close to the ground, seldom more than 1 foot from the surface. It consists of a single petal, very thick and leathery, and of the colour of the red Cabbage. The three flowers that I have seen all differed in form. The fruit is a solitary oblong head, covered when ripe with rows of brilliant red berries to the number of from 420 to 440. The bulb sometimes attains enormous dimensions. At Ajer Mantjoer I have seen some gigantic specimens, one of them so large that it took five men to carry it from the forest to my hut.

After reading Bock's account, the idea has occurred to me that this species may naturally die soon after flowering and seeding, so great is the strain on the stored-up resources of the tuber. The allied *A. Revierii*, from Cochin China, has twice died after flowering here, but as it produces small tubers or vegetative offsets freely, this does not so much matter.

The blossoming of this giant *Arad* seems to be the result of several, even if not many, years of starch accumulation, just as it is in the case of the Sago and some other Palms, and with Agaves, Bananas, and plants of similar character. I believe the Kew plant of *Amorphophallus Titanum* died soon after it flowered, and this would seem to be an additional fact suggestive of its tubers flowering but once in the course of their existence. It would be interesting to know if the tubers of *Dracontium* and other large Aroids behave in a similar way.

F. W. B.

***Cordyline indivisa vera*.**—Purchasers of this should be careful, as some do not recognise the identity and distinctness of this plant, and send out *C. australis* under the name of *C. indivisa*, an experience that has recently happened to myself.—F. W. B.

***Rondeletia speciosa major*.**—This is a good old subject not often seen, yet well worth more attention than is usually bestowed upon it. Where flowers are required for cutting, a specimen of this *Rondeletia* trained up the back wall of a stove, if not too shaded, or in some similar position, may be relied upon to yield a greater or less quantity of bloom nearly throughout the year, and the neat little clusters of flowers are by many admired for button-holes and similar purposes. Besides this, good flowering examples grown in bush form are very pretty when in full bloom, and they retain their beauty for a long time. It is a plant of easy culture, for cuttings strike root without difficulty, and if the plants are stopped freely while young neat little specimens can be obtained. Red spider must be guarded against and a free use of the syringe will keep it down.—T.

***Phoenix rupicola*.**—There are few Palms more adapted for house decoration or for cultivating under cool conditions than *Phoenix rupicola*. I have a very handsome pair, besides several smaller plants, which have been used for house decoration off and on for the past six or seven years, and they are now without blemish, being in fact perfect. They are placed in the house for a week or ten days, and then removed again to the conservatory for a like period.—A. Y.

Varieties of *Salvia splendens*.—The typical *Salvia splendens* has been long a popular favourite, but within the last few years a dwarf variety has made its way into cultivation. Several notes on this form have from time to time appeared in THE GARDEN, and it is such a good plant that it would

be indeed difficult to say too much in its favour. Regarding these dwarf *Salvias*, it would, however, be especially interesting to know if there is any difference between the varieties *compacta*, *Bruanti*, and *Le President*, for as far as can be judged without growing them all under similar conditions they are very much alike, if not actually identical. In addition to the typical form and its compact variety there is yet another—*M. Issanchou*—in which the blossoms are striped with white and red.—H. P.

***Fuchsia microphylla*.**—This tiny-flowered *Fuchsia* will in a warm greenhouse bloom well on into the winter, and, treated as the ordinary garden varieties, it is just as free-flowering as they are in the summer. A neat little bush about 18 inches high when laden with its pretty blossoms is very attractive, particularly so from its being very distinct from the *Fuchsias* in general cultivation. There is a second species of this class, viz., *thymæfolia*, which is, however, a taller grower than the preceding, though the flowers are of much the same size. *F. thymæfolia* may be employed for furnishing a column in the greenhouse if planted out, but *F. microphylla* is essentially a plant for pot culture. Both these small-flowered species are natives of Mexico, from whence they were introduced more than sixty years ago.—H. P.

CROTONS.

I QUITE agree with "Grower" in regard to the usefulness of the three *Crotons* he names (GARDEN, p. 484), yet I should hardly give these first honours, for there are others which colour equally well and are of a much better habit of growth. Taking Baroness J. de Rothschild, it is rarely one meets with this in a young state, except in long leggy plants, though the colouring is always exceedingly bright. For grouping, the tall plants may sometimes be used to advantage. In preference to the above I grow Emperor Alexander III., which has larger leaves and makes a better furnished plant, while the colouring is even brighter. Single-stemmed plants may be used as table plants, and when they get too tall they are effective, especially for fire-place groups, or the tops may be taken off and rooted again. *Mortfontainensis* is another highly coloured and very useful variety. It is a good grower and may be relied on to keep its colour. Many of the *Crotons* are very sportive, but this is quite an exception. Of all the *Crotons* *C. Newmanni* has the most red in the variegation. It is, however, a bad grower and is apt to lose its leaves, but when well grown it is exceedingly brilliant, the whole surface of the leaves being suffused with a bright glowing red. *Musaicus* is another highly coloured variety, which may be recommended on account of its constancy. The leaves are strap-shaped, but rather short, undulated on the margin, beautifully veined and mottled with deep yellow, which changes to a bright rosy red. I prefer this to the old favourite *undulatus*, though when the latter is well coloured it is very attractive, but it is very much inclined to run out.

Those referred to above are more suitable for grouping. For table decoration those with the long narrow leaves are most appreciated. Of these *Countess* is one of the most desirable. It has long drooping leaves, pale green, veined and spotted with yellow, which colour it retains. Of those which change to red there are none to surpass the old *majesticum*, which, when propagated from well-coloured tops, makes a very handsome plant. *C. Warreni* is one of the most elegant, but, as "Grower" states, it is only when grown with a single stem that it is seen at its best. I have never seen it in finer condition than when it was exhibited in the spring of 1880, on which occasion a first-class certificate was awarded to it by the Royal Horticultural Society.

With regard to the usefulness of *Crotons* for decoration, I think few estimate them at their proper value. Plants taken from the stove, especially while making growth, last but a short time; but take plants with matured growths and gradu-

ally harden them off, and they will last for months. As an instance of this I may mention that Mr. J. Wills once while speaking of their value told me that he had had some in a window box which had kept in good condition throughout the summer, and at the end of August they were still looking well. The sorts were *Disraeli*, an old favourite, and *Andreas*, referred to by "Grower." F. H.

***Aphelandra nitens*.**—All the *Aphelandras* are very pretty flowering plants, whose bright coloured blossoms are borne at almost all seasons of the year, but at no time are they more valuable than during the autumn and winter months. A very distinct species is *A. nitens*, a sturdy-growing form, with stout, leathery, ovate leaves, deep glossy green on the upper surface and purplish underneath. The large showy blossoms, of a glowing vermilion-scarlet colour, are borne in terminal spikes, as in most of the others. Besides this, especial mention may be made of *A. aurantiaca* and its variety *Roezli*, *A. fascinator*, *A. Leopoldi* with yellow blossoms, *A. cristata*, and *A. Chamissoniana*, whose flowers are of a distinct shade of chrome yellow. Both in this last and *A. Leopoldi* the showiest part of the inflorescence is the large bracts which subtend the blossoms, and in some cases nearly hide them, for these bracts are coloured very much as the blossoms themselves. From a foliage point of view alone most of the *Aphelandras* have much to commend them, for in *Roezli* the dark green leaves are shaded with a peculiar silver hue, *A. fascinator* has the foliage banded with white, the large leaves of *A. Leopoldi* have the course of the principal veins marked with a broad band of white, and in *A. Chamissoniana*, or *punctata*, as it is at times called, the narrow, deep green leaves are banded and freckled with silver. All the *Aphelandras* are of easy culture, and they can be readily increased by means of cuttings, or in some cases seeds. Old plants are apt to run up tall and naked; therefore a succession of young ones should be kept up, and they can then be grouped together as required.—H. P.

Carnations at Gunnersbury Park.—The *Carnation* is largely grown for winter flowering at Gunnersbury Park, and one house is wholly filled with the variety *Mrs. Leopold de Rothschild*, which, it may be interesting to mention, is a cross between *Miss Joliffe* and the old *crimson Clove*. The flowers show the parentage; they open of quite a salmon-rose, but chiefly more of a clear rose shade, and both colours are pleasing, whilst as a rule they do not split. This houseful of them has provided bloom for several weeks past, and is still gay. As regards habit, it is compact, free, and vigorous. Three other good kinds made note of were *Lizzie McGowan*, pure white; *Irma*, brilliant rose; and *Mrs. A. Hemsley*, of a fine deep crimson colour, not unlike the old *Clove* in this respect. We wish, however, the winter-flowering *Carnations* were more fragrant. Some have positively no scent at all, but by getting crosses with the old *Clove* this great failing may be remedied.

KITCHEN GARDEN.

SEED POTATOES.

It has long been regarded as one of the settled axioms of Potato culture that as seed, whole tubers are a long way superior to those which have cut surfaces, and that in no case should cut sets be used, except on an emergency, when only large tubers can be obtained for planting. Generally it is found that gardeners who save their own seed do select early and when most convenient not by any means the largest, but good medium-sized tubers, with a view to secure the greatest number of sound healthy plants and the least possible waste. Good seed houses do the same, and so far as possible make their

seed selections accordingly. Market growers and farmers take less pains; indeed, their methods in relation to seed storing for the winter, usually in clamps or pits, allowing the tubers to make more than one premature growth, and later because the sets are often large, cutting them into three or four pieces, are still as crude as they were fifty years ago. It is very hard indeed to make much impression on that particular field class of growers. They are so much outside the influence of the horticultural press, and therefore have less appreciation of better methods. One of the great faults of our existing stocks of Potatoes is that they produce too large tubers. The common desire, of course, is to fill the bushel as quickly as possible, and the bigger the tubers the sooner is that end obtained; but large tubers have inferior merit as food and they are a great trouble and a nuisance as seed. Could we clear out the bulk of our present too large-tubered stocks and replace them with a section that gave not less weight in a greater quantity of tubers of more even and useful table size, the gain would be great. Very often some sorts give few or none of what may be called useful and fitting seed tubers, and large ones, perforce, have to be employed. It is in such a case really worthy of consideration whether it would not be wise to grow expressly for seed a moderate breadth of the variety in poorer soil, as in that case a rounder, harder, and more useful class of tuber would result. It does seem possible that what is so desired may some day be secured, but, all the same, the attention of raisers may well be directed to this need, especially as it opens up a wide range in which new varieties of Potatoes may be utilised. It is true that now our present stocks may be very much modified if we would be content to grow them under less gross conditions. We give the crops too much of nitrogenous manures, which generates gross haulm and huge watery tubers. Were poorer soil utilised, and only phosphates and potash as manures, the result would be apparent in the direction of securing more starchy tubers and of more equable size. In relation to the proper size of Potato sets, I was a good deal interested in reading the other day a protest against the advice or practice to limit the stems or shoots of seed Potatoes to one only, on the ground that it restricted the root produce, as several stems must be so much more productive. That was not the assumption of a practical man, because experience has over and over again shown that single or, at the most, twin-stemmed Potato plants produce a far more even and heavier crop than do plants having several stems. Ample room, light, and air for the tops are as essential for tuber-development as are any other requirements, and these advantages are far more fully secured when the stems are nearly or quite single than when crowded. To secure this desideratum there is no better method than selecting moderately sized tubers for seed at the time of digging, putting them away into open airy sheds or outhouses to harden, being laid out thinly, and then for the winter keeping in cool, equable, though frost-proof sheds, either laid out on shelves or in shallow boxes. There is no possible method of keeping seed tubers superior to this. So long as the place is dry, cool, and airy, it does not matter if the tubers of the earliest varieties do make growth. At the most in such a case it will be limited to the strongest crown, bud, or eye, and so long as the tubers are dry, that shoot, if in ample light and air, will not push beyond an inch or so even if it lies there for months. The one shoot thus exhausting the seed

tuber's store of nutriment leaves little for the starting of other eyes, so that disbudding is seldom needed. It is when larger tubers are employed, each eye or bud having its own reservoir of nutriment, that several shoots are developed and disbudding is needful. I have long entertained the belief, and it is really a question in plant or tuber physiology, that any one bud can exhaust only the special reservoir of sap that is associated with it. Hence we find that a comparatively small, sound, well-matured set will throw as stout a shoot as will a tuber of three times the dimensions. That fact serves to show how wasteful is the practice of planting large tubers. There is an impression that large tubers are needful for seed when it is desired to keep a strain or stock of Potatoes up to the standard of merit. That is not so. If the smaller sets be selected from a good stock there will be no deterioration, but sets from inferior roots should always be rejected. A. D.

Colewort.—Colewort, or Collet, is, no doubt, a distinguishing name for a small Cabbage, and what is known as the green Colewort is one of the most useful of winter greens. In Scotland, Colewort appears to be synonymous with Kale. How the Colewort originated is not stated, but the common name may perhaps be taken as distinguishing a class of Cabbages eaten before the heads are full and close. Judging from the extent to which some London market gardeners are planting the green Colewort, it may be taken as representing a remunerative crop. Land that bore Scarlet Runners, Lettuces, Cauliflower and other crops has recently been ploughed and manured, and plants of good size put out by the thousand. Plants put out in July may be said to have stood still for a time owing to the drought, but as soon as rain came they started into growth, are now heading in rapidly, and will soon be in the market—at least when the sale of Brussels Sprouts begins to slacken. Coleworts furnish what is known as bunched greens, and as the plants are pulled when the heads are young and tender and not cut, as is the case with ordinary Cabbages, they are tied up in bunches by the stalks, six or so forming a bunch, a custom which gives rise to the term bunched greens. A good stock being of a dwarf and compact habit of growth, the plants are put out so closely, that they touch each other when fit to pull, and thus an acre of ground will hold a large number of plants. Those who grow Coleworts largely make two sowings; one in April or May, or earlier, and another in July and August. There is no advantage in sowing too early, as the value of the Colewort is when winter greens are scarce. The Colewort is a very hardy vegetable, and stands the severe weather as well as any crop of winter greens. What is known as the Rosette Colewort is a selection from the ordinary green, and produces its leaves in the form of a rosette. It was put into commerce by the late Mr. Charles Turner a quarter of a century or more ago. Some market gardeners prefer it to the old type; others the latter. But the common Colewort will frequently take on the rosette form, and the rosette will revert to the older type. When young and tender the Colewort is greatly esteemed.—R. D.

Improved Round-leaved Batavian Endive.—There has been considerable progress made of late years in the varieties of Endive as regards hardiness and flavour. From close observation the above variety is the best. It differs but little from the ordinary kind known as broad-leaved, but is more compact in habit with less stalk and more leafage, and is not bitter, like the elder variety, possessing a flavour more like Cabbage Lettuce. Of course with Endive hardiness is important, and this is far superior to the curled varieties on that account, as it stands severe cold if planted on a sloping warm border and protected during severe weather. This variety will give a late supply, and if a frame can be spared and the plants lifted with a ball there

will be no lack of Endive through the winter months. For the winter supply, sowing the second or third week in August is quite early enough if a good position can be afforded the plants afterwards. Thin sowing is important, as crowded plants are more tender and rarely survive the first frost. Sturdy plants are wanted for late planting.—G. WYTHES.

Jerusalem Artichokes.—The crop of Jerusalem Artichokes promises to be very large. The first root I lifted this year had a very large and almost solid lump of tubers, which were quite difficult to separate, so tightly were they packed together. Big and small they numbered fifty-seven; they almost filled a peck measure when picked and free from dirt and weighed 10½ lbs. The tubers are very clean and free from coarse roots. The past summer has suited the plants admirably, for nearly every head has flowered, and several of them have opened from three to five flowers each. I grow these Artichokes in fairly deep, but poor soil, and use nothing in the way of manure but some light hotbed stuff—mostly decayed leaves. A bit of ground sloping sharply to the north is devoted to their growth, and they give heavy crops from the same plot year after year.—J. C. TALLACK.

Storing seed Potatoes.—The practice adopted by many Potato growers of allowing the seed and refuse to remain in bags or heaps until the wet weather sets in and time can be spared to sort them over cannot be too strongly condemned, as during the interval heating often occurs, followed by premature sprouting and a loss of vitality. If more attention were paid to this matter, crops would make a better stand against the inroads of disease should a dull and humid summer ensue—J. CRAWFORD.

SOWING EARLY PEAS IN AUTUMN.

THE sowing of early Peas in the open ground is attended with so many risks that fewer are sown than formerly, when glass was less plentiful and one had to rely upon early or autumn-sown Peas for the first supply; but even with sowing under glass there are failures. These mostly occur through excess of heat, want of light and air and from the roots being crippled in their early stages. With proper attention (not forcing) there will be a good return and the produce earlier than when the seeds are sown in the open in November. Sowing should not be deferred after the first or second week in December. To get the best results, time and as little heat as possible are necessary. I prefer larger pots than are often employed, not less than 4½-inch pots. This was referred to last year in THE GARDEN, and I am pleased to see other cultivators consider it good practice. I do not attach so much importance to variety as some persons, as it all depends when the Peas are required and if a succession is wanted. If the latter, I advise two kinds—an early and what is termed a midseason or general crop variety, which will form a succession and give a larger crop than the earlier kinds. I do not recommend the small white round Peas, the pods of which come so very small that they do not pay for room occupied. I would advise a green wrinkled Pea with some marrow blood in it. For outside sowing the small type without any of the marrow strain is hardier, but for sowing as advised in this note, with shelter provided for ten or twelve weeks, there is less need of such Peas. For the past two years I have sown a large variety (the Duke of Albany) at this date, and it is only a few days later than the smaller kinds. By sowing a large kind there is a greater yield and the Peas look better on the table. Large Peas may be objected to on account of height, but this does not apply to Peas raised in pots, as they are dwarfed by the process, and if they are too tall they

can be topped. Duke of Albany with me last April when in full bloom was not more than 2 feet high, and planted much the same as the dwarf kinds 3 feet apart on a south border in front of some fruit houses. Our earliest or small kind was Chelsea Gem, an excellent kind, larger and superior to American Wonder. I also like William I., but Chelsea Gem is a few days in advance and much dwarfier, allowing a row of early Lettuce between the rows. As previously stated, I like 4½-inch pots for the small kinds, and even larger or 6-inch for the Duke of Albany, using good yellow loam with some spent Mushroom manure and free drainage. I sow thinly and not deep, having made the soil firm to encourage sturdy root-action. Little water will be required if the soil is moist till the seeds germinate. I stand the pots in cold frames, placing the pots near the glass as the Peas come through the soil, and covering at night. To retain moisture and induce early germination, a covering of cocoa fibre over the pots after sowing is beneficial. Peas sown in this way have many advantages over those raised in heat. They are much dwarfier, they do not suffer when planted out, as they are sturdy and soon come into bloom. The larger pot allows of more roots, which, if slightly opened out when planting after removing the drainage, soon take to the new soil. Having been thoroughly hardened by the removal of the lights when in the frames, they may be planted early in March without any fear of collapse. Peas raised in this way give little trouble, and come in most acceptable weeks in advance of those sown in the open in February.

G. WYTHES.

THE PROTECTION OF CELERY.

It would be both instructive and interesting if cultivators would give their experience as to what extent protection to Celery is needed, or if at all. According to my experience the decay of Celery is more often than not due to other sources than frost. During a severe or prolonged frost a little protection is of great assistance, but the continual covering and uncovering of the rows which some people subject their Celery to cannot but be positively injurious. It is very annoying after trouble has been taken to have good Celery to find that at midwinter the greater part has decayed. There is no doubt that the form of earthing which is adopted has much to do with early decay. By earthing too early, the blanching is done much too soon; consequently after a time decay commences, let protection from frost be ever so efficient. I have noticed in Celery that is over-protected that fermentation sets in through want of air and close confinement. Celery, however, to keep well must be well moulded up. A careful workman will see that this is efficiently done, the sides well sloped up and made fairly smooth, the soil being also well worked around the tops of each plant, which should, when earthing is finished, be exposed about 6 inches. Heavy coverings of litter or Bracken laid along the tops of the rows cannot but have an injurious effect, and late Celery will be in a worse condition at the turn of the day than even if left freely exposed.

I find the best plan, if the weather should become unduly severe and there is no covering of snow, is to lay some dry litter or Bracken Fern along the sides of the rows and then to shake a little of the very lightest and driest loosely along the top. If a heavy covering be put on and suow were to follow directly afterwards, it would lie very close, and afterwards when a thaw set in, it would become a wet and sodden

mass, and the Celery would suffer accordingly. Damp is the worst enemy to Celery. I may be wrong, but I am of the opinion that Celery will suffer more than usual from damp this season on account of the very open weather which we have experienced. Whatever form of protection is used it must be so arranged that both light and air can have free access. Covering over with a cap by having two boards nailed together thus ^ has been frequently recommended. This season, if occasion should arise, I shall use a covering which builders place along the tops of walls for keeping out wet and frost. Instead of being of wood it is made of corrugated zinc. This being fixed so that the tops of the Celery are not bent over, there is no danger of either light or air being excluded. In time of severe frost with a covering of litter along the sides so as to facilitate digging up and a little laid over the opening, I do not think there will be any fear of injury either from frost or damp. Celery that has been forced into a coarse growth by heavy applications of liquid manure and the too free use of artificial fertilisers will be the first to succumb.

A. Y. A.

Brussels Sprouts.—Whilst all who have grown what Mr. Wythes terms large or coarse varieties of Brussels Sprouts in gardens must admit that they are not suited for the deep rich soils of such places, I have found them to be first-rate for field culture; indeed they are very popular with the market growers, because under their somewhat rough-and-ready treatment these large sprouted forms come of medium height and size and are very solid, still further come very true, and give good hard sprouts right up to the last. These forms have undoubtedly helped to make Brussels Sprouts cheaper and more plentiful, but then they are all the more profitable. Without doubt Brussels Sprouts become not merely strong growers, but strong in flavour when grown on deep rich soil. Field ground is rarely ploughed deeper than 10 inches, but of course it is well manured. Still the ground invariably becomes hard, and because the base, too, is hard, the soil is so very different from that ordinarily found in gardens where it is trenched 3 feet deep. Here the plants will run up to 4 feet in height. I once saw a batch that had been sown where to grow and were then thinned out. The rows were 3 feet apart. This was at Heckfield, and Mr. Wildsmith determined to test the capacity of the Brussels Sprouts under this kind of treatment. The result never justified the pains thus taken, for the stems were of exceeding dimensions, the height proportionate, the leaves of enormous size, and the sprouts really like young Cabbages. The practice was not repeated. Still some gardeners raise their plants under glass that they may have them strong to put out a month earlier than they can be got from outdoor sowings. I have never seen any gain attached to that practice, as no one wants Brussels Sprouts in September, or indeed until the weather is getting cold. The market grower sows his seed in the open early in March and puts out his plants in June; they develop into stout, hard stems 2 feet in height, and have literally masses of very hard green sprouts all up them.—A. D.

Cypripedium microchilum.—The charming group of Lady's Slippers formed by *C. niveum*, concolor, Godefroya, and bellatulum—the gems of the Cypripediums—has not yet been used to any great extent by hybridisers, that is, compared with some other species. The number of hybrids possessing their blood is, however, being constantly added to, and, judging by the beauty and distinctness of those already raised, we may expect further good results. *C. microchilum* was raised by Mr. Seden from *C. niveum* and *C. Druryi*, and first flowered with Messrs. Veitch about eleven years ago. A plant in flower was shown by that firm at the last meeting of the Royal Horticultural Society. It is of dwarf, neat habit, with strap-shaped tessellated

leaves. Although showing unmistakably the parentage of *C. Druryi*, the influence of *C. niveum* strikes one as more apparent. The lip, as the name implies, is remarkably small, and both it and the lower sepal are of a porcelain white; the petals and the upper sepal are also white, but spotted with black-purple, a streak of purple also running down the centre of each. This purple streak is much more marked in *C. Druryi*, and is the most distinctive feature of its flowers.

GARDEN FLORA.

PLATE 939.

“BREEDER” FORMS OF *T. GESNERIANA*.

(WITH A COLOURED PLATE.*)

FLORISTS' flowers may be considered from two standpoints—from the florist's one and from that of an artist. The florist's and the painter's opinion of beauty will scarcely ever be the same; the florist mostly loves regularity, fulness, and in too many cases stiffness; the artist likes loose arrangement, peculiar irregular forms and fantastic colouring. The plates of THE GARDEN are all made by artists, who figure florist's flowers without troubling themselves very much about the florist's manner of looking at a plant. As I like truly artistic painting, I am a great admirer of THE GARDEN plates in general, but being a florist I look at a flower also from another point of view, and as a florist I sometimes consider THE GARDEN plates not as I think they might be.

[There is only one way to true art in this matter, and that is what is done for us—to draw what the artist has before him. This was done. The stems lost their rigidity on the way from Haarlem.—Ed.]

The figure of a plant or flower, as far as possible, should suggest some idea of the character of the whole thing, representing it in its natural position and as it is seen in the field or wherever it may be grown. I confess this is a very difficult matter in many cases. Take, for instance, these Tulips. They may be considered as florist's flowers, although they are neither regular nor stiff, and if the artist had seen them in the field he would not have figured them looking you in the face, as they never do in the field. The Darwin Tulips always stand quite erect in their high iron-like stalks. They may be rocked by the wind, they always return to their old position, and as they are the tallest of all garden Tulips, you do not see them from the inside, but rather from the outside, as a rule.

The artist, however, has arranged the cut flowers we sent him in such a way that the flowers look you straight in the face. He no doubt had his reason for doing so, and I suppose he did so, being struck with the particular beauty of the base of the inside of the flowers, the colour of which, as a rule, contrasts in a remarkable manner with that of the other parts of the flower. Not all varieties of Darwin Tulips show blue bases in the flower, many of them being of a pure white. We sent flowers of both groups, those with the blue base being selected by the artist for reproduction. This fact proves that there is a great difference in judgment about flowers when drawn by an artist not being a florist. The latter invariably prefers Darwin Tulips with white bases; the former seems to prefer those with coloured bases. Darwin Tulips are, as it is well known, a race of breeders, and as, according to English florists,

* Drawn for THE GARDEN by C. Jones from flowers sent by Messrs. Krelage and Son, Haarlem, April 7, 1893. Lithographed and printed by Ben George, Hatton Garden.

FORMS OF TULIPA GEORGINA

inaw set in, it would become a wet and sodden | of dwarf, neat habit, with strap-shaped tessellated | Hatton Garden.

those with white bases produce better "broken" varieties, they prefer the same, considering no other self-coloured varieties worth growing. There is no reason at all for such exclusiveness. The Darwin Tulips give excellent broken varieties, but they have not been offered in the character of breeders, as they have proved to be so very valuable for bedding before being broken; indeed, no other strain of breeders can rival them in glowing, dazzling colours, and as it takes a rather long period for them to break, there will be found perhaps one broken flower in a lot of 1000, which, of course, does not spoil the effect of the bed.

The Darwin Tulips, as has been stated, are late-flowering breeders. They originated mostly in French Flanders, which for a rather long time has been the centre of amateur Tulip culture. The last amateur collection to be found in that country, being one of the most renowned ones, was purchased by our firm, who have since introduced the varieties into the gardens both of Europe and America. I hope to have an opportunity of giving a description and history of the broken Flemish Tulips later; about the self-coloured breeders there is not very much to be said. Among the most meritorious varieties may be mentioned the following, viz. :—

André Doria, brownish black; Beyerinck, lilac; Charles Darwin, light bluish violet; Edmée, lilac, bordered lighter; Faust, violet-black; Hitchcock, dark carmine; Hoola van Neuten, lilac-violet; La Candeur, light coloured, white in the centre; Laurentia, carmine; Mrs. Stanley, rosy pink, with whitish centre; Nauticus, glowing claret-violet; Parthenope, lilac-red, bordered lighter, white in the centre; Pauline, rosy violet; Peter Barr, glowing dark violet; Prof. Michael Foster, dark carmine; Prof. Sargent, bright red with violet reflexion; Reine Wilhelmina, soft rosy white; Rev. D'Ombrain, brownish red, large violet basal blotch, bordered with white; Réville, lilac, basal blotch white, bordered with light blue; Schoubert, brownish black; Sieraad van Flora, violet; Stanley, dark violet-red, white basal blotch, bordered blue; Theodoor Jorissen, bright violet; Van 't Hoff, bluish violet, with white centre; Whistler, dark brownish red, small violet blotch, elegantly bordered with white; Mr. J. G. Baker, carmine; Panopia, cherry-red, tinted with lilac; Sarah Bernhardt, purplish carmine; Sir Dalton Hooker, brownish red; Souvenir de Douleur, greyish lilac; Vespuccio, dark bluish violet; La Tulipe Noire, the blackest Tulip of all.

All the varieties named above have been awarded first-class certificates by the floral committee of the Royal Netherlands Horticultural and Botanic Society. This fact deserves special mention, as the flowers were judged by a special Tulip committee consisting of the best Dutch Tulip growers. About two dozen other varieties gained second-class certificates, but I do not give a list of them, as I think the above selection sufficient. Although the range of colour may be considered by some as somewhat limited, the yellow being entirely missed in these varieties, on the other hand, it is safe to say that no more dazzling scarlet nor more absolute velvety black flowers can be found in the vegetable kingdom than may be found among the Darwin Tulips; such colours as purple, mauve, crimson, rose, and vermilion are exceptionally abundant.

They may be treated in the same way as other garden Tulips. They are quite hardy in our climate, and the only care necessary is to guard against the early night frosts in spring. The flowers are at their best about the middle of May when the early Tulips are over, and when it is too early for the soft-wooded plants to be brought out of doors. They then fill up

a blank in our gardens, and under these circumstances undoubtedly will be very useful, being especially effective when seen at a distance.—ERNST H. KRELAUGE, *Huurlem*.

* * * These are self-coloured forms of the well-known common garden Tulip, the parent of our florist or late-flowering Tulips as distinguished from the bedding or early-flowering forms. They were called "breeders" because they are those from which the florist varieties generally break. Confusion must arise from giving a new general name to a group of forms of a well-known and very old species, as to which there was no confusion necessitating a new group name.—ED.

THE WEEK'S WORK.

ORCHIDS.

THE weather is now exceptionally mild for the season, and as long as this lasts there will be no difficulty in keeping the plants in good condition, for during the whole of November there was nothing like fog in the air. We may have very cold weather soon, and to counteract the effects of the pipes being constantly well heated, let sufficient water be sprinkled on the paths and upon the stages under the plants. Some good growers recommend filling the evaporating troughs with water, but I do not, for when the pipes are well heated the water is being given in the form of vapour quite visibly, and this being continued night and day causes the house to be too much filled with moisture, and in the morning the foliage of some of the plants may be found covered with damp. Those plants that are well on the moist side at the roots will show it to the greatest extent. Probably the reason why it does not show to the same extent upon plants that are at rest is because the leaves have absorbed the moisture and may have caused material injury to them by promoting growth when they should be quite at rest. There should be no condensed water on the leaves at this season of the year. It is quite impossible to give definite directions as to watering. A hygrometer is a useful instrument in a house, and in that case it is easy to gauge the amount of evaporation, which should range from the saturation point after damping down to 6° or so above it. In the cool house it should range very little above the saturation point. If the weather is mild there is not much difficulty in opening the ventilators sufficiently to admit all the air that the inmates of the houses need. A good test to show whether the ventilators have been opened too much is found in the sudden falling of the temperature. This ought not to happen. In the morning, instead of the temperature falling after the ventilators have been opened, it is better that it should rise, and if this does not happen, see that it at least does not fall. In the event of very severe weather setting in, it may only be possible to ventilate a little about mid-day, and this in the most careful manner. I have before shown how the air can pass into the house over the hot-water pipes before it reaches the plants. Of course, the wall ventilators may also be covered with perforated zinc, which would still further break the current of air, and cause it to filter more slowly amongst the pipes. The stages in all our houses are of iron framework, upon which are placed slabs of slate. The slabs are covered with shell gravel, and each Orchid all through the houses stands upon an inverted flower-pot. Economy in fuel and efficient heating should be, and may easily be combined. It is important that stoking should be entrusted to a careful, thoughtful man. Some young gardeners have not much thought beyond filling the furnace choke full of fuel, and if the temperature is low they pull out the damper, and if it is high and inclined to rise they push it in. I do not say that it is not necessary sometimes to well fill up the stokehole furnace, but as a general rule it is an error to do so. If the houses become overheated

with a moderate fire, it is easy to damp down with ashes, and by pushing in the damper the temperature will soon be at the desired point again. This error very often occurs early in the morning. It is found, perhaps, that the temperature is too low, and in the face of this the outside temperature is at daybreak usually falling to the lowest point. The nervous cultivator rushes to his furnace, stirs up the fire and crams it full of fuel; but this is a mistake. If the fire is low, as it is likely to be, a large quantity of fuel will not get up the heat so quickly as a small quantity, and when the heat does get up later, the stoker has not much control over it, and may have to draw some of it out because he has not only been too late in heating his pipes, but has made them too hot. The right thing is to make up a moderate quick-burning fire. By the time the heat is up to what it ought to be, the fire will have burned low and can be made up according to the outside temperature. On a dull, cold day the fire might require to be well kept up, but if the sun breaks out, less might be needed.

At present the East India house is very attractive with a profusion of bloom upon the Cypripediums. The very pretty species *C. Spicerianum* is in full beauty, and it is interesting to note what a very large number of garden varieties has been raised from it. About three-fourths of the new varieties exhibited before the Orchid committee of the Royal Horticultural Society are its progeny in the second, third or fourth generations, and the further they are removed from the original source the less attractive they are. Crosses have been obtained from *C. Lathamianum* and from *C. Lee-anum*, but the best varieties of these two, which are, as is well known, crosses from *C. Spicerianum*, are still unsurpassed. The recent importations of *C. insigne* have given some distinct and very fine varieties besides the well-known *C. Maulei*. Free-growing species and varieties are best for seed-bearing parents, and poor growers should not be chosen for this purpose. It is better to use them as pollen-bearers and get the seed from varieties that will not disappoint us. J. DOUGLAS.

HARDY FRUITS.

MEDLARS.—Medlars are appreciated in many establishments, and might well, therefore, be more generally grown. They are mostly of a low, spreading habit of growth, and may well be grown as standards in plots outside of the garden walls where possible. Bullfinches are very partial to the flower-buds, or otherwise it is doubtful if failures to crop well would ever occur. Almost any kind of soil appears to suit them—at any rate they are not any more fastidious in this respect than the commonest of Pears. Dutch or Monstreus gives the largest fruit, but the quality is not particularly good. This variety is occasionally to be seen growing against a moderately warm garden wall, the trees under these conditions producing superior fruit very freely. The fruit of Royal is of medium size and more briskly flavoured than the Dutch, while the small-fruited Nottingham is the best flavoured of the lot, this variety also being a heavy cropper.

MULBERRIES.—These, again, are somewhat neglected, very few young trees being seen other than in nurseries. Large well-ripened fruit can be had during most seasons from medium-sized to large trees. Lawns or pleasure grounds would appear to be the proper place for Mulberries. In cultivated ground the trees are apt to grow too rankly to be productive, and in any case the trees afford too dense a shade for anything to grow freely near them. Grass also saves the fruit when it falls, as it is very liable to do directly it is ripe. The Large Black, or *Morus nigra*, is the variety principally grown. Any light loamy soil suits the trees, the latter being trained to a single stem with a view to having them as standards. Any branches that are inclined to take too strong a lead may well be shortened back, but, as a rule, very little pruning other than thinning out occasionally is needed, the trees being naturally of a branching habit of growth.

QUINCES.—These will thrive and do well where few or no other kinds of fruit can be profitably grown, viz., in low damp places, and in particular round the edges of pools, open springs, and such like. There is a fairly good demand for Quinces in the market, and most housekeepers know how to put the fruit to a good use, Quince jelly being greatly esteemed. The trees can also be grown as pyramids and bushes under the same conditions as Pears, but standards and half standards planted in the positions already indicated or in outside garden plots are the least trouble, and generally the most productive. They are principally propagated from suckers, which are plentiful enough about old trees, bushes and pyramids being formed in exactly the same manner as Pears are framed out, and standards are obtained by training up the leading growth and restricting the side shoots till the required height is reached, one or at the most two topplings being about all the further trouble necessary. The Apple-shaped Quince and the Pear-shaped are the varieties most generally grown, both being very prolific.

FILBERTS AND COB NUTS.—Some of the very finest clusters or bunches are obtained from large bushes growing on a rather strong clayey loam, and trained and pruned very much after the manner Red Currants are treated. This is the Kentish fashion, but very good crops of fine nuts can be had from bushes or trees rooting in almost any kind of soil and with little or no pains taken with the pruning. Where shelter trees are provided either for orchards or gardens, an inner line may well be formed of Filberts and Cobs, these also being all the more likely to bear well if somewhat sheltered during the flowering period. Under orchard culture pruning being practised every spring, the bushes should be planted 12 feet apart midway between the rows of standard Apples and Pears, and they may also alternate with trees of the two latter in the rows. Any that are intended to grow unrestricted should have more space, a distance of 18 feet apart being none too much. The start is usually made with strong suckers, of which there is always abundance being formed. These are topped at a height of 2 feet, with a view to having bushes or trees with a clear stem, and a good foundation will be laid by shortening back the young shoots during the next two winters. The Kentish bushes are gradually built up, as before stated, very much as basin-shaped Red Currant bushes are formed. Bushes and trees in a bearing state should not be pruned till it is seen where the most blossoms are produced, the value of a good supply of male flowers or catkins not being overlooked. Stunted old trees that have ceased to produce good crops of nuts may well be cut or sawn off well back to the main limbs, and this will be followed by a plentiful growth of young shoots, which should be thinned out freely at the next winter pruning and then be allowed to branch naturally. Thus treated the trees soon become productive, the nuts being in great bunches. Some of the best varieties are Prolific Filbert, Kentish Cob, Webb's Prize Cob, Cosford and Duke of Edinburgh.

WALNUTS.—Large old trees of these are gradually becoming scarcer, and to all appearance planting has been discontinued for many years past. Instead of so many forest trees being grown in the vicinity of private residences and farmhouses, their places would have been more profitably occupied by Walnuts and, in the more favoured districts, Spanish Chestnuts. The fact of the trees being a quarter of a century before they produce heavy crops of nuts ought not to deter planting any more than it does in the case of Oak trees. Something ought to be done towards benefiting future generations, even if only out of gratitude for what our forefathers did. Standard Walnuts are suitable for lawn trees as well as for planting in paddocks and parks generally. Comparatively small trees of Dwarf Prolific will bear freely, while the best for growing into large valuable trees are Thin-shelled and Common.

SERVICE OR EDIBLE CHEQUER.—In Kent and Sussex large old trees of this native fruit are to be found growing wild, presenting both a distinct and

ornamental appearance. The fruit is freely produced in flat bunches and has to be kept and otherwise treated similarly to Medlars, being preferred to the latter by many who have an opportunity of tasting them. This member of the Pear tribe, again, is well adapted for planting in large pleasure grounds, in hedgerows and mixed groups of forest trees. W. IGGULDEN.

THE KITCHEN GARDEN.

POTATOES IN POTS.—It is too early to force Potatoes by the aid of hot-beds; consequently where young Potatoes are required early in the season, it is much better to grow them in pots. A sufficient number of sets of either Sharp's Victor or Mona's Pride—these being the best for forcing—should be started into growth. Place them in a shallow box upon a layer of flaky leaf-soil, with a little sprinkled between. These, if placed in a warm house, exposed to the light and kept fairly moist, will soon produce some strong sprouts, which must be reduced to one or at the most two to a set, when the tubers must be potted. Nine-inch or 10-inch pots are the best, these accommodating two sets. The pots must be efficiently drained. The soil, which should consist of about three parts turfy loam, adding to this some Mushroom bed manure and burned refuse must be kept fairly moist and the pots be well exposed to the light, or the growth of the tubers will become drawn.

SEAKALE CUTTINGS.—Seakale that has been raised from cuttings is the best for forcing. The best cuttings are formed from the thong-like roots which strike out from the base of the older root-stock. Therefore, as the roots for forcing are being taken up, take particular care that these are not broken. Those the size of a small finger form the best, these being cut into 5-inch or 6-inch lengths. On no account must these be placed where they can have the least warmth, or the buds will start. Either tie up in small bundles or lay them in rows in soil in a cold frame or light shed, just leaving the tips exposed. In this position the ends will callus over and buds be formed. These will start into growth directly they are planted in the spring. The Lily White should be increased as much as possible, this being a variety of good quality when cooked, and also more suitable for very early forcing than the older kind.

FORCING FRENCH BEANS.—For forcing French Beans during the winter months a very light and efficiently heated structure is necessary. Nor must too large pots be used, 7-inch or 8-inch being quite large enough. The best variety for forcing at this season is Osborn's Forcing, this being a free bearer and also of compact growth. The pots must be efficiently drained and the soil used in a fairly moist state, so that when the seed is sown no water will be needed until it germinates. The pots should be filled up at once, as leaving a space for earthing is a needless proceeding, and at this early date causes the stems to decay. The seeds must be covered about 1½ inches. The pots can be stood close together in any position where they may receive the benefit of a little extra warmth, so as to ensure more speedy germination; afterwards they may be placed well up to the light. A night temperature of 60° to 65° is sufficient, allowing a natural rise by day. Water will have to be carefully applied at all times, but more especially during the early stages. Any attempt at gorging the plants with liquid manure must be avoided. Not until the pots are well filled with roots and the plants in need of support must this be given, and then only occasionally and in a perfectly clear state.

IMPROVING SOILS.—This cannot be better attended to than during the present season, or at any favourable time throughout the winter. Where there is a large stretch of ground I have found it of great advantage to spread a layer of litter over the surface. The past season has, no doubt, shown the want of the improvement of the soil which is needed by the crops being in a state of collapse, and this owing to the want of a fair depth of favourable soil. Old garden refuse, burned or otherwise,

any kind of manure, road scrapings, and such like material should be freely worked into the soil. Poor soil should never be brought to the surface, but be improved where it is by forking in the materials above named. Do not work over the ground if at all wet and sticky, or try to improve it by merely trenching, that is, turning the top soil to the bottom and placing the bottom uppermost, unless this latter should be known to be fertile. In this case bastard-trenching is the best.

A. YOUNG.

PLANT HOUSES.

STOVES.—TEMPERATURES, VENTILATION, &C.—Thus far we cannot find much fault with the atmospheric conditions outside as they pertain to plant culture under glass. I never remember a more favourable November than that through which we have just passed. In this district there has been an almost entire absence of the proverbial fogs, two days at the most coming under this head. With a comparatively clear atmosphere and no great amount of rainfall, the air has been more of a bracing character. It has been possible thus far to maintain a congenial temperature in our stoves without either having to fire hard on the one hand, or to have to hold them very much in check on the other. In extremely mild weather there is always a danger of the atmospheric moisture under glass being excessive (the same as it is outside at such times) through the fires being somewhat low. This should be guarded against by ventilation in a small degree on the one hand, and by distributing less moisture about the house on the other. During mild and dull weather in the winter a small amount of ventilation is even more desirable towards this end than when the sun is shining brightly and a somewhat keen wind blowing. In the latter case almost, if not quite, sufficient air will penetrate through the laps of the glass to serve the purpose.

Plants that are the most susceptible to injury from damp will show signs which should be noted, and will be by an observant eye. Personally I am no advocate for either extreme in temperatures as it relates to stove plants in the winter. I know of one noted plant grower who maintained a temperature of nearly 70° at night through the winter, and that successfully, but all the same such a temperature is never desirable, nor would I recommend its adoption. The other extreme of a low night temperature has its evils, damp being one of these, whilst it often reduces the plants to too much of a dormant state. A medium course is, I think, infinitely better, and this I would fix at from 60° to 64° at the time of making up the fires, allowing of a drop of 5° by daybreak; the lowest point would be 55°, but only for an hour or two when the fires are under good management. I would rather see 55° any frosty cold morning than 60° if a keen wind be blowing, calculating on a rise of 5° or 7° as soon as possible. At the very most 10° during the day is a sufficient rise for the next two months, and this should only be in favourable weather. The fires ought not to be held back too much in the afternoon, so that they have to be pushed towards nightfall with a possible rise when there should be a steady decline. With good management some of the night stoking can be reduced, the labour thus saved being far better expended in starting the fires extra early so as to have them well under weigh at daybreak, when if it be frosty it is often the coldest.

A deal may be accomplished in the way of protection to houses where exposed to keen cutting winds either by mats or canvas coverings, or the blinds if these be still retained upon the roof. Being very much exposed to the east winds our blinds are kept up, so as to be able to run them down in case of need. The blinds may not last so long by one season, but there is a considerable gain in firing as well as in maintaining a better state of things inside. On the roofs of low houses or plant pits the canvas coverings now so much in use, and which are tanned to make them last longer, are, I consider, preferable to mats. These

were first made at my suggestion some few years back, and are serviceable in many ways as plant protectors. For the sides of lofty houses they are a great assistance in maintaining a steady temperature. On roofs they should be removed early in the day, so as to give all the light possible. It is possible to keep low pits with a fair amount of covering too warm; a watch should, therefore, be kept on the thermometer, so that this mistake does not occur.

The troughs for evaporating purposes upon the pipes should be kept filled. The amount of moisture given off by these will be in proportion to the heat in the pipes, but some additional moisture by means of the syringe and the watering pot will be needed in frosty weather. It is not advisable in any case to give up the syringing altogether, otherwise both thrips and red spider may have too comfortable a time of it, favourable opportunities for its use being chosen. Watering should now be done with greater caution in several instances. Dipladenias, for instance, will rarely require any now; Allamandas and other deciduous plants but little (none if planted out). Evergreen plants, on the other hand, should not be allowed to suffer. Of these, the Crotons and Palms require as much as any plants, and next to them the Dracenas, more particularly if they happen to be pot-bound decorative plants. To allow either a Palm or a Croton to suffer is against all good culture, more particularly the former. Alocasias will not require nearly so much, nor will the Anthuriums, the character of the soil in which these plants are grown being such as to hold the water in a similar manner to that of a sponge. Bromeliads will need scarcely any water now, the store in their leaves being almost if not quite enough for their requirements. Gardenias should not be kept dry, nor should Ixoras, both being evergreen, and rarely if ever quite at rest. In the case of healthy plants they should be well looked to, any excess being at the same time guarded against. Basket plants oftentimes take proportionately more water than pot plants; see to it, therefore, that these do not get too dry, but should they perchance do so they ought to be dipped for the water to properly penetrate the soil. Of plants now in their flowering season or approaching, E anthemum pulchellum takes as much water as any plant, but others also should be generously, if carefully treated. J. HUDSON.

CHRYSANTHEMUMS.

SEASONABLE CULTURAL NOTES.

No sooner are the flowers faded than a start has to be made to prepare the plants for next year's supply of bloom. To obtain success, I advise an early start being made in preparing for next season's stock. To grow Chrysanthemums really well a long season of growth is absolutely necessary, at least where the blooms are desired in the best possible condition, according to their individual merits. In no way can the characteristic of each variety be so well developed as under the method of culture commonly known as the large bloom system. No matter how well plants that are cultivated to produce quantities of flowers are appreciated, they fail to convey what are the individual characteristics of each variety either in size of bloom, breadth of petal, natural form, or even colour. Take, for instance, one variety—Vivian Morel, perhaps at the present time the greatest favourite of all. When cultivated in bush form to give flowers in profusion the colour is lilac, of a pale hue very often, but when the number of flowers is limited to a few the colour is deep mauve. By obtaining satisfactory cuttings, a good foundation is laid. Some varieties are notably shy in producing any cuttings; some

discretion then is necessary in such cases in cutting down the old flower-stems. In the case of shy producers of cuttings, do not cut the stem down lower than to within 2 feet of the soil. Although the most desirable cuttings are those that push through the soil some distance from the stem, stem cuttings are better than none at all. In some cases where these stubborn varieties fail to throw up cuttings direct from the base, they often give cuttings from the stems after the plant is cut down to the height named. The objection to stem cuttings is that they are liable to form flower-buds instead of growth after they are rooted. Princess of Wales and its progeny often give trouble in this respect, and so do Princess Teck and its sports, none of which the exhibitor can afford to dispense with. Varieties like Queen of England and its numerous allies give cuttings in abundance direct from the base without the slightest trace of premature budding. Such as these then should be cut down to within an inch or so of the soil. It very often happens that these free-growing kinds have far too many growths springing up from the base to afford a sufficiency of space for each to develop properly. Where such is the case it is much the best plan to thin out these weakly growths and give more room to others, so that when the time arrives for taking the cuttings they will be sturdy and strong instead of being weak and attenuated in growth. Directly the plants are cut down the old stools should have a position assigned them where they will be close to the glass in a cool house or frame, simply protected from frost and damp. No place answers better than a vinery or Peach house at rest. Here the Chrysanthemums obtain abundance of light and air, which induces a stocky growth.

Care is necessary in supplying the old stools with water; too much is injurious, creating a paleness in the young leaves, which is objectionable. When the leaves are rendered so pale in colour, a long period often elapses before they regain their wonted vigour and colour. It is surprising how little water is needed to induce growth to be made from the base after the plants are cut down. Where the roots are washed bare on the surface they should be covered with a portion of sandy compost, adding to it decayed leaf mould, this having a decided tendency to encourage growth from the base that is firm and in every way desirable. In stubborn cases where growth positively refuses to move at the base it is necessary sometimes to rectify the drainage if this has got out of order, and even to plunge the pots in a gentle bottom heat and syringe the stems several times daily before a start into growth will be perceptible. The slightest sign of green fly should be dealt with at once by fumigating the house with tobacco smoke or by dusting the plants individually with tobacco powder and syringing them afterwards to cleanse the leaves of both powder and fly. Air upon all favourable occasions will induce a stocky growth.

E. MOLYNEUX.

Hairy Chrysanthemums.—Several varieties of the hairy Chrysanthemum were exhibited in good form last week at Norwich. This section is increasing in numbers and seems very popular with the general public. A good bloom of Mrs. Alpheus Hardy was shown, but the constitution of this variety is bad and makes it scarcely worth the trouble of growing. In contrast to this is the white form of Louis Boehmer, which is a lovely thing and a good grower. I venture to predict that this variety will be largely grown when Mrs. A. Hardy is forgotten. Louis Boehmer is too dull

in colour to be attractive. W. A. Manda is of a clear soft yellow colour and should be a great addition to the class, but the flower shown at Norwich was not in good form. This may be only a temporary defect, as the constitution is said to be perfect. H. Ballantine is another variety of good constitution and habit, colour terra cotta, changing to pale yellow. Already there are a dozen or more varieties of this section, and rigid classification being now the fashion at shows, they will before long have to be exhibited in a class exclusively devoted to them. While speaking of the classification of Chrysanthemums, I should like to say that there appears to be no provision made in the majority of shows for a popular and useful class—the hybrid pompons. Two excellent stands of pompons were disqualified at Norwich, presumably because they contained flowers of this class. I am not sure that this was the reason, but could see no other fault in the flowers, and I could not help regretting that two such pretty lots had to be passed by unrewarded.—J. C. TALLACK.

Single Chrysanthemums.—We have such intense interest shown in every direction at this season of the year in relation to exhibition Chrysanthemums, and the bigger apparently the better are they liked, that it is no matter for surprise if single forms should have to take a back seat. The grower for exhibition looks upon them with very scant admiration; on the other hand, ladies who love flowers because of their intrinsic beauty, and not because they win prizes, prefer the light graceful singles, and, perhaps, like them all the better, too, that, being grown without disbudding and with comparative freedom, they can cut for themselves and utilise the flowers in the most attractive way for house decoration. The giant blooms that are so familiar at exhibitions, when cut leave in plants a tremendous gap. Still further, they are as a rule too big and heavy for vase or house decoration. They are always best on the plants, and it seems to be a great shame after so much time and labour has been expended on their production, even for conservatory decoration, to cut them and employ them for domestic uses. That objection in no case applies to the singles; they flower in wonderful abundance, they need little or no disbudding, they are very light and elegant for vases, &c., and they will in a cool room endure for fully a fortnight if cut whilst still at their best. It is very probable that single varieties would be much more largely grown if they were better known.—A. D.

Chrysanthemum Beauty of Exmouth.—This variety has not this season been seen in such fine form as shown last year, the cause undoubtedly being the abnormally hot weather which the plants experienced during growth, and which caused the wood to ripen too much. The best blooms are produced from plants struck in March and topped in May, and for the final potting not using less than 10-inch pots. The object is to reduce the number of florets or petals. The plants should be well fed after the buds are taken, and the blooms are greatly improved if assisted with a little heat when they commence expanding.—W. J. GODFREY.

NOTES ON NEW VARIETIES.

THESE appear to be very numerous this season; therefore some discrimination is necessary in selecting those having the most merit. In addition to those already named I can recommend the following:—

MME. M. RICOUD.—This belongs to the narrow-petalled Japanese section. The colour is rose-lilac, tipped white, which passes away with age. It is a fine solid bloom.

INTERNATIONAL.—This flat-petalled Japanese is of huge size; blooms, but badly developed, measure fully 8 inches in diameter. It is, however, not a flimsy built flower. In colour it is pleasing, lilac, purple striped, florets semi-drooping.

GOLDEN WEDDING is an American-raised Japanese variety; when well grown and fully developed it is a grand flower, possessing as it does

such a richness of colour. The florets are narrow at the base, widening towards the points, which incurve slightly. In growth it is desirable, being robust, yet not too tall. Cultivators for exhibition should make a note of this variety.

ROYAL WINDSOR promises to make an excellent variety for decoration. The fully developed florets are creamy white, those not so, pink in the centre, which passes away with age. It appears to be a free-flowering variety—a desirable point in a flower of this class.

ROSE WYNNE has florets of great width and substance, in colour deep blush or pink, prettily veined.
E. MOLYNEUX.

SPOILING THE CHRYSANTHEMUM.

AN interesting communication from "J. I. R." in THE GARDEN, November 25, p. 479, draws attention again to the Chrysanthemum at exhibitions. Some years ago the subject of big blooms was thoroughly dealt with in these columns and bore good fruit, as shows at the present day are not so thoroughly inartistic as they were of old. It is possible now to go to an exhibition and discover an exhibit not usually asked for in the schedule, but rather set up merely to show how beautiful the flower is when boldly bunched.

The finest exhibit at the recent Aquarium show was Mr. Jones' display of cut flowers in large vases, an exhibit that surprised those hitherto wedded to the single big bloom classes. At the Drill Hall, Westminster, one has seen very many beautiful exhibits of cut Chrysanthemums, and the Royal Horticultural Society has distinctly set a good example by encouraging the exhibition of cut blooms with foliage and tastefully arranged. At the first November meeting one class was for a collection to be shown with foliage, and a rare assortment of blooms was the result, singles, Japanese, incurved, and other sections all well arranged, pleasing to the eye, yet many were very large. The monster blooms are made more ugly by cramming them on to boards far too small for them. The petals of neighbouring flowers getting intermixed, all natural beauty and grace are entirely lost. The groups and trained specimens are as formal as ever, the two arrangements at the Royal Aquarium being very difficult to beat in this respect. There is no occasion for this. The groups at summer exhibitions are often beautiful, and the Chrysanthemum is a splendid flower for effect if Palms and Ferns were interspersed to break up the bank of bloom.

"J. I. R." laments the existence of "Chrysanthemums as big as soup plates"—and the majority of those not concerned in getting prizes are of the same opinion. The flowers, as he truly says, are "simply impossible in a nose-gay or for any decorative purpose"—at least, they are of no value whatever for bouquets, although in very bold decorations they could be used, but smaller flowers would be just as useful. I have taken six names at random from a list of new kinds as indicating the size to which Chrysanthemum flowers are brought to at the present day: Excelsior, Lord Brooke, G. C. Schwabe, Mlle. Thérèse Rey, Waban and Eda Prass—all blooms nearly a foot across, very charming possibly when the plants are permitted to grow somewhat naturally, but positively ugly in the condition one sees them at exhibitions. The most handsome of the six is Mlle. Thérèse Rey, but this is not so pleasing to me as the old Fair Maid of Guernsey or Elaine. It is not only that the flowers are of greater bulk, but they are coarse, the petals broad, stiff, and if turned up at the apex, without any grace. Where, as "J. I. R." truthfully remarks, are the flowers that the artists of

Japan depict on their countless varieties of vases and fans with such infinite skill and artistic effect? They are certainly not seen at present-day shows, and, unfortunately, many beautiful varieties are rejected by committees because not adhering to a certain standard of size. All sections of the Chrysanthemum are treated in the same style. The single varieties—the most charming of all when grown somewhat naturally—are as big as it is possible to make them; the reflexed, Anemone pompons and other types are all under the same ban of a depraved taste. It would not matter so much if exhibitions encouraged the comparatively natural growth of the plant and the production of fairly normal flowers, but this is not the case. The shows are one-sided and only for exhibitors.

Another very important point alluded to by "J. I. R." is the growing of hardy kinds. We want, he says, "a race of Japanese that shall flower all through October out of doors. Then we shall want a hardy break of singles for late October and November blooming in our borders. Singles would be less affected by the frost and damp of our miserable autumns." The state of affairs is not so bad as here depicted, as shown by the many recent notes in THE GARDEN. On p. 499 the names of several kinds are given, and all in beauty on a late November day. From what one sees the Chrysanthemum is being much improved as a garden flower, and one hopes that the same marked improvement will be continued in the future. This year the flowers in October were superb, the pure white La Vierge in particular, a Japanese kind, the little bushes being covered as if under a wreath of snow. Our autumns are not always "miserable," and a fine day in the fall of the year is as beautiful as May or June. It would be well if raisers of new varieties strove to get good single kinds for out-of-doors. The flowers are frail, and stand wet and unpleasant weather generally better than other types. A spray of blooms is full of grace, and one may cut many handfuls for the house without seriously damaging the effect of the plants in the garden.

"J. I. R.," I am surprised, does not write about the colour of the present-day Chrysanthemums. The colour of the blooms in many cases is positively hideous—M. R. Bahuant and others that might be mentioned. The dull, dingy, dead-looking purplish tones are as bad as the dirty bronze shades, or coarse florets, such as distinguish varieties like the much-vaunted Waban. Louis Boehmer, although one scarcely looks through a horticultural journal without finding words of praise for it, is of a most objectionable colour. We have had some noteworthy exceptions, William Seward, John Shrimpton, and others, and the yellow kinds are, as a rule, remarkably bright, but the Chrysanthemum is not improved by making it as big as a mop or poor in colour, even if the shades are novel. The craze for novelty is astounding. It leads the raiser on to forgetting about the beauty of the flower, and seeks rather to gain new kinds because they may sell.—C.

— I am afraid "J. I. R." will find many who will disagree with him in his estimate of the Chrysanthemum as it is to-day, even if the old thread-like Japanese sorts of former days are gone. The popularity of Chrysanthemum shows proves that there is an increasing interest taken in them, and the fact of this aroused interest is traceable to the introduction of new sorts which appear in goodly numbers every season. It must be admitted there are sorts that lack grace and refinement, such for instance as Etoile de Lyon, but it must be known that these coarse-petalled blooms, although still

exhibited, command no favour at the hands of good judges, and will drop out of cultivation at no distant date, as others have done before. It is true that the incurved section cannot command the same popularity as do the Japanese, because in these there are no such changes brought about by seed-raising as in the case of the Japanese; still it would be a misfortune if everyone held them in such slight favour as does "J. I. R." To present them in their best form taxes the resources of many, if not most good growers; without skill they cannot be brought to that high state of perfection known to all the leading exhibitors, and surely "J. I. R." would not be in favour of going away with a section that requires the highest talent to develop it perfectly. No one can dispute that the methods of staging are stiff and unnatural, but those that are shown with long stems and foliage require so much more room in conveyance that the class does not become popular among exhibitors.

I quite agree with "J. I. R." respecting the need for a change in the system of growing and training Chrysanthemums. The orthodox trained specimen has but little beauty, and, apart from its use in the exhibition hall, there is really no useful employment for it so stiffly trained. At a local show which I attended during the present season prizes were offered only for naturally grown plants, and those which gained the premier award were certainly an excellent exhibit. They were neither disbudded nor stiffly trained, but were really good and freely-bloomed conservatory plants. If such as these were more commonly grown for exhibition, we should not hear such bitter remarks as pertain to formal specimens often possessing as many stakes as flowers. Popular favour is not with stiffly-trained plants now, and the sooner they are discouraged by societies who offer prizes for them the better, if others naturally grown can be substituted. Standards and pyramids are to my mind the most offensive of the several systems of training, because so unnatural; these are fortunately becoming less shown every year.—W. S.

SINGLE CHRYSANTHEMUMS.

IT is to be hoped that some day single Chrysanthemums will become as popular as the other sections. I have repeatedly heard the remark passed this season by gardeners that they do not like single varieties. I was pleased to see the high praise bestowed on them by "C." and "J. C. B." in a late issue of THE GARDEN. For cutting, I hold the same opinion as "C." respecting the pretty white flowering kind Jane. I do not hold Yellow Jane to be a counterpart of the white, because it is not so single as the last named and does not show so much of the eye, because of the additional florets obscuring it to some extent. The colour is most distinct—indeed, I scarcely think there is another possessing the exact shade of yellow. It is equally free in growth and flower. Miss Mary Anderson has a much bolder character in its broad-petalled flowers, and is always conspicuous as a decorative plant or as a vase flower. It has scarcely the same freedom of growth as the two previously named sorts, but this is no great fault, because an effective display is made by the conspicuously large Daisy-like blossoms. David Windsor is another very desirable sort, bearing crimson-coloured and rather large flowers, relieved by a yellow disc. It grows taller than many of the singles, and can be cut in long lengths for decorating vases in conjunction with the lighter coloured sorts. Florence grows very dwarf; indeed, this is the dwarfiest one we have, producing larger flowers than any I have named. To see this at its best, it should be slightly thinned where the buds are thickly clustered, otherwise the flowers being large it loses much of its character as a single. The colour is a very pale pink or blush, and when slightly disbudded it is a striking flower. Societies would have a popular exhibit, particularly with their lady patrons, if they instituted a class for singles either as cut flowers, shown in bunches similar to pompons, as decorative plants, or groups. A stipula-

tion might be made in the schedules where groups form a leading feature to the effect that some single varieties be required. Being dwarf in habit, free flowering, and withal of light and graceful appearance, the finish and general effect would be heightened by the introduction of a few varieties of these single Chrysanthemums.

At west of England shows they are seldom seen. I do not know of one that provides a single class for them in any form, and so long as gardeners hold them in such slight favour it will, I am afraid, be some time ere they will be represented as they deserve at our autumn shows generally. What is needed is that the leading societies possessing the means for providing a comprehensive schedule should take them in hand, even if it was done at the expense of some of the other sections, for the public, I am sure, would find an appreciable change if singles were given due prominence. —W. STRUGNELL.

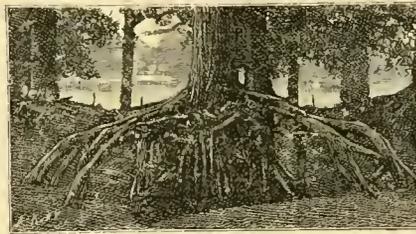

— We are pleased to see that raisers are taking an interest in these beautiful flowers. The best of all is Jane, sometimes called Snowflake, when it is not so disbudded that the flowers are of abnormal size. In one exhibit at the Drill Hall recently the flowers were quite three times their usual size and utterly spoilt, more like a show kind become single, much of the charming "frill," so to say, of the florets being lost. Why spoil the lovely single Chrysanthemums by trying to get them as big as possible? There are surely sufficient big Chrysanthemums to please the most fastidious. The flowers may be used in decorations with the most graceful effect, and arranged with Fern fronds or the feathery *Asparagus plumosus* gain in beauty. They may be had in perfection over a long season, blooming now and far into December and January. When the cuttings are struck late, such Chrysanthemums as these do not suffer from damp, as the larger Japanese and incurved, which in some years get much decayed. We should like to see in other colours a few more kinds of the character of Snowflake. The yellow counterpart is very beautiful, the colour very rich and clear, and a delicate rose, crimson, or other shades, if not of the objectionable brick-red so common now, would be worth striving for. The stiffer single forms are not pretty, but one sees quite a surfeit of these. A few are admissible, but not such a number as one notes at exhibitions. A few of the best varieties noticed recently are the two already mentioned and the following: Admiral Sir T. Symonds, raised by Mr. Cannell, is a fine yellow, the petals broader than in Yellow Jane, and the aspect of the flower is coarse when too large. Windsor is, perhaps, the best of that class, with chestnut-red flowers—not a colour we care about, but distinct and useful for a change. Gas Harris is one of the older single varieties, the flowers of a rose-lilac shade, yellow in the centre, and the plant is dwarf, bushy, and makes a good specimen. Lady Churchill is distinct, the colour of a terra-cotta shade, touched with yellow. Mary Anderson is the finest in form of all the single kinds; its flowers are smooth, the petals broad and white touched with rose. It has been much used as a parent in crossing, its face shape justifying such a use. Miss Ellen Terry has larger florets than the majority. They are of a cheerful magenta shade, the disc yellow. Miss Rose is delightful. It makes as good a plant as any of the single kinds, bushy, compact, and smothered with neat rosy flowers. This is indispensable. Mozart, rose-brown shade, touched with yellow; Scarlet Gem, with flowers of a rather dead red colour, but neat in form; and Souvenir de Londres, crimson, complete the list of the finest of the single Chrysanthemums.

Chrysanthemums at Gunnersbury Park.

—A very large collection is grown by Mr. Reynolds at Gunnersbury Park, and the large vineries are in great part filled with excellent plants. We made note when there recently of a few good kinds. One of the finest was Mrs. Alice Bird, a Japanese variety not often seen. The flowers are intense golden yellow, a most delightful colour. Gorgeous is another good yellow, grown here well, also the pretty

pompon Flora, which is rather early flowering, very compact, and exceptionally free. Where much decoration has to be done, it would not be easy to find a better kind than this. We noticed remarkably fine the large-flowered Anemone Delaware, a well shaped and bold flower, the centre yellow, and the guard florets of a creamy white colour. Another very good variety is Eynsford Gem, a small pleasing flower of a rich crimson-purple colour.

Chrysanthemum groups.—I quite agree with all that "A. D." (p. 478) says on the above subject. At many shows there is such a great amount of sameness that one scarcely troubles to look at them. At the same time I was glad to see a change for the better at two exhibitions lately, viz., Hereford and Leominster. At the former place the number of plants was limited to eighty, not more than one plant in each pot, and edging allowed. In both the first and second prize groups there was room for improvement, as the arrangements were a little too heavy. The first or cup-winning group had the colours well blended, and most of the flowers were Japanese. In front and round the sides the Chrysanthemums were faced with small Palms, and then with Roman Hyacinths and Adiantums, making a beautiful finish. The second prize group, which had well bloomed plants of *Eucharis amazonica*, with small Palms and Ferns as an edging, was very attractive. However, both groups would have looked better with fewer Chrysanthemum plants. At Leominster the most beautiful groups I have yet seen at any of the autumn shows were put up, and the competition was very keen.

A curious Fir tree. Engraved for THE GARDEN from a photograph sent by Mr. J. C. Tallack, Livermere Park, Bury St. Edmunds.

Only twelve Chrysanthemum plants were allowed to be intermixed with fine-foliaged plants in a space of about 50 square feet, so far as I could judge. It would take up too much space to enumerate either the Chrysanthemums or fine-foliaged plants employed, but they were light, beautiful, and so attractive to the ladies, that it was almost impossible to get near enough to examine them. I am sure the framers of schedules might with advantage to their societies give fair prizes for similar groups; not only would the show be rendered more beautiful, but the competition would be far more spirited. To prove this, it is only necessary to consider that it frequently requires two dray or van-loads of Chrysanthemums to make a so-called good group, for which if limited as above, and fine-foliaged plants allowed, one van-load would be ample, and the effect produced of a much higher order.—W.

Chrysanthemums in Guernsey.—The communication by Mr. Thomas H. le Lievre, of St. Martin's, Guernsey, on p. 480, is of more public importance than appears on the face of it. In common with many of my Chrysanthemum-growing friends I had begun to think that the raising of new seedlings was an extinct art in Guernsey, and that there was nothing to hope for in the future from the little island where so many of our once famous Japanese varieties were raised. Visions of Fair Maid of Guernsey, Ethel, Elaine, Peter the Great, Sarnia, all belonging to that class without saying anything about the host of incurved and Anemone sorts which also emanated from Guernsey raisers, are aroused in my mind by Mr. le Lievre's short note and cause me to wonder why such capable cultivators as Major Carey, Mr. Charles

Smith, Mr. James Downton, and Mr. Thomas Pethers have ceased to labour in the good cause. The correction will be gratefully accepted, and if Mr. Kelly has raised any other new Chrysanthemums besides the two very fine varieties alluded to it will be not only interesting, but rendering the public a service for Mr. le Lievre to give us a list of their names. In these days we receive so many new Chrysanthemums from sources so far apart, that the origin of some is most difficult to ascertain, and whenever it is practicable such information ought in my opinion to be recorded in the public press. If Colonel Chase and Violetta are fair samples of Mr. Kelly's seedlings he may certainly hope to compete very favourably with the new raisers who are now annually coming to the front.—C. H. P.

TREES AND SHRUBS.

A CURIOUS SCOTCH FIR.

THE accompanying illustration shows part of the trunk and roots of a Scotch Fir which grows in a grove on the Culford estate close to the high road, and near the church at West Stow, Suffolk, where it interests many passers-by. Altogether there are about 200 trees, mostly Scotch Fir, in the grove, and more than a dozen of them have been more or less undermined, as shown in the illustration. Although this undermining was done more than thirty years ago, and all the main roots have been exposed for that time, the trees are in the best of health and vigour. Evidently they were planted and not self-sown, as none of them have tap roots. In addition, however, to the spreading roots, each tree has several vertical roots, which number in one case as many as fifty, and vary in diameter from 8 inches to 2 inches. Most of these are perfectly upright, and some are knotted at regular intervals and look exactly as if trimmed pieces of the trunk had been put in to prop up the trees, but on examination they are found to be living roots. In many instances, too, these roots are not quite upright and have touched each other, with the result that natural root-grafting has taken place. Some of the trees have had their spreading roots cut off at about 4 feet from the trunk, and depend entirely on the vertical ones for support.

The topmost roots of the tree most prominent in the engraving stand just over 5 feet from the present ground level, and they cover a space of more than 18 feet in diameter before entering the soil. The height of the tree is about 50 feet, and the diameter of the trunk at 1 foot above the collar is 2 feet 3 inches. This tree is in the best position for photographing, and shows more spread of roots than either of the others, but there is another much taller and finer specimen, the trunk of which is over 3 feet in diameter; the spreading roots of this have, however, been much mutilated. Another tree has its roots packed so tightly together as to form a complete roof, impervious to rain, to the cave formed by excavation, which is big enough to form a perfect shelter for at least a dozen persons. In the roots of yet another an Elder has found a home and grown into a big bush. The excavations are jointly the work of rabbits and of sand sellers, who came to this grove for sand some forty years ago.

J. C. TALLACK.

Livermere Park, Bury St. Edmunds.

Clerodendron trichotomum.—This is quite hardy, except in very exposed places, and by the addition of this variety to a collection there is a

great gain, as we have so few shrubs which flower late in the summer months. The flowers appear in September and are produced in large terminal cymes, white, with a reddish calyx and delightfully fragrant. Being very reasonable in price, it is one of those plants which should find a home in most shrubberies. It thrives well in most soils provided there is free drainage. Being a deciduous shrub, it would, I think, be suitable for town planting.—G. WYTHES.

Daphniphyllum glaucescens.—This shrub, a native of Japan, is remarkable for its fine habit and rapid growth. We have examples that have been planted only a few years quite 8 feet high, so that I am inclined to think it will attain a greater height than was stated when introduced. It is a grand object for the kept grounds, having large leaves from 6 inches to 8 inches long and nearly 3 inches wide, of a delicate pale green colour on the upper surface, the under portion being of a bluish grey. The footstalks of the leaves are of a bright crimson colour, this forming a charming contrast to the bluish grey shade of the foliage. It is quite hardy, but there is one slight drawback in that it starts early into growth, and if planted in a very cold position the tender foliage is at times injured by cutting winds or late frosts. A little shelter is therefore advisable. There are other varieties, such as *D. viride*, with darker foliage and dwarfer habit, but in this variety there are no crimson markings. *D. jezoense* is another form, but not equal to *D. glaucescens*.—S. H. B.

Veronica Jardin Fleuri.—The Veronica alluded to on page 462 is, I should say, the variety which was sent out by M. Délaux, of Toulouse, I think, in 1885. It was one of a set distributed by that raiser, and when new was to be found in a few lists, but at the present time I only know of one nurseryman who includes it in his catalogue. It is certainly a very good dark-flowered variety, and one that blooms very freely in even a small state. These shrubby Veronicas are often seen in pots, and very useful they are in this way, but for beauty they cannot be compared with the bushes that may be met with in the more favoured districts of England, where they are quite hardy. Along the southern and western coasts fine examples may be met with, and they do well in close proximity to the sea.—T.

WATERSIDE TREES.

VERY little care is usually exercised in the choice of trees for planting by the water margin, let that be a lake, a pond, or the running brook, the common Alder, the Willow, or the Poplar being deemed sufficient for such places. This is, however, a great error. Take as examples the several distinctly cut or, as they are usually styled, Fern-leaved forms of the common Alder, the many beautiful barked Willows that we have at our disposal, or the uncommon varieties of swamp-loving Poplars, and it will be seen that there is no lack of ornamental waterside trees, and that the too common repetition of the ordinary Alder and Willow is by no means a necessity. Some of the more ornamental Willows have a most pleasing appearance when planted in suitable places by the water-side, and for this purpose perhaps none can compare with the golden Osier (*Salix alba vitellina*), the young twigs of which are bright yellow. Massed in fives or so, the effect produced by this Willow is very distinct and pleasing, and as it does well in dampish ground, it is well suited for the situations at present under notice. The common purple Osier (*S. purpurea*) contrasts markedly with the former, the bark being reddish or purple.

Of the Alders, one of the handsomest forms is that known as the Imperial Alder (*Alnus glutinosa imperialis*), in which the foliage is so beautifully cut as to resemble more that of a Fern than a forest tree. It is a capital subject for planting by the lake or pond-side, but looks best when viewed at some short distance away, and for this reason should not encroach on paths or roads. The varieties *A. glutinosa asplenifolia*, *A. glutinosa laciniata* and *A. glutinosa quercifolia* are all

worthy of notice on account of the beautifully divided leaves, and, succeeding well in damp places, may be used with the best results where the roots are constantly in a moist state.

The deciduous Cypress (*Taxodium distichum*) has few equals for planting by the river, pond, or lake-side; indeed, it would appear to flourish well where the roots are constantly in a partially submerged condition. Planted on an island, it looks well, the bright pea-green foliage, which changes to the brightest hues in autumn, being always remarkable and distinct.

Some of the Poplars are fitting subjects for the positions at present under consideration, but more particularly the varieties with cut or divided leaves, all of which delight to grow in damp ground. These are a few of the trees that might be used with good effect in beautifying the grounds by the water-side, but there are many more that might be included in an exhaustive article on the subject. A. W. D.

Tree labels.—Some years ago a suggestion was made, I believe in THE GARDEN, that in labeling trees the most important item next to the name was the date of planting. This, I think, most tree lovers will agree with, yet it is very seldom carried out, and a good deal of guessing has to be resorted to in order to arrive at the approximate age of the specimen. The date of planting would not occupy much space on a label, and it would be decidedly more instructive than the date of its introduction into this country, which one may often see on labels attached to trees and shrubs.—T.

Straffan, Co. Kildare, in winter.—It is now and then advisable to see a good garden in winter, the effects of many shrubs and trees and hardy plants being then seen in aspects totally different to those they assume during the warmer months of the year. At Straffan, for example, on a drizzling wet day in November, a really fine effect of colour was given by the breadths of common crimson Dogwood and groups of cardinal and golden Willows beside the river Liffey that flows through the place. In one or two places the Osiers have been thoughtfully blended with the Dogwood, and the result is a flush of richer and warmer colouring, which is very beautiful—so soft and mist-like on a dull day, that if painted on canvas one might be led to think that the painter had flattered the scene. One very pretty bit of colour and form is obtained by grouping the Dogwood and Osiers around a graceful Weeping Birch, the silver trunk of which emphasises the mass of colour below; while in another place a bold group of cardinal Willow forms a warm mist of soft flame colour against the trunks of a group of forest trees further away. Even on a November day such effects are charming as seen through the white mist that hangs over the turbid river, but in bright sunshine they are, of course, something more exquisite still. Beautiful as is Straffan already with its fresh lawns and stately Limes and Elms, improvements are being made, the river bank having been carefully cleared and thinned opposite the island in front of the house, and this is to be planted with bold groups of the best evergreen and deciduous trees and shrubs right down to the water's edge. A swampy piece of the island has also been planted with Ferns, Grasses, the larger-leaved bog plants and groups of *Typha latifolia*, amongst which the giant *Gunnera manicata* is to have a suitable position. Straffan is always attractive, but the Dogwood and Osiers have now become so effective, that it ranks high and deserves mention for its exquisite effects in winter also.—F. W. B.

Pyrus malus floribunda.—This was bearing a fine crop of its small yellowish fruits in the Epsom nursery, and we hope that the Crabs will be more planted in gardens. In every garden, large or small, this fine Japanese Crab should be planted, not for its effect in autumn, as there are showier kinds at that season, but for a profuse display of flowers in spring. A tree of this species in full bloom is a delightful picture, the slender branches wreathed with flowers in early May, the

buds deep crimson, but as they expand one sees the pure white of the inner face of the petals, the result being a charming contrast of colour. The tree is graceful in habit and of dwarf stature, forming a wide-spreading head. On this account it is valuable for small gardens, in which there is usually too great sameness in the things planted. It is cheap, very hardy, and grows quickly. A shrubbery is not the position to plant it, as here its graceful contour is spoilt. It is seen to advantage when the tree is on the outskirts of the lawn, where the characteristic habit is well displayed.

The Honey Locust (*Gleditsia triacanthos*)—During the winter, when devoid of foliage, the formidable spines with which the branches are studded cause this to stand out very conspicuously, for among all our hardy trees there is nothing whatever like it in this respect, as the branched spines, many of which are as much as 3 inches in length, are borne not only on the young wood, but also on the main trunk and principal branches of the tree. As a young specimen it is very noticeable, for, apart from the spines, the pinnate foliage, which is of a light shining green, is very beautiful, but as it increases in size these foliage distinctions are not so conspicuous. As a tree it bears a certain amount of resemblance to the common False Acacia (*Robinia Pseudacacia*), but it is, as a rule, more open in character. The Honey Locust is one of the latest of our trees to unfold its leaves in the spring, and in the autumn they usually turn yellow and quickly drop. The wood of the *Gleditschia* is said to be very hard and useful for many purposes, but in this country its only merits are as an ornamental specimen, for which purpose its distinctive features entitle it to more notice than it usually gets. An additional merit, too, is the fact that it will thrive better than many subjects in the immediate neighbourhood of smoky towns. It is a native of North America, and one of the many trees introduced from that region quite early in the last century. There are several varieties, but two of them are especially distinct, viz., a weeping form (*pendula*) and one (*inermis*) in which the large and formidable spines are wanting.—T.

OUR TIMBER SUPPLIES FROM ABROAD.*

THIS subject is of the greatest interest and importance, not only to those immediately associated with the production and consumption of timber, but to every member of the community. There is very great difficulty in arriving at the exact value of the wood imported into this country, but, on a fairly accurate calculation, it may be set down at £20,000,000 annually. The returns periodically issued by the Board of Trade afford an idea of the number of loads, and the figures given in this paper show the vast and far-reaching influence which timber has upon our national industries. There is no doubt that trade in timber is largely influenced by the condition of other trades; but, at the same time, it has to be borne in mind that our timber supplies have a very important influence on other trades. It is often supposed that for many purposes wood cannot be superseded by any other material, but this is entirely erroneous. It is in a large degree dependent upon the facilities by which timber can be supplied whether or not the same proportion shall be consumed. In many branches of industry timber finds a keen competitor in iron, in some instances in brick, and occasionally in stone. In these cases the ultimate consideration with the consumer is the question of cost. That the use of timber has enormously increased is clearly seen by the figures that follow; and this expansion is largely due to the ingenuity of those associated with timber production, in introducing such inventions and facilities as enable it to successfully compete in price with other materials. The credit of producing this result is to be shared alike by the forester, the timber mer-

* By A. T. Williamson, Kew Terrace, Edinburgh, in the "Transactions of Royal Scottish Agricultural Society."

chant, and the timber manufacturer. The timber merchant, it may be said, is merely the distributor, and has little influence in guiding either the production or consumption. This may be true as regards the merchant in other commodities, but, as will be seen in the following remarks, the merchant in timber has had a very great influence in the development of the trade.

In the year 1890 the total imports from foreign countries and the colonies amounted to 7,056,688 loads. This was made up of 2,278,374 loads of hewn or rough log timber, and 4,778,314 loads of sawn and manufactured wood. These figures show the large proportion that is brought in a prepared and partially prepared condition, being fully double the quantity imported in its raw state. This is a condition to be regretted on many grounds. The amount of money represented in the manufacturing cannot be less than £3,000,000, a sum which one would think might easily be conserved to our own workmen. The cost of freight for waste and superfluous wood is saved when it is in a manufactured state, but the superiority of our workmen and the greater excellence of their workmanship should do more than compensate for this item. This has been proved by years of practical experience in the large quantities of manufactured flooring and lining that are sent to the Australian markets, not from Sweden, but from Scotland, the timber being first imported from Sweden into Scotland, prepared here, and then exported again to Australia.

It may be interesting to look at the enormous development of the import of manufactured timber in the past thirty years. Although statistics of any value are difficult to procure, I have been able to get a fairly approximate table for London, which represents something like one-fifth of the whole country, and which may therefore give a fair idea of the whole. The increase in the total imports has been practically steady and continuous, but, looking at the raw timber by itself, it has remained stationary, or has had a backward tendency. For 1860, the number of loads of hewn timber was 233,000; for 1890, the number of loads of similar timber was 219,700. The quantity of sawn or manufactured timber bears a very marked contrast with this. In 1860, manufactured timber was imported to the extent of 7,125,000 pieces, while in 1890 they had grown to no less than 33,198,000 pieces. This advance has been a gradual one throughout the thirty years, each year as nearly as possible adding 10 per cent. to its predecessor.

We have given the total imports for 1890, viz., 7,056,688 loads. Deducting from this 507,058 loads of furniture woods from various countries, 6,549,630 loads remain of the more common supplies. These imports, chiefly drawn from Scandinavia, Russia, Germany, and British North America, are made up as follows:—

Scandinavia	2,643,666 loads
Russia	1,519,174 "
Germany	287,482 "
British North America	1,366,671 "
All other countries.	733,637 "

It is thus seen that Norway and Sweden furnish us with about 40 per cent. of our timber supplies, and the 2,643,666 loads sent to us are made up of 673,305 loads of rough and 1,970,361 loads of manufactured timber.

The question may naturally be put, Why is Scandinavian timber so much favoured by us? It must be better or cheaper, but that is only true to a limited extent. The great development of Swedish imports is a matter of only recent years. It is impossible to make an accurate comparison of the qualities of imported timber, treating it nationally, because the shipments of some ports are superior to the shipments of other ports in the same country; but, on the whole, the balance of quality in respect of both the Scots Fir and the Spruce, which form 90 per cent. of the imports, is considerably in favour of Russia. The freight from Russian ports is also generally from 10 per cent. to 15 per cent. lower than from the upper ports of Sweden, whence the larger bulk is shipped.

The Swedes, however, have displayed characteristic enterprise in adapting their conditions to meet the situation. They have greatly improved their machinery, more carefully selected their timber, and lowered their prices so as to secure British orders, and have thus equalised matters with their Russian competitors. Not content, however, with having placed themselves on an equal footing with Russia, they have turned the scale in their favour in the eyes of the British buyer by granting six months' credit on all transactions, the Russians being unable or unwilling to give more than three months. It is in this way that the merchant has had so much influence on the development of the trade, to which I made allusion in the early part of this paper. These specially favourable terms induced an accumulation of stock in our merchants' hands, and allowed them to place before the consumer, in the most favourable light, the merits of Swedish supplies, and generally influence their use.

The question arising here is, of course, Can Sweden maintain the annual output of such enormous quantities of timber? The answer is generally admitted to be, on the whole, in the affirmative. Great Britain and Ireland receive one-half of the total quantity of wood shipped; and, when the vast area is considered, it must be admitted that even the figures given are only capable of clearing out the woods of a comparatively limited area; and Scots Fir and Spruce being fast-growing trees, the re-afforestation is proceeding as quickly as the deforestation.

The Russian supplies come second in their amount. These are represented by shipments chiefly from Riga, Cronstadt, and Archangel. The Riga shipments are principally composed of Spruce deals and batteus, whilst the Cronstadt and Archangel are largely composed of Scots Fir or Redwood. Swedish timber has never been able to compete with Russian in respect of quality, and for all high-class joiner work architects demand that Archangel or St. Petersburg Redwood be used. The extent of the Russian forests is not known; and with regard to the prospects of their supplies being maintained, there is at present no question, nor will be for generations to come, in the ordinary course of events. A notable change has taken place during the past few years in connection with Russian Oak, which forms a rather important item in the exports. Formerly Riga, on the Baltic, was the chief port of shipment, the Oak being brought from the forests some hundreds of miles to the southward; but now the largest proportion of the Oak grown within the same regions as formerly is conveyed southwards, and is shipped at Fiume, in Austria. The Oak shipped at that port has acquired a high reputation for cabinet and furniture work. The German imports are comparatively small, and are largely made up of pit-wood and rough timber. Germany can scarcely be considered a great timber exporting country, being largely indebted to Sweden for her own supplies. France sends us, particularly to the British Channel, immense quantities of pit-wood, but her home supplies of heavy timber are quite inadequate to meet her wants. France imports, from Sweden and other countries, several millions of loads to meet home wants.

The supplies of timber from British North America, chiefly from Canada, amounting to 1,366,571 loads, although only half of the Swedish, represent quite as much money value. The chief item is the American Pine timber, a substitute for which has not been found in European countries. The maintenance of supplies from this source must be adversely contrasted with Sweden. Writers on forestry have deplored the waste in the American forests, and it is generally admitted that it is prodigious. At the same time, the vastness of the forest areas has maintained the equilibrium of the trade. While most kinds of timber have been, through competition, kept to the lowest value, Pine timber from Canada has not only maintained its price, but has actually experienced a steady rise. Consumption, or extra demand, has not caused this, but it arises from the fact of the demolition of the forests within reasonable distance of the seaboard. There is a growing ten-

dency to import manufactured Canadian Pine, and the figures of same, compared with hewn, may be quoted, the 1,366,571 loads being made up of 180,966 loads of hewn, and 1,185,605 loads of sawn and manufactured timber. There is less to be said against the growth of Canadian manufactured imports than that of Sweden, as the freight saved on deals and battens over logs is very considerable, the rate from Sweden being only about 8s. per load, while from America it is about 21s.

The vast forests of immense trees in British Columbia have recently been drawn upon for introduction into this country as a substitute for yellow Pine, but so far the experiment has proved unsatisfactory. The timber can be got larger and cleaner, but it lacks that mild nature which is characteristic of the Canadian Pine. It is found difficult to sustain a polish, and is too strong in the reed for fine household or ship work. The supplies in British Columbia are practically unlimited, and for rough work, in beams, &c., might be valuable, but the distance from our shores quite handicaps it in competition with other woods used for similar purposes.

Pitch Pine timber has taken a most important place in our industries. The supplies available are immense, and there is every probability that they will be maintained. The cheapness of this wood has popularised its use, notwithstanding the fact that the cost of freight is about 35s. per load. It is sold here at something like 50s. per load, which, with insurance and other charges, cannot leave more than 10s. per load at port of shipment. It is cut down, sawn, and transported a long distance for this sum, which gives us some indication of what could be done were our foresters at home to exercise their ingenuity on the question of transport from the woods.

Kauri timber from New Zealand now receives much favour. It is, however, classed as a fancy wood, and is only utilised for cabinet purposes, so it can scarcely be included in an article on common timber. New Zealand is too far away to draw upon for ordinary carpenter's timber, which really forms 80 per cent. of our imports.

A class of wood that is becoming popular is "Whitewood," called also "Canary wood" or "Butternut." It is taking the place of the long familiar yellow Pine, and the price being somewhat less, it is being generally used. The beautiful clean grain, free from knots and shakes, and the great width it is capable of producing, have acquired it a favour in most industries. It is imported from both Canada and the United States. The supply of it is said to be more limited than that of the yellow Pine, but statistics of the forests and their timber are not available for any practical purposes.

The total imports to Scotland in 1891 amounted to 878,924 loads. One-fourth of this was American timber, consisting of yellow Pine, pitch Pine, hardwoods, and Spruce; two thirds Baltic and north of Europe, Scots Fir, and Spruce; and the remainder made up of sundries—teak, kauri, and other special woods.

Before concluding, it may be interesting to take notice of an experiment being made at the present time by the Swedish shippers. Considering their British business practically established, the shippers conferred together and agreed to bind themselves to place their credit on nearly the same footing as their Russian neighbours. The effect of this action has not yet become fully apparent, but although these terms have only been in operation a few months, the decline of Swedish sales has been so marked, that considerations for the abolition of this rule are already exercising them. We have referred to this part of the subject with the view of showing how much more influence than the actual merits or demerits in price a hidden cause may exert on the development of a given industry. The question is a common one, Why will foreigners, removed from our shores by hundreds and frequently by thousands of miles, entrust our merchants with six months' credit, while our own foresters, agents, and landlords will not trust them a day, although the timber is retained in their own hands? Forestry in this country has little interest

for the mercantile community, but the foreigner gives us a substantial interest in the subject, and we in return reciprocate the benefit by obtaining our supplies of timber from abroad.

The Brush Bush for colour.—*Eucryphia pinnatifolia* is worth a note for the colour of its leaves in autumn—orange and scarlet, a pleasing contrast. It is hardy, except in the more northern districts of England, although a native of the southern part of Chili. When in full bloom it is of great beauty, the flowers large, white, set off with a central bunch of yellow stamens. They are produced in profusion, and are in charming contrast to the ample foliage.

***Viburnum plicatum*.**—This beautiful *Viburnum* is of note for the deep crimson purplish colour of its leaves in autumn, and is a thoroughly good-all-round garden shrub. We have seen splendid masses of it, but it is not grown so much as one might expect. In large places a bed of it on the outskirts of the lawn is very fine, the habit comparatively dwarf, spreading, and somewhat stiff, very different to the graceful Guelder Rose. The leaves are deep green, crinkled on the surface, and in fine contrast to the wealth of ivory-white flower-heads which wreath the shoots, creating a splendid picture in summer. It is a trifle tender, and should be planted in a warm spot sheltered from cold winds, and in a deep, moderately light soil.

ROSE GARDEN.

ROSES IN FLORAL ARRANGEMENTS.

ROSES are ever popular; no flower more so will be generally admitted, I think. When it comes, however, to a question of arrangement after they are cut a good many are at a loss. I have noted this more particularly in horticultural exhibitions where prizes have been awarded for bouquets, baskets, and other arrangements consisting of Roses only. The mistake so often made is that of formality, whilst overcrowding is almost as often seen. Too many colours enter into some arrangements, and in others it would appear as if the buds in various stages of development must be rigorously excluded. Large over-blown flowers are never desirable, but blooms with good long stems to them are requisite. Nothing associates so well with Roses as their own foliage, and as this can generally be had in quantity, there is no excuse for its absence. Take, for instance, the beautiful deep coppery colour of the shoots of *Perle des Jardins*; how well these harmonise with the pale and delicately coloured *Teas*. Long slender and trailing shoots can also be had for other purposes, whilst in large arrangements (as in vases of shallow design) the foliage of *Rosa rugosa* should be noted. In fact one has only to walk around a Rose garden to be able to see suitable foliage to use with the flowers. This does not, of course, exclude the use of Maiden-hair Fern or any other suitable kind; well-hardened pale green fronds of *Adiantum cuneatum* are always welcome. I have frequently used the bronzy foliage of *Mahonia aquifolia*; it stands so well, and will last out two or three cuttings of Roses, whilst in form it is very similar.

The illustration gives an admirable example of the informal arrangement of Roses with their own shoots and foliage. It shows what may be done with a judicious selection of material. When arranged in an artistic manner there is nothing in my opinion that will compare with Roses, particularly the Tea scented and *Noisette* varieties with soft shades of colour. It matters

not whether it be an epergne, vase, basket, bouquet, spray, or button-hole arrangement; in either case these Roses seem to appropriately lend themselves to the purpose. The season of these kinds, too, is a much more prolonged one than in the case of the Hybrid Perpetuals. At the present time I notice that a quantity of the imported flowers of the Dijon type from the south of France are being offered for sale by the flower girls in the streets of London. In their methods of offering them for sale they have made a new departure (at any rate I have not observed it before). It is to offer them just as they are, with their own foliage and buds, holding a small bunch loosely in the hand, thus forming a most suggestive arrangement in a *négligé* fashion. This is much

the beginning of this article to the fact of Roses being allowed to attain to too large a size before they were cut. This error obtains more in private establishments than in nurseries, probably from want of thought, but more likely from a disinclination to cut what promises to be a good bloom. "Circumstances alter cases," as the saying goes, but it does not alter the fact that a semi-expanded bloom is far better for cut-flower arrangements than a larger one. The florists use the buds to a good account, but they also disfigure the same by reflexing the petals artificially when it suits their purpose to do so.

GARDEN ROSE.

Roses for their fruit.—Many kinds of *Roses* are of note for their fruit, and this year, as with

Tea Roses loosely arranged in a vase.

better than bunching two or three together for coat flowers, or a greater number for sprays. By the way, as it pertains to sprays, I note also an improvement in several instances, but it is the *Roses* again that are in the foreground. It is to tie a few together in a haphazard or careless fashion, keeping the tying material confined to within about an inch or so of the flowers, leaving 3 inches or more of the extremities of the stems untied. In this way I have observed them several times, the tying material appearing to be quite small india-rubber tubing about the size of the stems and coloured green. The prevailing fashion of making what are termed "shower" bouquets cannot be made with more suitable material than *Roses*, particularly with the light-coloured and miniature varieties. Allusion was made at

many other shrubs, they are unusually beautiful. One notices the wild *Roses* of the hedgerows producing a splendid crop of hips. *R. rugosa* is well worth planting for its fruit alone; large bushes of this kind are very striking. *R. lucida* is charming on the rockery. We remember a fine plant on the Broxbourne rockery, its leafage of a fine glossy deep colour, and the berries of a crimson tone. It is one of the finest for its polished leaves and showy fruit. There is a variety named *Duplex*, the flowers double, cupped in form, and of a bluish colour. *R. villosa* is very showy with its red fruits, and two other good kinds are *R. spinosissima* and *R. cinnamomea*. *R. rubrifolia* may be added. The bunches of fruit are rich crimson and the leafage handsome.

A grand yellow climber.—Herewith I send you blooms of climbing *Perle des Jardins*, and as they are from plants barely twelve months old, and

each plant is carrying an average of fifty blooms in various stages, I think it is likely to prove a formidable rival to *Maréchal Niel*. In former notes I have advocated the growing of strong climbers in pots, and upon single rods. I have also recommended their being shifted into larger pots immediately the wood is matured in the autumn. The batch of plants now under notice was treated in this way, and I see a great improvement in their flowering over those forced in the 6-inch and 7-inch pots they were grown in. They are also earlier, although introduced at the same time. This variety was sent out in 1891 by Mr. Hendersor, and is an extra vigorous sport from the *Perle des Jardins* introduced by M. Levet in 1874. In every way it is equal to the old *Perle*, while I have no hesitation in saying one can secure ten times as many flowers from it during the dead of winter. Like the other climbers, it flowers from all well-matured eyes, and should be cut down to its base directly the crop of bloom is realised. I have this and other varieties trained up each side of a span-roofed house, and the quantity of bloom there will be during December and January far exceeds that obtainable under any other system of cultivation. The rods are about 2 feet apart, and the bloom buds from each almost meet. In this way they receive the full benefit of all the light, and being trained in a slanting direction the apex of the house is free and provides plenty of light for the other occupants. I shall probably grow the young rods on in the same position, ripening them out of doors during the next summer. The blooms sent are neither so large nor so heavy as those upon plants which are not being hurried quite so much. This variety is an improvement upon *Maréchal Niel* for out-door culture, being hardier and the buds less subject to injury from cold weather during the early summer, a frequent cause of disappointment with the *Maréchal*.—R.

The staying power of Roses.—On page 482 Mr. J. C. Clarke, writing upon the staying powers of Roses under glass, seems to me to refute his own arguments to a certain extent. I quite agree with him that Catherine Mermet and Anna Ollivier possess great staying powers, but surely the former must rank among our full-petalled varieties. It surprises me to hear such an authority as Mr. Clarke state that *The Bride* is not remarkable for lasting qualities, particularly after instancing Catherine Mermet as possessing this attribute in a great degree. As the two Roses are the exact counterpart of one another, except in colour (*The Bride* being a sport from Catherine Mermet), it is strange that one should possess staying powers and the other not. I have grown *The Bride* in quantity ever since its introduction, and my experience stamps it as one of the most lasting flowers we have. Even in the summer the flowers have kept comparatively fresh for a fortnight.—R.

Rose notes.—The article in your last issue from the pen of Mr. R. Irwin Lynch I have read with great interest. More than once have I been struck by the exceeding beauty of our wild Roses. Here (in mid-Sussex) *Rosa arvensis* (syn., *R. repens*) grows very freely both as a hedge plant and upon rough banks. On the deep clayey banks of a river in my neighbourhood I have been lost in admiration of this Rose. In this connection *R. repens* is more applicable than *R. arvensis*, lengths of 10 yards to 50 yards upon the river bank being quite covered with its creeping branches laden with white blossoms all through June and July. As your correspondent truly observes, there is a great variety of British wild Roses, and now that the single and semi-double varieties are becoming so popular, it would be well if more attention were paid to our native species and their varieties.—R.

Rose Margaret Dickson.—I am somewhat puzzled by "N. S.'s" remarks on this Rose in *THE GARDEN* (page 483). At one part of his note he states, fairly correctly, too, that "as a maiden it seldom blooms," but he subsequently says that under pegged-down treatment, which he has tried, it will without doubt rank as the best white Rose. The point left in doubt is, Has it flowered freely with him under this

pegging-down system? Margaret Dickson is undoubtedly a beautiful Rose, but so far we have had no season in England which has suited it since it has been distributed. I have grown it for three seasons. I think very highly of it as a flower and as a good grower, but apparently it is not yet acclimatised, and I think we must await a damp or a cool season to get the flowers in the perfection with which its raisers (Messrs. Dickson, of New-townards) can exhibit it. Some rosarians are already decrying it, as they are disappointed with the results so far obtained; but I think if we have patience we shall be well satisfied with its performance in the future.—CHARLES J. GRAHAME, *Croydon*.

MARKET GARDEN NOTES.

FINE open weather has enabled growers to get their work well advanced, and there is at present a very abundant supply of vegetables of all kinds. Work at present consists mainly in clearing off crops and getting ready for another season.

GLOBE ARTICHOKEs are being protected with litter in case of severe frost, for although we in some years could leave them quite unprotected, it is by no means safe to do so, as a profitable plantation may be ruined by a few exceptionally cold nights.

JERUSALEM ARTICHOKEs continue to increase in size until very late in the season, and for this reason it is advisable to cover the beds with litter and lift the roots as required for market. Although the dry summer weather checked their growth considerably, they have made good use of the autumn and are a heavy crop.

ASPARAGUS—The beds are now getting their winter dressing. The tops, all weeds, and a little top soil having been removed, a good coating of seaweed has been placed on the surface. This is preferable to manure when obtainable.

BROCCOLI is growing rapidly, and even the latest planted crops look strong enough to stand the winter. Layering for protection from frost is not much practised on the coast, for even when Broccoli is killed in walled-in gardens, the crops in open fields usually escape.

CABBAGE.—Planting still continues briskly. The earliest planted crops have made such rapid progress that they will soon be fit for bunching, and if the weather continues mild a good many will be marketed long before they were intended to be, as the autumn rains on soil unusually hot for the time of year caused very rapid growth during September and October.

CAULIFLOWERS of the Autumn Giant kinds are now in fine condition, and are being cleared off rapidly. The first crop, owing to the excessive drought, was by no means good, but later crops are fine, and the frost has not yet been sufficiently severe to injure the heads.

CELERY is much finer than one could have expected, as the drought was very severe during its early stages of growth.

LETTUCES are now in finer condition than they were in summer, having grown rapidly under the influence of mild damp weather. Protection will be necessary if a sudden change occurs.

TOMATOES still continue to ripen slowly in late houses, but the demand has slackened considerably with the return of colder weather. Outdoor fruits cut and hung up in glass houses have ripened well.

Fruit crops are being marketed as quickly as possible.

APPLES are keeping very badly; no matter what the variety or how carefully gathered, they all rot rapidly, even such hard good keeping kinds as Wellington and French Crab are just as bad as the softer kinds, and those who stored large quantities must be careful to remove the rotten fruit.

PEARS are mostly disposed of, except a few of the late dessert and cooking sorts, which are, as usual, repaying any care bestowed on them.

The planting of fruit trees and bushes is being done under very favourable conditions, and although the low prices of fruit may have checked planting in many cases, I do not think on the whole there is any great falling off. Doubtless

the profits on fruit growing were not very large, but the difficulty is to find any other crop that will give such a good return. Old worn-out trees should be grubbed up and replaced by healthy young ones, for it is a waste of labour to save the old trees when young ones are so cheap and come so quickly into bearing. J. GROOM.

Gosport.

SOCIETIES AND EXHIBITIONS.

NATIONAL CHRYSANTHEMUM SOCIETY.

DECEMBER 5.

THE last Chrysanthemum show of the year under the auspices of this society was held at the Royal Aquarium, Westminster, on Tuesday and two following days. It was the finest exhibition for the time of year that has ever taken place, and the competition was worthy of even a November show. In one class, that for twelve Japanese blooms, there were no less than twenty-one entries, and every class was thoroughly well represented. The flowers, too, were superb, especially the incurved. But the great feature of the exhibition, and one that we are delighted to see, was the free and bold arrangements from nurserymen. The good example set at the November exhibition of the same society was carried out to perfection on this occasion. Mr. Jones, Iyecroft Nursery, Lewisham; Mr. Davis, Camberwell; Mr. Owen, Maidenhead, and other growers had remarkably fine displays. The flowers in each case were cut with long stems, and brought out the beauty of the Chrysanthemum as a flower for decoration. The exhibition was alone worth a visit for these arrangements.

Cut Blooms.

The schedule, a not very large one, was confined chiefly to cut blooms, but the tremendous competition resulted in a large space being covered. The winner, out of eleven competitors, for twenty-four blooms, Japanese, not less than eighteen varieties, was Mr. Rowbottom, gardener to Mr. H. R. Williams, The Priory, Hornsey. It is worth while giving the names of the finer flowers, as they were superb for freshness and colour, particularly good being *Etoile de Lyon*, Mlle. Thérèse Rey, M. Bernard, *Beauty of Castlewood*, J. Stanborough Dibbans, Mrs. E. W. Clarke, *Pearl Beauty*, Princess May, Mrs. C. Harman Payne, Lord Brooke, G. C. Schwabe, *Princess Victoria*, E. Molyneux, W. H. Broomhead, *Boule d'Or*, and *Lizzie Cartledge*. One variety named *Umpire* is a poor thing, one of that objectionable type which is as much an incurved flower as a Japanese. The second prize was awarded to Mr. W. Collins, gardener to Mr. J. W. Carlile, Ponsbourne Park, Hertford, his finest blooms being those of *Vice-President Audignier*, G. W. Childs, a variety that has been greatly overpraised, *Etoile de Lyon*, and Mlle. Marie Hoste. Mr. H. Alderman, Morden Hall Gardens, Surrey, was third. It is worth mentioning, as the competition was so keen, that an extra prize went to Mr. W. G. Gilbert, gardener to Mr. Le Neve Foster, Sennowe Hall, Guist, Norfolk, who had a superb flower of *Etoile de Lyon*. In the class for twelve flowers, distinct, the first prize was awarded to Mr. Turk, gardener to Mr. P. Bosanquet, Penfield, Herts, who won against twenty competitors, all exhibiting good blooms. His flowers comprised *Beauty of Castlewood*, Pelican, W. Lane, *Etoile de Lyon*, Mrs. C. H. Wheeler, J. Stanborough Dibbans, E. Molyneux, Mrs. E. Beckett, G. C. Schwabe, *Vice-President Audignier*, Mrs. E. W. Clarke, and Mrs. J. S. Fogg. An excellent second was Mr. W. G. Gilbert, whilst Mr. E. Rowbottom was third. There were no less than eighteen competitors for six Japanese, distinct, and the best flowers were those from Mr. C. Cox, gardener to Mr. J. Trotter, The Grange, Brickendon. His blooms of *Vivand Morel*, G. C. Schwabe, Mrs. E. W. Clarke, *Beauty of Castlewood*, *Etoile de Lyon*, and Herbert Owen were very creditable for

the season. Mr. W. Collins, who showed Vice-President Audiguier, Col. B. Smith, Mrs. E. W. Clarke, Etoile de Lyon, E. Molyneux, and G. C. Schwabe remarkably well, was second, and Mr. H. Shoesmith, gardener to Mr. Hodgson, Shirley, Croydon, third. A class we were pleased to see was for twenty-four bunches, any varieties, but, unfortunately, the first prize exhibit, from Mr. C. J. Waite, Glenhurst Gardens, Esher, was far too crowded. The exhibit was utterly spoilt for this reason. It is a laudable object to have such classes, but the exhibitors must remember there is such a thing as tasteful arrangement. The reflexed variety Putney George was splendidly shown, the flowers rich crimson, tipped with gold—a rich contrast of colour. We preferred the second prize exhibit from Mr. C. W. Knowles, gardener to Mrs. Chas. Egerton, Solna, Roehampton, because less jumbled. One single variety named Mr. Robertson is of note, the flowers pink and white—a pleasing kind. A corresponding class to this was for twelve bunches, but confined to the Japanese section. We must make the same remark here as in the other case; the flowers were lumped together anyhow. Mr. C. W. Knowles won the first prize, and had good individual flowers, whilst Mr. W. Tipler, gardener to Miss Smith-Dorrien, Hartwell Villa, Aylesbury, was second. For six bunches, Japanese, distinct, Mr. A. Newell, gardener to Sir E. Saunders, Fairlaw, Wimbledon, was a capital first, Mr. C. W. Knowles second, and Mr. D. E. Crane third. A pleasing class was for twelve bunches of single varieties, three sprays in a bunch, the first prize being awarded to Miss R. Debenham, St. Albans, who had such fine kinds as Jane, Jenny Lind, narrow yellow coloured florets, Mary Anderson, and Souvenir de Londres; whilst the second award was made in favour of Mr. W. C. Pagram, gardener to Mr. F. Hobhouse, The Whit, Weybridge.

The incurved section was remarkably well represented. The competition was keen in the class for twelve blooms, not less than six varieties, the first prize being won by Messrs. W. and G. Drover, Fareham, Hants, who showed even, well-incurved flowers of Mrs. N. Davis, which is a little lighter in colour than Mme. Danier, Lady Dorothy, Lord Alcester, Princess Teck, Alfred Salter, Mrs. Robinson King and Mrs. Sharman, which has finely incurved petals of a creamy white colour. The second prize was awarded to Mr. W. G. Gilbert, and the third to Mr. H. Alderman. Sixteen competed in the class for six incurved, distinct, Mr. H. Alderman being first with excellent blooms of Golden Empress of India, Princess Teck, Lady Dorothy, Lord Alcester, Empress of India, and Barbara, whilst Messrs. H. Shoesmith and W. and G. Drover were second and third respectively. One class was for twelve blooms of the variety Princess Teck or any of its sports. Very highly finished flowers were those from Mr. H. Shoesmith, who was placed first. Mrs. N. Davis, Lady Dorothy, Hero of Stoke Newington, and Chas. Gibson were the principal flowers. Mr. W. G. Gilbert and Mr. G. E. Smith, second and third.

Two classes were provided for amateurs, one for six varieties, Japanese, distinct, in which there was very good competition. Mr. Thos. Lansley, Watford, was first. Etoile de Lyon and Beauty of Castlewood were well shown. The other class was for a tall vase—Mr. D. B. Crane, Archway Road, N., having a very pretty arrangement, and was placed first.

A special prize was offered by Mr. H. J. Jones, Hither Green, Lewisham, for six blooms, distinct, of any varieties introduced in 1892 and 1893. Mr. Rowbottom was first, showing Le Verseau, a full reflexed Japanese variety, rose-purple in colour, W. H. Broomhead, bronzy yellow, and several others, including Waban, an ugly flower, broad and coarse in the petals, and not worth a place in collections.

There were also classes for Cyclamens and Chinese Primulas, but the exhibitors were not numerous. The first prize for twelve well-grown Persian Cyclamens went to Mr. W. Cook, gardener to the Hon. Sir Charles Murray, The Grange, Old Windsor. Mr. W. Howe, gardener to Mr. H. Tate, Park Hill, Streatham, was first for a collection of

flowering, berried and fine-foliaged plants arranged for effect. The effect would have been better in this case if the spikes of Calanthe, instead of being stiffly tied to stakes, had been allowed to hang naturally.

Miscellaneous.

As at many other shows, the miscellaneous collections were more interesting than those in competition. The principal feature was the arrangement from Mr. Jones, which was most deservedly awarded a gold medal. Eleven large and handsome vases were filled with splendid blooms, representing all the leading novelties, which have been previously mentioned in THE GARDEN. Maiden-hair Ferns formed the groundwork, and the margin consisted of flowers in distinct blocks, so to say, of colour. This bold arrangement of flowers was carried out admirably by Mr. Davis, of Camberwell. Many vases were used, each filled with distinct varieties, and the exhibit in every way was worthy of this grower (silver medal). Mr. R. Owen, Maidenhead, who showed a splendid collection of seedlings and named new kinds, arranged the flowers with the greatest taste (silver-gilt medal). A similar award went to Mr. W. Wells, Redhill, for a bank of flowers, a novel, but certainly not a pleasing style of arrangement. Mr. C. Stevens, Putney, was given a silver medal for cut Chrysanthemums shown in bold bunches. A very fine group came from Messrs. H. Cannell and Sons, Swanley, comprising not only Chrysanthemums in great variety, but a noble collection of zonal Pelargoniums, amongst which especially worthy of note were the single varieties Mme. Melba, white, flushed salmon-rose; Etoile de Lyon, scarlet, white centre; Albion, white; Mme. de Bondeville, white, flushed with rose; Stella Massey, soft pink, and Ethel Lewis, rose, white eye, besides that splendid double variety, Raspail Improved (silver-gilt medal). Mr. T. Witty, Nunhead, had a group of Chrysanthemums of much interest (silver medal). A silver medal went to Messrs. W. Cutbush and Son, Highgate, for a delightful group of winter plants, comprising bunches of Mrs. Leopold de Rothschild Carnation, Orchids and Skimmia oblata Foreman, bright with a profusion of crimson berries. Mr. E. A. Holmes, Hackney, had decorative plants and Mr. E. Rowbottom Chrysanthemums, Chinese Primulas and other things (silver medal). Mr. J. R. Chard, Brunswick Nursery, Stoke Newington, had a table of Chrysanthemum flowers charmingly arranged in epergnes (silver-gilt medal). A similar award went to Mr. H. Perkins, Greenlands, Henley-on-Thames, for a collection of Amaryllis, Chas. Davis, a crimson variety, being of unusually fine form. A silver medal was given to Mr. C. J. Waite for vegetables remarkably well grown. A novel idea for wreaths consisted in having a cork foundation, with tubes inserted at intervals for the flowers. Mr. J. E. C. Neilson, Nunhead, S.E., was the exhibitor.

A meeting of the floral committee of this society was held at the Royal Aquarium on Tuesday last, when Mr. George Gordon took the chair.

First-class certificates were awarded as follows:

JUDGE HOIT.—A large Japanese Anemone-flowered variety with rosy blush quilled ray florets incurving at the tips and a rather flat white disc. Shown by Mr. H. J. Jones.

COLONEL T. C. BOURNE.—A Japanese flower of attractive appearance and good size. It has long flat florets of a deep rich wine coloured crimson and a golden reverse. From Mr. R. Owen.

LORD ROSEBURY.—An incurved bloom of the old florist's type. This is a large flower, and the petals incurve very regularly; the colour is deep purple-crimson. From Mr. R. Owen.

AMARYLLIS CHAS. DAVIS.—A large flower with broad crimson petals and a greenish white throat. Shown by Mr. Perkins.

Among other novelties were three curious small-flowered Japanese Chrysanthemums with thread

petals, said to have been received from Japan, but they were unnamed. A vote of thanks was awarded to the exhibitor, Mr. Morter. Miss Maggie Blenckiron, a large, broad-petalled incurved Japanese, rather loose, but of a bright canary-yellow, was good, as was Potter Palmer, an American seedling Japanese with short, stiff white petals. Richard Dean, a rich crimson and gold Japanese, was staged for the third time this season, and only lost a certificate by one vote. Several other flowers which have been mentioned in these columns of late were exhibited, such as Mrs. J. Gardiner, Pearl of Maidenhead, Niveum, Pearl Beauty, Mrs. F. L. Ames and C. B. Whitnall. A few novelties which looked promising were requested to be presented again.

PUBLIC GARDENS.

Recreation ground for West Hampstead.

—At a recent meeting of the Hampstead Vestry it was decided to open negotiations with Sir Whitaker Ellis, the agent for Sir Spencer Maryon Wilson, for the purchase of about ten acres of land situated in West Hampstead, for the purposes of a recreation ground.

Bushey Park, Hampton Court.—The First Commissioner of Her Majesty's Office of Works has consented to erect another gate for Bushey Park, Hampton Court, in accordance with the numerous signed petition presented to him a month or two ago. The new gate will be situated midway between the Hampton Wick and Teddington entrances to the park.

The College Park at Dublin.—Mr. Burbidge, curator of the University Botanic Gardens at Dublin, has lately been appointed by the Provost and senior Fellows to the charge of the fine piece of ground round Trinity College itself, a noble sort of play and pleasure ground in which the College stands apart in a stately way. We are glad of this, not only as an evidence of confidence in the curator of the College Botanic Gardens, but also for the sake of the College Park itself, as, without taking from its value as a play-ground and air-ground in a large city, it may be possible to add some further charms in the way of trees and garden pictures.

Proposed extension of the Embankment.

—The London County Council appears to have lent a willing ear to the suggestions of the Chelsea Vestry with regard to the extension of the Embankment. The Council have got so far as to be negotiating with the Vestry as to the contribution which the latter body is prepared to make toward the cost of the undertaking, and the Vestry have determined to make an offer of £8000 in cash, and to undertake the filling up of the ground adjoining the proposed Embankment wall, which is estimated to cost another £8000. This is an improvement which would furnish a large amount of work for the unemployed in the district.

The opening out of Gray's Inn Gardens

—The benchers of Gray's Inn, in reply to a communication from Clerkenwell Vestry, state that they are willing to entertain the proposal to substitute a dwarf wall and railing for the present high wall of Gray's Inn Gardens abutting on Theobald's Road, provided the Holborn District Board of Works would pave with wood the roadway from Raymond Buildings to Holborn Town Hall, and from the Town Hall to Holborn. In the event of the local authority acceding to this condition, the beautiful grassy and well-timbered gardens—of ancient and historic interest—will be exposed to public view, and the amenities of the neighbourhood appreciably improved.

Proposed new open space.—It was reported by the Parks Committee of the London County Council that the Vestry of Lee had asked for a contribution towards the cost of acquiring a piece of

land in Manor Lane, Lee, for a public recreation ground. The price asked was £800 per acre, and it was estimated that £500 an acre would have to be expended in laying it out, and that the cost of maintenance would be £550 a year. The site was contiguous to a district largely populated, and the nearest open space was Blackheath, upwards of a mile distant. The committee recommended the council to grant a sum not exceeding £2000 towards the cost (£6400), and to undertake its maintenance. Alderman Beachcroft moved that before taking action the Parks Committee should report as to whether it was prepared (and on what principle) to undertake the maintenance of small open spaces. The discussion was adjourned.

NOTES OF THE WEEK.

Ipomœa Horsfalliæ var. *Briggsi* is in bloom in the Victoria Regia house at Kew. It is a splendid climber for a stove, free, very vigorous, and bearing a profusion of splendid crimson-coloured flowers.

Two beautiful hybrid *Rhododendrons* which we noticed a few days ago at Manor House, Acton, are Princess Alexandra and Favourite. The former bears a well-shaped truss of massive flowers, each of a very delicate silvery blush colour, whilst those of the latter are rose.

Pleione birmanica.—*Pleione*, or *Cœlogyne birmanica*, as it is now called, was in bloom recently in the Kew collection. It is a rare species, and first found by Col. Benson on the Arracan Mountains at about 3000 feet elevation. The flowers are purplish rose in colour, and similar to those of *P. Wallichiana*.

Skimmia oblata Foremani, exhibited by Messrs. Cutbush & Sons, of Highgate, at the recent Royal Aquarium show, is a very useful and bright shrub for the greenhouse or for decoration at this season. The leaves are of a fine green colour, leathery, and the crimson berries are produced with great freedom.

Lithospermum prostratum, as grown here is not in the least herbaceous, but a veritable shrub if anything is. It exists in spreading masses of from 1 foot to 12 feet across, billowy tufts in some parts quite 2 feet high; it flowers nearly the year through. It is a lime hater, and quickly assumes a different habit when it gets into soil it does not like.—T. SMITH, *Nerry*.

Metrosideros floribunda, or *Callistemon salignus*, is a handsome Australian plant when grown in a large tub, as in the greenhouse at Kew. A specimen was in full bloom a few days ago and smothered with large Bottle-brush-like flowers of deepest crimson. The *Metrosideros* share the same fate as many another class of hard-wooded plants in gardens, and are rarely grown well.

Oncidium ornithorrhynchum is a charming Orchid, in bloom recently at Manor House, Acton. It is a good species for an amateur, bearing graceful spikes of purple-rose-coloured flowers at this season, whilst they are also very sweetly scented, not unlike new-mown hay. It should be grown in a basket and the flowers last a long time in beauty. There is also a white variety named *albiflorum*, which, however, is rare.

Salvia leucantha is a very distinct variety and makes a handsome plant for the greenhouse at this season. It is shapely in habit, the leaves abundant, narrow, deep green on the upper surface, but covered with a fine down underneath, whilst the flowers are produced in long spikes and quite woolly in aspect. They are of a mauve-rose colour, and against the white woolly covering very pleasing.

Medinilla amabilis in bloom in the stove at Kew reminds one of a genus none too well grown in gardens. *M. amabilis* bears a raceme of pleasing rosy coloured flowers and the leafage is of bold character. One of the most handsome of all stove plants is *M. magnifica*, which has very fine

flowers and foliage, the pendent racemes measuring about a foot in length, the flowers and conspicuous bracts rose-pink in colour.

Two *Chrysanthemums* of note now in the Chiswick collection are *Orange Beauty*, a Japanese variety, and the single *canariense*. It is not often one sees them in gardens, but they are well worth growing. The former produces a wealth of comparatively small flowers of an intense yellow colour, the lower petals suffused with chestnut-red. Those of the latter are soft yellow and of pleasing form. Both are delightful kinds for cutting.

Manettia bicolor, recently in bloom at Kew, is a bright flower too little seen in gardens. It has been long introduced, but is not by any means common. When trained in a kind of balloon-like form it is remarkably attractive, the leafage very abundant, and set off by a wealth of flowers, individually showy by reason of their scarlet and yellow colours. The plant is readily propagated by cuttings, and the wonder is that, blooming at a dull season of the year, it is not common.

Narcissus monophyllus.—The pure white Hoop-petticoat *Narciss* is a delightful bulb for pot culture. It should be grown freely for winter flowering, and the way to grow it is to plant the bulbs early, using sandy soil. After putting them in pans remove to a cool frame, where they should remain until the buds appear. If transferred to a mildly heated house they will expand freely. A succession may be easily kept up by relays. The flowers are useful for button-holes and choice decorations.

Lælia Dormaniana is a fine Brazilian Orchid sometimes described as a species, but supposed also to be a hybrid between *Cattleya bicolor* and *Lælia pumila*. A well-grown plant is in bloom at Manor House, Gunnersbury. It blooms very freely, but the flowers do not last a long time in beauty. The colour varies, but usually the sepals and petals are rich olive-green spotted heavily with crimson, the side lobes pale purple, whilst the centre lobe is deep crimson, white at the base.

Oncidium tigrinum.—This is one of the most beautiful Orchids in bloom now. We noticed several plants in beauty at Messrs. Shuttleworth and Co.'s nursery at Peckham Rye, and at Manor House, Gunnersbury. The flowers are not only of bright colour, the sepals and petals brown with yellow markings, and the lip self yellow, but sweetly scented like *Violets*. Its fine branching spikes are also in beauty at this season, and last fresh for several weeks. It is not difficult to grow well, and is as useful and attractive as any Orchid in flower in late autumn and winter.

Cymbidium affine.—A specimen of this beautiful species, which belongs to the thin-leaved section of the genus, was in bloom recently in the collection of Mr. Gledstanes at Acton. It is quite a gem amongst *Cymbidiums*, the leaves broader than in either of its relatives, *C. Mastersi* or *C. eburneum*, whilst the flowers are borne freely in a raceme, as in *C. Mastersi*. They are individually of great beauty, neat, and pure white, the lip crimson-purple in colour, with the side lobes spotted with the same shade. It is sweetly scented and valuable for winter blooming.

Plumbago rosea.—One of the best groups of this fine old plant we have seen recently was in the garden of Mr. Gledstanes, Manor House, Acton. The plants are in 1½-inch pots, dwarf, bushy, well furnished with rich green leaves, and bearing a free display of the bright red flowers. The plants are kept in a cold frame during the summer, and one is surprised such a bright flower is not more common. Unfortunately, near the vicinity of large towns fog soon spoils the flowers. This *Plumbago*, judging by its comparative rarity in gardens, might be considered almost a novelty, but it was introduced from the East Indies as far back as 1777.

Cyclamens of poor colour.—One cannot help noticing that the Persian *Cyclamen*, although far finer in many ways than the varieties of old, is not faultless in colour. It is too much the fashion to get purple, magenta, and dull rose or crimson shades into the flowers, which spoil otherwise

beautiful strains. This is a great pity, as the flowers are handsome in form, bold, and borne on sturdy peduncles, whilst the plants as regards habit have undergone manifest improvement. We hope raisers of new varieties will strive to get acquisitions of decided colour, and eradicate all traces of objectionable magenta or dull leaden shades.

Nicotiana affinis.—I quite agree with all that Mr. Flemyng says respecting this beautiful plant. It grew with much vigour in my garden this season, only ceasing to bloom when cut by frost, and towards evening the air was redolent with its perfume, which is always present more or less, but very faint in the day as compared with evening and night. It is a good flower for cutting, and lasts fairly well in water. Like many other half-hardy things, it produced quantities of good seed this year, some of which I have saved, but much was shed. I am curious to see if it will come up in the open ground from self-sown seed.—GREENWOOD PIM.

Tasmanian plants.—In Sir Joseph Hooker's great work, "The Flora of Tasmania," a copy of which recently came into my possession, there are several hundreds of coloured portraits of plants by Fitch; amongst them a very few seem to have found their way into this country, or if imported at all are to be seen only in botanic gardens. There are certainly many that ought to be better known here, and as the climate in some parts of the island at least closely resembles that of England, there is little doubt that a goodly number would be quite hardy with us. It looks as though it would be a happy hunting ground for the temperate or hardy plant collector. It is singularly rich in terrestrial Orchids, amongst which there are some extraordinary flowers. In shrubs and herbaceous plants there is a great variety that the ordinary cultivator never hears of. I am aware there are some Tasmanian shrubs to be found in a few nursery catalogues, but they seem a very small proportion of the large desirable number of plants indigenous there. From the large number of plants figured I have selected a few that I cannot help thinking would remunerate the importer. There are many hundreds of plants described, but not figured, out of which doubtless a large proportion would be equally worthy of culture.

—J. M., *Charmouth, Dorset*.

The weather in West Herts.—Another week of changeable temperature. On Thursday in last week the highest reading in shade was 49°, but on Saturday 35° was at no time exceeded, and on the following night the exposed thermometer indicated 19° of frost. The reading last mentioned is the coldest as yet recorded this winter. At 1 foot deep the temperature of the ground now stands at 39°, but at the depth of 2 feet is 2° warmer. On Friday there occurred a light fall of snow, the flakes of

which, however, melted on reaching the ground. On Saturday the sun was shining brightly for six hours, which is a splendid record for a winter month. November was the first unseasonably cold month since January. The total rainfall exceeded the average by nearly half an inch, bringing up the excess for the first two months of the present drainage year to $1\frac{1}{2}$ inches. The last Rose bloom of the season was destroyed by frost on November 22, which is nearly a fortnight earlier than the average date of its destruction in the previous eight years.—E. M., *Berkhamsted*.

OBITUARY.

MR. E. S. DODWELL.

THOUGH Mr. E. S. Dodwell had been ailing for a long time, his somewhat sudden death on the 30th of November came as a surprise to the many florists and lovers of the Carnation who knew him personally or by repute. He had, during a long and active life, been so prominently associated with the development of the Carnation and the improvement of its various sections, as to have become a central figure at Carnation shows, and a lawgiver to those who estimated the Carnation according to the florists' standards. Though he never refrained from zealously advocating the employment of the flower for border and general garden decoration, he ardently and successfully sought to add size and refinement to the flowers grown for exhibition. The selfs and fancies were equally his care, and he obtained from seed many of the former that take rank among the most approved border flowers. Of the many hundreds of seedlings he annually raised, all were planted out in the open and wintered there to bloom and display what qualities they possessed. Constitutional vigour Mr. Dodwell always held to be a matter of prime importance, and a year's probation in the open ground tested this fully. He had been a raiser of seedlings for something like a quarter of a century, making the Picotee and Carnation his first care. Of late years he introduced some very fine Carnations—bizarres and flakes, selfs and fancies. One of his latest productions was *Othello*, s.b., a brilliant flower that was shown in fine character in 1892, but which, owing to the smallness of the stock, could not this autumn be put into commerce, or only to a very limited extent. He took great interest in the more modern yellow ground varieties, and the Kilmurry yellow seedlings having passed into his hands a few years ago, he distributed several by name, and raised seedlings from them of high quality, so numerous, indeed, that they were sent out under numbers rather than under names. As a cultivator Mr. Dodwell excelled. When he settled in Oxford in 1881 he planned and laid out a Carnation garden the like of which probably does not exist in the country. For plants in pots he built shelters and structures that while screening the flowers from the elements, yet enabled them by full side exposure to be grown as hardy as if in the open. He usually cultivated some 3000 plants in pots, while almost the whole of his garden in the Stanley Road was aglow with Carnations of all types. A short, sturdy growth characterised his plants, and they had all the care and attention the devotion of a lifetime could give them. He systematically and scientifically cross-fertilised for the production of new forms. He had an intimate knowledge of the structure of the flower of the Carnation. As a dresser of flowers for exhibition he scarcely had a rival, and in setting up a stand of blooms he had a keen appreciation of contrasts of and harmonies in colours. His book on "The Carnation and Picotee," which may be said to sum up the experience and successful practice of a lifetime, is one of the classics of floriculture, and one can scarcely withhold regret that Mr. Dodwell was not a contributor to the "Carnation Manual" recently issued by the National Carnation and Picotee Society of London. Born at Long Crendon, Bucks, on November 28, 1819, he had just completed his seventy-fourth year.

He resided in his birthplace until he went to live at Derby in 1845, but meanwhile he had been engaged in commercial pursuits in London. While at Derby he became an enthusiast in Carnation culture, and becoming first an exhibitor and then a successful raiser, he not only effected marked improvements in the flower, but also taught better modes of exhibiting, raising the standard of excellence also. He gave a great impetus to the establishment of Carnation exhibitions in the midland counties, and for some years acted as secretary to the Midland Counties Horticultural Society. As a judge of Carnations his services were in great request. He was a contributor for some time to the *Midland Florist*, then edited by Mr. J. F. Wood, and to the *Florist*, then conducted by Mr. Charles Turner. In 1856 Mr. Dodwell, in conjunction with the late Mr. John Edwards, started *Gossip of the Garden*, a monthly publication that had a successful run for a few years. In 1860 he left Derby to reside at Clapham, London, where he grew Carnations with marked success, and in conjunction with others founded the National Carnation and Picotee Society (southern section). Mr. Dodwell left London for Oxford in 1881, and after breaking away from the London society, he in 1885 established the Carnation and Picotee Union. For nine years an exhibition annually held in Mr. Dodwell's garden in the Stanley Road, Oxford, was always largely attended, as the gathering partook of a much more social and friendly character than is generally the case. He was an assiduous and methodical worker up to the very last, harder indeed than many men work at this period of their lives, an indomitable spirit possessing him to the last. His death removes a master-mind and a master-hand from among the florists of England. Mr. Dodwell leaves a widow and several sons and daughters. He was buried in the Holywell Cemetery at Oxford on the 5th inst. R. D.

Death of Mr. W. Howard.—We regret to announce the death, at the age of 58, of Mr. W. Howard, of Southgate, one of the best known gardeners about London, from the time when he was gardener, many years ago, at Bedford Hill, Balham. He was not fortunate in recent years, but nothing damped his enthusiasm. He was an excellent plant grower, as proved at many exhibitions.

Plantains on Grass (J. D. C. L.).—On a part of the park here where this weed is very abundant there being more of it than of Grass, I had to make a new cricket ground some ten years ago, and as it was wanted for use the following season, the turf had to be used again, with the result that this Plantain was soon as thick as ever. I have adopted several plans for the destruction of the Plantain with varying success. Sulphuric acid (oil of vitriol) was as good as anything I have tried. A wide-necked pickle bottle is used to carry this dangerous article in, with a piece of copper wire fastened securely round its neck, having a lung loop by which to carry it with. A sharp-pointed stick which is held in the other hand is dipped (not too deeply) into the acid and driven into the crown of the weed. Every care should be taken when using this acid that it does not touch the hands, boots or clothes or it will burn them, and as a precaution gloves may be used. In the event of any accident it should be known to all who use it that immediate immersion in water is the only cure. Many of the patent weed-killers that are advertised will answer the same purpose as the acid, and are used in a similar manner. There are machines made to be charged with one or other of these weed-killers, but owing to their not being properly adjusted generally too much of the liquid is applied, which causes whole patches of Grass and weeds to perish. The variety of Plantain under question has a small bulb at its base, and I have had as great a success when the plant has been lifted by means of a daisy fork right out of the soil. When this course is followed the work should be done either late in autumn or early spring, and the whole have a

dressings of strong soil which should be brushed into the holes, and after the Grass begins to grow give the whole a thorough rolling. No one can expect to destroy the whole of these weeds in one season, as many plants that are now very small will by another year be much larger, but by following up the practice for a few years great improvement will follow. Another precaution is to take care that the plants left are not allowed to seed. In carrying out this work it is a good plan to have two lines stretched across the ground and the space between them thoroughly looked over, leaving the front line in its place while the back line is brought to the front, thus taking in another width. This prevents going over the same ground again.—C. WARDEN, *Clarendon Park*.

—"J. D. C. L." will find that a mixture of sulphate of iron and sulphate of ammonia, in the proportion of two of the former to one of the latter, and applied at the rate of 1 cwt. to 300 square yards, kills most weeds on Grass, fostering the growth of the latter. The time to apply this mixture is just before growth starts, and a dry period suits best. The iron sulphate should be finely ground, and the sooner it is applied to the land the better, as it has a tendency to set.—R. C. H.

Tree roots in wells.—I would beg for a little space to direct attention to what is really a very important matter. I have several wells, from one of which the water is taken for drinking. Some years ago this water became so bad that we could not drink it. I could not understand why such a change came about, as I was sure that no sewage or foul matter of the kind ever had a chance of entering the well. The water getting worse, the well was cleaned out, and then the cause of mischief was plain. The sides of the well were covered with tree roots, which found their way there in summer and rotted during the winter. This had evidently been going on for some years, so that there was a considerable accumulation of vegetable matter at the bottom. Our local builder tells me that this is a by no means uncommon state of affairs. In a well 20 feet deep the surface of the water was covered with a network of roots. In country districts where water for all purposes is obtained from wells, it behoves the owners to have them seen to every three or four years, that is, if trees are sufficiently near to admit of their roots making their way to the water.—J. C. B.

Gardeners' Royal Benevolent Institution.—We are asked to state that his Grace the Duke of Bedford has contributed £100; Mr. Bailey Wadds, of Birdsall, Yorks, £2 11s.; and the Reigate and District Chrysanthemum Society, £31 10s. to the funds of this institution.

Royal Horticultural Society.—The last meeting of this society for the year 1893 will take place in the Drill Hall, James Street, Victoria Street, Westminster, on Tuesday, December 12. The fruit, floral, and Orchid committees will assemble at 12 o'clock, and new Fellows will be elected at 3 o'clock.

Panicum plicatum.—I have some seed of this beautiful and stately greenhouse Grass that I would be pleased to share with anyone who cares for such things and who will send me a stamped directed envelope. Some of the seed is not yet quite ripe, so some delay may occur. In my little intermediate house it grows 9 feet or 10 feet high, its beautiful plicate leaves being often 3 feet long by 5 inches or 6 inches wide.—GREENWOOD PIM, *Monkstown, Dublin*.

Names of plants.—*G. C.*—*Cœlogyne fimbriata*.—*J. Davidson*.—*Cattleya labiata*, a good light coloured form.—*C. B. M.*—1, *Hymenophyllum dilatatum*; 2, *Asplenium longissimum*; 3, *Cattleya luteola*.—*G. Hudson*.—1, *Ficus religiosa*; 2, *Vanda Sanderiana*, poor variety; 3, *Pavetta borbonica*.—*H. Geraldson*.—1, *Nephrodium molle*; 2, *Asplenium viviparum*; 3, *Davallia canariensis*; 4, *Hymenophyllum erinitum*.—*G. Fisk*.—1, *Cattleya Bowringiana*; 2, *Pleione maculata*.—*Eustace F. Clarke*.—1, *Reineckia carnea*; 2, *Boussingaultia baselloides*.

"This is an Art
Which does mend Nature: change it rather; but
THE ART ITSELF IS NATURE."—*Shakespeare.*

ROSE GARDEN.

WILD ROSES.

THE able and interesting article of Mr. Irwin Lynch in the issue of THE GARDEN for November 25 last comes at an opportune moment, for if seedling Roses are to be raised now is the time to secure the heps, and to put them in boxes or pans of earth for the winter preparatory to sowing the seed in the spring. Moreover, there is no doubt that where plants of Rose species are desired, the most satisfactory way by far of obtaining them is from seed.

The fact that a considerable number of species are beautiful garden plants is being gradually recognised, and fine examples are now to be found in not a few gardens. But the difficulty, of course, remains that no amount of enthusiasm can make space enough for many species in a small garden, while in a large garden no amount of space will create enthusiasm. It would really seem as though, in Rose growing, enthusiasm varied inversely as the size of the garden. Yet it is only in large gardens that one can hope to see anything like a collection of Rose species, and of large gardens again only in those in which some unconventionality or naturalness is allowed. For it is in gardens where there is something of a wilderness—not using the term at all in the sense of a desert, but rather as indicating where plants may grow somewhat wilder than under the conventional garden restriction—that many of the Rose species, especially the native ones, may be seen to the greatest advantage; in such a situation as that shown in Mr. Alfred Parsons' beautiful picture of *Rosa arvensis*, the most beautiful of all our English Roses, with its wonderful contrast of snow-white petals and golden stamens unsurpassed in any other Rose, even if equalled by *Rosa moschata*. Growing on a wooden shed, I have a large plant of Bouquet d'Or, which was budded on a cutting of *Rosa arvensis*. Every year one long shoot from the stock is allowed to grow as it pleases, and the effect of the clusters of white blossoms, which, of course, expand before those of the scion, amongst the deep glossy foliage of Bouquet d'Or is very charming.

Some years ago I set about making a collection of growing plants of Rose species, and in this attempt to get the native and other Roses together, in which I received most kind and valued help from Mr. Irwin Lynch in the matter of heps of many species and varieties from the Cambridge Botanic Gardens, great numbers of seedlings were raised and planted out. Unfortunately, lack of leisure prevented my carrying out my

intention as fully as I had wished, and much of the original material is now a tangled thicket; but several species are still an annual delight, notably *Rosa hibernica*, a charming plant, masses of the delightful Burnet Rose (*R. spinosissima*), and a hedge of Sweet Brier (*R. rubiginosa*). In raising many seedlings of Sweet Brier I did not find much variation, but there are, of course, several double and semi-double forms of considerable beauty, in addition to Lord Penzance's many interesting seedlings, the most beautiful of which, Lord Penzance and Lady Penzance, the results of crosses with varieties of *R. lutea*, I believe Messrs. Keynes, Williams & Co., of Salisbury, hope to distribute next autumn.

I note, however, that to this species (*R. rubiginosa*) Mr. Irwin Lynch refers *Rosa macrantha*, which argues some confusion in the matter of names. For the *Rosa macrantha*, that has gained such popularity in gardens during the last few years, certainly does not answer to the description given by Mr. Irwin Lynch, as having "rather pretty flowers, though they are somewhat small"; on the other hand, it is one of the most magnificent of all the single Roses, and, as I understood, was referred by Mr. Baker to *R. gallica*.

In regard to *Rosa rugosa*, it is certainly worth while to grow the finest forms, although this involves their propagation by cuttings or budding, as they do not come true from seed. I have an extremely handsome crimson form, from which I have raised many seedlings, but none of them is nearly so fine either in flower or foliage as the seed parent; while many are as poor as *Rosa kamtschatica*, which is perhaps the least interesting of the feroces. The white variety, again, does not come true from seed; every seedling that I have raised from a plant, grown in a comparatively isolated position, of a fine white form has produced flowers of varying shades of dingy red—a fact that I fancy tends to dispose of the theory advanced at one time that the white-flowered *Rosa rugosa* was the original species and the red-flowered ones were varieties. "The red Rose came first," says a quaint German mystic, speaking of "the mystery of so-called *white* things as being ever an after-thought." Thus Walter Pater.* It may not be evidence, but the Germans are close observers.

Of other exotic species, *Rosa rubrifolia* is a charming plant for any garden, and though, as Mr. Irwin Lynch points out, the beauty of its red-grey foliage is especially remarkable early in the year, the plant is even more beautiful when in flower, and beautiful still in autumn with its varied tints of leafage and myriad bright red heps. A bold group of seedlings planted out on the Grass is a constant delight and attracts immense attention throughout the season. A similar group of *Rosa lucida* is also very attractive, with gleaming foliage and fresh rose flowers, succeeded by sealing-wax-coloured heps. In rais-

ing seedlings from *Rosa lucida*, *Rosa nitida*, &c., there seems a certain amount of variation and a tendency to intermediate forms, and it would not be surprising to find eventually the possibility of a reduction in the number of species of these glossy-leaved Roses of North America.

Rosa moschata (sometimes cultivated under the name of *R. Brunonis*) and *Rosa multiflora* (syn., *polyantha*) are two magnificent climbers, and *Rosa macrantha* (of gardens) is beautiful as a climber, or on a pillar or as a bush, its large flesh-coloured flowers with petals of great substance and rich yellow stamens rendering it one of the handsomest and most popular of all single Roses.

Rosa lutea and its varieties, more commonly known as the Austrian Briers, are of unique and surpassing beauty, and are deservedly popular, and if subsequent experiments in crossing with other Roses result as successfully as those already made in Lord Penzance's garden, it is more than likely that *Rosa lutea* will eventually figure as the progenitor of a very delightful series of garden varieties.

No doubt there are florists who, having set up an arbitrary definition of a particular flower, have no eyes for any beauty in any seedlings that do not conform to their preconceived model, and it is probable enough that some fine single Roses have been thrown away by raisers who were intent upon obtaining varieties with double flowers; but it is curious to observe that of garden varieties of single Roses that have been distributed of late years, none have proved entirely satisfactory. Moreover, one or two well-known raisers, knowing of my interest in single Roses, have from time to time very kindly sent me single-flowered seedlings that appeared in any way striking, yet it is quite extraordinary how rarely any one of them is of real value. Perhaps they are autumnal-blooming, and then their flowers are not particularly attractive; or they may have flowers of exceptional brilliancy, and then the plant is found to have no constitution. I have some single Roses that produce the most vivid flowers on plants that refuse absolutely to grow more than about 6 inches high.

But these, of course, are seedlings from varieties that have long been cultivated with double flowers—varieties, too, that have been for many generations selected with very little consideration of any quality beyond the doubleness of their flowers. The seedlings that Mr. Irwin Lynch desires to see raised from crosses between native and other single Roses are not likely to be of a nature lacking in vigour or freedom, and if only other raisers can be induced to follow somewhat on the lines so successfully laid down by Lord Penzance, there is little doubt that our gardens would soon be enriched by a fresh series of very delightful and novel Roses.

T. W. GIRDLESTONE.

Rose Margaret Dickson.—Replying to C. Grahame (p. 543), I may say that this Rose bloomed well with me under pegged-down treatment during

* "Marius the Epicurean," chap. ii.

the past summer. I do not think my former note upon p. 483 left much doubt about that fact, but I would not like to call it the best white Rose without more knowledge of it. I have grown it for two seasons, but the only time it flowered well was when pegged down.—N. S.

Rosa minima.—The so-called perpetual Roses cannot compare with this little gem for a perpetual blooming habit. It begins with the earliest, with *Rosa rugosa*, and lasts all other Roses out that I know, all the summer and autumn keeping up a constant succession, and that notwithstanding its miniature stature. My five or six-year-old plant is but 9 inches or 10 inches high, yet very bushy; this little specimen has never been without flowers since last May, and to-day it has plenty of buds that may open any bright day, and it is in this condition after three spells of frost, as much in one case as 10°. During the time I have grown it here there have been some trying winters, but the plant, which is fully exposed, has survived the worst, and that without the slightest protection.—J. Wood, *Kirkstall*.

Repotting Roses previous to forcing.—I do not advocate the repotting of all Roses immediately before forcing. What I advise and practise is to repot as soon as the wood is ripe, allowing the plants to remain in the open for some weeks longer and gradually draw root into the new soil. In the earlier portion of his article Mr. J. C. Clarke confirms me in this. When a plant has become thoroughly pot-bound and the soil is exhausted, there can be no question but that there is considerable advantage in judicious repotting. I do not find any greater tendency to extended growth of a flowerless character upon Roses repotted as I described than if left undisturbed. The whole secret of this lies in securing well-matured wood.—R.

THE PAST ROSE SEASON.

PROVIDED work has been properly attended to as it became seasonable, there should really be little to do among Roses during December, and with the exception of mulching and otherwise affording a slight protection against severe frosts, we may dismiss the present and take a look back upon the past Rose season.

The year 1893 is over as far as Roses in the open are concerned, although I can still (December 2) cut one or two from sheltered nooks upon walls. Last week I cut a really good flower of A. K. Williams, and the colour was as dazzling as during July or August, while the Chinas and one or two Teas most closely related to them have but just ceased blooming. The extreme earliness of such varieties where they were sufficiently sheltered from the frosts of April and May, together with their continuous blooming until November, must rank among the pleasures of the past season. All Roses, except the early summer bloomers of Hybrid Bourbon type, such as Charles Lawson and Blairi, and the strongest growing Hybrid Perpetuals under pegged-down treatment, have afforded a very lengthy supply of flowers. I do not call to mind any year when we were favoured with a better autumnal display. A second pleasing feature has been the general excellence of many of our oldest favourites, several of which were becoming almost unknown, and had been made the subject of much comment respecting their supposed deterioration. Beauty of Waltham, Duc de Montpensier, Senateur Vaisse, Xavier Olibo, Marie Rady and Duchesse de Caylus have been produced in their best form, while some of the more extolled and newer introductions entirely failed to keep up their prestige. In addition to a grand season for the later crops of Tea Roses, we have had much more depth of colour in the Hybrid Perpetuals

than is generally the case during a hot and bright summer. Indeed, the grand and glowing colours of Horace Vernet, Louis van Houtte, Duchess of Bedford and Eclair have been most remarkable. Turning to the maroon coloured Roses, we find scarcely any burning of their petals; therefore, the generally accepted theory that those of the Prince C. de Rohan, Abel Carrière and Victor Hugo shade delight in a cool season has been amply refuted during the one just passed. I do not remember to have seen a single blossom presenting the dull brownish appearance usually attributed to burning. Her Majesty, Mme. Lacharme, Alba Rosea, Comtesse de Serenye and Duchesse de Vallombrosa were all excellent with me during the bright summer of 1887, and it would naturally seem that the past would have suited them equally well. It was not so, however, nor did I secure a single flower in the slightest degree approaching to those of 1887. A circumstance which surprised me very much was the way the buds of these were scorched and withered by the heat, and yet the darker varieties of equally double form entirely escaped this evil.

Looking further back into the year—February and March—we had grand prospects, as the wood had come through the trials of winter in a most satisfactory manner. At pruning-time we had great hopes of a good Rose season, but these were quickly destroyed by the phenomenal heat and drought, these being rendered more injurious by a succession of sharp frosts at night. The plants broke into new growth vigorously, but the almost tropical weather, combined with drought, soon had disastrous effects, and the growth was in many cases blistered by the sun, while the roots could not find the needful moisture. Even where fortunate growers were able to supply water in almost unlimited quantity, the results were by no means so satisfactory as might be desired. Artificial watering when used as a further aid to genial showers is very valuable, far more so than when we are having a spell of extra bright weather. The relief from sunshine afforded during a few passing showers seems particularly grateful to plants in full growth. It was during the first or second week in April that I gathered my first blooms from the open air, and these consisted of Gloire de Dijon, Rêve d'Or and Reine Marie Henriette. At the same time we were having a series of sharp frosts, which were seriously affecting the growth of plants in the open borders. On south walls the effects were not so noticeable, probably because the heat of the wall from the remarkably bright sun we were having day after day was sufficient to protect them until the sun got round again. The majority of cut-back plants produced their summer crop during the earliest weeks of June and were much too forward to be of service in the exhibition tent; nor were there many blooms of sufficient quality to meet the high standard Roses have now reached, and I think many must have been grievously disappointed with the Rose shows of 1893. A few people in the north had really good representatives of the leading varieties, and Messrs. Harkness and Sons set a record it will be difficult and almost impossible to beat.

Undoubtedly the Rose of the year was Horace Vernet, which gained the medal as being the premier H.P. bloom in the nurserymen's divisions both at the Crystal Palace and Worksop. This Rose was introduced in 1866. Dupuy Jarnain was sent out in 1868, and gained the medal in the amateur classes at the Crystal Palace. Here we have two old Roses coming to the front and beating the host of

grand varieties introduced since their advent. The remaining in the amateurs' classes went to that fine Rose Mrs. John Laing. Although the Teas were by no means so good as might have been expected, the finest Mme. Cusin ever staged was shown this and The Bride being the two medal Teas at the metropolitan show. Mme. Hoste won both in the nurserymen's and amateurs' divisions at Worksop. There is one notable coincidence about the medal Roses, and that is the fact that the late M. Guillot gave us two which carried off four of the medals, and another winner in Mme. Cusin. No raiser has distributed a larger number of grand varieties, and his death on September 6 of this year was deeply and widely regretted. Three gold medals were awarded for new Roses, and although we might reasonably have expected the past summer to have been favourable to Marchioness of Londonderry, I believe from information received and also from its appearance at the Crystal Palace show, that we saw very poor specimens of its usual form. It is an ivory-white, of immense size, and short, robust growth. This and Mrs. Sharman Crawford were both staged by the raisers, Messrs. A. Dickson and Sons, of Newtownards, Ireland. The latter variety is bright pink with a shade of soft lilac, and from its form and habit promises to be a good useful Rose. The champion growers for the year exhibited their new sport from Heinrich Schultheis under the name of Mrs. Harkness, but it was not so good as I saw it at Chester the previous year. The third gold medal went to Turner's Crim Rambler, a Rose which will be extensively grown. It is an extra vigorous grower, and blooms in huge clusters of deep scarlet. Gustave Piganeau was the most prominent Hybrid Perpetual of recent introduction, and for twelve of any one sort it took all three prizes. This, together with the fact of its being the premier Perpetual in the two previous shows, at once stamps it as a grand acquisition.

One of the lessons of the year is the advisability of planting a good selection of varieties, many erstwhile favourites having almost entirely failed. Nor should Horace Vernet and Duchess of Bedford be planted by any who look for a permanent Rose of quality and freedom of bloom. This is one of the evils of Rose exhibitions, as many are led into purchasing varieties of little merit for general cultivation solely on account of the position they occupy upon the exhibition board. Deep cultivation, summer mulching, and judicious watering have all been necessary if good blooms were to be secured. Although the growth seemed at a standstill during the early part of July, and had a far more matured appearance than we often see in October, a few genial showers induced the Roses to push out new growths which carried the best general crop of the year. Plants which had a puny appearance, and looked as if their growth had finished, are now well furnished with wood, which has matured very well. The seedling Brier stock increases in favour, and has been particularly useful this season, its deep roots enabling the plant to make a much better stand against drought than those of the Manetti. Although the growth of Roses was much earlier than usual, the extreme dryness had the effect of making the stocks late in arriving at a sufficient size. My own were not budded until the latter part of August and during September, but the grand autumn allowed them to set firmly to the stock, and at present they have a very promising appearance. The attacks of insects and mildew were not so bad as we have experienced in former years,

although some few localities were as usual more affected than others. Birds have long been great favourites with me in the Rose garden; even the sparrow, mischievous as he often is in picking off the buds and tips of shoots, will eat the aphids and maggots with avidity. True, there are some seasons when they do not attack them so persistently; but during the early part of May and June, when aphides were most prevalent, I frequently noticed the sparrow very busy among them. The warblers and tits, also the gold-crested wren and several other small birds, did me good service in this respect. Red spider, red rust, and thrips were less conspicuous than usual during the autumn months, a most fortunate fact when we remember that this period was really the Rose season of 1893. More than once I feared mildew would ruin the crop, but the plants broke through from its attacks in a very gratifying manner. RIDGEWOOD.

Climbing Roses in Suffolk.—Some climbing Roses which were planted in the spring of 1889 on the south front of Ampton Hall, the residence of Mr. J. Paley, near Bury St. Edmunds, have made such remarkable progress, that a record of their growth may be useful. As the gravel terrace comes right up to the building, provision had to be made for the Roses by making a narrow border surfacing this with gravel after planting. This border is 2 feet wide and 2 feet deep resting on brickbats, mortar rubbish, and the like for drainage. Equal parts of mellow clay, top spit from pasturage, well rotted manure and mortar rubbish were well mixed for making the border, and this has suited the plants so well that they have almost covered the whole frontage, the crops of flowers being very large and the blooms individually very fine. The following notes give the heights to which the plants have reached, and one or two other particulars about them. Bouquet d'Or has reached the roof 24 feet from the ground, and turned under the eaves for another 3 feet. Belle Lyonnaise, Gloire de Dijon, Mme. Berard, Lamarque and Beauté de l'Europe are all about 20 feet high, and each has done so well that it is hard to say which is best, but Mme. Berard and Gloire de Dijon have been grand each year. Mme. Eugène Verdier, Mme. Alex. Bruel, Mme. Delpaul and Maréchal Niel come next with a height of 18 feet, and all have done well. William Allen Richardson is about 10 feet high, but during the past two years has not done so well as it did before; this, I think, is more the fault of the variety than anything in the cultivation, as I have always found that this Rose does badly after the first two or three years from the bud. Rêve d'Or from some unexplained cause has done worse than any, so I should imagine there is something wrong with the stock of this plant, as this variety does well in another part of the same garden.—J. C. TALLACK.

The vagaries of Roses.—There can be no doubt that Roses do vary considerably in different soils and localities. Duc de Magenta in one part of the grounds does well, and from the plants very fine blooms suitable for exhibition can be cut, while in another part of the nursery it fails altogether. Jean Pernet is another Tea which behaved in the same way. Ten to fifteen years ago I grew Dr. Andry well, but now it has suddenly ceased to give flowers at all approaching the quality of those I used to secure. Dr. Andry still figures very prominently in many first prize stands, nor have I heard others complain of its deterioration in any way. Souvenir d'un Ami, too, does not yield the same percentage of good blooms as formerly, and I could name many similar instances. In a friend's garden Pierre Notting is one of the finest and most reliable Roses, while in another Empress of India does well. Neither of these succeed with me. Cloth of Gold has given me a few good blooms this season; the first for a number of years. But in a garden not far from this it has been simply grand for the last fifteen

years. Horace Vernet is a poor grower with the majority of cultivators, yet in Mr. Mawley's garden at Berkhamstead it does well. Edith Gifford seems to do well with almost everyone but myself, while Captain Christy, one of my best and strongest Roses, thrives but indifferently well with neighbouring friends. Doubtless soil, stock, and position have a great influence upon Roses; still it is strange there should be so much difference under apparently similar culture and conditions. I could also name several instances of Roses refusing to open or coming quartered in some gardens, however varying the seasons may be, while the same varieties are remarkably constant and reliable in others.—RIDGEWOOD.

DOES SOIL CAUSE CANKER IN ROSE TREES?

I CANNOT say whether it does or not, because in all my experience I have never seen canker on any other Rose but Maréchal Niel, but from what we read in THE GARDEN with regard to this terrible disease, it appears to me pretty clear that soil does cause canker in Roses. For more than twenty years I had charge of a garden where such kinds of Apples as Ribston Pippin, Emperor Alexander, Lord Suffield, and Warner's King could not be kept free from canker, do what I would to them, yet I never saw any other Rose but the one I have mentioned affected in the same way. Five years ago I made a new garden, and planted many sorts of Apples and Pears as well as Roses. Canker has shown itself in many cases in the fruit trees, but not on the Roses in the open. That being so, it is very plain that all soils have not the same influence. My Maréchal Niel Roses under glass suffer from canker to a serious extent. What, however, concerns me most just now is a statement made in THE GARDEN recently by a competent and reliable writer that he had several well-known Roses besides Maréchal Niel that were affected by canker in the same house. This, I think, goes to show that the cause lies in the soil. While I think it is quite safe to conclude that some kinds of soils do promote canker in Roses, it is pretty clear that they differ in their composition considerably, sufficiently, in fact, to make all the difference between a serious attack and a light one. What this difference may be I do not know. At the same time it is evident that such information would be valuable, as it would enable cultivators sometimes to avoid those soils that predispose to canker. I would not, however, purposely avoid a soil because Maréchal Niel cankered in it, as I do not think that is any guide. Canker is undoubtedly an inherent constitutional defect in the Maréchal, and we must make the best of it; but when the same disease attacks other sorts, it seems to me that it is time to endeavour to trace the cause. It is well known that there have been at different times many remedies suggested for the cure of canker on the Maréchal Niel Rose. A few years ago scoring the stem with a knife for the purpose of allowing the bark or rind to expand more freely was given as a certain cure, but I have proved that the remedy is of no value whatever. I do not believe there is any remedy to prevent canker attacking the stem near the surface soil, but I do believe that above that point it is possible to stop it by preventing mildew from injuring the tender bark of the young shoots. I am satisfied that when the growth is attacked by mildew and the fungoid growth is allowed to remain long enough to do its work, canker frequently develops upon the parts so affected.

J. C. CLARKE.

Market flowers and fruits.—Chrysanthemums are very abundant and cheap, but the quality generally does not seem to be up to the usual standard. All the colours that are to be found among Chrysanthemums are represented in Covent Garden, but certain shades of yellow are most called for. A clear lemon-yellow is in high demand just now. Among whites, Mlle. Lacroix

is in high favour with the florists. Anemones, including the brilliant A. fulgens, are coming in in quantity from the south of France, also Violets and the Acacia called mimosa in Covent Garden. This is now very cheap, and has this year come in some weeks earlier than usual. The little Gladiolus-like Schizostylis coccinea seems to be growing in favour. In brilliancy it is only equalled by zonal Pelargoniums, which are remarkably fine and abundant for the time of year. Roman Ilyacincths are very good. Tea Roses from France are sold at about sixpence a dozen, and home-grown Van Thol Tulips are finer and cheaper than is usually the case in December. Grapes continue to be cheap. Black Hamburgs are over, to the regret of fruiterers generally, who prefer them to the tough-skinned Alicante, which forms the bulk of the supply from this time forward. Gros Colman is also in the market, but not plentiful as yet. St. Michael Pines are very fine, and so cheap, that retailers can sell them at about three shillings each. The best English Apples, such as Wellington, Ribston Pippin and Blenheim Orange, are disposed of largely at fair prices, but inferior kinds make very little, retailers showing a decided preference for the American Apples.—J. C. B.

Carnation Horace is one of the finest winter-flowering Carnations we have. It was sent out in 1892, received a first-class certificate at the Chiswick trials, and is in every way satisfactory. The colour is a rich scarlet, in the way of Winter Cheer. I like it better than the latter; it is stronger, and I think a little more free-flowering. This grand Carnation will certainly be very popular as soon as it is better known.—R.

ORCHIDS.

SPOTTED FORMS OF ODONTOGLOSSUM ALEXANDRÆ (CRISPUM).

I HAVE just received from Mr. Hunter, of Edinburgh, a fine spike of what appears to me to be the typical form of the plant figured by Bateman before he recognised this as being the plant that Lindley had named *O. crispum*. The spike bears fifteen flowers, which are pure white, flushed at the back slightly with purple and with a few spots of chestnut upon the lip. With this there comes a fine flower of a form which was named by Professor Kranzlin in the early part of the present year *O. crispum* (Hunter's var.). It certainly is very beautiful, the flowers being large and full, the sepals nearly as broad as the petals, the latter slightly toothed, ground colour white, all heavily spotted with chestnut, leaving the tips clear. The lip, which is of the true typical character, is white, heavily blotched in front with the same colour as the petals. These fine spotted varieties have been mostly found in the neighbourhood of Pacho, where Blunt first found them, and from whence so many of the fine forms sent out by Mr. Shuttleworth also came. The following are the best and most distinct of the many fine forms of this plant:—

O. ALEXANDRÆ COOKSONI is a fine form, which, like Hunter's variety, has the ground colour pure white, heavily blotched and spotted with brownish crimson. The lip is also of the same colour, having in addition a golden yellow crest.

O. ALEXANDRÆ DUVALI.—This is a very fine form, having large flowers, which are heavily tinged with purple on the outside, the inside of the flowers being pure white, the sepals and petals each bearing one heavy blotch of rich chestnut in the centre. The lip also has one bold blotch of the same colour in front and some few smaller ones round the crest.

O. ALEXANDRÆ MUNDYANUM.—This is a fine variety, which I saw a year or two ago flowering in the establishment of Mr. Sæder at St. Albans.

It is a noble flower, heavily splashed on the back with magenta-purple, in front white. The sepals and petals are all heavily blotched with reddish purple, while the lip also is much spotted with smaller spots. It is one of the finest forms of this truly beautiful plant.

O. ALEXANDRE WARNERI.—This, although one of the early forms, is amongst the best of the spotted kinds. It is a bold and handsome flower, round and full, measuring upwards of 3 inches across. The petals, much broader than the sepals and prettily toothed, are of the purest white, whilst the three sepals have each some six or eight medium-sized spots of rich cinnamon grouped in the centre, the lip being white, with a yellow crest and spotted with the same colour as the sepals. This bears a raceme of some ten or fifteen flowers, which are tinged with rosy carmine behind and make a superb display.

O. ALEXANDRE TRIANE is a somewhat similar form, but with smaller blooms, and the sepals are not so distinctly spotted, but more blotched.

O. ALEXANDRE STEVENSI is also a very fine form, marked very much in the same way as Hunter's variety, but the spotting is heavier and the colour more decided. The form known as

O. ALEXANDRE GUTTATUM has a smaller flower with narrower sepals and petals, which are all prettily undulated, with a bright paper-white ground, the sepals being heavily blotched and spotted with bright chocolate. The petals have one solitary spot on each; the lip also is densely spotted.

O. ALEXANDRE VEITCHIANUM is a grand form, in fact the best of all. The flowers are large, the sepals and petals broad, beautifully toothed and undulated, the margins pure white, with a feathery zone of rosy purple, blotched with very dark crimson. The large lip is white with a yellow centre, slightly spotted. One plant of this magnificent variety has only been found, and is now in the collection of Baron Schröder, The Dell, Egham, where it is a fitting companion to the superb form of *O. Pescatorei Veitchianum*.

There are numbers of spotted forms, but those noted above are, I consider, the best. *Odontoglossum Alexandre* does best in pots that are thoroughly well drained, using for soil good brown upland peat fibre. The plants, which should be elevated above the rim of the pots and be potted firmly, should be surfaced with some chopped ends of living Sphagnum and kept in a cool house, the best being one with a northern aspect. Much controversy has been raised on this question, some persons preferring a house with a southern aspect and endeavouring by shading to counteract the sunlight. This, however, signally failed. The best lot of *Odontoglossums* and other cool Orchids which I have ever seen was in the late Mr. A. J. Buchan's garden at Southampton. The plants were grown in a north house, kept nicely moist, with a free circulation of air. The temperature seldom fell below 48°.

W. HUGH GOWER.

Saccolabium giganteum.—H. Jameson sends me two varieties of this species. We are told that this is a very common plant in Cochin China, and also in the Burmese territory. It first flowered in the Bishop of Winchester's garden at Farnham Castle under the name of *Vanda densiflora*. It was then a very rare plant, but recent importations have made it of late years very common. Of the forms sent, No. 1 appears to be the variety known as *illustre*, having larger flowers, and, as "H. J." says, "on the fully formed spike the flowers are widely separated." It has a very bright coloured lip, with larger and brighter coloured spots on the sepals and petals. This form was introduced by M. Linden about ten years ago. No. 2 seems to be the ordinary typical plant, which has bright rich purple spots on a waxy white ground. I cannot help thinking that the cause of this shortening

of the spikes of bloom arises from some maltreatment when they are developing. The same thing has occurred with me in several species of this family, but mostly in the case of *S. giganteum* and *S. violaceum* when they flowered through the winter months, at which time there is more dryness in the atmosphere than in the summer months, when most of the other species bloom. I cannot but think it arises from this cause, for some plants which I had removed to a hotter and moister situation all developed spikes a foot or more long, whilst the majority of those left in the ordinary atmosphere of the house produced many short and deformed ones such as those sent. I would advise "H. J.," or anyone else growing this species, to treat it to a greater amount of heat and moisture as soon as the spikes of bloom begin to appear.—G.

Cypripediums—"T. B." sends me several flowers of Lady's Slippers for a name. No. 1 appears to be a very good form of *C. Meirax*, which was first obtained by Mr. Robert Warner. No records have been kept of its parents, but evidently *C. venustum* was one of them. No. 2 looks like a good form of the Veitchian hybrid *C. radiosum*, which has for its parents *C. Lawrenceanum* and *C. Spicerianum*. It has a pure white dorsal sepal, the base stained with apple-green, with a broad purple stripe in the centre and stripes of a paler hue on either side. The petals are deflexed and undulated, light green with brownish veins, lip brownish purple suffused with pale green. No. 3 is a magnificent form of *C. insigne punctatum violaceum*; it is not new, but it is one of the very best of the old forms. It was figured in THE GARDEN, Vol. XXI., t. 444. No. 4 is another hybrid raised by the Messrs. Veitch, called *C. vernixium*, a cross between *C. Argus* and *C. villosum*. It is a pretty flower, but now it has been superseded by many other kinds.—G.

Trichosma suavis (*J. Forbes*).—Thanks for the nice bunch of this pretty little fragrant Orchid, which was formerly named *Ceclogyne coronaria* by Lindley, and *Eria coronaria* by Reichenbach. It is a curious little plant, growing about a foot high, and being quite destitute of pseudo-bulbs. The sepals and petals are waxy-white, the lip being also white streaked with purple. There are several varieties of the plant, the flowers of some of them being much darker than others. I have seen a form in which the petals were marked the same as the lip. This was in the collection of Mr. Tautz when he had his fine collection at Shepherd's Bush. It has been grown in the Cattleya house by a great many people, but as the plant was found at a high elevation on the Khasia Hills, I like to grow it with the *Odontoglossums* of the crispum group. It should be potted in peat fibre and chopped Sphagnum Moss with which has been mixed a little turfy light loam.—G.

Lælia amanda.—C. Giles sends a flower of this plant saying it appears to be quite new. This plant has already been named by Reichenbach, and it obtains the name in some gardens of *Cattleya Rothschildiana*. It was introduced by Mr. Wm. Bull, of Chelsea, about twelve years ago, and it is a supposed natural hybrid between *Cattleya intermedia* and *Lælia crispa*. It is a very choice variety, having large flowers some 6 inches across, the sepals and petals rosy lilac, the lip being of the same colour in front, veined with a deeper colour, becoming rosy purple towards the base. It is of Brazilian origin.—W. H. G.

Lælia Marriottiana.—This is a very welcome addition to the winter-blooming species and seems intermediate between *L. autumnalis* and *L. furfuracea*, although imported by Mr. F. Horsman, of Colchester, as *L. majalis*, which it certainly resembles somewhat in habit of growth. The silver-skinned pseudo-bulbs are as large as pigeons' eggs and bear two slightly twisted green leaves. The peduncle is 18 inches to 2 feet in length and bears from three to five flowers at its apex, the weight of which causes the scape to arch over very gracefully. The sepals are ovate-lanceolate in form, 2 inches or so in length by half an inch to three-eighths of an inch wide; petals 2 inches long,

rhomboidal in form and overlapping the upper sepal. Both sepals and petals are of a bright soft purple-rose colour, the lip being ivory white, the connivent side lobes tinted with rose-lilac, the central lobe being deep rose-purple. The crest of two erect plates on the disc of the lip is white, having a yellow blotch or suffusion near its termination. Inside the base of the lip and near its apex there are a few slight purple or rosy markings, and the column is white, tinged with rose colour. It first bloomed in Sir Wm. Marriott's collection, after whom it has been provisionally named. The flowers are sweet-scented, especially at night. Its culture would appear to be similar to that required for *L. majalis*, *L. autumnalis*, *L. albidula*, *L. furfuracea* and other allied species, viz., an intermediate temperature with plenty of air and sunshine, abundance of water during growth and a cool and dry season of rest after the growth is fully made.—F. W. B.

Lycaste Skinneri gloriosa (*Thos. Hilby*).—The above is the name of the very fine variety just to hand. The flower measures upwards of 6 inches across. I have seen larger flowers. The spreading sepals are waxy white, suffused with pink, and the petals, which are hooded, are of a deep rose colour, the lip white in front, marked with rose at the sides. There are many varieties of this fine species. Mr. Skioner used to think the *Lycaste* would stand a greater amount of cold than *Odontoglossum crispum*, but it appears to thrive best and to flower more freely when treated to about 5° more heat. At least that is what I have experienced.—W.

Cypripedium Leeanaum (*G. Cooke*).—This was originally obtained between *C. Spicerianum* and *C. insigne Maulei*, and it has the pure white dorsal sepal stained with green at the base of the former parent and some of the spotted lines of the latter, the petals all more or less tawny with reddish veins slightly decurved; lip brownish purple with darker veins. This is a very free growing plant and an abundant bloomer, its bright flowers making a fine show. It likes the warmth of the Cattleya house, which I consider quite hot enough for it with a nice moist atmosphere all the year round.—W. H. G.

Cymbidium giganteum.—A highly coloured and large flower of this fine autumn-flowering plant comes to hand from "J. D." The flower measures 5 inches across, the sepals and petals being beautifully streaked with purple upon a greenish yellow ground; the large lip bright golden yellow, having a row of crimson spots near the margin. It is curious how these old favourites are obtaining a standing again amongst Orchid growers. Better varieties exist now than was the case some years ago when the flowers were much smaller and the sepals and petals were green.—W. H. G.

SHORT NOTES.—ORCHIDS.

A fine Vanda cœrulea.—"M. M." sends a very fine form of this plant. The sepals and petals measure some 5 inches across and are of a fine lavender blue, veined with a deeper colour, the small lip of a deep violet-blue. The sender says the spike had twelve flowers on it and that the plant has been grown cool, with an abundance of air.—G.

Cattleya Dowiana.—G. Kremer sends me a fine flower of this species, which has a somewhat novel appearance. In addition to the tips being tinged with purple, the veins of both sepals and petals are of a deep rosy purple. It is not new, however, as I have seen the same or similar markings upon one or two occasions, but it is well deserving careful attention.—W. H. G.

Odontoglossum Alexandræ with branching spikes.—C. Holt sends a part of a branching spike of what he thinks is a form of this species. Yes, it is a genuine typical form of the species, and a very good one, having broad sepals and petals nicely spotted. I have heard many people assert that all the branching forms are hybrids and that they are poor things, but the branch sent upsets both statements.—W. H. G.

TREES AND SHRUBS.

THE ANGELICA TREE.

(ARALIA SPINOSA.)

THERE are several of the hardier species of Aralia from China and Japan that well merit culture wherever choice shrubs are grown, and the plant illustrated in the accompanying engraving is one of the best for certain aspects and positions. Its light and feathery pinnate foliage, reminding one a little of that of the Ailantus or of Dimorphanthus mandschuricus, is different in effect from that of either, and most effective as seen backed by foliage of a dense and darker green hue such as that of evergreen Oaks or Hollies. Dimorphanthus mandschuricus is really a geographical form or variation of Aralia chinensis. A. spinosa is a native of North America and is much hardier than A. chinensis (=A. canescens of gardens). The specimen of A. spinosa here shown was grown in Devonshire, and seems to have a Yew tree or some other conifer as a background. In the College Gardens at Dublin there is a very fine specimen of A. spinosa, into the centre of which a bird-sown green Holly bush has grown so as to conceal the naked and gnarled stems of the Aralia in a pretty way. The general appearance is that of a Holly bush with Aralia branches protruding in all directions, and in August or September, when the point of each thorny shoot bears a panicle of its ivory-white flowers above the Palm-like tufts of leaves the effect is a very distinct and effective one, and quite unlike anything else in the way of flowering shrubs or small trees. Another species of Aralia, now placed by modern botanists in the genus Fatsia, is A. Sieboldi from Japan. This has the advantage of A. spinosa in being evergreen and not deciduous, as is that species.

In all mild and sheltered localities A. Sieboldi well deserves a place as being one of the largest leaved of all our evergreen shrubs. The one secret as to the successful growth of A. Sieboldi, however, is to plant it behind a north wall or in shade, and not in the full sunshine. One of the finest plants I know of A. Sieboldi grows on a rockery on the north side of a house in the Northumberland Road, Dublin, and as it has a dense background of Ivy and is near to the public road, it attracts the attention of many passers-by, and is an object lesson to all interested in the planting of sheltered town gardens with a northern exposure. Here I had failed with A. Sieboldi until Mr. Woodall, of Scarborough, who has travelled in Japan, kindly told me of this plant having such a great liking for a cool shady corner and not a sunny exposure. A. spinosa, on the contrary, cannot well be placed in too sheltered and snug a position, although it withstands wind well if it gets plenty of sunshine. Its quaint habit and effectiveness are well shown in the illustration, and those who plant for effect cannot well afford to disregard its unique character of growth.

F. W. B.

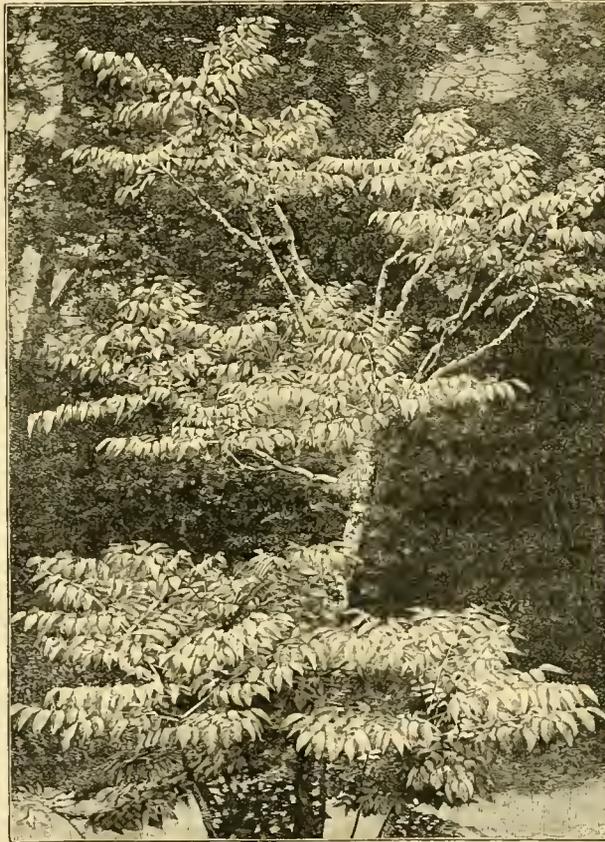

Mr. Mayor, of Paignton, Devon, who kindly sent us the photograph from which the engraving was made, sends us the following notes concerning it:—

The tree was planted long before I came here, and is nine years old. It seems rather a slow grower, is entirely deciduous, unlike A. Sieboldi, which is only partially so. It is one of the last to break into leaf and first to drop its foliage, which, however, assumes beautiful autumnal tints. It sends up suckers freely, which help to hide the stem. Together with other members of its own family, Dracaena australis, Chamærops humilis,

Phormium tenax, Eucalyptus globulus, and Bambusas of sorts, it gives to a garden a sub-tropical appearance rarely seen in cold, clayey districts, but common in Devon and Cornwall.

Cornus sibirica Spathi is a variegated shrub that has withstood well the recent hot summer. This is not always, unfortunately, the case with variegated things, the sun burning the leafage in such a way as to quite disfigure the shrub. C. sibirica Spathi is a comparatively new variety, the leaf golden yellow in colour, except an irregularly shaped green blotch in the centre, which well sets off the golden shade. It is a great point in a variegated shrub that its leafage is even richer under a burning sun, as this year.

The Sweet Bay in Scotland.—At Tongue House, on the west coast of Sutherland, at one time the residence of the Lords Reay, now the

Aralia spinosa. Engraved for THE GARDEN from a photograph sent by Mr. C. L. Mayor, Paignton, Devon.

property of His Grace the Duke of Sutherland—presently occupied by the resident agent, Mr. Box—there is an old garden containing many interesting plants not commonly met with. The climate is mild. I believe there is more than an average rainfall along all the west coast, but Tongue is very favourably situated in a bay, sheltered from the north by woods and rising ground, open to the south, and to the mild influence of the Atlantic and the Gulf Stream. On the front of the house is a fine old plant of Lonicera caprifolium leuca, the yellow Italian Honeysuckle, covering a considerable wall space and flowering profusely. The flowers are much larger than those of the common Honeysuckle and more pyramidal in shape. In the garden, on each side of an old doorway, two Sweet Bays are in luxuriant health. They are each 9 feet 6 inches high and 27 feet and 23 feet in circumference. They are a handsome pair, and I do not remember to have seen better anywhere in Scotland. Sweet Bays do well enough when the winters are mild,

but every few years a severe winter comes which cuts them down. It is only in sheltered, mild places, like Tongue, that the Sweet Bay grows into good specimens. It would be interesting to hear of good plants in other mild, sheltered places on the coast. In the garden at Tongue fine clumps of Schizostylis coccinea usually keep on flowering till close on Christmas.—D. MELVILLE, *Dunrobin Castle Gardens.*

USELESS AND UGLY PINES.

IN the catalogues nothing strikes us more than the number of useless and ugly Pines which are there offered for our delight. It is not only that we have to deplore the tender trees of California, which in their own country are beautiful, though, unhappily, not so in ours, but it is the mass of distorted, unnatural, and ugly forms—the names of which disfigure even the best catalogues— that is most confusing and dangerous. Of all the Pines brought to England which have become popular, the greatest failure is the Norway Spruce, which we see everywhere in Sussex and Surrey in a diseased state, save by streams or in wet bottoms. The Norway Spruce, where it does well, is a beautiful tree, and even a stately one; but we know that in nine cases out of ten in the home counties it will not grow well, although good specimens may be seen here and there in deep and moist soil. But what shall we say of its wretched varieties—dwarfed, compacted, starved, inverted? Even the careful Mr. Anthony Waterer, who knows the hardy conifer from the tender one, and many other valuable facts, puts some of these trees down as suitable for the rock garden, of all things in the world.

In one foreign catalogue we see no less than twenty-eight varieties of the Norway Spruce, in all sorts of dwarf and monstrous shapes—two of them, indeed, dignified with the name monstrosa—not one of which should ever be seen in a garden or plantation. The true beauty of the Pine comes from its size and dignity, as we see it in old Firs that clothe the hills of California or Spain or Switzerland. It is not in distortion or in green pincushions we must look for the beauty of the Pine, but rather in storm-tossed head and often naked stem, and all these ridiculous forms should be excluded from gardens and from nursery catalogues, too.

Another most unfortunate tree in this way, as helping to fill our gardens with graceless things, is the Western Arbor-vitæ (Thuja occidentalis). This, which is a very hardy tree, but never a dignified one, even where it grows in the north about Lake Superior and through the Canadas, is, unhappily, also hardy in our gardens. We have not the same objection to make against it that we have against the Spruce, because it really does thrive and form a hedge or tree of some size; but it has none of the qualities of a great Pine. Yet we regret to see this in one catalogue in no less than twenty-three forms, all dignified with Latin names, all of them absolutely useless

for the true pinetum, and though they may have some value as bosses of green in the garden, they are confusing to those who wish to get the true Pine.

There are beautiful things, new and old, worthy of the name of Pine without filling our gardens with monstrous absurdities, many of which are variegated. Of all the ugly things we know, nothing is worse than the variegated conifer, which usually perishes as soon as its variegated parts die. It often seems a bush full of wisps of hay.—*Field.*

THE PHILLYREAS.

IN some books several of the Phyllyreas are regarded as distinct species, but by Loudon they are referred to in the following terms: "All the kinds in cultivation are nothing more than varieties of one species." Considering that the most distinct of all the Phyllyreas—*P. Vilmoriniana*—was unknown to Loudon, most people will, I should say, agree with the above quoted remarks, as there is no very wide difference between the numerous forms in cultivation, while seedlings from any of them may vary a good deal from each other. They are certainly very ornamental evergreen shrubs, most of which are of a neat compact habit of growth. Their leaves are especially numerous and of a deep shining green tint. For some reason or other they are not often planted; why it is difficult to say, as the number of hardy evergreen shrubs is somewhat limited; indeed, judging by the way Laurels are grown almost to the exclusion of other shrubs, one would think that there was little else but Laurels at the option of the planter. There seems to be an impression that the Phyllyreas are tender, but they are certainly as hardy as many subjects whose ability to resist our winters is never questioned. *P. media*, which is considered by Loudon to be the typical species, was, according to the same authority, introduced in 1597, and several of its varieties about the same time. They are all natives of the south of Europe. The wood of these Phyllyreas has been recommended as a substitute for Box for wood engraving, the larger size being one especial point in its favour. The most recently introduced species is *P. Vilmoriniana*, also known by the specific names of *laurifolia* and *decora*. It is very distinct from the older forms, the largest leaves being nearly 6 inches in length, of a dark green tint, and leathery in texture. A specimen of this at a little distance bears a certain amount of resemblance to a Portugal Laurel. The flowers of this are white, sweet-scented, and about May borne for a considerable distance along the shoots. They are succeeded by small Plum-like drupes, which when ripe are quite black. As above mentioned, all the Phyllyreas are as hardy as many subjects that are not considered at all tender; still, an exceptional winter will in some cases injure them, but *P. Vilmoriniana* has passed unscathed through our most severe winters. There must have been some thousands of this sold within the last few years, so that it is now tolerably common. Like its allies, this Phyllyrea can be readily grafted on to the Privet, but plants obtained in this way are not always satisfactory, and as seeds are frequently ripened and cuttings strike root without difficulty if kept close in a cold frame, there is no need to increase the Phyllyrea by grafting. T.

Primula Forbesi.—This new and charming species was in bloom recently at Chiswick. Visitors to the meeting of the Royal Horticultural Society on November 14 will remember that it was shown and certificated, but the plant had been previously exhibited by M. Vilmorin, of Paris, at the December meeting last year. We scarcely think that *P. Forbesi* will become a very popular plant, but it is worth a place in all good collections. It was found both by the Abbé Delavay, a French missionary, in Yunnan, China, where it grows in marshes and rice fields, and by Col. Sir H. Collett, who discovered it in Eastern Burmah, where in the Shan States it

grows at a considerable elevation. It is quite a new plant, having been introduced in 1891. The flowers are produced in abundance in verticillate whorls, an almost perpetual succession being maintained. In form one may compare them to those of *P. farinosa*, and the colour is pleasing—rich rose-lilac, set off with a small deep orange-coloured eye. Apparently this species is easily grown. The leaves are small and quite overshadowed by the slender stems, which produce from three to six whorls.

FERNS.

FERNS AS TABLE PLANTS.

FERNS as plants for the dinner table as well as for other uses in vases have scarcely held their own since Palms, Dracenas, Aspidistras, Crotons and Aralias have become so general. I cannot really see, however, why this should be the case. There are many Ferns which are admirably suited for use in these ways, some of which are quite unique in their way. Take for instance a well-grown Silver or Golden Gymnogramma, or the same of *Adiantum Farleyense*; these are each quite distinct from anything else that is usually grown or accepted as table plants. In many ways Ferns are exceedingly useful when in pots from 3 inches to 6 inches in diameter. In order, however, to have such plants in the best presentable condition they should not be crowded together or be in any way overshadowed by other and larger plants. What is wanted is a symmetrical well-balanced plant not in any case drawn on one side; such a plant upon a table would look far from well. Again, plants of dense growth are not so desirable on the whole; for instance, a plant of *Adiantum Farleyense* or of *A. cuneatum* when in this condition (the whole of the surface of the soil being probably covered with rhizomes) would present too heavy an appearance. Plants in order to be the best suited for table uses should be grown on from the seedling state or from quite small divisions, so that the growth is concentrated in the one crown. Thus *Adiantum Farleyense* (again quoted as an example) if grown on from a single crown makes a far better decorative plant than if there be a mass of crowns in the one pot. It is a fallacy to suppose that when a plant has been once grown into what is desirable that it can be kept so for any great length of time. The *Adiantums* particularly will increase their crowns; thus the dense mass of smaller fronds results in due course. There are not in my opinion any Ferns better suited for the dinner table than the *Gymnogrammas*; both of the two well-known colours, the silver and the gold, harmonise well with other surroundings upon a well-appointed table. Take, for instance, the best of the silver section, *G. peruviana argrophylla*, grown on the system advised from the seedling state with a good strong crown, so as to secure fairly large arching fronds; no better plant could be chosen where blue and gold prevail in the other accessories. Take again *G. Laucheana* or *G. Alstoni* as representing the golden kinds; these suit the silver plate admirably and do not in any way look heavy or dull. Quite distinct from these is *G. schizophylla gloriosa*, a lovely variety when well grown and when displayed to the best advantage; its long drooping fronds make it just the plant for a tall silver vase similar to those used as wine coolers. These are about the best of the *Gymnogrammas*. Of the *Adiantums*, besides *A. Farleyense* and *A. cuneatum*, note should be made of *A.*

Collisi, which is at its best during the autumn, the fronds then assuming a delicate bronzy tint. *A. decorum* is excellent from single crowns, so also is *A. concinnum*, a Fern that is not nearly enough grown; this dies down in the autumn. *A. gracillimum* is another suited for the purpose, and the same applies to *A. mundulum* as well as *A. scutum*. Several of the *Pteris* family are strongly to be recommended; *P. argyrea* is a case in point in which the advantage of a single crown is well displayed. *P. tremula* is another excellent table Fern, being essentially useful during cold weather by reason of its hardiness. *P. tremula elegans* is a more slender growing form of the preceding, with crested pinnae. *P. cretica Mayi* is the best of this species as a table plant, being very light and elegant in its habit of growth. The old-fashioned Ribbon Fern (*P. serrulata*) should not be overlooked, nor any good forms of the crested varieties of this species. Of the *Aspleniums*, one of the best for the purposes under consideration is *A. laxum pumilum*, which has finely cut fronds of a pale glaucous green, being also a compact growing plant. *A. cicutarium* is a beautiful variety; it is not sufficiently known; the growth is very light and somewhat slender, but the fronds are quite self-supporting. *A. nobiliss* whilst in a small state is another capital variety. This gives about a score. Others could, of course, be named, but those quoted will give a sufficient indication of what is best suited to use as a table Fern. Plants intended for this purpose should be set aside so as to preserve them intact. They should not be overpotted in any case; this is a mistake. Where it is possible a marginal line of *Selaginella denticulata* may with advantage be pricked in around the rim of the pot, but its growth should not be allowed to exceed reasonable limits. Ferns as table plants during the winter can be strongly recommended; they do not take up much room, hence in removal from their growing quarters they may easily be placed in boxes to secure them against any injury. FILICES.

Acrostichum drynarioides.—In general habit this much resembles the *Aglaomorpha*. It is, however, quite distinct botanically; the spore cases, instead of being in round masses, are continuous, and cover the whole of the under surface of the long narrow terminal segments of the frond. As in *Aglaomorpha*, the lower portion of the frond is always barren and much broader. It is a most desirable Fern, but not nearly so well known as it deserves to be. It is found in Penang and the Solomon Islands, and will succeed well under the same treatment as recommended for *Aglaomorpha*. I may mention that the barren fronds so closely resemble those of *Polypodium heracleum*, that at first sight one may easily be mistaken for the other; the fructification is distinct, and adds much to its beauty.—A. HEMSLEY.

The Bear's-paw Fern (*Aglaomorpha Meyeniana*).—This beautiful Fern, to which a first-class certificate was awarded by the Royal Horticultural Society on November 28, is well worthy of the honour. The name was originally applied to it by Schott in 1835. In 1836 Prezl named it *Psygium*, and in Hooker's "Species Filicum," it is included with the *Polypodiums*. It is a native of the Philippine Islands. The fronds are produced from a short thick rhizome which is covered with brown woolly scales, which have given rise to its popular name, Bear's-paw Fern. In well-matured plants the fronds are from 2 feet to 3 feet long, the lower part pinnatifid, and when fertile the upper portion is pinnate and contracted, giving it a striking appearance; the fronds are of good substance. This distinct Fern thrives well in a moderate stove temperature. It may be grown in pots or as a basket Fern. I find the latter suits it best. When grown in pots the pot should

be filled up well so as to keep the rhizomes well above the rim. Rough peat and loam with plenty of sand, and good drainage, or some Sphagnum Moss may be used for potting. Plenty of moisture at the roots and a humid atmosphere are essential. It may be increased either by division or from spores. Seedlings, which are very slow at first, but which after they once get a good start grow freely, make much the best plants, as the rhizomes branch out more.—A. HEMSLEY.

TROPICAL FERNS AT KEW.

THE true Fern lover may at Kew not only find the tropical Ferns well grown and in as healthy a condition as can be wished, but he also will have many opportunities of satisfying himself that the most has been made of the peculiar habit of many of them. These plants have been carefully studied, their natural propensities have been particularly noticed and then very properly acted upon. Every possible advantage has been taken of the predisposition of many of the species, and it is owing to these repeated observations that we note the pillars or columns in the warm house beautifully clothed with the elegant foliage of various species of Lygodiums, the shoots of which attain extraordinary dimensions and extend from one column to the other, forming natural and very graceful festoons. The species employed for that purpose is the beautiful, strong-growing *L. dichotomum*, a native of Hong-Kong, the Philippines, Ceylon, and the Malay Islands. Its leaflets, 8 inches to 12 inches long and nearly 1 inch broad, are of a dark green colour, leathery texture, and of a bright shining nature. *L. pinnatifidum*, also a native of the Philippines, Ceylon, the Himalayas, and North Australia, is also a most useful plant for that particular purpose. Although somewhat in the way of *L. dichotomum*, it is readily distinguished from that species through the pale colour of its foliage, which is of a softer texture and also of a more or less hairy nature. Another very striking species is *L. japonicum*, which in gardens is usually found under the name of *L. scandens*, and which is extensively grown for the value of its long, slender, flexible shoots for decorations. The foliage of this species, though smaller in all its parts and of a more papery, tender nature than that of the foregoing, is remarkably pretty and produced in great abundance. Besides the beauty of their barren fronds, Lygodiums are also particularly attractive through their singular and pretty mode of fructification, which is disposed in the form of spikes, either in separate leaflets or in lax rows along the edges of the leafy ones. But it is only when grown to a large size and usually when planted out that these beautiful Ferns, which thrive apace in a compost of fibrous loam, peat and sand in equal parts, show themselves to advantage and produce their fertile fronds in quantities sufficient to attract attention.

Another mode of furnishing the space between the glass roof and the plants below consists in the use of

HANGING BASKETS

of various sizes. In that respect, again, very good hints may be taken from the plants employed in the tropical ferneries at Kew, where, besides the conventional *Aspleniums*, *Davallias*, and *Nephrolepis*, one cannot fail to admire the huge baskets of *Adiantum cuneatum grandiceps*, a beautifully crested form, of garden origin, of our common *A. cuneatum*, and particularly well adapted for this mode of culture through the elegantly drooping habit of its fronds, which is the result of the presence of heavy tassels situated at their extremity. *Adiantum Moorei*,

better known in commerce as *A. amabile*, under which name it was sent out by Messrs. J. Veitch and Sons some twenty years ago, is another subject of great beauty; this lovely species, native of Peru, is provided with slender underground rhizomes, which, when the plant is grown in baskets, protrude in every direction, and from which its elegant pale green fronds are produced in great abundance. The lovely *Gymnogramma schizophylla gloriosa* is also well represented at Kew, where very handsome baskets of it may be observed in various parts of the warm house—the finely-cut lace-like foliage of that beautiful Fern, native of Jamaica, forming a most pleasing contrast with the neighbouring plants, having coarser or less divided fronds. It may not be out of place to remind the reader here that this beautiful Fern thrives best in a light compost of fibrous peat, chopped Sphagnum, and silver sand in about equal proportions, and that this being a soil of a very open and porous nature, abundant and frequent supplies of water at the roots are required at all times of the year, without which treatment its beauty soon fades. *Asplenium longissimum* is another Fern which, when grown in baskets, usually attracts the attention of the visitor, and it must be admitted that its culture in private establishments is not nearly so extensive as it really deserves to be. This beautifully pendulous species, native of Penang, Java, Borneo, and the Mauritius, is, of all known *Aspleniums*, the one best adapted for growing in baskets of large dimensions; its very elegant fronds, each 2 feet to 3 feet long and provided with leaflets 2 inches to 3 inches long, are abundantly produced from a thick and slightly creeping rhizome, and being of an evergreen nature, the plant is furnished at all seasons with long lasting fronds of a dark green colour and of a shining nature. They usually produce at their extremity young plants, from which it may easily be increased. We have in *Selaginella Galeottii* one of the most beautiful plants adapted for growing in hanging baskets in a warm house where the atmosphere is tolerably humid, and nothing can be more ornamental and at the same time of easier culture than this lovely species of a slender nature and most elegant habit, of which magnificent baskets, perfect balls of verdure, captivate the attention of the visitor in the tropical fernery at Kew. It is a native of Mexico, producing trailing stems 1 foot to 2 feet long, from which its finely cut foliage of a bright green colour is produced in great abundance. Its propagation, like that of other *Selaginellas*, is readily effected by means of cuttings, and all it requires is an abundance of water at the roots all the year round.

Among the most striking Ferns which are grown in pots, we may mention, besides the highly ornamental *Marattias* with their massive fronds of a nature and of a habit totally different from other Ferns, some really grand specimens of the following

LARGE-GROWING KINDS:

The rare *Acrostichum aureum*, a beautiful semi-aquatic Fern of large dimensions, found in a wild state in swampy places all over the tropics of both hemispheres; *A. drynarioides*, from Penang and the Solomon Isles, and *A. osmundaceum*, a species from Ecuador and South Brazil, and perhaps the handsomest of all the known *Acrostichums*. E. J. Lowe states ("Ferns British and Exotic," vol. vii., p. 151) "that it climbs more than 20 feet up trunks of trees," of which it is said to eventually take entire possession. *Blechnum vulubile* is a most singular Fern of a distinctly climbing nature. It is a native of the West Indies,

Brazil and Peru, and from its outward appearance greatly resembles a gigantic growing Lygodium. The uncommon and always beautiful *Brainea insignis*, from Hong-Kong, is represented at Kew by several remarkably fine specimens, their heads of foliage being well proportioned to the dimensions of their trunks, which are of a comparatively thick nature and very seldom straight. *Lindsaya*, or *Davallia retusa*, under which name it is better known in gardens, is also in grand condition, the pale green colour of the leafy portion of its beautiful fronds forming a striking contrast with the claret colour of their stalks. The Malayan *Didymochlena lunulata*, the deservedly popular *Microlepia* or *Davallia hirta cristata*, various *Gleichenias*, mostly of Australian origin, *Lomarias*, and a unique specimen of the curious upright-growing *Polypodium irioides*, whose home extends from Northern India to Fiji, New South Wales, Zambesiand, and the Guinea coast, are also plants which never fail to attract the attention of the visitor. The same remarks apply with equal force to the beautiful *Acrostichum* or *Stenochlena scandens*, the majestic *Pteris moluccana* with elegantly pendulous ample fronds, and many other more or less rare and distinct kinds too numerous to be enumerated here. Among the

SMALLER GROWING FERNS

of special interest we note the plain-leaved miniature tree-like *Asplenium hjiense*, the transparent and filmy-looking *A. resectum*, and the extraordinary *A. scandens*, of most peculiar climbing habit; the diminutive and rare *Cassebeera triphylla*, the pretty *Cheilanthes farinosa*, and *C. (or, as it is better known in gardens, Adiantopsis) radiata*, the curious *Pteris ludens* and *P. sagittifolia*, besides a host of other species the names of all of which cannot be given here.

One of the principal features in the tropical ferneries, and one which adds great charm to the place, is the mode of culture adopted for *Platyceriums*, which are planted in cork, built so as to imitate a tree on which *P. aethiopicum* or *Stemmaria*, Hilli, Willincki, and the magnificent *P. grande* all appear to be in as natural a state as could possibly be devised

OBSERVER.

Four good white **Crocuses** in flower now are Boryi, with a few purple lines on the perianth segments, a golden yellow stigma, and white anthers; *Cartwrightianus albus*, pure in colour with a blood-red stigma and yellow anthers; *hyemalis*, with a few dark lines on the outer segments, a much divided stigma which looks like a little tangle of fine gold wire, and black anthers; and *Obesi*, with a single narrow purple line along the back of each perianth segment, a much divided deep orange stigma, and black anthers. They are all strong-growing, very hardy kinds. The recent sharp frosts appear to have done them no harm. *C. Imperati* opened its first flowers on Nov. 28, the earliest date I remember.—T. SMITH, *Newry*.

Carnations (Malmaison) at Whittinghame.—I herewith send you a photograph of a portion of a house filled with the deep pink Malmaison Carnation. The house contains over 300 plants, a large proportion of them being in 11-inch pots and the remainder in 6-inch pots. The photo was taken at the end of October, and it will be seen that the plants are partly in bloom. The large plants are now (end of November) in full bloom, each having from eight to twelve flower-stems, with flowers almost equal in size, but deeper in colour than those produced during summer. The layers were put down in June, 1892, potted into 3-inch pots when rooted, shifted into 6-inch pots in October and again into 11-inch pots in February. They flowered in due course during May and June, were

turned into cold frames until the middle of October and then housed as shown; consequently they have flowered twice during the year. The smaller plants are layers of the present year, but put into 6 inch pots as soon as well rooted and housed along with the large plants. Of this kind we have nearly 1000 either in bloom or throwing up their flower-stems, so we shall not lack plenty of flowers all winter and spring. The plants, large and small, are in robust health.—JOHN GARRETT, *Whittinghame, East Lothian.*

THE ROCK GARDEN.

CHOICE ALPINES AND OTHER PLANTS SUITABLE FOR THE ROCK GARDEN.

HAVING described the different methods of constructing rocks for various purposes, and having also dwelt on the planting of them, I will now enumerate the plants themselves. I will confine my remarks about plants chiefly to the most practical mode of cultivation, and the relative positions such plants should occupy in the rock garden, limiting botanical distinctions to a mere statement of size and colour in the case of plants not so generally known, and omitting descriptions altogether in the case of those well known. Neither can I profess to give anything like a complete list, but the plants here enumerated are almost without exception only such as have come under my own observations, and which I have repeatedly planted in rock gardens of every description.

In planting a rock garden it is not sufficient to know that this or that plant will grow to such and such a height or that the flowers are of such and such a colour, but the probable behaviour of the plant after planting is of the utmost importance. It is necessary to know whether the plants will spread quickly or slowly, whether they may be planted close together or should be kept far apart, whether growing downwards over stones or upwards would show the plant to the best advantage, whether a position on level or sloping ground would suit it best, or whether shade or bright sunshine would be most congenial to its existence, &c.

Although localities differ, and plants doing well, perhaps, in a certain position in one particular place may be found in a less flourishing condition in apparently a precisely similar position elsewhere, yet some material difference will be found to exist on closer examination, and an approximate adherence to the general cultural hints here given may be of service to those who have had but a limited experience in adorning rock gardens, and may help to guard them against mistakes which would be fatal to the plants.

From the list of plants given below I have purposely excluded all those that make tall growth, also such hardy perennials as are adapted more for borders or margins of shrubberies adjoining the rock garden than for the rock garden itself. Although taller plants of exceptional grace or beauty may be well suited to adorn the rocks here and there either as isolated specimens or grouped together, I propose to deal with these separately later on, and I will here deal almost exclusively with plants growing only a few inches in height.

SMALL PLANTS OF SLOW GROWTH SUITABLE FOR THE MOST SELECT PART OF ROCK GARDEN.

When planting a rock garden it is often difficult to know what to select from the enormous number of varieties. Hand-books and catalogues often give descriptions of plants which

although perhaps strictly correct, leave the inexperienced amateur in great doubt whether this or that plant is suitable for his purpose. The consequence is that neat and choice plants are too often killed by the more rapid encroachment of their neighbours of coarser growth. It is the grouping together of plants which presents the greatest difficulty, because, as a rule, too little is known of the mode of growth of the plants used and the space required by them. Even among plants only an inch or 2 inches in height some would cover a square yard of space in the same time that other dwarf plants would cover a square of scarcely 6 inches. I will, therefore, endeavour to enumerate the principal kinds of plants which are suitable for the most select part of the rock garden, and spread so slowly that they may be safely planted within a foot or less of each other without the danger of overcrowding for many years at least, and as the position the plants should occupy is after all the most important point, I have enumerated them in groups according to their requirements. Particularly rare and expensive kinds may be planted singly, but that mountain

No. 1.—*Phyteuma comosum* planted sideways in vertical fissures exposed to the sun.

plants generally look most effective when distributed in irregular groups or masses has already been pointed out. In the chapter devoted to the planting of upright or abruptly sloping fissures (see THE GARDEN, Sept. 16) I mentioned the fact that these fissures should always be the first to be dealt with in planting, and I will, therefore, deal with the plants for the most select part in the following order:—

1. CHOICE PLANTS OF THE SLOWEST GROWTH SUITABLE FOR PLANTING SIDWAYS IN UPRIGHT OR ABRUPTLY SLOPING FISSURES.

(a) PLANTS FOR SUNNY POSITIONS.—*Androsace helvetica*, *A. cylindrica*, *A. pubescens*, *A. pyrenaica*, *A. sarmentosa*, *A. villosa*, *A. Chumbyi*, *A. lanuginosa*, and *A. lanuginosa Leichtlini* will be found suitable. Of these *Androsaces*, *A. sarmentosa* and its variety *A. Chumbyi* spread more rapidly than the rest, and can scarcely be called slow-growing plants, and the same might be said of *A. lanuginosa* and its variety *Leichtlini (oculata)*; they are, however, so beautiful, that they cannot be excluded from the select part of the rock garden.

A. helvetica is perhaps the slowest and neatest of all. The varieties mentioned do exceedingly well in very narrow fissures filled with one part of gritty soil to three parts of limestone. *A. villosa* prefers limestone to any other rock. *Cerastium lanatum villosum* is a neat woolly kind lately introduced from Siberia, and must not be confounded with that coarse and rapidly spreading plant, *C. tomentosum*. The genus *Edraianthus* contains many gems of slow growth, whose Campanula-shaped blue flowers are among the choicest blooms of spring. Planting sideways in upright fissures seems to suit them better than any other position. The best are *E. croaticus*, *E. dalmaticus*, *E. caudatus*, *E. graminifolius*, *E. tenuifolius*, *E. serpyllifolius*, and *E. Puvilio*. The last-named variety will stand exposure even to the full south, but *E. dinaricus* prefers a westerly aspect. *Eritrichium nanum* is another gem well worthy of the most select corner. This lovely fairy Forget-me-not, like most plants covered with hairy pubescence, enjoys a particularly dry place in winter, and is one of the choice things considered most difficult to grow.

It should be planted sideways in an upright or slanting fissure fully exposed to the sun, but protected against winter rains by a projecting ledge of rock. The pretty little Cheddar Pink (*Dianthus cæsius*) is, perhaps, the best of this numerous genus for growing in a fully exposed upright fissure. *Geranium argenteum*, with its handsome silvery leaves and pink flowers, deserves a place among the choice things, though its growth would be somewhat quicker than most plants in this list. A space where it can spread to about 18 inches and a dry sunny position should be given to it. *Phyteuma comosum* does remarkably well planted sideways, but so that the roots can penetrate deeply into the narrow crevice. The illustration No. 1 gives a good idea of the peculiar shape of the flowers. *Paronychia argentea* is a striking plant with its peculiar silvery bracts, but unfortunately not quite hardy except in the southern counties.

The number of Saxifrages suitable for vertical fissures in a sunny position is so great, that I must be content with naming only a few of the choicest and best for the select rock garden, such as *S. aretioides*, *S. Boydi*, *S. Burseriana*, *S. cæsia*, *S. Frederici Augusti (luteo-purpurea)*, *S. lantoskana superba*, *S. longifolia*, *S. paradoxa*, *S. squarrosa*, *S. cochlearis*, *S. valdensis*, *S. calyciflora*, *S. diapsenioides*, *S. Rocheliana*. Most of these choice varieties prefer a little chalk or old mortar mixed with the soil, notably that queen of Saxifrages, *S. longifolia*, the planting of which was illustrated in the chapter dealing with vertical fissures (see THE GARDEN of Sept. 16). Most of the Stonecrops spread too quickly to be tolerated in the select part of the rock garden, but I would mention two kinds of very slow growth, viz., *S. brevifolium* and *S. latinervium*. Another very dwarf and pretty kind for forming a neat carpet between taller plants is *S. dasypphyllum*. The Houseleeks, too, are excellent for filling vertical crevices fully exposed to a scorching sun. Among the prettiest of them is *Sempervivum arachnoideum*, which, though plentiful everywhere, deserves, nevertheless, a

good position. *S. Powellii* and *S. Lagerri* are somewhat rarer kinds of the same type. *S. triste* has larger rosettes, of a deep bronze colour. *S. pumilum* and *S. globiferum* are also to be highly recommended. Besides these there are many scores of other varieties, most of which, however, would be more suitable for fissures in large rocks. *Silene exscapa* is a little gem for the select rock garden. It has a dense, hard cushion of leaves and rose coloured flowers. Though enumerated among plants requiring a sunny position, it should be at least slightly shaded against the midday sun. Of the genus *Umbilicus*, *U. spinosus* must be reckoned among the tiniest mites, while *U. chrysanthus* increases in size more rapidly. Both are very desirable and well suited for the driest and sunniest position.

(b) FOR SHADY OR PARTLY SHADY POSITIONS.—The number of plants suitable for vertical or abruptly sloping fissures in those portions of the rock garden which are on the north and west side, or are otherwise partly shaded by rocks, is not so large as that of plants requiring a sunny position, but they include some of the

garden should be without. It thrives best in an upright fissure on the shady side of rocks and loves abundance of moisture, but is, nevertheless, very averse to having water resting in the centre of its rosette of leaves, and requires, therefore, to be planted sideways. *R. pyrenaica alba* is still rare and expensive. *R. Heldreichii* has hairy leaves and requires less shade and moisture than *R. pyrenaica*. *R. serbica* is distinguished by paler coloured flowers. The number of *Saxifrages* thriving in a shady position is very large, but as most of them spread too rapidly to be admitted into the select part of the rock garden, I will here only mention *S. juniperina*, *S. sancta*, *S. aspera*, and *S. pyrenaica superba* as being among the neatest kinds and suitable for upright fissures. *Silene acaulis* and *S. pumila* thrive best in a sloping fissure with west aspect. *S. exscapa* requires a little more sun.

Exceter. F. W. MEYER.

(To be continued.)

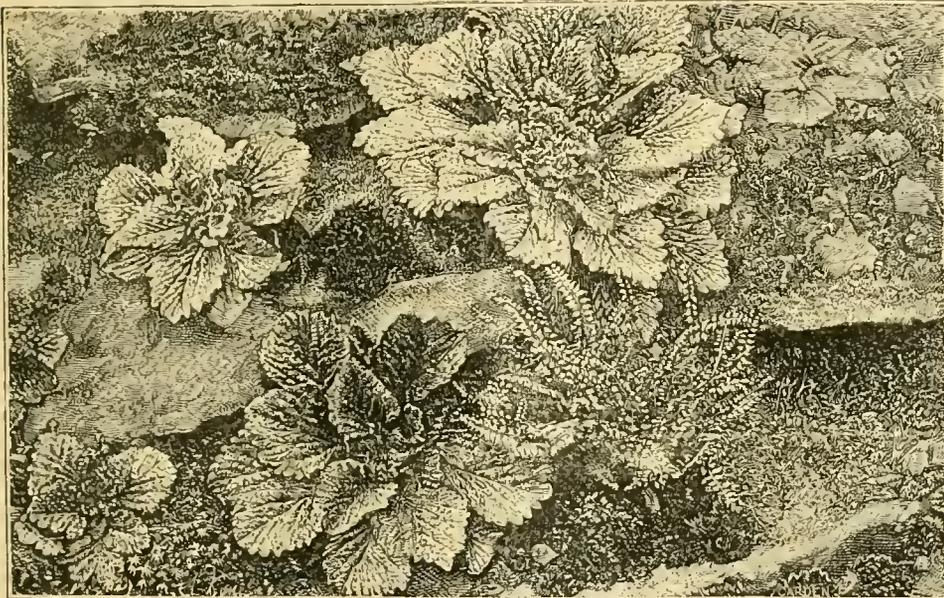

Campanula Portenschlagiana robusta.—I am inclined to think that this extra vigour is

When Peaches on open walls are attacked, the traps should be tucked in between the branches and the brickwork, and for *Chrysanthemums*, laid horizontally either amongst the growths or on the pots.—J. CRAWFORD.

CHRYSANTHEMUMS.

CHRYSANTHEMUMS AS SHOWN.

I HAVE taken the following notes of *Chrysanthemums* at various shows within the past week or two, and from quite different localities. The London season may fairly be said to have opened with the Crystal Palace show on November 3 and 4. At this exhibition the most prominent feature undoubtedly was the excellent condition in which the Japanese section was represented. No one would, I think, have ever dreamed, much less have foretold some fifteen years or so back, that the results of the present day could have been attained unto. No one can dispute that there has been a marked improvement during the past five years; what the next five years will bring forth is almost premature to forecast. There were not very many of the older varieties represented in quantity at the Palace which a few years back could have been counted by the score. There are, on the other hand, a few that promise to hold their own for years to come by reason of their most distinctive features. These are Edwin Molyneux, which I have never seen better than at this show, more especially the half-dozen which won the premier prize in a keen competition in the class for one variety only. Stanstead White in the same class was shown in beautiful form, very pure in colour, and not excessively large. Avalanche, another grand variety for almost any purpose, was hardly up to the usual standard of excellence, but there is no white in its way that can equal it. Comte de Germioy is not nearly so often shown now, but on this occasion it was in its best possible condition. Sunflower was well represented both in the half-dozen class and in the singles; it is very distinct, and its rich colour a great assistance in brightening up a stand. Mrs. C. W. Wheeler was in a few cases shown well, with remarkably broad petals. Although an excellent variety, Mme. Clemence Audiguier, of which I did not note one good bloom, was almost if not quite absent from the best stands. It is a beautiful flower when well grown and very distinct, but no doubt its height is largely against it; in my own case it was never better than this season. Val d'Andorre was hardly to be seen; I did not observe more than two good blooms. Thunberg, through being somewhat of a late variety, was not *en evidence*. Mr. H. Cannell, considered by some to be finer than the last named, was also conspicuous by its absence. Pelican, itself a late variety also, was represented by only a few. Harman Payne was, in a few cases only, shown in good condition. Of varieties introduced within the past five years there was an abundance. Etoile de Lyon was shown in better condition than usual, not so coarse or so large; it did not, therefore, stand out conspicuously by reason of its size. M. E. A. Carrière was staged in its best condition; so also was Mrs. Falconer Jameson, which has no doubt taken in a measure the place of Harman Payne. Mile. Marie Hoste is a decided acquisition, very distinct; this was also in first-rate form. Vivian Morel is another variety that will undoubtedly be seen for years to come; it was to be seen in almost every stand and in beautiful condition, a little variable in shading, it is true, but more often than not in its richest colour. Florence Davis I have seen better, but on the whole no fault could be found with its quality. Miss Annie Hartshorn was in several instances of the very best; its favourable appearance would no doubt increase its popularity. W. H. Lincoln was probably never seen finer, the blooms full and rich in colour. President Berrel (in nearly every case mis-spelt Borel) also stood out very prominently;

No. 2.—*Ramondia pyrenaica* planted sideways on shady side of rocks.

choicest kinds, of which I will enumerate a few of the principal varieties. Of the *Androsaces*, the species *A. ciliata*, *A. Lagerri*, *A. Chamejasme* and *A. Vitalliana* are the most suitable for the purpose indicated, though it must be borne in mind that none of them require shade in the proper sense of the word, but only protection against the mid-day sun. They are, therefore, admirably adapted for a position with a north-east or north-west aspect. *Haberlea rhodopensis* does best in moist peat on the north side of the rocks, as without shade and moisture it would soon shrivel up and die. Its bright rosy-lilac flowers with white throat make it a most desirable plant for the part reserved for the choicest things. *Linnaea borealis* is a minute trailer, with pretty evergreen leaves and white flowers tinted rose. A very large number of *Primulas* is most suitable for the upright or slanting fissures in half-shady positions; among the best and choicest are the following: *P. Allioni*, *P. Clusiana*, *P. denticulata*, *P. Floerkeana*, *P. glutinosa*, *P. marginata*, *P. minima*. *Ramondia pyrenaica* (see illustration No. 2) is a plant that no rock

more a matter of soil and situation than variety. Here in very sandy granitic loam it never becomes vigorous, but always remains a close tufted mass. Two or three years ago in a garden near Belfast, where the soil is stiff and cold, a bed was edged with it. It at once took so kindly to the situation as to run through and strangle the Box and grew right through the Pansies, with which the bed was planted; in fact, took complete possession. I have in my mind another garden near Dublin where it grows in the most vigorous way, making shoots 12 inches to 18 inches long. In this condition one might readily mistake it for a distinct kind.—T. SMITH, *Newry*.

An effectual trap for earwigs.—Each year these garden pests seem to become more numerous; indeed were not stringent means adopted for their eradication much valuable produce would annually be destroyed. I know of no better trap for them than the old-fashioned one, viz., short lengths of Broad Bean stalks placed in and around their haunts. If these are examined each morning they will be found to contain numbers of the insects, when they may be killed by sharply tapping the stalks on the edge of a bucket containing boiling water. If this plan is followed up, their numbers will soon be considerably reduced.

the blooms were large and massive. Turning to the varieties of 1892, no variety surpassed or even equalled Col. W. B. Smith; its appearance so strongly in such excellent condition will further increase its popularity; its colour, a light terracotta, is quite distinct, whilst the blooms are of fine proportions. It ran Edwin Molyneux very hard for the premier place in the one variety class. Lord Brooke, although not shown in such numbers as the foregoing, was nevertheless to be seen in very fine condition; it is a noble flower and of a very pleasing colour, the combination of yellow and bronze being so attractive. I am disposed to think it should be classed with the incurved varieties, however, for between it and M. R. Bahuant there is but little difference in form, the former having the broader petals. Wm. Seward, one of last year's introductions, maintains its character as one of the richest crimson coloured varieties. G. C. Schwabe has also come out well this season, and bids fair to be a useful variety. Of varieties more curious than beautiful, but little was seen of Louis Boehmer or Mrs. Alpheus Hardy; in spite of the trumpeting they received they do not maintain their popularity. Turning to the

INCURVED VARIETIES

as shown at the Crystal Palace, one would be inclined to think that the season had not altogether suited them. Those old standard varieties of the Queen of England family have been seen much finer, but on the other hand those of Mrs. Rundle were to be found in good form in at least one winning stand. The Princess of Wales section has held its own; the type, also Mrs. Coleman, Miss Violet Tomlin, Mrs. Heal, and Miss M. A. Haggas were all staged in good form. Of varieties more recently introduced, Mons. R. Bahuant stood out prominently as one of the very best, which it undoubtedly is; the half-dozen premier blooms were really models of an incurved flower. Baron Hirsch, introduced last year, was also plentiful; this also bids fair for popularity. Mme. Darrier was staged by a few exhibitors in very commendable style; it is very distinct. Mrs. Robinson King I did not observe in any stand; its doubtful distinctiveness from its parent the Golden Empress of India renders exhibitors cautious as to staging it. Another new variety, but probably one classed with the Japanese section of incurved, is Robert Owen; this also was not prominent. The season does not appear to have been favourable to Refulgens, which last year was the premier variety in the half dozen class, it is so rich and distinct and well worthy of a place. I only noted one good bloom. Jeanne d'Arc was, on the other hand, shown plentifully and in excellent condition. Of other sections there were not many that attracted notice by reason of their superiority save the one only exhibit of twelve single varieties; these were truly lovely and were as attractive if not more so than the best of the Japanese varieties. As their names have been given in the report of the show, it is only necessary now to allude to them. They can be most strongly recommended for cut purposes for vases in home decorations, also for bouquets and other made up arrangements. The exhibitor of these is to be strongly commended for the manner in which he staged them. Amongst the large-flowered Anemones, Delaware is well worthy of notice; it has a fine centre with broad guard florets. Mrs. Judge Benedict, another comparatively new variety, claims notice; its rose tinted florets and sulphur-yellow centre make it very distinct. Of the Japanese Anemones, M. Pankoncke should be noted; its broad purplish guard florets and somewhat lighter centre, also the beautiful build of the flower, are strongly in its favour. In the pompon section note should be made of the beautiful examples of the old, but still unsurpassed forms of Cedo-Nulli as seen in the dwarf specimens, the white, the golden and the lilac varieties being shown in the best possible condition. In the pompon Anemone section the most prominent variety of all was Mme. Montels, which although introduced in the fifties still holds its own. In

THE WESTERN DISTRICT,

on the borders of the Bristol Channel, the Japanese kinds still assert their supremacy, although not in such a marked degree as at the Crystal Palace when compared with the incurved varieties. The most striking kinds of the former at the show in question were Sunflower, which was in several instances remarkably fine, taking the premier position for six blooms of one variety as well. Mlle. Marie Hoste was shown finer than I have before seen it, one flower of this variety proving to be premier bloom in the show, it being a superb flower. Etoile de Lyon was also far above the average with deeply coloured flowers, although not excessively large. Vivand Morel, which as compared with the foregoing was larger, was also staged in excellent condition, but most variable in colour. Excelsior, a new variety of last year, was singularly good; it is most distinct and a decided acquisition as a front row flower. Puritan also stood out as a conspicuous variety. Avalanche, as before at the Crystal Palace, was not so good as in former seasons (it is to be hoped that this beautiful Chrysanthemum is not degenerating). Thunberg, which I do not think was staged last week, was here very plentiful and in its best style, rich in colour and very full. Mr. H. Cannell, which closely resembles the foregoing, being on the average larger, but with shorter petals, was also staged in first-rate condition (every stand of eighteen or twenty-four flowers should at least have one of these two distinct varieties). Glorioso in several instances was staged in its best style; I have not seen it so good for a long time; this also is very distinct. Sarah Owen was also represented by fine blooms, richly coloured. Lord Brooke was not shown so well as it has been seen this season. Mrs. Falconer Jameson, however, was staged in excellent form. The contrary was, however, the case with Stanstead White, whilst Col. W. B. Smith was not so good as it has been seen, the blooms appearing to be at least a week too old. Turning to the incurved varieties in the same show, there was a marked improvement since last week. These were decidedly better than at the Crystal Palace. One which was shown in the best condition was the Princess of Wales (in its various forms), to one of which, Mrs. Coleman, was awarded the premier prize as the finest incurved flower; a finer one I have not seen, it being of great depth and very full. This variety was to be met with in several stands. The Princess herself was also in the best possible condition, winning the first prize for six blooms of one variety. Miss Haggas and Violet Tomlin of the same family were both shown well. The Queen family were again comparatively weak, the best being Empress of India, which was good. Barbara, another kind often overlooked as not large enough, was seen to good advantage. Jeanne d'Arc was larger and finer than usual; it appears to be a season suited to its requirements. M. Bahuant was not so good as usual, but Lord Wolseley was staged in several instances remarkably good. Another variety seldom seen so good was Empress Eugénie; it was a prominent feature in several stands. Enamel, like the latter an old variety, was also staged well. The Anemone, the reflexed, and the pompon varieties were not staged in any quantity, the first being the best of these. Arrangements for effect in baskets were, however, a most pleasing feature, several excellent exhibits being produced. No flower lends itself so readily to decorative uses as the Chrysanthemum at this season of the year. It is a wonder considering this that more encouragement is not given by those who frame the schedules.

Returning once more to the

LONDON DISTRICT,

I was pleased to see in at least one local show an excellent competition for the prizes offered for Japanese varieties (twelve) to be shown with 15 inches of stem, to be staged as grown and in glasses or bottles of water. This proved to be a most interesting class, and several remarkably fine flowers were exhibited. In looking closely through the premier lot, not a second-rate flower was to be seen. This style of staging is really worthy of

more attention, the addition of the leaves being a marked improvement. At the same show there was a keen competition for the prizes offered for large-flowered Anemone varieties; these, where attention is given more particularly to their culture, appear to have enjoyed the past season. I never remember to have seen better on the whole. At another local suburban show the premier Japanese bloom was a grand one of Lord Brooke—a position I have not previously seen it occupy. It is, of course, to be taken into consideration that it is a new variety which has probably not yet been seen at its best. I am strongly disposed to think that it has a brilliant future before it. At yet another suburban show the groups were remarkably fine, quality of flower being one of the specifications in the schedule. Although this in a measure precludes the use of some of the best decorative varieties, no fault could be found with the way in which the best groups were arranged. The premier group was arranged in the manner advocated in these columns last autumn, viz., with the back well raised and the front equally as dwarf. It seems strange that exhibitors, on the whole, cannot see that by so arranging their plants they can get more on the same space with less overcrowding. These groups had to be finished off in the front with small-leaved plants so as to hide the pots, which is an excellent proviso, for pots (sometimes dirty ones) and sticks (not always painted) cannot be considered as being conducive to good effect. At this show six blooms of Sunflower, rich in colour, large in size and quite fresh, were placed first for any kind of Japanese, the second best being Vivand Morel, deeper in colour than usual. In the corresponding class for one variety of incurved, Queen of England, grand blooms, not over-large, but beautifully finished, stood the exhibitor in good stead; half a dozen John Salter, however, ran the former very close. The Japanese throughout in this case were very fine. This was notably so with Etoile de Lyon, which I never remember to have seen so good in any previous season, there being more refinement in the flowers. Mlle. Marie Hoste, Mme. Thérèse Rey, Lord Brooke, Col. W. B. Smith, G. C. Schwabe, and W. H. Lincoln all maintained their previous good reputation; so also did Emily Dale, Miss M. Haggas, Empress Eugénie (a beautiful variety, not nearly enough seen), Jeanne d'Arc, Violet Tomlin, and Princess of Wales amongst the incurved. One excellent addition was in this instance made to the schedule, viz., a class for cut Chrysanthemums in bunches for cottagers; for the prizes there was a keen contest, showing that such classes have only to be provided in order to secure competition.

Turning away from the metropolis once more, this time to

THE NORTH,

one could but be struck with the grand display of cut blooms in a large number of classes, the amateur growers in this case entering keenly into the fray. The finest flowers, both of Japanese and incurved in the largest classes, were from southern growers, a noteworthy fact; whether they will maintain the same position another season remains to be proved. At this show the finest incurved flowers shown so far this year out of London (at the National) were to be seen; they were models of good culture (and of patience also in the after dressing). In this exhibit it was difficult to point out individual blooms, all being alike good. Both the Queen and Princess families were strongly represented. The example of Lord Alcester in this stand won as the premier incurved flower, a grand bloom and very fresh; it was, however, run very closely by a unique flower of Hero of Stoke Newington. Of the Japanese section, Charles Davis, the bronze sport of Vivand Morel, won the premier prize, but it was run very closely by other grand blooms, notably by Etoile de Lyon. Others of this section which stood out well were Mme. Thérèse Rey, Col. W. B. Smith, Mlle. M. Hoste, and Mme. Baco (the last extra fine). A novel, but excellent departure was made at this exhibition in offering prizes for twenty-four blooms of Japanese arranged on a given space in

an effective manner with other accessories. The first prize was most deservedly awarded to a beautiful arrangement in an informal manner of grand blooms interspersed with dwarf and fine-foliaged plants. More of this kind of staging should be shown. The groups in the same show were remarkably good, totally different from what one is accustomed to see down south. Upon a given space the exhibitor is at liberty to do his best with Chrysanthemums combined with other fine-foliaged plants, the result being most beautiful groupings, mere mass of flower in no case being relied upon. It is a pity that such a group as the premier one could not be sent to one of the London shows as a pattern of good and tasteful arrangement. GROWER.

Chrysanthemum Mrs. Robinson King.—

I note in the last issue of THE GARDEN that this sport from Golden Empress of India is alluded to as having been shown at the Aquarium, the colour being given as deep orange-red. Surely this must be a mistake, or else it has sported again. I saw it only once, at least it only attracted my notice once. This was at a local metropolitan show. The bloom in question was rather flat, much after the form of Jardin des Plantes, whilst it was in colour as near like that old favourite as could be, the only variation being in size and in the petals. Mrs. Robinson King is much larger than Jardin des Plantes and the petals broader. I was at the Hull show, but did not note it there even shown well. It may quite possibly have been shown, but with such a crowd of admirers around the stands there it was not possible to investigate every exhibit. The N.C.S. supplement to "Official Centenary Catalogue" gives the colour as rich yellow; this well describes it.—H.

Chrysanthemum exhibiting: a suggestion.—It has often occurred to me that a dividing line between each exhibit of forty-eight, thirty-six, twenty-four or eighteen cut blooms would greatly assist in the general effect of an exhibition. To do this, why should not each exhibitor in these larger classes provide either two or three small plants of not more than 1 foot in height? At the most three would be sufficient for each such exhibit, as only one side by each competitor would have to be so divided. Light Palms, as Cocos Weddelliana and Areca Intescens, or light ornamental Grasses, as Eulalia japonica variegata or Carex riparia, as well as the variegated form, or the narrow-leaved Crotons or the finer of the Aralias. Any of these plants could thus be used in a most pleasing fashion. Such divisions would assist the judges also as dividing lines to a good purpose. I fancy I can hear some of the exhibitors saying that it would give them needless trouble, but none of the plants need be larger than 3-inch pots, or at the most 4 inch. Three of these would not occasion much more labour, but the effect of the show would be enhanced.—SOUTHON.

Chrysanthemums at Chicago.—The exhibition showboard, concerning which there was some discussion a year or two ago in America, appears to have been banished entirely from the World's Fair Chrysanthemum Show in Chicago last month. The current number of the *American Florist* contains twelve illustrations of the exhibits there, many of them being of cut blooms, which are represented as being staged in vases. The flowers which seem to have caused the greatest attraction are The Queen, George W. Childs, Beau Ideal, Mermaid, Mrs. Higginbotham, Robert McInnes, Mrs. J. G. Whildin, l'Enfant des deux Mondes, Harry Balsley, and Vivand Morel. Among the principal exhibitors such well known American Chrysanthemum specialists as J. C. Vaughan, Nathan Smith and Son, E. G. Hill and Son, and W. N. Rudd find a place, and altogether the exhibits were a most representative lot. They came from both the Atlantic and Pacific coasts, from Canada on the north to New Orleans on the south, there being twenty-one States represented. The report of the show is accompanied by a list of varieties exhibited, which at a rough computation may be taken at 110, almost all of them being of American

origin, and a number far less than we should have expected. The principal varieties from this side of the Atlantic were M. R. Bahuant, H. Cannell, Charles Davis, Jeanne Délaux, Domination, Bertha Flight, l'Enfant des deux Mondes, Kate Mursell, Robert Owen, Mlle. Thérèse Rey, William Seward, Source d'Or, and Vivand Morel.—C. H. P.

Incurved Japanese Chrysanthemums.—The increase in the number of Japanese varieties of Chrysanthemums is so rapid, that sufficient is now obtainable to make a full class of thoroughly incurved flowers in this section. This type of Japanese bloom may not meet with favour universally, but some people prefer them to any other kind. For my part I look upon varieties of the type of Belle Paule and A. H. Neve as being more typical of the Japanese flower; these possess grace and fulness of petal without being too stiff in appearance. Types of Japanese like Elaine and Maiden's Blush for example are not nearly so pleasing as those above-named, for the reason that they are too stiff in appearance, reminding one too much of the ordinary reflexed varieties. The following varieties belong correctly to the incurved section, and are not like many that were included when a class was formed for this section a few years since, and before varieties were as numerous as they are at the present time. Many sorts incurve their florets as they expand; for instance, E. Molyneux and Boule d'Or, but when fully developed they present a different appearance. The former is quite reflexed in character, and, therefore, in my opinion not entitled to be classed as an incurved Japanese. Foremost in this section is Robert Owen, probably the best of all belonging to this type; in colour it is orange-yellow, with a bronze suffusion. Louise, peach, or deep blush; George Savage, white, hirsute florets; Eda Prass, lilac, turning to blush; Rose Wynne, rosy pink; Amos Perry, rich yellow; Viscountess Hambleton, silvery blush-pink; Miss Anna Hartshorn, blush-white; Lord Brooke, rich bronze; L'Ami Etienne, pale lilac; Pearl Beauty, pearly white; Vice-President Calvat, crimson-red, reverse dull gold; Beauty of Castlewood, surface deep red, reverse orange-amber; Comte de Germiny, nankeen-yellow; Mrs. C. H. Wheeler, golden reverse, suffused red and bronze; Pelican, creamy white; Thunberg, rich yellow; Mrs. C. H. Payne, rosy blush, large and full; Mrs. Libbie Allen, clear yellow; Professor Wittmack, bright rose, paler reverse; Japonais, bronze-yellow; and Mrs. E. W. Clarke, purple-amaranth, belong to this class. All the varieties belonging to the hairy section come under the head of incurved Japanese.—Mrs. A. Hardy, Louis Boehmer, Queen of the Hirsutes, l'Enfant des deux Mondes, and W. A. Manda being the most important.—E. M.

Exhibition of decorative Chrysanthemums.—In many places this winter there will be an early scarcity of these flowers, at least from a decorative point of view. In ordinary seasons those who grow entirely on the big bloom system may look around, but in vain, for good supplies for drawing-room embellishment after the middle of December. Even the latest varieties when grown on this principle, are past and gone by the time the same sorts grown on the dwarf and many-branched system are coming into use. Large, highly-fed blooms are, moreover, much softer in texture, and quickly succumb to fog and damp. I am confident that if many who need cut flowers in quantity at the commencement of the new year would grow a few dozen plants in the old-fashioned way and not disbud, they would find them so useful, that in future they would double their number. My own plants which are grown for cutting only are never disbudded, and in spite of the forward season are only now coming to their best. My mode of retarding is, however, in part responsible for this. About the first week in October I arrange the plants in beds of four rows each, with paths between, afterwards fixing upright posts on either side, and carrying rafters horizontally from one to the other. Canvas fixed on home-made rollers is then extended over the framework each evening, and securely fastened with strong cords. Side walls are also provided of the same material

and fastened by loops to tenter hooks. These in windy weather remain untouched for days together. Treated thus till the leaves are off the Peach trees, the earliest varieties come into bloom quite as soon as wanted, while the later sorts not having been unduly excited follow on and flower at their proper season and in their best condition. It is astonishing how much frost the plants will stand with impunity if sheltered in the manner described; whereas if exposed to it, especially when in a wet state, their ruin is not only complete, but speedy.—J. CRAWFORD, *Coddington Hall, Newark.*

Chrysanthemums in paper collars.—Twenty years since it was the fashion at northern shows to display all cut blooms at exhibitions upon paper collars, or, what is perhaps more correct, upon bouquet papers. Gradually, however, the fashion died out to a great extent. I had no idea that it was still practised, but a visit to the late Sheffield autumn exhibition proved that the absurd fashion still exists. I cannot say positively in how many stands these frills were upon the flowers, but a considerable number of northern exhibitors still adhered to the fashion. Fancy a pure white bloom like Mlle. Lacroix or Empress of India being encircled with frilled white paper reaching fully 3 inches beyond the flower. In the large open classes these hideous accompaniments were not to be found, but in the minor or local classes they were common.—E. M.

GOOD DECORATIVE CHRYSANTHEMUMS.

THOUGH note-taking is very universal at the various exhibitions of Chrysanthemums, it by no means follows that it is the best way to get a selection of varieties for supplying the greenhouse with a good display of flowers during the autumn, as many of those most suitable for growing into bush form do not bear large enough flowers to compete with the giants that are to be seen at the various shows, though they yield an enormous quantity of small or medium-sized blooms, which for cutting are invaluable. What are usually referred to as semi-early or October-flowered Chrysanthemums are extremely useful, forming as they do the advance guard to the great bulk, which are at their best a little later on. Though the time of blooming varies somewhat according to the season, yet the following may be depended upon as a good selection for early flowering:—

Mlle. Lacroix, the well-known white, with its two sports, Annie Clibran, pink, and Mr. Charles E. Shea, yellow; M. William Holmes, crimson; James Salter, lilac-mauve, and its white form, Lady Selborne; Lakme, orange-amber; Mme. la Comtesse Foucher de Cariel, golden orange; Alexandre Dufour, purple; Bouquet de Dame, white; Bouquet Fait, pink, and its salmon sport, William Robinson; La Charmeuse, purple; La Vierge, large pompon, pure white; l'Île des Plaisirs, red; M. E. Pynaert van Geert, golden yellow; E. G. Henderson and Son, crimson and gold, with the old Elaine, pure white.

Other varieties that come in with the bulk of Chrysanthemums, but are now rarely seen on the show table, though they make grand bushes, are—

Alice Bird or Buttercup, a beautiful rich yellow reflexed bloom; Cullingfordi, crimson; Dr. Audiguier, amaranth-red; Edouard Audiguier, purplish maroon; Elsie, a beautiful reflexed cream-coloured flower; La Nympe, pink; Marabout, a white pompon, fringed like a Pink; Marie Stuart, a little white Anemone that blooms in great profusion; M. Crousse, that gives immense numbers of small bright crimson Japanese flowers; Mrs. James Carter, with creamy Thistle-like heads of bloom, very unlike any of the others; Pere Délaux, brownish crimson; President Hyde, rich yellow; Source d'Or, the popular market variety, of a deep golden tint; Tokio, scarlet-crimson, one of the brightest of this tint, and invaluable for cutting; with the pure white single-flowered variety Jane and its yellow counterpart.

Though many of the above were at one time to be seen at the various exhibitions, they have been ousted from their position by larger blooms, which are at the present time all the rage, though it

must be said that many of the newer forms even with very large blooms are much dwarfer in habit than was at one time the case, and consequently many of them are very desirable for growing into bush form. A selection of a few large-flowered Japanese for this mode of culture would include

Avalanche, white; Alberic Lunden, carmine-crimson; Cesare Costa, crimson; Col. W. B. Smith, old gold; Edwin Molyneux, crimson; Etoile de Lyon, lilac-rose; Florence Davis, white, tinged green in centre; Gloire du Rocher, reddish orange; Kentish Yellow; Mme. de Sevin, rosy purple; Mlle. Marie Hoste, white; M. Bernard, amaranth; Mrs. F. A. Spaulding, nankeen; Mrs. G. C. Schwabe, pale rose; Mrs. Falconer Jameson, bronzy orange; Phœbus, rich buttercup-yellow; R. C. Kingston, purple; Sunflower, yellow; Viviani Morel, mauve; Val d'Andorre, chestnut-red; W. Tricker, distinct rose; W. H. Lincoln, yellow; and Louis Boehmer.

Many of the new varieties sent out during the present year are of good sturdy habit, among them being—

Beauty of Exmouth, white; John Shrimpton, velvety crimson; Charles Davis, rosy bronze; William Seward, deep crimson; Princess Victoria, creamy white; Middleton Clarke, crimson-red with golden reverse, and white Louis Boehmer. All of these belong to the Japanese section, the new incurved varieties being much less numerous.

Where flowers are required late in the season the following are among the best to grow for that purpose—

Boule de Neige, hybrid pompon, pure white; Golden Gem, reddish bronze; L. Canning, pure white; Princess Blanche, cream; Lady Trevor Lawrence, white, and its primrose-coloured sport, Kate Mursell. Of incurved varieties, Princess Teck, white; Mrs. Norman Davis, yellow; Hero of Stoke Newington, pink; and Miss Marechaux, white, are all good. T.

Chrysanthemum Mary Anderson.—This is undoubtedly the most popular of all single-flowered varieties, and no wonder when its numerous qualities are taken into consideration—the perfection in form of its flowers, the delicate tint of colouring, the free manner in which its blossoms are borne, coupled with the compact habit of growth. At the Birmingham autumn exhibition held in the Town Hall this year, Messrs. Thomson had a pyramid 8 feet high and 5 feet wide at the base of this Chrysanthemum. Eighteen plants in 6-inch pots were employed in building it. The blooms were of full size, one only on a shoot. The whole gave one the impression of a huge pyramidal plant, rising out of a base of small flowering and fine-foliated plants. Behind this pyramid were arranged Palms, making a splendid background for the delicately tinted Chrysanthemum blooms. Again, at the Lincoln Chrysanthemum show this variety was effectively employed to form the base of two mounds in a first prize group of miscellaneous plants. Above the Chrysanthemums towered remarkably well-grown single-stemmed Crotons and Dracœnas, the effect being charming. The Chrysanthemum pots were hidden by a row of Adiantum Farleyense intermixed with Caladium argyræ as a relief.—E. M.

Chrysanthemum groups at Torquay.—At the autumn exhibition at this fashionable southern resort a very effective method of treating the groups of Chrysanthemums is employed. In the large room connected with the Bath Saloons the competitive groups are arranged in circles on the floor. The conditions of competition are that not less than eighteen varieties shall be included. Ferns are allowed for the front, which does away with the necessity of exposing the Chrysanthemum pots, as must be the case where no other plants are allowed. The group in question is confined to a diameter of 8 feet. Another is provided also 1 foot less in size. Still another is arranged for in the schedule to consist of but twelve varieties, thus providing ample opportunity for all classes of cultivators. In any of these groups the Chrysanthemums are not to exceed 6 feet in height. This is a commendable restriction, as it is an inducement to cultivators to employ dwarf growing varieties. The centre of each group must consist of one tall

Palm or fine-foliated plant. This addition is a great help in relieving the otherwise uniform surface of the groups. Alternately with these groups others are arranged with miscellaneous plants in the form of a square and raised 1 foot above the floor, which admits of small drooping plants being included in the margin. The tallest plant in these groups must not exceed 10 feet. Along the sides are exhibits from nurserymen in the neighbourhood consisting of groups of Palms, winter-flowering plants, Orchids and Chrysanthemums. These make a pleasing foil to the gay colouring in the centre, and certainly add to the beauty of the display. The room is abundantly lighted, and as the exhibition is generally favoured with sunshine, the effect is most charming. Abundant space is provided for promenading amongst the groups, and as they are seen at all points, there is no opportunity for exhibitors to display the forest of bare stems, sticks, and pots too often to be found in some Chrysanthemum groups. Considering that private gardens of large size are but few in the neighbourhood, the display got together annually is certainly creditable.—E. M.

Chrysanthemums at Glasnevin.—The largest and best group of plants grown under what is known as the bush method, or perhaps more correctly speaking the natural style of growth, I saw last month at the Botanic Garden at Glasnevin. One large lofty house was devoted entirely to them, and a magnificent display it was; some hundreds of plants were on view. Here could be seen not only the newer varieties, but older ones, as James Salter, Bonquet Fait, and the like that are hardly ever seen now-a-days at exhibitions and seldom in private gardens. The rage now-a-days is for those sorts that give the largest blooms. Considering the unsuitability of the summer quarters Mr. Moore has for his plants—a position facing north, behind a range of high houses and partly overhung by tall stately trees as well—the wonder to me is how he obtains so good a display. Many persons wonder why the plants are not here cultivated to produce the orthodox large blooms, but under the adverse condition of the summer quarters I think Mr. Moore justly grows what is the most suitable for his purpose and convenience. Those persons who know what the requirements of Chrysanthemum plants are for the production of large blooms know perfectly well that if the plants are not matured by thorough exposure to the sun, it is impossible to obtain the finest results. The plants in question are topped but little, if any, and are simply allowed to grow away in a natural manner. Disbudding of the flowers is not practised, the result being a mass of bloom from all varieties alike, which is creditable to all concerned and immensely appreciated by the public, as was apparent by the numbers present at the time of my visit, one cold day toward the end of November. I was told that on a Sunday afternoon the crush was so great, that the greatest difficulty was experienced in getting through this Chrysanthemum house.—E. MOLYNEUX..

SHORT NOTES.—CHRYSANTHEMUMS.

Chrysanthemum Snowdrop is a charming little pompon, the flowers small, neat, and pure white, with a yellow centre. It is very free.

Chrysanthemum Mrs. Bourne is a Japanese raised by Mr. Owen, with florets of tremendous length and rather broad. The colour is light rosy mauve, with a silvery reverse.

Chrysanthemum Mme. Rozain.—A Japanese incurved variety raised by Rozain-Boncharlat. A big solid bloom with very long florets, of a rosy mauve shade. This is one of the best French varieties of the season.

Chrysanthemum Marion is a delightful pompon kind. It should be taken as a model for this section, the flowers being small and of exquisite shape, whilst the colour is of a deep orange shade, the petals a little fimbriated.

Chrysanthemum Putney George, a reflexed variety, has been well shown this autumn. It

is one of the finest of its class for colour, the flowers large and crimson, the reverse of the florets golden yellow and tipped with the same shade.

Chrysanthemum La Nympe is rarely seen in collections. It is a Japanese variety, or Japanese reflexed, and when grown with little stopping of the shoots is very beautiful, the flowers not large, but pleasing in form, and lilac-peach in colour. The habit is comparatively dwarf, and a wealth of bloom is produced.

Chrysanthemum Marion Dingle.—English seedlings are always interesting. This variety was raised by Mr. Robert Owen, of Maidenhead, from seed saved from Stanstead White. It is a Japanese variety of large size, with very long florets. The colour is pure white, with just a faint shade of green towards the centre.

Chrysanthemum Le Colosse Grenoblois.—Without exception this variety, raised by M. Calvat, is the largest flower ever seen in England. As shown at a recent meeting of the National Chrysanthemum Society it was rough, ugly and coarse; but if it can be shown in presentable form by English growers, its size will unquestionably give it a place on the show-boards at our principal exhibitions. The florets are numerous, but rather narrow, and the colour is white and rosy.

GARDEN FLORA.

PLATE 940.

HIMALAYAN RHODODENDRONS IN IRELAND.

(WITH A COLOURED PLATE OF R. ROYLEI.*)

SIR JOSEPH HOOKER in the concluding sentence of the preface to his noble work, "Rhododendrons of Sikkim-Himalaya," says "their headquarters are on the lofty ranges of the Eastern Himalaya, where the mild and moist atmosphere is eminently suited to their habit." It is only where these conditions prevail that an adequate idea of the beauty of these plants can be obtained, and of what they must be in the gorges and sheltered spots of the lofty Himalayas. Coming from a high elevation and from a pure and moisture-laden atmosphere, coddling and confinement are thoroughly distasteful to them, and the starved and stunted specimens so frequently seen in pots give a very poor idea of what the same species may be in our climate when growing in the open air in suitable soil. The climate and soil of parts of Ireland seem to suit them admirably, and in Wicklow, Cork, Donegal, West Meath, and other counties rich and representative collections are to be found. Probably the best private collection of species of Rhododendron, with the exception of that formed by the late Mr. Mangles, is to be seen in a Wicklow garden, to the owner of which the plants are a source of immense interest and thoughtful care. It was in this garden that the accompanying plate of Rhododendron Roylei was painted. The plant from which the branch was cut forms a compact bush some 7 feet high, which about the middle of May was covered with small trusses of deep purplish red flowers, with a peculiar bluish sheen on the lower portion of the outside of the corolla tube, and formed a sight not easily to be forgotten.

* Drawn for THE GARDEN in the garden of Mr. Acton, Rathdrum, Co. Wicklow, by H. G. Moon. Lithographed and printed by Guillaume Severeys.

MIMULUS LEWISII (PURSH) COVILLE

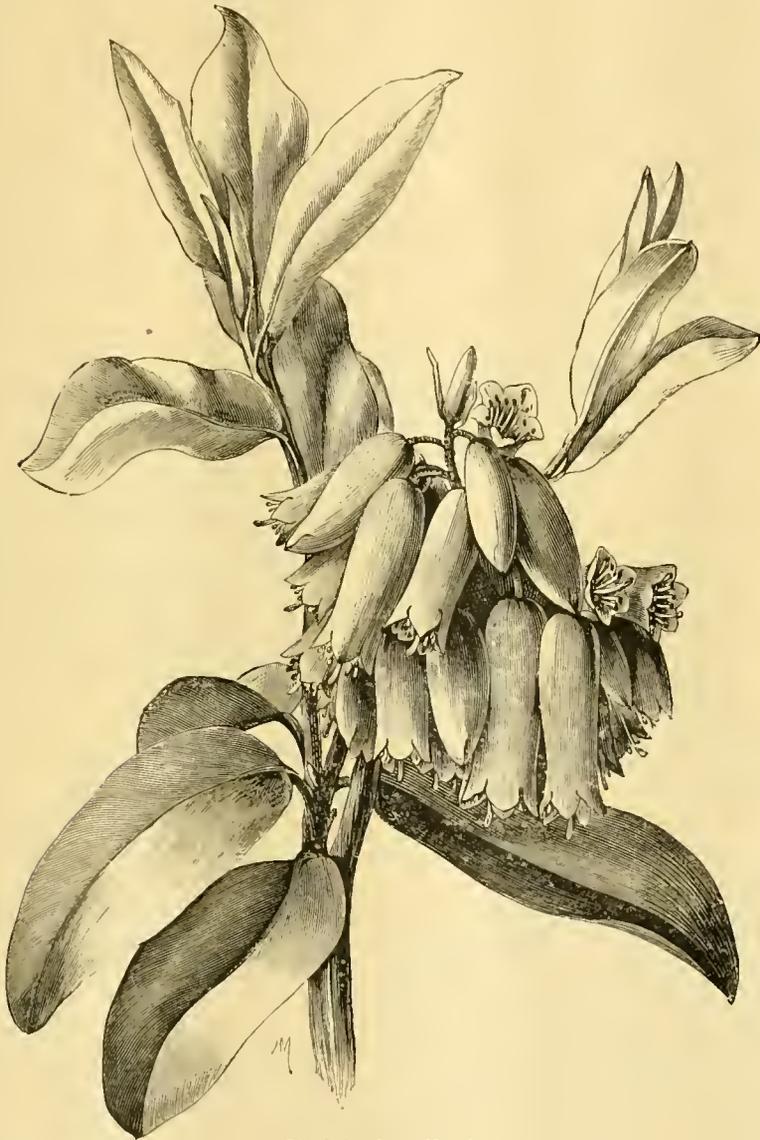

A layer from this plant, which is in a moister and more sheltered position, is nearly 9 feet high, and when standing beside it and looking through the flowers towards the sun, a rich and brilliant effect is produced, quite different from that of looking down on the flowers. This species—if it be accorded the dignity of specific rank—is rather more delicate than such species as *R. arboreum*, *R. barbatum*, or *R. campanulatum*, and should, therefore, be planted in a more sheltered position. It

given in *THE GARDEN*, September 24, 1881 (page 328). *Rhododendron barbatum* is a very welcome species, as its brilliantly coloured heads open in March, and it is sufficiently hardy to stand in an exposed position. The flowers should be protected from severe frost, which causes them to turn black. The largest specimen in this Wicklow garden is 15 feet high and as much through, and each year it flowers very freely. Not less brilliant are the flowers of *Rhododen-*

A large plant of *Rhododendron grande* (*argenteum*) had 93 expanded heads of white flowers on May 17, 1890. It was then 13 feet high and stood alone and unprotected in a plot of Grass sheltered by large Silver Firs, which formed a noble background to a noble plant. The old bark peels off the stems of *R. grande*, as in the case of *Arbutus Andrachne*, leaving a smooth and polished surface. The distinct colour of the foliage and young branches, as well as of the flowers of *R. Thompsoni*, places it in the very foremost rank in the species of hardy *Rhododendrons*. It is a very free grower; the individual flowers are large, deep blood red in colour, and of a peculiar waxy texture. It flowers a little later than most of the species already mentioned. In this Wicklow garden the following amongst the rarer species of *Rhododendrons* have proved to be perfectly hardy: *R. calophyllum*, *R. campylocarpum*, *R. Falconeri* var. *eximium*, *R. Hodgsoni*, *R. Keysi*, *R. niveum*, *R. Shepherdii*, *R. triflorum*, and *R. Wightii* (true).

As before stated, it is not only in Wicklow that the species of Himalayan *Rhododendrons* flourish in Ireland. The finest plant of *Rhododendron Keysi* is probably that in the rich collection of Mr. Gumbleton at Belgrove. Near Fermoy, Sir R. H. Kinahan has a very good collection of species and hybrids, some of the specimens being very large and in perfect health. In the Co. Westmeath there is at Knock Drin a good collection of species growing very freely. Most of the species at Knock Drin have been raised from seed collected by the owner or sent to him from India, and their history is known from the date of sowing the seed. In Donegal, on the shores of Lough Eske, Mr. Wallace has collected together many choice species, and it is really surprising to note how they grow in well-drained bog land. *Rhododendron Aucklandi* makes shoots nearly 18 inches long, clean, and healthy, and *R. Thompsoni* is a glorious sight here when in full flower. On the Grass slopes near the house are some very fine specimens of *R. arboreum* and its varieties with pink and with white flowers. Mr. Henry Hart, in another part of the same county, is forming in a sheltered position in a wood a large grove of Himalayan *Rhododendrons*, and here again one notes with astonishment how freely they grow in the Donegal climate; in fact, with the exception of small tracts of Co. Wicklow, they grow more vigorously in Donegal than in any other part of Ireland.

A feature in many gardens throughout Ireland is the number of fine specimens of *Rhododendron arboreum* and of its varieties, as well as some fine seedlings from *arboreum*. These plants attain very large dimensions, 10 feet to 20 feet high and as much through; they flower very freely, and are very hardy—one of the best and hardiest forms being that with pink flowers variously spotted and of various shades of pink, intermediate in appearance between the plants figured in "*Rhododendrons of Sikkim-Himalaya*" under the names of *R. Campbellii* and *R. lancifolium*, but not having tubercles on the petioles as in

Rhododendron Keysi.

delights in moisture about the roots. *Rhododendron Dalhousiae*, *R. Edgeworthii*, and *R. Nuttallii* are the only species which have proved not to be hardy in Wicklow; true, they have lived there for several years, but they get crippled by spring frosts, do not flower, and eventually dwindle and die. In this garden *R. Aucklandi* grows into a bush 12 feet high, carrying numerous heads of large white flowers, which are sweetly perfumed, and were it not for its rather straggling habit it would probably rank as the finest species of the genus. A coloured plate of it is

dron fulgens, which open soon after those of *R. barbatum*, but the habit of the plant is quite different. It forms a spreading bush 4 feet to 6 feet high, the underside of the leaves being covered with beautiful white tomentum, which changes to brown as the leaves get older. The flowers of these two species suffer much from attacks of the bluecaps and blackcaps. Attracted apparently by the brilliant colour, they visit the flowers and soon discover the rich store of nectar, to get at which they tear the flowers to pieces, so destroying many fine trusses in a short time.

the latter species, and having the under side of the leaves silver, not brown.

Botanic Gardens, Glasnevin.

THE WEEK'S WORK.

ORCHIDS.

I WAS looking over a very fine collection of Cypripediums the other day and was much interested, not only in the varied forms and colours of the flowers, but also in their long lasting character both for cutting and when left upon the plants. These warm house Cypripediums are so easily grown, that anyone can manage them. A temperature of 60° in winter with a moderate amount of moisture in the atmosphere is what they like. They are also easily increased. I bought a small plant of *C. Spicerianum* some six or seven years ago, and I have now fifteen plants, which are large enough to be divided again, so that the number may be more than doubled. In the collection I have alluded to the variety occupying the most prominent position was *C. Leeanum*, the varieties *giganteum* and *superbum* being the best. Many Orchid fanciers have produced these garden varieties by crossing the best forms of *C. insigne* with *C. Spicerianum*, but I have not seen any to surpass the forms which were raised by Messrs. Veitch in their Chelsea nursery, and named *superbum* and *giganteum* respectively. They are mainly distinguished by the large size of the dorsal sepal and the purity of the white thereof. The variety *T. E. Haywood* is always in flower at this season of the year, and now the plants are strong, the flowers have greatly improved not only in size, but in brightness of colour. *C. T. E. Haywood* is a cross between *C. Veitchi* and *C. Druryi*, and therefore the colours cannot be very rich. It is well known how difficult it is to obtain plants of *C. Fairrianum*, nor is it an easy species to grow well. I remember a good grower making the remark that the only Orchid he ever saw benefited by drip from the roof was *C. Fairrianum*, and in winter, too; this may give some clue to its culture. My object in alluding to this species, so much coveted by Orchid fanciers, is to recommend *C. Niobe*, which has been produced by crossing *C. Fairrianum* and *C. Spicerianum*. An old garden hybrid, *C. vexillarium*, is also good, with a good deal of its parent, *C. Fairrianum*, in the dorsal sepal.

Amongst desirable Orchids in flower at the present time is *Ceologyne barbata*; it is not one of the easiest to manage, and cannot be said to be free flowering. I saw it the other day in Messrs. Veitch's nursery with fifteen flower-spikes on one plant, and seven to nine flowers on each spike. The varieties of *Cattleya labiata* which are now passing out of bloom are being succeeded by *Lælia anceps*, of which many of the ordinary varieties are now in bloom, with a few plants of the beautiful *L. anceps Sanderiana*. The white forms of *L. anceps* are flowering much better with me than they have yet done; why I cannot say, except that they require much sunlight when making their growth, and this they had in greater abundance than usual last summer. I believe the plants do better when the roots are made outside the pots in which they are growing. This is unavoidable, as each new growth pushes out so far ahead of the last formed one, differing much in this respect from the ordinary variety, which forms quite a compact, neat-habited plant. As giving variety, the following *Oncidiums* are useful at this season of the year: *O. cheiroporum* is a charming little Orchid, which I find does very well in the cool house in summer, but should be placed in the *Cattleya* house in winter. The delightful fragrance of the flowers is much appreciated at mid-winter. I grow it in small pans suspended from the glass roof. *O. pulvinatum* is also producing its long spikes of small yellow flowers very freely; so also is *O. Forbesi*, which does not always succeed; the flower-

spikes seem to exhaust the plants if allowed to remain year after year until the flowers fade. I have just been admiring some handsome spikes of bloom which have been cut from plants which have produced similar spikes six years in succession. They were grown in a low span-roofed house in pots and placed very close to the glass roof, the temperature being such as *Cattleyas* flourish well in. *Cymbidium giganteum*, also in flower, is altogether distinct from *C. Lowianum*, but in growth and the general treatment required they resemble each other. There are other Orchids in flower, some of them a little out of season, such as *Lycaste Skinneri*. *Lælia autumnalis* is yet very bright, and I saw a pure white variety in Messrs. Veitch's nursery during the past week. In the cool house there are always varieties of the popular *Odontoglossum crispum*; contrasted with it and suspended from the roof in pans and baskets are numerous well-flowered plants of *Sophranitis grandiflora*. This pretty little Orchid is not only valued as a cool house Orchid, but being so nearly allied to the *Cattleyas* and *Lælias* can be fertilised with their pollen, and from it have been obtained some of the most valuable garden hybrids, as its rich deep reddish crimson tint is uncommon and not known at all in the *Cattleyas*.

Cattleyas often assume a yellowish tinge from various causes. One is from a white scale, which at first may work unseen underneath the thin papery covering which partly envelops the pseudobulbs. If the leaves begin to change from their deep green to a paler green, fold back this covering which closely adheres to the bulbs, and if there is any fluffy appearance underneath, there is the scale, which can be easily removed with a sponge and soft soapy water. This troublesome parasite does much mischief to other Orchids, besides *Cattleyas*, if it is not observed in time and promptly dealt with. *Cattleyas* also suffer sometimes by being kept over-dry in winter. They should certainly be allowed to become dry at the roots in winter before having water given to them, but if this withholding of water is too much practised, then the leaves will show it before the bulbs shrink much. Thrips also do much mischief before it is observed, and plants that are very liable to be attacked by this active little parasite should be periodically dipped in a solution of tobacco water. The best way to keep *Cattleyas* clean is to fumigate them well with tobacco smoke in winter. Over-heating the hot-water pipes and over-dryness in the atmosphere will also cause many plants to become unhealthy.

J. DOUGLAS.

THE KITCHEN GARDEN.

SNOW'S WINTER BROCCOLI.—If the weather should prove mild this variety might be left where growing, but as this is uncertain and also as a moderately severe frost would spoil the young heads as they are forming, the better plan would be to form some kind of protection, so as to guard against injury. If any deep or cool pits are available, the plants could be lifted and placed in these. Here they will grow and form useful heads if kept well ventilated. In few gardens, however, can glass protection be afforded. If the plants are taken up and laid in carefully on a sheltered border, but not too closely together, and a rough framework erected over the whole, so as to carry mats, and in case of a spell of very severe frost an additional covering of litter or Bracken, every one will form a useful head at a season when they will be sure to be appreciated.

BURNT REFUSE.—The value of this useful material cannot be over-estimated, not only for working into the surface for the various crops at seed-sowing time, but also, if it could be spared, for Peas, this assisting the crops wonderfully on those soils where the haulm is apt to grow weakly. I have a fire going continually summer as well as winter, and although this is not convenient in all gardens, yet at this season of the year all rubbish, prunings, and so forth should be collected together and be well charred, not over-burnt until they become red, but just sufficiently to crumble down.

A large heap of this mixed with night soil and allowed to stand for twelve months and at the end of this time turned, will form a good top-dressing for Roses and Vine borders. All rubbish which has been collected together during the summer months should now be well turned over, forking out the coarse to be burned. Some freshly slaked lime mixed with the whole will assist in destroying the grubs.

BURNING SOIL.—The addition of burnt soil to heavy clay land assists wonderfully in getting it into free working order. Of course a plentiful addition of burnt refuse and other like materials will answer the purpose, but such material is not always at hand. The soil in the process must only be charred, not burned red. Soil-burning is not at all difficult. The first process is to make a fire of small coal as a feeder to other smaller fires. A ring of clay or rough lumps should be formed about 3 feet across, and within this space make the fire. When well alight, add some lumps of rough soil, sprinkling some small coal amongst them. As this becomes alight add other clay and small coal until the heap is formed. If the fire should burn through, this must be stopped by adding some clay and fine coal. When it is seen that the mass is burned sufficiently, it must be opened out and spread over the surface. Land which is being broken up and in which there is a deal of Couch Grass in the top layer forms good material for burning.

PREPARING FOR FORCING.—A good supply of leaves should be collected together for forcing, for although these may not be required for a few weeks, yet by having the materials which will be required for the purpose well in hand, there will not be any hindrance. Even where the forcing of vegetables is mainly carried out by the aid of hot water, a supply of fermenting material composed either of fresh leaves or leaves and litter combined cannot be over-estimated. Suitable soil should also be collected. It is not often convenient, nor is it advisable to use fresh soil. Old Cucumber and Melon beds, potting soil and such like material will suit admirably. Leaf-soil and burned refuse, or even old Mushroom bed manure should also be added, the whole making a suitable compost for the forcing of vegetables.

A. YOUNG.

FRUIT HOUSES.

LATE GRAPES.—As might be expected, the wood on late Vines has ripened well, and the foliage is falling away almost as freely and evenly as leaves part from Chestnut trees. Whether the crops shall be still left hanging on the Vines or be cut and bottled ought to depend upon circumstances. The bunches keep better in a snug dark room than they do in a house where the temperature fluctuates considerably, or which cannot be kept uniformly cool and dry. By careful attention the temperature might perhaps be kept at from 45° to 50°, and the house quite dry, but even if the Grapes do keep well under these conditions it would be much better for the Vines to be lightened of their crops and be given a thorough rest during January and February. While yet there is a considerable number of Apples and Pears stored in an ordinary fruit room, this is scarcely the place for Grapes to be hung in, but it might answer well when it can be kept drier, constantly dark, and more nearly air-tight. Mineral and soda-water bottles, or any half-pints made of clear glass, are the handiest for suspending Grapes in, as in this case it can always be seen whether or not the wood to which the bunches are attached reaches well into the water. Nothing but clear hard water need be used, and there is no sense in changing this, a little fresh being carefully added whenever required. See that the bunches swing clear of the bottles, and that every decaying berry and all rubbish are cut out directly they are seen.

PRUNING VINES.—There ought to be no further delay in completing the pruning of all the successional Vines as well as any of the late ones that have been cleared of bunches. Very hard pruning in the case of the laterals is the surest way of

keeping the spurs short, but it is possible to overdo it, neatness not being the sole aim. If the laterals are shortened to the first bud, this being close up to the old wood, the chances are the bunches resulting will be somewhat small, and in some instances there may be no "shows" at all. If the laterals of Black Hamburg, Madresfield Court, Foster's Seedling, Muscat of Alexandria, Alicante, Alnwick Seedling, Gros Colman, Lady Downe's, Mrs. Pearson, Mrs. Pinco's Muscat, and other free-bearing varieties are shortened to the second bud, this usually being about 1 inch from the old wood, there is little likelihood of bunches being either scarce or too small. If extra fine bunches are desired, then the plan of cutting to the first large plump bud, no matter how far this may be situated from the rod, should be tried. Buckland Sweetwater, unless the roots are confined to a small border, Gros Maroc, Golden Queen, Duke of Buccleuch, and Gros Guillaume usually produce the finest bunches from young canes, what is known as the long rod system of training and pruning answering well with these comparatively shy bearers. The next best plan is to prune to a plump bud, or say to the third or fourth from the old wood. By keeping the spurs a good distance apart, or sufficiently so for two lateral growths to be laid in, one being from the back bud, foreshortening can be practised every winter, and no unsightly spurs be formed accordingly.

PRUNING YOUNG VINES.—Any that are at all feeble, as well as the majority of those newly planted, ought to be freely shortened back with a view to promoting a much stronger growth next season. Supernumeraries, or those that are to be cropped heavily for one, or at the most two seasons and then rooted out, ought to have been stopped when about 9 feet in length and no pruning be needed now other than cutting out all laterals. When young permanent Vines are growing strongly there is no wisdom in pruning the leaders severely, the foundation of straight and strong rods being laid by leaving them to a good length, heavy cropping being avoided. When the leading canes measure 2 inches or rather less in circumference, they may safely be left to a length of 7 feet, this length being added to or lessened according to the size of the canes. All laterals on quite young canes should be cut cleanly out and those on the older wood be shortened as advised in the case of established Vines. As previously intimated, the wood is well ripened this season, but those who have any doubts about the wounds closing sufficiently to prevent bleeding when sap movement commences should dress them with either Thompson's styptic or ordinary painter's knoting.

CLEANSING AND DRESSING VINES.—This ought to follow closely upon the pruning. It should be thorough, but not quite so drastic as former generations of gardeners considered indispensable. It is a very great blunder to denude the rods of their natural covering in the shape of old, as well as new bark, and there ought therefore to be no skinning, scraping and polishing, as of old. Quite the looest of the bark may be removed, especially near the spurs, but no more than this, and certainly no exposing or cutting into the fresh bark. All this was previously done with a view to searching out insects and their eggs, lurking places for the former also being stopped. The same desirable end may be attained with far less trouble and with greater safety by simply giving the rods a thorough scrubbing with quite hot soapy water, and if there is any doubt about this being a sufficient precaution, following with a dressing of Gishurst compound, 8 czs. of the latter being dissolved and then mixed with one gallon of clayey water and well brushed in, this also being a mild preventive. If mealy bug has shown itself, first scrub the rods and then dress with a mixture of gas tar and clayey water, a quart of the former being enough for adding to a gallon of the latter. This should be kept well mixed, and ought to be thin enough when cold to admit of its being brushed into every crevice. There is really no perfect and safe remedy for mealy bug for winter application, but the one given answers well if what few escape are hunted for frequently after the

Vines have commenced active growth. The present is a good time to paint the woodwork of vineries, and failing this it should be scrubbed with hot soapy water, the glass cleaned, and the walls dressed with hot lime water. All rubbish should be cleaned out, inside borders loosened, the much trampled soil taken out and a rich top-dressing given. If the borders are at all dry let the top-dressing follow a good watering.

PLANTING VINES.—Early in February is a good time to plant ripened canes, but if advisable to defer planting to that period of the winter it would be unwise to put off the preparation of the border till just before it is wanted. Advantage should be taken of comparatively dry, open weather to collect the requisite quantity of fresh turf, or other soil of a good loamy character, and also wood ashes, charred soil, charcoal, and old mortar rubbish. If for an outside border, keep it all in a heap on dry ground and cover with corrugated iron or shutters, so as to ward off the rains. Inside borders may well be formed at once, and the soil will then be somewhat warmed by planting time. No particular soils or mixtures are absolutely necessary, but the following compost can be strongly recommended. To every six cart-loads of turfy loam, roughly chopped up, add a cartload each of nearly fresh horse droppings, wood ashes, charred soil and charcoal mixture, and old mortar or lime rubbish, two bushels of dry soot, and three hundred-weight of mixed ground bones. This, well mixed and firmly put together on a well-drained bottom, ought to grow Grapes to perfection.

PRACTICAL.

PLANT HOUSES.

FORCING PLANTS AND SHRUBS.—Where there is the prospect of a considerable demand for cut flowers or plants even during January and early in February, it is now time to be making arrangements for early forcing. To defer the starting and then have to excite the plants in more heat than is good for them is bad practice. It not only weakens the plants, but causes the flowers to be more flimsy; hence they do not last so well. An early vinery just about being started, or a Peach house under the same conditions, will be very suitable for many of these plants. The moist atmosphere with not too much fire-heat is far better than a higher temperature. A bed of leaves to plunge the pots in would be an additional advantage, a genial moisture always arising therefrom, which is admirably suited to forced plants. Those should be chosen for first early forcing which are known to respond readily when placed in warmth. Lilacs will do this very satisfactorily, no sorts for early work surpassing Charles X, a well-known kind, and Mme. Legraye, a pure white variety with fine flowers and solid trusses, equally as profuse as the first named, and one which I think will be a formidable rival to it if it does not even find more favour when better known. Established plants of *Azalea mollis* will now start kindly into growth. I say "established," for these are infinitely better for early work than newly potted ones, the buds of which drop at times in an annoying fashion. Another promising plant for early forcing is *Cerasus Watereri*, which does not yet appear to be sufficiently known; it is a vigorous growing variety with large double blossoms, white, with a blush tint at times. This double Cherry should be noted. *Prunus sinensis flore-pleno* (the double Plum) when established in pots also forces well, but it is none too plentiful in gardens. The only Rhododendrons that should be started yet are *Nobleanum* and *Early Gem*, both of which are pre-disposed to flower extra early. The Guelder Rose when well prepared is also reliable; so is *Deutzia gracilis*. Thoroughly well-established plants of Tea Roses will also start kindly now, choosing the most reliable kinds. *Gloire de Dijon* is one of these; *Isabella Sprunt* is another. It is a waste of material to attempt to force such as the finer Rhododendrons, *Andromeda floribunda* or *Kalmia latifolia* yet. A relay of the other kinds above mentioned should, however, be in a cool house or

where the frost can be kept from them, so as to be in readiness for a succession. Of Indian Azaleas there is no white to beat *Deutsche Perle* for fine individual blooms or the old *indica alba* for a profusion of flower. *A. amona* should not, of course, be overlooked, nor should *A. obtusa*, its companion plant, with bright red flowers. Of other sorts, *A. paniculata*, with variegated blossoms, is very free. These are all better than having to resort to the later kinds thus early in the season. In dealing with these Azaleas, look sharply after thrips, for if placed in vineries it may be the beginning of trouble that will afterwards be regretted. If a proper forcing pit can be arranged for, it will be all the better; ventilation can then be given when needed and other items of culture better controlled than in either vineries or Peach houses.

BULBS.—Roman Hyacinths are flowering well this season, with more secondary spikes than usual. These when potted early come on so much more kindly, it being then an easy matter to regulate the supply. A splendid succession to this valuable kind is the straw-coloured French Hyacinth, which has beautiful clear pale yellow flowers. It is a welcome change to the preceding in colour, there being no other early yellow variety that can at all approach it. With us it is now showing flower. Roman and Paper-white Narcissi are easily got into flower at this season. Grand Monarque should be grown more for early flowering, being very reliable; we shall cut it in January. The common double Daffodil, potted early and well rooted outside, will now be quite fit for forcing, but too sudden a change must not be given; ours are coming on strongly in a Peach house. The earlier sorts of Hyacinths, other than those already alluded to, should now be fit for uncovering (if it be not already done); these should always be placed by themselves, so as to be easily accessible without disturbing the main batch. In the course of a week or two it will then be possible to start them in a tolerably strong heat. See to it that the main batch is well protected if frost set in at all severe. For this reason I prefer when I can spare the room to have them in frames. Where an early growth has been obtained upon Freesias these also will bear gentle forcing; they seem this year to be growing more kindly than usual. Early started *Lilium Harrisii* will now bear more heat, but care should be taken that the soil does not get saturated. A forcing pit or an early vinery will be a good place for them. Where the Cape Tuberoses are grown for an early supply the growth should now be well on the move; if a steady bottom heat can be given, these plants will appreciate the assistance thus afforded. These would come on well in a Pine stove or Cucumber house, a brisk temperature suiting them. Lilies of the Valley will start all the better if in a bottom heat of 85°, the crowns being covered with cocoa fibre or Sphagnum Moss to keep them equally moist. Crowns of these must for the present be chiefly relied on.

JAMES HUDSON.

BOOKS.

THE ORCHID SEEKERS IN BORNEO.*

THIS is a book of adventure admirably suited for boys or young men interested in the wonders of tropical vegetation as they sit around the winter's fire. We cannot compare the work with "The Plant Hunters" of the late Captain Mayne Reid, for example, but it is interesting as dealing with a newer country and different scenery. The plot is a simple one and the scene is that of Borneo fifty years ago, when the late Sir James Brooke was establishing the presidency of Sarawak. The anomaly of engrafting a modern plot upon an older scene, period and action is not a matter of

* "The Orchid Seekers: A Story of Adventure in Borneo." By Ashmore Rattan and Frederick Boyle. Illustrated by Alfred Hartley. London: Chapman and Hall, Limited. 1893.

so much consequence; but we had expected from its title this story would have been more artistically told and that it would have had a much better ending than it really has.

The scene opens in the hothouses of an Orchid importer—a Mr. Ryder—who had heard a story of a wonderful blue Orchid being seen in Borneo, as told by an eccentric old sailor named Bounce. An Orchid collector—Ludwig Hertz (in whose one-armed personality the reader may perhaps think he recognises the late veteran collector, Herr Roezl)—is by Mr. Ryder commissioned to go to Borneo to find the fascinating “blue Orchid,” and he finally embarks on that wild goose chase, with Bounce as guide and Mr. Ryder’s two sons as amateur assistants. We do not think that there are many mothers so bold and brave as Mrs. Ryder, who so complacently allows both her sons to embark on such a risky adventure. In Singapore Bounce distinguishes himself by killing a Malay who is “running amok,” that is, he is mad and striking with his dagger or kris at everyone he meets in the streets until he is himself cut down. Then the party get afloat and experience a brush with pirates before they land at the capital of Sarawak and make the acquaintance of the Rajah—a quiet Devonshire gentleman who founded the little kingdom of Sarawak and made Kuching, or “the town of the cat,” the thriving little port it is to-day.

After Kuching there are expeditions into the interior and escapades among monkeys, deer, pigs, snakes and alligators. Again, they are in danger from hostile natives, and then in fear of the Chinese settlers and traders, who have their secret societies and treacherous spies everywhere; but the story itself must be read in order that it be fully comprehended. As a traveller in the country named, one feels that but scant justice is done to the luxuriant and abundant forms of life and the beautiful scenery that is so often to be seen in that sunny land. We find nothing particularly local in the descriptions, if we except Sarawak, nothing of Bruai, the capital, the great water city of Borneo—the “Venice of the East,” and there is but little mention of the great mountains of the country, and nothing at all relating to that misty paradise of the giant Pitcher plants—the gigantic mountain range of Kina Balu, the “Chinese Widow” mountain in North Borneo, for the absence of which even the glimpse of the enchanted “Valley of Bidi” cannot quite compensate us.

Tropical life is to be seen at its best in Borneo: the beautiful, and one could well spend a lifetime there among its birds or butterflies alone. The Coleopterous insects or beetles are also very large and varied, and the fresh and salt water fishes of the Malay Archipelago are a revelation in size, form, and colouring to one in the main accustomed to the sombre-hued sea fruits of our northern shores. Even the splendid fish market at Venice pales into insignificance as compared with that at Singapore or at Bruni. But most of our readers will be more interested in the plant treasures of the country, and here they may, perhaps, be a little disappointed, even if not led astray. There are several species of Vandas met with in Borneo, Vanda (Renanthera) Lowi, for example, but V. teres of the Indian continent is represented there by V. Hookeri, and it is extremely doubtful whether Dendrobium macrophyllum has ever been found in Borneo, and the actual habitat of Cirrhopetalum Meduse is unknown, although it came to England from Singapore, in which island I have searched for it in vain, although aided by the most acute of plant-hunting natives. Nor is Cypripedium Fairrieanum a native of Borneo, where Herr Hertz is made to discover it at p. 256.

In the introductory note or preface we are told that when Mr. Ashmore Rassin, one of the two authors, formed the idea of writing this story for the “Boy’s Own Paper,” he consulted Messrs. Sander & Co., of St. Albans, who referred him to Mr. Frederick Boyle, a gentleman who was on the staff of the late Rajah Brooke in Sarawak many years ago. Hence the technical details, the outline of the tale, are his, and for all statements

therein, historical, local or scientific, Mr. Boyle is responsible, and we are left to infer that Mr. Rassin erected the literary superstructure on Mr. Boyle’s facts. The result is an interesting book for young people, or others who wish merely for an amusing tale, but the book seems a little disappointing to one who knows a little about Orchid seeking in Borneo and of the vast and beautiful country itself.

After all, however, one must not take a story book like this too seriously, and to those who know nothing of Borneo and its people, it may teach a good deal that is worth knowing. The authors are to be heartily congratulated on having produced a work in which the adventures are not only possible, but probable as well, for most of them are even to-day by no means exceptional.

Sarawak, where the scene is laid, is to-day a little independent state, ruled by a nephew of the good and gentle Rajah alluded to in this story. Our readers may remember that the late Miss North paid two visits to the Court here, and it was from this territory, near the mines, that Mr. Everett brought to her the first specimens of the wonderful Nepenthes Northiana, some time afterwards introduced by Curtis, the collector for Messrs. Veitch. Here also Sir Hugh Low discovered at the warm springs near Peninjau the lovely Renanthera Lowi, and Cypripedium Stonei platyanium still lingers in the tree tops of that sunny paradise.

One very pleasant custom of the native Borneans is their love and respect for their jungle or forest flowers, or as Mr. Boyle pleasantly puts it at p. 388—

Malay servants have a pleasing habit—not learned from their masters—of setting bowls full of fresh flowers about a room every day. Not infrequently new species have been discovered in this manner, for those people, so indolent as a rule, will give themselves trouble to find and gather flowers that please the eye. When Mr. Bentley (the manager of the antimony mines) rose one morning the bowl already stood upon his dressing-table as usual, but instead of a variety of blooms it was filled with one species—long sprays of a bright blue Orchid. Mr. Templar, managing director of the Borneo Company, had asked him to send home any striking plants which the natives declared uncommon. This gentleman’s collection was one of the best in Europe at the time. No Orchid so striking had Mr. Bentley ever seen, and the Malay “boy,” observing his interest, volunteered the statement that neither he nor any of his comrades recognised the flower. It grew upon a Tapong tree within a few yards of the bungalow. Mr. Bentley must have passed beneath it a thousand times, but that morning only had its buds unfolded. Though sprays enough had been gathered to deck the tables and to adorn the head of every servant a great mass remained. The plant was duly sent to Mr. Templar, who returned a cheque for £100. But when his collection was sold the “blue Orchid” of Borneo had vanished, and it has never been heard of since.

Since the period alluded to in this story many parts of Borneo have been diligently searched by collectors, but Bounce’s “blue Orchid” has not been again seen. Low, Lobb, St. John, Burbidge, Veitch, Curtis, Boxall, and others have alike failed to find not only this rarity, but many others supposed to exist in the wild forests of that luxuriant land.

Those interested in the flora of Borneo should not fail to consult Low’s “Sarawak,” a work now rare, but rich in facts; also St. John’s “Life in the Forests of the Far East,” and Burbidge’s “Gardens of the Sun.” Miss North’s “Recollections of a Happy Life” contains also many notes of her sojournings in that island, and her sketches of its fruits and flowers can be seen in the “North gallery” at Kew, while specimens of musical instruments, weapons, shields, paddles, specimens of natural history, and the gigantic Nepenthes pitchers from Kina Balu can be seen in the Veitchian museums at Chelsea.

With the exception of its erratic scientific information and its rather tame conclusion, this book has our hearty commendation, and is just the book to be given as a present to boys.

TUAN BUNGA.

THE ORCHARDS.*

In the preface to this work the author states that his object in bringing out the small treatise under notice is “to introduce a commercial industry much needed at the present time which will give from the soil a profitable return for capital and labour invested.” Now if this book had been published ten or more years ago, Mr. Cranston might with some reason have written about the introduction of a new industry, but at this comparatively late date he is distinctly behind the times. Not only is he very much behind with his advice, but the treatise itself is not up to date. It consists principally of generalities, instructive particulars, and which should comprise diagrams to aid the novice in planting, woodcuts to better guide the tyro in grafting, as well as forms of trees, and illustrations of insect pests, and the different forms they assume, being completely absent. Several very good books on the subject of fruit growing for profit have already been published, some cheaper, some dearer than Mr. Cranston’s, and it ought to have been the latter gentleman’s aim to surpass these in as many ways as possible. Instead of reviving the, comparatively speaking, time-honoured platitudes about the great advantages of hardy fruit culture as compared with ordinary farming, and which has not yet been wholly proven, the author would have done better to have enlarged and given reliable advice as to what should be done with the fruit after it is grown. It is all very well to point out that “mid-season and soft fruits sell best, and should be sold off immediately they become fit, the market, however, being watched and prices ascertained before they are offered for sale,” but the question is, what can be done with the fruit when buyers cannot be found? In all directions we hear complaints of the great glut in the markets, much fruit not even paying for the cost of picking and sending to the markets. What is wanted is some perfected scheme of distribution, and it is in that direction that would-be benefactors of the occupiers of small holdings should turn their attention. This season the trees flowered so strongly and profusely, that heavy crops of most kinds of fruit were had in spite of the unfavourable weather experienced during the flowering period, and, judging from the present state of the trees, there will be nearly or quite as much bloom next year. If, therefore, those who profess to have the welfare of British farmers at heart will grapple with the difficulty of getting rid of the fruit at remunerative rates after it is grown, they will have done good service. All cannot set up jam factories nor adopt the various methods of drying, candying and canning briefly touched upon by Mr. Cranston; and even if they could, it is very doubtful if they would find a ready sale for their products. That there are many towns and villages in non-fruit-growing districts badly supplied with perishable fruit there is no disputing, but how to reach them is the difficulty.

At the commencement of Mr. Cranston’s treatise sound advice is given as to the improving of old orchards, many of which are undoubtedly in a wretched plight at the present time. Our forefathers failed to use good judgment in their choice of sites, crowding of the trees also being a great mistake that ought to have been remedied by their present owners. This is what the author of “The Orchard” says on the subject, and which will be generally agreed with:—

In many districts will be found orchards planted in the worst possible situations, often in low, damp, or wet grounds, shaded frequently by large trees. In other instances may be seen plantations growing underneath woods, where no sun can shine upon them for half the year. Again, we often find orchards planted on very exposed situations, upon hard, poor brashy ground, open to winds from every quarter, and the trees driven and growing in every conceivable form and position. There is very little chance for trees to thrive or return any profit to the growers under such conditions, and before our

* “The Orchards. Fruit Culture for Small Holdings.” By J. Cranston, King’s Acre, near Hereford.

orchards can become as profitable as they should be this state of things must be remedied.

Suitable sites and soils are among the principal factors in ultimate success with fruit trees, but all are not in a position to either pick and choose or even vary their sites so as to be prepared, as at Toddington, for all emergencies. The advice then to the effect that fruit trees should be planted on every holding "throughout the length and breadth of the land," as being more profitable than corn growing, is, to say the least, mischievous and misleading. It is said that everything can be proved by figures, and Mr. Cranston, in common with those who have advised before him, places some very glowing returns before his readers. Will they bear testing? I am strongly of opinion they will not. Why one of the best managed fruit farms in Gloucestershire was only paying 5 per cent. on the outlay eight years after the start was made, and yet not a particle of fruit was wasted, the bulk of it being bottled or preserved. In this

his. That orchards in some localities do pay well must be conceded, but I am afraid the old saying that "fools build houses which wise men buy" will be varied to the effect that "greenhorns plant orchards only for others to step in and take the profits." If those that plant cannot hold out till the orchards are beginning to be remunerative, the chances are those that succeed them will have the best of the bargain. This points to the necessity for legislation in the direction of an improvement in the Land Tenure Act, the outgoing tenant receiving compensation for unexhausted improvements in the shape of young fruit trees. The security of tenure may now be had as tenant or freeholder under the Small Holdings Act; but what about the compensation for the fruit trees when a tenant can no longer "keep his head above water?"

The selections of varieties of all kinds of hardy orchard fruit are thoroughly reliable, being almost identical with those published by several other

and Pears must be left on the trees until they are fully matured before being gathered, and those intended for storing away must be gathered when fully ripened, otherwise they become shrivelled and lose in weight and quality." Now when we speak of fully ripe fruit, it is usually supposed to be quite fit to eat or at its best, but this ordinary acceptance of the meaning of the word does not find favour with Mr. Cranston, ripeness, according to his ideas, being when the fruit parts readily from the tree and before the chemical changes requisite for rendering it fit to eat have taken place. If novices leave their fruit hanging on the trees till they think it fully ripened, they will spoil a lot of it, and some better advice ought to have been forthcoming in "The Orchard." W. I.

FLOWER GARDEN.

RICINUS ZANZIBARENSIS.

THIS, the seeds of which were received from East Africa, represents an entirely new and distinct class. The plants attain great dimensions, presenting a splendid aspect with their gigantic leaves, which surpass in size and beauty all the species and varieties hitherto known. The seeds are also very distinct, they being of a large size and of new and exquisite tints. *R. zanzibarensis* produces light green leaves of 2 feet to 2½ feet across, with whitish ribs, and may in its general appearance be compared to a luxuriantly growing giant *Aralia Sieboldi*. The stem, branches, and fruit are also of a light green colour; seeds beautifully speckled carmine on a delicate pink ground. *R. zanzibarensis maculatus* is equally handsome and of the same large dimensions as the preceding variety, but differing in the colouring of the leaves, which are coppery bronze when in a young state, changing afterwards to a dark green with reddish ribs; stem and branches coppery-brown; seed white, blotched brown. *R. zanzibarensis cinerascens* has very large leaves of a brownish-purple, changing to dark green with lighter ribs; stem reddish brown; seeds grey, speckled blackish-brown. *R. zanzibarensis niger* has bronze foliage passing into dark green with reddish ribs; stem light brown with a glaucous hue; seeds black.

We have to thank Messrs. Haage and Schmidt for the electro as well as the description of the various forms of this new Castor-oil Plant.

FLOWER GARDEN NOTES.

As the time is now at hand when all flowering deciduous shrubs will have to be carefully headed back where at all events they are encroaching upon surrounding subjects, it may be advisable to give the reminder that as nearly all of them strike readily from cuttings, a good stock can by this means be easily secured. The type and varieties, for instance, of *Deutzia scabra*, *Weigela rosea*, *Ribes sanguineum*, *Philadelphus coronatus*, *Althæa frutex*, one or two of the *Hydrangeas*, and *Forsythia suspensa* are examples of beautiful and useful shrubs. Cuttings of these and others of a similar nature may after the pruning be inserted firmly in a compost consisting of one half sandy loam and the other half fine leaf soil. It is best to put them in some kind of rough frame and give them the benefit of an old light during very bad weather. The substitution of the best of such flowering shrubs for the masses of common and other Laurels that were planted so largely in many pleasure-grounds in bygone days is always a step in the right direction, and they may also be recommended for positions in the more open wild garden, whether it be in large beds on turf, or on large open borders facing dense shrubberies, hitherto devoted, perhaps,

Ricinus zanzibarensis.

case the orchard sites were varied, the soil suitable, few or no mistakes were made in the selection of varieties, and every inch of ground was fully utilised to the extent of hundreds of acres. Isolated cases, or a few particular crops, do not prove anything beyond the fact that there are a few "good hits" occasionally. It should also be remembered that the holders of small farms cannot all adopt the system of forming mixed plantations, but the majority would have to be content to go to work more on the old lines. What it would cost to prepare and plant an acre or more of ground is stated by the author, who also gives an approximate estimated yield per acre, as well as other good reliable information, but quite forgets to add how long the planter has to wait, or whether one year or twelve years, before the tempting figures are reached. I will do Mr. Cranston the justice of adding that his estimates are moderate compared with those of others that have appeared previously to

authorities; but if the author could not consistently furnish a novel selection, he might and ought, at any rate, to spell the names of those he has given correctly. In the Apple lists he adopts both methods of spelling Beefing, has Quarrinden for Quarrenden, leaves the final "e" out of Reinette, has Tylor's for Tyler's, Wykin for Wyken, and spells Pear Durondeau Durondeaw, this not comprising all the mis-spelt names. In another place, when advising upon root-pruning, we are told to "dig well underneath so as to get at the large 'top' roots," instead of tap roots, this being a very bad oversight indeed. An author who preceded Mr. Cranston on the same subject, that is to say, the cultivation of hardy fruit for profit, overlooked Damsons entirely beyond one brief valueless reference, but he made no such blunders as are apparent in "The Orchard." Yet another instance by way of substantiation of this assertion. On page 53 Mr. Cranston states that "late Apples

almost entirely to annuals. In either case a good arrangement in planting in lieu of the mixing usually practised is to devote each large bed or a large portion of border to a separate family in its several varieties. The display hitherto furnished by the annuals may be continued, all shrubs being planted sufficiently wide apart to allow for a sowing between them, selecting for choice the dwarf annuals. The floral display of the earlier shrubs, as the Ribes and Cydonias, will naturally be past before the annuals come, but in this case the occasional clumps of foliage rising above the bright carpet of flower will afford a pleasing contrast to the same. Suitable annuals would be the new dwarf Candytuft, *Clintonia elegans* and pulchella, *Limnanthes Douglasi*, *Saponaria calabrica*, the Portulacas, *Silene pendula* compacta, the miniature French Marigolds, the compacta strain of Petunia and a few others. Where the planting of occasional ornamental trees in connection with flower garden and pleasure ground is in contemplation I should like to suggest the advisability of a very careful consideration of surroundings before the trees are placed in position. Both in the case of coniferæ and deciduous trees there are situations ruined by injudicious planting, blocking out nice bits of landscape with large specimens, or partially filling some bold slope with such things as the smaller *Cryptomerias* or *Thujas* where Silver or Douglas Firs or a few of the biggest deciduous trees would be far preferable. Half-a-dozen conifers that may be recommended as being suitable specimen trees are *Cedrus deodara*, *C. atlantica*, *Cryptomeria japonica*, *Abies Morinda*, *A. brachyphylla* and *A. concolor violacea*. It must, however, be borne in mind that suitability of soil on the one hand and possibility of shelter on the other are important factors to be considered in the planting of some of the choicer coniferæ; their chance of longevity, or at any rate their annual rate of progress, is materially affected thereby. Striking examples of both the above qualifying factors are close at hand, in firstly the Deodars and the Japanese Cedars. In the case of the Deodars we have in one part of the grounds trees barely 40 feet high, but girthing 7 feet just above ground level, whilst others are not more than three parts the size in girth, but have run up straight as gun barrels to a height of 70 feet. Shelter is an important factor towards the successful growth of *Cryptomeria japonica*. So screened by surroundings that it does not come under the influence of driving gales, its leader runs up straight and true; whereas in exposed situations it gets bent and often partially or entirely broken out, so that a shapely specimen is seldom secured. Exotic deciduous trees also vary greatly in habit in different soils and situations; for instance, the different forms of growth in *Ginkgo biloba*, in the Virginian Bay, in the Kentucky Coffee tree, and in the Apple and Pear Service. It is fortunate in the interests of true flower gardening that some of the above trees or others of a like ornamental character are now often called for to fill occasional sites in large gardens as opposed to the umbrella-like Bays and Portugal Laurels that were so much in favour a quarter of a century ago.

DAFFODILS.—Where Daffodils in quantity are naturalised in the flower garden and cut flowers from the same are required as early as possible, it is a good plan to leave a coating of autumn leaves on one or two large clumps in sufficient quantity to keep out the frost. I had ample testimony last season of the value of this in the case of some covered Tenby Daffodils which showed a considerable length of grass when the leaves were removed at the end of the January frost; they came straight away without further check and were very quickly in flower. Any positions between lawn and shrubbery where the turf may be in an indifferent state, owing perhaps to the heading back of large shrubs, will serve admirably for the naturalisation of Daffodils in variety, and if the stock of these is somewhat limited, I have found it a good plan to make a thin planting of the small-leaved *Periwinkle* any time from now through the winter when the state of the ground permits, and then dot in the Daffodils at the end of the following

summer. If, as suggested above, they are in considerable request as cut flowers, the selection of varieties at planting time must be made with the idea of securing a lengthy season.

Claremont.

E. BURRELL.

NELUMBiums IN AMERICA.

I AM very pleased to see the interest taken in aquatics in the old country, but I cannot but think that some of your contributors do some guessing, as certainly "W. W." does in THE GARDEN, NOV. 11 (p. 435). As far as my experience goes in handling Nelumbiums, although many report failures, no plants are more readily transplanted or raised from seed. Tubers are preferable, as they will establish themselves and bloom profusely the first season. Although hardy in a sense, yet I find that, disturbed early in the season and exposed to changes of temperature, they invariably suffer, and failure when planted is often the result. Tubers dug on the arrival of spring are a little excited, and when conditions are favourable for active growth, there is little risk attending such planting. That such tubers will travel well and stand a journey of several hundreds of miles I can verify, for I have sent tubers from New York to the Northern States on the Pacific, a distance of over 3000 miles. I have sent to Madeira and also to the Imperial Gardens at St. Petersburg with success. The establishing in pots, as "W. W." states, will not do at all. Nelumbiums raised from seed invariably flower the second year, although I must admit there are exceptions; but *N. speciosum* and *N. s. roseum* will flower from seed the second season, but not grown, as "W. W." suggests. Seed planted in March and placed in a tank with water at a temperature of 70° will germinate in from seven to ten days, and just as rapidly as the seedlings grow should they be repotted or placed in pans of good rich loamy soil, and by June 1 they will be strong plants. As soon as sub-tropical bedding can be carried out, Nelumbium plants should be planted out by the edge of the pond in shallow water and the shoots (main runners) headed for deeper water. Here they can have three months' summer growth, with the result (barring unforeseen accidents) that they will take care of themselves, with the prospect that they will appear again the following April or May. If plants (seedlings) instead of being planted out in the pond are placed in tubs and stood in warm quarters outdoors, they will also make rapid growth and mature tubers that will bloom another season. I do not advocate growing Nelumbiums in tubs, as they, with all other aquatics, are voracious feeders, and the probability is that the plants would soon get starved out in a tub, and failure would be the result.

W. TRICKER.

Dongan Hills, N. Y., U.S.A.

CAMPANULA MURALIS.

So highly do I appreciate Mr. Wood's notes, that I was extremely reluctant to criticise in any way that on the Bavarian variety of *Campanula muralis*. I am glad to find that I must to some extent have misunderstood the tenor of his remarks, and that it is on account of the increased size, colour and succession of flowers that the slightly increased vigour is appreciated. One of the beauties of the alpine garden is the dwarf habit of so many of its occupants, and one is reluctant to see these

discarded for more vigorous growers. I have only had my plant for a short time, and it is just possible that it may not be the same as that spoken of by your correspondent. I hope however, to test this, but in any case a flower which commends itself to such competent judges as Rev. C. W. Dod and Mr. Wood do not deserve to suffer from neglect. The question of nomenclature, which I have raised by a chance remark, is not at all new to me, and all who have experienced the difficulty of endeavouring to unravel the mysteries of the names of the dwarf *Campanulas* will appreciate the points involved. Mr. Wolley Dod has told us in his admirable article on *C. garganica* on page 506 that he has reduced nearly a dozen names to the two species *C. Portenschlagiana* and *C. garganica*. No doubt this is correct from a botanical point of view, but should we want to obtain the dwarf *Campanula*, which is known to several nurserymen as *C. muralis* and as distinct from *C. Portenschlagiana*, for what are we to ask if it is to be absorbed under either *garganica* or *Portenschlagiana*? From a garden point of view it is distinct enough, although in view of the authorities adduced by Rev. C. W. Dod and Mons. Correvon, the name may not be strictly correct. My attention to the difference between the two plants was first attracted by the drawing of *C. muralis* in Maund's "Botanic Garden," vol. iii, plate 121, where a plant is figured which is distinct from *C. Portenschlagiana*. In the descriptive letterpress it is said "It has been called *Portenschlagiana* by the German botanists Romer and Schultes, but is quite distinct from that species as figured in the "Flora Græca." I had considerable difficulty in obtaining a plant which appeared to correspond with the engraving, but I believe that I have now in my garden the one thus figured by Maund. It is of considerably dwarf habit than *Portenschlagiana*, has more open flowers, and is at least distinct enough to deserve a name to distinguish it from the other. In general appearance it appears to have more resemblance to *C. garganica*, but its habit of rooting is like that of *Portenschlagiana*. Another thing which I have observed is that *C. garganica* is very liable to be destroyed by slugs in my garden either in the seedling stage or when of full size, while *C. Portenschlagiana* and what I am growing as *C. muralis* have complete immunity.

In view of the confusion of nomenclature, might I venture to suggest to Mons. Correvon the desirability of dropping the name of *muralis* as applied to the larger form generally known as *Portenschlagiana*. I hope Mr. Wood will give us his opinion regarding a distinct name for the plant, which he also seems to grow as *muralis*.—S. ARNOTT, *Rosedene, Carse-thorn, Dumfries, N.B.*

I have read with much interest the remarks of your numerous correspondents upon the Bavarian Bellflower, which after all is not found in Bavaria. My interest is still growing, and I should feel extremely obliged to any of your readers who will tell us what *Campanula muralis* is. It is figured in Maund's "Botanic Garden," vol. vii, No. 603, and also again in Wooster's "Alpine Plants," plate 43, fig. 1. Here we have a charming little Bellflower, not at all common in cultivation at the present time. It is not *Campanula Portenschlagiana* of Romer and Schultes, a name adopted by Alphonse de Candolle in his "Exhaustive Monograph of *Campanula*," published in 1830. Neither is the plant in question *Campanula garganica*, which is also figured in Maund's "Botanic Garden," vol. vii, No. 587, and also in Sweet's "British Flower Garden," vol. ii, p. 252. *Campanula muralis*, as figured in the above-mentioned books, is much more allied to *Campanula garganica* than to *Campanula Portenschlagiana*. It is an evergreen plant with smaller

leaves than *Campanula garganica*, but the individual flowers are much larger, not so deeply cut, of a pale blue colour, and borne on erect flower-stems. The leaves are glabrous, crenate, reniform on short foot-stalks. Some years ago I received a *Campanula* under the name of *C. mollis*, which turned out to be the large form of the true *Campanula Portenschlagiana*, a plant which is fairly common in cultivation. This is easily accounted for, as it is a very free grower, and can be divided almost at any time.

There is an excellent figure of *Campanula Portenschlagiana* in De Candolle's "Monograph of the Campanulas." He mentions two varieties of this plant, one with smooth leaves, generally found in cultivation in this country, and a second, *Campanula Portenschlagiana* var. *velutina*. The ordinary type of this *Campanula* is one of the most persistent bloomers we have; even now at this dull season it is quite gay with flowers in a cold frame. While upon the subject of *Campanulas*, can anyone give me some information about a little *Campanula* which has been doing duty for *C. Raineri* (Romer and Schultes), to which it bears, however, very little relation? It is a very dwarf plant, with yellowish green leaves. It is evidently related to *C. pulla*, but differs from it with respect to its foliage, which is densely covered with hairs. It was for a long time sold for *Campanula* G. F. Wilson, but it is not the variety which the late Anderson-Henry named after Mr. Wilson. The plant is fairly common in collections, and is worthy of a distinct name.—W. H. STANSFIELD, *Southport*.

KITCHEN GARDEN.

EARLY PEAS.

VERY few gardeners now-a-days resort to the old practice of sowing seed in November, preferring rather to raise the requisite number of plants under glass in February or March and to turn these out into the open ground at the first favourable opportunity. In this manner quite as early dishes can be gathered and fairly heavy crops obtained with even less trouble than has to be taken with the late autumn-sown rows. It does not follow, however, that early Peas should not in most cases enter into our calculations at the present time or even earlier; but, on the contrary, preparations ought as a rule to be made for this important crop long before mid-winter arrives. Some soils are so constituted as to admit of their being dug and sown at almost any time, but where there is a fair amount of clay in the soil, or just enough to render it somewhat stiff to work, then it will usually be found necessary to lay it well up to the disintegrating influences of frosts, frosty winds, sunshine and rain sufficiently long for it to get into a free working condition by the time seed has to be sown or plants put out. Anything in the shape of lumpy ground does not suit Peas, or indeed any other kinds of vegetables, and if one turning of the soil is not sufficient to pulverise it to a good depth, then it may well be re-dug long enough in advance of seed-sowing or planting for the lumps brought to the surface to be broken down by a fork, hoe or rake. No mistake will be made in digging in some half-rotten horse stable or mixed farm-yard manure, either being far superior to the poor rotten stuff in the shape of old hotbed material that too often has to be relied upon by private gardeners. If buried a good spit deep it need not be disturbed should the ground have to be re-dug. I find the site previously occupied or newly cleared of early Peas admirably adapted for autumn and winter Broccoli, the first preparation being sufficient to meet the requirements of both crops.

Early Peas are very generally assigned an extra favourable position, or what is thought to be such, viz., a good length of border in front of a south wall. If that is the only raised portion of the garden with a sunny aspect, then it is where the earliest Peas, if we except the very foot of the walls, can be had; but when the more open quarters are also sloping southwards, then the upper portion will grow early Peas to perfection, the south borders being devoted to the production of a variety of other equally valuable crops, including Strawberries. Do what we will or give the benefit of wall shelter and the sunniest of sunny aspects, private gardeners can scarcely beat market growers in the matter of earliness of crops. Too much shelter, coupled with a deep and rich root-run, favours the growth of haulm rather than early productiveness, and that is where the farmers have the advantage. Too much shelter includes the common practice of using stakes for early Peas. Instead of these being necessary for the latter, they might well be wholly dispensed with, a considerable saving in the shape of labour and stakes, when these have to be bought, being effected accordingly. Stakes do not tend to increase production of anything but haulm, and it is my impression that rather the best crops are had from the unstaked rows. There is yet another strong point in favour of doing without stakes. When stakes are used, the rows are mostly arranged from 3 feet to 4 feet apart; whereas if none are to be employed, a distance of 2 feet apart is sufficient for all varieties that do not attain when supported by stakes a height beyond 4 feet. In the open fields Telephone is frequently sown in drills drawn 30 inches apart, and yet the rows never run into each other. After being moulded up the plants grow erect till they become top-heavy, when they gradually settle down till they rest on the ground, after which the points once more strike upwards, the weight of pods they soon after produce not wholly dragging them down again. A mulching of strawy litter would save the pods from being splashed, though this is only a matter of choice, it being a very simple proceeding to rinse any clean that may appear to need it. Only the most reckless picker would greatly disturb the haulm till the end of the crop was nearly reached, and if my experience is any criterion, the picking would commence two days earlier from unstaked rows than from those of the same age and variety growing alongside and supported by stakes. Early Peas are not often too plentiful; it is more frequently the other way, in fact. If, therefore, avoiding the use of stakes admits of nearly double the number of rows being grown than formerly, it follows that the gatherings will be heavier and oftener than would otherwise have been the case. A few rows may well be planted out from pots or boxes, plants thus forwarded under glass usually being a few days earlier in coming into bearing than those resulting from sowing seed direct into the open ground. In order to have a close succession and heavy crops the seed should be sown as early in February as the ground can be got into a good working state.

Pea seed will be considerably dearer than usual, that is if retail charges are increased in anything like the same ratio as the wholesale prices. There is also every likelihood of much old seed finding its way into gardens, and there will be all the more necessity therefore for extra pains being taken with the preparation of the ground for its reception. It is also a matter for consideration whether or not it is advisable to give a trial to some of the cheaper varieties,

or such as the market growers find succeed admirably. I am of opinion we shall never have a thoroughly reliable wrinkled-seeded variety for affording the first gatherings. American Wonder, English Wonder (a great improvement on the latter), William Hurst and Chelsea Gem are all good dwarf, early varieties, but the seed, if sown early in February, is liable to perish in the ground, and such is too often the case with other wrinkled-seeded varieties when sown early. Those varieties with nearly or quite smooth seeds are the best for early sowing, and if not left too long before gathering, the quality is not so very much inferior to that of the early wrinkled-seeded forms. William I. is still one of the most popular varieties for early sowing, and I can also testify to the good quality of Exonian, this being nearly a week earlier. Experienced market growers have formed a very high opinion of Harrison's Eclipse, preferring it in fact to any other early variety. A considerable quantity of good seed of this variety was saved last summer, and being largely bought up by some of the leading wholesale houses, private growers will have no difficulty in getting a supply. It is my intention to sow at least two quarts of Eclipse, and if it succeeds as well under garden culture as it does in the open fields, no mistake will have been made in favouring this sort at the expense of other varieties with more glowing descriptions, and which will be quoted at much higher prices.

W. IGGULDEN.

Spinach in exposed positions.—How much better this vegetable stands severe weather if not coddled in any way and kept clean and thin. I recently saw some beds that had been grown thickly and under trees for shelter present a deplorable condition after 15° of frost; whereas that sown in the open freely exposed is uninjured. For early sowing in the spring a sheltered spot may be beneficial, but I feel sure for the winter supply coddling is a mistake. A well-drained quarter is much better than shelter overhead. Of course, with winter Spinach more depends upon the time of sowing than upon the variety, as nearly every kind is hardy. It is the excessive wet combined with insect attacks at the root that often injures the plant. I only grow the round-leaved or what is termed summer Spinach. It certainly is an improved form, namely, the Victoria, but quite as hardy and more productive than the winter variety, which runs to seed so quickly in the early spring. I find sowing on firm land of great advantage, the growth being hardier, the foliage thicker, and less liable to injury. On our light soil we roll and tread the ground, and after severe frost give a dressing of wood ashes between the rows and a good treading afterwards.—G. WYTHES.

White & yellow Turnips.—In the south of England there is a decided aversion to yellow-fleshed Turnips, and so long as good white-fleshed ones can be had in plenty it is difficult to sell the yellow ones, although they are fully equal, if not superior to the white-fleshed ones. It is now several years since there was such a plentiful supply of good white Turnips fit for market as at the present time. Twenty bunches for a shilling is not a very profitable affair for the grower. There is a glut of green crops as well as roots, for owing to the intense drought there was every appearance of vegetables being scarce and dear; but with the genial rains everyone started planting green stuff or sowing Turnips, the result being that the great heat in the soil, coupled with a mild autumn, caused such a rapid growth that fields and gardens are full of crops ready for market. On examination I find that the best Turnips are the White Stone or Green-top Stone. They are of good shape, very clean-fleshed and tender. Many of the red-skinned sorts are hard and warty and by no means so inviting to the eye as the white ones.

There is still a great quantity of white ones to dispose of, and if severe frost sets in, both Turnips and other crops are rather too luxuriant to withstand it. I have lately pulled a great many of the best white Turnips and laid them in trenches, covering the roots right over with soil, but leaving the tops exposed.—J. G., *Hants.*

Globe Artichokes from seed—In severe winters these have suffered badly, and in many cases seed sowing has been resorted to for the production of stock. It is not advisable to obtain plants from seed if it can be helped, as the seedlings are often so poor that it pays well to obtain suckers or offsets, even if the expense is much greater. The great objection to plants from seed is their inferior quality. In no case have I ever seen a good stock obtained from seed, no matter from what source it was obtained. Those who only have room for a limited quantity and are getting short of suckers would do well to carefully detach the small suckers of this year's growth before covering up the plants. These may be potted up and kept in cold frames, and will make nice plants for spring planting if a small ball of earth is taken with the roots at the time of potting. Little water will be required during the winter. I have also stored in boxes, but prefer potting, as there is a saving of time when planted with a nice ball of roots.—S. H. B.

Deep cultivation.—The past season has proved very conclusively the great value of trenching the soil, or double digging it at least 2 feet deep. On soils of almost every character its advantages have been more or less marked, but on very light soils the effect has been most apparent. Vegetable crops that were put in at the same time on deeply-worked soil as on that dug in the ordinary manner have proved in the one case a success, and in the other a failure. Unfortunately, labour is so limited in many gardens, that deep cultivation is almost out of the question. At the same time, I think an effort should be made to trench at least a portion of the kitchen garden, so that the whole may be done in, say, four years. In my own case from this time until the end of January, whenever weather and time permit, a quarter of the vegetable ground is dug from 2 feet to 3 feet deep, putting any vegetable refuse or manure in the bottom and leaving the surface as rough as possible. Early in February every part of the garden that has been dug is dressed with agricultural salt at the rate of 5 cwt. per acre; this serves several very useful purposes on our light soil, it retains moisture, manures the ground, and destroys vast quantities of slugs and other insect enemies. Possibly the salt would not be advisable on clayey soil, as it would make it still heavier, but for light soils it is excellent. With the exception of Peas, all crops have grown splendidly on the ground so treated, and the long drought has not affected them in the least. Cauliflowers and Lettuce especially have developed into great size on the deeply-worked and salted soil, and are remarkably free from grubs, &c., that spoil their appearance. Since adopting the above method about twelve years ago clubbing at the root has not once occurred amongst the Brassica tribe, though very prevalent previously.—W.

Rotten Celery.—I have never been more disappointed with the early Celery than I am this season. It attained to a good height and was apparently healthy and sound when earthed up for the last time at the beginning of October. It had no rain upon it from that date until I commenced to lift. Yet for all this I have scarcely a sound stick in a row of about one hundred plants. In many instances the centres are entirely rotten. I hoped that the evil would be confined to the white variety, but on examination found the red to be in the same condition. Had the summer been excessively wet and humid, or had earthing-up been performed when stems and foliage were in a saturated condition, I could have understood it; but after such a tropical summer, and considering that the plants only received three or four artificial waterings during the growing period, and that the soil was placed round them when

perfectly dry, I cannot arrive at any definite conclusion as to the cause of decay. I am not the only sufferer in this district, as Celery in many other gardens is similarly affected. It would be interesting to know how it is turning out in other parts of the country, and also whether Mr. A. Young, Mr. Iggulden, or any other correspondent can solve what to me is at present a mystery.—JOHN CRAWFORD, *Coddington Hall.*

ORCHARD AND FRUIT GARDEN.

WINTER TREATMENT OF GOOSE-BERRIES.

REPEATED bad attacks of caterpillars and red spider have so greatly weakened innumerable Gooseberry bushes, that it is advisable in very many cases to root them up and replace with new ones. This may not quite meet the views of those who have charge of the gardens or orchards, as the case may be, but unless the bushes recover surprisingly during the next season, not a few of them will to a certain extent be so far dead as to render rooting out imperative. I do not, however, advise any very drastic measures in the case of comparatively young bushes or any that would pay for being taken in hand with a view to restoring them to a healthy, productive state. It is the ugly old space-filling bushes that have thoroughly exhausted the ground in which they have so long been established, and which are now so debilitated as to be past restoration. Waste no further time or space over these, and expend more labour, manure, and such like on those that will most probably respond to the restorative measures taken. What is wanted is a stronger wood growth, and not till this takes place will the bushes once more produce good crops of fruit. Those that broke very feebly last spring will most probably start even worse next season, that is if the caterpillars or red spider or both together were again at work on what leaves formed. In all such cases I would recommend a rather free use of the pruning knife, as it is very certain this will not entail a loss of crop, for of fruit there will be none worth mentioning, and it will be one step towards promoting a more vigorous growth of young wood. All straggling growths ought in particular to be freely shortened back to better placed inner wood, this admitting of the spaces between the rows being cropped with vegetables or Strawberries if need be. In some instances poverty at the roots has been largely responsible for the weakly growth that red spider so quickly destroyed, and not till the soil has been enriched somewhat will the bushes ever again become really profitable. Private growers too often overlook the fact of heavily cropping fruit bushes being nearly as much in need of manure as ordinary vegetables. For the first three or four seasons well-prepared garden ground is sufficiently rich to support the bushes, but this will not last for ever. Market growers give their bushes a liberal dressing of strong farmyard or stable manure every second or third year, and private gardeners will do well to be nearly as liberal with their manure. It is during the winter that this should be applied, and always in the form of a mulch, it being a great mistake to either fork or dig among fruit bushes generally. Gooseberries are essentially surface rooting, and nothing should be done to either damage or drive the roots downwards. Bushes that are in the habit of forming more young shoots than are desirable do not stand in need of much manure,

but a light mulching would not be wasted on these even, and in any case it is unwise to wait till they show signs of debility before attending to their wants.

We are apt to associate red spider with hot, dry summers, and it is naturally most troublesome at such times. As it happens, however, red spider will thrive in quite a showery season, apparently defying the rainfall no matter how heavy it may be. Caterpillars, again, are equally tenacious of life, while the cocoons resulting are absolutely frost-proof. What the former cannot make much headway against is a solid soil. They can neither enter nor the flies leave it freely, and that is why some places enjoy a comparative immunity from this very destructive pest. In addition to keeping the digging fork or spade out of the soil about the bushes, it is also an old and good plan to make it still closer and firmer by tramping. This coupled with a mulching of manure may, and most probably would, have the effect of minimising the caterpillar attack next season, very few egg-laying flies escaping. One of the oldest and still one of the best remedies for caterpillars that can be tried is spent tanner's bark. Wherever this is freely used among the bushes, caterpillars are conspicuous by their absence; not, however, I think, because of any destructive agency washed down from the bark, but simply owing to its effectually enclosing the flies, supposing the latter duly hatch when the cocoons are thus buried. The bark as it decays affords a certain amount of food for the roots and effectually checks rapid evaporation and cracking of the soil. A good surfacing of soot and lime over and among the bushes acts beneficially enough, but is scarcely worthy of being termed a remedy for caterpillars. There is more to be said in favour of the laborious plan of removing all the surface soil well down to the roots, and to a distance of about 2 feet from the stems, or say as far as the branches reach, and this being either burnt or buried deeply, a considerable number of cocoons will be got rid of. Then if the old soil be replaced by a good rich compost, following upon a dusting of newly-slaked lime, this will further benefit the bushes.

The troubles of Gooseberry growers are not all caused by red spider and caterpillars, but eating birds being even more troublesome in some cases. Planting under or covering over quarters already well furnished with bushes with permanent wire-netting-covered structures is a good remedy, this also serving to ward off blackbirds and such like when the fruit is ripe. Unfortunately, we, under such circumstances, shut out our friends as well as enemies, there being some few birds that will even eat Gooseberry caterpillars. Nothing larger than $\frac{3}{4}$ -inch mesh galvanised wire netting should be used, or small birds will undoubtedly force their way through, and the fronts of the structures ought also to be so formed as to admit of lengths, or, say, large netting-covered shutters, being taken down when it is desirable that birds shall find their way in. I must further add that the framework of any such structure must be strong, or otherwise a great weight of snow may break down the lot. Bullfinches are not easily deterred from their feast on Gooseberry buds but both these and house sparrows may be considerably checked by a free use of cheap black thread over and about the bushes. This can be very rapidly attached to the branches by means of Royle's garden webber, the aim being so to distribute it as to greatly impede the movements of the birds. Well coating the branches with a mixture of soot also acts as a deterrent of bird attacks. Use equal quantities of newly-slaked lime and soot,

this being mixed with water and made sufficiently thin to admit of its being distributed with a syringe. If stale lime is used it will not long stick to the wood and buds, and in any case it may be necessary to repeat the dose before the winter is very far advanced. Those who have been in the habit of drawing their bushes up together in the form of a pyramid are advised to still adhere to this very old and very effective preventive of bird attacks. It is a rather rough job, and the two pair of hands that have to do it should be protected with strong leather gloves, and the branches ought to be well bound up together, tar-twine being used for keeping them in position. If properly done no bird can well find its way into the centre, and only a very few of what may be termed the underside buds are ever taken. So troublesome are birds in places, that it is not safe to let down these bushes till the buds are quite green, anticipating this period of growth sometimes leading to the ground under the bushes being strewn with the remains of the birds' expensive feast in less than twenty-four hours after the bushes are opened out.

Early pruning is also a mistake where birds are known to be troublesome, removing a considerable portion of the young wood rendering the clearance of buds on the rest of the bush easy and certain. In all such cases pruning should be delayed either till the most critical period, this being when the buds are just moving, is past, or even a little later. Market growers do not prune nearly so hard as most private gardeners, and they usually obtain heavier crops accordingly. The most they do is to remove much or all of the undergrowth or that which is so near to the ground that the fruit cannot be kept clean, a little foreshortening sometimes delayed till the fruit is large enough to pick and market, and scarcely any thinning out being practised. It is the hard pruning that causes the formation of very much more young wood than is desirable, and the market grower's bushes though large, are never such impenetrable thickets of growth as might perhaps be imagined. W. I

Apple Adams' Pearmain.—This Apple, frequently met with in old orchards in the west of England, is, I consider, one of the best late dessert Apples in cultivation. It is of fine quality and handsome appearance. Like the majority of late dessert Apples, a warm soil is needed to bring out its highest qualities. This season on our heavy and cold soil it is excellent, the hot weather having suited it admirably. It does well either as a bush or orchard standard, but the leading shoots must be shortened sufficiently in the earlier stages of the tree's growth, or the growth will be rambling.—Y. A. H.

Apple American Mother.—There are few more handsome Apples than this. It is also of fine quality, being tender, and for an Apple having quite a melting flesh with a very pleasant aroma. The only fault I find is that it is not such a free bearer as one would like. It does well either as a pyramid or a bush. It is also well suited for growing as an espalier or even as a cordon.—Y. A. H.

Damsons.—I quite agree with "W." as to Damsons being a most remunerative crop. Whether they are adapted for planting on any class of soil or in any district is, I think, an open question. At least nowhere have I seen the Damson thrive so well as in the west of England and in Kent. In the former district the trees grow to large dimensions, and when I say that I have known trees produce 450 lbs. weight of fruit the value of such trees may be imagined. As regards there being a ready sale, no other fruit crop can be disposed of so readily, the reason probably being that the Damson is not very plentiful in many parts of

England. As stated by "W.," the encouraging of a strong growth is of the greatest importance, there being no fear of the trees failing to bear freely where a strong early growth is made. The Damson is also very partial to moisture at the roots, for although it will thrive just as well in a hedgerow, that is if the soil is suitable, as in the more open ground, yet I suspect on account of this accommodating nature some people have planted it on dry banks; consequently they have failed. Large quantities of Damsons are bought up hereabouts for dyeing. What a useful fruit it is, too, for laying by for winter use, as it may be stored in jars until the following summer. Damsons can be preserved very simply. The jars are filled in with alternate layers of sugar and fruit, and then covered with a piece of paper and placed in a gentle oven to bake. Place them in over-night, and the following morning pour some hot mutton fat over the top, so as to exclude air, and then tie down. Either for making into tarts or, as I prefer, mixed with Apples they make capital puddings or pies.—Y. A. H.

Apple Byford Wonder.—I was pleased to read "W. G. C.'s" note on the above Apple, as from close observation at the recent meeting of the R.H.S. it appeared to be a first-rate variety. The note at p. 502 was opportune, confirming the award recently given it. The variety in question would readily have received a higher award could its cropping qualities have been known. The note referred to speaks highly of it as an excellent cropper, its cooking qualities being unequalled. Being a late Apple is a great point in its favour. Had "W. G. C.'s" opinion been given a little earlier, his remarks would have been appreciated. In the awards to new or little-known varieties of fruit there is often a difficulty as to the habit, bearing, and other points. These should be always given by the senders. I feel sure this Apple will be a good addition to our somewhat limited list of really good late kinds, having size, quality, and productiveness in its favour. The fruits staged were grown on standard trees, an important point for large growers.—S. H. B.

SOCIETIES AND EXHIBITIONS.

ROYAL HORTICULTURAL SOCIETY.

DECEMBER 12.

THIS, the last meeting of the present year, was by no means devoid of interest in any department, although the amount of table space occupied was not so much as on some former occasions. Now and then complaints have been made regarding the light of the Drill Hall, and that not without cause, this last meeting being another case in point. With the best appliances for lighting, with the electric light near at hand, it is a wonder that the authorities who have the management of the hall do not take the advantage of it, which one would think they could easily do. In doing this they would in a measure cement the attachment towards the hall which has been formed by many exhibitors, and leave no real cause for an exodus again to South Kensington.

Orchids were represented by a great variety of good things, Cyripediums again standing out in a prominent manner; also some good Cattleyas as well as Odontoglossums.

The floral committee had nothing before it of such excellence as the superbly grown plants of *Nepenthes* from Messrs. Jas. Veitch and Sons; these were splendid features. From the Royal Botanic Gardens came a few rarities of unusual beauty, plants rarely seen in private establishments. A grand display of *Chrysanthemums* remarkably good for so late in the season was made by Mr. R. Owen; these were a most attractive feature. In the way of fruit there was a very fine collection from Messrs. H. Lane and Son, Berkhamsted, the noteworthy feature in which were the perfect finish, fine size and choice selection of varieties

Some excellent selections of vegetables were sent by Messrs. Veitch and Sons, as well as from the Chiswick Gardens.

Orchid Committee.

First-class certificates were awarded to—

LELIO-CATTELEYA NYSA, a hybrid variety of great beauty, the parentage of which was not given. The blossoms have the sepals and petals of a soft blush colour suffused with pale mauve, the lip being large and finely formed, of a dark purplish crimson, with the throat of a golden shade (cut examples). From Baron Schroeder, The Dell, Egham.

LELIA FINCKENIANA.—A very robust growing variety, presumably a hybrid, nearly allied to *L. anceps*, which it in a measure resembles. The one spike bore six flowers, in which the sepals and petals were of a creamy white with a deep mauve blotch on the lip edged with white, the flowers being of medium size. From Mr. Fincken, Hoyland Hall, Burnley.

CYRIPEDIUM FASCINATUM (*C. Spicerianum* magnificum × *C. hirsutissimum*), in which the outline of the flower, save the dorsal sepal, is characteristic of the last-named parent in colour and spotting, but larger; the dorsal sepal shows its relation to its other parent with a shading of vinous purple; a fine hybrid. From M. Jules Hye Lysen, Ghent.

Awards of merit were adjudged to—

ZYGOPETALUM ROSTRATUM (a species first introduced from Demerara in 1827), the growth of which is dwarf and compact, the labellum being white with dark veins, the sepals and petals of a pale bronzy green; a distinct species. From Messrs. Sander and Co., St. Albans.

CYRIPEDIUM VENUSTUM MEASURESIANUM.—A very pretty form of the species, the colours being a pale green and golden yellow, totally devoid of the darker colouring of the species, quite a distinct variety both in flower and growth, the pinkish suffusion of the underside of the leaf being absent. From Mr. Measures, Cambridge Lodge, Camberwell.

CYRIPEDIUM ENONE (*C. superbiens* × *C. hookerianum*).—A fine hybrid, with the distinctive markings of both its parents and the size of the former with the colour in a measure of the latter parent, a bold flower, the petals densely spotted, the growth being robust and sturdy. From Messrs. Veitch and Sons, Chelsea.

LYCASTE IMSCHOOTIANA (*Lycaste Skinneri* × *Maxillaria nigrescens*), the flowers of which are of a pale greenish yellow, densely marked with minute-like coloured spots, the central portion being of a rich golden shade, the growth vigorous. From Mons. Linden, Brussels.

ODONTOGLOSSUM CRISPUM THOMPSONIÆ.—A splendid variety, with large robust arching spike, bearing fifteen flowers of extra size, the sepals and petals being of great breadth, pure white, with a faint blush shading and a few distinct chocolate spots, a fine form. From M. Linden.

CYRIPEDIUM WARNHAMENSE (*C. Curtisi* × *C. lævigatum*).—A very distinct hybrid, the dorsal sepal taking after *C. Curtisi*, the petals darker, freely spotted, and drooping, the labellum large and extra deep, thus denoting *C. lævigatum*. It is a bold-looking variety, the spike twin-flowered, and the growth vigorous. From Mr. Lucas, Warnham Court.

CYRIPEDIUM SALLIERI AUREUM (*C. insigne* × *C. villosum*).—The petals of this bear a striking resemblance to those of the latter parent in every way, whilst the labellum is similar. The dorsal sepal is quite after its other parent, save in the absence of white, the ground colour a pale yellowish green with dark spots. From Mr. Ebner, Woodlands, Beckenham.

Botanical certificates were voted to—

PLEUROTHALLIS SCAPHA.—A very singular looking Orchid, more remarkable than beautiful. From Mr. Measures.

LYCASTE LUCIANA, the flowers of which are shaded with lake, a distinct variety. From M. Linden.

DENDROBIUM GLOMERATUM.—A new species from Eastern Malaysia, with small deep mauve flowers and a dark orange lip. From Messrs. J. Veitch and Sons.

Messrs. B. S. Williams and Son had an excellent group, comprising several good *Cypripediums*, as *C. Io grande*, with distinct dark spotting on petals; *C. Pitecheri* (Williams' var.), a splendid dark hybrid; *C. Sallieri*, a good form of *C. insigne*; *C. Harrisianum*, a fine specimen plant, freely flowered; *C. enfieldense*, a distinct hybrid, with broad petals; *C. marmorophyllum*, with remarkably fine foliage, putting *C. Lawrenceanum* in the shade; *C. robusticum*, a hybrid with dark flowers of a rich shade, after *C. Schroelerianum*; also *C. Osbornei*, a dark hybrid. *Lælia anceps*, *Calanthe Mylesiana* and *Oncidium obryzatum* were also shown (silver Banksian medal). *M. Linden*, Brussels, sent *Oncidium Phalæopsis*, a pretty specimen; *Odontoglossum crispum amplissimum*, a beautiful arching spike bearing fourteen flowers of very pure colouring; *Catasetum virens*, a singular variety with pale greenish white flowers; *Lælio-Cattleya Stehegoleffiana* (*Lælia grandis* × *L. labiata*), the flowers of which were pale blush, with deep crimson markings on the lip; *Cattleya labiata*, cut blooms; *Cypripedium Robinianum* (*C. Parishii* × *C. Lowi*), with the character of the latter parent in a great measure, and *Odontoglossum guttatum sulphureum*, a fine form, with pale straw-coloured flowers marked with light brown (silver Banksian medal). Messrs. Sander and Co. had a diversified group, containing several forms, greatly varied in colour, of the montanum varieties of *C. insigne*, both the light and dark colours being well represented. *C. Lynchianum* superbum bearing traces of *C. Spicerianum*; *C. Ridolfianum* (*C. Wallaertianum* × *C. insigne*), distinct, with curious dorsal sepal incurved and large in proportion to the rest of the flower; *C. nitens* and *C. Masonianum*, both good forms, were staged. Of other things there were several fine varieties of *Lælia anceps*, as *L. anceps Sanderiana*, one of the best and most distinct; *L. a. Percivaliana*, another beautiful light form; *L. a. alba*, pure white, medium size; *L. a. Oweniana*, with bright rosy flowers and deep purplish crimson lip; and *L. Gouldiana*, nearly allied to *L. anceps*, with rosy-mauve flowers; *Brassia Leeana*, with yellowish or old gold coloured flowers (silver Banksian medal). Messrs. Veitch and Sons sent a choice lot of plants, comprising several hybrids as well as species. Of the latter there was a fine specimen of *Cœlogyne barbata* with twelve good spikes well developed; *Catasetum Gnomus*, a curious dark-coloured species; *Sophranitis grandiflora*, a large panful, freely flowered; *Lælia anceps Sanderiana*, a fine mass, with three strong spikes and fifteen flowers and buds, the expanded blooms being large, the sepals and petals pure white, the lip large and finely marked with violet-purple; *Oncidium pulvinatum*, a pretty species, and *O. cheiroporum*, a dwarf plant, with short spikes of small pale yellow flowers. There were several of the best hybrid *Cypripediums*, as *C. nitens*, with fine flowers; *C. Harrisianum* superbum, the best form; *C. Leeaunum*; *C. T. B. Haywood*; *C. Creon*, extra fine; *C. Pylæus*, after *C. Sedeni*, and *Cattleya Pheidona*, a beautiful pale, almost white hybrid, with a faint marking of purple on the lip. A cut three-branched spike with five fine flowers of *Cypripedium Sedeni candidulum* was also included (silver Banksian). Messrs. H. Low and Co. sent a small group in which were several beautiful examples of *Odontoglossum Roezlii* and the white variety, also a good example of *Vanda Sanderiana* with one spike; *Lycaste Skinneri alba*, with one flower; *Cypripedium Haynaldianum*, a very distinct species, and *C. Smithi* (*C. Lawrenceanum* × *C. ciliolare*), which is much after the former parent; as well as *C. Mrs. Canham*, a large flowered hybrid (silver Banksian). Mr. Wythes, Syon House, sent a quantity of fine spikes of *Calanthe Veitchi*, very richly coloured and well developed. These were very tastefully set up with long fronds of *Adiantum concinnum latum* in an effective manner; *C. vestita* in variety was also included with the *C. Veitchi*, making in

all a first-rate exhibit (silver Banksian medal). Of other small exhibits there were a few fine forms of *Cypripediums*, as *C. Leeaunum superbum*, *C. insigne Sanderæ*, and others from Baron Schroeder's collection. Mr. Vanner, Camden Wood, Chislehurst, sent *Cypripedium Io-Spicerianum* (its parentage denoted by its name), a very pretty hybrid, and *C. pulchellum* (*C. grande* × *C. candidulum*), which comes near to the Veitchian *C. leucorrhodium*, but the pouch is rather darker. Mr. Wigan, Clare Lawn, East Sheen, showed *Cypripedium Wiganianum*, a twin-flowered hybrid with large flowers, presumably a descendant of *C. Harrisianum* × *C. Boxallia*. From Mr. Hainsworth, Blackheath, came a small plant of *Cirrhopetalum ornatisimum*, more curious than pretty. Mr. Lucas had a fine variety of *Compactia macroplectron*, a beautiful Orchid with *Barkeria*-like flowers of a pale rosy-purple, also *Dendrobium infundibulum*, a species of which *D. Jamesianum* is the best type; *Phaius marmoratus* (green-leaved form) with pale yellow flowers, was also included. Mr. Ashworth, Wilmslow, Cheshire, showed *Lælia anceps Amesiana*, one of the best forms of this fine winter Orchid, also *Cypripedium Leeaunum superbum* and *Lælia elegans Wolstenholmie*, a choice species. An Orchid of great interest and one now seldom seen was *Lælia exoniensis* (*L. crispa* × *L. purpurata*), one of the first, if not the first hybrid raised in this genus by Messrs. Veitch (the flowers were richly coloured). It came from Mr. Wells, Broomfield, Sale. Mr. Statter, Stand Hall, Manchester, had a small exhibit of *Cypripedium Lucenianum superbum*, which has some resemblance to *C. Boxallia*; from the same source came *C. Leeaunum*, Stand Hall variety. Mr. Measures also showed *Cypripedium Celeus* (*C. insigne* × *C. villosum*), which has a distinctly spotted dorsal sepal. A grand spike of *Cymbidium Traceyanum* came from Baron Schroeder's collection, and received a cultural commendation; it had a number of remarkably large flowers which are very distinct in their markings.

Floral Committee.

First-class certificates were awarded to—

NEPENTHES AMESIANA (*N. Rafflesiana* × *N. Hookeriana*).—A remarkably fine hybrid with the well defined characteristics of both of its parents, being quite as robust in growth as *N. Rafflesiana*, with the form of the pitchers as in *N. Hookeriana*, but larger in a marked degree, and darker in colouring also, the plant bearing eleven pitchers—a splendid acquisition. From Messrs. Veitch and Sons, Exotic Nursery, Chelsea.

COSTUS IGNEUS—A very distinct plant from a genus seldom exhibited. The species in question has rich orange-scarlet flowers, the growth about 1 foot in height. It is a tuberous-rooted stove herbaceous perennial with fleshy leaves introduced from Bahia in 1822. From Sir Trevor Lawrence, Burford Lodge, Dorking.

PLATYCERIUM STEMMARIA (syn., æthiopicum), from the Guinea Coast and Angola (1822), a truly grand species, which has been heard of and seen occasionally, but not in such fine condition as in this case; this plant is, under good cultivation, a robust grower, with fronds of unusual substance, the under-surface having a downy coating. From Mr. H. B. May, Dyson's Lane Nursery, Upper Edmonton.

Awards of merit were voted to—

CHRYSANTHEMUM MRS. MARION BOURNE (Japanese incurved).—An extra large flower and very full, form of *Mme. Clemence Audiguier*, but darker, a grand exhibition variety. From Mr. R. Owen, Maidenhead.

CHRYSANTHEMUM GOOD GRACIOUS.—Another unusually large Japanese variety with narrow incurved petals, pale blush-pink, very full, stated to be an introduction from Japan. From Mr. Owen.

A botanical certificate was awarded to—

MASSONIA AMYGDALINA (Baker).—A new species of remarkably dwarf and compact growth, the flowers being white and individually insignificant, but with a most fragrant perfume as of Almonds.

Messrs. J. Veitch and Sons sent a superb selection of the very finest of the *Nepenthes*, all denoting high cultural skill. These were *N. Wrigleyana*, a splendid dark-pitched variety, each pitcher being of extra length and of a deep reddish shade; *N. Morgania* in fine form, with its pitchers of a brick-red colour, being almost entirely of this shade, very distinct; *N. Burkei excellens*, a species from the Philippines, more richly coloured than the type, the pitchers extremely handsome; *N. Northiana*, a noble growing species, paler in colour than many, but remarkably distinct, a fine form; *N. Chelsoni*, after, but decidedly lighter than *N. Amesiana*, certificated at the same time; this plant had twenty-four pitchers upon it; *N. Curtisi superba*, another splendid variety, the pitchers of a blood-red colour, mottled with greenish yellow; *N. mixta*, previously certificated early in the autumn; and *N. Dicksoniana*, a very superior hybrid, with its pitchers quite distinct and of extra large size. Messrs. Veitch and Sons also had a promising new *Veronica* named *Purple Queen*, the growth of which is extremely dwarf and compact, the flowers of a bright purple (silver Flora medal).

Mr. R. Owen sent a grand collection of *Chrysanthemums* for so late in the season. Besides those certificated there were several unnamed seedlings as well as new named varieties of much promise; Henry Perkins, a dark bronze incurved Japanese; Mrs. Smith Ryland, a golden incurved, after Lord Brooke, but lighter; Le Prince du Bois, recently certificated; Charles Blick, a dark rich yellow, after Sunflower; Golden Wedding, a well-known new Japanese, of great promise; Abbé Mendenhall, pale primrose; Golden Gate, a splendid yellow; White Etoile de Lyon; Secretary Farson, a bronze incurved; Mrs. A. Rogers, a deep yellow, very full; John Noble, extra large, with wider petals than in Edward Molyneux, and of a darker colour, and a few others. Mr. H. B. May had another of his characteristic groups of Ferns, consisting this time of several varieties of *Platycerium*, as *P. grande*, a fine young specimen; *P. stemmaria* (see certificate), *P. allicorne*, a healthy young piece, also its major form; *P. Willincki*, a distinct species from Java; *Hymenodium crinitum* (the Elephant's-ear Fern), developed surprisingly well; *Pteris Victoriae* (a selected form), of free growth, distinct and elegant; *Davallia Tyermani*, *D. Griffithi*, and *D. hirsuta*; *Pleopeltis fossa*, with thick but narrow fronds of very rigid character; *Lomaria platyptera*, after but finer than *L. gibba*; *Pteris tremula Smithi*, the tessellated variety; *Nephrolepis exaltata plumosa*, a plumose form of this old Fern, of dense growth, but very compact; *N. Duffi*, a pretty plant, and *Acrostichum irioides*, with very narrow Iris-like fronds (silver Flora).

Messrs. H. Low and Co. had a finely-grown lot of *Cyclamens* similar to, but in better flower than at the last meeting (silver Flora medal). Messrs. J. Laing and Sons, Forest Hill, exhibited a good miscellaneous group of decorative plants, in which was a fine mass of *Odontoglossum grande*, with a number of spikes, not being a made-up plant. Other good things consisted of *Dracena Doucetti*, several *Anthuriums*, as *A. Laingi*, the best white, and *A. Andreanum sanguineum*, *Ericas*, *Cyclamen* and other things in season (silver Flora medal). Mr. Balderson, of Corner Hall, Hemel Hempstead, showed an intensely dark velvety crimson *Primula*, the darkest and richest colour yet seen, but no award was made, as only cut spikes were staged. Sir Trevor Lawrence had a grand mass of *Primula Forbesi*, which improves upon acquaintance. Mr. W. Wells, Redhill, had the golden yellow incurved *Chrysanthemum Mrs. L. C. Madeira*, and Mr. Tranter, Henley-on-Thames, showed *Nicotiana affinis variegata*. Messrs. B. S. Williams and Son staged *Amaryllis*. From Kew Gardens came a few choice and unique exhibits. These were *Brownea Crawfordi*, a hybrid between *B. grandiceps* and *B. macrophylla*, which had immense heads of rosy scarlet flowers. *Thunbergia mysorensis*, with pale orange and dark crimson flowers, was exceedingly showy, the long and continuous flowering character of this plant standing it in good stead. *Bomarea oligantha* with deep orange flower,

and darker markings, and *B. patacoensis*, a Peruvian species with orange-red flowers in large trusses, were both attractive. Quite a gem was the Cape Ivy (*Senecio macroglossus*), a slender trailing plant having Ivy-like foliage of small size and Marguerite-like flowers of a pale yellow. This was figured in THE GARDEN of August 2, 1881 (p. 90).

Fruit Committee.

There were some interesting exhibits before this committee in the way of collections of fruit and vegetables and miscellaneous exhibits.

A first-class certificate was awarded to

ORANGE EDITH.—This is of great merit, round, pale yellow, with thickish rind and small leaves. It is also of good flavour. From Mr. Stevens, The Gardens, Sidbury Manor, Sidmouth, Devon.

An award of merit was given to—

CABBAGE CHRISTMAS DRUMHEAD, grown in the Society's Gardens, Chiswick. This is a medium-sized Cabbage, very firm and solid, and of a beautiful mild flavour when cooked. It is of special value for winter use.

The finest exhibit was a grand collection of Apples from Messrs. H. Lane and Son, Great Berkhamsted. There were seventy dishes of fruit staged, and all perfect specimens, some of the dessert varieties being very good. Notable for their high colour and showing the effect of so favourable a season were Warner's King, Bismarck, Hollandbury, and Lane's Prince Albert. Other good dishes comprised High Canons, Hoary Morning, Norfolk Beaufin, Baumann's Red Requette, Adams' Pearmain, Beauty of Kent, Bramley's Seedling, Sandringham, Lewis's Incomparable, Mrs. Barron, Schoolmaster, and Cox's Orange (silver Knightian medal). From Messrs. Laing and Sons, Forest Hill, came a small collection of fruit, chiefly Apples, about thirty dishes being staged. The best were King of the Pippins, Mère de Ménéage, Bramley's Seedling, Gloria Mundi, Lane's Prince Albert, Cockle Pippin, and Vicar of Beighton (bronze Banksian medal).

Mr. G. Goldsmith, The Gardens, Leonardlee, Horsham, sent a new Apple much like Cox's Orange in shape, size, and colour, the tree having been sent in mistake for the above variety. The fruit is quite distinct in flavour, but failed to get an award, as it is inferior in quality. Messrs. Veitch staged an interesting collection of Kales, some well known and a few less so. The Palm Tree Kale was the most novel, being of erect growth, with long narrow leaves, firm, and of a dark green colour; this is grown more abroad than in this country. It is of Italian origin, and not nearly so tender when cooked as the Scotch Kales, having a thicker midrib and less succulent growth. There was a good lot of the variegated or ornamental foliaged kinds, also Late Curled and Chelsea Exquisite Curled, a dwarf selection of the Scotch Kale. A good variety of Brussels Sprouts named Ne Plus Ultra, a tall variety with small sprouts, was also staged in this collection. From Mr. Owen, The Royal Gardens, Frogmore, were sent some fine cordon growths of Tomatoes named Frogmore Selected, a variety recommended for winter fruiting. The fruits somewhat resembled Chemin. A large dish was also shown, and the committee desired to have the fruit sent again in the early spring to test the winter bearing qualities. From the society's gardens was sent a representative collection of Cabbage in season and Brussels Sprouts. A nice lot of the Christmas Drumhead referred to above was staged, also the St. John's Day, a variety with medium-sized heads, solid, of somewhat lighter green colour than those of Christmas Drumhead and less flat, but of equally good flavour. Couve Tronchuda or Portugal Cabbage was also staged. Two varieties of Brussels Sprouts which had been on trial at Chiswick were also sent. A very dwarf variety from Messrs. Dobbie, Rothesay, was specially good, being well covered with sprouts of a medium size and very firm. Messrs. Sutton's strain was also noticeable for its dwarf habit and free-producing qualities. A new form of Grape scissors was sent by Messrs. Osman,

Commercial Street, E., for the opinion of the committee. These were sent to Chiswick for trial and report next season.

NATIONAL CHRYSANTHEMUM SOCIETY.

On Monday evening last a meeting of the general committee of this society was held at Anderton's Hotel, when Mr. R. Ballantine presided. A vote of thanks was passed to Messrs. E. D. Shuttleworth and Co., of Albert Nurseries, Peckham Rye, for the loan of Palms and fine-foliaged plants they had sent free of charge to decorate the room on the occasion of the annual dinner recently held, and which was attended more largely than that held last year. Several other votes of thanks were passed to those who officiated in the arrangements on that occasion. At the late flowering exhibition held this month a gold medal was awarded to Mr. H. J. Jones for his table of cut Chrysanthemums, silver-gilt medals to Mr. W. Wells and Mr. R. Owen, and silver medals to other exhibitors, which awards were confirmed.

The secretary announced that the following shows would be held in 1894, viz., one on October 10, 11, and 12, one on November 6, 7, and 8, and another on December 4, 5, and 6. The judges appointed are Messrs. Inglefield, Owen, Herrin, and B. Wynne at the first; Messrs. Lyne, Prickett, Orchard, H. J. Jones, Beckett, G. Gordon, Bevan, Barron, Langdon, and Tegg at the one in November, and Messrs. Kipling and Stevens at the show of late-flowering varieties in December. It was also reported that the total revenue received to date amounted to £653 10s. 2d., and that the reserve fund was now £54 9s. 4d. New members numbering 163 had been elected for the year, of which thirteen were then proposed, including Mons. M. L. de Vilmorin, of the firm of Messrs. Vilmorin-Andrieux and Co., of Paris, as a foreign member.

In the absence of Mr. C. E. Shea, the secretary read his paper on "Judging Chrysanthemums," which will appear in the society's new schedule. The author referred to the narrow margin by which some important prizes were sometimes won, and pointed out the necessity for the N.C.S. to set up a standard of judging independent of the idiosyncrasies of judges, some of whom preferred one type and some another. Mr. Shea considered the attributes of a show Chrysanthemum to be diameter, depth, solidity, colour, finish, breadth of petal and freshness, but contended that these should not all have the same number of points allotted to them, the first three being entitled to the greatest number. Mere novelty, he thought, ought not to count extra points, for some new flowers might be shown in such a form that would show far less capable cultivation than older varieties. It was incumbent on the society to formulate a definite basis or means of judging that should take the place of mere personal opinion. He thought the N.C.S. should be a sort of university for the education of the judges of the future. The time, too, that was placed at the disposal of the judges was frequently inadequate to the work involved, and exhibitors, by late arrivals and tardy staging, sometimes still further curtailed the time. Mr. Shea also spoke of the qualifications of a judge, and upheld the view that a good judge need not necessarily be a cultivator himself. The paper was listened to with much attention, and a discussion upon it subsequently arose.

A meeting of the floral committee of this society was held on Wednesday last at the Royal Aquarium, when Mr. Harman Payne occupied the chair.

Although the number of novelties submitted for adjudication was few, the meeting was rendered more attractive than usual at this advanced date in the season by a capital display of cut Chrysanthemums from Mr. R. Owen, of Maidenhead, to whom a silver medal was awarded in recognition of his exhibit.

First-class certificates were awarded as follows—

OWEN THOMAS—A fine, broad, incurved Japanese bloom, with florets of medium width, curly at

the tips, and of good length. The colour is a clear shade of rich canary-yellow. Exhibited by Mr. R. Owen.

GOOD GRACIOUS.—A most distinct variety of the Japanese type. The petals are of very great length, tubulated, curiously twisted and curled; the blooms are large, but rather loose, and the colour is light blush-pink passing to white towards the centre. Also shown by Mr. Owen.

Among other novelties, Secretary Farson, a large incurved Japanese, very solid and compact, of a rosy-bronze shaded yellow, was commended. John Noble, an incurved Japanese, carmine-crimson, tipped yellow, with a light crimson reverse, was requested to be shown again, as was W. G. Newett, a Japanese with very long drooping florets, colour pure white, shaded yellow in the centre. Other promising varieties were H. M. Pollett, Mrs. Marion Bourne, New Year's Gift, and Mrs. F. L. Ames.

A resolution was made that the variety Henry Perkins, formerly certificated as an incurved variety, should be transferred to the Japanese incurved section in the society's official catalogue. A new expanding show board designed by Mr. C. E. Shea was also highly commended.

National Rose Society.—The annual meeting of this society was held on the 7th inst. at the Hotel Windsor, Westminster. The Rev. W. Wilks presided. There was a fair attendance of most of the leading rosarians of the day, but as there was no question pending for settlement which was likely to cause much discussion, there was not the same interest taken in this year's proceedings as at the two preceding meetings of 1891 and 1892. There were, however, two rather important new regulations passed, viz., A, that in the future on the requisition of twenty members of the society a special meeting can be called to discuss any specified question, and B, that in future, seedling Roses and sports are eligible for competition in the classes reserved for new Roses. The former rule affects the society in general and the latter the hybridisers, more especially Messrs. Dickson, of Newtownards, Messrs. W. Paul and Messrs. Paul & Son amongst our own great rosarians. The financial statement of the society is comparatively satisfactory, the balance credit brought in being £31 16s. 7d., and that carried forward being £81 19s. 3d., the difference being mainly obtained by an unfortunate fact, viz., the absence of competition this year at the society's shows, the prize money offered not having been competed for or won, this fact alone making a difference of £45 8s. as compared with 1892, and this notwithstanding the fact that there were more classes in 1893, and also that in the smaller classes the fourth prizes were restored to the schedule. The subscriptions have increased by £8, but as the new membership shows an increase of fifty-five to the roll, the losses through death or resignation must be considerable.

—Such of the subscribers to the catalogue fund as have not paid their donations will oblige by doing so at an early date to Mr. Charles Grahame or Mr. E. B. Lindsell, the honorary secretaries thereof, who wish to close the list.

The Gardeners' Royal Benevolent Institution.—The time for the election of pensioners to the funds of this institution is fast approaching, and the numerous appeals for support which have already reached me show that, as usual, there will be more candidates than vacancies. The most painful cases are those of individuals who are applying for the second, and in some cases the third time. These facts alone should induce the rising generation of gardeners to join the society. Many, no doubt, with large families, or through sickness, are so handicapped through life that to them even a guinea a year would be a great consideration, and for such I have nothing but sympathy. To hundreds, however, who have no such drawbacks and are in possession of health and vigour, a guinea per annum would not be a great sacrifice. Formerly there was some excuse for gardeners refusing to join the society, as influence was then the principal agent in securing the election of candi-

dates; but since the adoption of rule 5 and more particularly rule 10, the wisdom of which has been proved by the increase of members, all member candidates are placed on a more equal basis, and the weakest have not to go to the wall. I hope ere long to see the annual income of the society so increased that the committee will see their way to make the allowance for each recipient half as much more as it is at present. Finally, I would ask every gardener to give the matter his serious consideration, remembering how much good the society has done in the past and how much more it might do in the future if only its hands were strengthened.—J. CRAWFORD, *Coddington Hall, Newark.*

NOTES OF THE WEEK.

Echinops Ritro.—This seems to be more free-flowering this year than usual. In the early summer it bloomed most profusely. On November 11 I cut several well-expanded heads, and there were many more to follow.—DORSET.

Chrysanthemum Golden Gem is one of the most beautiful of all Chrysanthemums, and especially useful for flowering late in the year. The flowers, of a bronzy crimson colour, which passes into yellow, are produced in free, graceful sprays; they are not large, and last a long time in water by reason of the stout petals.

Dianthus japonicus, or *D. pulcherrimus* (well figured in "Flore des Serres" and "Jardins de l'Europe," vol. ii., p. 199) has, I regret, disappeared from cultivation. I should be glad of a single cutting of this plant, which fifteen years ago I had by the hundred. In one autumn my plants dwindled away owing to being grown in an unsuitable position.—MAX LEICHTLIN, *Baden-Baden.*

Chrysanthemum latifolium.—I consider this much better than *Pyrethrum uliginosum*. Its blooms being of a purer white and the centre yellow make it far more ornamental. As a plant to cut from in late autumn it is invaluable. I have cut good blooms of this in seasons gone by well into November. These hardy border plants should be encouraged where the demand for cut flowers in autumn is great.—J. C. F.

Hedera atropurpurea.—This variety is very conspicuous in the winter months for the rich chocolate—almost black—colour of the leafage, a perfectly constant characteristic, not changing, as so many variegated ivies, which are too often variegated only in name. *Atropurpurea* is robust, very free growing, finely veined and worth a place for its rich colouring in the winter months. A good plant is in the Chiswick collection and stands out conspicuously against other kinds.

Tomatoes in winter.—Good, fresh-ripened Tomatoes are highly appreciated by many, and this holds good at Lindisfarne, Bournemouth, as there they are grown all through the year. When looking through the garden there in the middle of December I noted a fine lot of plants trained close to the glass on the south side of a span-roofed house. These were full of fruit, many ripe, some just set and the plants full of bloom. I was told by Mr. Spong that he found no difficulty in keeping up a continued supply during the winter and spring. The plants were from cuttings struck in August.—DORSET.

Masdevallia tovarensis.—Few more useful Orchids flower at this season and for the best part of the winter than *M. tovarensis*. We have noticed it in many collections in full bloom, the flowers being acceptable for cutting at Christmas. It is a native of Colombia and found at a high elevation, hence little artificial heat is necessary for its cultivation. No other *Masdevallia* is of such value for its flowers, these being snow-white and lasting long in perfection. They are borne in twos or fours on scapes about 6 inches high, and when the plant is in full bloom it presents a mass of white. Pots or shallow pans may be used.

Pear Josephine de Malinea.—"Y. A. H." (p. 502) recommends this to be grown on walls.

According to my experience in the south it is far better from bush or pyramid trees than from walls. When living in North Hants I found that the fruit from trees grown in the open was of far better flavour than from those on walls, and in North-west Dorset it is just the same. I have now (December 13) in the fruit room some from open trees and from walls, and the former is by far the better, although not quite so large. It is true the tree does not make a good pyramid, but as a bush I find it does well. I have never found this kind of bad flavour.—J. C. F.

Pulmonaria dahurica.—It is about six or eight years since this was plentiful here. M. Froebel, of Zurich, paid me a visit and was so taken with the plant, that I, in compliance with his wish, placed the whole stock in his hands. It appears, however, that the climate of Zurich did not suit it, or that M. Froebel lost sight of it at the very moment it most wanted attention, and in consequence all stock on the Continent has gone. I used to pot the plants in August, in September bringing them into a sheltered place, and in October into the greenhouse. I kept it rather dry over winter, and planted it out in March or April in a half-shady situation. There was no possibility of increasing it in spring. This had to be done in August before repotting. If it cannot be found in some out-of-the-way place in England, it will be lost for some time until re-introduced from its native habitat.—MAX LEICHTLIN, *Baden-Baden.*

Christmaa Drumhead Cabbage.—This variety was this week favourably noticed by the fruit committee of the R.H.S., and an award of merit given it. It is not the first time it has been shown. I exhibited both it and St. John's Day last June at the Drill Hall, and have on one or two occasions recommended it in THE GARDEN for use at this season and early in the year. I am much pleased with the above variety, as it is of exquisite flavour when cooked and very hardy. Those who find the Rosette Colewort too tender in exposed positions would do well to plant this, as it does not burst or open after frost like the Colewort, and is much like it in flavour when cooked. Being a medium grower it may be planted rather closely. For cutting in May it is not so good, as it comes larger, is inferior, and much later than *Ellam's*. I do not intend to grow it again at that season, but for cutting through November, December, and early in the year it is of much value, and will become a leading kind, as its good quality and hardiness will be of great service to those who require vegetables in quantity.—G. WYTHES.

Iron roofing for sheds.—I am surprised to see the use of galvanised iron condemned in a recent number of THE GARDEN. My experience of the corrugated iron roofing is that it is incomparably cheaper than either tiles or slates. The latter are a continual source of expense, repairs being so frequently needful, besides not keeping out the wet so thoroughly as the iron, which is absolutely rain-proof. I cannot understand why "considerable expense devoted to the roofing of sheds with galvanised iron is wasted." Nearly ten years ago I had a long shed covered with this material, and from that day to the present time it has not cost me a single penny, and is as good as ever. Contrast that with some cottages and outbuildings roofed in the ordinary way. These are yearly needing attention by reason of tiles cracking or blowing off. I am never done with them. Not only is the galvanised iron cheaper in itself than either tiles or slates, but the expense of putting it on is much less. With respect to ordinary iron, I am astonished that any builder should recommend it for roofing. I can quite understand that it would soon rust away if not kept painted. Iron roofing is by no means pretty, but with me, as with most people, the picturesque has to yield to cheapness and utility.—J. C. B.

** We are sorry for you. Why, there is a rainfall from the frost that gets inside an iron roof. This alone should be fatal to the iron roof in many cases. Even this mild autumn we have seen iron

roofs weeping drops as soon as warmth dispelled the frost. A well-laid slate roof will last several iron roofs; and there are better roofs than slate.—ED.

The weather in West Herta.—A mild and stormy week. The day temperatures were remarkably steady; in fact, during the seven days ending Tuesday, the highest readings in shade ranged only between 45° and 48°. Wednesday was particularly warm for the time of year, the temperature rising to 55° at midday. On Saturday night the exposed thermometer indicated 10° of frost, but the temperature remained at this point for but a very short time. The temperature of the ground now stands at 41° at both 1 foot and 2 feet deep. There have been as yet only four days this month without some rain, the total measurement amounting to 1½ inches. Soon after 1 a.m. on Friday night there occurred a brief, but sharp fall of hailstones. The wind came entirely from some southerly point of the compass and has been at times very high. The most boisterous winds were, however, recorded on Tuesday, when during the three hours ending 5 p.m. the average velocity amounted to as much as 38 miles an hour, and for one of these hours the record rose to 42 miles, direction S.S.E. Some of the squalls during this heavy gale were singularly fierce. The velocity last mentioned is the highest recorded here for any hour since March 22, 1887. There is one important lesson taught by such wind storms as those recently experienced, and that is the necessity of firmly staking or otherwise securing in position all newly-planted trees, shrubs, Roses, &c.—E. M., *Berkhamsted.*

THE inaugural dinner of the Friends of Horticulture was given by Sir Philip Currie at 1, Connaught Place, on November 29. The following members were present: Mr. Thiselton Dyer, Mr. Charles Ellis, Sir Godfrey Lushington, Mr. A. B. Freeman Mitford, M.P., Mr. William Robinson, Mr. Henry Yorke. The next meeting is fixed for Wednesday, February 14, at the Savoy Hotel.

OBITUARY.

Death of Mr. J. Wells.—On Saturday last at Osborne Park Nurseries, Potter's Bar, Middlesex, Mr. J. Wells passed away. He it was, I believe, who planted and trained the fine wall of cordon Pear trees at Holme Lacy, Hereford, when gardener to Sir H. Scudamore Stanhope. I believe after leaving Holme Lacy he took the above-mentioned nurseries, which he carried on for many years. He was considerably over 80 years of age, but of late had suffered much. My father, being his manager, I both saw and heard a good deal about him. It seemed very sad to me when I thought of the master hard deprived of its skill that had so carefully tended those cordon trees, one of the earliest examples in this country, I suppose. Many a chat have I had with him, the Pears at Holme Lacy being an especial theme of his.—J. J. CRAVEN.

Iris Kashiriana and I. Bartoni.—Can any of your readers tell me whether these Irises or either of them are amenable to ordinary treatment in English gardens, and if so whether they are anywhere procurable? White Irises are somewhat uncommon.—J. C. L.

Names of fruit.—*T. Tyler.*—1, Rymer; 2, Hollandbury; 3, Alfriston; 4, Lord Derby; 5, Bergamote d'Espereu.—*Miss Robinson.*—Impossible to name from such a specimen as you send.—*Forcell.*—Apple Fearn's Pippin.—*H. Attwater.*—Seed fresh specimens.—*A. Chapman.*—1, Suzette de Bavay; 2, Baronne de Melo; 3, Passe Colmar.

Names of plants.—*Forcell.*—1, Panicum sp.; 2, looks like a *Justicia*.—*R. Brooker.*—1, 3, and 4, seedling forms of *Cupressus Lawsoniana*; 2, *Ligustrum sinense*; 5, *Cupressus nutkaensis*; 6, *Thuja occidentalis*.

No. 1153. SATURDAY, December 23, 1893. Vol. XLIV.

"This is an Art
Which does mend Nature: change it rather; but
THE ART ITSELF IS NATURE."—*Shakespeare.*

CHRYSANTHEMUMS.

CHRYSANTHEMUM NOTES.

THE season just closed has been of great interest to cultivators of Chrysanthemums and to those who visit the many exhibitions, whilst the blooms have been seen in marvellous beauty. Many thought the exceedingly dry summer would leave its mark on the plants in such a way as to cause the flowers to develop extra early and to be of bad form, but growers have overcome all difficulties and have presented blooms, both early and late, which would, as I have remarked, favourably compare with any that had gone before. The incurved kinds, with a few exceptions perhaps, may have been surpassed, this being the case with the Queen of England group especially. But, on the other hand, the charming Princess of Teck family has never been seen in such quantities nor finer. Those who depended on the late-set buds of the variety Princess of Wales and its numerous progeny have been disappointed, and the hint will be useful, for we may be some time before another year so favourable to late buds as this last presents itself. I may here note indications of new interest amongst new growers and amateurs in this old class of Chrysanthemums which require so much care to cultivate. Whilst from a dozen to twenty repeatedly compete in a single class, as has been the case, there is no danger of the Japanese ousting the incurved flowers from collections. It must, however, be said that it is to the many new and beautiful forms of the Japanese Chrysanthemums we must look for sustained interest in the autumn flower. To those who object to extra large size in these blooms, it may be interesting to find that this year other qualities, such as form and colour, have been to the fore. One of the most admired of all, Mlle. Thérèse Rey, is not gigantic, but there is a refinement about the flower so taking, that size alone we may be sure will not belong to the future type. It is not my purpose now to defend the modes of exhibiting which obtain at the present time, but I would like to put on record a few individual blooms or stands of blooms that I have seen this year which appear to me worth remembering. The best blooms belonging to the Queen family were a fine Lord Alcester, which gained premier honours in the first prize stand of Mr. Lees at Hull, an incurved stand admitted the best seen during the year. A fine Empress of India was in the first prize lot at Sheffield. Golden Empress has been fair in most exhibitions, but I did not see a single good bloom of John Lambert, so fine last year. Alfred Salter has been represented by some very good specimens, and the oldest of the type, Queen of England, much below the usual form. Ner has the deep yellow Mrs. Robinson King been seen in anything like good form. Hero of Stoke Newington in the stand referred to was magnificent, probably never better, whilst two blooms of Lady Dorothy at the last Aquarium show were splendid specimens. Mrs. Norman Davis, another member of the Teck family, was seen in good form at this show. I have not

seen many notable blooms among the Princess group, usually such a great help to exhibitors, but Mme. Darrier has been extra fine all round; this is an acquisition to the incurved class. Baron Hirsch is another gain, and when distributed more freely will be a leading kind. The flower of Prince Alfred which gained a prize for the best incurved in the show at Blackheath was as good a bloom of that old kind as could be. M. R. Bahuant was finely exhibited in the second prize stand in the large class at the Crystal Palace, and at the same exhibition the perfect, but small, Mrs. G. Rundle, George Glenny, and Golden George Glenny were never seen to better advantage than in the stand that was first. Of the newer incurved sorts seen this year Lord Rosebery will take a prominent place. It may be called an advance on Violet Tomlin. Mrs. John Gardiner, said to be, like the above named, a genuine seedling, is a richly coloured flower like Mrs. Coleman. Wm. Tunnington is another first-rate sort of large size, nice shape, and dark Indian-red colour. Robert Petfield, although seen last year, is not yet distributed, but the flowers shown this season have enhanced its reputation. Lucy Kendall is a useful addition to the Princess of Wales family, but I fear the dull shade of rose will not be in favour of Brookleigh Gem. Several other incurved sorts have been seen, but they bear evidence of Japanese blood in them, so much so that it will be a risky matter to include them in the company of the true Chinese. M. Norman Davis (Calvat) is the best of these, and was in good form a week ago at the Aquarium, but the floral committee of the National Chrysanthemum Society refused to include it as an incurved. Henry Perkins is quite as much a Japanese flower, and so is Vice-President Jules Barigny.

THE JAPANESE CHRYSANTHEMUMS

have been seen in such large numbers and generally so fine that there is more difficulty in selecting particularly fine specimens. Individual taste, too, comes in, and one cannot help being led away by a certain style. For instance, your reporter of the late National exhibition, in recording an exhibit in which the variety Waban figured, said that it was so ugly as to be unfit to be included in collections. To my own taste, this sort in good form is a thing of beauty. There are a distinct curl and grace in its formation that seem the reverse of ugly, and the colour—white, with purple-rose edges—something to admire. The season has suited the red and yellow Edwin Molyneux. When seen like the bloom which gained the premier prize at the Kent County exhibition, there are few, if any, nobler sorts in existence. The greatly admired Vivian Morel appeared to me not in such fine form generally; but a stand of six blooms at Bromley and the premier Japanese flower at Croydon were specimens to be remembered. Col. W. B. Smith was grand everywhere, and, along with the richly-coloured G. C. Schwabe, must be included in the best half-dozen sorts we have. Lord Brooke is a magnificent flower, the florets folding inwards. This has been good both early and late. Robert Owen, again, is a fine type of the incurved Japanese, there being a magnificent bloom in a stand of twelve Japanese hailing from Kent at the December show. The stand did not obtain a prize, hence the particular bloom was not recorded. The variety is shy in giving cuttings, and may be a year or two yet ere it be found in general cultivation. Wm. Seward and John Shrimpton have not fully come up to the high opinions formed of them last year. I am convinced, however, that they are the best crimson kinds for all purposes of

growth yet known. The former seems to have been grown too strongly, as by far the best blooms I saw of it were with Mr. Davis, Camberwell, who had cultivated it without undue disbudding. The latter I had very fine myself, and shall grow it extensively another year. Beauty of Exmouth is another variety that has not reached the expectation mark. The raiser of this assures me over-growth and a hot summer are the cause. Florence Davis, the same style of bloom, has been very fine. Miss Anna Hartshorn has been seen in splendid form, and the waxy quality of its incurved florets is much admired. The hairy-petalled sorts are not yet popular. There was a certain novelty about Mrs. Alpheus Hardy that caused a great run for it, but I believe most people have given it up because of its weakly constitution, and the white Louis Boehmer is a poor substitute. Hairy Wonder and a few other pretty novelties will be heard of and may revive the waning interest in the hirsute Chrysanthemums. Avalanche, once most famous of whites, is either deteriorating or the newer kinds are better, for good blooms of it were not to be seen this autumn. The same may be said of W. H. Lincoln. Wm. Tricker again holds its own among rose-coloured sorts, and was good everywhere. Sunflower has not yet been beaten as a yellow. An old yellow which has been discarded by many growers, Thunberg, was seen in magnificent form at Reigate, six blooms of it being one of the notable stands of the year. The terra-cotta W. W. Coles is now a most uncertain sort and hardly worth keeping in choice collections, whilst Mlle. Marie Hoste has been good all round. Etoile de Lyon will still be grown, especially for late blooms. It then assumes a pretty colour and is not the giant in size it is so often painted. Undoubtedly, the best forms for exhibition, and indeed all purposes, are to be found amongst the

NEW OR RECENTLY INTRODUCED VARIETIES.

Mlle. Thérèse Rey has already been noted. Mme. Edouard Rey is a grand specimen of the incurved Japanese. One of the blooms that gained a certificate of the National Chrysanthemum Society early in the year was admittedly one of the best developed blooms ever seen. Golden Wedding is a very fine deep yellow, and will run Sunflower very hard for premier place. It is a strong grower and an easy one to manage. The plants arrived late in the spring from America, and through the journey were some time before they made another start, but enough has been seen of it to form a high opinion of its merits. Louise is a very lovely blush-white flower with incurved florets. It is dwarf in growth, has good foliage, and will be included in the choicest collections. H. Shoemith was much admired when seen at the floral committee meeting in October. This body, however, could not give it a certificate, as one bloom only was submitted. It has the characteristic of Mlle. Marie Hoste, but is a light yellow in colour. Charles Davis, the bronzy sport from Vivian Morel, is first-rate. Probably the finest bloom seen of it was the one adjudged the best Japanese flower in the show at Hull. Col. Chase is a very fine form of the true flowering Japanese type. Very deep in build and of fair diameter, it commends itself by the distinct colouring—deep blush with creamy yellow shades. Violetta, of similar build, has a distinct and pretty pink shade of colour. Both are first-rate growers and will become popular. Golden Gate is a splendid new kind of fine shape and large proportions, yellow, with bronze tinge, a good habit of growth, and altogether one of the choicest yet received from

America, and Niveum, from the same source, is a fine rich-petalled pure white, full and pretty in form. President Borrel blooms rather early, but is quite the best of the dark purple-rose-coloured varieties. It was seen in fine form at the Crystal Palace exhibition. Eda Prass is not quite new, but not till this season have its qualities become known. It is one of the handsomest of the incurred Japanese forms we have and easy to cultivate.

H. SHOESMITH.

Chrysanthemum W. H. Lincoln.—Last season I called attention to the value of this variety as a late bloomer when grown as a bush plant without any disbudding. This year I wish to verify that statement, as even during this early season it is in fine condition this last fortnight of the old year, and to all appearance likely to remain so for some time. There are few varieties which are more suitable for growing in the bush form if stopped about twice. Nice plants may be grown in 8-inch pots.—A. Y.

M. Calvat's seedlings.—An exhibit that created much interest at one of the floral committee meetings of the National Chrysanthemum Society was a stand of Japanese blooms from Grenoble. It contained several kinds of great merit, and those on the look out for novelties will do well to note the following: Mme. Carnot is a fine addition, the bloom composed of a mass of fluffy white florets, folding in a most graceful manner. Professor Lackman is a large slightly incurred Japanese, dark rose in colour, bright and pretty. President Leon Say has orange-buff flowers, very large, drooping, and the build first-rate. Mons. Chas. Molin is of a deep buff colour, the blooms well developed and promising.—H. S.

New Anemone-flowered Chrysanthemums.—Several excellent additions have been made to this class during the season now ended. Mlle. Nathalie Brun is an Anemone proper, with white guard petals and the cushion or centre cream colour. This is high and well developed. John Bunyan is a first-rate Japanese Anemone sort; the guard florets, which are long, are light yellow, and its well-defined centre is of a deeper hue. W. W. Astor has the guard petals long and blush-white, the centre being of a pink, shaded yellow colour. Ernest Caille is a very good addition to the class. The colour is a buff, tinted rose.—H. S.

Grouping Chrysanthemums.—The number of Chrysanthemums grown by Mr. Burbidge in the Botanic Gardens, Trinity College, Dublin, is not large, but the manner in which he arranges the plants in the new house just built is worthy of note. Instead of mixing them indiscriminately as regards their colour about the house, he has them grouped in separate colours; a mass of yellow, lilac, purple, white and red and so on. Very effective they look in this way—quite a pleasing change to me after seeing so many show groups in England where variety of colouring in the smallest space is the main object of exhibitors.—E. M.

Chrysanthemums in bunches.—It seems likely that the aspect of exhibitions will be greatly changed in the future. At the recent exhibition of the National Chrysanthemum Society at the Aquarium, several miscellaneous collections consisted of bold bunches of flowers, set off, as in the case of Mr. Jones, by the bronzy green leafage of the Mahonia. There seems not the slightest reason why such a system should not be followed in a great measure in the competitive classes and relieve the monotony of long rows of blooms, at present so crowded together as to prevent the individual flowers being seen. We noticed that some of the smaller blooms were almost hidden by the recent monster kinds.

Prices of new Chrysanthemums.—In reply to "T." (p. 517), may I say that if half-a-guinea a plant is considered a high price for a Chrysanthemum in England, it is not so in France. Many new

seedlings are sent out by French raisers at a far higher figure than that, and have been for years past. An average price for new Chrysanthemums distributed by any of the leading growers in France would range between 12s. and 24s. apiece, and certainly £1 for a plant of a new variety is nothing new, as many of our importers well know to their cost. "T." seems to be a little behindhand with his information concerning the hairy variety Mme. Ferdinand Cayeux, because the transaction alluded to took place last April, if not before. This variety was illustrated and described in *Le Jardin* of Paris on January 5, 1893, and shortly afterwards was introduced into this country, where it can now be purchased for three shillings.—CHRYSANTH.

New Chrysanthemums.—I note that one of our nurserymen who makes a speciality of Chrysanthemums, in announcing the acquisition of a number of American seedlings, states that 1400 of them are selected from a total of 35,000 new varieties raised in the States last year. That our American friends really suppose they have raised 35,000 new varieties in one season is at least open to doubt, for that number is, I should think, intended to represent the plants that were raised from seed and flowered in order to prove them, in which case it is certainly misleading to speak of them all as new varieties, for a large number of them would, as a matter of course, turn out to be very inferior. If one cultivator is going to give us anything like 1400 new varieties, the official catalogue of the National Chrysanthemum Society will at its next issue be of formidable proportions, and the naming of Chrysanthemums, which is now manifestly overdone, will be quite a farce. That great strides have been made in the Japanese section of Chrysanthemums within the last few years is well known, but at the same time it would be interesting to know what percentage of those put into commerce (many at high prices) are ever grown more than a season or two. A perusal of the list of varieties that occupy prominent positions at the different exhibitions will show that they are drawn from a limited number, some of the varieties, as in the case of Etoile de Lyon at the recent Chrysanthemum show at the Aquarium, indeed cropping up with monotonous regularity on nearly every board.—T.

The best white Japanese Chrysanthemums.—Mr. Cannell in his Chrysanthemum catalogue refers to Beauty of Exmouth as being, with Florence Davis, the finest white since Avalanche, which was distributed in 1887. The varieties above-named may therefore be taken to represent the three best white-flowered Japanese Chrysanthemums, at least according to Mr. Cannell's opinion, with which many will agree. On another page of the same catalogue, however, an element of confusion crops up, for Eynsford White, distributed in 1889, is spoken of as the best and most solid white ever sent out. For general purposes, however, I should prefer the three first-named varieties, all of which are of good constitution, while Eynsford White, though a beautiful flower, is certainly less robust than they are.—T.

Late Chrysanthemums in small pots.—I lately saw in a private garden a lot of the late-blooming varieties in 6-inch pots. The cuttings were struck in June, so that the plants had not a long enough season to run up much to height. Robust-habited kinds, such as Golden Gem, were not more than 18 inches high, carrying about a dozen buds. Plants of this description must be of great service at Christmas and the new year, as they can be used for room decoration and in other ways that larger plants are not suitable for. Varieties of compact habit, like Cullingfordi, Bonle de Neige and Princess Blanche, are especially good for this form of culture. The first-named, though not one of the latest bloomers, can be had at Christmas and the new year by topping the young growths as soon as the cuttings are well rooted. The colour of this Chrysanthemum renders it invaluable for late blooming. The incurred kinds are not so suitable for blooming in such small pots; they require a much longer period of growth to

give them the strength necessary to perfect their blooms. It is in any case rather difficult to get them to incur after November.—J. C. B.

A new treatise on the Chrysanthemum.—Mr. J. Udale has recently published a little work entitled "Chrysanthemums: their History and Culture." It consists of a paper-covered treatise in fourteen chapters on such subjects as early history, sports, synonyms, classification, propagation, and various phases of cultivation, together with some remarks on dressing, staging, and insect pests affecting the flower. We might, in a recent work, almost have expected to find something about cross-fertilisation and seedling growing, especially as there is so great an interest among cultivators in such matters, but English authors have as yet had but little to say on these matters. The work appears to have been intended more for local than general circulation, and is published by M. Smith, *Guardian* Office, Droitwich.—CHRYSANTH.

MORE NEW CHRYSANTHEMUMS.

SINCE the compilation of my article, "Some New Chrysanthemums," on page 457 there have been several other meetings of the floral committee of the N.C.S., and the flowers there staged have been quite as numerous and equally as interesting as those shown at the meetings held earlier in the season.

Those mentioned and briefly described in the subjoined list appear to me to be the best of the later shown flowers, and several of them have very narrowly escaped being awarded certificates, which is evidence of their high quality from the exhibition standpoint.

Mme. Carnot (Jap.).—Very large full bloom, florets long, curly, twisted and intermingling, colour pure white. First-class certificate.

Deuil de Jules Ferry (Jap.).—Large broad incurred florets, a beautiful shade of rosy amaranth.

Professor Lackman (Jap.).—An incurred form of bloom, large, purple-amaranth, with rosy reverse. First-class certificate.

Celtic (Anemone).—Short guard florets, good centre, a self-coloured flower; colour rosy chocolate.

Wm. Tunnington (inc.).—Deep golden bronze and crimson. First-class certificate.

President W. R. Smith (Jap. inc.).—A bloom of large size, long florets, rosy blush.

Mrs. T. Denne (Jap. inc.).—Long florets, deep rosy purple. First-class certificate.

Niveum (Jap.).—A fine white bloom with long florets. An American variety.

Golden Gate (Jap.).—A large spreading flower, colour a deep rich tawny yellow. First-class certificate.

Cecil Wray (Jap.).—Very long florets, colour pure bright yellow. First-class certificate.

M. P. Martignac (inc.).—Rather narrow florets, well-formed flower, colour golden yellow.

Miss Maggie Blenkiron (Jap.).—One of the incurred type, broad petals, colour canary-yellow, bronze outside.

Potter Palmer (Jap.).—A big flower, with short stiff florets, rather pointed, colour white.

Judge Hoitt (Jap. Anemone).—Ray florets arc quilled and incurred, pale blush. The disc is rather flat, colour white. First-class certificate.

Richard Dean (Jap.).—Very large and full. Long crimson florets with golden backs.

Lord Rosebery (incurred).—A bloom of good size. A perfect incurred. Colour rich purple-crimson. First-class certificate.

M. Norman Davis (incurred).—A closely incurred flower with reverse of bright golden yellow.

Mrs. Smith Ryland (Jap. incurred).—Large broad florets. Colour bright yellow, crimson inside, tips of petals very curly.

Mr. H. Jackson (Jap. incurred).—A globular bloom, rich yellow.

Mr. C. R. Bessent (Jap. incurred).—A large bloom, colour pure white.

Prince du Bois (Jap.).—Narrow curly florets, very large and globular bloom, colour pure yellow. First-class certificate.

Col. T. C. Bourne (Jap.).—Very long flat florets, a rich wine-coloured crimson. First-class certificate.

C. H. P.

STOVE AND GREENHOUSE.

HALF-HARDY CACTI.

I WAS very much interested in Mr. Overbeck's article in THE GARDEN of December 2 (page 517) as to his successful open-air culture of several of the most beautiful Echinopsids or "Hedgehog Cacti," although I by no means share all his faith that "photographs are incapable of exaggeration," since some of us know that under certain conditions the most alarming distortions and untruthful pictures are quite possible even to photography—an art generally supposed to be most truthful in its effects. The illustrations given, however (pp. 516 and 517), are certainly most faithful, and they bring some early recollections to my mind. As a lad it was my good fortune to live in a village—Somersby, near Oakham—not Tennyson's Somersby in Lincolnshire, but a Leicestershire hunting village, best known as the home of the late Col. Fred. Burnaby, and the birthplace of Dr. Benjamin Ward Richardson.

Here every window almost down the one long main or "High Street" was full of flowers, and, singularly enough, great diversity of taste was shown, a great variety of window plants being grown. A large old-fashioned bow window abutting apse-like on the street was full of Primroses in spring, Pelargoniums or Geraniums, of course, in summer, while in autumn Campanula pyramidalis, with its tall blue and white-blossomed spires, used to attract much attention. The next resident grew the old golden and red velvet-tinted Calceolarias—quaint, long-pocketed flowers on tall plants. Another window was famous for its Fuchsias, another for its Wandering Jew's-beard or Clambering Sailor (Saxifraga sarmentosa), and drooping blue-flowered Campanula fragilis or C. Barrelieri, while very shady windows had Ferns, Aralias, Aspidistras, both rarities then, and hanging baskets of Linaria cymbalaria, and those opposite scented-leaved or zonal Geraniums, Musk, following the Hyacinths and Crocuses of the spring. But the windows I remember best were those of the village doctor, Mr. Henry Hudson, who was fond of cactaceous plants of all kinds. Here for the first time I saw great white or pale rosy stars of the Echinopsis and the white, rosy pink or scarlet Phyllocacti, Mammillarias and Mesembryanthemums, and last, but not least, two or three species of Aloe, and especially a gigantic specimen of the old Aloe variegata (Partridge-breasted Aloe), which was healthy, and produced several spikes every year in a pot of sandy soil and lime refuse from an old wall. As plants for a sunny window, Cacti of the best kinds are deserving of extended culture, and I hope Mr. Overbeck's practical remarks on his plan of growing them will be largely followed. To plant them out on a warm sunny border in May or June and to dig and store the plants carefully, "like Echeverias without water in the winter," is a resting system so simple and efficient, that too much prominence cannot well be given to it in these pages.

But to return to my story of thirty years ago. The good old doctor left the village and all his treasures—his plants, went with him, but last spring I saw one plant that reminded me of him still remaining in the little railed-in strip in front of the house. It was the well-known Dielytra spectabilis, which to my certain knowledge has existed there for at least thirty years, and

every spring sends up its stems a yard high, tipped by elegant racemes of its rosy heart-shaped flowers. F. W. BURBRIDGE.

Carnation Duke of York.—This is undoubtedly one of the finest Carnations sent out in 1893. It belongs to the tree or perpetual-flowering section, and is most distinct. The size and build of the bloom are perfect, while the scent is as marked as in the old crimson Clove.

White Carnations.—The best all-round white I have grown is La Neige. It is free, and much like Miss Jelliffe in habit. Although the blooms are not large they are perfect in shape, and with the slightest fringe at their edges. Another grand white may be found in Caroline Schmidt, the flowers of which are larger and more deeply serrated than those of the former. Nurse Finns is a very large, smooth-petalled flower of great weight. When fully expanded it is of the purest white.—P.

Croton Baroness James de Rothschild.—In a quite recent issue of THE GARDEN there was a recommendation of this variety for decoration. Since that appeared I have seen a beautiful stock of young plants in 6-inch pots, from 18 inches to 2 feet high, clothed to the pots with well and richly coloured foliage. I was hardly prepared to see it in such quantity. Speaking of this variety and a few others, I was told by the growers, Messrs. Fromow and Sons, Chiswick, that the best of the plants were already bespoken for decoration in London. Being so richly coloured, this Croton when well grown is evidently much sought for; the one fact of its looking so fine when under artificial light adds to its attractiveness. C. undulatus and C. aneitensis in the same nursery were both coloured surprisingly well. Each in its way is not yet beaten.—G.

Lachenalias in pots.—How useful Lachenalias are, yet of late years they seem to have fallen into disrepute, if one may judge by the comparative few that are now met with. They require to be potted in good rich material and grown on all winter in a cool greenhouse temperature well up to the roof glass. The least coddling causes the foliage to become drawn and flabby, and the flower spikes correspondingly poor. Two parts good holding loam and one part thoroughly decayed manure suit them well. Weak liquid manure may also be given three times a week with advantage when the bloom spikes are developing in the spring. For arranging in baskets with Cyclamens, Primulas and small Ferns they are most useful. Some gardeners grow them in ornamental wire baskets in a compost of loam, moss and manure. The young plants are pricked into the top, bottom and sides of the basket, which is then suspended from the roof of greenhouse or conservatory, and regularly watered throughout the winter. In March and April their graceful mottled foliage and golden flower-spikes form a pleasing contrast and are very elegant. After flowering, the plants should be placed out-of-doors at the base of a wall where only a small amount of sunshine reaches them, and be allowed to take care of themselves until September, and when half an inch of new growth has been made they should be shaken out, the flowering bulbs separated from the small new offshoots and repotted. When the plants are left in the same pots two years in succession both foliage and flowers will be meagre. Of the varieties in cultivation, tricolor and Nelsoni are, I consider, the two most useful for pot culture.—JOHN CRAWFORD.

Echmea fulgens.—This easily-grown Bromeliad is in some places flowering just now, and when in this stage it is decidedly bright and showy. The large shining green leaves are arranged in a bold vasiform manner, while from the centre of the tuft the flower-stem is pushed up. This, which well overtops the foliage, is stout and branching, and bears a considerable number of flowers of a bright scarlet tipped with purple. These blooms remain fresh a considerable time, and a flowering specimen forms, especially at this season, a very attractive object in the stove. This Echmea

flowers at different periods of the year, but a second Bromeliad now in bloom can always be depended on for its winter-flowering qualities. This is Vriisia brachystachys, whose leaves, flower-stem, and all are less than 1 foot in height, but for all that it is wonderfully bright and effective. In this the pale green leaves recurve in a very graceful fashion, while the blossoms are arranged in two opposite rows on the upper half of the stem. The large bracts which form the most conspicuous part of the inflorescence are at the base bright crimson shaded with purple, which gradually merges into the orange of the upper part. These bracts retain the brightness of their colouring for months, but the clear yellow flowers, which even when fully expanded are partially hidden by the bracts, do not last long. This may be kept in health in pots 4 inches or 5 inches in diameter, and will flower freely every year. These two Bromeliads if given thorough drainage, and potted in a compost consisting principally of fibrous peat with a liberal dash of sand, will with the ordinary treatment of the general run of stove plants succeed perfectly.—T.

Manettia bicolor.—That no hard-and-fast rule can be laid down for the flowering period of this beautiful little twiner is well shown at the present time, for a couple of specimens at Kew are (and have been for some weeks) thickly studded with their bright coloured blossoms, while last May at the Temple show Messrs. Veitch exhibited a well-flowered specimen then at its best, and lastly in the "Dictionary of Gardening" the month of March is given as its flowering season. In any case it is a plant that deserves more extended cultivation, for though introduced from the Organ Mountains, in Brazil, in 1843, it is now very rarely met with; indeed twenty-five years ago it was far more common than it is now, though nothing has really cropped up to take its place. This Manettia is a very slender yet quick-growing twiner that will soon cover a few sticks stuck in around the edge of the pot. This Manettia is of easy culture, as cuttings of the young shoots strike root readily, and if grown on freely they soon form effective flowering plants. In the summer this Manettia will succeed in the greenhouse, but at this season of the year it needs the temperature of an intermediate house or cool part of the stove. Though flowering at various times of the year it follows as a matter of course that the brightly coloured blossoms will in most cases be appreciated to a greater extent during the dull days of winter than at any other time.—H. P.

PANDANUS VEITCHI UNHEALTHY.

I HAVE in a stove here several plants of Pandanus Veitchi which damp off badly. On some of them this complaint has started on the leaves near the point in the form of yellowish spots, which have gradually gone on until they reached the centre of the plant, while the centre of others has gone wrong. The plants were sent from a London firm of nurserymen, and in coming here had experienced the sharp grip of frost that we had about the beginning of November. After they came I discovered they were rather badly infested with bug. I thereupon had them sponged with Fir tree oil and black soap dissolved in tepid water to the ordinary strength. They were then placed in a stove with the heat ranging about 65°. They were syringed several times, and of course the house was aired on all available occasions. Do you think that some of the solution they were sponged with having got lodged in the centre of them, or water when syringing would cause this damping?—D. N. M., Northumberland.

** I have seen and also had under my charge plants of Pandanus Veitchi which have given trouble in a similar way to those of "D. N. M." The primary cause is without doubt to be traced to the chill the plants received in transit, and this may have been further aggravated by the solution used to eradicate the mealy bug. In my own case the plants were used out of the stove; being surplus stock, therefore their loss was quite immaterial,

but the indications in respect thereto were quite similar to those now under notice. Having some plants also on one occasion which had to be kept in a plant pit that had a very flat roof, I noted that the drip which was troublesome had penetrated the heart of the plants. In this case it was neither cold nor exposure, but the wet which caused two plants to die. *Pandanus Veitchi*, like all others of the same genus, is a heat-loving plant, being very sensitive to cold such as would be experienced in transit during a frost. Had the plants previously been kept warm enough, or had they been used for decoration? is a query that should be solved also. What is meant by ordinary strength I do not know; if it means the prescribed strength, it should not cause harm in the usual way. The after-syringing may also have done harm in causing the solution as well as the water itself to penetrate to the hearts of the plants. I certainly would not advise syringing them at this season of the year. On the other hand, it is far better to keep them dry overhead, whilst at the roots no excess should be allowed. The drier the plants are now kept, the better will it be for them. In fact, this is the only remedy so that the plants can be preserved for stock. Any suckers that are large enough to detach, if only with leaves from 3 inches to 4 inches long, should be taken, these being inserted in 2½-inch pots, and then kept warm, but not too moist.—G. H.

THE GIANT ARAD.

(AMORPHOPHALLUS TITANUM.)

I FEEL certain that "F. W. B." did not see *Amorphophallus titanum* when it flowered at Kew in June, 1889, or he could not have "belittled" that event by describing it in *THE GARDEN* (p. 531) as "a fine-foliaged plant with some elegance of habit . . . but perhaps the less often it flowers the better, seeing that the plant is almost unapproachable at that period of its existence." Both botanists and horticulturists hitherto have been unanimous in looking upon the flowering in England of this giant from Sumatra as an event of the greatest interest and an achievement of which Kew might justly be proud.

I do not remember that the full story of this plant has ever been told in *THE GARDEN*, and even if it has, it is of sufficient interest, in the light of what was said last week by "F. W. B.," to deserve to be retold.

In 1878, Dr. Beccari, a Portuguese botanist and traveller, discovered in Sumatra an Aroid with a tuber as large as a Cheddar cheese, and weighing half a hundredweight. From the tuber sprang a solitary leaf with a straight shaft-like stalk 10 feet high and as thick as a man's thigh, bearing a many-times divided leaf-blade like an immense umbrella with a spread 45 feet in circumference. This was the leaf which "F. W. B." describes as "fine foliage of some elegance." But the flower of this giant *Arum* was even more wonderful—a huge bell or trumpet turned mouth upwards, a yard deep and wide, coloured creamy white outside and claret-purple inside, and standing erect in the middle of this a thick club-like spadix 7 feet long and 10 inches thick at the base, coloured chrome-yellow. Imagine a flower almost of the dimensions of Big Ben at Westminster being objected to because it happens to have a disagreeable odour! Beccari sent seeds home and a seedling plant was presented to Kew in 1879. This plant grew larger and larger, whilst all the others in European gardens died, and in 1888 the dimensions of the Kew plant were: tuber 18 inches wide, 12 inches thick, 57 lbs. weight; leaf 6½ feet high, stalk 20 inches in circumference, blade 26 feet in circumference, or over 8 feet across. In the winter the plant rested, and in the following June it developed a flower which measured 6 feet 9 inches in height, the club-like spadix being 5 feet long, the bell-shaped spathe 3 feet deep and 4 feet across the mouth. I was one of the few who saw the flower wide open; this was at about 8 o'clock in the evening. By the following morning the mouth of the "bell" had folded in somewhat. The form of the flower when open

was as beautiful in proportion and outline as the flower of the common *Richardia*. The smell lasted only a few hours and was never even noticed by the public. The flower was propped open by means of wire rings placed inside; thus treated it lasted about a week. I have never seen any flower so wonderful in size, form and colour as this, and I would walk a good many miles to see it again, and I believe "F. W. B." would gladly accompany me. Unfortunately, the plant has since died, as "F. W. B." states, but it did not die soon after flowering. On the contrary, the flower was succeeded by a leaf of fair size, and after a season of rest this was followed by a still larger leaf. The tuber rotted during the resting period of 1891-92. From this it does not appear quite certain that the plant does not survive the flowering period, although there is some comfort for the loss of such a noble plant in the suggestion. I wish some collector would test the feeling of English horticulturists with regard to this plant by introducing it again. It is not in cultivation in Europe now.

"F. W. B." inquires if other large-tubered Aroids die after they flower. The following do not, as far as my experience goes: *Amorphophallus campanulatum*, *A. Rivieri*, *Anchomanes Hookeri*, *Arum crinitum*, *Dracontium*, *Godwinia gigas*, *Synandropadix*, *Taccarum Warmingianum*, *Thomsonia nepalensis*. W. W.

BOUVARDIAS.

AMONGST *Bouvardias* I am more impressed than ever before with the usefulness of *Priory Beauty*. In its freedom of flowering as well as style of growth its counterpart is to be found in that well-known old variety *Vreelandi*, from which I am disposed to think it is a sport. The colour of *Priory Beauty* is a soft rose-pink, a favourite colour with many admirers of the *Bouvardia*.

MRS. ROBERT GREEN, rather more vigorous than *Priory Beauty*, is a sport from *President Cleveland*, which is probably closely allied to *Vreelandi*, being almost a counterpart of it. This latter variety is, I surmise, the source from which *Alfred Neuner* originated. Mrs. Robert Green is in the form of its flowers very similar to *Vreelandi*, but its colour, a delicate light salmon-pink, makes it also a decided acquisition.

PRESIDENT CLEVELAND is by far the best scarlet for winter flowering; both in freedom and the quality of its flowers it surpasses *Dazzler* as much as this latter variety does the still older *elegans*.

VREELANDI is still for cutting one of the best; its flowers are of the purest white, and these can be taken with a good length of stem from well-grown plants.

ALFRED NEUNER, as a double variety, continues to hold its own. By some who have to supply cut flowers that will stand well when cut it is much sought after. Its pretty counterpart with blush-pink flowers, *President Garfield*, improves on acquaintance. It makes a beautiful button-hole flower.

SANG LORRAINE, described as a brilliant vermilion-scarlet, and *Triomphe de Nancy*, as a bright orange red, are rarely if ever seen in good condition. Does anyone now grow them? I am anxious to know, as they were highly praised a few years ago. G. H.

Solanum capsicastrum from seed.—It is generally supposed that this useful plant does not berry so well when grown from seed as when propagated from cuttings. I have grown it from both seeds and cuttings, and do not find any difference. As seedlings are far less trouble, I have decided in favour of these. It is necessary to sow the seed early, say about the middle of January, and the plants must be grown on freely. No delay must occur in potting them on until the size they are to fruit in is reached. They may be grown on in warmth until large enough for fruiting, when they may be plunged in a bed out of doors, or if kept inside all the air possible must be given. While growing, the syringe should be used freely. Syringing should be discontinued, how-

ever, while the berries are setting, but may be resumed after they are well set. In growing seedlings there will be a little difference in habit, &c. By carefully selecting the very best for seed annually, considerable improvement may be made in the course of a few years. If plants are not required to ripen their berries until Christmas, the syringe may be used later on in the season and will prevent the berries setting so early. Seedlings may be grown on without any stopping, as if the plants are given plenty of room they will branch out naturally. Some of our market growers grow them on and finish them off under glass, while others turn them out of doors quite early in the season. Those kept under glass if properly treated are generally the best, as the foliage is clean and bright.—F. H.

Forcing double Daffodils.—The old double Daffodil may be brought into flower by the middle of January if carefully treated during the early stages of growth. I first became aware of this some four years ago by seeing some beautiful pots in a London nursery at the above-named date. Since then I have always made a feature of forcing Daffodils. Bulbs of the largest size and best quality are necessary for such early work, and should be potted at the end of September, placing five or six in a 6-inch pot in good holding loam, afterwards standing the pots upon a hard bottom to prevent the ingress of worms. The bulbs should then be covered with about 4 inches of leaves, and remain unmolested till the middle of November, at which time they should be taken indoors, plunged in a bottom-heat of 65°, and have a top heat of from 60° to 65°. Daffodils, unlike *Hyacinths* and most of the *Narcissi*, at this early date make root growth at a greater ratio than top-growth, so that by the time an inch of growth has been made from the crown of the bulb, there will be abundance of roots to support it. If it is doubtful whether the blooms will open by the desired date, the pots may be placed on boards over hot-water pipes and remain there until the flowers are half expanded, care being taken to supply the roots with abundance of water daily. After this a cool house temperature will suit them best. Daffodils will last a long time in a cut state.—JOHN CRAWFORD, *Coddington Hall*.

Veronicas.—The varieties of *V. speciosa* are not grown so much for autumn and winter flowering as they deserve. The type was introduced from Van Diemen's Land in 1835, and we have now a number of beautiful forms with flowers displaying considerable range of colour, amongst the best being *Blue Gem*, dwarf, free, and pale blue; *Celestial*, sky blue in colour; *Impératrice*, rich blue; *Marie Antoinette*, pink; *Eveline*, rose-lilac; and *Reine des Blanches*, pure white. Neat bushes in 5-inch or 6-inch pots are welcome during the dull months of the year.

SHORT NOTES.—STOVE AND GREENHOUSE.

Carnation Leander is a decided improvement among the deep yellow selfs as regards vigour and hardiness; the flowers are deliciously scented.

Carnation Mr. Hulse.—This new variety is quite distinct, and seems equally as free as *Winter Cheer*. The colour is intense scarlet and remarkably clear. A few plants of this variety have been very showy during the past month. It promises to become one of the best winter flowering scarlet kinds.—R.

Carnation Florence Emily Thoday is also a good new variety introduced during the year 1892; colour pure white, large, smooth petals, making a grand flower with a sound calyx. This variety is particularly sweet-scented, a good grower and free bloomer. Its freedom of growth and bloom make it a grand market *Carnation*.

Carnation Cyril is a new scarlet variety; the blooms are large and of good substance, and the plant grows strongly. In *Duke of Eife* and *Duke of Clarence* we have two more scarlets of grand quality. I think the former is the better of the two for winter work. These three are among the best in their colour, and with *Winter Cheer* and *Horace* are sure to please where deep scarlet varieties are wanted.

FERNS.

NEPHROLEPIS.

ALTHOUGH this does not form a very extensive genus, I do not think that anyone will dispute its great decorative value where plants for covering bare rockwork are in demand. In Messrs. Veitch's show house at Chelsea the smallest growing species at present known, the lovely *N. pectinata*, a native of Tropical America, which, according to E. J. Lowe, was known in some of the English gardens as far back as 1820, forms a worthy companion to the interesting *N. philippinensis*, which was introduced some twelve years ago from the Philippine Islands. Some parts of the rockwork which are completely deprived of soil are entirely clothed with the growth of these two species, forming a most beautiful covering, which for elegance and freshness cannot be surpassed by any other Ferns.

The larger-growing species, such as *N. acuta* or *ensifolia* and *N. exaltata*, the fronds of which often attain 4 feet in length, are equally useful for the decoration of the greenhouse and of the conservatory. This latter species was, according to Lowe, introduced into the Royal Gardens, Kew, in the year 1793. Beddome, in his "Ferns of Southern India," gives it as a native of the Anamallays and the Neilgherries; while, according to Eaton ("Ferns of North America"), it is found growing on decomposing vegetable matter and on the trunks of trees, particularly the Cabbage Palmetto, in South Florida. The same authority adds that it is also found in Mexico, the West Indies, Central and South America, South Asia, China, the Pacific Islands, Australia, and part of Africa. A grand example of the use to which these and other large-growing kinds may be put with advantage is shown in the exceedingly handsome fernery at Nash Court, Faversham. Although usually considered a warm house plant, *N. exaltata* at Nash Court is by Mr. Humphreys grown to perfection in a structure where, during the winter, the temperature frequently falls below 40° and occasionally below 35°, but it must be borne in mind that the roots of these plants being in the open ground are not so sensitive to the cold as they would be if they were confined to pots or pans.

Should any other examples be required to persuade amateurs and growers of the great decorative value of *Nephrolepis* in general, I would advise them to pay a visit to the tropical fernery at Kew Gardens, where they would have the satisfaction of seeing grand specimens of the above-named species, and also of the majestic *N. davallioides* and of its beautifully crested variety here illustrated, and which there are grown as bracket plants against a wall, a position in which they form ornamental masses of a striking and attractive character. This, however, is not the only position in which these useful plants delight, for all of them, either small or large growers, are well adapted for baskets, and their foliage being naturally of an elegant and drooping character, they form perfect balls of gracefully hanging foliage, which, provided the plants are well supplied with water at the roots all the year round, remains in good condition for a very long time. Most of the species are also well adapted for growing on dead Tree Fern stems and for covering perpendicular walls and pillars or columns, as they require but very little soil, and can for a very long time be kept thriving almost exclusively on moisture.

The fronds are in most, if not in all, cases produced from crowns disposed at various inter-

vals on long, thin, rapid-growing stolons or rhizomes of a wiry nature. It is by means of this peculiar feature that *Nephrolepis* are mostly increased, although with the exception of the magnificent *N. rufescens tripinnatifida* and the pretty *N. Duffi*, all other known species produce spores which germinate very freely. The most practical way of propagating these Ferns consists in planting them in a shallow bed made of chopped Sphagnum, coarsely broken peat and silver sand in about equal parts. In such a compost of an open nature the rhizomes can freely run and produce young plants, and when these have produced three or four fronds they may be severed from the parent with safety. *Nephrolepis* may also be propagated by means of the tubers with which such species as *Bausei*, *cordifolia*, *philippinensis*, *pluma*, *tuberosa* and *undulata* are provided. These

Nephrolepis davallioides furcans. Engraved for THE GARDEN from a photograph sent by Mr. G. J. Anson, Upper Clapton.

tubers, varying in size from a small Hazel-nut to a Walnut, are of a succulent nature and found underground, and the soil which contains them must, all through the winter, be kept in a moderately moist condition, so as to prevent them shrivelling up, this being an essential point as regards securing a healthy, strong spring growth.

The species and varieties of large dimensions most suitable for decoration are the typical *N. DAVALLIOIDES*, or *Davallia*-like *Nephrolepis*, a distinct plant of very robust habit and readily recognised from all other known species by its unique mode of fructification. The fertile leaflets, longer and narrower than the barren ones, have their lobes cut much deeper, and each of these lobes is terminated by a single spore mass, which, as in *Davallias*, is situated at its extreme point.

N. DAVALLIOIDES FURCANS, which forms the subject of our illustration and is remarkably effective under any condition, is of comparatively recent introduction. According to Schneider, who, in "Book of Choice Ferns," vol. ii. (p. 590), states that "it was introduced into European gardens by Messrs. J. Veitch and Sons, this variety is so different from the type, that it is questionable whether the plant really is a form of *N. davallioides*, although such was Moore's decided opinion. The most essential characteristic, that of the fructification being disposed at the extreme point of the lobes of the fertile leaflets, is altogether absent, the barren and the fertile leaflets being of the same nature and there being no contraction noticeable." It is a very valuable plant for growing in hanging baskets of large dimensions, where it is particularly attractive.

N. HIRSUTULA.—A form of the better-known *exaltata*, from which it is readily distinguished by the softness of its foliage, which is of a downy nature and a greyish colour.

**N. PLUMA*.—A very handsome species, with beautifully pendulous narrow fronds of a soft papery texture and pale green colour. Native of Madagascar, from whence it was introduced accidentally, some of its tubers, of a somewhat woody nature and of a dark brown colour, having been found among the roots of *Platy-cerium* sent to Messrs. Veitch.

**N. BAUSEL*.—A plumose form of *N. pluma*, from which it differs by its much dwarfer habit, but especially by the nature of its leaflets, which, instead of being entire like those of the typical species, are divided nearly to the midrib and have a very pleasant and striking appearance.

N. RUFESCENS TRIPINNATIFIDA.—A free-growing, very handsome plant of upright habit, very useful either as a pot plant or as a Fern for planting in the warm fernery. Its beautiful fronds possess a peculiarly massive, yet feathery appearance, their broad leaflets, of a soft papery texture and dark green colour, being regularly three-times divided to the midrib and their margins being on both sides deeply cleft and overlapping, much in the way of the Welsh Polypody, or *Polypodium cambricum*.

Besides *N. pectinata* and *philippinensis*, the most distinct among the smaller-growing kinds are:—

N. BARTERI, an Indian species differing from all others through the leathery texture of its short bluntish leaflets, which are as thick as those of *Cyrtomium falcatum* and of a very pleasing pale green colour.

N. CORDATA COMPACTA.—A beautifully compact-growing variety of upright, vase-shaped habit, with fronds all starting from one central crown, from which they spread in all directions. Their leaflets are also of a more leathery texture, of a deeper glossy green colour, and much more closely set than these of the typical *N. cordifolia* or *tuberosa*, from which it is supposed to be issue.

N. DUFFI.—This is a thoroughly distinct, barren plant of most elegant habit, and best adapted for pot culture. The fronds, which have their leaflets comparatively small, rounded at the summit, toothed at the edges and overlapping, terminate in a handsome tassel, which varies in size according to the amount of heat and moisture to which the plant is subjected.

**N. UNDULATA*.—A comparatively dwarf stove species which, according to Lowe, was introduced into the Royal Gardens, Kew, in 1818 by the Right Hon. the Earl of Derby from Sierra Leone, West Africa. Its fronds, of an arching habit, are furnished with narrow-oblong pointed leaflets of a thin papery texture and of a cheerful light green colour. This species also produces small tubers, from which it can be propagated after its resting period.

There are in commerce several other species and varieties which are more or less closely

related to those above described. Nearly all *Nephrrolepises* are of an evergreen nature, but those here marked * are entirely deciduous, and from want of knowledge respecting their habit have often been lost during their resting season, when growers usually keep them so dry that the tubers have ceased to exist long before the time comes when they should start into growth again.

FERN LOVER.

PLATYCERIUMS.

(STAG'S-HORN FERNS.)

THERE are few Ferns which present such distinct characteristics as the above. All the *Platyceriums* are epiphytes, yet they appear to derive much benefit from decayed leaves and other vegetable matter. In their natural habitats the broad basal fronds which clasp the tree stems spread forward and form good receptacles for falling leaves. I think cultivators often omit to take into consideration the fact that plants growing under artificial conditions are deprived of much nutriment which they are provided with through various agencies when growing naturally, and consequently we often find starved and weakly specimens, where if treated more liberally they would succeed much better. The best known species is the ordinary

P. ALICORNE, which is easily propagated, and will thrive well either in the cool greenhouse, intermediate house, or the stove. When grown in a suitable position it forms a most imposing object. The peculiar, broad, concave, barren fronds completely cover the surface, while the fertile fronds form a distinct contrast, being narrow at the base and gradually widening, the broad extremities being deeply and irregularly lobed. They vary somewhat in growth according to culture. There are also some distinct forms of this useful Fern. Among those imported from Australia I find some with shorter fronds, which grow nearly erect, the terminal lobes drooping over and being of a deeper colour than those from other sources. This Australian variety is sometimes grown under the name of *P. alicorne majus*.

PLATYCERIUM GRANDE.—This requires stove treatment, and is a distinct and noble Fern. It can only be increased from spores, and these do not germinate freely. The plants are also very slow growing. We have some four or five years old which have not yet produced any fertile fronds, though they have some very broad basal fronds. Native of the Philippine Islands, Northern Australia, &c. It was first grown at Kew in 1842.

PLATYCERIUM STEMMARIA (ethiopicum).—The above, to which a first-class certificate was awarded at the last meeting of the Royal Horticultural Society, is one of the most imposing of our cultivated Ferns. It is by no means a new introduction, having been grown at Kew as far back as 1848, and in "Johnston's Dictionary" the date of introduction is given as 1822, but I do not find any authority for living plants in this country previous to 1848. The chief characteristics of this species are its thick, massive fronds. The barren ones, which grow erect, are 18 inches to 2 feet high, broad, rounded and sometimes deeply lobed, the fertile fronds from 2 feet to 3 feet long, narrow at the base, gradually widening and divided down about half their length into two broad lobes, which are a pair deeply lobed. The greatest width of the fronds is about 2 feet 6 inches. The fronds are very thick, the surface covered with woolly down. It is a native of West Africa, and thrives well in an intermediate stove temperature. Like the well-known *P. alicorne*, it is readily increased from the young plants formed from root-buds. These young plants may be taken off as soon as the first basal frond is well formed. They may be started in pots, using peat, Sphagnum and Moss, and the pots should be filled up a little above the rims. As soon as the young plants have made some roots

and have developed another frond or two they may be fixed on pieces of fibrous peat, or pockets made of virgin cork for hanging against a wall may be used. It is remarkable that such a noble Fern should have been so much neglected, especially as it may be so readily propagated. The above is sometimes confused with *P. bifforme*, from which, however, it is very distinct. I do not think the latter is to be found in cultivation in this country at the present time.

PLATYCERIUM WILLINCKI is another very pretty Stag's-horn Fern. Seedlings of this will soon make fertile fronds. The barren or basal fronds are small, and the fertile ones narrow at the base, terminating in deeply-cut segments of a pale glaucous green and of a drooping habit. It is a native of Java, and though of more recent introduction, is better known than some of the older species. *P. Hilli*, from Queensland, and *P. Wallichii*, from the Malayan Peninsula, are also worthy of note; the latter, however, is not often met with. It somewhat resembles *P. grande*, but the fertile fronds are shorter and broader.

A. HEMSLEY.

The Cushion Fern.—This remarkably handsome and highly decorative Fern, known in commerce as *Balanium culcita*, is a native of Madeira and the Azores, where it is found at 2000 feet to 3000 feet elevation. Its popular name is derived from the nature of its crown, which is densely clothed with a woolly covering of a soft silky nature and a brown or tawny colour. It is a very effective Fern, growing naturally in very swampy places, as the presence of *Hymenophyllum tanbridgeense* generally found among the imported clumps clearly indicates. Its foliage is ample, and reaches when fully developed fully 3 feet in height, the strong upright stalks of the fronds being quite 18 inches long. Their leafy portion, of similar length and triangular, is three times divided to the midrib, of a somewhat leathery texture, bright green colour, and very glossy. This Fern, of striking appearance, is very valuable for planting in cool ferneries, especially as smoke and fog have very little effect on its foliage. It is comparatively rare, although it forms one of the principal attractions in Messrs. Veitch's ferneries, where it grows luxuriantly in a compost of two parts peat and one part chopped Sphagnum without any sand. On account of its natural habitat it is advisable that, either grown in pots or planted out, it should have at all times plenty of moisture at the roots.—
FERN LOVER.

NOTES FROM A NEW ZEALAND GARDEN.

SEPTEMBER 6.—This morning I cut a bloom of a variety of double Daffodil which I have had for some time, but which up till now I have merely tolerated for its individuality of form. It is one of the double yellow *Telamonius* varieties, which I received some years ago under the name of *Tratus cantus*—an absurd name in both its parts, but one which I think I have seen in Dutch catalogues. I take it to be an attempt to latinise the name of *Tradescant*, and conjecture that the Daffodil ought to be called *Tradescant's Daffodil*. However that may be, there is no doubt about its distinctness from other double forms. In the first place the flower is almost erect upon its stem, and does not nod, as is the case with other varieties. The flower which I cut this morning and which I have now before me is really very beautiful; the parts of the perianth are short, broad and firm, overlapping each other considerably, and standing out almost at right angles to the axis of the flower. The perianth seg-

ments are of a deep primrose, whilst the crown is a solid mass of golden yellow petals, mixed with a few bright primrose segments, like those of the perianth, as is mostly the case in the doubling of Daffodils. Usually the flowers come very green—not, however, that I object to the green-yellow in some of the double Daffodils; it is often an added charm. Further, the scent of this Daffodil is peculiar, quite different from that of the varieties it otherwise most resembles, suggesting the sickly-sweet scent of the Dandelion flower. No doubt Daffodil growers more learned in the flower than I am will recognise this Daffodil under its name of *Tratus cantus*, and I should be glad to learn something of its history from those who know about it. My experience with it so far leads me to think that it is not so robust or easy of increase as the common double Daffodil. The most distinctive features in its appearance are the stiff and upright habit of the flower and stem, the relative shortness of the perianth segments, and a general habit of squatness.

SEPTEMBER 7.—I have been looking up Dutch catalogues since I wrote the above paragraphs about *Tratus cantus*, and I find that Roozen gives this as the Dutch name of pseudo-*Narcissus grandiplenus*, which, again, I find described and figured in Burbidge's book. From the figure I have no doubt that this is my Daffodil. Mr. Burbidge gives Parkinson's long name for this Daffodil—"pseudo-*Narcissus aureus maximus flore pleno fine roseus Tradescanti*," which I am not sure that I can translate in an entirely satisfactory way. What is "fine" whatever? The *Tratus cantus* is evidently *Tradescanti*. Mr. Burbidge speaks of this Daffodil as a "distinct and beautiful form." Till this season I should not have been disposed to agree with him, but the flower I cut to day quite persuades me of its beauty. On turning up Roozen's catalogue for the present year (autumn 1893), I find *grandiplenus* still entered as a synonym of *Tratus cantus*; but then in the same list occurs the name of another Daffodil, "*Tradescantus* (Parkinson's Rose Daffodil)." This is evidently offered for Parkinson's "*roseus Tradescanti*." Which is which, can anybody tell?

SEPTEMBER 8.—I have been interesting myself this spring with the curious phenomenon of

DOUBLING IN DAFFODILS.

When a Rose becomes double, it is the result of the conversion of stamens into petals. But this is only very partially true of Daffodils. The flowers of the double trumpet Daffodils seem to consist of a tassel formed by alternate tongues of perianth substance and of corona substance. On dissecting one of the most double of Daffodils, namely, *pumilus plenus*—a flower that always presents the Rose form, and in which at first glance there seems little distinction of parts—I find to begin with four distinct filaments (in a second flower, indeed, all six). The tassel of the flower consists of tongues of

light-coloured perianth segments, inside of each of which is attached a corresponding tongue of deeper golden crown substance, the two coalescing towards the base, as perianth and crown do in the single flower. For the most part the segments of the corona are cleft down almost to the perianth tube, but sometimes two or three segments remain uncleft with the corresponding perianth segments attached behind. In the first flower I examined there were thirty-two such pairs of segments, no segment of crown being without its corresponding segment of perianth. It is not only the difference of colour and texture that serves to distinguish perianth from corona segments, but the difference of shape also. The tongues of perianth substance are entire at the edges and of the lanceolate shape proper to perianth segments, whilst the edges of the corona segments are irregularly frilled. It would seem, therefore, that the principle of doubling in this flower is that of the Hose-in-hose, one flower, perianth and crown, placed within another. The organs of fructification in the centre are quite distinguishable. In some very double forms not only are the filaments present, but they terminate in proper anthers full of pollen. Sometimes, however, two or three filaments coalesce, and broaden out into a comparatively wide petaloid strap. A friend has brought me what I had just been wishing for—a flower of *Narcissus capax plenus*, which interesting variety I have not yet succeeded in growing. I cannot find in this flower any trace whatever either of the crown or of the organs of fructification. In the specimen before me each of the six segments of the perianth is multiplied six times and the doubling is very regular, each of the outer segments having the other five more or less regularly superimposed upon it, so that the flower retains its six-rayed appearance. In the centre of the flower there are a few small irregular straps, which may possibly be the stamens converted into petal substance, but in colour and texture they are identical with the outer segments. Whither has the crown vanished? I should like to know whether any other case of doubling similar to this is known amongst *Narcissi*. The double odorus (Queen Anne's Jonquil) consists, like the double pseudo-*Narcissus*, of alternate perianth and crown segments, somewhat irregularly sandwiched. The perianth segments decrease in size towards the centre, whilst the crown segments increase. Stamens and pistil are traceable, but have broadened more or less into strap-like processes. The doubling in the Peerless Daffodils is particularly interesting. There is, for instance, that versatile variety known by various names—*albus plenus aurantius*, Orange Phoenix, or Eggs and Bacon. In my garden a complete change of forms may be found ranging from the almost single Peerless Daffodil, with six pale perianth segments and an unbroken orange cup, up to the full plethoric form, where the orange cup is split into segments, which, alternating with pale perianth segments, form a large rose-shaped flower. In the less double forms of this

Daffodil, where the orange chalice remains entire, the doubling is represented by a mass of mingled perianth and crown segments closely packed within the cup, and distinguishable by the striking difference in their colour, the lighter coloured perianth segments rising up above the others, which are of a pronounced orange. The double variety known as Codlins and Cream (*albus plenus sulphureus*, or Sulphur Phoenix) differs from the full form of the last-named Daffodil, Bacon and Eggs, only in the colour of the broken crown segments, which are of a deep straw colour. But, as far as I am aware, the Codlins and Cream variety never shows that less full or semi-double form in which the outer wall of the crown remains entire. I should like to know whether such a form of this Daffodil exists in other gardens. The third of the trio of double Peerless Daffodils, and in my opinion the most beautiful, that known as Butter and Eggs (*aurantius plenus*), differs from the other two in having its perianth segments of a decided yellow, whilst its crown segments in colour come midway between those of Orange Phoenix and Sulphur Phoenix. I have a late blooming Peerless Daffodil in my garden, unnamed, which might stand for the less double form of Butter and Eggs. Its crown is always entire, but is packed inside with a dense mass of crown and perianth segments. This is really a curious Daffodil. The crown, as I have said, is quite an entire cup, and is of an orange-yellow, but inside the wall of the cup there spring up six perianth segments, which stand erect above the cup to the height of three-quarters of an inch, and have very much the appearance of the standards of a small yellow Iris. I have been employing a vacant hour in carefully examining the anatomy of the semi-double *Narcissus incomparabilis*, semi-double aurantius, and semi-double albus (Orange Phoenix). I find in both varieties the stamen filaments considerably multiplied, traces of from a dozen to twenty filaments being observable. Some of these filaments, but very few, have distinguishable anthers, which, however, apparently contain no pollen. On the other hand, there are sessile anthers which adhere to those irregular tongues of crown substance that crowd the inside of the cup and constitute the doubling, as far as it goes. Further, these sessile anthers contain tolerably abundant supplies of pollen, which come off on the finger. The fuller the flower becomes, the less perceptible do those sessile pollen-bearing anthers become, until at a certain stage of doubleness they vanish altogether. I suppose, however, that such pollen has no fructifying virtue in it, otherwise it would have been used for obtaining hybrids with other varieties.

SEPTEMBER 9.—*N. Macleayi* is in bloom to-day. It is an interesting *Narcissus*, but not, in my eyes at least, specially attractive. It increases at a very slow rate. The foliage differs from that of most of the *Narcissi* that seem akin to *Macleayi*, lacking the grey bloom that characterises the grass of most trumpet Daffodils. Its foliage, as well as certain

features of the blossom, it derives, I fancy, from some *Tazetta* ancestor. Emperor is coming out in quantity. How truly imperial a flower it is! and so hardy and accommodating, that you could never take it for a thing "born in the purple." I have not yet tried it amongst Grass, considering it, to tell the truth, though it is pretty abundant with me, too precious to be treated with anything but the best possible border cultivation. Horsfieldi is breaking into bloom. Between this Daffodil and Empress I find it difficult to distinguish. Horsfieldi is smaller than Empress, and, in my experience, quite ten days earlier. On the other hand, I have Empresses purchased from a dealer here that came into bloom with Horsfieldi, but, in my belief, they are Horsfieldi. True Empress is altogether a finer thing than Horsfield's Daffodil, lovely as that flower is. Empress and Horsfieldi are vigorous in our soil and climate, and increase at a fair rate, but on the whole I should say they are less robust than Emperor. I cut to-day the first bloom of double odorus (Queen Anne's double Jonquil). It is a neat little flower that one could ill do without. I do not find it very robust. Indeed, though I have had it for four or five years, I do not think that I possess a larger number of bulbs now than was first given to me. Mr. Barr, in his little book on the Daffodil, mentions a second form of the double odorus as being "not unfrequently met with in old-fashioned gardens"—this second form being after the way of *capax plenus*. This would be a desirable acquisition, and if it is frequently to be met with in old-fashioned gardens, why is it not in Mr. Barr's catalogue? Sir Watkin (from old bulbs) has opened to-day, and for the first time in my garden has shown his true form—perianth sections broad and overlapping, as in THE GARDEN illustration; a noble Daffodil. This is evidently one of those *Narcissi* that require working up before you can have it in its best form. My imported bulbs, now flowering for the first time, give shabby flowers in comparison with the blooms of established bulbs, and I do not suppose my best blooms yet really show what this Daffodil can do. The dimensions of a freshly-opened bloom are: 4 inches across from tip to tip of perianth segments, mouth of chalice varying in breadth from 1 inch to $1\frac{1}{4}$ inches, depth of chalice $1\frac{1}{8}$ inches. A bloom brought me by a friend is larger than this, but mine has only just opened, and Daffodil flowers grow a good deal after they first open.

The following Daffodils are now blooming in my garden for the first time, the bulbs having been received from England late in 1891—December:—

1. *N. BARRI ORPHEE*.—An exquisite little Daffodil. At last, after many disappointments, I must believe in "primrose cups edged with bright orange-scarlet." I do not quite agree with the catalogue, which describes the cup of Orphée as "primrose." The cup of my lovely flower is of a deeper shade than primrose, having almost a suspicion of orange, but the exquisitely crimped edge is really a red-orange. The whole star-like flower is in every way beautiful.

2. *N. INCOMPARABILIS LEEDSI*.—Also a pretty Daffodil, though not so exquisite as *Orphée*. The mouth of the chalice is of a deep orange—reddish certainly, but to describe it as orange-scarlet seems to me an exaggeration.

3. *SPLENDENS* is another of the so-called "orange-scarlet" chalcid varieties of Peerless Daffodil. If my flower is true (as it ought to be), I cannot think how it came to be named *splendens*. In one catalogue I find the description to run: "Large, broad, imbricated sulphur perianth; large cup, edged orange scarlet, very handsome." But little of this description suits my flower, which is hardly distinguishable from *Leedsii*, and is, perhaps, not quite so fine. I take it, therefore, that I do not yet possess *splendens*, but must send for it again, and wait another couple of years before I see the true thing.

4. *MAGOG*, one of the Peerless sulphur varieties, is not quite so large as I expected it to be, having been misled probably by the name, but it is a pretty variety and worth having. So far the perianth is a little "floppy."

5. *VARIIFORMIS*.—A little trumpet *Narcissus* with a very pretty golden crown, charmingly reflexed and frilled at the edge; perianth segments short and curiously creased, like the petals of a Poppy just bursting its sheath. I am very much pleased with this acquisition, but if this Daffodil succeeds with me, I suppose I must expect to find it very variable in form.

6. *PALLIDUS PRECOX VAR. ASTURICUS*.—A charming little flower, happily described by Mr. Barr as "refined." It seems quite distinct from the typical *pallidus precox*, and is noticeable for the relatively great length of the perianth tube and for the twisted and drooping character of the perianth segments. I note also that the perianth tube, besides being proportionately very long, is also very green.

SEPTEMBER 14.—I am at last forced to the conclusion that this is the very worst Daffodil season in my experience of over twelve years. For the last fortnight, when the garden should have been at its best, it has been raining very heavily, with an interval of only two days, and these not successive, when the clumps had just time to lift their battered heads, only to be again beaten down. Such heavy-headed varieties as *Codlins* and *Cream and Butter and Eggs* have been bent by the still rain-down on the soil, where they lie splashed into ugliness. The large masses of *Wilmer's Double* are still yellow enough in the distance, but, looked at closely, they are frayed and washed out. Even *Emperor*, which I have never before seen yield to stress of weather, has a battered appearance. All the cernuus Daffodils—delicate in texture and colour—have had their beauty spoiled by the storm. Varieties that lie low, like *minimus*, have, of course, fared ill. The only really storm-proof *Narcissus* in my collection is the *odorus*, which has not turned a hair so far as I can see; whereas the *Jonquil* has suffered considerably. Perhaps I ought to add to the *odorus* the *Leedsii amabilis*, which, so far, has not suffered much; but then it is only coming into bloom, and its springy lightness has protected it. So far, this season the Daffodils have shown themselves at their best only on one evening, which I noted at the time. On the following day the rain set in, and it is impossible now that the flowers can be in very good form this year. Fortunately, there are several varieties yet to come into bloom, amongst them *Empress*, and if the

weather improves, of which it makes no promise, we may still have fine flowers, though the general effect has been spoiled. So far, no member of the poeticus family has yet opened. *Angustifolius* is just bursting, but this year I believe *ornatus* will be abreast with it. What has been so disastrous to the flowers has been greatly helpful to the foliage, as since good foliage makes good bulbs, the abundant rain may produce good results next season—cold comfort, however, for present disappointment. The abundant rain will probably largely benefit the various *Narcissus poeticus*, all of which delight in moisture. Indeed, most years I find it necessary to give a little water to the double poeticus before it will swell its spathes into bloom, and even then some of the flowers fail to come to anything. I shall look for good double flowers as the result of this rain.

SEPTEMBER 21.—I certainly did not expect the Daffodils to make again this season such a brave display as they are making this evening, but I leave my lament as it stands, to show what probably is the mood of most Daffodil growers when they are tried with a fortnight on end of the worst weather. The result of the large amount of moisture has been, I think, to prolong the blooming season of the various varieties, and to give great substance to the late-blooming flowers. Up to date there is no kind of Daffodil grown by me in any quantity that may be said to be fairly over, with the exception of a very handsome medium-sized trumpet Daffodil, single, of a rich golden yellow colour. *Telamonius plenus*, of which, be it observed, I cut the first bloom in June, is still glorious. A good many clumps are past their best, over indeed, but far more are now in prime form, or little past it. The question of successional flowering is one that has forced itself on my attention this year more than usual, some clumps of Daffodils having quite finished flowering, whilst other clumps of the same variety in the same border, and quite as much or more exposed to sunlight, are coming into bloom. To give an instance. Three clumps of a very fine sulphur trumpet Daffodil—so like *albicans* as to make any difference of little account—came early into bloom. First one clump went off that was planted on a raised sunny rockery. Then two others followed, with the exception of half a dozen flowers in one of the two, which are at present at their best. Now two fresh clumps are out, making the season of this Daffodil a very long one. The reason for this lateness is to be found in the fact that in early spring fresh earth was heaped over these late clumps, and consequently it took them longer than they counted on to get to upper air. Similarly with two clumps of *minimus* planted within 2 feet of each other on the same exposure, the flowering of one is over, the other is on. I can quite see the possibilities of retarding Daffodils for a considerable time by the simple expedient of heaping soil above them, but, of course, it must be done early, just as the grass is breaking through the ground.

There is a wonderful beauty in the garden to-night. The Plum trees and Pear trees, very full of blossom this year, are now in their best dress, and they set off the Daffodils as much as they are set off by them. Everyone who has ever grown Daffodils knows what lovely moonlight flowers they are. Their moonlight is, of course, very different from their sunlight beauty. So with fruit trees; they, too, have their own peculiar effect in the moonlight. I have before me in a vase a few interesting flowers which I cut this evening. *Imprimis*, two of the poeticus section—*angustifolius* and *ornatus*, which varieties have come with me almost abreast this year, *angustifolius* to the front perhaps by half a head. *Angustifolius* is a pretty, graceful *Narcissus*, valuable for its earliness, but it cannot compare in richness of substance or purity of colouring with the later poeticus *Narcissus*—*recurvus* for instance. "Truly wild in the Alps of Central Europe" Mr. Burbidge says of it, and he ought to know. It impresses myself as not being a true poeticus at all, but a hybrid between a poeticus and something else—a flower much after the manner of the hybrids grouped under the name of *Burbidgei*. *Ornatus* is a *Narcissus* that increases slowly with me as compared with *angustifolius* or *recurvus*, but I cannot think that it is slow of increase elsewhere, since it is quoted at so cheap a rate.

Several of the hybrids classed under the general name of *Barri* are now in bloom with me for the first time from bulbs introduced in 1891. *Miriam Barton* is a neat and singularly chaste looking flower, perianth and cup shades of clear pale yellow, the cup of a slightly deeper shade than the perianth; *Maurice Vilmorin*, a handsome flower with orange-stained cup, is an acquisition; *John Stevenson*, pretty, but not particularly choice; *Cynosure* is a striking Peerless Daffodil, with handsome star-like perianth rays and a fine orange cup. *Duke of Bucc'each* I do not find in Mr. Barr's catalogue, but it is well worth a place in any catalogue, for it is a beautiful Peerless Daffodil with a large spreading cup of a fine shade. These various Daffodils to the discerning eye no doubt present interesting and sufficiently marked differences of character, but one can quite understand the contention that certain varieties find their way into the best catalogues without any great claim to distinctiveness of character. A slightly longer or shorter perianth tube, a shade more or less orange in the cup, the perianth rays a fraction longer or broader than we find in some already existing named variety may easily seem to many people who love the flower hardly sufficient grounds for cataloguing a new variety. That sweet Rush-leaved *Narcissus tenuior* has expanded its first bloom with me. Its scent is even sweeter than that of the *Jonquil*, and if there is any heredity in scent, would seem to point to *Tazetta* parentage. I do not find *tenuior* nearly so free flowering as the *Jonquil*, though the bulbs multiply at a fair rate.

Dunedin.

A. W.

ORCHARD AND FRUIT GARDEN.

LATE DESSERT APPLES.

VERY few gardeners can boast of a good supply of dessert Apples after Christmas, yet there is no reason why they should not be as plentiful in spring as during the autumn and early winter months. It is simply a question of planting the proper varieties, skilful treatment and careful storage, which will ensure a supply until Apples are ready again. Cox's Orange Pippin will usually keep up to the middle of January. Braddick's Nonpareil will afford a splendid succession, as the fruit is handsome, of fair size (see illustration), rich flavour, and the tree is a great cropper grown either as a standard or bush. The fruit should be left on the tree until quite ripe, as it not only keeps better, but the flavour is finer. If picked before fully ripe, the flesh is apt to become somewhat tough and dry. I have always found it best to gather the fruit at various times, picking the ripe ones and leaving those not ready for a week or so longer; by this means the fruit will be excellent for dessert at any time from the end of November to the middle of April. Another first-class dessert Apple whose season is the same as the above is Roundway Magnum Bonum. So good in every respect is this Apple, that it only requires to be more generally known to make it a popular variety. The fruit is rather large, russet green in colour, and tinged with red on the sunny side; tree a moderate grower and a good bearer. Egremont Russet is an excellent Apple for spring use, flavour rich and juicy. It will keep until the end of April. This variety appears specially suited for garden culture, as small bushes have fruited freely with me. It is well worthy of a place in every garden however small. Ashmead's Kernel Improved is a fine flavoured Apple. It was awarded a first-class certificate by the Royal Horticultural Society a year or two ago. The tree succeeds well in any form, and the fruit is fit for use at any time from January to May. Court Pendu Plat is one of the most useful dessert varieties; owing to its late blooming it escapes most of the spring frosts. The tree is a heavy cropper and the fruit is of fair size, handsome, of good flavour, and will keep until early in June. Mannington's Pearmain is a well-known heavy cropping variety, often producing a crop when other kinds fail. The fruit is of moderate size and superior flavour. Duke of Devonshire is better known in the north than the south; its excellent flavour, long keeping qualities, good habit, and heavy cropping powers ought to bring it into greater prominence. I have for several years sent in good dishes of it for dessert on Midsummer Day. Sturmer Pippin is one of the best known late dessert Apples, keeping well in a suitable fruit room until the early Apples are again fit for use. As the tree is a vigorous grower and very prolific, it should be included in every garden that has to afford a continuous succession of Apples.

Many other sterling varieties of late dessert Apples might be named, but a long list is unnecessary, and all the kinds mentioned have proved very satisfactory with me on a light porous soil, and a great many of them were equally good when I had to deal with heavy land.
W. G. C.

Pear Glou Morceau is one of the best of late Pears, especially after a warm season like the last summer has been. It is now probably the best-

flavoured Pear brought into Covent Garden Market. It is a free bearer and does well on most soils, excepting those that have cold clay beneath.

Apricot, Oullin's Early Peach.—This appears to be the best early variety. For several years it has not failed to bear moderate or heavy crops of medium-sized fruits of extra fine flavour, while other kinds on the same wall have been more or less a failure in some seasons. Another advantage is that the branches do not die so mysteriously as in Moorpark. Liquid manure has a marvellous effect on Apricots, causing the fruit to be much larger and earlier than on trees which had received none.—W.

Bush fruit planting.—When carrying out the annual planting operations the bush fruits should not be overlooked or neglected. Undoubtedly October and November are the best months for this work, but all are not able to get through the work so early, and very little if any difference will be seen ultimately in bushes planted early or late in the winter so long as mild and open weather is chosen for the work. Currant and Gooseberry bushes are often kept cumbering the ground for years after they have passed their prime, and the same remark applies, in perhaps a less degree, to Raspberries. No doubt this is often the result of having no available young bushes to take the place

Fruiting branch of Apple Braddick's Nonpareil.

of the old ones, but cuttings are so easily struck and brought on to bearing size that this should be no excuse. There may be a slight lessening of the bulk of fruit from young bushes, but the fruit will be much finer and more satisfactory, Currants selling at from 6d. to 1s. per peck more when taken from young bushes than these do from plants past their best; there is also much less trouble in picking the finer fruits. Wholesale clearances of plots might not be wise, but a row or two at least could be destroyed yearly. Very old stools of Raspberries get their roots matted together, this and the dead remains of previous growth making good progress impossible. As plantations are made to last a few years, the ground should be trenched and heavily manured. Raw manure, however, is not good for the roots, and where this has to be used a good plan is to crop the ground once after trenching and before planting the bushes. This answers a two-fold purpose, as it enables the manure to become mellow and gives the ground a chance to settle. All manuring done after planting should be in the form of an annual mulching, and no digging should ever be permitted between the bushes.—J. C. TALLACK.

Pear Winter Nelis.—This is considered by some to be a difficult kind to grow, but I have never found any difficulty in having it of a good size, and the tree with me always crops well. The tree is not a strong grower, but when placed in a

favourable soil with a good position the growth is satisfactory. During the last twenty years I have grown it in three different gardens and with the best results. I consider it the most reliable kind grown. I know a garden which, like this, is low-lying, and here the owner had only three that he considered reliable as to flavour out of some forty kinds. I grow it on a south-west wall (the wall is rough stone) on a raised border. Although the tree is not a large one I had six dozen fruit from it. I am now planting it on a west wall to try and prolong the season. One of its great merits is that the fruit ripens gradually, and most of the high-flavoured kinds have not this quality. It may be had of good size from bush trees. When in Norfolk recently I saw some fairly good sized fruit from trees grown in this way.—JOHN CROOK, *Forde Abbey.*

CORDON FRUIT TREES.

WHEN we consider the beauty and usefulness of this class of trees, it is strange that they should not receive more attention. There are thousands of climbers planted for hiding bare and ugly walls that are not so attractive as a well-grown fruit tree would be in the same situation. The best form is no doubt trees on the cordon system; planted about 15 inches or 18 inches apart, they rapidly cover the bare walls. And what is more beautiful than a fruit tree blooming from base to summit? By planting cordon Apples and Pears, selecting varieties of large size and high colour, they are almost, if not quite as striking while in fruit as in bloom, and the amount of fruit such trees will produce is astonishing. For exhibition, such fruit is most difficult to excel, as it attains a large size, beautiful colour, and a most delicate bloom, causing many to exclaim that it has been grown under glass. More than once or twice I have been very close to being disqualified through judges thinking the fruit was glass-grown.

Some of the largest Pears that I have seen this year were grown on a well-known exhibitor's house, and they easily took premier honours when exhibited, yet neither soil nor position was very good. Many cordon trees fail through being too restricted, but the great length of wall they have on an ordinary dwelling house suits them admirably, and I would strongly advise their being planted, putting Pears in the sunniest aspects, Apples on the sides facing east and west, and Plums or Cherries on the northern side, or failing these Gooseberries would succeed well. There are acres of bare walls not only on houses, but buildings of other descriptions that would give a very handsome return if covered with choice fruit trees. In these days of high pressure everything that can be turned into a source of revenue should receive attention, or if not marketed it would come in well for home consumption or for giving to friends. The following varieties of Pears I have found to succeed well grown as cordons: Louise Bonne of Jersey, Clapp's Favourite, Souvenir du Congrès, Flemish Beauty, Doyenné Boussoch, Doyenné du Comice, Pitmaston Duchess, Beurré Hardy, Beurré Bachelier, Beurré Dumont, Beurré Superfin, Fertility, Marie Benoist, Marie Louise, Nouveau Poiteau, Glou Morceau, Easter Beurré, and Josephine de Malines. In ordinary seasons the above list would afford a supply of Pears from August to the end of March, and if the trees be well supplied with liquid manure the fruit will be of large size and fine colour. The Apples are most satisfactory as cordons with

me are Duchess of Oldenburg, Ecklinville Seedling, Worcester Pearmain, American Mother, Cox's Orange Pippin, Beauty of Bath, Cox's Pomona, The Queen, Bismarck, Gascoigne's Scarlet Seedling, King of Tompkins County, Peasgood's Nonsuch, Lane's Prince Albert, Wealthy, Mère de Ménage, Cardinal, Stirling Castle, and Bramley's Seedling; all the above have cropped well and produced splendid fruit, being the best cut of over sixty varieties grown on the system named. Most of the varieties named have, naturally, a fine colour, and when ripe look beautiful hanging against a wall and surrounded with nice green foliage. When the trees commence to fruit freely plenty of liquid nourishment should be supplied, as the soil is frequently drier near the walls than out in the open garden. Not only cordons, but many other wall trees annually fail owing to drought. If a thorough soaking could be given every fortnight all through the summer months, the trees would derive great benefit. Liquid manure might be applied late at night or early in the morning, thus avoiding unpleasant smells.

W. G. C.

Pruning Vines.—Many amateurs who possess a few Vines are often at a loss as to how to prune them, and frequently call in a jobbing gardener to perform the operation. Many of these men called in possess little or no knowledge of how the work ought to be performed, and if Grapes are produced the following season, it is more owing to the accommodating nature of the Vine than to skill in pruning. Only a few days ago I saw some strong Vines treated in a barbarous manner by one of the jobbing fraternity; all spurs had been cut off close to the main rods. The owner himself, I think, would have done no worse if he had pruned them. A few hints to such may perhaps be serviceable at this season and enable them to prune their own Vines if they cannot engage the services of a qualified man. At the same time I would urge amateurs to employ a capable man, if obtainable, in preference to doing the Vines themselves. As soon as the major portion of the foliage has fallen the pruning should be done as this reduces the chances of bleeding when the Vines start into growth in the spring. Supposing the Vines are trained on single rods up the roof, all side shoots or laterals should be cut back to one or two good buds. Sometimes the first bud nearest the main rod is small; if so, cut to the next bud, which, as a rule, is large and good and produces the finest bunches. If the side shoots have been too crowded, some of the weaker and worst placed may be cut clean away; 1 foot to 18 inches apart is a nice distance for the spurs or side shoots. If the Vines are young, the leading shoot forming the main rod must be cut back according to the strength of the rod. When the growth is weak it will strengthen the Vine if only about a foot of young wood is left; but if strong, about 3 feet may remain, always cutting back to a bold, well-placed bud. When there are several rods attached to one Vine, each one should be 3 feet apart and treated as described above.—W.

Apple Gospatrick.—This, raised by Mr. Ross at Welford Park, Newbury, is an early Apple, but of great merit. I should imagine that King of the Pippins is one of the parents of Gospatrick, as it possesses several of the qualities of this variety. The growth of the tree is free, and small trees bear heavy crops. The fruit also keeps well into December, though termed an early variety. This season the fruit was exceptionally good and could be used for dessert. This variety first came into notice at the great Apple congress at Chiswick in 1883, and since that date Mr. Ross has staged it in fine condition. It is certainly worth a trial where new varieties of Apples are being planted.—G. WYTHES.

Apple Tibbett's Pearmain.—This variety is not so much seen as it deserves. It is one of the best for kitchen use, coming in during the last three months of the year. Splendid examples are grown in Kent, chiefly in the Maidstone district, and it is well worth including in the list of ra-

liable cooking Apples. The fruit is large, conical, and angular, greenish bronze streaked with reddish brown on the exposed side; flesh dry and slightly acid. The fruit of this variety this season has been of great size and even small trees have borne very heavy crops. I do not recommend it for orchard culture, but in the form of a bush or as a pyramid it will be found valuable.—G. W. S.

STEWING PEARS.

STEWED Pears, when presented in good condition, form a dish that proves very acceptable to most people who enjoy "sweets" of any kind, and if more trees were planted of varieties the fruit of which is fit for stewing instead of second-rate dessert sorts, there would be far less need to import such large quantities. As yet I have not heard of trees of stewing or baking varieties being planted on a large scale with a view to competing with the Americans in the Pear canning or bottling industry, but it is to be hoped this branch of fruit culture for profit will not long be neglected. With ordinary Pears, or those that are grown for marketing either direct from the trees or after they have been kept for a time, there is bound to be considerable waste at times, owing to gluts in the market; but in the case of stewing Pears these could be bottled or tinned, the former from choice, according as they were fit, none being spoilt. Properly placed on the markets, there would be no difficulty in effecting sales at remunerative prices, stewed Pears fast becoming an almost indispensable item in the *ménu* of dinner parties, large and small. Nor ought housekeepers and cooks to be content with preparing Pears for the table only just when they happen to be available. Some few varieties keep well, but the bulk do not, and bottling should therefore be largely practised while yet the fruit is in a sound state.

Some few of the varieties classed as dessert Pears are really admirably adapted for stewing, and, in fact, this is about the best use they can be put to. Foremost among these I would place the Chaumontel. With me this well-known variety fruits very freely against a cool wall, and abundantly as a pyramid, failing but seldom. This season some of the fruit are of fairly good quality, and doubtless would have been still better if the trees had a more favourable position. For stewing it is excellent, the fruit keeping sometimes till March. Standards, pyramids and bushes all yield heavy crops, but the fruit is, naturally, very much finer from wall trees. Vicar of Winkfield is second to none as a stewing Pear, and not unfrequently the fruit is of sufficiently good quality for the dessert. This season, owing to varieties of higher class keeping badly, the whole of the crop of Vicar is being kept for eating, but when the cooks can have this variety they prefer it to all others, no artificial colouring being needed, and the quality is much liked. The Vicar of Winkfield is one of the heaviest croppers we have, whether grown against cool walls or espalier trained, or as standards, pyramids or bushes. At Cardiff Castle there are some very fine naturally-grown pyramids of this variety, and which, when I last saw them, were literally breaking down with fruit. I cannot afford to let the cooks have many fruit of Beurré Diel for stewing, as it is serviceable and good in an uncooked state. Being coarse-grained it stews capitally, and is one of the varieties I would largely plant. Some seasons there might be found a good demand for this Beurré for dessert, and in any case it would bottle well. It succeeds well against moderately warm walls, and

in the warmer parts of the country all forms of trees growing in the open rarely fail to produce heavy crops of fruit. Duchesse d'Angoulême is even coarser in the grain than Beurré Diel, and though largely grown, very rarely becomes sufficiently melting to use uncooked. Much the finest fruits are, as a rule, produced by wall trees, but in Kent I have gathered them nearly one pound in weight from strong pyramids. In this neighbourhood standards of this variety are also very productive, and, all things considered, it ought to be included among the stewing Pears that might well be grown extensively for bottling. Beurré Clairgeau, again, enjoys a certain amount of popularity in some quarters, more especially on account of the very productive habit of the trees. The tree is naturally of an erect stiff habit of growth, and last summer I came across several extra tall trees very heavily laden with fruit. Being of great size and at times brightly coloured, the fruit sells fairly well, but the quality is decidedly poor. It is a fairly good stewing variety, however, and should be grown as such.

Of stewing Pears proper, there are not many that can be recommended. Catillac is perhaps the most extensively grown, as being one of the best keepers. There are, or were not so very many years ago, some fine old standards of this variety to be met with in sheltered Kentish and other orchards, and which rarely failed to produce good crops of heavy fruit. Unless sheltered the fruit on standards is liable to be badly blown about by winds. Very heavy fruit is usually had from pyramids, and also wall trees, though the latter ought not to be tolerated unless the walls are of considerable extent. Those who delight in sensational fruit should certainly grow Uvedale's St. Germain, and which under the name of Belle Angevine has been exhibited in Covent Garden 3 lbs. or more in weight, but it is not a profitable Pear all the same. Of late years it is doubtful if many trees of it have been planted, the present generation of gardeners having a better use for the walls under their charge. Uvedale's on the Pear stock would, and has been permitted to do so in former years, cover an enormous area of bricks and mortar, and yet at the most produced about one fruit to every 2 feet square. There is something, however, to be said in favour of large bushes and standards of this variety being planted, as the fruit, in addition to being fine, keeps till well into the spring and cooks admirably. Bellissime d'Hiver also attains a great size, and though less well known than Catillac, which variety it somewhat resembles, it is considered by good authorities superior to it. This summer very good crops were produced by standards and pyramids, and the fruit will keep if need be till April. The good old Verulam is also well worthy of being freely planted either as a pyramid or a standard. It is a sure bearer, the fruit being medium-sized, keeping till the end of February, and requiring no artificial colouring when cooked. Gilgil cannot be trusted to keep late or much after December, but it is of attractive appearance, and one of the best for stewing. It may be grown either as a bush, pyramid, or standard, and rarely fails to bear good crops. For a stewing Pear it is rather small.

M. H.

Apple Newton Wonder.—This promises well, and will no doubt become a leading variety. I have seen it exhibited on several occasions in very fine condition. It received a first-class certificate in December, 1887, from the Royal Horticultural Society. I saw it in June last year as firm and good as if just gathered from the trees. I somewhat resembles a Blenheim Orange, and ha

some of the good qualities of a Wellington. It is a handsome fruit, large, of nice colour, and keeps sound well into May. These late fruits should find favour with growers for market, as they will keep till good prices can be obtained. Though the cost of storing must be taken into account, good prices, if the fruits are plump, can always be realised.—G. WYTHES.

Apple High Canons.—This much resembles Wellington in shape, but the flavour is quite distinct, and what is more the tree is more reliable in cold, wet, heavy soils. It was certificated in 1884. It is one of the latest Apples we have, its season being April, May, and June, a time when there are none too many sound fruits. High Canons may be grown where the Wellington does not thrive. I saw some trees at Maidstone loaded with fruit. I have only grown it as a cordon, but it does well in any form, I understand. When cooked the flavour is distinct from that of most kinds, as it possesses a somewhat spicy, but agreeable taste.—S. H. B.

Apple Tyler's Kerrel.—I saw this variety in fine condition in Messrs. Veitch's nursery, Langley, Slough, in the early autumn. Though the cordon trees of this variety I have borne very freely fine fruits, they had not got the same finish as seen at Langley, these being noticeable for their high colour and perfect shape. This variety makes a grand orchard tree. It is a large heavy fruit with a pleasant acid flavour and a good keeper. Though its season is given as December and January, I have had no difficulty in keeping it well into March. This variety was awarded a first-class certificate at the Apple congress in 1883 at Chiswick, and Mr. Barron's report is that it is a first quality fruit and very handsome. This season I have noticed it as being one of the best dishes in most large collections.—G. WYTHES.

* * We have also seen this variety doing remarkably well with Mr. Bunyard at Maidstone, small trees being loaded with fruit.—ED.

NOTES ON CORDON PEARS.

THE demand for cordon Pears seems to be yearly increasing, and the large stock grown by nurserymen who make a speciality of them would seem to indicate that they have faith in the continued demand. For small gardens, where the desire is to grow a fair number of varieties on a small area, the system is about the best that can be followed. The close attention of years has now enabled the specialist to recommend with great confidence the best varieties for the purpose, although given a suitable soil there are few that will not take kindly to the treatment. I think a well furnished wall of cordon Pears when the fruit is approaching the gathering stage is one of the sights of a garden, and, with the planting season at hand, I fancy we should all be inclined to welcome any information forthcoming as to the behaviour of different sorts on various soils. The following notes are from a cordon wall now four years planted, and I may mention that in running along the trees the other day to do the little required in the way of winter pruning I found a fine promise for another season. The soil is a sandy loam, the aspect north-west. William's Bon Chrétien and Clapp's Favourite, nearly contemporaries in season, each make good cordon trees and bear well. Louise Bonne does well, the fruit much finer and better than from old wall trees. Beurré d'Anjou bears well, but the fruit is second class in quality, the tree of weakly habit, and makes very poor growth. Marie Louise d'Uccle is a grand cordon variety and very prolific, fruit handsome, but it never ripens satisfactorily. Chaumontel is not a success as a cordon, weakly in habit, fruit inclined to split. Duchesse d'Angoulême is worthless, and will be taken out. Conseiller de la Cour and Van Mons Leon Leclerc which I class together, as they are similar in shape and of the same season, do well. The trees are healthy, vigorous, prolific, and ripen up well, large, handsome fruit of very fair quality. Doyenné du Comice is fairly free, fruit of fine size and grand quality, habit of tree not

altogether satisfactory, weakly, and makes little annual progress. Winter Nelis is not often recommended as a cordon, but it does well here. Beurré Diel makes a splendid cordon and bears well, fruit not first-class, but better than from old trees. Glou Morceau is an excellent variety as a cordon. Olivier des Serres is not satisfactory, the fruit small and cracks badly, habit of tree poor. Josephine de Malines makes a vigorous cordon, rather shy in bearing, but fruit of good size and fine quality. Triomphe de Jodoigne is a useful Pear, the trees healthy and strong, free bearer. Beurré Bachelier is free, fruit large and handsome, but of very indifferent quality. These are a few varieties which have been specially noticed both in the fruit and also the constitution and general character of the trees. The experience of the last two years has shown that on this aspect the spring protection I have hitherto been able to give (a double thickness of half-inch fish netting) is not sufficient, so with the view of preventing the godly promise being nipped in the bud, I must get enough tiffany for another spring to go the length of the cordons. Many of the trees not being as yet near the top of the wall, the tiffany will have to be fastened some 18 inches down, and then thrown out from the wall by means of uprights and a cross rail. E. BURRELL.

Claremont.

A good late Plum.—I was surprised to have some really plump, nice-looking freshly-gathered Plums brought to me by an amateur during the last week in November, or several days after the blizzard which swept over this part, and which I thought had finished off all the open-air fruit. The flavour had been considerably reduced by the freezing, but for cooking they were still quite passable, and the owner assured me that he had gathered a very heavy crop that had extended over many weeks. The variety is, I believe, called Wyedale, and it is certainly well worthy of extended culture, even if only fit for cooking. As a market fruit it would doubtless command a ready sale.—J. G., *Goport*.

Peach Amsden June.—At p. 503 this variety is recommended for open walls by Mr. Crawford, who is inclined to try it under glass. I feel sure he will not regret this, as I have forced it hard for three years and consider it one of the best kinds of recent introduction. Last year I had ripe fruits of this variety the second week in April and in quantity from a young tree which bore freely the season before, and this year it is again covered with fruit-buds. I sent a short note to THE GARDEN in 1892 on the value of the above variety for forcing. I wish I could say the same of the capricious Alexander, as given the same treatment it is a long way behind Amsden June. I have this season planted it on open walls seeing how well it does indoors, and am much pleased to see how highly Mr. Crawford speaks of it. As stated, it is a large fruit with high colour and good flavour, which are wanting in many of the American varieties. Being very early adds to its value.—G. WYTHES.

The Wyedale Plum.—This is the latest Plum I have ever seen and one that should be better known, as there is no difficulty in keeping the fruit till December. I have gathered nice fruit the third week in November in late seasons. This year it was over a little earlier than usual, owing to the hot summer. The fruit when gathered will keep sound till late in the year if stored in a cool room. I have some half-dozen standard trees with good heads. These supply a good lot of late fruit. The Wyedale is a sure bearer, as since the second year after planting the trees have not failed to crop freely—some years too freely. The fruit being firm and acid, for cooking late in the year it is very valuable. It is oval-shaped, of medium size and a deep purple, closely resembling a late Damson in colour. It was first brought to notice by Messrs. Rivers, who exhibited it at the late October meeting of the Royal Horticultural Society in 1886, the committee thinking it a valuable introduction as a very late fruit. It was then

shown in large clusters, the branches being cut with the fruit. I am surprised this variety has not found more favour as a market fruit, as I feel sure it would command a ready sale. Why should so many early varieties of this fruit be grown, causing a glut when they command so low prices? Seeing how well Plums grow in some districts, for instance in Worcester and Herefordshire, a few trees of this variety would prove a valuable addition to the market sorts, and being such a free cropper it would prove a sure source of profit. Strange to say, the Winesour, which does so well in the north, is a total failure with me here. It never bears a fruit, but the above variety does grandly. The growth of the Wyedale is compact and not too vigorous.—G. WYTHES, *Syon House*.

Apple Colonel Vaughan.—This, known also as Kentish Pippin, is a desert variety of great excellence, and succeeds well grown as an espalier. It is fit for use at the present time in this district, but in ordinary seasons in January. It is of medium size, somewhat conical in shape, carries a fine crimson colour, while the flesh is firm, white, and juicy. In some gardens it crops annually, while in others it is a biennial bearer, but then the extra yield compensates for the season of rest. Wherever espaliers are to be planted, a tree of this variety may well be included.—J. CRAWFORD, *Coddington Hall, Newark*.

Pear Josephine de Malines.—In THE GARDEN, p. 502, and again at p. 570, this Pear is alluded to. I quite agree with both "A. Y." and "J. C." as to its value as a winter variety for the desert. My trees are free grown bushes, and these I much prefer to any other form. I only once saw a tree on a wall with a good crop, but bush-grown trees will invariably bear well. This variety is one that is disposed to fruit best from the terminal buds upon strong shoots; spurs do not in my experience bear nearly so well, whilst the fruit is smaller also, the large fruit at the best being only of medium size. This latter fact is all in its favour so as to ensure perfect development. Our autumns are none too favourable to the perfect maturation of the latest kinds save in the most suitable soils and situations; hence medium-sized fruits are the most likely to attain to this essential standard. To aim at large fruits in the case of late Pears for the dessert is a popular delusion that should be expelled. It is not possible for large fruits to have the same flavour as medium-sized ones. Josephine de Malines will hang on the tree very late in the autumn, and when ripe it keeps sound for weeks.—POMONA.

THE COLOURING OF GROS COLMAN GRAPE.

THE longer I grow the Gros Colman Grape and the more I see of it in other places, the more am I convinced that the general cultural treatment it receives is wrong. I and many others formerly thought that to bring this Grape to perfection its roots must be confined to an inside border, be started early in the new year, and be treated to a strong Muscat temperature. With all these supposed advantages, however, my bunches, although large enough for anyone, never finished so as to carry a Damson-like bloom. I at first laid the blame to the sunless seasons, but have since proved that I placed the saddle upon the wrong horse, and that my treatment, although suiting such sorts as Mrs. Pearson, Trebbiano, and Royal Vineyard, was unsuited to the wants of Gros Colman. These views were confirmed when visiting Kelham Hall, some four miles distant from here. Mr. Webb, the gardener, has this Grape in the grandest possible condition in several vineries both on its own roots and inarched on Mrs. Pince. The crops are heavy, the berries enormous, as large as Orleans Plums and as blue as Sloes. These Vines are not started until March, and even then are not, strictly speaking, forced, but merely assisted, the ventilation being closed in good time in the afternoon in order to husband sun heat. The vineries are not of modern construction, and are,

therefore, only moderately light. This suits the foliage, as every grower knows only too well how liable it is to discolour and turn up at the edges, afterwards becoming a prey to red spider. Plenty of moisture is thrown about during the daytime, this being needful to support the woolly under surface of the large leaves. The situation of Kellam Gardens is somewhat low, close by the banks of the river Trent, and the surroundings are correspondingly cool and moist.

This, again, apparently suits the roots of these Vines, which, by the way, occupy outside borders. The distance between the Vines is not great, 2½ feet at the most, and the laterals, which are disposed freely up the rods, are allowed to extend considerably beyond the bunches, so that they are abundantly shaded. The berries are always well coloured by the middle of September. I feel convinced that what this noble and useful Grape needs for its perfect development is a structure with a fair amount of timber in the roof, an inside and outside border combined, or, better still, one entirely outside, formed of a moisture-retaining loam, with plenty of rubble as a corrective. It should be started not sooner than February, be allowed as much lateral extension as can be exposed to the action of sun and light, and be given no more heat than that of a warm greenhouse, closing early on fine afternoons to dispense as much as possible with the necessity for fire heat. Water should be distributed freely about the floors and walls throughout the day, with abundance of pure fresh air. It should have a house to itself, as in a mixed collection water is generally withheld from the roots as soon as the earlier varieties are ripe, to the great detriment of Gros Colman. This is a noble Grape, and when fully ripe it is pleasant without being too aromatic, and every palate can enjoy it. From Christmas onwards it is of all others the Grape for invalids.

JOHN CRAWFORD.

Coddington Hall, Newark.

SHORT NOTES.—FRUIT.

The winter moth.—Mr. S. T. Wright, of Glowston Court Gardens, writing to us on December 14, says: "The attack of caterpillars on fruit trees will be severe next spring, as the winter moth has deposited immense quantities of eggs on the trees."

Apples keeping badly.—In this county (Worcestershire), and the coldest part, it was only the very early varieties which went off quickly, the winter or later varieties keeping as well as usual, these being left on the trees as long as possible. It must be, I should think, a matter of climate, as I note Mr. J. Groom, from Gosport, says that Wellington and French Crab are as bad as the softer kinds. With me Wellington is excellent, and likely to remain so.—Y. A. H.

Carnation Winter Cheer.—This variety is grown largely by Mr. Wythes at Syon House Gardens, Isleworth. It produces plenty of flowers, and these do not unfortunately split like so many indoor and outdoor Carnations. The plant is strong in growth, compact, and flowers throughout the winter, whilst comparatively little heat is necessary to get the buds to open well. The colour is crimson, touched with scarlet—a bright and welcome shade at this season.

Brownea Crawfordii.—A permanently striking feature in the Palm house at Kew is made by a large group of Brownneas. Amongst the different kinds, *B. Crawfordii* is just now most conspicuous by reason of its carrying several of its huge and brilliantly coloured flower-heads. Although the Brownneas are leguminiferous plants, the flower-heads are very like those of a Rhododendron. *B. Crawfordii* has rounded trusses 9 inches in diameter, carrying from sixty to eighty tubular flowers, which individually are 3 inches long, 1 inch across the mouth and bright rosy scarlet. As a foliage plant alone it might rank amongst the most striking, having large pinnate leaves 2 feet long, the pinnae 1 foot long and 3 inches in diameter.

This *Brownea* is a hybrid and was raised by the late Mr. W. H. Crawford, of Cork, from *B. grandiceps* and *B. macrophylla*.

GARDEN FLORA.

PLATE 941.

THE NEW HARDY WATER LILIES,

(WITH A COLOURED PLATE OF NYMPHEA MARLIACEA CARNEA.*)

I LIVE in some dread of the hybridiser and watch his ways with misgiving in breaking down the distinctions of natural species. Though we gain enormously by raising seedling forms, the results of hybridising distinct species are not so great a gain to hardy shrubs

wild state (though I have once or twice seen picturesque effects from it, as at Middleton Hall), but when people see that they may have in England the soft and beautiful yellow and the fine rose and red flowers of the tropical Water Lilies throughout summer and autumn, they will begin to take more interest in their garden water-flowers. Even the wretched formless duckponds which disfigure so many country seats will begin at last to have a reason to be. The change will be, I hope, the means of leading us to think more of the many noble flowers and fine-leaved plants of the waterside, apart from Water Lilies. A great many handsome plants frequent the banks of rivers and lakes, and are never seen so well anywhere else. The rich soil brought down by rivers is a great aid in the growth of waterside plants, and those who have never

Bud of N. Marliacea carnea (natural size) gathered from open water at the end of October.

and flowers. I very much prefer a wild Sweet Brier to a hybridised one, and many hybrids are poor and ugly, but we owe a deep debt of gratitude to M. Latour-Marliac, who has given us an addition to our hardy garden flora which cannot be over-estimated. He has added the large and noble forms and the soft and lovely colour of the Eastern Water Lilies to the garden waters of northern countries. If this merely meant a gain of the beauty of the individual flower, our debt would be great and we would have good reason for gratitude; but it is not only that. The splendid beauty of these plants will lead people to think of true and artistic ways of adorning garden waters. Our own poor Water Lily was always neglected and rarely very effective, except in a

* Drawn for THE GARDEN (natural size) by A. F. Hayward, October 10, 1893, from plants grown in open water at Gravetye, Sussex. Lithographed and printed by Guillaume Severeyns.

seen them in this their natural position have little idea of their beauty or even size. Apart from the true water plants, there is also a whole series of noble hardy flowers which should be massed in natural ways by the side of water, like Iris, Meadow-sweet, Loosestrife, Globe Flowers, Knotworts, and many others, some of them, like the rosy Meadow-sweets (*Spiraea venusta* and *S. palmata*), flowering with these Lilies. In such ways we shall get gardens of lovely colour and form free from all trace of the pastrycook gardener.

Here is a portrait which M. Marliac sent me of himself. In my own garden I have had great success during the past year with these Water Lilies, which flowered till the middle of autumn, noble buds and flowers being gathered towards the end of October. Many may think that the sunny days of the present year may have been sufficient to account for this suc-

cess, but Lord de Saumarez had tried at Shrubland all the then obtainable Water Lilies of this never-to-be-forgotten raiser, and in the by no means favourable years preceding 1893 all did well and flowered admirably. As Shrubland is a long way north of London, the area over which these Lilies may be grown in the open air includes a great stretch of the most fertile part of England. My own plants are entirely in the open air, and I do not fear loss from cold. The first kind I had (Marliacea) was not in the least affected by the frosts of several years. Most of the new kinds were planted in the spring of the present year, and in a few months we got very good blooms, and red Water Lilies were visible at long distances a few months after planting.

Should there be limits to cultivating these plants in the open garden in the north, it will be quite easy to keep them in houses in the winter and turn them out in the summer. Another very interesting aspect is what may be done in greenhouses and warm houses in cold or unsuitable places, and many may in that way enjoy their fine forms and lovely colours quite near the eye, though the greatest merit of the plants is the giving us quite new and beautiful pictures in the open garden. In view of the great interest of the subject, and of the fact that so little was known of the way in which M. Marliac had originated his beautiful Water Lilies, I felt the best way was to go to the fountain-head for information, and he has kindly sent me the following account of his precious work.—W. R.

— In reply to your request for some account of my operations in hybridising Nymphaeas, I have the pleasure of sending you the following summary of particulars on this subject. Although I am a passionate admirer of all the beauties of the garden, the flora of the waters has always been my favourite study; and so it came to pass that, greatly encouraged by the wonderful results which attended the hybridisation of a host of other special subjects, I resolved to experiment in a similar manner with the Nymphaeas.

About the year 1879 I commenced the work in earnest by crossing the finest types of hardy and tropical Nymphaeas which I had in cultivation here. These early attempts were at first negative in their results, but soon afterwards I scored an unexpected success in obtaining a hybrid with deep red flowers, the seed parent of which was *Nymphaea pygmaea alba*, fertilised with pollen from the flowers of *N. rubra indica*. Unfortunately, and to my great disappointment, this magnificent specimen proved hopelessly barren, and from it I obtained neither seeds nor offsets, so that, after having tried in vain to reproduce it, I gave up the task and turned my attention in another direction.

In order to obtain plants of a really ornamental character, I considered that it was especially necessary that I should make it a point not to employ as seed parents any subjects except such as were very free flowering,

and by rigorously adhering to this principle, I succeeded, little by little, by means of numerous sowings and strict selections, in raising types which were in every way improved in the form and other characteristics of their flowers. It was thus that one of these new subjects (*N. alba*) fertilised with pollen from the American species, *N. flava*, produced *N. Marliacea Chromatella*, which has achieved such a high reputation. In the following year I obtained the hybrid *N. odorata sulphurea* from a similar crossing of *N. odorata alba* with *N. flava*, and the last-named species has also been the pollen parent of *N. pygmaea Helvola*.

About the same time two species bearing a high character made their first appearance in gardens, viz., *N. sphaerocarpa*, a native of Sweden, and the elegant *N. odorata rubra*,

Mons. B. Latour-Marliac.

found at Cape Cod, in North America. The sparse-flowering character of *N. sphaerocarpa* (a diminutive possible sire by the side of my first-raised hybrid, which might well be proud of being the offspring of *N. rubra indica*) determined me to reject it for hybridising purposes, and I gave all my attention to the fascinating American species, *N. odorata rubra*, which, employed as the pollen parent, with my choicest specimen of *N. alba* as seed parent, rewarded me with the sweet *N. Marliacea rosea* and *N. Marliacea carnea*. *N. odorata rubra* was subsequently the parent of the beautiful *N. odorata exquisita*, the colour of which is pink approaching to carmine. As the last-raised specimen of this first group of my hardy hybrid Nymphaeas, I must mention the remarkable *N. Marliacea albida*, the flowers of which have not yet been surpassed in size by those of any other Nymphaea.

In the year 1889 the Universal Exhibition was held at Paris, and my small collection of the above-named hybrids timidly took the road to the metropolis, to see if possibly they might attract some notice from amateurs in the midst of the plant-wonders there. Their graceful elegance, however, was appreciated, and they came back radiant with the distinction of a first prize. What a change has taken place since then! And with how much more assurance would that first collection have made the journey to Paris if they had undertaken it in company with the splendid generation which has since made its appearance!

The success achieved at the Universal Exhibition put fresh life into my ambition to make further advances, and I applied myself assiduously to the work, with the object of effecting a cross which would produce plants with flowers of a very bright red colour much superior to the colour of *N. sphaerocarpa* and *N. odorata rubra*, which I had proved to be incapable of supplying the desired improvement. After numerous trials and experiments, I at last succeeded in attaining the object of my desires in a hybrid, the flowers of which are of the same colour as those of the tropical *N. rubra*, the plant, moreover, possessing the invaluable property of bearing seed—a property all the more precious from the circumstance that the plant does not yield any offsets.

As I had anticipated, this hybrid could not be sent out, as its seedlings could not be relied upon to resemble it; in fact, it has produced seedlings the flowers of which exhibited a whole scale of intermediate shades of colour, from soft pink to the deepest red. Those varieties, however, which it is impossible to render permanent through the failure of their stems to yield offsets have proved very useful for hybridising choice varieties of the stoloniferous and profliferous kinds, and it is from hybrids of this kind that I have obtained the series of those remarkable hardy novelties which, during six months of the year, embellish the waters of pleasure-grounds with a never-failing display of their splendid flowers. Most of these new plants are already catalogued under the names of *N. Robinsoni*, *N. Seignoureti*, *N. Laydekeri rosea*, *N. liliacea*, *N. fulgens*, *N. Marliacea ignea*, *N. Marliacea rubra punctata*, and *N. Marliacea flammea*. Others, not less brilliant, will soon be added to the list, and I may mention, in passing, that several of these have been already described in **THE GARDEN**.

The acquisition of a red-flowered hybrid Nymphaea which yields seed has opened up a new prospect by affording the means of effecting crossings with the yellow-flowered kinds, the result being the production of quite a legion of Nymphaeas bearing flowers which exhibit singular shades of colouring, such as orange, vermilion, gold colour, &c. Some of these splendid kinds have been already introduced to the public, the first of them which flowered being named after the editor of **THE GARDEN**, a compliment due to

him in return for the great interest which he has taken in the advancement of the culture of hardy Nymphaeas.

The blending of the Nymphaeas of the Castalia tribe (which are found in various northern countries) with the Lotuses of the tropics is now an accomplished fact; but another important task remains to be carried out, namely, the hybridising of the Castalias with plants of the cyanea section, which includes a great number of superb blue-flowered Nymphaeas. This is a work which is well calculated to stimulate the enthusiasm of hybridisers.

In conclusion, I have to say that, notwithstanding my very great partiality for the Nymphaeas, I can appreciate the stately beauty of the Nelumbiums, and I have endeavoured, by making repeated sowings, to obtain some hardier and more free-flowering forms of these plants than those of exotic growth. *Nelumbium Osiris*—one of my seedlings—possesses these two important qualities, and I think it is destined to prove a powerful aid and factor in effecting this desirable improvement.

Such is the record of my labours amongst the Nymphaeas. May my enthusiasm for the flora of the waters spread and induce many others to follow my example in endeavouring to extend and enlarge the domain of horticulture.—B. LATOUR-MARLIAC.

THE WEEK'S WORK.

THE KITCHEN GARDEN.

FORCING SEAKALE IN THE OPEN.—Where Seakale has to be forced in the open ground it is of little use to commence forcing before Christmas, as up till then the roots will not have had that rest which is so essential for their making a strong start. Whether it is advisable even now in many cases to commence forcing is an open question, as with a plentiful supply of green vegetables and few roots of Seakale to depend upon, the wisest plan, unless of necessity it must be had early, would be to wait for a few weeks longer, the produce being all the stronger accordingly. When forcing does commence, what is wanted is a steady and lasting heat, which is best secured by providing a bulk of equal parts of leaves and fresh stable litter, which should have been turned two or three times. If this is not done, the temperature is not equable. At least, it quickly rises and then as suddenly falls. If stable litter is used alone, it acts similarly, and besides there is the danger of a sudden increase of steam, which, if not dispersed, very quickly injures the young growing points. Seakale pots should be used, and if boxes have to be used, see that these have movable lids. The material must be well packed around and between them, and at first keep a look out that the temperature does not rise unduly high. If this is likely to happen, the lids should be tilted to let out the heat.

TEMPERATURES FOR MUSHROOMS.—Now that we have got into what is generally the coldest period of the year, Mushroom beds will not keep in bearing unless a genial and equable temperature can be maintained within the structure. Where a regular supply of Mushrooms is looked for and no attempt is made to keep up a genial warmth, the supply will naturally fall off suddenly. The beds may not be spoiled and they may even bear again when a genial time arrives for their so doing, but a growing temperature must be maintained if

Mushrooms are to be secured. For this reason, if the temperature can be maintained at 55° or a few degrees lower in very cold weather, there need be but little fear of the Mushrooms failing, that is, other conditions being right. If the pipes are overheated, some old mats or bags should be laid over them to temper the heat, or the atmosphere will become arid, this being very inimical to the growth of Mushrooms. Very often a growing temperature may be maintained by the aid of fermenting material, a heap of this being placed within the structure and turned occasionally, the ammonia which is given off being very beneficial. In unheated sheds and such-like places where beds are made up, the temperature must be kept up by coverings of dry litter or hay. If it becomes damp through contact with the bed, it should be turned occasionally, placing the drier outer covering near the bed. If this is not done, the spawn is apt to be drawn through into the damp litter.

PREPARATION OF MATERIAL.—In collecting the manure, see that there is a fair proportion of short litter with it, as if only droppings are used, they are apt to heat very violently. Some turfy loam may also be used with good effect with manure that is apt to heat violently, the Mushrooms often being much improved in quality by so doing. When soil is used it must be well intermixed with the manure before the bed is made up. Not much soil is needed, about one part to six being ample.

STORE TURNIPS.—Although the smaller or medium-sized roots are keeping well enough, yet this season the larger roots are showing signs of decay. If the smaller roots are stored by themselves, there need be but little to fear, as the larger roots could be looked over and used first. But if by chance the roots are all together, the smaller and sounder roots would become tainted through contact; consequently they would decay and the supply be lessened accordingly. For this reason all should be turned over, taking out any that are in the least decayed. A. YOUNG.

ORCHIDS.

THE last meeting of the Royal Horticultural Society for the present year, held on December 12, afforded an excellent opportunity for Orchid cultivators to show the great wealth of bloom that may be obtained at this season of the year. Lovely varieties of *Laelia anceps* were shown, the spikes, as they ought to be, left hanging loosely without any support. Garden varieties of Orchids were very numerous, and will doubtless be exhibited more freely in the future than they have been in the past. Sometimes the progeny does not surpass in beauty or even equal either of the parents, but seedlings are interesting, and as all amateurs can become raisers, an added charm is given to Orchid culture which is continuous and instructive in the highest degree. There are pleasure, interest, and instruction in the entire process from the time of pollenising the flowers. There is first the interest arising from watching the sudden collapse of the flower that has been touched with the pollen, while another by its side of the same age will remain in perfect condition. Not always will a seed-pod form, although the pollen has apparently taken effect, but a week or so will satisfy the operator that he must make another attempt. The pods may form perfectly and grow to their full size, but they may be filled with imperfect seed, and twelve months may elapse before they are ripe. Less time suffices sometimes. The chances are that the seed will be perfect, and it should be sown at once on the surface of the compost in which an allied species is doing well. A register of all the crosses made should be kept, with the dates of hybridising, ripening of the seed, sowing it, and flowering; such register is most useful for future reference. One of the prettiest exhibits made at a recent meeting of the Orchid committee was a number of handsome spikes of *Calanthe Veitchi* arranged their full length in vases, the green being supplied by the graceful foliage of *Asparagus plumosus*. This exhibit was

sent from the Duke of Northumberland's garden at Syon House by Mr. Wythes. There are now other very beautiful varieties of the deciduous *Calanthes*, all of which we owe, as well as *C. Veitchi*, to the work of the hybridist. The flowers last in a moderately cool room for at least two weeks after being cut. In this there is a great difference, some cut flowers fading very quickly in a room crowded with people, and which has also been very much heated. I have tried spikes of *Calanthes* in a room which has only been comfortably warm, and they have lasted three weeks. *Calanthes* are amongst the easiest of Orchids to cross-fertilise; moreover, flowering plants may be obtained in three years or less from the time of fertilisation. As the *Calanthes* are now either in bloom or throwing up their flower-spikes, the leaves will either have decayed or they will be in a decaying condition. Let all such be removed and arrange the plants with a groundwork of Maiden-hair Ferns or something else amongst them. The spikes are certainly more effective with some kind of greenery arranged amongst them and placed so as to hide the bare pseudo-bulbs. Not much water is needed now, but it is an error to allow the soil to become dust-dry until the flowers fade, when water may be withheld. Amongst the Orchids not taken in hand by the hybridist are the *Vandas*—at least we do not yet hear of any result from fertilising the flowers, and yet what remarkable hybrids might be obtained by crossing such grand things as *Vanda Sanderiana* or *V. cœrulea* with the *V. suavis* and *V. tricolor* groups. All cultivators of these *Vandas* are anxious to grow them so that the leaves are retained from top to bottom, but they do not all succeed; only a few seem to hit the right method of culture, which implies more than the mere details of watering, ventilating, &c. It is evident that a high temperature is not what they require, for some plants retain their foliage in quite an intermediate temperature. In fact, in all the successful instances of cultivation known to me the plants have been grown in a house which in winter would fall as low as 50°. I was quite successful in cultivating *Vanda suavis* and *Vanda tricolor* some fifteen or twenty years ago in a half-span house put up to grow Pines in, and in which the temperature could easily be kept to 55° at night without overheating the pipes. The *Vandas* were placed on a stage against the back wall of the house, and at no great distance from the roof-glass. The point in their favour was the ease with which the temperature could be kept up even in the most severe weather without heating the pipes more than the hands could bear comfortably. There was no ventilation underneath the plants. It is very difficult to give any reason for the lower leaves of *Vandas* turning yellow and dropping off. It is evidently caused by exhaustion. I have observed the loss of the leaves to occur after blooming, and when the spikes have been allowed to remain six weeks or more upon the plants two or even three pairs of leaves die off suddenly. I have also known it happen to a fine plant of *Vanda suavis* which had been two days at a flower show. The long bare stems of the *Vandas* are certainly unsightly, and the cultivator feels that he has been filled every time he casts his eyes upon them. How to treat such plants is the next question. If they are left alone new growths are more likely to break out from the stems than if they were furnished with leaves, and they will in time furnish the base of the plants. Again, if the plants are turned out of the flower-pots in which they are growing and the underground stem is shortened, the plants may be placed considerably deeper than they were before. The flower-pots should be filled three parts of their depth with loose, but clean potsherds, the remainder being sweet, fresh Sphagnum and drainage. The underground Sphagnum very speedily decays, but a fresh growth ought to be encouraged upon the surface. As a rule the best roots are found above ground; these that push into the decayed Sphagnum very often fail to some extent and sometimes die outright. I believe next month is a good time to repot *Vandas* of the above types.

I observe also that a few of the white varieties of *Læia* aconceps that have missed flowering have started to grow and are freely pushing out roots, although they have been kept comparatively dry; those of them that require repotting will also be seen to next month. Any repotting or surface dressing that can be done at that time should be seen to as soon as possible after the new year.

J. DOUGLAS.

PLANT HOUSES.

SEASONABLE NOTES.—Thus far most of us cannot complain of severe frosty weather to cause any anxiety as to the welfare of plants in general, and what, too, has been an additional advantage to those of us who are located within the fog area, as it relates to gardens surrounding our large towns and cities, is the almost entire immunity which we have experienced this past autumn season. No glass has, up to the present, been washed here upon the outside of the roofs, nor does it need it in any sense. The weather, on the other hand, has been such as to permit of ventilation being carried out extensively compared with most seasons. Naturally, we cannot hope to escape without some spell of frost; it is well, therefore, to be on the safe side.

If any greenhouse or semi-hardy plants are still in positions where there is any apprehension of danger they should be looked to in time. Fuchsias sometimes get caught by being left too long in the cold. It is far safer and better in every way to keep them just free from frost; if not under greenhouse stages, a cellar is a very good place. When compelled to house in sheds the pots should be covered to a good depth with litter, which should be as dry as possible. Hydrangeas should also, if in pots, have some protection afforded them in a similar way, more particularly the best form of the variegated variety, which is, comparatively speaking, a little tender. Other shrubs which are, as a rule, hardy when planted out, are not always so when in pots, hence a little protection is far better. Of semi-hardy, but extremely useful plants, *Aloysia citriodora* is an instance; this I prefer to keep just out of the reach of frost, but not excessively dry at the roots, otherwise the wood will often die back and the plants be partially weakened. I have, when compelled to do so, kept Agaves in dark places, but I do not like the plan. In one place I had them in a large stovehole for want of better accommodation, and, considering all things, they kept well. *Agapanthus umbellatus* will stand a few degrees of frost, but I would not risk this plant below freezing point. So long as frost can be excluded, light is not really necessary in any degree whilst this semi-bulbous plant is resting. No water should be given during the winter, nor until the spring is fairly advanced is any needed, otherwise the plants will not flower so well. Lilliums should be kept safe from frost, so also should *Spiræas* which have been potted up for forcing.

Up to the present it has been quite possible to keep herbaceous *Calceolarias* in cold frames or pits. These will bear a little frost even to the freezing of the soil upon the surface better by far than a coddling course in what is not quite a cold greenhouse. *Cinerarias* will not bear quite so much cold, but so long as the frost is kept away from them, they, too, will be better than in anything like a warm house. Moisture in both cases is enjoyed by these plants, but any excess so as to cause injury to the foliage must be prevented. In order to accomplish this more readily, each plant should be stood upon a pot in preference to its resting upon the soil; more room is thus afforded for the circulation of air. So far *Lachenalia tricolor* and other sorts in pots will not have come to any harm in cold pits where ordinary protection has been afforded. I would much prefer to keep them thus plunged up to the rims in ashes and near the glass than have them in a greenhouse a long way removed from it. *Campanula pyramidalis* I always kept in cold pits, the pots plunged over the rims, so that they are not seen, the lights

being off on all favourable occasions with air at other times when absolutely not freezing. With a frost the lights are kept close, and mats thrown over if extra severe; even then they get frozen, but sudden changes are avoided, and no harm accrues. Christmas Roses planted out in a cold frame are moving kindly. I prefer this method for cut flower supply to that of potting. Intermediate Stocks in pots for spring flowering should be kept quite dry at the roots and as dry as possible atmospherically. From October to March I never water Stocks in pots when wintering them in cold pits. Carnations in pots for spring flowering and Pinks for forcing when in pits should also be kept on the dry side, being freely ventilated when the weather admits. These will be far safer and better if in cold pits than in those where but a slight amount of warmth is applied. Personally I much prefer to keep the stock of *Chrysanthemum* cuttings taken at the end of the flowering season in cold pits than in any sort of house. There is no drooping of the foliage; in fact scarcely any attention, short of protection against frost, is needed. I bank up the sides of the pit with a lining of short litter and protect thickly with mats on the glass, and no harm ever comes to the stock so treated. *Echeveria secunda glauca* is kept tolerably safe when banked up against the wall of a house, but of the two I prefer to keep it in cold pits, mats of course in either case being placed over the plants. All frames and pits whatever they may contain should be looked to as closely as a house to see that no broken glass remains unrepared.

JAMES HUDSON.

HARDY FRUITS.

BLACK CURRANTS.—These may be planted or transplanted at any time up till the end of February, always provided the ground is not frost-bound or badly saturated with water. Black Currants thrive best in a rather strong loamy soil, and if well prepared at the outset, the bushes will succeed without much further trouble for many years to come. Shallow hot soils should be deepened for them as much as possible, either by trenching or by the addition of fresh soil, a surfacing of clay or marl improving the texture considerably. Good room should be allowed the bushes, especially when the soil is rich. A distance of 5 feet apart each way is none too much space. Those with clear stems are to be preferred, though these are not absolutely necessary, natural bushes, or those largely reinforced by suckers, answering well. The three best varieties are Black Naples, Baldwin, and Lee's Prolific, the first named being perhaps the most generally serviceable. The pruning may also be completed now. Thinning out and foreshortening are principally what have to be done, the fruit being borne on the young wood formed the summer previous. In order to keep the bushes well within bounds, cut back the straggling outside and leading branches to better placed inner shoots, and then thin out the remainder of the young shoots so as to have them thinly distributed all over the bush. Quite young bushes should be freely cut back for at least two winter prunings, this being the surest way of laying a good foundation. Always keep the centres a little thin. Cuttings made now from young wood and inserted not less than 6 inches apart in rows 15 inches asunder on an outside border will most probably all strike root and form about three good shoots next summer. The shoots selected should be long, firm, and straight, be shortened to a length of 12 inches to 15 inches according to their vigour, be cut clean across just below the lower joint, and have all but the three or four uppermost buds cut out and be then firmly dibbled in to a depth of 6 inches.

RED AND WHITE CURRANTS.—Much as regards soil for and time of planting of Black Currants also applies to Red and White Currants, and these should certainly have quite as much room. Standards with a good clear stem 4 feet in height may be dotted among the bushes, or arranged at the back of a single line of bushes alongside of

garden walks. A wire or other fence may also be furnished with upright trained growths or cordons. A foundation should be laid by training two leaders horizontally, shortening these to a length of 12 inches at the autumn or winter pruning; from the shoots resulting, training one upright and continuing another as a leader, this being repeated another year or two, or until enough upright branches are obtained. The end upright growths should be merely a continuation of the leader. All should be about 9 inches apart and be gradually trained upwards till the limit is reached. Spaces midway between Pear and other fruit trees against cool walls can be thus utilised for Currant culture, and by matting over the ripe fruit it can be kept very late. If standards are desired, confine young plants to a single stem and train upright till the requisite height is reached, when the topping and pruning should be the same as are practised in the case of bushes. Red and White Currants produce their clusters from the basal buds thickly formed at the union of the young shoots with the old wood and the spurs generally formed by hard pruning. After, therefore, a bush sufficiently large has been formed, the winter pruning merely consists in cutting back all the young shoots to 1 inch or rather less of their base, but if the bush can be improved by the addition of more main branches, leave well-placed young shoots and shorten these to a length of from 6 inches to 8 inches, allowing them to advance the same length each year till the full height is reached, all being then well clothed throughout with fruiting spurs. Quite young bushes should be freely cut back till a good foundation has been laid, the centre always being kept open and the branches 9 inches apart. Shorten the leading shoots on these to 6 inches or 8 inches each winter, and cut back all the side shoots as just advised. The main branches must be built up thus gradually, or otherwise they will be badly furnished with fruiting spurs. Remove all suckers, and give trees that crop heavily a surfacing of manure, this being more effective if covered with a little of the soil. Cuttings should be made and inserted as advised in the case of Black Currants. It should be added that the Red Dutch and Houghton Castle are good heavy cropping red varieties; La Versailles being also grown if extra fine berries or such as will take prizes are desired. White Grape and White Dutch are good White Currants.

GOOSEBERRIES.—These transplant very readily whenever it is mild during the winter. The propagation, on the lines laid down in the case of Currants, may also be carried out and young bushes procured and planted. Some of the most reliable and good are Whinham's Industry, Whit-smith, Rifleman, Crown Bob, Lancashire Lad, Rar-dom Green, Rosebery, Companion, Keepsake, Gunner, Early Sulphur and Warrington. The last-named is the best keeper and should be the most extensively grown. The small-berried Red, White and Yellow Champagnes and Turkey Red are of excellent quality, while if extra large-fruited varieties are desired, London, Ploughboy, Antagonist, Snowdrop, Green Overall, Shiner, Thumper, Catharina, Careless, Leveller, Mount Pleasant and Lion's Provider are considered second to none. All are best grown with a clear stem, and the Lancashire or large-fruited varieties especially so, most of these being of a somewhat trailing habit of growth. Gooseberries delight in a fairly deep, free-working soil, very stiff and cold, or light and hot ground not suiting them at all well, though even these might be made fit for their reception by the addition of material that would either lighten or make them firmer and more retentive, as the case may be. The majority of the varieties will eventually require good room, and the bushes may well, therefore be disposed 5 feet apart in single rows, or the same distance each way when several rows are grouped together. Till the bushes well occupy the ground, the spaces between may be cropped with vegetables; but the less the ground is disturbed immediately about them the better, surface mulchings, but no clogging, being advisable. In order to fully utilise permanent wire netting-covered structures, intersperse standard Gooseber-

ries among the ordinary bushes, and blank spaces on the back walls may be covered with either single or two-branched cordons, or upright trained trees formed exactly as advised in the case of similarly trained Red Currant trees. Wire fences may be covered with Gooseberry trees in the same way, the pruning in all such cases consisting in shortening all lateral growths to within 1 inch of their base and the leaders to a length of 10 inches, this being the surest method of having the main branches or cordons well furnished with fruiting spurs. Pruning may be done now if birds are not in the habit of interfering with the buds, or it may be deferred till the buds are on the move. The heaviest crops are usually had by leaving a goodly number of unshortened young shoots all over the tree, the pruning consisting in foreshortening, removing the very lowest shoots and lightly thinning out the rest. Some growers adopt the plan of shortening all the young wood back to the old wood, clusters of fruit being then had from the main branches. Use the knife rather freely on quite young bushes till a good foundation is laid.

W. IGGULDEN.

IRON FENCES VERSUS LIVING AND PICTURESQUE FENCES.

The iron fence bids fair to ruin the beauty of the English landscape, unless people see its ugliness and its drawbacks as a fence, its great cost, and the further cost of daubing it with tar, paint, and maintaining it in good repair. With bullocks on one or both sides of an iron fence, its fragility as a fence is soon seen. It is of no use as a shelter, nor as a protection from interlopers, as it often forms a ladder for all who want to get over with ease. As a boundary fence it means the loss of all privacy, and is harder and uglier than a gridiron. Lately I saw an estate of much natural beauty, the charms of which were stolen away by miles of iron fences. The roads near were bordered by them, placed on an excellent bank which would have grown a good live fence. Anyone could get over anywhere, and with this fence and its hard black lines in the foreground, much of the beauty of the landscape was lost. Used to fence the pleasure ground or by drives, the effect is most annoying to anyone who knows how much more beautiful some live fences are. There is nothing an iron fence does that an "old-fashioned" one will not do better, while it always looks well with its Ivy, Ferns, Primroses, and varied life. The ill opinion of the old-fashioned fence arose from its being so often neglected, and allowed to be overgrown by trees until no longer effective.

It is not only the tradesman emerging from the town who fancies there is no fence so perfect as an iron one. Such an idea would be excusable in mechanics, and many others who have not studied the question of fences from the point of safety, endurance, and beauty, and who fear the expense and trouble of forming a living fence. But we regret to see the plague of iron fencing extending to some of the finest country places where there are good views.

No fence is so good as a live one on a bank. One objection to it is its weakness at first, and the necessity of protecting it when small, but these are not insurmountable. It is the custom to plant Quick fences small, and then protect them with elaborate fencing on either side—wearisome work, for which there is no need if people would take the trouble to get plants strong enough to form a good fence to begin with. With strong Quick, and a mixture of Holly, or other strong bushes, a good fence can be made at once without protection being needed. In every country place it would be easy to have a few lines of young and vigorous Quick put out in fields in lines a yard or so apart, where they might get stout, and be ready for fencing at any time. Where there are underwoods with Quick growing in them, it is often easy to grub up suitable bushes, cut them down half way, and plant them in a fence, always on a bank.

I have done this with success and without losing a bush, but should prefer to have a few lines of stout Quick ready to take up at any time, because it is less labour. Most fences should be on banks with "dicks" where the ground requires them, because the bank itself forms a fence against lambs and small animals, and the added soil that goes to make the bank gives much better growth. Three years ago I formed a fence of this sort, every bush of which was gathered in the underwood near; the line of bushes was so strong that there was no need to fence them. To prevent, however, any chance of cattle rushing through, a thin Larch pole was run through along and just below the top of the fence, supported by the bushes, and no animal has since passed the fence or injured it. The slender tops of Larch lying in a wood near were used. This fence will be good for as many years as it is wanted, and be a shelter as well as a fence. It was made three years ago, and will not be touched or require the slightest attention for some years to come. It should be clearly understood that in the formation of this fence we had not even the cost of the ordinary "stake and heather" protection commonly used in remaking rough fences. The tough bushes did it all themselves, the bank always helping them in all ways. Consider this as compared with the costly galvanised or iron fence, with its dangers, ugliness, and coldness!

By far the best fence for farm and general work is the living fence—the most satisfactory and least expensive in the long run, and the most beautiful in its effect upon the landscape and for its varied life. I mean the living fence that is not too trim, as annual or frequent trimming is not necessary. Small, "skinny" Quick fences are not so handsome as rougher and larger fences. As regards the constant clipping of fences, it is a doubtful practice. In good arable farms it may be desirable, but in most districts where fields are large the fence should also be a shelter—a bold, free-growing screen, with Bramble, wild Rose, Ferns, Ivy, and other scrambling things that like to live in it. I have many such fences that do not want attention for years at a time—on banks, as they always should be. They are better furnished at the bottom than some of the constantly clipped hedges. To plant on a bank may in some very dry soils, and where there is a low rainfall, seem a mistake, but the bank itself doubles at least the depth of the soil, and the protection of the bank and its little dick is a great gain to fencing, by allowing Briers and wild Roses to fill in the bottom of the hedge, and so prevent small animals from making tracks through. My fences round woods are only re-made when the underwood is cut, say every ten years. That is sufficient. The mass of wood behind and the strong growth in the fence itself are such that no animal makes an attempt on them. The only source of weakness in such places is hedge trees, and I take care to remove them.

Trees are not the only hindrances to good fences. No matter how well a hedge may be planted, or how good the selection of plants may be, if the hedge is annually cropped, or is permitted to grow wild, it is certain to become useless in the end. A hedge can be kept in good order for generations by cutting and laying it every ten or dozen years, and the owner of such a fence deserves to suffer if he does not take care that this small outlay shall be made when the time comes round. It is enormously less than the cost of painting the iron fence and keeping it in repair.

PLANTS TO USE AND AVOID.

To use bad fencing plants is folly, for not only is the money thrown away, but the work is never done. I have planted some thousands of Quick this season in lines 3 ft. apart for the sake of getting strong bushes to make fences, and some Cockspur Thorn, of which I saw an excellent fence in France in autumn. I am not so sure about the Cherry Plum, which grows well in some places, but is not so tough as a Thorn, and in some cold soils, where the Quick is all we want, the Cherry Plum will not thrive. A few Sloe bushes may be used,

but they are not so tough and lasting as Quick. A few seedling common Hollies not over 3 feet high are good here and there, and, where there are not many rabbits to bark it, nothing is more beautiful when planted than Holly. Hollies have the advantage of growing under trees better than any other fence plant. Considering the protection they afford to stock, it is surprising that they are not more largely grown for shelter in stock-raising districts. We prefer them not clipped and grown naturally. One very often sees beautiful, almost natural fences of Holly and Quick in the forest districts of the south of England, and among Holly hedges well formed in better land, those at Woolverstone, in Suffolk, are the best I have seen. Unless, however, in open places where rabbits are few, Hollies are pretty sure to perish when rabbit food is scarce. I have planted several thousands within a few years, and none are intact that are not protected by wire. Sweet Brier, Dog Rose, and cut-leaved Bramble are very good to mix.

It is as necessary to avoid bad fencing plants as to select and grow good ones. The worst is the common Privet, the ghost of what a fence plant should be. Its rapid growth deceives, and it is often used with a dangerous sharp-pointed iron fence outside as a guard, and perhaps, at the same time, to be the death of some animal. Privet is a rapid grower, or seems so at first; it is never so strong a grower in the end as Quick, Holly, or wild Rose. The quicker the Privet grows the worse it is, and the plant should never be seen in a fence. Laurel is also poor. It is a soft useless fence plant, apt to be killed in cold districts and in valleys. Spruce is, unfortunately, sometimes used in hedgerows, and is most unfitted for them for many reasons. The common Elder is always a source of weakness in a fence, and should never be chosen.

OAK FENCING.

Where there are beautiful views, people who enjoy landscapes will do well not to mar them with iron fencing; such things crossing the foreground of the finest landscapes can only ruin them. In some cases good views are kept by a sunk fence, and to prevent them from looking hard or deceptive in any way we may throw a garland of wild Roses along the top of the wall, which marks the position of the fence, and always looks well. But in many other cases, along important drives perhaps commanding interesting views, a finer thing by far than any iron fencing is the strong split Oak post-and-rail fence. There are many estates where Oak is abundant, and where the men are accustomed to split it up into stout heartwood posts and rails. This is not necessarily a dear fence, and it is a very beautiful and efficient one if well done. In colour it is perfect, improving as it gets older. Such a visible tangible fence will last for many years, and might come in the foreground of a picture by Corot or Turner. For dividing lines in stockyards, too, nothing is so good and safe as a split Oak fence. Where good effects are thought of, nothing is more important than good post-and-rail fences in certain places on the farm, where we want to keep animals back without hiding the view, and where shelter is not required. Oak park fencing is pretty, and in many cases efficient, but too expensive to be done on a large scale for field work. Nor should I rank it as high as a good live fence, because of its cost, repairs, and the quickness with which it is often destroyed when old.

WHAT TO DO WITH IRON FENCING.

Many places possess a good deal of iron fencing, and the question may arise as to what to do with it where it is an eyesore. It is best to use it in positions where wiring is necessary to prevent young trees from being destroyed. Temporary wiring may suffice for a season around crops, but will not do for young plantations; also in gardens where much thought is given to outdoor flowers, it is impossible to enjoy them if ground game be let in, as Carnations, Tea Roses, and many of the finest things would soon disappear in hard weather

owing to the rabbits and hares. An iron fence allows us to wire directly on it; but, as such fences near the house are a great eyesore, they should be concealed by shrubs or hedges of Holly, Sweet Brier, or other shrubs. It is easy to do this by a little care in planting. Where pieces of water are near, they often help to shorten the line of wire fencing round pleasure grounds and gardens, but water is unsafe in winter, as rabbits and hares easily cross it in frost. Wire may be used without iron fencing, it is true, but in that case, being fragile in itself, it would have to be supported by something else. The iron fence at once protects and supports it. Young plantations, too, are hopeless without permanent wiring, *i.e.*, less than seven years of secure fencing will not be safe. This applies not only to young Pines and Larch, but to Ash, Poplar and young plantations of most other hard-wooded trees as well. If there is any iron fencing to spare, it may be used in all such fencing of young plantations and also of fruit gardens, and such fencing should be done without hideous disfigurement of the landscape.

THE FENCE AS A SHELTER.

Apart from the ugliness of the iron fencing, its giving no shelter whatever is one of its worst points, as a good live fence gives excellent shelter for sheep and other animals. The prim, neat little hedge is not so good as a shelter, but enormously better than an iron fence. A well grown fence, cut down and re-made after a lapse of seven to ten years, gives very good shelter indeed. There are many such shelter fences, with Holly and Thorn allowed to grow at will, with an interlacing of Ivy, seated on a rough bank. Such lines as these in the direction of the prevailing winds could not fail to be helpful for stock in exposed fields. We have plenty of materials to form such fences as hardy and enduring as the bank itself. We might even have them evergreen if we used the Holly largely. The shelter of a good line of naturally grown Holly on the north side of a high field in an exposed district would be equal to that of a shed. There would be no great difficulty in establishing such Holly fences in open farming districts where rabbits do not abound, but it is not so easy in wooded districts. Seedling plants, not large—*i.e.*, 1 foot to 3 feet high—are the best to use. It is a good plan to buy some very small seedling Hollies, and let them get strong in a nursery, so as to be able to get a few when mending or making fences. The more ordinary materials, too, with an occasional Holly intermixed, give very efficient shelter indeed. The Ivy runs through such fences and makes them very pretty, tying them together with its graceful lace work, and its growth seldom chokes the Quick or other plants.

PLAIN WIRE, BARBED WIRE, AND NAILS IN FARM FENCES.

Fences, through neglect, are often allowed to get in a disgraceful condition on farms, which if they were watched, and once a year weak places and gaps stopped by planting a few strongly rooted living Quick, instead of sticking in a few dead bushes of any kind which come first to hand, the fences would remain good for any number of years, and would never require the use of barb or plain wire either for fencing or gap-stopping. It is certainly a cheap and ready way, but woe to the poor animal who chances to get entangled in it during the night. In most cases the worst accidents happen in the night, when the poor animals cannot see their danger when frightened by dogs or in other ways. On some farms and estates we see every kind of fence except the good living one—anything to stop the gap for the time, without any thought of the future. The consequence is that it is never-ending work repairing broken wires, replacing the dead fences, and straightening iron fences. Nailed wooden fences are a great mistake. If posts and rails must be used—which is at times inevitable—rails put in a mortised post will last very much longer than the nailed ones. Nails are often a source of danger to cattle rubbing

themselves against the posts in which the nails are driven, as the wood decays. A living White-thorn fence, or mixed with Flornbeam and Holly and Briers, on a substantial broad bank, is the fence for general farm purposes. On large estates, and where landscape beauty is taken into consideration, large fences are often necessary, also round pasture fields for shelter; but on large arable farms the sturdy hedge on a good bank is what is wanted, as it does not interfere in any way either with the cultivation of the land or the crops. It is as much to the farmers' interest to watch their fences as closely as they do their crops and stock.—*Field.*

KITCHEN GARDEN.

A RUNNING FRENCH BEAN.

PERMIT me to inform Messrs. Sutton and Sons (see p. 504) that the Longford Climbing French Bean referred to by Mr. W. Iggulden attains to a height of from 6 feet to 7 feet in these gardens, and that it must be ten or twelve years since Mr. Iggulden first saw it in full bearing here in the month of September, as it had been since the middle of July, and continued to yield long, straight, handsome pods until cut down by frost. Mr. Iggulden and several other gardeners who accompanied him on that occasion expressed their astonishment and gratification at seeing the two or three long rows of French Beans of the above height and heavily laden with pods of the description indicated which met their gaze for the first time. All the gardeners that have visited Longford during the interval for the first time have expressed themselves in similar terms, including one visiting here in September, 1892, who had seen Messrs. Sutton and Sons' Tender and True a short time before.

I make my first sowing of this Bean about the middle of April in a drill about 3 inches deep and 60 yards or 70 yards long, depositing the seed about 6 inches asunder zigzag in the drill, covering in the ordinary way, drawing soil well up to the plants on either side as soon as they appear above ground and protecting from late spring frosts by tiffany supported by forked sticks. Later on the haulm is staked, giving Pea sticks about 7 feet high. This done, a good mulching of half-rotten manure is laid on either side of the row. This preserves the soil in a uniformly moist and warm condition about the roots during the summer and early autumn months, the substance of which, when water is given, is washed down to the roots to the benefit of the crop. Two more sowings are made at intervals of a fortnight from the time stated above and in the manner indicated. I may here say that as the Beans are gathered as soon as large enough for cooking, successional pods set and swell higher up the bine with great freedom until cut down by frost, like Messrs. Sutton's Tender and True. The Longford Climbing French Bean was raised by me many years ago from seed saved from a plant of Canadian Wonder, which evinced a disposition to run high above all the other plants growing in the same and adjoining rows.

H. W. WARD.

Longford Castle, Salisbury.

Stachys tuberifera.—Evidently this now fairly well-known vegetable does not bear drought well. During the past summer the plants flagged considerably, and for a long while they seemed almost dead. When rain came they soon recovered and started to grow again, but the check told badly on the tubers, which are smaller than usual, and hence more difficult to prepare for cooking. The tubers being naturally small, their one fault, any falling off in size is unfortunate, so I shall in future endeavour to select a moist and well-manured spot in which to grow them. This is making its way into popular favour. Bulk for bulk, it will not bear comparison with other root crops, but when properly cooked it forms a dainty dish liked by almost everyone. The tubers should not

be lifted until required for use, as they soon shrivel and become discoloured, but they will become plump again if steeped in cold water. When the ordinary means are taken for keeping frost out of the ground to permit of easy digging, *viz.*, by covering with litter, no more should be covered than are likely to be soon wanted, and the litter must be removed when the weather is mild, or the tubers will soon start into growth and become quickly spoiled.—J. C. TALLACK.

Cabbage Lettuce All the Year Round.

A week or two since a note by "G. J. H." calling attention to this excellent Lettuce appeared in THE GARDEN. When this Lettuce was sent out I have not the means of knowing, but the name has been familiar for many years. Many varieties are introduced from time to time, all supposed to be of exceptional merit, but there is not a variety either for general crop or for winter use equal to All the Year Round. I have had quantities of plants this autumn that were quite 6 inches across the hearts, these being firm and perfectly sound. The seeds were sown in drills on a south border, and sufficient plants were left in the rows to form a crop, the thinnings being transplanted. These are now in fine condition for wintering. Light span-roofed frames have been placed over them for winter protection in preference to lifting and planting them under glass.—A. Y.

Improved Round-leaved Batavian Endive.—I quite agree with Mr. Wythes as to the value of the above excellent Endive. It is the best possible substitute for Lettuce we have, well-blanching produce having quite a nutty flavour. Knowing its merits, I made provision for a large supply, and I never remember Endive to have kept so well as this season. The curled-leaved section is all very well for garnishing, but for salad it is not to be compared with the Improved Round-leaved Batavian. It is also very easily blanched. This season, having more plants than I could accommodate with glass protection, the plants were lifted and placed on the floor of a fairly light and cool shed, and for the past few weeks I have been cutting beautifully blanched hearts.—A. Y.

CLIMBING BEANS.

REFERENCE to the climbing form of the Canadian Wonder dwarf Bean named Tender and True recently made naturally leads to the inquiry, why should runner Beans in gardens be, as a rule, so severely limited to the scarlet form when there are several others that give greater variety, and if known would always be acceptable at table? I saw this Tender and True form in the late autumn at Longford Castle in 1892. It had grown to a great height and was cropping abundantly. It is evident that its height, moderate under ordinary culture, is much greater when in strong holding soil. Very much, too, depends upon the way in which the pods are kept gathered. Like all the climbing and dwarf Beans, the harder the pods are gathered, the longer will the plants continue to fruit. Under such conditions Scarlet Runners will grow from 12 feet to 14 feet in height if tall sticks be supplied. Both the white and scarlet-flowered forms of the rough Dutch runner give very little variety in flavour, but the long narrow-podded forms have more flesh relatively, are stouter and more succulent than are the giant podded forms, which are soft and puffed. A special feature of the Ne Plus Ultra and Prize-winner types is that they keep their pods young and tender so much longer than does the Painted Lady or the old Scarlet Runner. That is a great advantage, whilst also the pods, just as freely produced, are more than half as long again. We have, so far as this class of runner Bean is concerned, gained immensely by constant selection. The running form of dwarf Beans is nothing new, but in previous cases it has been found very difficult indeed to render it constant. In the case of Tender and True that difficulty seems to have been solved. The old Cascknife Runners are excellent, and the best, such as Fillbasket, very productive. These have long and

somewhat curved pods, but the flavour is very like that of the dwarf Bean. These seldom grow tall, from 5 feet to 6 feet generally, but much depends on the quality and retentiveness of soil. These were once highly favoured and much grown by cottagers, but they have been displaced by the newer long-podded scarlets. All the same it is a matter for surprise that a row is not grown in large gardens, so that variety in runner Beans may sometimes be found on dining tables. One reason, perhaps, for the too fugitive nature of many Bean crops is that the seed is sown far too thickly. I have always noticed that where Beans are running tall, all the same bearing profusely, and especially where grown to produce fine show pods, the plants are very thin. Where the rows soon fail at some 5 feet in height, the plants are found to be far too thick. The same remark applies to all those pod-bearing plants which soon get starved at the roots. Six inches apart is not at all thin for either dwarfs or runners, and very often the plants are from 10 inches to 12 inches apart. Allowing that the soil was equally deep and good, it is most probable that the thin-sown crop will give a much heavier return than will the one sown thickly. D.

Protecting blanched Celery.—"A. Y. A.'s" note will probably assist once more to raise the not unimportant point in relation to late winter Celery, whether tall or dwarf varieties are best for that season? In the case of tall sorts, unless planted very wide apart, it is hardly possible to earth up other than very thinly at the top, and it is here that frost begins always to injure the plants. In the case of dwarf varieties, such as Dwarf White Incomparable, White Gem or others of that class, even if the rows be but 4 feet apart, it is possible to earth up to the very tops of the plants with fully 4 inches or 5 inches thickness of soil on either side, leaving a flat top some 8 inches to 9 inches broad, and on which can be stood either broad weather-boards \wedge shaped, or, as "A. Y. A." suggests, a rounded covering of corrugated iron, or even ordinary wire Pea guards may be stood along on the top and over the projecting leafage, and on that be laid some Fern or litter. Such protection would prove of great value to the Celery, but would hardly be possible in the case of tall, narrow ridges. Any plan is better than allowing the litter furnished as protection to be tight on the leaves. No harm may be done in dry frost, but so soon as rain or snow comes, then great injury results. It is really most important to keep rain and snow water from getting into and about the blanched Celery, for so long as the stalks are dry the frost does less harm. For that purpose there is nothing better than some impervious roofing over the plants. It is not at all easy to fix such over the sharp-pointed ridges of tall carthed Celery, except some form of support be fixed in or on the rows to sustain it. As to relative degrees of hardiness, I think the dwarfier forms, if not hardier, at least being more easily protected and being, too, usually of firmer texture, have the advantage. So far we have had a fine time for Celery, as the rains, though much needed, have not been excessive. It is not until the new year is in that Celery will be fully tried.—A. D.

Coleworts.—"R. D.," referring to these delicious autumn and winter Cabbages, states that some market growers prefer one, some the other. I found during a long residence amidst market gardens that whilst both sorts were grown, the flat, broad-headed Rosette was the most freely planted—indeed, at times, in blocks of several acres. Still further, a good stock of it would be so true, that of ten thousand plants all would have exactly the same character. I think such constant reference to these Coleworts in THE GARDEN has done much to arouse private gardeners' interest in them, as I have seen the Rosette in many gardens of late. That it is the hardier of the two kinds there can be no doubt, the hardy green or conical-headed being rather earlier and once fully headed, splitting or decaying under hard frosts. Another reason why the Rosette variety is so widely grown is that because marketed in bunches the flat broad

heads make the larger looking bunches in the market. Still further, because so roughly handled in the pulling and loading they are less liable to harm. It is to be deplored that this class of greens should be sent to market in this crude way. Pulled and thrown into heaps, roughly handled in tying into bunches on the tables, tossed by pitchforks up into the vans, and in dirty weather soused into big tubs of none too clean water before final loading, no wonder they come to the market sadly deteriorated. How much better is the method of some other growers, who having huge two bushel baskets with lids cut the greens and pack them on the field, keeping them clean and handling them tenderly. It is a pity that all our winter greens, and indeed most vegetables, are not sent to market in this way, for very often they are most roughly used, especially when stacked direct into vans from which manure has just been unloaded.—A. D.

Parsley in spring.—In large private establishments where Parsley is much in demand in winter a scarcity often occurs during April, May and June. As a rule, only limited frame or pit room can be spared for protecting Parsley; consequently the remainder has to take its chance, which in a period of severe frost is but a poor one. The crowns if not destroyed are often so badly crippled, that new growth follows slowly and the supply fails until spring sowings are fit to gather. As a rule plants which have yielded throughout the summer and autumn months persistently run to seed, thus rendering the produce poor. In order to provide against such emergency, seed should be sown in a warm position about the third week in July, and in due time the seedlings thinned, so that abundance of air can circulate through the bed. In November protection must be given by a frame, or failing this, 12-inch boards placed along the sides and ends and secured at the corners. On these may be placed any odd lights which are at hand. Parsley of this age and character will stand a severe winter far better than the sappy crowns of older plants, and springing into active growth in February, will carry on the supply until the early sown batches are fit for use. In many cases Parsley would be more plentiful in winter if those who consume it would take more care of it. If the sprigs that are used for garnishing are thrown into a basin of fresh water from time to time, they may be preserved for a week or ten days.—JOHN CRAWFORD.

ORCHIDS.

LÆLIA AUTUMNALIS.

Growers of Orchids have had a fine time this year, owing to the absence of fogs that have usually spoilt all the flowers of this species long before now. Some flowers of *Lælia autumnalis* from J. Simpson are from a plant which he says has flowered for five years in succession, and is now in the most robust health. The blooms I have before me are all from the country, as this plant would appear to have lost favour with London growers, because the fogs during the past few years have cut the flowers off even before they opened. Some London growers, too, I have noticed have given up the cultivation of *Calanthes* for the same reason, but this year will, I think, have a great deal to do with their revival. One person I know is doing his best to add plants of both *Calanthes* and several of the Mexican *Lælias* to his collection again, for he says, and with a deal of truth, "that he cannot bear to see the flowers cut off by the fogs, but it grieves him to be without them when we have seasons like the present, and for the future he intends growing them." Mr. G. Tucker sends me some grand forms of the typical form, measuring upwards of 4 inches across the petals, which with the sepals are of a very deep rosy purple. The three-lobed lip is

white, saving the oblong front lobe, which is of a deeper rose-purple than the petals. The flowers, borne in a terminal cluster six or eight together, last a long time in full perfection, and yield a pleasant perfume. Mr. Law-Schofield sends the variety called *bella*, which he appears to think is a very grand form, but he says the flower is past its best. It appears to be a fine variety, but it was a long way past its best, and I can say nothing more than it looked like a nearly white flower. There had been some colour in it, but I could not say where or what it was like. With this also came some very good typical forms which I need not refer to. Thomas Eastwood also sends some very large flowers which, but for their unmistakable perfume, I should take for something different. The blooms are of a rosy mauve, becoming paler towards the centre of the flower. This is the variety *venusta*, which was figured in THE GARDEN some few years ago (Vol. XXV., t. 438). It is a very distinct and handsome form. G. Gubbins sends some flowers which I can only call poor, thin, and weak forms. I should like to see them another year, for there are some very distinct looking blooms, which may come finer next season. J. Hitchcock also forwards the fine pure white form which I have recently noted. It appears to be finer than I have hitherto seen it, the sepals and petals rounder and fuller. From H. Evans comes the grandest lot I have seen, not only this season, but at any time. It consists of two whole spikes of blooms, one bearing four, the other five flowers. He says the finest he has is bearing seven of these large purplish crimson flowers, which become paler towards the base, and measure about 5 inches across. This, called *atrorubens*, is by far the best of the varieties of *L. autumnalis* which has yet been brought to my notice. The flowers are large and handsome in colour. *Lælia autumnalis* was introduced to our gardens in a living state some fourteen or fifteen years ago by the Messrs. Backhouse, of York. Their system of growing these, as well as all other Orchids, was to give them an abundance of air, so that when one went into the house to look round there was evidence that the ventilation had been well looked to. There they were fully exposed to the action of the sun. I have frequently seen them growing on top shelves with the lights quite off them. During the growing season *L. autumnalis* must be well supplied with moisture at the roots, and it also likes a liberal supply overhead from the syringe as well as in the atmosphere. The pots must be well drained, and the potting soil should consist of good brown peat fibre and some chopped Sphagnum Moss. W. H. GOWER.

Notes from Syon House.—The *Calanthes* at Syon House were a few days ago in full beauty. Mr. Wyles confines his selection chiefly to *C. Veitchii* and the beautiful *C. vestita*—two of the most useful species that bloom at this season. Many of the spikes of the former were upwards of 4 feet in length, and this year they have been more beautiful than usual, as fogs have not been troublesome. Ferns form the base, so to speak, and relieve the effect of baldness. It is a pity that these types are not grown more in quantity, as they last over several weeks, are extremely bright and may be cultivated, as here seen, with success near towns. Their great enemy is fog, and the flowers quickly succumb—almost as soon as those of any Orchid. When not formally tied up or in any way deprived of natural grace, the racemes are charming; but at the recent Aquarium show each spike was fixed to a small stick and lost much of its characteristic beauty. The plants are grown in this warm house throughout the year, being kept for the greater part of the time on shelves near the light. Several

plants of that fine old Orchid, *Zygopetalum Mackayi*, were in full beauty, and very good forms. The flowers were well marked and the spikes strong. The *Zygopetalums* last long in bloom and are amongst the most useful of Orchids for amateurs to cultivate. Amongst *Odontoglossums*, *O. crispum*, *O. Pescatorei* and *O. grande* were of note—three of the most useful species in cultivation. *Masdevallia tovarensis* is grown largely. It is a very charming species; the flowers, produced with great freedom at this season, last many weeks fresh, whilst their size and purity fit them for button-holes. One of the finest masses of *Cypripedium insigne* we have ever seen was in bloom—a large bank of flowers, each specimen bearing a remarkably free display. The house is only just heated to keep out frost, and during the summer the plants are kept in a cold frame. It is quite unnecessary to give so much heat as is often the case. *C. Sedeni* and *C. Dominiannum* were also in bloom. It is seldom one sees the last-mentioned hybrid, amongst the first raised by the late Mr. Dominy, having for its parents *C. caricinum* and *C. caudatum*. The flowers are of quiet, but distinct colouring and display well the characters of both parents. In bloom in a small basket suspended near the light was *Cattleya Walkeriana*, a charming species not common in ordinary collections. The flowers, compact in shape, the sepals and petals rose-purple, the lip of a much deeper shade of this colour, are sweetly scented.

Masdevallia Garriana (*J. T.*).—This undoubtedly is the name of the plant of which you send me a bloom, and which you say has fourteen flowers open. It is a hybrid between the fine scarlet-flowered species known as *M. Veitchi*, by far the largest and finest kind yet known, and the yellow one called *Davisi*. It was raised by Mr. Seden in the Messrs. Veitch's nursery. These *Masdevallias* do not appear popular, because most people will persist in growing them in too great heat and setting them up in the light of a bright span-roofed house, which causes them to go brown and spotted. *Masdevallias* should be grown in a lean-to under a north wall.—*W.*

Comparettia macroplectron (*G. Burton*).—It is late for this plant to be flowering, but it is so beautiful withal that it is highly appreciated wherever seen. "G. B." speaks of the plant having sent up a double lot of flower-spikes, these began to come up before the blooms on the first flower-spoke were done. The blooms are large and handsome, of a deep rosy magenta, and extremely showy. The *Comparettias* should be grown in the *Cattleya* house, and be kept just moist all through the winter months.—*G.*

Cypripedium vexillarium.—*J. Ashby* sends a very fine variety of this exceedingly handsome hybrid for an opinion. I may say it is the largest flower I have ever seen, and perhaps the very best colour d. Size, however, is not in my estimation the making of a first-class variety, for a medium-sized bloom of this kind has always taken my fancy. A flower like that sent, possessing both size and colour, is worth looking after.—*W. H.*

Leptotes bicolor.—*G. Cowley* sends me two spikes of this exceedingly pretty little Orchid with three blooms on each, asking if I had ever seen it with so many before. I certainly had never seen it before with more than two flowers. This plant is a native of Brazil, and I think of the cooler parts too, so that it will thrive in the cool house, keeping it fairly moist through the winter. The flowers last a considerable time in full beauty. The flowers are pure white, the lip also white, blotched at the base with violet purple.—*W.*

Cattleya Regnelli (*Thos. Wilson*).—This appears to be the species or variety that you send. The flowers are large, nearly 5 inches across. In general appearance and growth it resembles *C. Aclandiae*, but, unlike that plant, the side lobes of the flower now under consideration form a complete hood over the large and stout column. I have no doubt it is simply a colour variety of *C. Schilleriana*. The plant grows well upon a block of wood in the *Cattleya* house, and enjoys a fair

share of water during the season of growth, but after flowering I like to remove it to the cool end of the house, and to give only just sufficient water to keep the bulbs and leaves from shrivelling. In the spring remove the old soil from about its roots, replace with new, and let it revel in heat and moisture.—*W. H. G.*

Cattleya Percivaliana.—*C. Jeffreys* sends me three blooms of this species in as many varieties, and asks if they are not as beautiful as the much-praised *C. labiata*. There are a great many forms of this plant about and many bad ones, so that the plant got a very bad name. The form you label No. 2 only requires size to make it as valuable as *C. labiata*. This is about the smallest variety in the *labiata* section, but there are such a warmth and richness of colouring in the lip, that no others can approach it. I think this form requires more heat than the whole of the other varieties comprising the section.—*W. H. G.*

Masdevallia Davisi.—*H. Clarke* sends me a very fine bloom of this species. The flower now sent is large and handsome, measuring some $3\frac{1}{2}$ inches from the end of the tail upon its dorsal sepal to the short slightly incurved one of the lower ones, the colour being rich golden yellow. It is a charming species, but the flowers are useless for cutting, as they soon shrivel up.—*H.*

Cypripedium calurum.—"A. R." sends me a magnificently coloured form of the plant, which was originally obtained by the Messrs. Veitch and Sons, of Chelsea. The leaves are of a rich green and the scape is erect, bearing but one flower at a time. The flowers are dark reddish behind, the petals crimson half way up, the colour in other parts white, streaked with pale green. The bold pouch-like lip is rich crimson, the unfolded lobes creamy white, freely spotted with purple. This plant, like many others of the hybrid *Selenipediums*, revels in strong heat and moisture.—*W.*

Cypripedium Spicerianum.—*G. West* says, Do you not think this is a magnificent form of this beautiful Orchid? Yes; the form and the colour are very fine, the almost round dorsal sepal being of such a pure white, with a broad central streak of chocolate. *C. Charlesworthi* is a different plant, yet it appears to be near this species, having a dorsal sepal somewhat similar in shape. The colour in the only flower I have seen is soft rose, the petals and lip being brownish, the former slightly deflexed, and not so prettily undulated as in *C. Spicerianum*. *C. Charlesworthi* will no doubt be largely employed by hybridisers.—*G.*

HYBRID CYPRIPEDIUMS.

In making notes of, or if merely inspecting the hybrid *Cypripediums* now shown at nearly every meeting of the R.H.S. Orchid committee, one cannot fail to observe to what an extent *C. Spicerianum* has been employed as one of the parents. It can be traced in that splendid hybrid *C. Leeannum* and its variety *superbum* in a most decided manner, the dorsal sepal being so very prominent, much larger even than in *C. Spicerianum*. In *C. Lathamianum* the same trace of parentage is clearly visible, and again in *C. Niobe*, one of the later *Veitchian* hybrids, as well as in *C. Calypso*, also coming from the same establishment. In many of the later hybrids shown during the past and present season further instances could be quoted, but these can be found in the descriptions given from time to time in the reports of the R.H.S. Orchid committee. Another species whose presence as one or other of the parents of several of our finest hybrids is *C. Lawrenceanum*, a Bornean variety; wherever this variety enters into the question there is an evidence at once of vigour and distinctive marking of the foliage, both of which features are so marked in this species. Another species which has been the parent of some of the finest hybrids in cultivation is *C. superbiens*. *C. Morganæ* (*C. superbiens* × *C. Stonei*) is an instance of this; so also is *C. Mrs. Canham* (*C. superbiens* × *C. villosum*). *C. caudatum* has also entered into

the systematic raising of hybrids to a considerable extent. No better instance can be quoted than that of *C. Schreöleræ*, which must be classed with the very finest of the *Selenipedium* group of hybrids. Another good old Orchid (*Cypripedium insigne* in its best forms) is also playing an important part, *C. Leeannum superbum* being a case in point. The very distinct features of *C. Fairrieanum* as a species are clearly traceable in *C. vexillarium* and in that exceedingly pretty hybrid, *C. Arthurianum*. *C. levigatum* leaves its mark in *C. selligerum*, although the outline of the flower is more that of its other parent, *C. barbatum*, one feature being the twin-flowered spike. Turning to a comparatively newly-introduced species, *C. bellatulum*, which will yet play an important part as a parent, there has been just recently an instance, the other parent being *C. Lawrenceanum*, two totally diverse species thus uniting in producing that fine hybrid *C. Lawrencei*. *C. Stonei*, a fine old species, leaves its distinctive features in a decided manner in that splendid hybrid, *C. euryandrum*, which must be classed as one of the best. *C. T. B. Haywood* has for one of its parents *C. Druryi*, whilst the other is *C. superbiens*. The latter is well known as one of the finest species; the former is not so frequently seen, nor does it appear to have been much used for hybridising. The result in this case has, however, been excellent. In *C. H. Ballantine* the traces of *C. purpuratum* are clearly evident in the dorsal sepal, whilst *C. Fairrieanum* enters into the contour of the flower. Those two fine old species, *C. villosum* and *C. barbatum*, when united, resulted in the production of *C. Harrisianum*, which will stand for years as one of the best, although it is not by any means one of the most recent hybrids, a plate of it having appeared in the *Floral Magazine* of April, 1869; since then this hybrid has been largely used for further increases. *C. grande*, which is a mammoth in growth, with large flowers also, is a splendid acquisition to the *Selenipedium* group, being the result of crossing *C. longifolium* with *C. caudatum*, the vigour of the former being enhanced, whilst the colours of the latter have been intensified. Another remarkably fine hybrid is *C. ænanthum superbum*. Of *C. ænanthum* there are also markedly distinct forms. Besides the one instance already alluded to in which *C. barbatum* was one of the parents, there are also two at least additional hybrids of sterling merit. *C. selligerum* is one of these, in which *C. levigatum* was the other parent, and *C. vexillarium* is the other, wherein *C. Fairrieanum* was employed. Further instances could be quoted wherein the superior qualities of each parent have been imparted in a most marked degree to the offspring. These hybrids are now so frequently used for fertilising, that it becomes increasingly interesting to watch the development of the bigeneric hybrids. Of those so used, *C. ænanthum superbum*, *C. Harrisianum* and its variety *violaceum*, *C. Leeannum superbum*, *C. Arthurianum*, *C. Sedeni*, and *C. Ashburtonæ* have already resulted in further increases. It is impossible to forecast what may yet be seen, but there is one feature that I have noted which gives additional interest to these hybrids; it is the increase in the twin-flowered spikes, also in forms of more continuous blooming character. I suppose we must wait a little longer to see hybrids from *C. Rothschildianum*, *C. Chamberlainianum* and *C. Charlesworthi*, each so distinct in itself.

ORCHIDS.

Orchids at autumn exhibitions.—At some of the numerous *Chrysanthemum* shows in various parts of the country Orchids form most interesting features. Considering the very uncertain state of the weather at that time of the year, it is somewhat of a risky process to exhibit the plants extensively. This is all the more so when the varieties in question are taken from a warm house into a chilling atmosphere, the destination not infrequently being a hall none too well heated at the best. Considering this state of things and the risk of injury that is run, I think it would be a capital plan if encouragement were given to cut Orchids arranged in boxes or glasses. There are

quite enough good things in season to be able even from a rather limited collection to make up a good assortment. *Cattleya labiata* in its rich and varied forms would of itself alone make a fine feature; besides this there is *C. Bowringiana*, a very beautiful species. Turning to *Lælia anceps* with its diversified forms, there is another good choice. *Cypripedium* alone would make a good show. Of other Orchids there are *Vanda cœrulea*, *Calanthe Veitchi*, *C. vestita* in variety, and other more recent hybrids. *Dendrobium Phalaenopsis Schrœderianum* alone would be most attractive. *D. formosum giganteum* is oftentimes not over until December, and besides these there is *Zygotum Mackayi*. What a beautiful effect these would make when tastefully set up with foliage accessories, as *Asparagus plumosus*, *Maiden-hair*, and other Ferns. Perhaps some of the societies will take note of this and provide accordingly, thus not endangering the plants of their supporters. It is the two days' shows which undoubtedly cause the most harm; still enough harm can be done in one day to take weeks and even months for the plants to recover.—GROWER.

Orchids and the past hot summer.—I am rather curious to know what will be the result of the past hot and sunny weather upon those Orchids which for future flowering depend largely upon the thorough ripening of this season's growths. In my own case *Dendrobium Wardianum* is already pushing out its flower-buds, and the young growths are fairly on the move. To still retard these plants would, in my opinion, be a mistake. I do not intend to do this, but propose to let them come on steadily in a temperature of 60° minimum. No doubt other growers have had a similar experience.—GROWER.

***Lælia pumila mirabilis* (G. Cowan).**—This is a fine bloom and a rare variety, producing flowers much larger than the old form of *L. pumila*, and not having the characteristic lip markings. The flower, too, is much more undulated; the sepals and petals are dark rosy-purple, the side lobes of the lip of the same colour, with the margins of a deep rosy-purple, the middle lobe large, with an almost white throat. It comes near *L. Dayana*, but I fail to see the ribs which are upon the lip in that species. It is a charming flower, and the plant should be well taken care of.—W.

***Saccolabium violaceum*.**—J. Philipson writes saying he has a spike of this species over a foot in length, and bearing upwards of sixty flowers. The lip is rich violet, the sepals and petals white, conspicuously marked with violet. This is a very fine plant from the island of Luzon and some others of the Philippine group, where it grows low down at mostly the sea level. Under cultivation it will only thrive with great heat and moisture. It comes nearest to *S. giganteum*, from which it may be readily distinguished by the markings of its leaves and in the flowers not having any fragrance.—W.

SHORT NOTES.—ORCHIDS.

***Calanthe vestita*.**—James Galloway sends me a grand spike of this, the flowers being large and richly coloured. Cut the leaves away and provide Ferns and small Palms for the *Calanthes* to stand amongst.—W. H. G.

***Dendrobium Cassiope*.** which comes from Mr. Law-Schofield, of Rawtenstall, is a very charming hybrid having pure white flowers with a deep maroon stain at the base of the lip. It appears to be a very free-blooming plant.—W. G.

***Odontoglossum Alexandræ Josephinæ*.**—This is a prettily spotted form of *O. Alexandræ* (crispum), flowers of which come from Mr. Dorman, of Sydenham, who says the blooms are small. His gardener says the smallness of the blooms is owing to the season, but the fact is that the variety seems to me to be naturally small flowered.—G.

***Sophranitis militaris*.**—This, I think, is the name of the variety of *S. grandiflora* which comes from Mr. Law-Schofield, the colours being very rich and the petals broad. The lip is also somewhat differently marked, having but a little yellow on the base of the

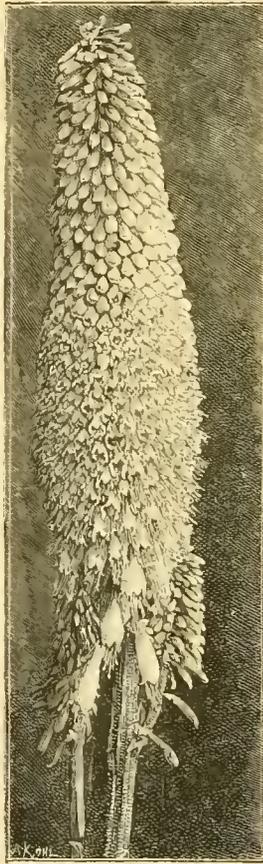

side lobes. This variety is one of the prettiest, and I think should be marked as distinct, although I do not wish to attach any specific importance to it.—W. H. G.

***Odontoglossum mulus*.**—A fine branching spike of this bearing thirty flowers comes from Mr. Dorman, of Laurie Park, Sydenham. This is from a plant which has been in his possession some thirteen years. The flowers have a rich yellow ground colour, banded and spotted with dark chocolate. It is a strong grower, having made strong bulbs and leaves, so that I should say it is likely to flower every season now.—W. H. G.

FLOWER GARDEN.

KNIPHOFIA OBELISK.

The splendid *Kniphofia*, of which an illustration is given in the accompanying woodcut, is

Kniphofia Obelisk. Engraved for THE GARDEN from a photograph sent by C. G. van Tubergen, Jun., Haarlem.

one of the most beautiful of quite a set of hybrids of these handsome plants which we owe to the exertions of Max Leichtlin. Other cultivators have produced beautiful forms such as the varieties John Waterer, Otto Mann, Max Leichtlin and others, but all these owe their origin to red-flowered species, and do not much depart from the typical forms. Since the introduction, however, of yellow-flowered species, such as *Kniphofia comosa*, a new field was opened to the hybridiser. The predominating colour in these new hybrids is yellow in all shades of tints, varying through orange to a crimson-scarlet. In habit the plants vary quite as much as in the colour and form of the flower-spikes. Of some, whose parentage to *K. Leichtlini* must be very near, the foliage is narrow and deciduous, and the spikes not more

than 3 feet high. Other varieties have massive foliage some 3 inches or 4 inches broad, the spikes attaining a height of 7 feet. The variety *Obelisk* (the variety here figured) is a very robust growing one with ample and broad leafage and very free-flowering; the spikes attain some 5 feet in height, and the flowering portion is about 15 inches long. As may be seen from the accompanying cut, the form of the individual flowers is quite different from that of the common Flame Flower (*K. aloides*). The colour of the spikes of this glorious plant is a pure golden yellow and so unlike that of any of the older varieties, that persons who see this for the first time are always very much struck with its most handsome appearance. Strong spikes often produce two or three additional spikelets, as shown in the accompanying engraving. Another most beautiful variety of nearly the same colour is

TRIUMPH. To which of the two the palm of excellence ought to be given is difficult to decide. I think *Triumph* is a little more free-flowering than *Obelisk*; one plant, an offset, planted out in the spring of this year gave no less than ten strong spikes in succession. A most vigorous variety of gigantic proportions is

STAR OF BADEN-BADEN, which requires a very large space, and throws up spikes more than 7 feet high; the colour is a straw-yellow.

OPHIR, though not producing very large spikes, has a very attractive orange-yellow colour; this variety is very free flowering.

LACHESIS, one of the hardiest *Kniphofias* with which I am acquainted, is a variety of extraordinarily luxuriant and rapid growth, the colour a deep yellow turning into straw colour. Turning from the yellow varieties, we have

LEDA, a most beautiful and early flowering form about 4 feet high; the flowering portion of the spikes is about 12 inches long, of a very handsome coral-red with an orange tinge. This and *Sirius*, in habit and form of the flower-spikes nearly identical, though *Sirius* has the darker-coloured flowers of the two, are two ideally beautiful *Kniphofias*, the plants neat growing, nearly rosette-formed, and the spikes not too high and of a very attractive shade of colour.

MATADOR seems to have nobilis for one of its parents; the spikes are very large and broad, the colour a deep red.

In our deeply dug, rich sandy soil where water can never be stagnant, all the above *Kniphofias* safely pass the winter outside if care is taken to ward off the superfluous water which gathers in the central parts of the plants, and which may prove disastrous when suddenly sharp frosts occur.

C. G. VAN TUBERGEN, JUN.

Hardiness of the Cape Hyacinth.—I read with some surprise Mr. Burrell's remark on p. 520 in THE GARDEN of December 9 that this bulb will only stand outside in mild winters or under favourable circumstances, as this is quite contrary to my experience. Some few years back, when the plant was becoming popular, it was thought to be essential to lift the bulbs before hard frost set in, but I have never adopted the plan nor suffered loss through leaving them in the ground. I should think that the tenderness is more imaginary than real, and with 6 inches of soil over the bulbs they are perfectly safe. I have some that have been among hardy *Fuchsias* for several years, and as a proof that I have no fear of losing them, I have just had 500 more planted in a large bed among dwarf shrubs. I recall to mind one special instance which appears to show that the supposed tenderness is non-existent. A large group of this bulb and *Torch Lilies* grew together, and many seedlings of the *Galtonia* came up one spring. They were left alone, and to my astonishment many of them flowered the second year. On examining them I found the bulbs only just beneath the surface of the soil, and they were con-

siderably smaller than a *Narcissus* bulb; in fact, some no larger than large *Crocus* bulbs. The winter previous had been severe enough to kill some of the choicer *Tritonias* in the bed, yet these Cape Hyacinth bulbs with their scanty covering of soil escaped, and I attributed their early blooming to their being so shallow. It would certainly be interesting and instructive to hear what the experience of others has been, as if, as it seems to me, this bulb is perfectly hardy, everyone should know it. There are few finer things among autumn flowers, and if there is no necessity for annual lifting, it can be blended with other things in some more or less permanent arrangement that will stand several years.—A. H.

Arabis.—Whilst the common *Arabis alba* will always be found in cottage gardens and in market gardens where propagated in immense quantities every autumn, it will long also find a place in ordinary gardens not only as an early border flower, but also for growing on rockwork. For flowering, the green form is much better than the silver-leaved or variegated variety, though that too grows strong and flowers freely. If needed for its leafage, then the flowers should be gathered. But for edgings and especially for its foliage none are better than the close, compact and almost rosette-like golden variegated *lucida variegata*, though sometimes called *mollis variegata*. This should not be allowed to bloom, indeed does not do so much. The plants should be lifted and be replanted both to have them very evenly placed and to increase the stock every October. The variety does not increase fast, but in a few years a very fine stock of plants may be secured. Once obtained it will be hard to lose if but ordinary care be taken to keep the plants safe.—A.

Iris kashmiriana is not in this country a very vigorous grower, but this I believe to be chiefly due to the fact that while it needs in summer more genial moisture than do most of the large broad-leaved moisture Irises, it resists winter wet. Moreover, retaining as it does much of its foliage in winter, it is apt to be damaged by frost and snow. In fact, instead of being left to itself, it needs to be nursed rather carefully or, at least such is my experience, it disappears, and the finest blooms I ever had were from a plant protected by lights, otherwise I cannot say that it needs any special treatment. *I. kashmiriana* is extremely variable, and *I. Bartoni* (Miki) is, I now think, a mere variety of it. Last winter Mr. W. M. Conway brought me from Abbottabad a form which I hope will prove more vigorous than any which I have yet received.—M. FOSTER.

Campanula muralis.—In answer to Messrs. Arnott's and Stansfield's notes on *Campanula muralis* in the last issue of THE GARDEN, let me state that the *Campanula muralis* in the Herbarium de Candolle as synonymous with *Portenschlagiana* is a very polymorphous plant, as I saw that many of those plants sold by us to customers, and so coming from the same source, take different habits if grown in peat or in limestone, in dry or in moist climates. I saw in England and also in Paris specimens which came from me; both are quite different in aspect, but have the same botanical characters. Only from the botanical characters can one determine the names of these plants, and not by the aspect of their growth. Perhaps often the *Campanula Morettiana* is cultivated as *muralis*. But let me remark that De Candolle says in the "Prodromus," vii., p. 475, on *Campanula garganica*: "Variet. caulibus foliisque glabris vel pubescentibus, foliis plus minusve dentatis, &c.;" and upon *C. muralis*: "Affinis *C. garganica* sed corolla non profunda 5-fida." There is a variety pubescens. I believe that the culture and the position in which they grow bring about the variation of the plant in question more than anything else, and that if all these forms were cultivated together under the same conditions, they would, perhaps, revert to the type.—H. CORREYON, *Geneva*.

Nelumbiums.—Mr. W. Tricker (p. 564) does not discourage would-be cultivators of *Nelumbiums* in the British Islands. Of course, I "guessed" that *Nelumbiums* might be established in ponds here,

because it has not yet been done, and I also "guessed" that we might try after what I had heard from friends who have lately been in the United States and from others who reside there. Among the latter I am pleased to be able to number Mr. E. D. Sturtevant, of New Jersey, whose labours among the Water Lilies have been both extensive and successful, and whose knowledge of them has often been communicated to THE GARDEN. For sound practical information on the cultivation of *Nelumbiums* and water plants generally in America, I would recommend those interested to consult Mr. Sturtevant's paper in THE GARDEN, XXIX. (1886), p. 255. I can assure Mr. Tricker that what I stated on p. 435 with regard to the establishing of *Nelumbiums* was not "guessing." I should be delighted if I could say with him "no plants are more readily transplanted or raised from seeds," but if I had said so, friends on this side could have accused me of worse than guessing. I speak from considerable experience when I recommend beginners with *Nelumbiums* to purchase only established tubers. At the same time I know they can be transplanted without this, for I lifted and packed the plant which Mr. Sturtevant first established in his submerged meadow in New Jersey some twelve years ago. But for one such success I could name at least half a dozen failures. I intend to make the most of the directions Mr. Tricker has given us, though it does not follow that they will answer here.—W. W.

PLANTS, &C., FROM AMERICA.

LIKE "A. A." in a recent issue of THE GARDEN, I also annually get a few plants and seeds from America, some of which prove decided acquisitions, while others are of much less value. Worthy of being included in the former is the semi-aquatic

PONTEDERIA CRASSIPES (Water Hyacinth).—This is distinct in growth from the ordinary class of plants, while its blooms are so delicately transparent and combination of colouring so lovely as to attract the notice of all who see them. In a little warmth it is almost a continual bloomer and very easily cultivated. The only fault I have with it is that the spikes of bloom last such a short time, and are too delicate in texture to bear packing or rough handling. Its exquisite beauty is best seen on the plants. I have an idea that it is not as yet much known nor extensively grown in this country.

OXALIS ORTIGIESI is another gem of the first water, which forms a bushy plant a foot to 15 inches high, bearing small pale yellow flowers in bunches; leaves three-lobed, bronzy green above, the under side a shining metallic dark red; the stems are also a dull red. As a table plant it is most useful and ornamental, the foliage and stems producing a telling effect under artificial light. This also is of the easiest culture, and requires but little heat. It may be raised readily from cuttings.

VERBENA SEA FOAM is about the best *Verbena* I have seen. It is a first-rate grower, its creeping stems rooting freely as they grow, thus saving the necessity of pegging down. It is also free from the ruinous disease—at least, it is so here. It is a profuse bloomer, covering itself with snow-white flowers, which are sweet scented—a delicious Cowslip perfume, wherein lies its chief merit. It has here sported into various colours, identical in scent and habit with the white variety, but as none are more useful than it, I have not preserved them. As to

CHILDS' GLADIOLI, my experience of them differs from "A. A.'s," for I find them early, useful, and effective. Of the beautiful autumnal annual,

COSMOS BIPINNATUS, I have had some good colours from America, but of Childs' hybrids—tried for the first time this year—not one flowered, so I have come to the conclusion that our most favourable summers, tropical as the past has been,

are not sufficiently long for these to be successfully cultivated in the open here.

ENOTHERA ROSEA (the Mexican Primrose) must take a foremost place as a dwarf trailing hardy plant. It blooms freely throughout the summer season, is of a lovely bright pink colour, paler towards the centre. The plant grows from 6 inches to 9 inches high, its habit devoid of stiffness. It thrives in almost any kind of soil, and is readily increased from cuttings. It does well on our rocks, good clumps being attractive.

MYOSOTIS PERFECTION has not yet quite come up to my expectations.

CANNAS.—I seem unable to establish those sent over; they dwindle for a time and eventually die. Several attempts have proved futile.

FUCHSIA STORM KING is a good grower, producing immense blooms in lavish profusion.

I have many more plants from America, but the foregoing strike me at present as being the most noteworthy. Of shrubs, but few are as yet sufficiently developed to enable one to finally decide on their merits or otherwise.

Among fruit I have tried

MUSK MELONS EMERALD GEM AND BANANA but although easy enough to grow and free croppers, they proved coarse and inferior in quality to the best green-fleshed varieties of this country, hence they have been discarded. My notes would be incomplete should I not mention that peculiar novelty,

THE GREAT JAPANESE WINEBERRY. This is in every way a desirable plant to grow, being attractive at all seasons of the year; even its reddish mossy stems are effective during the winter, while its summer clothing of bold hairy leafage and its large clusters of fruit are decidedly ornamental. Its greatest peculiarity lies in the fruit being enclosed in a burr, similar to unexpanded Moss Rose buds, until it is ripe, when the burr opens, showing a berry of a glossy scarlet colour. In this, I think, it is unique, and worthy of a place in any garden, however select. It appears to me to belong to the Raspberry family. I am forming a bed of it to test its usefulness as a fruit, and hope to report thereon in due time.—J. ROBERTS, *Tany-bwlech*.

—In compliance with "A. A.'s" suggestion, I give my experience with American plants. I have at different times received large numbers of plants and seeds of things not obtainable in England from New York and other parts of North America, and, on the whole, have no reason to be dissatisfied with the results. "A. A." has no right to expect in this fickle and cool climate the same measure of outdoor success as is obtained in a country where three or four months of equatorial summer can be had, and where Maize, Water Melons, Peppers, as they are there called (Capsicums of various kinds), Egg Plants, Tomatoes, and Sweet Potatoes are common field crops. The glowing descriptions and treatment in American catalogues do not generally apply to other countries, and buyers must use their judgment in cultivation. There are hundreds of plants quite hardy in this country, but no amount of coaxing will induce them to flower unprotected. The best guide is to find out their native country and treat them accordingly. *Ipomœa pandurata* I flowered last year in a pot and trained on the roof of a half-span house. Unfortunately, the tuber perished in the winter, but I mean to get it again and try another mode of wintering it. Childs' hybrid forms of *Hibiscus* are, I believe, selections of *H. grandiflorus roseus*, quite hardy in dry soils, but rarely flowering satisfactorily outside. I grow them in large pots, keep them in a sunny situation under glass until the flower-buds begin to open, then move them to a more shady part of the house to prolong their flowering season. They require liquid manure and abundance of water. These belong to the herbaceous section of the family and die down to the ground after blooming, breaking afresh from the crown. *H. chrysanthus* can be

obtained in many places in this country. It is as easily grown as a Willow, seeds freely, and can thus be raised in abundance. Some writers regard it as an Abutilon. Out of a host of other things obtained from America I may mention several kinds of Sweet Potatoes, Pea-nuts (*Arachis hypogæa*), Chufas, a kind of tuberous Grass, dwarf Okro (*Hibiscus Abelmoschus*). All these I have cultivated, but not in the open ground, although the catalogues give such directions, and, with the exception of Chufas, which did not swell their tubers sufficiently, with gratifying results.—J. M., *Charmouth, Dorset*.

NOTES ON HARDY PLANTS.

Saxifraga Mertensiana.—I am obliged to Mr. Dewar (p. 500) for the information so kindly given respecting the cultivation of this plant. It is, as I feared, my climate is too cold for it, and I see that Mr. Dewar's success is owing to frame culture. This is rather away from my point. Speaking under a heading of "Hardy Plants," I spoke only of my treatment of this under hardy conditions, and if a plant will not live through all its natural life course in the open air, it is not practically a hardy plant in the climate where it has been so tried. Frame culture is practically greenhouse culture, merely a question of degree after having gone over the open-air line. I am pleased, however, to know that cold frame treatment will do for this plant, as I believe it is one of those things worth a little more than ordinary care.

Aster alpinus speciosus.—I am also obliged for the Baden-Baden notes (p. 500), but I am still in a fog as to "what is what." I am certain about my facts that there is more than one variety under the name of *speciosus*, and there is another with the name of *superbus*, a much larger plant in all its parts, and with very large flowers on stout stems. It is most interesting, however, to know that there is a natural variety so authorised by Dr. Von Regel.

Eremuri.—I see no reason why these should not be planted now if the roots are from pots, in which case they are very different to those that might be taken from the open ground, for they go into their new quarters with all their roots and fibres intact. It is certain that when set in the open ground, with a piece of glass to throw off wet for the first winter, the roots can fare no worse than standing in airy cold frames; and if you do keep them in frames they must have air continually or they will get into growth far too early. My own plants are kept in an old broken frame, practically as cold as the open air, excepting for the wet that is thrown off, and I am sure that I could give them more comfortable quarters in the open ground and better treatment otherwise were it my wish to plant them out. I merely mention this to show that where plants are intended to be grown in the open they are better placed there at once rather than coddled in pots or frames. Whilst speaking of *Eremuri* I may mention that some fresh seed collected and sown in September has in a large measure vegetated already. No doubt the bulk will remain invisible until spring, but this fact is worth bearing in mind when we recall that foreign or imported seed is a year or more before it germinates.

Herbaceous Pæonies.—By herbaceous Pæonies I mean all the herbaceous kinds as distinct from the Tree Pæonies—a point of some importance when we consider the matter of propagation, root-division, and transplanting, because all the herbaceous species are tuberous-rooted, the arboresecent species not so. The present is a safe and fairly good time to divide the roots and transplant provided there is no frost in the ground. A month earlier, however, would have been much better, as plants lifted this month will show by the number of new roots that are being developed from the tubers and the collars of the various species. It is true that the most tedious part of the business of dividing old Pæonia roots is due to the way in which the large tubers twist among one another. In many cases of other kinds

of plants it would be helpful to clear the roots by washing them, so that it could be better seen where and how to cut, but with regard to Pæonies if you wash the roots they will be greatly injured, as under ordinary circumstances the water would cause the tubers to expand so quickly that they would rupture vertically and almost the whole length. Just in the same way as when Celery is dressed and placed on the table after being in water, it both splits vertically and curls. There is another point that should be kept in mind when dividing Pæonies. Many kinds which make very long tuberous roots, the albiflora section, for instance, are much retarded if they lose their tubers. This class is not like the officinalis section in rapidly repairing such injury, but as well as being slow to do so, it will not flower until it has again developed a full complement of strong roots, and further, the roots that may be severed from the albiflora class if they have no crown, do not grow and form crowns as the broken pieces of root will of other kinds. This should not be forgotten, for most of the finer named Pæonies belong to the albiflora section, so it will be seen how important it is to deal with the roots carefully when being moved or propagated.

Gerbera Jamesoni.—I should say that this is not a safe plant for the open garden, unless in very exceptionally favoured climates, such as Bournemouth, Torquay, and the south of Ireland. I believe that under suitable conditions it is a good doer, and though from what I have seen of old roots they are somewhat hard and forbidding to the propagator, I have found that young offset green shoots strike quickly in warmth.

Woodville, Kirkstall.

J. WOOD.

NOTES OF THE WEEK.

Erica hyemalis alba.—One does not see the white variety of this popular Heath so often as the type, but it is a valuable winter flower, free, white, and very pleasing when grouped with the other.

Iris stylosa alba (syn. *I. unguicularis alba*) has been blooming very freely for several weeks, and is still throwing up numerous flower spikes, showing how much it has benefited by the late hot, dry summer, as this Algerian Iris is by no means free-flowering, generally, in this country.—W. O., *Fota, Cork*.

A rare Orchid in bloom at Kew now is *Cœlia bella*, an exquisite species, with flowers reminding one a little of those of a *Freesia* and pure white, richly tipped with maroon at the apex of the segments. The pseudo-bulbs are of a yellowish tint, but this does not detract from the beauty of this charming Orchid.

Strobilanthes isophyllus is a useful plant for flowering in the greenhouse at this season. It produces a wealth of mauve-lavender flowers in pleasing association with the deep green leaves. It was introduced into English gardens in the year 1845 and is not at all difficult to grow. The *Strobilanthes* comprise a large genus, but *S. isophyllus* is one of the best of all, free-growing and valuable for the soft delicate tone of the flowers.

Passiflora corœula in this neighbourhood has much enjoyed the past hot summer, flowering most profusely on all open walls and houses where planted, and being now most ornamental with numerous egg-shaped yellow fruits. The background of dark green leaves shows up the yellow fruit to the best advantage. The unusual fruitfulness of this trailing plant may be attributed to the hot, dry summer.—W. O., *Fota, Cork*.

Cypripedium politum.—This interesting hybrid was in bloom recently in the nursery of Mr. Morse at Epsom. It is a cross, at least supposed to be, between *C. barbatum* and *C. venustum*, the plant when well grown producing plenty of flowers, which individually are not of such poor colour as those of many of the earlier hybrids in which *C. venustum* was used as one of the parents. The

dorsal sepal is veined with purple, the petals marked with a similar shade on a delicate green ground, and the lip purple-brown.

Calceolaria Burbidgei.—For weeks past this hybrid *Calceolaria* has been flowering in the greenhouse at Kew, and it is in perfection now, bearing a profusion of its soft yellow flowers, a peculiarly beautiful shade. It is not often one sees this distinct hybrid between *C. Pavoni* and *C. fuchsifolia*. It makes a vigorous growth, the stems reaching over 3 feet in height, the leaves bright green, downy, and ovate. It is too large for a small greenhouse, but in structures of fair size it may well have a place for its distinct aspect and beautiful yellow flowers.

Two Chrysanthemums of note in the greenhouse at Kew are *Meg Merrilies* and its sport *Ralph Brocklebank*. We mention these varieties for the reason that now-a-days one sees little of such free, graceful kinds, the flowers of which do not approach the absurd standard of size required by the majority of growers. At one time they were in every prize-winning collection, but such kinds should not pass out of cultivation. The plants at Kew are a mass of bloom, and the sulphur-white colour of *Meg Merrilies* and the deeper yellow of the sport are most pleasing.

Lachenalia aurea.—This is one of the finest of the *Lachenalias*, and for a long time past we have noticed it in bloom in the Cape house at Kew. It is synonymous with *L. tricolor aurea*, and is also called *L. quadricolor lutea*. *L. aurea* and *L. Nelsoni* are the two handsomest of the genus, and deserve to be more largely grown. The flowers of *L. aurea* are a rich self gold colour, and produced on a sturdy erect scape. Worthy of note also in the same house is the showy *L. pendula*, a vigorous and free-flowering species, the flowers varying in colour, but usually of a reddish tint tipped with green, and, unlike those of *L. aurea*, produced close together on the scape.

Hechtia argentea.—This is a remarkably handsome and rare bromeliaceous plant. We have made note of it for the beautiful silvery colour of the leaves, each measuring about 2 feet in length, rigid, spiny, and quite hiding the pot. They are arranged in rosette fashion, and at this dull season for indoor flowers the rich silvery colouring has a distinct effect. An exceptionally fine specimen is in the succulent house at Kew. The *Hechtias* comprise a small genus of about six species, natives of Mexico. *H. Giesbreghtii* is better known than *H. argentea*, and somewhat like it, but in the latter one gets the distinctive silver coating to the upper surface of the leafage.

The *Calanthes* at Kew are well worth a note and comprise several kinds. Of course, the chief plant is *C. Veitchii*, which, happily, has remained in bloom many weeks, owing to the comparative absence of fogs. There are forms of it, one at Kew named *rosea* having flowers of a very deep, yet bright colour. *C. vestita* is a relief to the masses of spikes of *C. Veitchii*, and one form—*C. v. Turneri*—is regarded by some as a distinct species, and thus placed in many catalogues. The flowers are practically white, the centre or eye of a rose colour and larger than those of the type. It is a native of Java.

Blue flowers in the winter.—There are none too many of these to be had in either stove or greenhouse at this season of the year. In the stove *Eranthemum pulchellum* makes one of the brightest of plants, producing a profusion of its deep blue flowers in constant succession for a long time. True, the blue flowers do not show up well at night, but, nevertheless, by daylight they are exceedingly pretty, making a beautiful addition to a stove in conjunction with *Poinsettias*. It will thrive well in a damp position, and the flowers last a fairly good time when cut, as the advanced buds will open in succession to the expanded blooms.—G. H.

The **Shell Orchid** (*Pholidota conchoidea*) is one of the most interesting Orchids in bloom in the Kew collection. It gets the specific name from

the pleasing shell-like aspect of the flowers, the pendulous slender racemes appearing as if packed with a multitude of small glistening whitish brown shells, the raceme coming from the top of the pseudo-bulb. It is well worth a place in all good collections. The plant at Kew is growing in a basket near the light and is of vigorous growth. The leaves are large and dark green. Although individually the flowers are not attractive, they are borne so freely that they make a good show. The *Pholidotas* are found in India and the Malayan Archipelago, reaching to the north of China.

Narcissus blooming twice a year.—In THE GARDEN, December 2, "F. W. B." (p. 522) speaks of the *Narcissus* blooming the second time this year in Cornwall. I observe the same thing has occurred here, or, I should say, is taking place here now, as we are just now able to pick a number of trusses of Paper-white in the open border, and the bulbs are throwing up hundreds more, which, should we not have hard frost, will no doubt go on expanding all through the winter. The bulbs that are blooming here have been planted for many years, but have never before been observed to bloom twice in the same year. No doubt the past hot, dry season is responsible for their doing so now.—WM. HARRIS, *Upcott, Barnstable.*

Centropogon Lucyanus is a fine plant too little seen in gardens, although in bloom at this season when its bright rose-carmine tubular flowers are welcome. This is a comparatively modern acquisition, a hybrid raised in 1856 by M. Desponds, of Marseilles, between *C. fastuosus*, which has rose-coloured flowers, and *Siphocampylos betulifolius*, a species with red flowers, introduced in 1842 from the Organ Mountains. It is not difficult to grow, plants being readily raised from cuttings taken early in the spring. The results are always better from young specimens, which are more vigorous, and produce finer flowers than older examples. The brilliant colour of the *Centropogon* at this season is desirable as a relief to the ordinary forced things one sees in stoves and warm greenhouses.

Christmas Roses are very beautiful just now at the foot of the mound near the Cumberland Gate in the Royal Gardens, Kew, the bold masses of plants flowering exceptionally well this season, owing to the comparatively mild weather of the past fortnight or so. This is exactly the spot for the Christmas Rose—shady, sheltered and moist, and we wish this lovely winter flower were more freely planted in gardens in good masses—not a tuft here and there on the border. In a thoroughly well-drained loamy soil abundance of bloom is got and the growth increases year by year. The clumps must not be disturbed for many years, and once planted should be left practically alone, except for an occasional top-dressing. At Kew a quantity is planted, and the effect of a mass of white flowers at this season is delightful.

Two interesting Bamboos in the Kew collection near the river are *Bambusa Ragamowski* and *B. pygmaea*. Both are dwarf and useful for forming bold masses in the garden. The former has very large leaves, more so than in any other dwarf Bamboo, the finest leaves being produced on the shoots that appear away from the parent plant. It is a native of China and Japan, hardy and synonymous with *B. tessellata*. It is well worth getting a good group of this species in a comparatively sheltered part of the garden for the fine effect produced by the broad handsome leaves. *B. pygmaea* has not been introduced many years from Japan, and, as suggested by the name, it is so dwarf—a few inches only in height—that a carpet may be formed of it in not too exposed spots. The leaves are bright green above, but underneath of a glaucous tint. It grows quickly and is easily increased by division of well-established tufts.

A note on Irises.—At this season several charming Irises bloom, and when grown in pots are very pleasing in the greenhouse—a relief to the usual run of things one finds in winter. In sheltered spots and when the weather is mild I. Bornmülleri, I. *Histrio* and the rare I. *sophonensis*

will open their flowers. I. *Histrio* is the earliest of the reticulata section to flower, and will sometimes send its blossoms through the snow. It is very hardy, and the sky-blue colour, veined and netted with white, is delightful. I. *sophonensis* also belongs to the reticulata group and bears a resemblance to the parent, the flowers longer, the standards rich purple, set off with blue veins, and the falls of the same blue shade, but enriched with yellow, whilst the growth is only about 3 inches in height. Fortunately, such kinds as this and I. *Histrio* are not difficult to grow in a sandy, loamy soil, selecting a sheltered position. In the event of severe weather occurring, place a handlight over the clump to protect the flowers.

Cymbidium Tracyanum.—Amongst the many fine Orchids exhibited at the Drill Hall on December 11, the one of most interest and value was this unique *Cymbidium*. It was a cut spike from a plant in Baron Schröder's collection at Egham. The spike carried seventeen flowers, which are remarkable not only for their size (they are the largest of all the *Cymbidiums*), but also for their rich colour. The sepals are $3\frac{1}{2}$ inches long and about 1 inch in diameter, the ground colour being a tawny yellow striped with conspicuous maroon lines; the petals are similar in colour, but smaller. The lip is of very large size and three-lobed; the front lobe is creamy white streaked with crimson; the side lobes are yellow striped with red. That portion of the spike bearing the flowers is upwards of 4 feet in length. *Cymbidium Tracyanum* appears to be related to *C. giganteum* and *C. grandiflorum*, but is, of course, infinitely superior to those species. It is finer than even the best forms of *C. Lowi*, in an importation of which it came to this country. It flowered three years ago with Mr. H. A. Tracy, of Twickenham.—B.

Autumn tints.—Last year I had occasion to speak of one or two remarkable instances of accidental, yet strikingly beautiful blendings of colour in autumn leaves and berries as seen in the neighbourhood of London. This autumn was to be seen on the wall of a lowly cottage in Sussex a very happy harmony of colouring in the leaves of two plants, little thought of, I fancy, by the occupier of the cottage at the time of planting. A good example of the common Virginian Creeper (*Ampelopsis hederacea*) and another of the variegated Honeysuckle (*Lonicera aureo-reticulata*) had been planted within a couple of yards of each other against the wall, and allowed to ramble very much at will, the branches intertwining with each other. They had reached the top of the wall and hung down in graceful festoons, the scarlet foliage of the one and the clear golden of the other making one of the most pleasing mixtures of colour when viewed from a little distance anyone could wish to see. True, the effect was short-lived, but none the less desirable on that account; such flashes of autumnal leafage live for a long time in the memory. Another happy effect in the way of colouring I happened to see this autumn in a large nursery. It was produced by the mixture, on a large border of shrubs, of *Prunus Pissardi* and large plants of richly coloured *Aucuba japonica*. As the leaves of the *Prunus* deepened in tint the effect was superb. Crimson or scarlet and gold in flowers or leafage when brought into union by Nature or by the hand of man never fail to please. As an example of Nature's handiwork in this direction, take the *Chrysanthemum* called Putney George.—J. LOWRIE.

Costus igneus.—This was very noticeable among the plants exhibited at the last meeting of the Royal Horticultural Society, and a first-class certificate was certainly worthily bestowed on such a beautiful flowering plant. There are about half a dozen species of *Costus* in cultivation, but this is by far the showiest member of the genus. It is a fleshy rooted subject that pushes up stout, erect stems from 1 foot to a yard in height. Each shoot is terminated by a flattened cone-like arrangement, from which the flowers are produced; sometimes two or three are open together, and as each bloom is quite $1\frac{1}{2}$ inches in diameter, they make a

goodly show. Their colour is a deep bright orange. Given the treatment accorded to the general run of free-growing stove plants, it will both grow and flower well, or planted out in a bed of moist soil in a warm house it will soon form a good mass or clump that will flower for months together. In this way it used to form a conspicuous feature in the Water Lily house at Pendell Court before that interesting collection of plants was disposed of. Flowering examples may also at times be met with in one of the stoves at Kew, but, despite its beauty and the fact that it is really not a new plant, this *Costus* is seldom seen. It was introduced by M. Linden from Bahia in 1882—not 1822, as stated in THE GARDEN, page 568. Propagation is easily effected either by division or by cuttings of the weaker shoots, so that it would not take long to work up a stock, and I venture to suggest it is one of those subjects for which nurserymen would find a ready sale.—H. P.

SEASONABLE NOTES ON DECORATION.

GENERAL.—Probably more flowers and plants are required for decoration at this season of the year than at any other. For a fortnight before and as long after Christmas, there is a constant round of festivities of one sort or another. What with hunting and hunt breakfasts, shooting the coverts and dinner parties at night, there is a great call upon the resources of the garden. In order to make the most of everything some little ingenuity is necessary in the use of the flowers, whilst if it be frosty weather additional care is needful to preserve the plants, which are taken out of their growing quarters from coming to any harm. At such times it is an all-important matter to have a good supply of such plants as need not be afterwards kept for use another season. These can then be consigned to the rubbish heap, save only sufficient to work up the stock another year. As much as possible plants of comparatively hardy constitution should enter into the arrangements so as to preserve others that are of a more tender character from injury. More depends upon proper care and attention in the preservation of decorative plants than is at times credited thereto, whilst in the use of cut flowers some considerable amount of forethought is necessary both in the selection and the disposition of the material at command.

FLOWERING PLANTS, &c.—With nothing more than the average convenience of a well-ordered garden, it is possible to have *Poinsettias* of good quality, the old variety and *P. plenissima* (the double form) being the best late kinds. With a reserve for next year's stock it will not matter if a few of these do come to grief; this they will not do very quickly provided they are well-rooted plants and that they are not over-watered. *Primulas*, both single and double, are invaluable, but the plants should not be in large pots, those $4\frac{1}{2}$ inches in diameter being quite large enough. The same applies to *Cyclamens*, except in the case of extra good plants, which may be used when in 6 inch pots. *Erica hyemalis* and *E. gracilis autumnalis* will be just in their full beauty; so also will the earlier of the *Epacris*s. These will all last well if looked after carefully. Turning to bulbs, we can obtain an invaluable supply from Roman *Hyacinths* and *Duc van Thol Tulips* (various colours), but notably the scarlet and the yellow. As decorative plants these should be kept as dwarf as possible, whilst $4\frac{1}{2}$ -inch pots will be far more useful than larger ones. Turning to berried plants, the most important as well as the hardiest yet in season are the *Solanums*, which if well established will stand well. *Aucubas* when hastened on will be also in colour, not otherwise; these are, of course, the hardier of the two. Both *Rivina humilis* and *Ardisia crenulata* are valuable as a change in the form of berried plants.

FOLIAGE PLANTS.—To use quite tender plants is a mistake when it can be avoided; thus *Areca lutescens* is sensitive to cold, far more so than *Cocos Weddelliana*, whilst the *Kentias* are almost as hardy as any *Palms* grown. *Pandanus Veitchi* is tender; in its place use therefore *Anthericum*

variegatum or *Enlalia japonica variegata*. Of the coloured *Draenas*, *D. terminalis* is still the most reliable; whilst of the green-leaved sorts, *D. congesta* is the best, save as specimens. *Asparagus plumosus nanus* and *A. tenuissimus* are both of the greatest possible service; so also is *A. deflexus*, which has a future before it in decorations as a basket plant. *Cyperus alternifolius variegatus* is a trifle tender, but it lights up so well; hence, it should be used. Crotons when well prepared being thoroughly well ronted and each kind in its true character as regards colour, can hardly be dispensed with. It should be borne in mind that the broad-leaved kinds, with leaves about the size of those of Laurel, are the hardiest sorts. The variegated form of *Ficus elastica* also tells well, so does the variegated variety of *Draena australis*. Of other Palms, *Phoenix rupicola* deserves mention, so does *Euterpe edulis* when well grown. *Aspidistra variegata*, of course, is in the front rank. Of Ferns, none are more appropriate or suitable at this season than the Gold and Silver forms of the *Gymnogrammas*, *Pteris argyrea*, *P. Victoriae* and other kinds of light growth. Dense-growing plants with dark green foliage should be avoided as far as possible.

SPECIAL PLANTS.—These will consist of *Calanthe Veitchi* and some few *Cypripediums*; chiefly, however, forms of *C. insignis* and *C. Spicerianum* and occasionally an *Odontoglossum*, perhaps. From the stove it will be possible to use *Aphelandra Roezliana*, a beautiful dwarf plant with orange-scarlet flowers and silvery foliage, and out of the forcing pit will come Lilies of the Valley, of which the best possible use should be made. The *Bertolonias* are beautiful objects at any time, their colours coming out well under artificial light; to use them without protection would be unwise, but if covered with bell-glasses no harm will come to them; the glasses if quite clean cannot be considered unsightly. *Amasonia punicea* is not sufficiently known as a winter decorative plant from the stove, nor is *Reinwardtia tetragyna* grown nearly enough; it makes a beautiful display with its Linum-like yellow flowers. *Plumbago rosea* and *P. coccinea* are both more satisfactory when used as plants instead of being cut; so also is *Euphorbia jacquiniiflora*.

CUT FLOWERS.—These are largely in request, and every means should be taken to make the most of them. When used for the decoration of the dinner or supper table they should be taken off immediately afterwards to a cooler place, where they can be re-assorted and put into more water; this will greatly freshen them for use again. This using of flowers over and over again is not perhaps always agreeable to those who think they have a right to them at the close of the evening's festivities, but it is the way to make the most of them at a time of the year when flowers are none too plentiful. I always think that more colour in arrangements at this season is excusable, a good display being the object aimed at when the attractions of the garden are confined to a limited space. I do not mean by this that persistent overcrowding or the mixture of too many colours is commendable; far from it; the work can be done without that. A free use should be made of *Poinsettia* tops, *Eucharis amazonica* in the spike, not so much in single flowers. *Calanthe Veitchi* in the spike makes a beautiful display. In using flowers in this way it is all the easier to rearrange them differently for another night's entertainment.

DECORATOR.

The weather in West Herts.—Another very mild week for the time of year. On each of the three days ending Saturday the temperature in shade rose to 50°, while on Monday night the thermometer exposed on the lawn never fell lower than 40°. On the coldest night, however, the same thermometer indicated 9° of frost. At 2 feet deep the temperature of the ground now stands at 42°, and at the depth of 1 foot at 41°. The only wet days of the week were Tuesday and Wednesday. On the latter day for a few minutes at 1 25 p.m. there occurred a very heavy shower of hail. The winds

mostly came from some southerly point of the compass, and were at times very high.—E. M., *Berkhamsted*.

Carnation disease.—I have just received some Carnations from a trade grower, and several of them are badly infested with the fungus that in many localities renders the open-air culture of this otherwise hardy flower impracticable. Distributing diseased plants shows either great carelessness or a want of moral perception on the part of the vendor. Take the case, for instance, of an amateur with a quite clean lot of plants, and who may never have seen a diseased one. Receiving an infested plant and not recognising the danger will probably taint the whole of what might otherwise have remained a perfectly healthy stock. An experienced Carnation grower would at once burn or return to the vendor plants thus infested, and I strongly counsel those who may not be well acquainted with the disease to carefully examine any plants they may purchase or obtain in any way, and if the foliage is marked with dark blotches to destroy them at once. I feel sure that many a fine collection of Carnations has been permanently injured by the introduction of one or two diseased plants. The worst of it is that once the disease declares itself in a garden it never seems to completely disappear. In a very favourable year it may not appear, and may even remain dormant for two or three seasons, but with the advent of a very wet summer or unusually damp winter it will reappear and be as destructive as ever. Some localities are, by reason of their elevated position or low average winter rainfall, so favourable for the growth of Carnations, that the disease never is able to get hold of them. In many places where fogs prevail in December and January the Carnation can hardly be termed an open-air flower. The saturated atmosphere is certain sooner or later to bring on an attack of the fungus. I have quite given up the idea of keeping Carnations all the year round in the open ground. For a year or two they may do very well, and then comes a damp winter and most of the plants get so crippled as to be of little value. This has happened to me several times, so that I am, though much against my will, obliged to shelter my Carnations in frames, just keeping off heavy rains, snow, and fog from the middle of November till March. I do not pot the plants, but lay them in light soil, and they come out in spring with fairly good balls of earth to them. It is only in this way I can rely on bringing Carnations through the winter.—J. C. B.

Destroying tree stumps.—I wonder the explosive *Roburite* is not more often used for this purpose where there are many roots to be blown up. The larger and sounder the roots are the more effectively *Roburite* does its work. In careful hands, blowing up roots by this means appears both simple and safe. The present price of *Roburite* is 1s. a pound, and it is exploded by means of an ordinary fuse and detonator.—A. L. Y. MORLEY, *Great Brington, Northampton*.

PUBLIC GARDENS.

Gift by Mr. A. F. Buxton.—The Parks Committee reported that Mr. Buxton had offered to the Council two bronze statues to be placed in the gardens of the Victoria Embankment, and suggested that they should be placed to face each other across the gate at the south-east corner of the garden in front of the School Board offices. The statues had already been delivered to the superintendent of the gardens. They recommended that the Council accept the offer of Mr. Buxton, and that authority be given to arrange for the erection of the statues in a suitable position. This was agreed to.

Improving Waterlow Park.—The Parks Committee reported that, during the process of cleaning out the lake in Waterlow Park, a large quantity of mud had been deposited in a low-lying part of the park. The mud was being gradually

dispersed over the various parts of the park, and the result was to leave the place where it was stored in a most unsightly and unsatisfactory state. They had considered how this part of the park could be made more attractive, and were of opinion that the best plan would be to form a second lake. The ground was the lowest in the park, and was at times unfit for public use by reason of its swampy nature. The overflow water from the existing lake would be received into the one which they now suggested instead of being carried away by drains. A sum of £1000 was provided in the estimates for the work, but they proposed at present only to form the lake and leave the work of embellishment to be carried out hereafter. The proposal of the committee was to leave nothing to be desired, for the park had cost the Council very little. The report was agreed to.

Another open space for St. Luke's.—It is probable that in the course of a few months St. Bartholomew's Square, St. Luke's, will be thrown open to the public as a recreation ground. The governors of the hospital, who are the freeholders, have indeed agreed to let the ground to the local vestry at the nominal rental of 1s. per annum, provided the Metropolitan Public Gardens Association lay it out as a pleasure ground for the people, and the vestry maintains it hereafter. The association, ever ready to increase the number of open spaces, has cordially accepted its part of the contract. It only remains, therefore, for the vestry to agree to the terms offered to them.

Open spaces.—At the monthly meeting of the Metropolitan Public Gardens Association, 83, Lancaster Gate, the Earl of Meath presiding, progress was reported in the laying-out of Victoria Park Cemetery, St. Mary's Churchyard, Woolwich, a triangle in Penn Road, Islington, and the Battersea riverside space, and it was agreed to grant seats for the embankment at Wandsworth and for the Bishop's Mead, Fulham, and to offer them for Deptford Green, to enter into negotiations respecting the laying-out of the charchyards of All Hallows, London Wall, St. Mary's, Bow, and St. James's, Pentonville, Albion Square, E., Trinity Square, E., Bartholomew Square, E.C., and other spaces.

Death of A. K. Angus.—We regret to announce the death, from rheumatic fever, of Mr. A. K. Angus, which occurred last week at the Carlton Hotel, Leicester. Prior to becoming the landlord of this house Mr. Angus was a gardener. He was born at Ellon, in Aberdeenshire, in 1853, and started his gardening career at Ellon Castle, afterwards going to Keith Hall, the residence of the Earl of Kintore, near Inverurie. He afterwards came to London to the gardens of the Royal Horticultural Society, Chiswick, where he had charge of the fruit department. He left this situation, and was for some time at Gunnersbury Park under the late Mr. Richards. He returned to Chiswick, and on leaving went to take charge of the gardens at Warter Priory, the seat of Mr. C. H. Wilson, M.P., which he managed successfully for several years. In Leicester, where he had resided for nine years, he was highly respected, and much sympathy is felt with his widow in her bereavement.

Plantains on lawns.—The best and simplest remedy is plain salt. A pinch put on the centre, not pricked in, in dry weather will in a few days eat into the plant and entirely destroy it, and do no harm to the surrounding grass.—REV. CANON ELLACOMBE.

Creosote for stages.—Will any reader say if creosote is injurious to plants? I have two early vineries in which I intend to put up a stage for a month or two on which to stand *Cinerarias*, &c., till they come into flower. I would like to paint the boards with creosote.—A. G.

Names of plants.—*R. J. Davies*.—*Begonia nitida*.—*J. H.*—*Libocedrus decurrens*.—*Hamilton Leigh*.—*Hæmantus natalensis*.—*James McNab*.—*Odontoglossum gloriosum*.—*J. R.*—Probably *Calanthe Veitchi alba*; please send another specimen.

"This is an Art
Which does mund Nature : change it rather; but
THE ART ITSELF IS NATURE."—*Shakespeare.*

FLOWER GARDEN.

HYBRID CAMPANULAS.

REFERRING to page 565, I think Mr. Stansfield is mistaken in saying that the Campanula with cernuous dark purple flowers and sickly yellow leaves is not the true G. F. Wilson raised and distributed by the late Mr. Anderson-Henry. I had it either from Mr. A. Henry himself or from Mr. G. F. Wilson soon after it was raised, and have always known it by Mr. Wilson's name. Two or three years ago I saw another hybrid Campanula at Millmead Nursery, Guildford, bearing the same name. It is of stronger growth and has healthy green leaves, but seems to be the same hybrid as the other, viz., *C. carpatica* × *C. pulla*. I thought at first the chalk soil of Guildford might be the cause of the difference, but I have grown them together without their assimilating. I could not learn the history of the green-leaved variety; it may have come in some garden accidentally. As an illustration of this, I may mention an excellent and old hybrid Campanula twenty years ago known as *C. Hendersoni*. I should guess it to be a cross between *C. pyramidalis* and *C. carpatica*. It is so floriferous, that if not frequently propagated it dies out, so it is easily lost; but it is preserved in one or two nurseries. A few years before the death of the late Mr. Tymons, who lived near Dublin, that gentleman sent me a Campanula which he found in his garden, growing, he said, as a spontaneous seedling. This was in every respect identical with what I had always known as *C. Hendersoni*, but as Mr. Tymons had never grown that hybrid, its reproduction was an accidental coincidence. Mr. Tymons' hybrid found its way to nurseries, from which it is still sold as *C. Tymonsi*, and is another instance of the hopeless muddle to which nurserymen reduce nomenclature. While on the subject of hybrid Campanulas, I may mention two or three others which I have long known, two with long pendulous flowers—*C. van Houttei* and *C. Burghalti*—am not sure how the latter is spelt. The former has flowers of pale satiny blue, the other purplish white. Both are very robust and enduring, but, like most hybrid Campanulas, absolutely barren of seed.

There is another hybrid raised and distributed by Mr. Anderson-Henry called *C. haylodgensis*. This, too, has unhealthy-looking yellow leaves like Campanula G. F. Wilson. The flowers seem as if they might be intermediate between those of *C. pumila* and *C. carpatica*, and the habit is dwarf and not robust. These are all the hybrid Campanulas I know except those of the so-called species of the *C. rotundifolia* type, which, including *C. rhomboidalis*, intermix freely and their crosses are fertile. The other Campanulas seem to produce hybrids sparingly, and I have never known a spontaneous hybrid of them except of the class mentioned produced in my garden.

Mr. Stansfield asks about *C. Raineri*, for which he says C. G. F. Wilson is made to do duty. The true *C. Raineri* will always be scarce in nurseries, as it is rather difficult to keep. I have had it two or three times, but none of the Italian Campanulas, except *C. garganica*, thrive on this cold damp soil. The best piece of *C.*

Raineri I ever saw in a garden was at Munstead, where it used to seem quite happy. It is a plant of very dwarf habit, not more than 3 inches or 4 inches high, with small downy leaves like those of the rough variety of *C. garganica*. The flower is erect, widely expanded, and as large as that of *C. carpatica*. The characters are well described in Koch's "German and Swiss Flora," except that he says the flowers are cernuous, which is a mistake. The plant is very sparingly distributed in the Alps of Northern Italy and the Southern Tyrol.

Edge Hall, Malpas. C. WOLLEY-DOD.

P.S.—In a monograph of the genus Campanula by De Candolle, published at Paris in 1830 (kindly lent by Mr. Stansfield), I find a very good description of *C. Raineri*. The flowers are there described as nearly sessile and erect. The mountains round Lake Como are mentioned as its chief home.

NOTES ON HARDY PLANTS.

Polygala Chamæbuxus purpurea.—There is not one, but many varieties, I believe, with flowers more or less purple, that is, with that part of the flower which breaks away in colour from the typical yellow. I have seen flowers of a puce-purple, of a bright rose-purple, and some almost crimson, as well as intermediate shades, and I have also proved that some of these varieties have their colour qualities fixed, appearing with young stock grown under varying conditions; but I could readily believe that the paler purples might be affected more or less by cultivation, say, according to the quality of soil, degree of moisture, or even exposure.

Crococsmia v. Tritonia.—I am much obliged to "W. W." for the reference he gives on this subject. Of course, we all want to be right, and I for one am willing to do even a little groping in order to attain that end, for, so far as I can see, there is likely to be a little difficulty as to what the hybrids may most lean to—*Tritonia* or *Crococsmia*. I am afraid some authorities and raisers of the hybrids have not always been clear on the botanical distinctions—after all very, very narrow ones, and my remarks, if re-examined, will be found to be of the more practical character. I saw the difficulty when I penned my note, but as my object was more to speak of the usefulness of the flowers and their culture, I made my remarks referable to *Montbretia* a sort of compromise, because the class of flowers under notice would be better understood from the past usage of that name for many allied hybrids. Of course, the changes recently made in regard to these genera will be right beyond doubt, but some of us sometimes intentionally or unintentionally fail to follow the leaders for the sake of convenience or purely practical purposes, or both. This, I am afraid, will not seem sound reasoning to botanists or desk gardeners, but those who have a deal of gardening to do, the handling of many hundreds of species and varieties, together with a deal of correspondence and therein have to respect the nomenclature of others, find the numerous changes of names often laborious, sometimes impossible and always inconvenient in garden work.

Primula Forbesi.—As a greenhouse plant this is very pretty, but as a perennial or hardy plant of no value.

Trolliuses.—It will never do to plant these roots at the present season in soil heavily dressed with partially decomposed manure. I know no hardy plants whose roots are more susceptible to decay when they have been newly moved or divided and come in contact with manure than some of the Ranunculads, notably the tuberous and fibrous-rooted Anemones, Hellebores and Trolliuses. The place for the manure is on the surface after planting, but for my own part I would not employ it there even until the plants had made a year's growth. As a matter of fact, until they are

established they want no food in the way of manure, and there can only be the risk that such masses of roots as the Globe Flowers carry may be contaminated by the decaying matter. It is precisely for this reason that young plants become established more quickly and otherwise are more satisfactory than very big roots. If large clumps are being transplanted, the soil should not be shaken out of them; if by any chance it is, the roots should be dipped in water and immediately dressed with soil or sand. This in a way divides all the fibrous roots from one another. Should this strike you as being too much trouble or scarcely necessary, try it and you will find that it is trouble or care that will pay. Set plants so treated with others in the ordinary way, that is, with the root strings all promiscuously jammed together, and watch the results. Rarely have I found the prepared roots to go the wrong way, but invariably I used to find the big wig of roots a mass of black decayed matter at the end of a year or so, when I dug them up to see why they had dwindled almost to nothing. It is common knowledge that strong roots of Globe Flowers dwindle very much after the first season and often die. I believe that the true cause of this is implied in the above remarks.

Hepaticas.—These constitute a group of flowers of the first importance for winter flowering in the open ground as distinct from hardy bulbous flowers, and as I have a word to say about the timeliness of their being planted, I may also as a sort of sequence place the note after that on Globe Flowers as their faulty planting is very liable to, and often does, cause similarly bad results. You may not much longer put off the planting of these early flowers. Not only may the ground at any time become frost-bound, but it would be unreasonable to expect good results in February and March if you have not completed the planting by mid-December. As to the mode of planting, if you can have the roots in clumps with soil adhering, so that the root-strings cannot come together in masses and cause each other to decay, so much the better. As already hinted, this Ranunculad is susceptible to injury very much in the same way as the Trollius, and unless you deal very carefully with large roots it would perhaps be better in the end to plant small ones; but there is no other reason why you should not begin with large specimens that would be showy the first season and continue to flourish afterwards.

Aster Novi-Belgii nanus is, I believe, the authorised name for the pretty dwarf variety which before went under the name of *hybridus nanus*. It is but 1 foot high at the most, and its very bright rosy purple flowers are produced in profusion. It is an exquisitely beautiful rock plant for the late season just when rockeries most want a bit of fresh colour. There is also another very dwarf Aster that has borne the varietal name of *nanus*, from 6 inches to 18 inches high, and it has often been confounded with *N.-B. nanus*, but if studied in a growing state it is self-evident that it belongs, as the Aster committee have placed it, to *vericolor*. Like the other varieties of the species, its flowers open white, and then change to two other distinct shades of red and blue-purple. This too is a beautiful plant for the rockery, and its panicles of bloom are of the showiest character imaginable. I wish somebody could tell me where I could procure *Aster diplostephioides*, which I fear I have lost.

Campanula muralis (Bavarian variety).—No doubt this specific name, like many others belonging to this genus, can be shown to be superseded, and the term "Bavarian variety," which I took the precaution to place in parenthesis, was only employed because I knew of no other name (neither is any yet shown that I am aware of) for a variety better than its type—be that *muralis* or *Portenschlagiana*. Whether it is a natural or cultivated variety I know not, and cannot therefore say whether the geographical name has reference to habitat or cultivator. It is not, however, a plant of yesterday, and as I had not seen the name questioned before, I ventured to employ it for the practical purpose of, in the shortest way, directing

notice to a good flower by the name by which it could be recognised, and by the only one by which as yet we can know the variety intended.

Dog's-tooth Violets.—In planting these so late as the present month you will encounter two risks compared with earlier planting. First, the tubers are apt to deteriorate seriously when kept out of the ground so long, and those which have received a spot of decay, however small, might be just as well thrown away as planted. Those that have remained sound will be found to have become shrunken. In planting these, they should be surrounded with comparatively dry soil or sand, and then kept sheltered from rain for a few weeks. This, when properly managed, prevents the over-dried tubers from swelling too rapidly and rupturing themselves, after which they rot. There can be little wonder that these planted unreasonably late, compared with the early season at which they should flower, so often fail. On the other hand, if you plant early, say in August, you can hardly go wrong.

Woodville, Kirkstall.

PLANTING LILIES.

DESPITE the fact that the advantages of planting or potting Lilies as early in the season as possible have been many times pointed out in THE GARDEN, it does not appear to be sufficiently recognised, for many people if about to purchase Lily bulbs do not do so till quite a month of the new year and often more has passed away; whereas if these self-same bulbs had been planted two months earlier (which could have been done in the case of most of them), they would be well rooted by the end of January. If about to transplant Lilies in one's garden, this can be carried out whenever they are fit, but in the case of imported bulbs it is, of course, necessary to wait till good well-ripened examples reach this country. Simple transplanting is best carried out whenever the flower-stems decay, and on this point I feel sure that many of the failures with *Lilium candidum* are owing to the operation being delayed too late in the season. Where this Lily succeeds the best advice is to leave it alone, but if transplanting is absolutely necessary, let it be done early in August, or at the latest before the month is out, and I venture to say that it would not be necessary to chronicle so many failures as one hears of at the present time. This Lily is often very hardly treated by dealers in bulbs, for the bulbs are often seen exposed for sale on dry shelves at a time when those in the open ground will have pushed up their tuft of radical leaves, from the centre of which the flower-spike will in due course make its appearance. From bulbs in such a shrivelled state it is, of course, useless to expect a good return in the shape of flowers, and an equally barbarous method frequently seen is that of lifting the bulbs after their radical leaves are developed, as, of course, the roots are then very active and suffer accordingly, not only in being bruised and broken when lifted, but also from exposure afterwards. In the case of most Lilies a good time to transplant them is towards the end of September and in October, but in purchasing bulbs it should be borne in mind that many kinds chiefly come from Holland, and they do not ripen off quite so soon as they do with us, so that it is usually about the end of October before we get the best bulbs from there. Those from Japan are later still, for whereas the first consignments were disposed of on October 19, they were not so well ripened as those that have been imported since. In the case of Lily bulbs that are taken up before they are thoroughly ripened, and packed as those from Japan are, they generally look well enough when first opened, but small spots of decay, probably where they have been slightly bruised, soon appear on some of them, and often the entire bulb becomes affected. Those that reach here from the middle of November to Christmas are usually the best. The large dealers in bulbs who receive great quantities of Lilies both from Holland and Japan with a very limited amount grown in this country do not appear to be

all of one accord as to the most suitable way to keep them in a condition for sale, for by many they are kept quite dry, as in the case of Hyacinths and Tulips, and by others laid in soil, cocoa-nut refuse, or something else in the same way. Both of these methods have their objections, for, in the first place, the bulbs soon become shrivelled and lose a good deal of their vitality, and in the next case, that is those placed under conditions favourable to growth, the roots at the base soon become active and are injured by removal.

The way to prevent this is to purchase all Lily bulbs within a reasonable time, that is before Christmas at the very latest, and place them in their permanent quarters, either potted or planted out. Instead of this practice being generally followed, I know from my own experience, and on the authority of some of our large Lily dealers, that there is a great demand for these bulbs when the return of spring revives additional interest in the garden. Of course at that late period it is only those that have been laid in beds in the open ground and lightly covered that are in a condition to yield even passable results, and in the case of the Lilies so treated there is a very great difference in the behaviour of the various species. Thus most of the Martagon forms will refuse to flower in anything like a satisfactory manner, while on the other hand the upright cup-flowered forms do not suffer from the removal nearly as much. Of this section *L. umbellatum* or *davuricum* in its different forms is sent here every year in large quantities from Holland, and being cheap and a trustworthy flowerer it finds a ready sale. I have seen this bloom well when the stems were grown 3 inches or 4 inches before the bulbs were lifted. *L. auratum* and *speciosum* in their various forms will also flower fairly well if lifted after the flower-stem has begun to push up, but the bulb is weakened very much more by this mode of treatment than if planted or potted at the proper season. In recommending the purchasing of all imported Lilies before Christmas, one notable exception suggests itself, and that is the Neilgherry Lily (*Lilium neilgherrense*), which sometimes in this country does not flower till the end of the year. The stock of this is principally kept up by bulbs collected in their Indian home, which, as a rule, do not reach here till January or February. These imported bulbs, if in good condition, can always be depended upon to flower well the first season, but in the second year the display of bloom will be much less. From its late season of blooming this is essentially a greenhouse Lily. H. P.

OLD BREEDER TULIPS.

HAVING been fond of these old-fashioned late-flowering or cottage garden Tulips for many years, during which time I have grown them in large quantities and from many sources, I should like to say how much I admired the beautiful coloured plate in THE GARDEN of Dec. 9. I think Myrheer Krelage is a little hard to please in insisting that your artist should have drawn the Tulips *à la* Van Eiden instead of *à la* Van Huysum. I know a little of flower painting and think Mr. C. Jones' drawing and colour most delightful, because so faithful in every way. No doubt any artist would prefer to draw flowers as they grow rather than after they had been cut and tossed about in a box for a day or two, and all that the best of painters can do is to paint faithfully the thing before their eyes as it really is, and not—as they are often told—it ought to be. The older method of drawing florists' flowers was to make a stiff and formal sort of a diagram, and then to colour it in a hard, mechanical way. One way of seeing how inartistic, because untrue, such drawings can be would be to place the plate of which M. Krelage complains beside a Tulip plate in any published work illustrating these flowers. It is hard to do one's best, as I feel sure Mr. Jones really did, and then receive blame because he did not draw the flowers "another way," as the cookery books have it. The exquisite colouring and subtle perspective

shown in the Tulip plate alluded to are really artwork of a kind but too rarely seen.

As to the name "Darwin Tulips," I object to it entirely, seeing that these old breeders were grown in both Holland and England long before the Darwins were heard of or known; hence, we are led to surmise that the name Darwin "was merely selected for trade purposes." They exist all over the country in old cottage and country house gardens, where they are prized for their grace of form and richness of colouring, good qualities which are admirably shown in the plate.—F. W. B.

I notice M. Krelage's remarks on my drawing of Tulips in THE GARDEN of Dec. 9 also your note attached. M. Krelage says: "The florist's and the painter's opinion of beauty will scarcely ever be the same." Well, for art's sake, perhaps it is better that this difference should continue. The geometrical flower forms the florists would have us draw are only fit for catalogues. "The artist likes *fantastic* colouring," says M. Krelage. Some may, but the true artist certainly not; he paints colour as near as he can to Nature as he sees it. M. Krelage complains that the flowers that I painted look you straight in the face, which they do only when the wind blows them over. Please imagine that the wind has been kind enough in this instance to do so to exhibit to us the pretty blue base of the flowers.—CHAMPION JONES.

NARCISSUS TAZETTA MICRANTHUS.

MR. G. F. WILSON, F.R.S., of Heatherbank, Weybridge Heath, has kindly sent me a flowering scape of a white-flowered Narcissus that most nearly approaches the above small-flowered pure white form of *N. tazetta* as figured long ago by Jordan and Fourreau, a single flower of which I reproduced in my "The Narcissus," plate xxxi., fig. 8. The plant is very much like a diminutive form of *N. papyraceus*, or the "Paper-white" variety as sold for early blooming. Now the small variety named *N. tazetta micranthus* by Jordan and Fourreau is said to be wild near Toulon; whereas Mr. Wilson's bulbs were collected by his son, Mr. Scott B. Wilson, in the Canary Islands; so that one's first inference would be that the plant represented Herbert's *N. (Hermione) canariensis*; but on comparing the fresh specimen sent with Herbert's original drawing, or with the actual specimen at Kew, or with my own figure on t. 48 of "The Narcissus," a considerable difference is at once observable, the scape being much stouter and the flowers at least twice or thrice the size. Still, Herbert's *Hermione canariensis* was a species founded apparently on a solitary specimen illustrated at p. 109 of his book of drawings and MS., now in the library of the Royal Horticultural Society, the original dried specimen, which is of extreme tenuity, being preserved at Kew, as I have before stated. Now comes the question whether *N. tazetta micranthus* may not be also found to extend to the Canary Islands, or whether Herbert's slender *N. canariensis* may not be a far more variable plant than even he, a cultivator, could have supposed. If the specimen is a typical one, then certainly Mr. Scott B. Wilson's plant is very different, and seems to prove that *N. micranthus* grows in the Canary Isles, and may there when not in flower be mistaken for *N. canariensis* proper. Herbert in his "Amaryllidaceæ" illustrates another small white-flowered Narcissus, viz., *N. dubius* (pl. 43, figs. 6, 7 and 8), which he decided is the same as the *N. pumilus* of Redouté's "Liliacées," and he further says that *N. dubius* must be considered as a variety of *N. papyraceus*, and that Redouté's *N. (Queltia) pumilus* must be "expunged as a nonentity." In recent years, however, Mr. P. Barr and others have obtained or collected bulbs of *N. dubius* from the vicinity of Nîmes that look quite distinct from any forms of *N. tazetta*, having narrow semi-Rush-like foliage more resembling that of *N. juncifolius*. Then Mr. Moggridge in his "Contributions to the Flora of Mentone," t. lxxi., b, c, d, figures *N. dubius*, and considers it to be quite different to *N. papyraceus* and its smaller forms,

such as *N. Panizzianus*, a phase near to *N. micranthus*, which he illustrates on the same plate. *N. dubius*, true, is more like a white form of the yellow *N. juncifolius* than any form of *N. Tazetta*, the leaf section being very distinct, but it is very difficult to grow and flower. The specimen Mr. G. F. Wilson sends me bears in all five open flowers and seven unopened buds, and although the bulb which produced it was certainly collected in the Canary Islands, yet the plant is different from the true *N. canariensis* as illustrated and founded by Herbert. It is quite probable that several forms of the ubiquitous *N. Tazetta* are found wild in the Canary Islands, as they are on the mainland of Morocco, and it is just now especially desirable that bulbs of the true *N. canariensis* of Herbert should be obtained. Long before Herbert's time several very small forms of pure white *N. Tazetta* and of *N. dubius* were figured in the "Campi Elysii" of Rudbeck, father and son.

F. W. BURBIDGE.

FLOWER GARDEN NOTES.

No long time must elapse after the arrival of new catalogues before some of the things required for the garden in the summer of 1894 will have to be noted and ordered, and each succeeding year finds an increasing wealth of subjects suitable for such work. Many, for instance, remember the introduction of such things as *Nicotiana affinis*, tuberous *Begonias*, and the *Margarita* strain of *Carnations*, which, with other easily raised plants, have helped so much to beautify our gardens. Different situations will have their different descriptions of seedling plants; thus, the commoner varieties of annuals that are used with great effect in masses in the wild garden, subtropical annuals that will develop in a few months into tree-like dimensions and help to beautify many a glade and shrubby border, and yet, again, other annuals of excellent habit and long-sustained flowering properties that can be used with marked and telling effect in the more formal garden, or for such special work as vases, pans, boxes, baskets, or raised beds. One has to make up his mind quickly as to the number of things likely to be wanted for the latter purposes, as an increase in the number of seedlings means a corresponding decrease in the number of plants to be raised from cuttings. Many of the special things, too, want sowing early in the year; the seed may be some time coming through, or the plants require a long season of growth before they are ready for their summer quarters. *Cobæa scandens*, so useful as a trailer and for quickly covering pillars, balconies, &c., such ornamental foliaged plants as the finely-cut *Grevillea* or the broad-leaved *Cannas* are all long in germinating, and should be sown early and liberally to ensure strong plants in sufficient quantity. Flowering plants of considerable size that will be required for pot work, as, for instance, *Amarantus salicifolius* in variety, *Nicotiana affinis*, and *Salvia patens*, must also be sown early; strong plants in 4-inch pots, well hardened, will then be available by the end of May. If the stock of tuberous *Begonias* is limited or the strain not satisfactory, a packet of reliable seed may be sown towards the end of January and the best seedlings selected therefrom. The flower garden display for 1894 of these *Begonias* will be mainly from tubers selected for colour and habit from 1893 seedlings. I should like to add a reminder as to the great value of the comparatively new fibrous kind, *Begonia semperflorens atropurpurea*, for summer bedding. If grown along quickly from the seed pan and shifted singly into fair-sized pots, plants which will flower abundantly may be had. Beds of *Margarita* *Carnation* did so well this year, despite the unfavourable summer, that this acquisition will again be used liberally. I like to sow from the middle to the end of February thinly in boxes, placing the latter in a cool house. The seedlings may be transferred to a frame made up on a bed of leaves so soon as they can be handled. *Centaurea candidissima*, the best of white-foliaged plants of its size, must be sown towards the end of January.

I have this year noted specially the hardness of this bright and useful plant. A bed from which intervening plants of *R. V. Raspaal Pelargonium* were removed, being afterwards rather heavily mulched with the decaying foliage of *Taxodium distichum*, has come safely through 20 degrees of frost. Mention of this *Centaurea* reminds one of a plant easily grown from seed that forms an admirable contrast to it in lieu of the more tender *Coleus* and *Iresine*, viz., Dell's *Crimson Beet*. This is, I think, the highest coloured of its class, although the so-called *Dracæna-leaved* may be of more graceful habit. A batch of this may be sown at any time towards the middle of March, two or three seeds in 3-inch pots. There is a class of annuals now raised from seed for the formal garden which from their habit of growth and duration of flowering season makes them good companions for the *Begonias*, *Pelargoniums*, *Ageratums*, &c. Of these the best and most enduring are *Petunias*, *Verbenas*, *Phlox Drummondii*, and dwarf *Marigolds*, equally as showy and far more lasting than the commoner annuals, besides, either from their natural habit or by the free use of pegs, being suitable for almost every description of bed. I think the best of these are *Petunias*, the display is so brilliant and long-sustained. Seedlings of these, also *Verbenas* and *Phlox*, should be pricked out from the seed-pans as soon as they can be handled either into boxes or pits emptied of forced *Potatoes*, if any such are available. Give the seedlings enough room, so that they grow into nice plants by turning out time, and pinch once or twice to keep them sturdy and compact. Care must be taken in the selection of beds for the different varieties of *Petunias*; some of them grow so vigorously that any amount of pegging will fail to keep them within bounds. Such a strain should be planted in large beds where there are as dot plants some nice specimen coniferæ 4 feet or 5 feet high. *Petunias* also rank among the best window-box plants. Plant two rows, allowing the one to trail over and hang down, and insert a few twigs of *Pea* boughs at the back on which the back row plants may run at will; a splendid bank of bloom some 3 feet or 4 feet in depth is thus obtained. The above comprise most of the subjects for first or second early sowing; other useful plants will be mentioned in future notes.

E. BURRELL.

Claremont.

Crocossia aurea and its varieties.—I am sure Herr Max Leichtlin will absolve me from any blame for the "ill-treatment" he has suffered with regard to his variety of *C. aurea* called *imperialis* (see p. 512). My knowledge of the plant is, as stated on p. 462: In December, 1888, a plant called *C. aurea* var. *imperialis* was presented to Kew by Herr Max Leichtlin, who wrote: "I send you a bulb of *C. aurea* var. *imperialis* which has been raised here. It grows to a height of 3 feet and likes a rich soil. It is deeper in colour than and twice as large as typical *C. aurea*." At about the same time Mr. O'Brien sent a plant of his variety *maculata*. These were planted separately in a bed in a warm greenhouse, where also we placed a tuft of the South African *Lissochilus Kretsi*, among which there were a few corms of *Crocossia*. They all flowered in the following summer, and whilst variety *maculata* was exactly as described by Mr. Baker, that called *imperialis* was identical with the plant growing with the *Lissochilus*, and distinct in colour and width of segment from Mr. O'Brien's plant. Possibly Herr Max Leichtlin's plant was not true to name, but I have never seen any other variety than this under the name of *imperialis*. I am, however, in a position to corroborate what he states with regard to the improvement made by him in *C. aurea*, as I possess three flowers given to me years ago by Mr. Goldring, who had received them from Baden-Baden. They are labelled "Specimens showing improvement in flowers of *C. aurea*—1, type; 2, first improvement; 3, the variety *macrantha*." The last named is a gigantic flower, being 3½ inches across, and each segment is seven-eighths of an inch wide, quite ovate, and overlapping. I have, however,

never seen this plant alive. If Herr Max Leichtlin possesses it, perhaps he could spare a corm for the Kew collection. It is evidently a very fine variety, perhaps the finest of all. Mr. J. S. Whall is quite right in preferring to winter his *Crocossias* in sand, but the difficulty is to keep them from growing and getting weak during the winter unless they are kept dry. The "runners" have to be sacrificed if the corms are dried. At Kew we do not lift them, but cover the beds with dead leaves for the winter. Sometimes, however, alterations compel us to lift them, and then they have been wintered as advised on p. 462.—W. W.

HARDY ERYNGIUMS.

IN the *Jardin Alpin d'Acclimatation*, in Geneva, we now cultivate fourteen different kinds of hardy *Eryngiums*, all belonging to the "Blue Thistle" group, so called on account of the colour and of the spiny character of the plants.

ERYNGIUM ALPINUM is a very rare species found on chains of the Alps in Switzerland, Savoy, and Tyrol. It is a neat and curious plant, 2 feet or 3 feet high, with heart-shaped leaves, not cut at all, and borne on long petioles. It bears one to three heads of flowers and a marvellously cut involucre, very finely incised and of the deepest blue. The upper leaves and the superior part of the stems are of the same colour, and retain that curious bluish tint when cut and preserved for the winter. The flower-heads are large, and the involucre measures more than 4 inches in diameter. The flowers appear from June till August. A good deep soil and a partially shaded situation suit it best. It is reproduced only from seed. It is one of the best of alpine plants either for the herbaraceous border or for the rockery. It has been said that *E. alpinum* grows upon the Rocky Mountains, but neither in Boissier's herbarium, De Candolle's, nor Delebert's, nor yet in Asa Gray's books do I find any mention of this fact. Until some American reader corrects me, I shall assume that this plant is not American. In the Pyrenees the genus *Eryngium* is represented by quite another species,

E. BOURGATI. The plant is hardly a foot high, has very deeply incised and divided, rough and spinescent leaves of a bluish or whitish green, and very strongly nerved. The flower-heads are not so large as those of *E. alpinum* and are whitish; the involucre is of quite another character, and formed of spinescent, narrow and very hard leaflets, bearing a thorn at their summit, and becoming pale blue at flowering time, which is June till August. It endures well the hottest sun. The highest summits of Sierra Nevada and Morena, in Spain, give us another very interesting *Eryngium*, called

E. GLACIALE. It grows upon barren summits between 7000 feet and 9000 feet in altitude, and is very rare in gardens. It has a dwarf habit, not more than 8 inches high, and bears from one to three flower-heads, surrounded with an involucre of the same character as that of *E. Bourgati*. The leaves have long petioles, are whitish nerved, spiny and deeply cut. Its flowering season is June and July, and it needs a rockery with a sunny aspect. The stems and involucre become bluish from May to the end of July. It can be increased only from seed. The chains of the Apennines and of the Southern Alps, in Tyrol and Croatia, give us the fine

E. AMETHYSTINUM. Its leaves, with whitish nerves, are long and very deeply cut. The flower-heads, borne on stems 2 feet long, are of a deep amethystine-blue, not so large as those of the preceding species, but they are very numerous and form a corymb. The stems, involucre and leaves in the summer-time are all quite blue. If we go into Turkey over the Balkans, or into Greece, we find the interesting

E. CRETICUM. The growth of this plant is quite distinct, as the stems at half their height suddenly divide into many branches, so as to form an umbrella-shaped top. The branches are of the deepest

blue, and the numerous little heads are set in spiny blue involucre. This plant needs full sun and dry sandy soil. In the Caucasian mountain meadows we find the elegant

E. GIGANTEUM, which is somewhat analogous to *E. alpinum*, but differs from it in its leaves, which are more ovate and elongated, and in the involucre, which is not cut, but toothed only, spinescent and of a very hard and leathery texture. In the Taurus and Libanus ranges we find

E. FALCATUM with ovate, entire, radical and often trilobate leaves and a stem $3\frac{1}{2}$ feet high, bearing numberless small heads of flowers with spinescent little involucre, which are blue from June to September. It grows freely in any sunny place.

E. PLANUM grows in Siberia and the Ural Mountains, and differs from *E. falcatum* by having its radical leaves cordate, with long petioles, and never trilobate, and having also the bracts of the involucre narrower and longer. In Asia Minor there are three important *Eryngiums*—*E. Olivierianum*, a tall growing species with very hard leathery involucre; *E. cœruleum*, which extends to the alpine heights of the Himalayas, and *E. multifidum*, nearly allied to *E. amethystinum*. There are three other European kinds which are worth cultivating, although their stems do not turn blue. These are *E. maritimum*, a glaucous species, growing by the sea-shore; *E. spino alba*, of the Cevennes Mountains, and *E. vulgare*.

All these *Eryngiums* are interesting and well worthy of cultivation. They grow so easily from seed that it would be very easy to introduce them into America, where they would certainly prove valuable, since they endure the hardest winters as well as the hottest and driest summers. They all are very easy of cultivation here in our garden at Geneva.—H. CORREYON, Geneva, Switzerland, in *Garden and Forest*.

SWEET-SCENTED PELARGONIUMS.

TO THE EDITOR OF THE GARDEN.

SIR,—I am sending for your inspection a large leaf from a seedling sweet-scented Pelargonium. The plant was discovered self-sown in an Onion brake; it was carefully watched through the summer, lifted and potted in the autumn and grown on in a cool greenhouse. The stem is $1\frac{1}{2}$ inches in diameter already, the plant quite 30 inches high from the rim of its 8-inch pot and furnished to the base with these large handsome leaves. It has not yet bloomed, but should its flower prove as relatively fine as the foliage, it will be a splendid acquisition. I grow these scented Pelargoniums chiefly for cut greenery in the winter, and plunge or plant them out in summer for the same purpose. I have already collected over seventy varieties, but am sorry to say have only about sixty remaining. I hope the two or three other sprays I send you will show how useful they are for mixing with all flowers by reason of their diversified forms, not to mention their invaluable fragrance. I have plants from the collection of the late Miss Frances Hope, of Wardie Lodge, Granton, N.B., besides many others collected from every part and from old, small and big gardens. When in flower altogether in one house in spring they are most attractive and interesting, though not showy. I find it difficult to get them properly named, no nurseryman having them under the same appellations, and as they are apparently not much sought after, care is not sufficiently exercised in cataloguing them correctly. I have had from several sources no fewer than six totally different plants under the name of Lady Scarborough. The Dowager Lady St. Oswald had, I believe, a nice collec-

tion at Nostell Priory, and I was fortunate enough to get cuttings of them all, and I often come across odd varieties in my travels in various gardens that I do not possess and have not seen before, so there is clearly still a field for a collector. I have some promising young hybrid seedlings coming on. Seed was freely produced on most of my plants last spring, but I am sorry to add that no record was kept or system observed in hybridising them. None of these seedlings, however, look to me to be of such promise as the Onion bed seedling, the appearance of which in the conservatory at present is more that of a well-grown *Aralia japonica* than anything else. I should be glad to meet with other collectors of these plants and exchange varieties. I see no leaf in Sweet's "Geraniaceae" at all resembling that of my seedling.—DORA H. GROSVENOR.

* * * A most interesting and charmingly varied series of these delightful plants.—E.P.

THE WASTE OF GARDEN GROUND.

THERE are hundreds of gardens about the country where there is a lamentable waste of good garden ground, and the productive capacities of which are sadly circumscribed. Especially is this true of old gardens which are found attached to residences built many years ago, which have become the picture of neglect, and many new ones, by reason of unskilful or inappropriate planting, or by planting things unsuited to the soil and position, fail completely to yield that of which they are capable under different conditions. It is because these things exist that I have headed this paper "Waste of garden ground." Unfortunately, many persons who are the possessors of such gardens are careless as to their condition, mainly perhaps because they fail to see improvement is practicable, though when a change is made, as sometimes happens, and a gardener who knows his business takes one in hand, this change for the better is at once discernible.

Let us look into one of these neglected gardens, and what meets the eye? We see old and useless trees that shut out the best of the morning sun, and prevent anything like the ground beneath them being cropped to advantage. Shrubs planted singly or in clumps have out-grown all reasonable dimensions and encroached upon soil that would otherwise be productive, or they have grown tall and, becoming bare at the base, are unsightly objects. Then there are overgrown hedges that rob the extent of the garden of many yards of good ground, and which might be cut in, as in the case of the shrubs, and converted into pea-sticks, firewood, &c., or be burnt to supply wood ashes. One sees fruit trees and bushes crowded and cankered, overgrown and interlacing each other, and occupying ground for which their annual crops prove no equivalent. In the gardens of the working classes, and especially of agricultural labourers, there are to be seen many overgrown trees shading the ground and preventing the growth of green crops which would prove much more largely remunerative and acceptable—gardens that with better cultivation might be made to produce double what they do and everything of better quality if the tenants could be made to increase their interest in cultivating them, cutting down an old Maple or an overgrown Elder in the hedgerow, repairing broken-down fences, cutting the hedge close in, making the walks few and straight and no wider than 3 feet, and covering every inch of fence or house-wall with something useful or beautiful.

In the summer I was called upon to go through a group of Berkshire villages and make awards to the best gardens. The most favourably tilled and cropped gardens were those where the cottages had as inhabitants workmen following other occupations than those of agricultural or garden labourers. Some were working carpenters or bricklayers, or

men who were following some occupation on their own account, and in nearly every case the gardens were remarkably well kept. Perhaps the farm and garden labourer, after following work all day, found any continuation of it in the evening somewhat irksome and monotonous, while to the artisan it came as an agreeable change from a mere mechanical occupation. Many of these cottage gardens were far too large to be kept in anything like good condition by the head of the family, who had but little, if any daylight in which to work in autumn and winter, and if such gardens could be divided among two or three occupiers, or a portion employed to rear some agricultural crop, it would be better than allowing them to go to waste as they do now. R. D.

Myrica californica.—One may search for this in vain in most catalogues, yet it is a decidedly ornamental evergreen shrub, and one especially noticeable just now by reason of its bright green foliage. The two commonest members of the genus are our own Sweet Gale or Bog Myrtle (*Myrica Gale*) and the North American Candleberry Myrtle (*M. cerifera*), both of which, however, are not nearly so much seen as formerly. In general aspect *M. californica* differs widely from either of these, forming as it does a free-growing bush in this country, though in its native state it is said to reach a height of 30 feet or 40 feet. At a little distance it bears a certain amount of resemblance to an *Arbutus*, the narrowish bright green leaves being from 3 inches to 4 inches in length. The genus *Myrica* is by no means an extensive one, yet it is of wide geographical distribution, for the five species which are mentioned in the "Dictionary of Gardening" are *M. californica*, *M. cerifera*, from Canada; *M. Gale*, Europe, Northern Asia, and North America; *M. Nagi*, China and Japan; and *M. quercifolia*, Cape of Good Hope. They are all uncommon at the present day, and difficult indeed to get from nurseries.—H. P.

A Japanese Hemlock.—Of the Hemlocks found in Japan, one is northern and the other southern; both are common at high elevations, and one at least forms extensive forests. The great forest, which covers the Nikko Mountains at an altitude of more than 5000 feet above the ocean, is composed almost entirely of the northern Hemlock (*Tsuga diversifolia*), which is distinguished by its bright red bark and by its small leaves and cones. This Hemlock forest, which is the only forest in Hondo which seems to have been left practically undisturbed by man, is the most beautiful which we saw in Japan. The trees grow to a great size, and while they stand close together are less crowded than the trees in an American Hemlock forest under which no other plants can grow, and light enough reaches the forest floor to permit the growth of Ferns, Mosses and many flowering under-shrubs which clothe the rocky slopes up which this forest stretches. We found *Tsuga diversifolia* in scattered groups on the rocky cliffs of Mount Hakkoda, in the extreme north of Hondo, the most northern station which has been recorded for this tree, which is still to be introduced into our gardens; but, south of Nikko, it was replaced by the second species, *Tsuga Tsuga*, which we saw in great beauty on Koma-ga-take, where, however, it does not form a continuous forest, but is scattered in groves of considerable extent among deciduous trees and *Pinus densiflora*. It is this southern species which is cultivated in our gardens, where it appears to be as hardy as our native species, which it surpasses in its more graceful habit and in its broader and darker coloured leaves.—*Garden and Forest*.

Vines with coloured leaves.—Will any reader tell me the names of Vines that colour well in autumn—purple, red, or any other tint? Among the species, varieties of our own or of continental gardens, there must be some distinguished by beauty of colour more than others, and for any help from your readers I will be grateful, as I wish to see what may be done with Vines for their beauty of form and foliage.—DUBLINENSIS.

ST. CATHERINE'S COURT.

This ancient, yet particularly well preserved residence is situated rather more than four miles north-east from Bath and is reached by narrow, old-fashioned lanes, winding through a very picturesque tract of country. The exact age and little or nothing of the history of this favourite resort of antiquaries and others interested in ancient buildings I am unable to give, though there must surely be some mistake made by those who assert that all traces of its history have disappeared. That it existed early in the sixteenth century is evident from the following extract from an old book on bygone days, the title of which I failed to note down during the short time it was in my possession:—

John Malte, the King's taylor, was highly esteemed by Henry VIII., who entrusted him with

months. The Court as well as the church has been restored at different times, and it is thought the beautiful porch shown in the engraving was added during the reign of Charles I. Mrs. Drummond, the present owner of the place, is a member of the Strutt family, who have for a long time held possession of the Manor, and who have spent considerable sums in restoring the house, fortunately without destroying or marring the good old style of architecture for which St. Catherine's Court and other places in the same district are noted.

The structure being located on the side of a rather steep hill, with a road immediately below it, has rendered it a very awkward place for the landscape gardener to lay out, and to all appearances no serious attempt has ever been made to do much other than form terraces on

very delightful summer resort, and presents a by no means desolate appearance in the winter.

W. I.

The recent galea and newly-planted trees.—Wherever any large amount of new planting has been done this past autumn, those in charge thereof will do well to turn their attention to the present condition of the trees. This will apply to nearly all trees, but more particularly to such as are exposed to the full force of the wind. Evergreens, as Fir trees, Hollies, Cupressus, Thujas, and similar plants, will all feel the effect of the wind if not steadied. We may before long have a downfall of snow to further aggravate the case of loosened trees. The work of steadying should be done in a careful manner, first applying a band or bandage to prevent friction, then the tying should be secure. At the same time it will be a good plan to tread around the trees, so as to

St. Catherine's Court, near Bath. Engraved for THE GARDEN from a photograph sent by Miss A. E. Wilmot, Warley Place, Essex.

the education and guardianship of Ethelred, his illegitimate daughter by Joanna Dyngley, alias Dobson. She was always represented as Malte's natural daughter, and the king in the 38th year of his reign granted to John Malte and Ethelred Malte, alias Dyngley, the manors of Kelston, Bath-easton and Katherine Court, which had belonged to Bath Abbey, and soon afterwards were obtained in marriage with Ethelred by John Harrington, of Stepney, as her dower. That gentleman, by his second wife, Isabella Markham, was father to the celebrated Sir John Harrington, Knight, Queen Elizabeth's godson.

The church of St. Catherine's, which gives its name to the Court, was originally built in 1499, and this small, but very substantial structure was evidently the burying place of the Harringtons—a very quaint monument in the chancel being one of the attractions to numerous tourists who visit the place during the summer

the south and east fronts, those so well shown in the accompanying woodcut being the west and south ones. Anything in the shape of a formal modern garden would be altogether out of place in connection with St. Catherine's, and it is to be hoped that future owners will not attempt to greatly alter its character. When it is stated that the lawns and terraces run into the kitchen gardens, there being no border line between the two, and that in some places there are turf steps leading up to terraces where too often we find far too much stonework, that there are several large, if not particularly well-formed, clipped Yews in pairs and Ivy-clad forest trees everywhere, it might perhaps be thought that some change might be made with advantage, but I hold it would be a mistake all the same. Everything is old-fashioned, and in that lies the charm of the place. It must be a

make them firm at the roots. The appearance of stakes may not look quite the thing, but it is far better than dead or injured trees. One season will usually be sufficient for this safeguard. The choicer the tree the greater should be the care taken of it. Large standards of such as Planes and Limes are often loosened after planting, but instead of laying on one side, may still be upright; through the greater faculty of recovering their position. These ought not to escape notice.—H. G.

A useful protector for plants.—When plants have to be taken out of their growing quarters during frosty weather for decoration, some protection is absolutely necessary. Instead, however, of doing this in a temporary or makeshift fashion, it is far better to set about it in a systematic manner, so as to have the appliances at hand whenever they are needed. Many a good plant, which it has taken months to grow to a state of perfection and which would last for many more,

has been permanently injured by thoughtless exposure, the blame in the end falling not on this, the true cause of injury, but upon the position it has occupied, be that ever so favourable to its safe keeping. It is not often that a contrivance is arranged to effect this, but it is as essential where much decoration has to be done, let the weather be what it may, as the hand-barrow upon which the plants are carried. One plan is to have a light framework fitted to the hand-barrow in a secure manner and of any height, so that the barrow can be carried safely with one or two to steady the top, in addition to two pairs of hands for the removal. A light framework can be easily made by any handy man where a carpenter is not within easy reach. Upon this light framework some of the stout brown paper as prepared by the Willesden rot-proof and water-proof process can be fixed very easily with ordinary tacks or small wrought nails with large heads, what are termed clout-headed ones being the best. This paper has only to be strained tightly upon the frame and the work is done, provision being, of course, made at one end for the putting in and taking out of the plants—a kind of door, in fact. Such an erection could so be made as to take on and off any hand-barrow, according to the weather. The brown paper is extremely light, being at the same time quite impenetrable to wet and keeping out quite as much cold as wood that is twice its thickness. I am surprised that this, the Willesden rot-proof and water-proof paper, is not more generally adopted. There is no reason why our Chrysanthemum exhibitors should not employ it for the making of the boxes in which to carry their show blooms on boards. These "boards" even might give way to the paper strained on light frames, thus saving quite half the weight in many cases. This would be no small gain where excess has to be paid by railway transit. There are now ideas about concerning the make of show boards, why not of the material also?—SOUTHON.

STOVE AND GREENHOUSE.

BORNEAN FETISH PLANTS.

AMONGST the numerous plants used for sacred or votive uses in the Malayan Archipelago there are three or four deserving of some notice. They are the *Dracæna* or *Cordyline terminalis* with red or carmine leaves, the yellow-stemmed Bamboo, the Rice-field Lily, and *Plumeria rosea*, or as it is more usually designated, in the vernacular of the island, "The Dead Man's Flower," its stems being thrust into the sod of every newly-made grave, so that the rich perfume of the *Plumeria* or *Frangipane* (as it is called in the western tropics) usually indicates the vicinity of a native burying ground. The fourth species is *Eurycles australasica*, a plant sacred to the Rice or Paddy fields, in one corner of which it usually occupies the place of honour, no one daring to molest it in any way.

The first named species, *Cordyline terminalis*, is wild in Polynesia and Eastern Australia, and is, curiously enough, one of the most widely diffused of all fetish plants in tropical countries, and our culture of the plant and of its numerous seminal forms is quite modern as compared with the affection long entertained for the plant in the eastern tropics. It may not be generally known, but the thickened root-knobs of this and other *Cordylines* as well as those of *Yuccas* are by no means bad eating when roasted in a forest fire.

The following extract relating to this *Dracæna* and other "fetish" plants is taken from Low's "Sarawak" (pp. 272-274), a rare and very interesting book of travel, full of curious facts about tropical life, &c. :—

The *Dracæna* resembles the species known to botanists as *Dracæna terminalis*, and is not a na-

tive of the island. It is planted near their houses and around the "Bulu Gading" or Ivory Bamboo, which is held in great reverence. This beautiful cane, one or more tufts of which are found near every village, grows to the height of the largest of the genus; its stems are of a bright yellow colour, with a smooth and ivory-like appearance. Beneath its shade, and amongst plants of the crimson and pink-leaved *Dracæna*, is generally erected a little Bamboo altar, covered in winter from the rain with a roof, but more frequently open. When protected, a ladder is usually placed for facilitating the ascent of the spirit to the offerings upon the stage, which are placed there on all their festival occasions. When the altar is roofed, it in general resembles a Dyak house, and thus becomes a little temple. No worship is paid to the tree, but the place on which it stands is considered sacred; and a plant is always procured and tended with care in every village until it becomes a large and handsome bush. Its gracefully beautiful stems and foliage probably first attracted the attention of these people, and induced them to suppose plants, which were to them of so pleasing an appearance, equally the favourites of the gods.

There are very fine groves of this noble yellow-stemmed Bamboo at the village of Kiau, at the foot of the great Kina Balu Mountain, so celebrated as the home of the largest and rarest of all the Pitcher Plants or *Nepenthes*, *Rhododendrons*, *Orchids*, &c., many of which, although well known to botanists, are as yet unintroduced to our gardens. One of the handsomest, however, of all the fetish plants is the "Bunga Si-kudip," or Rice-field Lily, which the natives plant out when they sow the rice fields during the wet monsoon, and they bring in the bulbs after they have flowered at the rice harvest which takes place during the dry monsoon. According to Mr. (now Sir) Hugh Low—

The Bunga Si-kudip, as it is called by the Dyaks of the southern branch of the Sarawak River, and amongst whom it is held in the greatest esteem, though known, I believe, to all the tribes, is the plant described by botanists as the *Panacratium amboinense* or *Eurycles coronata*, or *E. australasica*, a native of the Moluccas and other islands to the eastward, but as far as is at present known, a stranger to the flora of Borneo, in the western parts of which the order *Amaryllideæ*, to which it belongs, is only represented by one species of *Crinum*, which is found on the muddy banks of the river. By the Si-booyoh Sea Dyaks this plant is called Si kenyang. By the Dyaks of the southern river the roots of this bulbous plant are preserved with jealous care, being always taken up when the Padi is ripe, and preserved amongst it in the granaries, to be planted again with the seed Padi in the following season. It bears a beautiful crown of white and fragrant flowers, which rise about a foot above the bulb; the only plant which I saw in a flowering state was at Sennah, and no consideration would induce the owner to part with it. These and other Dyaks assert that the Padi will not grow unless a plant of the Si-kudip be in the field, and on being asked respecting its origin they answered "that Tuppa gave it to mankind with the Padi, and requested them to take care of it," which they now do. The plant I saw in flower at Sennah had a Bamboo altar erected over it, on which were several offerings, consisting of food, water, &c. I think there can be little doubt that the plant has been brought with the Dyaks from the country whence they first emigrated to Borneo, and as it is not at present known to be an inhabitant of any country west of the island, it would follow that the people came from the eastward, perhaps from the opposite island of Celebes; but conclusions of this nature cannot be drawn until the habitat of the plant be better ascertained. Should it be found to be held in the same veneration amongst the Kyan tribes, and the wild inhabitants of Celebes and the Arafouras of the different islands to the eastward become better known, the fact of this plant having been carried westward may be of considerable importance in setting at

rest the long agitated question regarding the direction in which the tide of population in the eastern islands flowed.

As this *Eurycles* is now known to come from Australasia and the islands to the east of Borneo, Mr. Low's references and conclusions may be taken as so far proven. In the Bruni district, *Panacratium zeylanicum*, however, is grown in place of the *Eurycles*, or Brisbane Lily.

F. W. B.

Oranges in small pots.—Oranges are very bright when grown in small pots and used for decorations of various kinds. The only fault is that from our experience the leaves quickly fall off, but this may be obviated to a great extent by keeping the plants in a warm greenhouse if possible, the dry air and dust of dwelling-rooms quickly spoiling healthy specimens. One sees them at the present time hawked in the streets or sold in shops. If kept in the greenhouse until wanted they will remain in beauty over a long season.

Amaryllids in flower.—A perusal of the interesting and valuable list of "Plants, flowers, &c., certificated by the Royal Horticultural Society from 1859 to 1893" reveals the fact that nearly all the numerous garden varieties of *Amaryllids* which have been awarded certificates were exhibited in the months of February, March and April, thus showing that the spring is their usual season of blooming. The pretty *A. reticulata* flowers during the autumn and early winter, and this feature is transmitted to some of its progeny, of which, however, there are not many. These facts being pretty generally understood, it was a surprise to many to see a large group of numerous varieties of *Amaryllids* exhibited at the National Chrysanthemum Society's meeting at the Westminster Aquarium on December 5. They certainly attracted a considerable share of attention, and as many of them still had unopened buds, they would under favourable conditions remain in beauty for some time, and in the depth of winter their large and showy blossoms would in many cases be especially valuable, more particularly where Christmas decoration on a large scale is carried out. Possibly the almost tropical summer we have experienced had a good deal to do with the anticipating of the usual flowering season by a couple of months, but in any case it would be very interesting to know whether the plants had received any special treatment to induce them to bloom thus early. The plants alluded to were shown by Mr. Perkins, gardener, Greenlands, Henley-on-Thames. Some flowers of the *aulica* class were noticed and a few lighter tinted forms, as well as the large bright-coloured flowers, which are now so well known.—H. P.

Pandanus javanicus variegatus.—Until the advent of P. Veitchi, this was the only variegated form that was grown. It is still well worthy of cultivation. As a table plant it is not so good as P. Veitchi, but as a vase plant in larger sizes it is a worthy companion to that variety. Another of its features is the additional row of spikes upon the underside of the midrib, these being set in the opposite direction, so that it is not an easy matter to tie up its leaves if that has to be done.—H. G.

Acalypha Macfeeana.—Although a first-class certificate was just recently awarded to this richly coloured decorative plant when shown by Mr. H. B. May, and that most deservedly, it is not altogether a new plant, having been introduced from the South Sea Islands in 1877. This is another instance in which an introduction has won its way on its own merits. It is easily grown and readily propagated in an ordinary stove, but over-potting should be guarded against, otherwise the additional vigour thus imparted will increase both the height and the size of the leaves beyond what are really desirable. Plenty of light should be accorded it, somewhat after the manner of a *Cruton*, whilst too much moisture is not desirable, otherwise the leaves will be soft and flabby. This is one of those decorative plants which can be quickly grown on from cuttings, there being no

need to try and nurse a plant that has suffered from exposure so long as a few stock plants are in hand for the requisite further increase.—H. G.

The variegated Pine-apple (*Ananassa sativa variegata*).—Although this plant has been in cultivation for many years, it is not yet any too plentiful. Its mode of increase of course is slow. I once had the good fortune to possess a plant which instead of developing a single crown formed a cluster of crowns with scarcely any fruit. In this case I took about three dozen small plants from the one top; this is a rare occurrence, however, or else the price of a good plant would now be less than it is. There is another, but much inferior variegated variety; therefore, it is always necessary to mention the botanical name. This sort has quite a different habit, being semi-erect instead of gracefully arching over the pots. It is needful to keep the plants as close to the glass as possible to ensure a compact growth and the richest possible colour.—H. G.

THE DOUBLE CHINESE PRIMULA.

BESIDES the *Chrysanthemum* there are other flowers we cannot spare from our gardens at this season of the year, and next to it I would place the varieties of the Chinese *Primula*, double and single. They are exhibited, and sometimes in splendid form, at the various exhibitions in November. I allude now principally to the double varieties. In some schedules prizes are offered for Chinese *Primulas*, no allusion being made to their being single or double; exhibitors, therefore, show as they please, and it happens sometimes that the judges have to deal with half-a-dozen plants of the single varieties competing against as many double sorts, or single and double mixed; this makes it more difficult for the judges to arrive at a just decision. In some cases a class is provided for each, and it is well that it should be so, for some allowance ought to be made for the greater difficulty of producing the plants of the double *Primulas* which must be grown from cuttings in the spring; whereas the single forms can be produced in any quantity from seed. I have seen the double varieties well shown at the Brighton exhibition. The old double white so well known to the growers for Covent Garden Market is usually well shown, and when grown to the highest standard of excellence, and the plants uniform in size, with a good head of bloom, the effect is excellent. There is a type of double variety with much larger, more double flowers, pinkish white, mottled red, and sometimes nearly white, occasionally exhibited. This type was shown some fifteen or twenty years ago by Mr. R. Gilbert, gardener to the Marquis of Exeter, in three or more varieties which seemed to be distinct at the time, but they have long since been merged into one variety. A salmon-red variety was also grown at that time which is still in cultivation. The pinkish white mottled variety was exhibited in capital condition at the Kingston *Chrysanthemum* show this year by Mr. Mease, (the Gardens, Downside, near Leatherhead. I well remember the fine growth and profuse bloom of Mr. Gilbert's plants exhibited at South Kensington, but they did not come up to the high standard of the plants exhibited by Mr. Mease, which were not too strong in growth and most profusely flowered. They were thought so highly of by the judges, that a silver medal given for the best examples of culture in the show was awarded to them.

The culture of these double varieties of Chinese *Primulas* is not at all difficult when once the details of the work are well understood. The plants require to be propagated from cuttings, to which a piece of hard stem is attached. The plant should be quite dry at the roots before removing the cuttings, and great care must be taken with them until they are well rooted. Each cutting should be planted in a small flower-pot containing sandy soil. I find a mixture of loam, leaf-mould and clean white sand answers best for them. The compost should be rather moist when it is used, for it is better not to water the cuttings for a few days, as an over-supply may cause them to rot from the

cut portion upwards. Place them in a close hand-glass or in a propagating frame inside the house. The top of the frame or light should be removed daily and the glass be wiped dry. The mere act of doing this gives the plants abundance of fresh air, and this, added to the removal of the condensed water, prevents any damping off. I have struck cuttings of these double varieties without any casualties merely by not forgetting to remove and wipe the glasses daily and by not giving any water until roots had begun to push from the cutting. When they are in a close frame they do not dry up much. As soon as it is seen by the growth of the young plant that it has fairly started, it ought to be removed from the glass case into the freer air of the house, and this may be continued until all are rooted. When the 2½-inch pots are well filled with roots, repot the plants into 3-inch pots, and all through their growth an open, moderately rich soil is best for them. For the second potting I use loam two parts, leaf-mould one part and an addition of decayed manure, with enough sand to keep the compost open. When the plants have once started to grow they push forward very rapidly and should be repotted as they require it. Cuttings struck in the spring will grow large enough to need an 8-inch flower-pot for each. During the summer and autumn months the plants should be placed in ordinary frames, so that the lights can be drawn off in fine weather. The main point in the culture of these, as indeed of most greenhouse flowers, is to give them plenty of air, exposing them well during summer. This causes a compact, hardy and healthy growth to be made, which is sure to result in the production of good trusses of flowers. Flimsy foliage, with long, drawn-out leaf-stalks, naturally produce flowers of similar quality to the leaves. When the growth is made and the flower-buds well formed in the autumn, the plants should be placed in an airy greenhouse near the glass, and in cold damp weather artificial heat and a rather dry atmosphere with ample ventilation are necessary to prevent the plants damping off at the neck. Single and double varieties are alike liable to damp off in a close atmosphere, and the conditions are aggravated by a low temperature.

J. DOUGLAS.

SPIRÆA PALMATA FOR POTS.

THIS is one of the finest hardy plants we have for forcing, or rather I should say for early flowering in pots, for it does not require forcing, but simply to be grown under glass with just sufficient warmth to keep out frost. If required very early it may be given a little more warmth to start it. It starts best if the crowns are well covered with cocoa-nut fibre refuse, say about 3 inches thick. This may be shaken off when the crowns begin to show through. The plants may be placed under a stage or anywhere out of the way until they have started. After they are well started they should be removed to where they can get as much light as possible. As the foliage develops a little liquid manure will be beneficial. The plants will require a considerable quantity of water, as if allowed to once get too dry the edges of the leaves turn brown. It is advisable to stand the pots in water when the plants are well advanced. Care must be taken not to give them too much warmth, or they will run up tall and weak.

English grown clumps should always be used in preference to imported ones, as the latter never make such good growth or fine foliage. Grown in 6-inch or 8-inch pots they will make fine specimens and come in at a time when large flowering plants with good foliage are not very plentiful.

Medium-sized clumps may be potted up as they are taken from the ground, but larger ones will require to be broken up, as the centres will have no good crowns. If broken up even to single crowns they will do equally well. About eight strong crowns will make a mass. A great recommendation for this *Spiræa* is that it makes a large specimen with little trouble, and the bright rosy-pink flowers and fine foliage are very attractive. I grew a few plants of the white variety last year

and found it equally suitable for pots, though not so tall growing as the pink, and as there are so many other good white flowers for early flowering, I shall not recommend it too strongly. *Spiræa astilboides* is a more desirable plant; this I should grow in preference to the elder favourite *japonica*, being of a lighter and more graceful habit. Hitherto this has been rather expensive, but it may now be bought at a reasonable price, and may be given the same treatment as *S. palmata*. F. H.

NOTES FROM THE ALBERT NURSERIES.

WHEN in the extensive nurseries of Messrs E. D. Shuttleworth and Co., Peckham Rye, a few days ago we made note of many interesting plants. This nursery is one of the largest near the metropolis, and devoted to all kinds of plants from Palms to hardy flowers, whilst the firm has also grounds at Fleet, in Hampshire, where perennials, Roses, and fruit trees in particular are grown.

There are upwards of twenty houses, and the majority of them are 100 feet in length, so that one can judge of the extent of glass. The Palm house is very large and contains splendid specimens, including *Kentias* of remarkable dimensions. *K. Fosteriana* is represented by a superb plant; also *K. Belmoreana* and *K. Canterburyana*, whilst one sees thousands of the pretty *Cocos Weddelliana* in all stages of growth. *Areca lutescens*, *A. Baueri*, and *A. sapida* are the chief species of this genus. We have never seen a finer collection of *Gecnomas*, beautiful Palms that are none too common in gardens. *G. gracilis* is one of the most popular, and grown in immense quantity. It does not get so common as some, as the seed germinates slowly, but when of suitable size it is a gem for table decoration. *C. Seemani* is also of note as a Palm for choice decorations. It is impossible to enter into details respecting the Palms here, as every species and variety worth growing are represented. Another important feature is the *Draçæna*, and the kinds with attractive foliage are in fine character. We made note especially of two kinds, *D. Lindenii* and *D. Massangeana*, both handsome plants when well grown. The former has the broad foliage green with yellowish-coloured stripes, so to say, down the centre, but in the case of *D. Massangeana* this is reversed. The *Crotons* are cultivated also on the same extensive scale, and every variety of consequence is included. Three very fine kinds are *C. Hawkeri*, in which the leaves are green and yellow; *C. Queen Victoria*, one of the most popular of its class, and the leaves of fine colour; and *C. Mortii*, the foliage of this being deep orange blotched with green. When over fifty varieties are to be seen, one is struck with the great variety amongst the various forms. In addition to those already described, we may mention as of much merit *Aigburth Gem*, the leaves finely coloured with crimson, and a very distinct variety, *Chelsoni*, *Flambeau*, *Baron James de Rothseild*, and *Laingi*.

Ferns are grown in large quantities, and one might almost call this a Fern nursery. The demand for quite small plants for table and other forms of decoration is very great. It is interesting to notice that these grown so largely are comparatively few, although the collection itself is extensive. Besides *Adiantum cuneatum*, the greatest demand is for the *Pteris*, especially *P. cretica* and its varieties, *albo-lineata*, *cristata*, and *Mayi*. *P. tremula* and *P. t. Smithiana* are also favourites for rooms. One house is almost wreathed with *Asparagus plumosus*, and it is only by visiting such a nursery that the immense popularity of certain indoor things is apparent. Thus, *Arancaria excelsa* is grown in thousands for rooms and other purposes, and houses are filled with *Marguerites* for blooming about Christmastide.

The collections of *Fuchsias*, Chinese *Primulas*, and *Pelargoniums* in various sections are of great merit. The Ivy-leaved class is increasing in popularity, and it may interest our readers to know that a very good half-dozen kinds are the following: *Galilee*, rose-pink; *Jeanne d'Arc*, white, touched with very pale lavender colour; *Louis Thibaut*, rich red; *Mme. Thibaut*, pink; and *Souvenir de Charles*

Turner, the flowers very large and rich pink, with a feathering of maroon on the upper petals.

One house was in large part devoted to the Lily of the Valley, which it is interesting to know was in bloom on the 1st of November, and shown at the Aquarium on the 7th, when an excellent display of it was made by this firm. A plant in full bloom was *Impatiens Sultani*, which we are sorry to see is gradually dropping out of cultivation in many private gardens. It is, however, too good to neglect and very easily grown. Few things are brighter in colour or more free-flowering. Azaleas of all kinds, *A. mollis* especially, are largely grown, and note may also be made of the Orchids, which form not the least interesting feature. They are chiefly of the more popular kinds, as *Celogyne cristata* in variety and *Odontoglossum crispum*. *Lycaste Skinneri* was in bloom, and when a good collection is cultivated one sees much variety in the colours of the flowers, particularly of the lip, which varies from self crimson through many beautiful shades. *Oncidium tigrinum* quite scented a large house, the fragrance like that of Violets. Few Orchids are so beautiful at this season as this species.

In such a nursery as this many plants not usually seen in gardens are grown. Thus in one house is a large batch of *Sonerilas*, bright little flowers, which are acceptable at this season. *S. maculata*, or *S. orientalis*, as it is also called, is the principal kind, and even when out of bloom it is conspicuous for the green and silvery leaves. We do not care greatly for variegated plants as a rule, but a yellow-leaved bedding *Lobelia* is worth a note as of use in summer arrangements. It is a good yellow, not sickly, and retains its distinct character even in the winter.

Amongst other plants noted were *Carex europæa variegata*, a charming little Grass, very graceful, the leaves narrow and distinctly variegated. Also beautiful was the old, but handsome *Cissis discolor*, which, though not often seen in private gardens now, was not many years ago grown in every stove. The large Palm house contains *Aspidistra lurida* and the variegated variety in quantity. For room decoration, corridors, and even shop windows no plant is more useful. It resists cold, dust, dirt and even neglect better than any other plant used for the same purpose. These are brief notes only of a large and important nursery, but sufficient has been written to show its interesting and varied character.

TUBEROSES.

FEW flowers are more valued in autumn and winter than the Tuberose. Especially is this so where there is a large and constant demand for such as are useful in button-hole work. Tuberoles, it must be admitted, are suited to this class of work, and alike useful are they in wreaths, crosses, or bouquets. It is now possible to have them in bloom almost all the year round, and though, of course, in common with all flowers, they open very slowly in the depth of winter, yet it is satisfactory to know that a fair percentage of their flowers expands tolerably well. To secure the flower-spikes from accident, a stick should be placed to each, with a loose tie to admit of future growth, and if the pots are stood closely together, little harm should result. At this time also keep them free of the side growths that form about the bulbs to the detriment of the flowering stem and flowers. Give the plants abundant supplies of water at the root and weak liquid manure every other day. Syringe freely and regularly so as to check as much as possible the progress of red spider, thrips and the like, which are almost sure to infest them. An occasional watering overhead with clear soot water will also conduce to the same end. Best of all, perhaps, is an occasional syringing with quassia chips and soft soap. Take a 6-inch potful of the quassia chips and place in an old saucepan with soft water, and boil steadily till the whole of the chips have sunk to the bottom; then drain it off and add a large teaspoonful of soft soap, stirring

well till dissolved, adding sufficient cold soft water to make two gallons of the whole, but if not sufficient, increase the proportion of chips and soap till enough has been made to give a good syringing all round. In using the syringe for this purpose the jet is always preferable to the rose, because with the former a steady spray is maintained, and all sides of the plants can be reached. It is a mistake to dash quantities of these insecticides against the plants, because the great bulk goes to the soil and is lost; whereas with the jet a mere mist-like spray is the result, and has the effect of just damping the leaves and stems. A spraying of this kind may be repeated frequently and at a very trifling cost, and gardeners should not lose sight of this cheap and effectual remedy. In the case of Tuberoles persevere with it while the plants are yet outside and the insects less numerous. When the plants are housed the drier atmosphere conduces to their rapid increase, when they frequently get the upper hand. Provide abundance of air on all favourable occasions, and daily while the plants are in frames at closing-time give them a nice sprinkling overhead with a fine rose. This will also tend to keep insect enemies in check. From time to time the most forward may be introduced into warmth as required, and with care a supply of flowers may be kept up till the end of the year.

E.

A note on zonal Pelargoniums.—The zonal Pelargoniums exhibited on several occasions recently by Messrs. H. Cannell and Sons, of Swanley, have been remarkably fine, and a few kinds of especial merit we have made note of. The new Double Life is a poor thing compared with the splendid single zonal varieties, with flowers of beautiful colour and form. One of the best of all is *Mme. Melba*, the flowers white, touched with light salmon-red in the centre, and *Etoile de Lyon* is bright and effective. It is of the *Souvenir de Mirande* type, rather too loose, however, but the reddish scarlet colour, passing to white in the centre, is very distinct. A good word may be said for *Raspail Improved*, the flowers being larger and fuller than those of the parent, and of the deepest crimson colour. A good white is the single *Albion*, and other single kinds worthy of mention are *Mme. de Boideville*, white, flushed with rose-salmon; *Ethel Lewis*, rose, white centre; and *Stella Massey*, which has flowers of a delicate pink colour.

Peperomia argyræa (known also as *P. Saundersi*).—Having for several years grown this beautiful little Aroid as a decorative plant I can recommend it with confidence. My first attention was called to its beauty not by personal observation, but from noting that others frequently admired it. It is easily grown, being readily increased by division in the spring. The temperature of an average stove suits it well, and it resists the damp with impunity.—H. G.

Phrynium variegatum.—This near ally of the *Maranta* and *Calathea* is a decidedly beautiful decorative plant, being also very distinct. I have noted it several times this year in mixed groups in which it has played an important part. It is not what may be termed a dinner-table plant as that qualification is generally understood, but it is none the less most useful in that way, as it is also for other indoor purposes. This plant is beautifully variegated with creamy white on a bright pale green ground; the variegation is greatly diversified, no two leaves being at all alike. It is an instance in which a plant has surely won its way upon its own merits. A first class certificate was awarded to it in 1886 under the name of *Phrynium jucundum*.—H. G.

Increasing Malmaison Carnations.—In THE GARDEN, Dec. 2, J. Crawford details his method of propagating this plant by making an incision in the shoots selected, much the same as for layering, and binding the wound round with damp Moss instead of burying the wounded part in soil; but why propagate this Carnation by either of these methods? My method of propa-

gating this Carnation is as follows, and I rarely lose a cutting: When the side shoots are 4 inches or 5 inches long I strip them off, remove the lower leaves with a sharp knife, pot them singly in very sandy soil and peat in 2½-inch pots and plunge in a close frame, watering as required. In about a month the cuttings are rooted and ready for 5-inch and 6-inch pots. After hardening off place outside.—WM. HARRIS.

Croton undulatus.—This variety, which was introduced by Messrs. Jas. Veitch and Sons from the South Sea Islands, and first put into commerce in 1870, still holds its own by reason of its very distinct and unique character. When well coloured there is not a variety to surpass it, the markings or blotches of the brightest crimson on a dark, almost olive ground are in such contrast to each other, whilst the peculiar wavy line of the leaves is another distinct feature peculiar to this species, for a true species it is without any doubt. It has also the property of retaining its foliage for a lengthened period in the best possible condition. The younger leaves have pale yellow markings on a light green ground, changing with maturity to the deeper shades first alluded to. The growth is not in any sense heavy or dense, thus making a capital table plant when well developed, and of not more than 1 foot in height. Croton growers who have not given this excellent variety a trial are advised to do so.—GROWER.

THREE GOOD WINTER YELLOW-FLOWERING PLANTS.

BRIGHT yellow flowers, though most welcome, are not plentiful at this time of the year; yet anyone having an ordinary greenhouse or a cool conservatory may without any difficulty have a grand display of *Abutilon Golden Queen* and *Linum trigynum*, and wherever the temperature of a house can be kept at a minimum of 60° during the winter, a third plant, the lovely *Linum tetragynum*, may with advantage be added to the list. Little need be said here about the *Abutilon*, as other varieties with flowers white, pink, and red of various tints are well known and found in nearly every private garden where cut flowers are in requisition during the winter. There, under a generous treatment and planted out in the border of the greenhouse or of the conservatory, either against a wall or as pillar plants, they produce in great abundance their lovely flowers, which are so well adapted for bouquets and for table decorations.

ABUTILON GOLDEN QUEEN is a decided improvement on the better-known *Boule d'Or*, being of better habit and a much more profuse bloomer. Its beautiful bell-shaped flowers of a particularly bright yellow colour are produced from the axils of the leaves at nearly all times of the year, and a plant so treated forms a most attractive sight during the dull months of the year. *Abutilons* are easily propagated from cuttings, which root freely at almost all seasons, although those struck in early spring are the best. They may also be considered clean plants, the only insect to which they are subject being the green-fly, which is readily destroyed either by fumigating or by syringing the plants, especially the underside of the foliage, where the vermin generally collects, with a weak decoction of quassia chips, which leaves no unpleasant smell and is very effective.

LINUM TRIGYNUM is the commercial and popular name for *Reinwardtia trigyna* of Dumortier, a very neat-flowering plant of shrubby habit, native of the mountainous parts of the East Indies. Although of equally easy culture, this plant requires a little more attention than the foregoing, but at this time of the year its flowers, of a rich orange-yellow colour, amply repay the cultivator for any extra care bestowed upon it. *Linum trigynum* is essentially a greenhouse plant, and is best adapted for pot culture. Its propagation is effected by means of cuttings made in March and April, and these if properly treated form in the course of the season bushy, well-furnished plants in 4½-inch pots, which during the dreary months of the year

greatly assist in the decoration of the greenhouse and conservatory. The strongest shoots produced from plants which have been cut back soon after they have done flowering form the best cuttings, which should be inserted in a compost of a sandy nature and kept in a close propagating frame where they root readily, after which they should be potted singly in a mixture of fibrous loam, partly decayed leaf-mould, and silver sand in equal parts. To ensure free growth it is advisable to add a small quantity of some fertiliser to the above-named compost. When rooted, and until they are fairly well established in the pots in which they are to flower, the young plants benefit by being kept in an intermediate temperature, while in autumn a position in a low frame where plenty of air and sun can be admitted is best, as it is necessary to ripen the last-made wood to favour the formation of the flower-buds. During their growing season, and especially while in a young state, the plants must be frequently pinched to ensure their growing into a compact shape. The last pinching, however, should take place not later than the end of July, or there is a danger of not allowing sufficient time for the formation of the flower-buds, especially if it should happen to be a rainy season. A temperature of 50° to 55° is that in which the flowers open best and are least likely to damp off. On account of its being subject to red spider *Linum trigynum* must be frequently syringed, and care should be taken that the water reaches the under part of the foliage. During the hot weather, from July to September, when the plants are best stood outside altogether, it is advisable to give them three or even four syringings a day, preference being given to rain water whenever procurable. After flowering the plants may be cut back and subjected to similar treatment, but it is preferable to propagate and grow fresh plants every year. Left to its own resources, *Linum trigynum* forms a straggling, unshapely bush varying from 2 feet to 3 feet in height.

LINUM TETRAGYNUM is another beautiful yellow flowering plant of shrubby habit, but its requirements are not met by cool treatment. It is a native of India, and must be grown in a warm house all the year round. If we only judge by the outward appearance, we find that it has a great affinity with the plant just described; indeed the differences are mostly botanical, inasmuch as its flowers, as the specific name *tetragynum* implies, are four-styled; whereas those of *L. trigynum* are three-styled. As a decorative plant for winter it is of as great value as the other; its flowers, which are produced in greater abundance, are disposed in large fascicle-like racemes at the summit of the branches and branchlets; they are of a very pleasing pale primrose-yellow colour, and often 1 inch in diameter. The plant, as may be seen by some handsome species now very attractive in Messrs. J. Veitch and Sons' nursery, is sometimes literally covered with its delicate *Convolvulus*-like flowers. The propagation of *Linum tetragynum* is not limited to cuttings only, as this pretty species produces underground suckers, by which it may also readily be increased. S. G.

Impatiens auricoma (the Golden Balsam).—The above is the name which Professor Baillon, of Paris, has given to a remarkably handsome plant recently introduced to Europe quite accidentally. The history of *Impatiens auricoma*, like that of several other plants of great merit, such as *Begonia Rex*, *Pteris argyrea*, &c., also introduced accidentally, is very singular and interesting. The plant was originally discovered some ten years ago in Madagascar by Mons. Leon Humblot, who sent the dry materials necessary for identification and classification to Professor Baillon, who then described it in the "*Bonplandia*"; but its introduction in a living state was purely accidental. Some two years since M. Humblot sent to a nurseryman friend of his in Paris—Mons. L. Landry—a few Orchids and Tree Ferns, all of which arrived dead. Two stray seedlings, however, developed themselves upon these Tree Ferns, and it is from these plants that the entire stock of the beautiful Golden Bal-

sam has been worked. This new-comer is a vigorous grower, with distinctly toothed dark green leaves, from the axils of which the flowers are abundantly produced and above which they stand conspicuously. Each individual flower, borne on a slender upright peduncle, is of a peculiar helmet shape and of a bright yellow colour, which forms a most pleasing contrast with the dark hue of its equally ornamental foliage. It is a remarkably handsome plant, which, like the well-known and deservedly popular *I. Sultani*, is suitable for either stove or greenhouse in the winter and very useful for outside decoration during the summer months, especially in somewhat sheltered places, being of a hardier nature than the beautiful, but shy-flowering *I. Hawkeri* and more robust, though quite as free-flowering as *I. Sultani*. It is readily increased by means of cuttings, which, like those of the other species to which it is related, root freely at almost any time of the year. This striking plant will be distributed next spring by Mons. Godefroy-Lebeuf, of Paris.—G. S.

FINE-LEAVED BEGONIAS.

THERE is now among the fine-leaved *Begonias* an infinite variety, some being suffused all over as with silver, whilst the combinations of pale green, dark green, bronze and silvery

A fine-leaved *Begonia*.

variegation in many kinds are beautiful in the extreme. Some of these form quite a picture of themselves, and are well worth a study. These *Begonias* are most accommodating plants, being of free and vigorous growth. They are excellent plants for an amateur to grow in his greenhouse, where he does not let the temperature ever fall below 40°. For the stove and intermediate house they are also well adapted. Where a wall which is unsightly wants covering with growing plants, these *Begonias* are first-rate material to use. All that they seem to require is just sufficient soil to establish themselves; after this their roots will ramify in all directions and cling to the bare wall, more particularly if it be bare brickwork. If the position be a damp and shaded one, these *Begonias* do equally as well or even better than under what might be thought to be more favourable conditions. If they are required to cover a dry wall, all that one has to do is to keep them well supplied with water. I have been particularly struck with the beautiful effect produced by their use in a planted-out fernery. Here the roots will delight to ramble and cling to the rockwork, particularly sandstone. Thus grown in a cool fernery they will generally retain their foliage all the year,

looking bright and cheerful in the dull days of winter. As pot-plants their value is pretty well known and appreciated for the decoration of plant houses. They also make capital decorative material for the house, in many instances being singularly appropriate to the surroundings. Small plants usually face all one way; thus they are well adapted for vases upon brackets, niches, or corners. They are most accommodating as to soil, but that which is light suits them best; mellow loam, leaf-mould, and sand answer well. Large pots are not at all requisite, but rather to be avoided as a disfigurement than otherwise. Propagation is simple and easily effected by the leaves; all that one has to do is to prepare a pan with sandy soil, and then after cutting through the ribs of the leaves to peg one or more upon the surface of the soil, the outer portions of the leaves being cut away. Plenty of young plants will soon be the result. This is far better than the cumbersome system of dividing the older plants, whereby the beautiful effect of a small plant is lost.

A variegated Sax frage.—When at Syon House Gardens recently we made note of the variegated variety of *S. sarmentosa*, the "Mother of Thousands," named *tricolor superba*. It is very handsomely variegated, the roundish leaves deep green in the centre, passing to a lighter shade and surrounded with a zone of creamy white, touched with rose at the margin. With age this variegation gets more attractive.

CHRISTMAS TREES AND EVERGREENS.

THE trade done in these subjects from the middle of December well into January is something enormous around London alone, and there is no reason whatever to doubt that the same condition of things is found in other centres of activity as well. One scarcely knows whether to deplore this cutting of so much good material, evergreens more particularly always serving such good purposes as shelters during the winter season, or to approve of it as a means of affording to great numbers of children and larger assemblies also additional pleasure and enjoyment at a season when we all like to see cheerfulness predominant in the household as well as at other gatherings. The use of such means of decoration has descended to us through a long series of years, dating, as in the case of the Mistletoe, back to druidical times and customs. To say that it is a relic of barbaric usages would not be right, for the Druids certainly could not be looked upon in that light. Turning to other parts of the globe, both in the eastern and the western hemispheres, we find that at certain periods of the year the inhabitants make use of the products of the vegetable kingdom as it exists around them. Some instances of this were, if I remember rightly, recorded by the authoress of the "*Voyage of the Sunbeam*" when calling at islands in the Southern Seas. The records in Holy Writ also bear on and confirm the use of the products of the localities therein mentioned, and not in a symbolic sense at all. Taking all things into consideration, the use of Christmas trees and cut evergreens must, I think, be justified on grounds of expediency alone.

With care, cut evergreens can be chosen so as to benefit the plants instead of being any injury to them. To cut them indiscriminately cannot be too strongly condemned; this is barbarous in the extreme, and such customs should not be allowed to exist. At the first glance it seems a waste to cut down or root up so many Firs as Christmas trees,

but with a moment's reflection it occurs to me that if it were not for the demand in this particular article not nearly so many would be grown; thus, after all, it is not perhaps a waste, but merely an outlet for superfluous stock.

I note in one of the gardening papers what an enormous number of Christmas trees is disposed of by one firm alone. Having seen this immense stock I can vouch for its accuracy; 20,000 trees, from dwarf ones that could be stood upon a table to tall ones which in many rooms would touch the ceiling, were to be seen just recently at Messrs. Fromow and Sons, Chiswick Nurseries, a sight to be wondered at as indicating the great demand at present existing. The majority of these trees were in pots or being potted, so as to go out in as complete a manner as possible. The number of pots alone leads one to think of the future and their use; many no doubt will be turned to a good account for other plants afterwards. Evergreens in a cut state come into the London markets by hundreds of loads, many such loads coming from districts where the Holly, the Yew and the Box all thrive in the best manner possible. As to berries, the crop is a variable one in the case of the Holly, some sorts in my own particular case being much better cropped than others, the variegated varieties being on the whole the best. Fortunately, there has not been any severely prolonged frost, otherwise the berries would have been attacked by the birds as a means of livelihood where the crop of hips and haws is not an abundant one. Judging from the prices of Holly, the country supply is considered a good one as regards berried shoots. Continental Mistletoe, as usual, is present in by far the largest quantities, and perhaps it is as well that it should be so, in order that home-grown examples may be spared in some degree. Those who have looked forward will no doubt have sufficient supplies of dried Grasses and flowers, to which well-developed fronds of the common Bracken are no mean addition. FILICES.

TREES AND SHRUBS.

THE TRUE PINETUM.

MANY have noticed the failures, from every point of view, of what is called the pinetum in many country seats. It is, perhaps, incident to the beginning of all things that failures should occur, but the failure of the pinetum is general. Distorted and grafted trees, the cemetery look and the toy-like shapes, the planting without artistic grouping or massing for any real effect, a "spotty" appearance everywhere, varied by labels—anything more wearisome to people accustomed to see trees in broad, natural masses could hardly be devised. A better way is to plant fewer sorts in bolder masses, paying more attention to the kind, *i.e.*, making sure that it is what we like and that our climate will mature, and in which it will be quite hardy in all seasons, unlike many of the Mexican and even the Californian conifers, which are not really hardy in Britain, though some of them, like the Monterey Cypress, may make a great show for a few years in a seaside place like Dublin, Sligo, or Bournemouth. We have to avoid the rubbishy varieties which are sent out, variegated with disease; these are very nice in the nursery, but who ever saw a decent plant of them anywhere else? Then there is the grafting danger. Some new kinds of Pines are put on common stocks, which can only be disastrous. It is enormously better to buy a thing on its own roots, and if it will not live on its own roots, let it die. Apart from the plan of planting bold groups of things we know will do, like the Corsican Pine, the Larch, Scotch Fir, or any other hardy Pine we may fancy, there is the slightly different plan of planting a large number of kinds together.

We are now dealing with a field of about 9 acres, in which, instead of making one mass of a Pine, we are trying from a few hundreds to a score of each hardy Pine that interests us. Instead of labelling them and sticking them out in a formal way, as in pinetums, we plant the whole field as if planting Larch or Scotch, but a little more openly, because most planting of this kind has been much too thick hitherto. Why people should put in young trees 18 inches apart, as we often see them, we cannot tell. As nine people out of ten never thin in time, it means death or weakness to the trees. So we plant our little Pines never closer than 5 feet in the line and 3 feet apart, and so we fill up the field with anything promising in the way of a Pine. In such a wood we should thin the trees very carefully and early so as to secure fair development, and finally, when the trees become large, it would be easy to cut delightful walks through the wood, so that in general effect in the landscape, and in detail, such a pinetum would be as interesting an expression of this great family of plants as one could well see. There are, of course, no labels, as what is not worth knowing is not worth growing; and when one plants a number of a Pine it is not easy to forget it.—*Field.*

The Scarlet Oak in Surrey.—Mr. Anthony Waterer sends us some of his Scarlet Oak foliage, splendid in hues this year as usual. We wish some one who knows the American woods would tell us of all the Oaks that show fine colour there, as they are important trees for us. In their case, however, their natural vigour is interfered with by grafting, which prevents any clean and free growth, and on many soils leads to the death of the tree. The really hardy American Oaks should be grown on their own roots from seed. Seed is plentiful, and if it would not carry well it would be easy to get over during winter, seedling plants raised in America. It is curious how rarely one sees these Scarlet Oaks in our parks or even pleasure grounds. This, we think, is owing to the deaths through grafting. So many plant in single specimens, that the losses through death are not always seen. If we plant in groups or masses and use grafted stuff, we are lost, and anyone can then see the extent of the loss.

The deciduous Cypress (*Taxodium distichum*).—In some sheltered situations, usually in low ground near water, this handsome tree carries its foliage well into the winter long after it has turned brown. When this is the case a good specimen is very striking, the effect being glorious when lit up by the winter sun. The graceful and delicately tinted foliage when in the green state, too, is very lovely, and quite unlike that of most other trees, to which it forms a good contrast. How seldom do we see really good trees such as this planted with any attempt at boldness, so as to gain the best possible effect from their use; more often than not a single specimen only is planted where a dozen might be used with far better results, and even then the chances are that it is spoiled in its younger days by being choked with scrubby Laurels or some other dense undergrowth that keeps both light and air away from tree and soil, and from which good, but slow growing things are lucky to escape with life and vigour enough to develop into something like trees.—J. C. TALLACK.

MISTLETOE.

JUST at this season the olive-green twigs and pearly berries of the Mistletoe are thrust upon our attention, so it often follows that many attempts are made to propagate it just now by sowing its berries on the branches of Apple or Hawthorn, or Oak, Poplar, or Pavia, as the case may be. This is wrong, however, for the berries or seeds are now unripe, and the weather is too cold for them to germinate even if they were.

The ordinary notion as to the propagation of Mistletoe by means of seed or berries is to slit or pierce the young bark of the host plant, or tree and then push the berries into the slit. Now, in all good gardening operations there are three or four things at least necessary to success, *viz.*, to do the right thing at the right time, and in the best manner in the proper place or under the most suitable conditions. But most people do not quite bear this axiom in mind, and they often fail to get Mistletoe berries to grow. Having had considerable practical experience in this matter, and having often failed, I think that at last I have found out how Mistletoe may be grown from seed as easily as Peas or Beans, and the information may be of interest to those who would fain have it growing in their gardens. The best practice is not to cut or slit the bark at all for the due reception of the seeds or berries, but to press or rub them on to a smooth, young, healthy branch of Apple or Hawthorn with the fingers. The berry is a little slippery at first, but as the viscid pulp dries you will find the seed firmly glued or gummed down to the clean bark. Two or three berries thus stuck on may be covered with a bit of black muslin or crape to secure the seeds from the birds, which sometimes peck them off the branches unless protected in this way. If the bark be slit or cut its cut edges at once turn brown and harden into corky layers of tissue inimical to the growth of the seeds.

The right time to thus affix the seeds to the bark of the host plant is in April or May, because at that time the berries are ripe and the seed inside is fully developed, and probably its growing points or radicles will be seen protruding like little green pin's heads amongst the sticky pulp.

Where missel thrushes abound it may be necessary to net or otherwise protect the seed-bearing Mistletoe, or they will probably steal every berry during hard frosty weather, so that there will be none left to sow. The proper method having been above described, the best place and conditions are to fix the berry on the underside of the fresh and healthy branches of Apple, Crab, Hawthorn, Oak, Pavia, or Poplar as the case may be and opportunity occur. A young Apple tree of strong growth like Blenheim Orange Pippin suits Mistletoe perfectly. So does a young and healthy Hawthorn or Pavia rubra. Mistletoe is rare upon the Oak in England, but can easily be established on the young free bark of healthy trees. I have seen Mistletoe luxuriant on Mountain Ash and on the White Beam tree, both species of *Pyrus* or *Sorbus*, of the fruits of which the larger species of thrush is particularly fond as well as of the Mistletoe berries—hence, no doubt, their popular names.

Now having rubbed ripe fruits of Mistletoe on to a suitable host tree in April or May, the seed will gradually appear to shrivel away and seem to vanish altogether; but, unless pecked off or otherwise knocked away, it will not really have done so. The first thing that happens is the protrusion of the green growing point, or rather the radicle of the seeds. These curve over and fix their thickened ends (which resemble a fly's foot somewhat) into the young bark of the tree. In order to support its growth the contents of the seed are gradually absorbed, and finally only a mere scrap seems to remain where the plump seed originally had been. But if you look closely at the bark in the following autumn, say six months after sowing, you will observe the bark of the Apple branch swollen above and below where the seed was placed, and perhaps a green point or two of growth may be seen to appear about the centre of the swelling, and by the spring the first twin pair of leaves will have developed and the plant is firmly established under the bark of the tree. As above treated Mistletoe is slow perhaps, but its growth is as sure as that of a Pea or a Bean, and there is no really difficulty in introducing it wherever it may be desired. I have now several sowings in different stages on Apple trees as thus treated during the past three or four years, and I am now experimenting on other host plants, such as Oak, Plum, Poplar, Medlar, Quince, Pinus and Horse Chestnut, in place of the genus Pavia. The luxuriance of

Mistletoe on the genus *Pinus* in Austria and on Poplars in Brittany and Normandy and France is well known.

Having succeeded so well in growing Mistletoe, I am now most anxious to try other vegetable parasites of similar character, such as the *Loranthus europæus* of Europe, and the American Mistletoe (*Phoradendron*) of the United States, and seeds of both or either of these would be very welcome in due season, together with a note as to the host plants on which they best and most luxuriantly grow in their native habitats respectively. The above is my own simple and successful practice, but I shall, of course, be glad to hear of a better or even of "another way."

F. W. BURBIDGE.

THE TIMBER OF EXOTIC CONIFERS: USES AND COMPARATIVE VALUE.*

THIS subject embraces such a wide field for discussion, that to enter particularly into every detail would involve an amount of description which to most people would seem uninteresting and superfluous. I shall therefore confine my remarks to the timber of some of the most tried trees, apart from many of those of early introduction already so well known as to require no mention here—amongst the most prominent of the latter being the Larch, Silver Fir, and Norway Spruce, three most valuable trees in this country—and those of later introduction, of which little is known of the value or quality of their timber. It may be taken for granted that it is now beyond question that many parts of this country, especially Scotland, are exceedingly well adapted for the profitable growth of many of the exotic conifers, the variety of soil and diversity of climate giving us a great range of natural adaptation—our deep, narrow dells and glens contrasting very favourably with the natural habitat of several of the varieties after named. But we must not expect that we can ever produce timber of the same size and quality as that produced in the true and natural home of the trees enumerated below. Yet it is not too much to expect, judging from the examples found in Scotland and elsewhere, that with proper selection of soil, situation, exposure, and climate, four necessary conditions, we can greatly improve our timber supply, if not in quality at least in quantity, although it is to be regretted, for many reasons, that quantity takes precedence of quality. A large volume in a given time is really what is wanted since iron beams have taken the place of those of timber. Whatever opinions may be entertained by experts or by persons having only a very limited knowledge of timber as to the commercial value of many of our exotic conifers, compared with the native variety and those of early introduction, I have by using the timber proved to the satisfaction of all who have seen the wood in use that they are very valuable indeed, both in regard to colour and beauty of "grain" as well as durability. The data for comparative value I have taken from over 40,000 measurements, and by giving a well-known tree, the Scotch Fir, as a standard of value, the values of all are easily arrived at. For example, Scotch Fir at 100 gives Larch a value of about 216, and with this in view I shall fix the standard of average value of Scotch Fir at 100 per unit.

Taking the old nomenclature, I begin with the beautiful

ABIES ALBERTIANA.—The timber of this tree is valuable on account of its elasticity. It is quite equal to the Larch, and not unlike the wood of

that tree, though as yet its durability when grown with a moist soil has to be proved. Except in that case, what is known of the timber of this tree grown in this country proves it to be valuable. The wood is of a yellowish white colour, fine-grained, and takes a good polish; the saplings make first-class ladders for slaters, plumbers, and the like, much lighter and stronger, and in every way more reliable, than the Norway Spruce. Value 200.

A. CANADENSIS.—The wood of this tree resembles that of the foregoing generally; is less elastic, but better adapted for house-fittings. The wood when old is hard, fine-grained, and stains dark brown under treatment with French polish or varnish. Good for railway-line posts and housework. Value 75.

A. DOUGLASSI.—The timber of this valuable tree resembles very much that of the Larch, though not so strong or heavy as that wood, owing no doubt to its very rapid growth. It is capable of being profitably used in all works in which Larch is used, except for boat skins, riddle and basket making. The wood is extremely easy to work, and when dressed does not warp and twist like the Larch. It takes varnishing well, and polishes to a rosy brown colour. There is little doubt that wood from trees well matured by age will be quite equal in every respect to that of the Larch, and can be used in all architectural work where the yellow and other Pine timber are available, and with much better effect, owing to its colour. For Gothic roofing, principals, purlins and sarking it cannot be equalled. Value 225.

A. MENZIESI.—The timber of this tree at first sight resembles that of the common Norway Spruce (*Abies excelsa*), but a closer acquaintance proves it to be a much more valuable wood than the latter, being tougher and more easily worked. The common uses of the wood are for roofing and fittings of agricultural and other buildings, and for lining rooms on the "lap-joint" system. Massive dining-rooms, studies, &c., done with this wood are extremely beautiful, and examples of the work are to be seen in the Birnam Hotel, near Dunkeld, and several of the best houses on the Murthly property. The wood is easily worked, though similar to common Spruce, and is suitable for piles, aqueducts, staves and headings for dry goods casks, as also packing-cases, and where closely grown is suitable for herring barrels. Value 220.

A. MORINDA OR SMITHIANA.—In appearance the timber of this tree is a facsimile of that of *Abies Menziesi*, but with this difference, that the tree being much slower in growth, the timber is harder and more brittle. The wood does not appear to possess valuable qualities, being of less value than that of the *Abies excelsa*. Value 55.

A. ORIENTALIS.—The wood of this tree as grown in this country resembles very much that of the black American Spruce (*Abies nigra*), but is much more valuable on account of its toughness and durability. The "grain" is very marked by the autumn growths being so dark in colour and those of the earlier part of the season white. Having only seen one log of Scotch-grown *A. orientalis*, I am not able to give any particulars. It is not a fast grower, but the wood has the appearance of being valuable. Value 75.

ARAUCARIA IMBRICATA.—The wood of this tree when aged is extremely hard and fine-grained. The heart-wood is of a rich brown colour; it polishes well, showing beautiful silky shades, owing to corrugations in the growth. Under certain treatment it appears like the American Birch in figure, except that the Pine lines are seen in both the end and longitudinal sections. The timber ebullises well, and, besides the common uses of Pine timber, it is adapted for various articles of furniture, and is easily worked. Value 140.

CEDRUS ATLANTICA.—The timber of the Mount Atlas Cedar is so well known that describing it may be out of place. The wood is very fragrant, beautifully marked, and polishes well. It is highly suitable for bedroom furniture and linings of drawers, cabinets, sideboards, and the like, but the chief use to which it should be applied is flooring for bedrooms. No moth will venture near where this wood is used, and no carpet would be required.

It diffuses an agreeable odour, which is believed by some to have a slightly narcotic effect and to be beneficial to health. Value 141.

C. DEODARA.—The same remarks apply to the use of this wood and other particulars. Without the aid of the microscope it is impossible to distinguish the wood of the one variety from that of the other, they are so similar in every respect. The timber of the three Cedars (*atlantica*, *Deodara*, and *Libani*) is very similar, and one may be sold and used as any of the three trees. The value of the *Deodara* is about 142.

CRYPTOMERIA JAPONICA.—The timber of this tree is of a beautiful red colour, strongly scented. The wood is very suitable for the same purposes as the foregoing Cedars; makes beautiful architraves, panel frames, mantelpieces, and flooring. It is light and very tough, but easily worked. Value 130.

CUPRESSUS LAMBERTIANA.—This tree produces very valuable timber, having an agreeable odour. It is suitable for many purposes, but its chief uses are for furniture, the fittings of the best classes of dwelling-houses, drapers' shops, and the like. From its lightness, hardness, and beautiful colour it is altogether a most desirable wood, and being a rapid grower in favourable situations in this country, is valuable as a forest tree. Value 283.

C. LAWSONIANA.—The timber of this tree is also of fine quality and strongly scented. The wood, which is easily dressed, is elastic and of a yellowish white colour. My experience of this wood is very limited, but, judging from the little I have gained, I think it will be a useful and lasting timber. Its commercial value is about 120 to 185.

C. MACROCARPA.—To the unaided vision the wood of this Pine is in every way similar to, but having a little more density than, that of *Cupressus Lambertiana*. The same remarks apply to this timber as to that of *C. Lambertiana*. Value 190.

LIBOCEDRUS DECURRENTIS.—Why this is called "White Cedar," while its timber is nearly as red as that of the Californian Redwood, one is at a loss to understand. In a young state the timber is of a yellowish white colour, but the heart wood, which begins to form usually about the eighth year, is of a mahogany-red colour, strongly scented; strong, elastic, durable, and easily worked. It is highly suited for furniture, for finishings for superior houses, and for shop fittings, as well as for the commoner uses for which Pine timber is adapted. Value 110.

PICEA GRANDIS (Douglas).—A tree producing timber superior in quality to that of *Abies Douglasi*, but less in quantity in a given time. The timber is very white, elastic, and easily worked. It is suited for most purposes for which Pine timber is used—scantlings, beams, and general roofing and flooring. In general appearance the timber of this tree is somewhat unique. Value 160.

P. LASTOCARPA (Lobb).—This tree produces timber more dense than the foregoing, of the same colour, but having larger knots and more inclined to heart-colour earlier than the *grandis* of Douglas. It does not, in my experience, produce nearly the same amount of timber in a given time as that tree. Value 140.

P. NOBILIS.—A tree producing harder timber, but quite as easily worked as either of the foregoing. It is durable, and when well-seasoned is hard and light, eminently suited for architraves, panelling and framing for doors, windows, and the like. In the young state it is not to be recommended for flooring, as it is apt to get "scooped" out between the growths, leaving narrow ridges like corduroy. Its value is about 170.

P. NORDMANNIANA.—This tree is of much slower growth than the tree last named. The timber has the same appearance, but is harder and apparently more durable. In one or two instances the timber shown to me resembled very much that of a fast-grown *Picea pectinata*, but timber from trees I have known had very little resemblance to the wood of that tree, especially the heart-wood. The timber is useful for any purpose for which ordinary Pine is adapted. Value 125.

* Paper read by Mr. D. F. Mackenzie at the Conifer conference, Oct. 7, 1891.

P. PINSAPO.—The wood of this tree does not appear to be very valuable. It is difficult to work, very brittle on account of the numerous knots, and rots quickly when in contact with the soil. This and the timber of *Picea cephalonica* and *Picea numidica* resemble one another so closely, that it is almost impossible to distinguish the one from the other. Value 96.

PINUS AUSTRIACA.—The timber of this tree is well known to most people. It is coarse-grained, tough and durable, but considerably inferior to the Scotch Fir. Value 70.

P. CEMBRA.—From the slow rate of growth, the timber of this tree is of very good quality as a rule, being hard, even-grained, easily worked, and very durable as flooring, scantlings, window and door framing. Its value is about 60.

P. EXCELSA.—The timber of this tree is coarse, soft, easily broken, and not very durable. The wood is faulty through the numerous "pools" of resin throughout the entire structure, induced, no doubt, by the ulcerated condition of the bark, a disease to which this tree seems especially liable. As to bulk of timber it is about equal to Scotch Fir. Value 100.

P. JEFFREYI.—This tree produces valuable and durable timber, very regular in growth, though rather soft while in the young state. It produces heart-wood rapidly, and thereby becomes valuable for any purpose to which Pine timber may be applied. Its value as to timber and quality is 140.

P. LARICIO.—A well-known tree, fairly fast grower, wood soft at first, but very hard when matured, durable and easily worked. The wood is quite suitable for every purpose for which the timber of the best Pine is used, and its comparative value is about 125.

P. MONTICOLA.—The timber of this tree is valuable both from the great bulk produced in a given time and from its elastic quality. It is easily worked and stains beautifully. The wood is light, tough, and durable, but liable to the depredations of moths. It produces wood highly suitable for house furnishings, for which purpose it should be cut in winter, to lessen its liability to attacks by moths. Its value as compared with Scotch Fir is 210.

P. PONDEROSA.—The tree produces what may be called dense, heavy-grained timber. The heart-wood is full of resin and of a yellow-brown colour, the autumn growth being marked by a very distinct line of a dark Spanish brown colour, which gives the wood a character of its own. The timber is exceedingly well adapted for piles for jetties, embankments, &c., flooring, joisting, and roofing; but probably railway sleepers, for which it would excel the best Larch in point of duration, would be the chief market for the timber. It is difficult to work, oil being constantly required for the tools in working. The few specimens I have had cut up exceeded in specific gravity anything I have seen in the Mar, Rothiemurchus, Nethy, or Dalnain forests of thirty years ago. It promises to be a very valuable timber when at full maturity. Its value is about 125.

P. PYRENAICA.—A tree producing timber similar in appearance to austriaca, but finer grained, more elastic, and better adapted for general purposes. Value 75.

P. RIGIDA.—Like the *Pinus ponderosa*, the timber of the *Pinus rigida* is heavy and full of resin, and in other respects very similar, being durable, useful for the same purposes, and equally difficult to work. So far as I have had opportunity of observing the growth, it is slower and more formal than that of *Pinus ponderosa*. The value is 95.

SEQUOIA (TAXODIUM) SEMPERVIRENS (the Californian Redwood Tree) produces beautifully coloured wood, suitable for many purposes, chiefly shop and house fittings, panelling, dados, picture-frame and mirror backs, mantel-pieces, &c. The colour under French polish is a rich "porty" brown, having, however, the Pine markings quite distinct. The timber is not very durable in contact with damp, but as it absorbs oil very freely it can be made lasting at pleasure. Like the Kanri Pine, it is well adapted for carriage panels, and forms beautiful work when used with Butternut (*Caryo-*

car nuciferum). In any of the home-grown specimens I have seen or have cut up I have not observed any "curly" wood, but no doubt time would produce that figure in the home as well as in the foreign article. For bulk as well as for beauty of timber this tree is very valuable. As compared with Scotch Fir its value is 204.

WELLINGTONIA GIGANTEA.—The timber of this tree resembles in colour that of the foregoing; it is, however, more porous, lighter, not so durable, and fractures more easily. It is very liable to be attacked by fungi, but withal is a very good timber, and is chiefly suitable for the same purposes as the *Sequoia sempervirens*, and for any of the purposes for which Pine timber is adapted. The growth alone gives a value of 370 as compared with Scotch Fir at 100.

It will be observed that I have omitted many very useful trees from the above list. Had I been writing a theoretical paper on the subject, I should probably have doubled the number, but I have confined my remarks to the timber of such trees as are well known to myself—trees the timber of which I have had cut up and put into use. As must be well known, the timber was cut from comparatively young trees, not in any way matured by growth: at the same time they have been compared with the Scotch Fir, Larch, &c., of the same age and under the same circumstances. As to the comparative values, the figures given represent the conclusions arrived at by actual measurements and personal observation. While this is the case, I feel satisfied that in many cases the values I have given will fall far short of what the actual value will be when the trees arrive at maturity in this country. I have little doubt most of those trees I have named, and many I have omitted, will carry out the profitable rate of growth till maturity. If I am nearly correct in such an assumption, there is a great and profitable future in store for those who will at once begin to plant on a large scale the trees named.

It may not be amiss for me to say a word about the planting of one or two varieties, because the success or otherwise of that operation has a marked effect on the quantity and quality of the timber produced. If my advice were asked by the owners of large, or even small, woods and plantations that have become "blanky" through the injurious action of the winds and other causes—conditions very common in the woods throughout Scotland—I should at once advise the planting of these spaces with those beautiful trees *Cupressus Lawsoniana*, *Abies Albertiana*, and *Thuja gigantea*. I need not here enter into reasons for such advice further than to say that these trees of all others are pre-eminently suited for such work. For pit wood alone these trees are invaluable. In, say, twenty-five years an acre of these would be worth about £60, planted as above or even in forests by themselves. In this respect they would on a given area, in a given time, exceed the value of the best Larch. The great drawback at present is the cost of the plants. Unlike other commodities, however, demand in this case would cheapen the article. What I advocate here about *Cupressus Lawsoniana*, *Abies Albertiana*, and *Thuja gigantea* is no mere theory. In 1886 I bought a quantity of the above plants, described in the catalogue as from 2½ feet to 3 feet, and a few *Picea grandis* (Douglas) 3 feet. I planted these where the winds of the previous winter had uprooted all the trees. At the present moment many of those plants are 16 feet high, having a diameter of over 6 inches at 1 foot from the ground, nearly every tree having a 6-foot length suitable for common pitwood. In some cases they are planted at less than 9 feet apart,

in others more. Under the above treatment *Cupressus Lawsoniana* produces more timber than *P. grandis*, although the latter is quite as tall, but it will not bear crowding, while the other varieties will stand quite thickly together without harming each other. A quality possessed by the *Cupressus Lawsoniana* and the other two trees I have named is that crowding makes their timber of better quality, while the quantity produced does not seem to be appreciably diminished. The three are undoubtedly shelter-loving trees, and should be treated as such in order to get the greatest possible bulk of timber in a given time.

I feel I cannot close this paper without recording a curious fact observed in the working of the various Pine timbers I have named. It was found that the wood of those Pines having three leaves in a sheath was, as a rule, much harder than that of those having only two, while all those having five leaves in the sheath were uniformly soft, and when dressed had a silky appearance. So general is this characteristic that one could almost at once tell to what class a certain plank of Pine timber belonged. The same rule holds good with the *Abies* tribe, the timber of the true Spruce, as represented by the Norway Spruce, being quite distinct in appearance in every particular from the pseudo variety represented by *A. Douglasi* and others. This distinction is also plainly visible in the timber of the Silver Firs, the variety represented by *P. Pinsapo* being quite like the timber of Spruce, while that represented by *P. nobilis* resembles the wood of the five-leaved Pines. While these characteristics are pretty general, it is well known that soil, exposure and elevation have a very marked effect on the figure, quality, and quantity of timber, so much so that it is difficult to get the "points" of character constant unless the trees are grown side by side and in masses.

GARDEN FLORA.

PLATE 942.

THE HONEY BALM.

(WITH A COLOURED PLATE OF *MELITTIS MELISSOPHYLLUM*.)

BEE BALM, **Bastard Balm**, and **Honey Balm** are all local names for the charming plant figured in the accompanying coloured plate. It is the only species known to botanists, although Thunberg mentions a *Melittis japonicum* in his observations on the flora of Japan, published in the *Linnean Transactions*, vol. ii., page 338, and which is the *M. melissophyllum* of "Flora Japonica," page 248. I have never met with this species, if such there be, and in the "Genera Plantarum" the latter plant is not noticed, the distribution being confined to Europe. It is found in copses from Wales and Gloucester to Cornwall and Sussex, though the large-flowered variety known in gardens as *M. grandiflorum* is a form that is more often found in the garden than the field. It is, however, by far the showier of the two, and forms a beautiful compact flowering plant, perfectly hardy in all soils, and invaluable even in small collections. It flowers from May to July, and when first open emits a pleasant fragrance, which, unfortunately, is not lasting. It is, however, a splendid bee plant, a large quantity of honey being secreted from the glands at the

* Drawn for THE GARDEN by C. Jones in the Royal Gardens, Kew. Lithographed and printed by Guillaume Severeys.

base of the flower. Clusius mentions a form of this plant found in Switzerland which is in all respects smaller, the flowers being pale red, sometimes white. There is also a white form of the larger flowered form, and I remember having seen a very fine specimen at Benthall Hall, in Mr. Maw's rich collection. It is, unfortunately, rare, and I consider it much finer as a decorative plant than the form figured here. *M. melissophyllum* grows about 18 inches high, and will be found a useful plant to associate with the dwarfed *Dracophyllums*, the *Scutellarias*, the *Thymes*, and other low-growing labiates in the rock garden. A strong grower, it requires plenty of rich soil, a not too dry situation, and abundance of sunlight. It is readily increased by division, which may be done either in early autumn or spring.

THE WEEK'S WORK.

THE KITCHEN GARDEN.

THE seed catalogues will now be coming in, and a careful examination will have to be made as to what improvements can be made in the season's supply. Notes taken during the past season will have to be looked up, for although we may not have a repetition of the season now closing, it will have been observed that some kinds of vegetables did well during the intense heat. The superiority of the produce in many instances was, perhaps, more a matter of careful cultivation, not exactly at the time, but through precautions taken during the less busy season. It is of little use to make a note of supposed superior varieties of vegetables if ordinary care is not taken in making due preparation of the soil. The failure may have occurred solely in some instances through the want of this due preparation, and I cannot too strongly impress the advantage of improving soils at this less busy season of the year. We all know a good supply of water is useful in any garden, but this will not save crops if the soil is only shallow worked, especially that of a light and gravelly nature.

ORDERING SEEDS.—Although some kinds of seeds will germinate when more than a year old, it is much the wiser plan to secure a fresh stock every season. Old seeds do not germinate at all freely, and sowing these often leads to untold disappointments. At this time perhaps it is seen that fresh seeds must be had, with the result, perhaps, that the crops are much later than intended. A system which I have relied upon for years is to keep a copy of the previous year's seed list, and improve upon this the following season, that is if it is open to improvement. Old standard kinds I know I can rely upon, but novelties I always add with caution. Do not grow a supposed improved variety until the novelty has been given a fair trial. A good word of advice I can offer to younger men who may have had little or no experience in making out a seed list is to try and secure the previous year's one from the seedsman if it cannot be had otherwise. The mistake must not be made of ordering too many kinds of one vegetable, as if so, confusion will surely arise. A little of this kind and a little of another does not find favour with cooks, or even those who may have to partake of them. Peas are often ordered in large quantities, and it is no uncommon occurrence to see almost as many varieties as there are rows. All kinds of seeds should have the highest percentage of germinating power this season; so the seed order need not be increased to what is more than thought will constitute a sufficient supply. I do not advise cutting it down too low, as often unforeseen failures occur, and employers do not care to see the seed order added to after the first supply is in.

SEASONABLE WORK.—The old stock of Pea and runner Bean sticks should be overhauled, and it will then be seen what new ones must be added.

The taller Pea sticks may be of little value for the use they were subjected to last season, but by cutting off the decayed ends they come in for dwarfier kinds. In windy districts it is often necessary to have some kind of support for even French Beans. Short pieces of spray are useful for this purpose. These may be cut out now and tied up in bundles for future use. In country districts Birch brooms often have to be made. The Birch for another season's use should now be cut, tied up in bundles and stacked evenly in a dry and airy shed; not, however, on the floor, but overhead. By cutting the Birch whilst the sap is dormant the wood becomes tough, and so wears well. If left until the sap is rising, the wood is very brittle and will withstand but little wear.

ROOT CROPS.—Such crops as Salsafy, Scorzonera, Parsnips and Artichokes retain their flavour better and are also more tender when boiled if left in the ground. It is at this time that these vegetables are appreciated, making, as they do, a welcome change. Although I do not advise that the whole of the roots be taken up now, yet a few might now be lifted and stered in sand on the floor of a very cool shed. Especially is this necessary if a spell of frost should come. A supply will therefore be assured for at least three weeks. If the supply of salad is not likely to hold out, some roots of Witloof may also be taken up and stored similarly, so as to be at hand in case of severe frost. The roots, by being left in the ground until now, give better produce when forced than if taken up earlier.

A. YOUNG.

ORCHIDS.

UP to the time of writing I cannot say that the fogs have touched a single blossom of the most delicate kind, and owing to the generally mild weather there has been no need to overheat the pipes to keep up the temperature. Those who wish for full details as to heating, ventilating, damping down, &c., can refer back for the last six weeks, and the instructions there found will be available now and for a few weeks longer. I often feel when writing these calendars and explaining about the cool house, intermediate house, East India house, &c., that the gardeners in charge of such houses may think some of my instructions a little too trivial. Many gardeners now called upon to grow Orchids, although they have had a regular training for the ordinary routine of gardening, have not had the advantage of cultivating Orchids in their youth. Another class of Orchid growers is the amateurs who have never had a training for garden work, but who like to grow their own plants. Some of these have such an innate love for gardening, that they gradually, as it were, feel their way, and succeed in growing plants which have taxed the ingenuity of the best professional Orchid growers. As an example of such I can quote the Rev. Francis D. Horner with his wonderful specimens of *Cattleya citrina*, grown as no professional Orchid grower known to me has ever yet grown them. Anybody can grow this species and flower it well for a few years, or I presume as long as its native energy lasts, but who can take charge of worn-out plants and bring them back to rude health again? I have questioned Mr. Horner as to his treatment of them, which he freely communicates, but I have not been able to lay hold upon any detail that would account for his extraordinary success, except that the roots are never allowed to get so very dry as some persons have an idea they ought to be. They have a *Cattleya* house temperature, but an atmosphere that is never so dry in winter as a *Cattleya* house usually is, for in it are grown many species which naturally do not succeed well with a dry air even in winter. I noticed that *Dendrobium Wardianum* was in a fair way of establishing itself in the same house. The plants were making most extraordinary growths and also flowering well, and this led me to question the wisdom of placing the plants of this lovely species in a greenhouse temperature and allowing the soil to become so dry that the growths shrivel considerably. They do very well with this treatment for a few years, but, to the chagrin of their owners,

they, after a certain period, show symptoms of decline, and grow so poorly, that they have to be discarded as not worth troubling about. A good many Orchid growers may remember the furore caused by the exhibition in London of a splendid specimen of *Vanda cœrulea* with four immense spikes upon it. The plant was subsequently sold for about eighty guineas, and, as far as I could ascertain, the gardener who produced this fine plant was not an Orchid grower, nor did he make any pretence to practical knowledge of the subject. The plant had been put into a *Cucumber* house, and took twelve years to produce its first flowers; whereas under the usual system of culture the plants flower splendidly the second or third year after their introduction.

A good Orchid grower called here the other day, and on observing some plants of *Lælia majalis*, he informed me that he had recently seen a collection, and the only Orchids doing well were plants, of this same *L. majalis*, and they had been grown in a house with no shade at all. I have before alluded to the fine collection of *Phalænopsis* belonging to the late Mr. Partington, and the gardener who grew them so well informed me that he kept the atmosphere well on the dry side in winter, and in summer a double shading was used whenever the weather was too hot and the sunshine likely to affect them; moreover, the paths and stages, which were of coarse gravel, had a good dressing of salt annually. Chemists might say that salt could not have any effect by evaporation, but a gardener or an amateur feels his way to success, and may be quite ignorant of chemistry or any other science. It is well known that the *Phalænopsis* is found in its native habitat so near the coast line, that the plants are almost washed by the salt spray. Experienced Orchid growers are also well aware that certain plants will do very well in one position in the house, but if shifted to another position in the same house they may not do quite so well, and it is also remarkable what a very large number of species and varieties of Orchids can be grown in one house when the right positions have been provided for them. I have grown *Phalænopsis*, *Cattleyas*, *Cypripediums*, *Dendrobiums*, *Oncidium*, *Aerides*, *Epidendrum*, *Vandas*, *Lælias*, &c., all in one house, and would not hesitate at any time to undertake the culture both of *Cattleya* house Orchids and those belonging to tropical countries together by simply arranging those requiring most heat at the warmest end. I would give the *Cattleyas* 2° or 3° more heat than is usually recommended, and the warm house plants 2° or 3° less. Moreover, it would not be wise to attempt the culture of any Orchids difficult to grow. An amateur had better go in for such Orchids as *Cattleya Mossiæ*, *C. Mendeli*, *C. labiata*, *Lælia anceps*, *L. purpurata*, *Cymbidium Lowianum*, and such *Odontoglossum* as *O. citrosum*, *O. vexillarium* (*Miltonia*) and others. An immense number of *Cypripedium* can also be grown in the *Cattleya* house, and the flowers are so long-lasting either on the plant or in a cut state, that they are considered the best possible plants to grow either for home use or to cut for market.

The cool house Orchids are quite distinct from the others in their requirements, and it does not answer to grow them in the *Cattleya* house even. Cool house Orchids are not at all difficult to grow, in fact they are the easiest of all, and the flowers of most of them last long in good condition—so long, that the plants become exhausted through the efforts to support them. Some of the best species and varieties are the popular *Odontoglossum crispum* in its numerous varieties, the more graceful *Odontoglossum Pescatorei*, *O. triumphans*, *O. Halli*, and *O. luteo-purpureum* with their numerous natural hybrids. It has been found exceedingly difficult to cross-fertilise these *Odontoglossum*s to obtain good seed from them in our gardens, but where different species grow together in their native habitat they are frequently cross-fertilised by insect agency, and by the colour and form of the flowers it is not difficult to distinguish the source from which they have been derived. The *Masdevallias* are easily grown, and the most

useful are *M. Veitchiana*, *M. Harryana*, *M. Lindenii*, *M. ignea*, *M. Davisii*, and the pretty little *M. tovarensis*. The few *Oncidium*s which succeed in the cool house surpass any that are natives of more tropical climes, such as *O. macranthum* and *O. Marshallianum*. There is no need to set any house entirely apart for Orchids. We grow many beautiful Ferns in our cool house, including the best of the *Gleichenias*, and all our *Chrysanthemum* cuttings are struck in it. In fact, all Orchid houses should be made interesting by the presence of other tropical plants suitable to the temperature.

J. DOUGLAS.

PLANT HOUSES.

THE CONSERVATORY ARRANGEMENT.—Every effort should now be made to have this department as attractive as it is possible to make it. In order to do this more effectually so as to admit of a few plants which in the usual course should have more warmth, it will be found advisable to slightly increase the temperature. Thus, if 45° as the minimum has been the rule, 50° might be aimed at just for a few weeks, less of the two certainly than beyond that standard. This increase will require to be modified in a measure by increasing the atmospheric moisture if *Camellias* in any number are permanent occupants of the house, or if they are in pots, these also needing more at the roots as well. By choosing the warmer end it is thus possible to keep late *Poinsettias* and other moderately hardy stove plants with a fair amount of safety. It would not of course be advisable to risk plants that are not increased annually from cuttings, or which it is intended afterwards to grow on. In a cooler temperature the chief thing to guard against is over-watering; when plants are thus being used they take far less water, the better plan being to allow them to be almost on the point of flagging before giving them any.

By having a good supply of such flowers as the Roman Hyacinth, not forgetting the newer addition in this way, the straw-coloured French variety, which I take every opportunity of recommending because of its colour, a pale, clear yellow, it being at the same time as free as the well-known Roman. *Duc Van Thol* Tulips (the crimson, the scarlet, the yellow and the white) are also extremely useful now; so are the double Roman and the early Snowflake *Narcissi*. The essential advantage of these early bulbs is that they can be used in places where we would not care to place double *Primulas* or well-grown single varieties, as well as *Carrations*, *Ericas* and *Eparises*. If the bulbs be shaded or have an otherwise unfavourable position, it is not of material consequence as far as the future is concerned. The grouping should therefore follow in each particular case, according to its peculiar circumstances. The bulbs, it is as well to add, will look all the better if covered upon the surface with a little green Moss, as the pots will not be any too well hidden with foliage. If Moss be scarce, a small Fern, if stood between each pot of bulbs, will have the desired effect. The better and more particular plants, as far as position is concerned, should have the most light and other advantages given them as far as possible. The Ferns used should be of the hardier kinds, as *Pteris serrulata* and small *Aspleniums*, such sorts as *A. bulbiferum* and *A. flaccidum* in 3-inch and 4-inch pots; a stock of such size and kinds is always useful.

CLIMBING PLANTS.—The climbers in the conservatory, if not already thinned out or pruned according to their several needs, should have this attention given to them. Indiscriminate pruning is altogether a mistake; thus to prune *Habrothamnus Newellii* now would be utterly wrong; rather save every shoot and prune immediately after the flowering season in the spring. Another instance is the well-known, but none too frequently grown *Bougainvillea spectabilis*, which in contradistinction to *B. glabra*, flowers from the terminals of the previous year; here, again, pruning would be wrong. Instances need not be multiplied beyond these two. *Lapagerias* should be carefully thinned,

merely taking away the weaker or spray-like shoots. See that this plant does not get dry at the roots; it should never suffer from this cause. Look closely after young shoots, which in favourable positions may soon be pushing up from the base, and guard against slugs and even snails; these shoots appear sometimes farther away than one would for the moment think of looking. Where large or medium-sized plants are in pots or tubs and there is any idea of planting out, it had better be attended to at once, using rough loam and peat, turfy and fibrous, with a liberal addition of road scrapings or silver sand.

Plumbago capensis may be pruned hard and be thinned freely, too much wood if left being a check to strong growth, which is the best for flowering. *Tacsorias* should be pruned moderately, spur-pruning rather than cutting hard back being advisable. *Solanum jasminoides* should be cut back freely, otherwise it becomes master of the situation. *Cobæa scandens* requires similar treatment, but the best check to this climber is to drape its shoots, letting them as far as possible hang downwards, thinning out the rest as growth proceeds. Roses in conservatories which are not kept absolutely cool are rather awkward to manage at times, being predisposed to start into growth too soon. To remedy this in a measure it is best to keep them quite on the dry side for the time being. Any climbers which are known to be a trifle tender should, if possible, be dropped from the roof to where it is a little warmer. Thus treated, they may be kept safely. *Passiflora quadrangularis* is thus wintered here in a house which in the coldest parts often drops to 36° and lower, but the plant in question has its roots near the pipes and the shoots away from the glass. The white scale often troubles conservatory climbers that are of a hard woody character. Wherever this pest exists, no time should be lost in attacking it with determination whilst work in other quarters is not so immediate and pressing.

JAMES HUDSON.

FRUIT HOUSES.

PINES.—If ripe fruit is wanted in May, a batch of well-prepared plants of the Queen variety should be started not later than the first week in January. A light compartment, or the warmest and lightest end of a larger house ought to be got ready at once, commencing by thoroughly cleansing the glass and woodwork, the walls being limewashed. A brisk bottom-heat is most essential, and if it is generated by either good Oak or Beech leaves in quantity, that will answer best. A mixture of spent tanner's bark and leaves is sometimes tried with good results, but tanner's bark alone is not recommended now-a-days, owing to its heating powers being greatly impaired in the tan-yard. Stable manure is apt to heat too violently and does not last long enough. Some kind of plunging and gently heating material is needed even if the bottom-heat supplied by hot-water pipes is very strong, a very dry heat being undesirable. Plants to be started ought to have their pots well filled with roots and should have been previously kept somewhat cool and dry at the roots. A bottom-heat of about 90° should start the flower-heads quickly. Plunge rather loosely at first, well ramming the heating material about the pots after it is seen there is no likelihood of injurious overheating taking place. A top-heat of 70° by night and an increase to 80° on sunny days is sufficient to start with, and after giving just enough water to moisten the soil in the pots, keep the plants on the dry side till it is seen flower-heads are showing. If watered too freely many of them may commence a fresh leaf growth instead of fruiting. A rather moist atmosphere should be maintained by damping down the walls and floors. Should there be any fruit well advanced towards ripening, these also would be benefited by an increase of bottom-heat, the plants being plunged alongside those newly started. These must be kept uniformly moist at the roots, a little liquid manure being given each time water is required. When

colouring commences give no more liquid manure and little or no more water.

SUCCESSIONAL AND YOUNG PINES.—In order to be certain of a good succession of fruit during June and July, a portion of the stock of fully grown plants of Queens should be kept for starting a month or six weeks hence. These must be kept rather cool, the temperature of the house ranging from 55° to 60°, and the pots being plunged in comparatively cool, moist material, no water should be needed or given for the present. Extra strong well-rooted suckers of Cayenne and Rothschild if shifted into their fruiting pots now and kept growing in a brisk top and bottom heat would develop into good plants for fruiting next winter. Use a rough fibrous loamy compost, avoid over-potting, and water very carefully at the outset. Other rooted suckers should have the benefit of a bottom heat of about 75°, the top heat being kept at 55° to 60°. They ought not to be allowed to become very dry at the roots, but if all are looked over every week and watered when dry, no severe check will be experienced and premature fruiting be prevented accordingly. Strong suckers from late fruiterers may be taken off and placed in 6 inch pots, these being plunged in a bottom heat of 85°, the top heat being kept at from 60° to 65°.

FIGS.—The earliest crops are best obtained by the aid of trees in pots, these being plunged in a brisk bottom heat of about 80°. If the pots are set on loose brick piers the heating material can be banked up round them, loosely at first, and when the heat declines, more solidly, renewing it when necessary without disturbing the pots. Start with a top heat of from 50° to 55°, increasing this another 5° after top growth has well commenced. Syringe overhead freely at least three times a day, and keep the roots uniformly moist. Strongly-rooted trees should be given a rich top-dressing when top and root action has commenced, a mixture of equal parts of turfy loam and nearly fresh horse droppings answering well. Trees rooting in narrow borders or otherwise restricted ought now to be in readiness for starting, but may well be kept cool for another three weeks. Later trees should be pruned, taking care to leave a sprinkling of well-ripened young shoots all over the trellis or wall area. A few of the longest and most naked branches should be sawn off near to the main stems, others being shortened back to well-placed back growths, this being done with a view to keeping the centre of the trees properly furnished with bearing wood. It is not safe to syringe Figs with petroleum and water, and if there be any mealy bug or scale on the trees, the better plan is to well scrub the whole of the wood with thoroughly hot soapy water. The old wood may also be dressed with a weak mixture of clayey water and gas tar, though if the scrubbing with hot water is properly carried out there ought to be no necessity for this. The borders ought not to be neglected, but should be kept regularly moist, a fairly rich top-dressing being given in all cases where the soil is well occupied by roots. Avoid planting young trees in a rich compost. A mixture of fresh loamy soil and mortar rubbish, three parts of the former to one of the latter, is quite strong enough at the outset, and even this must be put together firmly, or the growth of the trees may be very sappy and unfruitful for the first year or two.

EARLIEST PEACHES.—These have started quickly and strongly, and that, too, without the aid of much fire-heat. Supposing the night temperature was kept at from 45° to 50° by night and 5° or rather more higher in the daytime, an increase all round of 5° may be given with advantage. When the trees are coming into bloom, cease overhead syringing for a time and attend well to fertilising the flowers. This should be done towards midday, and either with a camel's-hair brush or, better still, a rabbit's tail tied to a long stick. Most pollen will be found on the small flowering varieties, and if these are touched over first, some of it will be transferred to the flowers of the less free setters. Very little disbudding ought to be resorted to just yet, and not many young growths should be rubbed off at one time.

EARLY STRAWBERRIES.—Those given the benefit of a gentle bottom-heat have started remarkably well. Before the flowers expand, move all the more forward plants to shelves at the back of forcing houses where they will open strongly and be more easily attended to. Many probably will have a ready struck root from out of the bottom of the pots, and in any case they ought not to be suddenly shifted from moist to comparatively dry quarters. If the shelves are covered with a good thickness of fresh Moss and this be kept constantly moist, the roots will soon take possession of this and the plants be otherwise benefited. When the flowers are fully expanded, the pollen ought to be evenly and surely distributed with the aid of a camel's-hair brush, the plants being gone over towards noon every day. Unless this is done the chances are a light crop of imperfectly formed fruit will be the outcome. Introduce more plants into the pits to be started in bottom-heat, and more should also be placed on shelves in gently heated Pea-houses and vineries, where they will start strongly, if slowly.

PRACTICAL.

KITCHEN GARDEN.

FORCED POTATOES.

THE demand for forced vegetables in most establishments seems to be constantly increasing, even in gardens where there is but little convenience for such work. The trouble to bring things forward where there is no proper accommodation is considerable, but this seems to be taken little account of, some people who have a garden thinking that everything ought to be grown in the same manner as if all the modern appliances that are needed for their successful growth were at hand. Over-crowding, as all gardeners know, soon causes weakly shoots. Much, however, may be done by having a thorough knowledge of a plant's wants, but no amount of experience will cause things to grow to perfection if the surroundings are adverse to their growth. Take for example a frameful of Potatoes. The sets of these are usually started in shallow boxes in heat; they are afterwards planted where the soil and surrounding atmosphere are warm and moist. Owing to the fermenting material employed in making up the bed, growth pushes freely in the course of a few days, so that the young tender shoots appear above the soil. Earthing up is then done, by which time the heat of the bed begins to decline, and if there be no means of raising its temperature, growth receives a check, which usually comes at a time the young tubers are forming, so that they do not grow out so rapidly as they ought or as they would had the same degree of warmth been maintained. No doubt this difficulty to some extent may be obviated by having properly heated pits, for then there would be a more uniform temperature, but where the cultivator has to depend for his heat on fermenting material he is placed at a great disadvantage. Look at the conditions under which Potatoes are grown naturally; there we find the outer soil gets warmed as growth proceeds, till by the time the tubers are formed it has reached the maximum temperature, so that instead of there being any hindrance, growth goes steadily on till the tubers have attained their full size. If this be taken into consideration, it will then be understood that in forcing this vegetable the heat of the soil in like manner should be maintained, if not increased as growth proceeds, instead of being allowed to decline, as is so often the case, causing the tubers to set their skins prematurely and to eat watery. It is much the best plan to plant in pits heated by hot water and

not requiring any heating material, as by this means there would be no decline in the temperature of the soil. The beds should be well drained and at least 9 inches of soil used for planting. The soil ought not to be nearer to the glass than 18 inches, for if the foliage comes into contact with it, it is liable to be injured through frost. Water should be sparingly used for this crop, and the soil should be rich enough in the first instance to cause a free growth without the aid of any fertiliser; in fact, it cannot well be too rich if it is light and porous. A little kainit, however, is very beneficial to the young tubers if given before earthing, unless the soil naturally contains salt. Sufficient moisture must be maintained in the soil to keep the plants growing, but at no time should it approach a wet state, for this has a tendency to lower its temperature, thereby causing stagnation in growth. Air should be admitted on all favourable occasions, but the temperature should never be lowered by so doing, for, though it is necessary to plant life, a sudden lowering thereby brings on disease. As the foliage of Potatoes is so near the glass when grown in pits, a great amount of air circulates amongst it by passing through the laps of the glass; but should sufficient not be admitted in this manner, a ventilator placed in front of the pipes will usually admit all that is needed in such weather. When the sun is bright in the middle of the day, the lights may be tilted a trifle at the back, but a cold current must be strictly guarded against. H. C. P.

Rhubarb Prince Albert.—I believe this is still the best forcing Rhubarb in existence if it can be obtained true. This, however, is a difficult matter, as various sorts are palmed off as Prince Albert which are altogether inferior to it. Some years ago I obtained roots from an Essex garden where I knew the true variety existed, and have ever since been able to pull Rhubarb in three weeks from the time of placing the stools in heat. In the garden above referred to I have seen it in snowy weather in spring pushing its heads through the slight mounds of litter which had been placed over the crowns to protect them. It is of medium stoutness, of a deep crimson colour, and is a great favourite in the kitchen. One characteristic of the true Prince Albert is the absence of a cavity down one side of the stick, which may be seen in nearly all other sorts.—JOHN CRAWFORD.

TOMATOES FOR WINTER USE.

THERE is no disputing the fact that Tomatoes are most in demand during the warmer parts of the year, and would be even during the winter months if they could be had as cheaply. From March till the end of September well-ripened Tomatoes are largely eaten in a raw state as a salad, and if good sound fruits, or any ripened on the plants in heat, were forthcoming in colder weather, there would yet be many only too glad to have them daily in an uncooked state. Why there are fewer in the markets at this time of year is principally because it does not pay to grow them, or rather market growers are under the impression that such is the case. In this I think they err somewhat, and would strongly advise them to make yet one more attempt to cultivate Tomatoes for winter consumption. As far as very many private gardeners are concerned, there must be no complete break in the supply of Tomatoes. Common vegetables are plentiful enough, and what we want during the winter is choicer kinds with a little character about them. In Tomatoes are comprised so many good qualities, that their value during the duller

parts of the year can scarcely be over-estimated. Even if they only tended to create an appetite, that would be much in their favour, but, if experts are to be believed, they combine medicinal properties with their other qualities. Instead, therefore, of so much room and attention being bestowed upon their cultivation from March to October would it not be a step in the right direction to take proper precautions to have them good and fairly plentiful from November till February inclusive?

In order to be thoroughly successful with winter Tomatoes, an earlier start with the plants must be made than is often thought necessary, or otherwise failure, partial or complete, is almost inevitable. The crops will not go on setting and swelling freely during the cold short days of the late autumn and winter months, and it is only a waste of house room and fuel trying to make them behave differently. No; the crops must be set in August or September at the latest, and they will then be nearly or quite fully grown before the unfavourable weather arrives. The seed should be sown in June and the plants got into their fruiting quarters late in July or early in August. Some of the fruit may ripen before it is really wanted, but by far the greater bulk would not do so, but would ripen slowly and surely in succession during the whole of the winter. No one ought to keep a house or houses empty waiting for a stock of Tomato plants to fruit during the winter, but if they were regarded as a close and natural succession to Cucumbers, then few or no mistakes would be made. Late Tomatoes might also succeed a batch of early Tomatoes that have been fruited in pots.

Pot culture also answers well in the case of winter Tomatoes, these being either set on the back shelves in three-quarter-roofed forcing houses, or along the fronts of the same, the plants being trained up the roof with one stem only. They succeed equally well, sometimes even better, in boxes of different kinds, and require less water than when in pots. They are still less trouble when planted out in a border or narrow ridge of perfectly fresh loamy soil. Tomatoes should never follow Cucumbers as far as the soil is concerned, as the latter are only too likely to leave a legacy of eel-worms behind, than which there are no worse enemies to Tomato roots, and therefore to the crops. When the start is made much later than the dates given, there should be no planting out in beds or ridges of soil, or the chances are very many of the plants will die off in an almost unaccountable manner. Soon after a cluster or two of fruit has set, a close observer may notice a contraction and discolouring at the stems just above the soil, but it may be several days or even weeks before the plants flag badly, owing to the disease having effectually cut off the connection with the roots. Apparently this is simply the outcome of tropical plants being treated more as denizens of the temperate zone, as it has been repeatedly proved that pot plants seldom behave similarly, owing, presumably, to the extra warmth that reaches the roots. Other troubles may also be caused by being either too free with the watering-pot or manures of any kind, while diseases of a fungoid nature are inevitably rife and destructive if too much moisture is maintained in the air. Very high temperatures are not recommended, but it does not follow Tomatoes will long stand being exposed to low temperatures and damp. If they can be kept at about 55° by night and from 60° to 65° in the daytime, a little air being given on mild days, they will do well, an occasional drop of from 5° to 10° in frosty weather not signifying much. When the roots

are well furnished with plants hung with great clusters of fruit—and this is by no means difficult of achievement, always provided the start is made in good time—there are no such failures in the winter. Once the fruit is nearly or quite fully grown, it will ripen well even though disease does over-run most of the leaves, but if late-planted Tomatoes become diseased, they will not do much good. It is worthy of note that neither fruiterers nor those who eat Tomatoes are fastidious as to the form and colour of the fruit during the winter, though perhaps they would be more particular if they were more plentiful. Those varieties with a little of the Large Red blood in them are naturally the freest setters, and they are of passable quality, but Chemin Rouge, Challenger, and Ham Green Favourite set freely enough and are of decidedly superior flavour. W. I.

A running Kidney Bean.—On page 504 of THE GARDEN of December 2 there appears a note from Messrs. Sutton and Sons, respecting the remarks made by Mr. Iggulden (p. 472) describing and recommending a climbing French Bean he saw at Longford Castle some years ago. Messrs. Sutton say that a variety sent out by them in 1892 under the name of Tender and True is exactly what Mr. Iggulden describes as having seen at Longford. This, to some readers, may be misleading, and we therefore think it necessary in our own interest, as well as on public grounds, to state the following facts. The Bean Mr. Iggulden refers to was raised by Mr. H. W. Ward, of Longford Castle Gardens, and in March, 1891, he sent us a trial packet. Our trial of it in that year and in 1892 and 1893 so confirmed the good report we had received of the Bean in 1890, that we have obtained the entire stock from Mr. Ward, and will distribute it at once under the name by which it was certificated at both Taunton and Exeter flower shows in August last. We grew a row of Tender and True alongside of it this year, and it was apparent to the most casual observer that the two were distinct from one another, for while, as Messrs. Sutton state, Tender and True was only 4 feet high, our Bean ran up to 6 feet or 7 feet, and was proportionally more vigorous in every way and much more prolific. The same conclusion was come to by a well-known writer on vegetables who saw Mr. Ward's Bean growing at Longford, and had before that seen Messrs. Sutton's Bean growing.—R. VEITCH AND SON, Exeter.

ORCHARD AND FRUIT GARDEN.

WORK IN THE ORCHARDS.

OWNERS of neglected old orchards are at last awakening to the fact that these would well repay for being taken in hand with a view to gradual renovation. Doubtless the finest fruit, as a rule, is to be had from comparatively young trees, but these latter are many years before they attain a size equal to the production of 20 bushels or more of fruit, while in the case of that valuable variety Blenheim Pippin, large old trees are much the surest bearers, fine fruit being also had from them. In most cases neglected trees are of poor varieties, and in any case much too crowded, perhaps badly overrun by Moss and Lichen, and nearly always starved at the roots. All these shortcomings have been duly brought home to many proprietors of orchards, and remedies also suggested, but surely the propounders of the latter had no conception of the interpretation that would be put upon the latter, or their advice would have been more explicit. For instance, one owner of large standard Apple trees decided to re-graft these

with superior varieties, and being under the impression, or having heard that a considerable number of grafts should be placed on each tree, had sawn the trees off just below where the stem commenced to branch, and then inserted the grafts as thickly as possible all round the edge. When I saw them about one half were growing strongly, and the prospect of ultimate crowding and confusion was only too evident. In any case it is a mistake to cut down the trees thus severely, as the aim should be to change their character, and yet not have to wait three or four years before fairly heavy crops of fruit are again had from them. The proper course to pursue is to cleanly saw off the branches 12 inches or so from where they have divided a third or fourth time, this being done now, and to insert one or two grafts in each when sap movement commences next spring. It should also be decided now what varieties are to be used as scions next spring, and the requisite number of straight young shoots ought to be obtained and half plunged behind a north wall, fence, or hedge. Bundles of this young wood should be opened out before being plunged in the ground, or otherwise those in the centre may fail to touch the soil and dry up accordingly. Being stored in this manner they will keep perfectly fresh, and the sap movement will be considerably retarded. Seeing that the union of scion with the stock is more likely to take place when the sap movement in the latter is in advance of that in the scion, the importance of retarding the latter becomes evident enough. There is also another good reason why the scions or grafts should be looked up now. Deferred till near the end of the pruning season, the chances are the requisite supplies will not be available.

In the same neighbourhood that I saw the re-grafting already alluded to, another orchard owner had applied very drastic renovating measures, or what were intended as such. The tops of the trees were at one time undoubtedly far too crowded for producing profitable crops, and as a matter of fact only the outside branches of the outer rows and quite the upper surface of the rest had borne good crops for a long time past. When, however, thinning and pruning became the order of the day, enough wood was cut out to fill several waggons after being made into faggots. That is not the first time by a long way that I have seen orchard trees thus recklessly thinned out, and according to precedent it will be several years before the recovery is complete. Thinning out when long delayed must be moderately severe, but the process should extend over two or three years. When the limbs are lopped off wholesale, this must have a most paralyzing effect on the roots, and does so to the extent of materially checking top growth for at least one clear season. All the half dead underwood may safely be sawn cleanly out at once, but the thinning out of the better placed branches should be of a more piecemeal character, the aim being to let more daylight and air into the centres of the trees, and also to promote the formation of fresh healthy young wood. This latter should gradually replace the older wood till eventually most of the latter is got rid of, and it will then be found that the crops of fruit obtained will be very much superior in quality to what were previously produced. Where the outer branches run too much into each other, practise fore-shortening or the cutting back of straggling branches to better placed inner ones, and this whether the trees are old or comparatively young. There should be no jagged or gaping wounds made by downward strokes of the bill-hook, but the pruning should be principally

done with a small saw, the edges of the wounds being rounded off with a chisel.

Clearing the main branches and trunks of Moss and Lichen is a remedial measure that no one will err in adopting in some form or other. These parasites effectually exclude air and moisture from reaching the inner bark, and, in addition, afford protection for the larvæ and eggs of various insect pests. Scraping the stems and principal branches with an iron scraper of some kind is usually recommended, but I am of opinion that this somewhat laborious preliminary—for that is all it can be termed—is scarcely necessary. A free use of quicklime is one of the best remedies I know, and the simplest and most effective way of applying this is neither by shaking it through a bag all over the limbs when these are in a moist state, nor by mixing with water and brushing into the bark, but rather by mixing it with water and distributing it with a syringe or garden engine. Enough caustic lime should be dissolved in water to make this quite white without greatly thickening it, and after being passed through the finest of wire sieves this mixture must then be driven well into every crevice in the bark and very freely all over the lower part of the tree generally. This will be followed by the gradual disappearance of the Moss and Lichen, and unless the surroundings are low and badly drained, an occasional repetition of the dose will keep the trees free of the parasites in after years. Some few orchards may need draining afresh owing to the old drains being choked by the roots of either the fruit trees or, what is more probable, some of the large shelter trees that are wrongly tolerated near to very many orchards. Great overhanging Elms, Beeches, and such like should be cut down, and new deep drains formed midway between the rows of orchard trees wherever found necessary. Surface or open drains are also of good service in some few cases.

FEEDING.

The fact of fruit trees greatly impoverishing the soil is too often overlooked by many owners of orchards. The Americans, on the other hand, are fully alive to the importance of well sustaining the fertility of the soil, and resort to an easy and good way of accomplishing this. Instead of turning cattle and horses, including very destructive colts, into orchards to graze upon the trunks, limbs and branches of the trees as well as the Grass, our more shrewd rivals prefer to fold sheep among their trees, and feeding stuffs being liberally used, the sheep fatten rapidly, and at the same time greatly enrich the soil. In many cases there is nothing to prevent a similar practice being resorted to in this country with equally as good results. On cultivated ground a mixture of superphosphates and kainit would not unfrequently prove beneficial to the trees, this being applied now at the rate of three pounds of the former to one and a half pounds of the latter to each fairly large tree, this being sown well away from the stems and lightly stirred in with a hoe. It is, however, the grass covered orchards that are most impoverished and of which I am principally writing, and for these 5 cwts. of superphosphate of lime, mixed with 3 cwts. of kainit, would be none too much for one acre of ground. Well crush any lumps there may be, mix thoroughly, and sow broadcast over the whole of the ground. Unless applied now there is very little likelihood of these slowly-acting manures being washed down to the roots in time to do any good next season. Farmers and all who have large liquid manure tanks connected with their mixed cattle yards need not look beyond these for a good supply of manure.

The rainfall having been fairly heavy, the manure will be sufficiently diluted to apply direct from the tanks, and it is during the winter, or while yet the roots are inactive and the ground sufficiently moist to absorb and retain the manure, that it should be very freely given. Applied when the weather is hot and dry or when the ground is dry, strong farmyard liquid manure is worse than useless, and may easily do more harm than good. A heavy dressing of good, partially decayed farmyard manure, from 20 tons to 30 tons per acre being none too much for a first application, would also act most beneficially, this being spread broadcast, and applied now would have a good chance of being largely dissolved and washed down to the roots by the rains that should fall between this and May. If the dressing is delayed till the spring, much of the manure may cake badly, and the juices never reach the roots accordingly. Better, therefore, run the risk of some small portion of the manurial elements being washed down into the drains by the rains than that all of it should be locked up. Top-dressing with a mixture of fresh soil, and either good solid manures or mixtures of chemical manures, wood ashes and such like are sometimes recommended, and occasionally very curiously applied. Breaking up the surface of the ground and top-dressing to a distance of not more than 4 feet from the trunks of old orchard trees is little short of so much labour wasted. The feeding roots are principally or wholly as far away from the stem as the principal branches spread, and unless the top-dressings reach to a distance of not less than 10 feet from the trunks, I fail to see any great benefit that is likely to be derived from their application. There ought to be no deep digging resorted to, but the surface should be very lightly broken up with a fork so as not to disturb many surface roots, and instead of turving over again, roughly chop up the turf and return Grass side downwards. This will have the very beneficial effect of letting the air well into the roots, and the Grass will grow again quite soon enough. Old orchard or even single tree sites ought not to be replanted with young trees, though very many owners go to work in a manner to indicate they either think differently or else have not given the matter a second thought. Ground that has supported fruit trees for fifty years and upwards must be completely impoverished of very much that is needful to sustain fresh trees in a healthy, profitable state. Where a few old trees have either been blown down or grubbed out it may be desirable to plant some to take their place, but there ought to be no wholesale replacing of old trees by young ones. The stations for what few fresh trees are planted should be formed well away from where the old trees stood, and for every one of the latter put in two new ones, as it is very certain these will never attain the dimensions of the first occupants of an orchard. Nor is this all that ought to be done. The stations for new trees should be of not less than 6 feet in circumference, and much of the old soil to a good depth be either replaced by fresh loam, or be enlivened by a fairly rich loamy compost such as I have often advised should be given fruit trees. The collars of newly-planted trees ought to be kept well above the ordinary ground level to allow for sinking, while strong stakes should be placed to each tree and animals warded off.

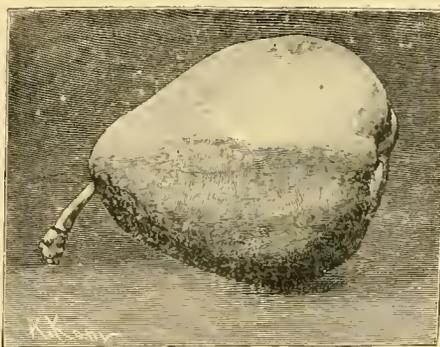

W. INGOLDEN.

Regrafting Apple trees.—Notwithstanding the enormous crop of Apples grown in this country during the present year, I question

whether it will make much difference to the sale of imported ones, for what with the bad keeping of kinds that usually do keep well, and the comparatively few varieties that are grown specially for keeping much after Christmas, there is a long period during which imported fruit is relied on by fruiterers, for the simple reason that they cannot get home-grown. I think we grow far too many early and second early sorts and neglect really late keepers. It is an undoubted fact that a great number of kinds that would keep for months are not only sold, but used direct from the tree, and that keeping for any length of time has not yet received the serious attention of English growers. My impression is that anyone going into Apple culture on a large scale ought to make the proper storage of the fruit one of the first considerations. I should advise the heading down at once of all the early sorts that do not find a ready sale, re-grafting in spring with some of the really good keepers, such as Wellington, Lane's Prince Albert, Bramley's Seedling, French Crab, Court Pendu Plat, Golden Knob, Alfriston, Northern Greening, &c. If re-grafting is done on the small branches it does not take long to get full bearing trees again.—J. G., *Hants.*

THE PEAR APPLE.

I SEND you a photograph of two Apples, which with many others of the normal shape grew on

The Pear Apple. Engraved for THE GARDEN from a photograph sent by Mr. Smale, Torquay.

one tree in the garden of Major Chillingworth, Torbay Hall, Torquay. The right hand fruit which you have engraved has the form of a Pear. Several gardeners who have seen it have mistaken it at first sight for a Pear, so complete is the resemblance. Yet it has the skin and eye of the Apple. Is it at all probable that the pollen of the Pear can have had any influence on this fruit? I should like to have an opinion on this point, or can any reason beyond mere chance be given for the form the fruit has taken? It is proposed to take care of the pips, sow them, and await the result.

W. B. SMALE.

Pruning Gooseberries.—In the excellent article on Gooseberries by "W. I." (see p. 566) reference is made to the fact that market growers prune far less, but get a great deal more fruit than many private gardeners. Gooseberry bushes at least ten years old, and which have never had any pruning more than to take out some of the strongest shoots for cuttings, are by no means too thick, from the fact that after the first three or four years they make but little wood growth indeed, even the terminal growths being short and stubby. It is the hard cutting that causes a forest of sappy shoots, and which when once begun necessitates still harder cutting to clear the centres of the bushes. As Gooseberries gathered in a green half grown state pay better than when allowed to get

fully ripe, market growers do not mind the bushes being thicker than would be thought correct by those who grow for exhibition. I was led to adopt this plan by seeing it practised in a small private garden, where, on noticing the enormous crop borne by some bushes, the gardener said the bushes had never had the knife at all. "We plant," said he, "young trees, let them grow in their own way, and when they get too big we plant young ones, grubbing the old ones up and burning them." Although a good many would not like the extreme course of dropping the pruning knife altogether, I feel certain that there would be a much more abundant supply of Gooseberries if pruning were more moderately done and later in the season.—J. G., *Gosport.*

The keeping of fruit.—Several notes have appeared upon this subject from various correspondents in different parts of the country both in this and other gardening papers. The most noticeable feature in my case has been the forward state of the dessert Pears; this appears to be pretty general. The only kinds now left in the fruit room are Beurré Rance, a splendid crop of medium-sized fruit which never fail to ripen in the best possible manner; Josephine de Malines, larger than usual, but not a heavy crop, a few dozens only for once in place of several bushels; and Ne Plus Meuris, also thin this season. The first named will, however, carry the season on towards the end of February without any difficulty. Catillac, still the best all-round stewing Pear, has as usual borne a heavy crop, which is of deeper colour than usual, being more fully matured after the manner of Jersey fruit. Now and again a fruit is found which has gone off or "turned sleepy," to use a familiar expression, but no fault can be found on the whole. Of Apples, I have this year one of the best and cleanest crops of Wellington, medium-sized, but clear in the skin, the past season having evidently suited it, the black spots being quite absent. Blenheim Orange is disposed to shrivel a little, but King of the Pippins is keeping well, as are most other kinds. In many instances the fruit this year has had to be gathered earlier than is wont to keep it from falling; probably this and the more rapid ripening have been a fertile source of non-keeping.—POMONA.

Well-ripened fruit buds.—On all sides one cannot fail to note the very promising appearance of fruit trees this pruning time, the buds being plentiful, whilst they also look sound and plump, all the wood likewise being thoroughly matured. I have been trying to forecast the future crop as to its early or late period of flowering, and have come to the conclusion that the well-matured buds will not start any earlier, if they do so early as usual, or, in other words, my impression is that the season will not be an early one. I have more than once noticed that it is the immature wood which starts into growth first, and I see no reason why this should not follow with the fruit buds; hence the latter if well ripened will not start so quickly. I may be wrong; still my impression is strongly in this direction. There has not yet been any too much rainfall for the fruit trees; this also is a consideration to be taken into account as regards the coming spring and the future crops.—G. H.

THE ORCHARDS.

TO THE EDITOR OF THE GARDEN.

SIR,—In the review you kindly gave of my treatise on fruit culture, "The Orchards," in last week's GARDEN your critic's remarks on the shortcomings and clerical errors are perfectly right and justifiable, but I cannot admit or agree with him that the industry I am advocating is ten years behind the times, or that the subject at the present time has no claim for further development. No doubt if the same interest had been taken twenty years ago as now, the country would have been greatly benefited; but even now, however late in the day, it will possibly take another ten years before the cultivation of fruit by the farmer is brought up to a high standard. I have not the pleasure of

knowing your correspondent, and have no knowledge as to the locality from which he draws his conclusions, but I can imagine that it must be advanced and "quite up to date" in all matters of fruit culture. I am, however, quite competent to speak as to the conditions of my own and the adjoining counties, and can vouch for the truth that there is not one farmer in a hundred who knows anything about fruit growing, and it will take a vast amount of teaching before he is brought to understand what to grow and how to grow it. In advocating the culture of fruit upon every holding, I am not so rash as to suppose that it will entirely take the place of corn growing, nor have I advanced such a theory; but what I do advise is that it should be adopted as an adjunct to the farm in all localities where fruit can be grown, and this together with other industries would be the means of helping the farmer to pay his rent. But for a farmer to stubbornly persist in growing corn at present prices can only result in his ruin. By having recommended this industry to the farmer in this manner, I fail to see where the "mischievousness" comes in or how "misleading." Rather than disparage such an important industry it would be far wiser to do everything possible to encourage the production of a better class and quality of fruit, as well as to extend its cultivation; and when a better sample has been produced and sent in proper condition to market, there will be no difficulty whatever in selling or realising good prices. It is the amount of rubbish that is sent into the market that kills it and ruins sales and prices. Only a week or nine days ago I was in Covent Garden Market, and there saw barrels and baskets of Apples, miserable, wretched samples one would hardly suppose people would take the trouble to pick up. That a readier outlet and a better means for the grower to dispose of his fruit are needed everyone must admit, and when fruit of a better class and quality is produced and more pains taken in grading and packing, these difficulties will soon be overcome. "W. I." gives an instance of a large fruit plantation in Gloucestershire which had been under cultivation eight years before it was made to realise 5 per cent. profit. Surely if small fruits had been grown and mixed plantations made, there would have been no occasion to have waited eight years before making profitable returns. Against this I can give an instance of a farmer in this neighbourhood who three years ago planted fifty acres of Strawberries; the second year he had a good paying crop, and the third, viz., last year, he realised between £30 and £40 per acre. I do not say that all farmers can do this, but there are few farms where something in the way of fruit growing cannot be done. Nor do I wish to make believe that there are no drawbacks to fruit-growing, or that there are not occasional failures, but under good management I maintain that fruit growing in this country is a profitable investment, and that money is to be made at it. The same cannot be said of other crops (excepting perhaps Hops) that are now being grown on the farm.

King's Acre, Hereford.

JOHN CRANSTON.

ROSE GARDEN.

FORCING HYBRID PERPETUALS.

GRAND and varied in colour as the Tea-scented and Noisette Roses are, we are obliged to go to the Hybrid Perpetual class for anything darker in colour than Reine Marie Henriette. True, there are others—Souvenir de Thérèse Levat and Alphonse Karr for example, but these are not so suitable for forcing as some of the freer blooming Hybrid Perpetuals. The superiority of the Teas over the Hybrid Perpetuals for this purpose is so marked, that we can have little encouragement to grow any others than the very dark shades. Even with such free-flowering varieties as General Jacqueminot, we do not find the quality in their second crop maintained so highly as is the case with Teas.

In addition to the variety named we have Prince C. de Rohan, Fisher Holmes, Annie Wood, Abel Carrière, and Charles Lefebvre which will afford intensely deep colours not to be found in the Teas. All of these grow freely, and will produce a large number of useful blooms if not pruned too severely. Medium size and quality, with quantity, seem to me the chief object in early forced Roses, and where a stout shoot of 3 feet to 5 feet has been produced upon the plants, it is a great mistake to prune this so hard as the majority of Hybrid Perpetuals are served. When pruned hard we get two, or at the most three blooms from such a growth. I counted the blooms upon some of our plants last season, and found them average nine flowers to each shoot of this style and strength. But these had not been cut back to within a foot or so of the joint they broke from; in short, they were treated as nearly like pegged-down plants as the fact of their being in pots would allow. The plants were stood on one of the side borders of my Rose house, and a few short sticks fixed either in the pots or in the soil between them as the length of the shoots required. It being impossible to keep each plant's growth confined to its own pot, I did not attempt anything in this direction, but simply tied the shoots down to fill up the space as evenly as possible. This, the last week in December, will see the same border filled again, and as it has proved so successful a method of getting a number of dark-coloured Hybrid Perpetuals, I propose to give my routine of operations from this point.

Before bringing the plants into the house I trimmed out the few weakly shoots there were, looked to the drainage, and mulched them with a rich compost. This is generally done before they are stood into a pit towards the latter part of October, but pressure of work during the past autumn compelled me to place them under cover and do the mulching, &c., while shifting them to their flowering quarters. I do not approve of this so well as if done earlier. Throughout their growing and blooming period they are treated exactly the same as other pot Roses, and are, in fact, in a house occupied by Teas and Noisettes, with the exception of this one side border. Where the shoots are grown on any but the horizontal system I find them far too tall for side borders; nor do they flower throughout their length, all but the few eyes at their extremity remaining dormant. When grown as I have endeavoured to point out, I get flowers from almost every eye, and I have had shoots of Abel Carrière bearing two dozen blooms at once. Good as this Rose is outside, it is far better under glass, and provides a deeper and more glowing maroon than any other of the dark varieties when under cover. I think this section of Roses derives much of the velvety characteristics from a freer ventilation than it is safe to afford them under glass. The average height of the growths will not exceed 2½ feet, including the depth of the pots, so that it is evident they are very suitable for a low bench or border when grown as above. Taken as a body, I do not think the Hybrid Perpetuals will bear so hard forcing as the Teas, and so make it a practice to omit them from my earliest batch. Those I am now treating upon will have very steady heat until I can see the flower-buds; after this point there is no danger in hurrying them on. Like the climbing Teas and Noisettes, they will have their wood which has flowered cut away soon after the blooms are secured, strong growths from the base being the most useful for a second season. The fact of cutting this growth away allows of the blooms being gathered with as much stem and foliage as they possess, and thus greatly increases their value and beauty. Many of my readers have admired the heavy crops of bloom seen upon a bed of pegged-down Roses, and can imagine from that picture the usefulness of this system under glass. When pruning them back, I stir over the surface soil and stard the pots a little closer together, growing the stout sucker-like shoots in an upright direction similar to the young rods of Maréchal Niel and others. They do not often reach more than 4 feet, although I have had them occasionally go to double that

length. Ripening of these rods is secured by standing them outside during summer and autumn, and they are encouraged to grow strongly until this time. It is a mistake to feed with artificial and liquid manures while they are flowering and withhold this aid during the time their later growth is being made. Vary these stimulants about every two weeks, change of food being very beneficial. R.

CANKER IN ROSES.

ON page 518 Mr. J. C. Clarke has a very interesting note upon the above. I am glad that he, too, thinks soil has a great influence upon canker in Roses. Respecting canker upon Apples and Plums, I think both soil and stock have great influence. During the past summer I saw a quantity of fruit trees upon their own roots. Ribston Pippin and Lord Suffield were remarkably healthy and quite free from any canker, but young grafted plants of the same varieties were entirely ruined by it. In this case soil was not so much the cause as the stock; both were growing side by side. I have noticed many instances among Roses where one plant out of many developed canker with exceeding rapidity, and yet its neighbours under precisely similar conditions were exempt. One such case occurs to me where I carefully lifted the plant, and gave it and the soil a thorough overhauling. I did not find any swelling at the point of union which seemed sufficiently severe to cause this attack; several of the healthy plants possessed quite as much. Nor was there any difference in the soil. But when I made a thorough examination much was explained, to my thorough satisfaction as far as this instance was concerned. An overflow pipe from a cesspool ran from 3 feet to 4 feet deep in the soil. This was made of the common clay pipes used for land draining, and the roots of the Maréchal had penetrated the interstices and forced the pipes more open still. Consequently the surrounding soil was charged with moisture and a strong fertiliser. I found a good proportion of the roots quite dead, and attributed this to the saturation all through the dormant period with so powerful liquid. As a rule I have found canker more prevalent upon cold soils, especially those which lie very wet during the winter. Strange to say, I find it upon extra light soils also, so that this does not prove the soil to be the only cause. Nor can the stock be blamed entirely, for plants upon their own roots are also subject to canker.

There is much in Mr. Clarke's note respecting mildew attacks upon young wood, and I believe this and any little injury of similar nature may often lead to canker. I will not go so far as to say it causes it, but in the case of varieties so subject to this disease as Maréchal Niel and William Allen Richardson, I am certain it conduces to its development. In all cases where I have cut open and carefully examined any of the protuberances caused by canker above the soil, I have found a few insects. These have varied, but none the less it seemed that they had punctured the bark in a young state and been feeding upon the sap which exuded. We get very much the same protuberances when the American blight attacks Apples, and it certainly seems as if insects had the same effect with canker. We know how fond insect life is of the sweet juices which exude from any injury, and which would, if left undisturbed, soon form into a healthy callus. In a previous note I called attention to unequal growth, or rather disposition towards this, as a probable cause of canker, and I think we can either find one of the above causes strongly pronounced, or else a combination of many.

About ten years ago I was called in to look at a house filled with Maréchal Niel Rose. The plants had covered the roof and were breaking most satisfactorily. The owner was looking forward to a most profitable crop and contemplated filling other houses in the same manner. These were all grafted plants and had been grown in 10-inch pots the first season. Stood upon a bank of turfy loam

down each side of the house, they had soon rooted through the pots. After the first crop they grew rampantly, and when it was contemplated to remove them to the open for more efficient ripening, they were so firmly rooted into the turfy border that this was found impossible. I saw them the following spring and they had then been covered with more soil some 3 inches above the pot. Just as the buds were forming it was evident they were one and all developing canker rapidly; in fact, hardly any of the flowers were worth cutting. I saw them being removed and every one had been constricted at the root where it emerged from the bottom of the pot. In some cases the swelling was enormous and upon both sides of the constricted part.

RIDGEWOOD.

The Sweet Brier.—There have been several notes of late on wild Roses and their fruits in addition to the interesting and instructive article from the pen of Mr. Lynch, but the common Sweet Brier hardly ever has its due. Very few plant it in any quantity, and yet it is charming nearly the year round, for scarce has the last of its hedges fallen before the buds begin to burst. Through autumn and winter, however, it is one of the brightest and best in fruit, which hangs in rich clusters long after every leaf has fallen, and provides many meals for birds and ground vermin. In addition to its many aspects of beauty, the Sweet Brier is a most useful plant for protecting the garden from marauders. Cattle will not face it, and a good fringe at any vulnerable point of the garden will be found valuable.—A. H.

Rosa lucida.—Now that wild Roses are coming to the front this should be largely planted. We have a large fringe of it, and even when flowerless, leafless, and shorn of the last of its hedges, it still stands out conspicuous from its kindred by reason of the red bark of the shoots. When the sun shines upon the bushes they glow with colour, and produce as fine an effect as the Siberian Dogwood or the Cardinal Willow. An isolated bush would have the same effect, but as these wild Roses need no cultivation, they should not be treated as rarities or planted niggardly. They would admirably clothe the banks that are too often covered with the monotonous Laurel, Privet, and similar poor common things that are seen everywhere in great quantities.—A. H.

Cloth of Gold, or Chromatella was sent out in 1843 by Coquereau, and was in great favour until the appearance of *Maréchal Niel* in 1864. It is rather tender, but quite as strong a grower as *Maréchal Niel*. I cut some wood from a very old plant a few days ago; the stem is completely covered with Lichen, and is 4 inches or 5 inches in diameter. This plant carried a fair amount of bloom during the past summer, and has made excellent growth. As this is thoroughly matured and the plant stands in a sheltered position, which it has occupied for considerably over twenty years, the prospects of a comparatively good show of bloom next year are good. I use the word "comparatively" advisedly, for this Rose is perhaps the shyest bloomer of all the strong growers. During the past summer I had several blooms upon maiden plants, but have not been so favoured before. A few two-year-old standards gave a fair crop some years ago, but being rather exposed to a frosty wind the following winter they were too much crippled to pay for their room. In warmer countries this is really a grand Rose, and from the manner in which the brave old specimen I have under notice has behaved, I am inclined to think it might be grown to advantage in the Isle of Wight and the warmer parts of Cornwall. Cloth of Gold will submit to no pruning. The knife should never touch Cloth of Gold except to cull a bloom or remove dead and frost-bitten wood. Comtesse de Beaumetz, a seedling from this, introduced by Nabonnand in 1876, is not sufficiently distinct.—R.

Rose Anna Ollivier is one of the grandest and most reliable Tea-scented Roses grown. For indoor or outdoor culture it is equally valuable.

Sent out by M. Ducher in 1872, it soon became a general favourite. Its constitution and habit are both as good as could be desired, while its freedom of growth and bloom is remarkable. I do not know how to describe the colour, as it varies so much. I have often cut three or four blooms from one plant which were so different in colour, that one would not recognise them as the same variety were it not for their foliage and wood. The blooms are cupped, large, deep and very full centred; the petals large and stout, while their lasting qualities, both on and off the plants, are remarkable. Buds cut when just bursting will open into large blooms and seem to grow almost as freely in water as upon the plant.—R.

ROSE ROOTS IN DAMP SOILS.

ONE of the most difficult things to understand in Rose culture is the behaviour of the Dog Rose when it is brought into cultivation, if I may use such an expression in connection with its use for standard Roses. When growing wild it thrives luxuriantly on a dry hedge-bank, and also in swampy ground, but take it from either of these positions and plant it in a naturally damp, undrained soil, and work a Rose upon it, and the probability is that not more than 10 per cent. of the stocks so worked will support the Rose in a satisfactory condition after the first year. Left to grow in its own way the stock will thrive vigorously, but as soon as it loses the support of its own branches and has to depend on the growth of the Rose to maintain its vitality it declines in vigour, showing that the influence of the union with the Rose is not appreciated. Although the conditions I have described are not imaginary, it may be that they are far from being general; in fact I know they are not, but the explanation of the behaviour of this stock under such conditions may help perhaps to explain the cause of failure in some isolated cases.

It is not quite correct perhaps to speak of Rose roots in this instance, as they do not actually come into contact with the soil, only so far as they exercise an influence through the stock. But that this influence is greater than we sometimes imagine, is clear when anyone attempts to grow standard Roses on a heavy undrained soil. For a period of over fifteen years I have had opportunities of watching the behaviour of Roses in such a soil, during which time it has been proved that they will not be satisfactory after the second year; the plants do not die, nor does the growth die back, as is the case with standard Roses in some soils, but the branches get so weak and the flowers are so small, that one cannot recognise what they are. Dwarf Roses on the Manetti stock are much more satisfactory in the same garden. Those worked on the La Grefferaie stock, however, cannot survive a severe winter. Seeing that a clay soil is the best root medium for standard Roses, it seems strange that they will not thrive in it if it is not well drained. This was, however, recognised by a large Rose grower of my acquaintance more than thirty years ago. I have reason to remember this, as I assisted in laying down drains over quite one-third of a large nursery, and more recent experience shows that the same argument is good to-day. It must not, however, be supposed that all clay soils require draining for Roses. It all depends on the character of the subsoil at 18 inches or 2 feet below the surface. If at that depth it retains moisture to the same extent as that above it, it is very clear that it is necessary that it should be drained for standard Roses. Quite apart from the nature of the soil is that of the position of the garden. If that is low, lying, as many gardens are, on a level with the surface or not far above that of a river or stream of water, draining or planting on raised beds is a necessity. The experience in the garden to which I have referred makes it clear that the most suitable stock for Roses can only be chosen when the character of the soil is understood.

J. C. CLARKE.

ORCHIDS.

ERIOSIPS RUFIDOBULBON.

It is very pleasant to find that Orchid growers are hunting up the old favourites of years gone by, and trying again to grow these plants in a satisfactory manner. Charles Edwards writes to me asking the reason his plant never flowers. He also says he has had the plant some five years, that it grows well, and now has much longer and better bulbs than when it was imported. He says he has obtained this success by growing the plant in a warm stove. This is where I think he has made a mistake, for I have grown it in a house with many of the *Sobralias* and *Epidendrums* of the tall-growing kinds, and my plant of this Orchid flowered annually. It used to be rested in the cool house with the *Odontoglossums*, for it must be remembered that this species is found growing mostly on the stems of Palm trees in the state of Antioquia at some 4000 feet or 5000 feet elevation, and fully exposed to the sun. As to your question as to its being the true plant, I have not the least doubt about it, as you say the pseudo-bulbs have a rough skin like the hide of a crocodile, freely spotted all over with purplish-brown. The flower-spike issues from the base of the pseudo-bulb and is nodding, about a foot long, bearing many flowers. The sepals and petals are of a rich orange-brown; the lip spurred, and the side lobes of a purplish-brown, the middle lobe white, spotted with purple, and stained with orange at the base. It flowers during the autumn months, so that your plant having shown no signs of blooming this season, you will have to wait until next year. The drainage for this plant must be good, so that nothing of a stagnant nature lies about the roots. If in the spring-time the soil is found to be in a sodden and worn-out condition, the plants should be repotted. They should be hung up in the sun and light during the summer, but in the winter it is best to take them down and stand them on a side stage. The soil should be composed of good peat fibre and chopped Sphagnum Moss. During the summer season this Orchid likes an abundant supply of water, and even in the winter, although a very much reduced quantity is requisite, do not allow it to become exceptionally dry. It is a beautiful species and well deserves extended cultivation.

WM. HUGH GOWER.

Maxillaria Sanderiana.—This was found by Klaboch at about 4000 feet elevation in the mountains of Peru. I have found the plants do best when kept in the cool house for part of the year, but when the spring comes round I would take them into the coolest part of the Cattleya house. The plant is a robust grower and produces its large blooms very freely. It succeeds well as a pot plant, but I prefer to grow it in a basket so as to allow some of the flower-spikes which I have seen decumbent find their way out. These baskets must be well drained. For soil use good brown peat fibre and Sphagnum Moss in about equal parts. During the resting season the plants must be kept tolerably dry, but not so as to injure the bulbs or leaves.—W. H. G.

Pitumna nobilis.—"J. S." sends a spike of this for a name. The plant is scarcer than it used to be some few years ago, I think; at least I do not see it in collections in anything like the numbers that I used to, many of the plants having been killed by being grown in too great heat. I have found this thrive and flower most freely kept in the same temperature as *Odontoglossum Alexandræ*. This plant was introduced some years ago by M. Linden, of Brussels. Its pure white, sweet-scented flowers are very suitable for button-

holes, &c. The individual blooms are some 3 inches across the petals, and upwards of 2 inches across the lip, the whole being of the purest white, having an orange-coloured eye-like spot at the base of the lip. As the plant always flowers at this season of the year, its value for cutting may naturally be inferred. Pot in peat fibre and Sphagnum Moss, and keep the plants in a good moist condition. During the resting season, too, it requires to be kept moist.—W. H. G.

Sophranitis violacea.—This is a very pretty and showy plant that used to be grown in the late Mr. Day's collection. The flowers are of a rich clear violet colour, and they continue in great beauty a considerable time. It likes a cool temperature with a considerable amount of moisture, and thrives best on a block of wood.—W. H. G.

Thrixspermum unguiculatum.—J. Berry sends me a flower of this plant which he says he bought as *Phalenopsis grandiflora* some three years ago. The flower before me is quite 2 inches across, thick and fleshy in texture, the middle lobe small, pale yellow with crimson dots. The plant when growing might be easily taken for some species of *Phalenopsis*, but the delusion is quickly dispelled when the blooms appear. It is not so showy as a *Phalenopsis*, but it is a species well deserving attention. This plant thrives well treated in the same manner as a *Phalenopsis*.—W. H. G.

Cœlogyne barbata.—Although this plant has been introduced between fifty and sixty years, it is at the present time by no means a common Orchid. At present fashion appears to run more on the *Odontoglossum* and *Cattleya*s of South America than on the cool Orchids of Northern India. How much would be lost by the entire neglect of the latter was well exemplified by a panful of this *Cœlogyne*, beautifully in flower at the Royal Horticultural Society's meeting on Dec. 11. This plant had numerous spikes 18 inches high, which produce the flowers in a cluster near the top. Each flower is 3 inches across, the sepals and petals being of the purest glistening white. In striking contrast with these is the lip, which, although white on the outside, is covered inside with numerous brown hairs; it is to this bearded character that the name refers. This species belongs to the same section of *Cœlogyne* as *C. ocellata* and *C. corymbosa*, all of which are well worth cultivation. For the greater part of the year they may be grown cool, although a little extra heat in spring when they are commencing growth is an advantage.

Chysis Oweniana.—Under this name there was exhibited at the Drill Hall, Westminster, on December 11, a very pretty *Chysis*, quite distinct from the well-known types of the genus, *C. aurea* and *C. bracteata*. The pseudo-bulbs were 15 inches to 18 inches long, and nearly the same thickness throughout, and therefore without the curious swelling in the centre, which is so distinctive a character in the two older species. The flowers, of which there were nine on the raceme, were produced in a terminal head; each one was $1\frac{1}{2}$ inches across, in colour white, stained with pale purple towards the tips. The bases of the sepals and petals are depressed so as to form a kind of cup, in which the lip appears to be almost enclosed. The front lobe of the lip is white, stained with purple; the side lobes also are white, with dark purple lines. The bases of the two lower sepals form outwardly protruding chin. With the exception of *Chysis aurea*, all the species now introduced are very handsome Orchids. *C. bracteata*, indeed, when well grown belongs to the very first rank.

SHORT NOTES.—ORCHIDS.

Oncidium tigrinum giganteum.—A very fine variety of this plant comes from Mr. Potter. These flowers quite took me by surprise when I opened the box. Each measured upwards of $3\frac{1}{2}$ inches in length, the sepals and petals prettily undulated, almost black, and transversely barred with thin lines of pale yellow. The front lobe of the lip is broad,

of a rich bright yellow. It is by far the best variety that has come under my notice. I saw it last season and it was just as fine. I would propose the name of *giganteum* for it.—W. H. G.

Mr. Wheatley's Cattleya (*C. Dowiana aurea* *Wheatleyana*) (*R. Johnson*).—This is undoubtedly the same plant as figured in the "Orchid Album," t. 168, under the name of *C. D. a. Statteriana*, as I have the dried flower and can compare it. I see that M. Linden figures the same plant under the name of *C. Hardyana-Statteriana*. I cannot help thinking it is an absurd name, as there is nothing to suggest the fine natural hybrid named in honour of Mr. Hardy, and as the name of *C. aurea Statteriana* has been already given to another *Cattleya*, I would suggest the name given above by me for this plant.—W.

CHRYSANTHEMUMS.

SEASONABLE CULTURAL NOTES.

A MOST important point towards success is the early insertion of the cuttings. To have blooms of the finest quality the plants require a long season of growth in a cool temperature. It is useless to strike the cuttings late, and then by hurrying the plants on in a warm temperature to attempt to make up for loss of time. Early propagation induces the proper maturation of the tissues of the plants. Apart from the results gained by early propagation there is the advantage of getting rid of the old plants. The month of December I consider is the best to take the cuttings in, but where these are difficult to obtain at that time the first two weeks in January will suffice, especially for some of the free-growing Japanese sorts. I always start with those that are of rather weak growth, such as Princess Beatrice, Princess Teck and its sport Lady Hardinge and Empress Eugénie amongst incurved sorts. These, of all varieties, object to "coddling" in even the slightest way. Cuttings 3 inches long taken some distance from the old stem are the best, rejecting all with even a trace of the presence of a flower bud in the point. The best compost to employ is half loam and leaf soil, with a free admixture of sharp silver sand. Growers of the old school were accustomed to insert four or six cuttings around the edge of 3-inch pots, placing the pots on a shelf in a cool house. Cultivators, however, have gradually realised the advantage of placing the cuttings singly into small pots. The older method checked the plants in their infant stage when potting them off singly. Where but one cutting is inserted in a $2\frac{1}{2}$ -inch pot the plant is easily transferred to a larger pot, and thus experiences no check. A gentle bottom heat was provided, too, to hurry on the rooting process by some; this, however, had the effect of weakening the plants, and is now superseded by placing the pots in a small frame on the stage of the greenhouse, vinery or Peach house. By keeping the frame closed, with the exception of removing the light for an hour or so in the morning to get rid of condensed moisture, the risk of the leaves flagging is avoided. If no air at all were admitted, many of the cuttings would damp off, the point being generally soft and succulent at that stage. As a further means of guarding against the chances of a loss of the leaves and cuttings, the glass should be wiped dry every evening.

My experience prompts me to say that the carrying out systematically of all these apparently trifling details is in the end a decided advantage, because the cuttings root in a shorter time, more time for growth being the consequence. It is surprising what a small quantity of water the cuttings require after the soil is well soaked at first. Many of the cuttings will be nicely rooted in three weeks, during which time not a drop of water has been required.

When the cuttings are nicely rooted air must be admitted gradually with a view to strengthen the plants direct from the base. As some varieties require a couple of weeks longer than others to become thoroughly established in the pots, it is wise when examining them to place the earliest

rooted plants in a frame by themselves, so that they may obtain more air, but not to the detriment of the weaker growing sorts, which require longer time to form roots. The flagging of the leaves from exposure is a sign that the plants are not sufficiently established. When this does not take place the sooner the plants are placed on a shelf close to the glass in a cool house the better. Here the soil will more quickly become dry, necessitating a greater supply of water. In this stage the plants would quickly suffer from want of moisture. Tepid water should in all cases be used with a view to prevent the leaves changing to a pale green caused by a check to the roots. E. M.

Guernsey Chrysanthemums.—As "C. H. P." is desirous of having the names of the Chrysanthemums raised by Mr. Kelly, I append the following list: Violetta, Col. Chase, Cecil Wray, Edelweiss, Undine, and Enid Dobree. Mr. Kelly has other good seedlings, which will probably be sent out another year.—THOS. H. LE LIEVRE.

Chrysanthemum Marie Therese Bergman.—This is an excellent addition to the single-flowered Chrysanthemums. The flowers are pure white, the individual blooms being about the size of those of Mary Anderson, but not so regular in outline. The flowers, however, are borne in greater profusion than in that excellent and popular variety, and the habit of growth of both is about the same. This is the type of single Chrysanthemum that should be encouraged.—A. Y.

Chrysanthemums in vases.—Whilst many people do not care for the large blooms of Chrysanthemums arranged on show boards, yet they cannot but admit that they have a very handsome appearance when a dozen or more are arranged in suitable vases with a fair length of stem, with the addition perhaps of other foliage to set them off. The majority of the large blooms which I grow are used in this way. I know it is very easy to make complaints as to the very artificial mode of showing the blooms on boards, but the question is, how is it to be improved upon? If all cut flowers were shown with long stems with healthy foliage attached, it is quite evident growers at a distance would not be able to compete, as it would be impossible to support them in water until the time came for staging. When the stems can be put in water within an hour or so of being cut, the foliage will keep fresh for some days. I have also noticed that the deeper in proportion the stems can be placed in water the longer will the flowers remain fresh. This fact must not be lost sight of if Chrysanthemums are to be exhibited in vases.—A. Y.

Dwarf Chrysanthemums for exhibition.—Would "H. S." kindly give through THE GARDEN a list of two or three dozen dwarf varieties of Chrysanthemums suitable for growing on the "big-bloom" system? Tall-growing varieties over 5 feet many find a difficulty in housing; whereas such kinds as W. H. Lincoln, Mons. Freeman, and J. S. Dibbens could be housed by most gardeners. Many in Malvern wish to grow about two or three dozen plants for large blooms.—S. N.

** The following varieties, all belonging to the Japanese section can be depended upon to produce large exhibition blooms. Most of them do not grow beyond the height required, and the rest, which are noted, may be cut back about the middle of May, at which time the plants should be in 5-inch or 6-inch pots. They may be headed back to within a foot of their base, and placed under glass for a couple of weeks, or rather in a position where glass can be put over them to ward off excessive rain, it being important that the roots be kept on the dry side until new growth is formed. When the latter is 3 inches or so in length, the plants should be shifted into the flowering pots. G. C. Schwabe, carmine-rose; Kentish Yellow, light yellow; Miss Dorothea Shea, terra-cotta; John Shrimpton, rich crimson; G. W. Childs, maroon; Avalanche, white; E. Beckett, yellow; E. Molyneux, dark red; Marie Hoste, creamy white; M. Bernard, purple-rose; W. Tricker, bright rose and white; President Boirel,

rich dark rose; W. H. Lincoln, yellow; Val d'Andorre, orange-red; Eda Prass, flesh-white; Louise, bluish white; and W. G. Newitt, white, will suit your purpose. Those which may be cut back are Wm. Seward, very dark crimson; Col. W. B. Smith, old gold, darker shade; Mlle. Thérèse Rey, creamy-white; Florence Davis, white, green tinge; R. C. Kingston, deep purple; Vivand Morel, mauve; Sunflower, yellow; Stanstead White; and Le Versceau, rose.—H. S.

NOTES OF THE WEEK.

Azara integrifolia.—Sir Herbert Maxwell brings us sprays of this charming shrub—a standard 7 feet high in the open air—two days after Christmas from his garden at Monreith, Wigtonshire, N.B. It is a singularly distinct and pretty bush.

Chrysanthemum Eugene Lanjaulet is an Anemone pompon variety, in full beauty recently in the Chiswick collection. It is a charming flower, neat, free, and bright in colour, the centre rich yellow with paler guard florets. The sprays of bloom are delightful for cutting, and we think this class should be more grown for decoration.

Crocus chrysanthus is a bright species we recently noted in bloom, also a form named *superbus*, the rich golden-yellow flowers relieved by coral-red stigmata. It is a brilliant flower, and welcome on a sunny winter day. There are four varieties, namely, *albidus*, *cœrulescens*, *fuscotinctus*, and *fusco-lineatus*, but the type is as showy as any.

The **Callipsyches** comprise an interesting genus but seldom seen in gardens, although *C. aurantiaca*, that blooms at this season, is a bright flower. They are amaryllidaceous plants, and can be grown under similar conditions to the better-known *Amaryllis*. During growth abundance of water is required. This should be gradually withheld as the leaves decay, being careful, however, not to let the bulbs shrivel.

Rosa macrantha.—Mr. T. W. Girdlestone, in his interesting article on "Wild Roses" at page 547 in issue of Dec. 16, notes my saying of this, that it has "rather pretty flowers, though they are somewhat small," and refers to some confusion in the matter of names. I may be allowed therefore to mention that *R. micrantha* was intended, the above name resulting probably from an undetected misprint.—R. I. LYNCH.

A charming **Orchid** in bloom now in the Kew collection is *Zygopetalum Rollissoni*, which is synonymous with *Maxillaria Rollissoni* and *Promenæa Rollissoni*. It was introduced from Brazil as far back as 1813, and grows well in a small pan suspended near the light in the intermediate house. The flower is small and neat, the sepals and petals very pale yellow, whilst the lip is of a much richer shade, spotted with crimson.

Siphocampylus betulæfolius.—Until the mention of this on p. 593, I have not seen it noticed anywhere for many years. I grew it forty years ago, and it is perhaps the prettiest *Siphocampylus* of any, all of which are too little known. It is more of a shrubby woody character than most others, the foliage pale green shaded with yellow, the flowers long, on long stems, red, tipped with yellow. At the time mentioned it was to be found in most of the large nursery catalogues, but seems now to be quite lost.—J. M., *Charmouth, Dorset*.

Chrysanthemum Harlequin.—Herewith I send you two long sprays cut from a large plant of the above-named *Chrysanthemum*. I could cut a good sheaf or two if required. It is a most excellent kind for Christmas blooming, and I have grown it several years for that purpose. It naturally grows long-jointed and will not do with late stopping; ours were pinched the last time about July 1. There has been no bud-thinning. The colour is, as you will see, of the Source d'Or type, each floret tipped with pale gold. It shows up

well by artificial light.—H. J. CLAYTON, *Grimston Park, Tadcaster*.

Schizostylis coccinea is a useful winter flower for the greenhouse. We noticed it grown largely at Kew, and mixed with white lilyacinthus the crimson flowers are very pleasing. It is not often one sees well-grown plants in gardens, but the winter *Gladiolus* is acceptable at this season, when variety is wanted in the greenhouse, as a relief to the stereotyped Chinese *Primulas* and *Cyclamens*. The *Schizostylis* is not difficult to grow, and notes have recently appeared in THE GARDEN as to its culture. When grown in the open the most suitable spot is a sheltered warm corner, or such a place as would suit the *Belladonna Lily*, the soil being light and well drained.

The past dry season.—Amongst the many unusual effects resulting from the protracted dry summer is the futile attempt of several biennials to flower the first season. A number of *Ipomopsis elegans* here have thrown up flower-stems to the height of 2 feet, but, of course, no flowers matured, and now the plants look as if they were decaying. The same thing has occurred with *Erythrolæna conspicua*, a robust, red-flowering, Thistle-like plant, which was pushing a flower-stem vigorously until arrested by the cold. This likewise looks as if it would perish. Happily, however, I have a few plants that were not turned out; these have their rosette crowns unaffected.—J. M., *Charmouth, Dorset*.

Chimonanthus fragrans.—This is flowering with unusual freedom this season, no doubt a result of the hot, dry summer, which prevented gross growth and thoroughly ripened the shoots that were made. The best kind is that known as *grandiflorus*, of which we have several bushes that are quite smothered in bloom. They have a warm site and a very firm root run—in fact, the soil of the border has never been loosened since the bushes were planted. Under such conditions they invariably flower freely. Such pruning as is required is best done when the plants are in bloom, by cutting the shoots with their flowers moderately freely, selecting those that would have to be removed later on. It is a most welcome flower in the house, a few sprays scenting the largest room, their fragrance and freshness enduring for many days.—A. H.

Hardy Cyclamens are commencing to bloom freely in the nursery of Messrs. Barr and Son, Long Ditton, and good clumps of *C. ibericum*, a form of *C. coum*, make welcome masses of colour in the late winter, when, as this year, the weather is mild. The *Cyclamens*, apart from the flowers, are attractive by reason of their pleasing foliage. Several varieties are in this nursery, one of the most beautiful being *C. ibericum Atkinsi*, the flowers pure white, relieved by a purple spot at the base of the segments; whilst there are other kinds, named respectively *rubrum*, *roseum*, *lilacinum*, showing the diversity of colour in this class. To enjoy *Cyclamens* they should be planted in sheltered spots on the rockery, amongst Grass, at the foot of an old wall and similar places where they are in a measure protected, not from want of hardness, but as a shelter to the flowers. Light vegetable soil suits them best, and when in a suitable place, warm, partially shady and sheltered, as they are at Livermere Park, they produce abundance of flowers. They are very charming also grown in shallow pans, and under glass are not exposed to rains and frosts.

Winter-flowering Carnations.—It is a very nice thing to have a good show of Carnations in bloom at Christmas, but the list of English varieties is very small. Miss Joliffe, Winter Cheer, La Neige, Duke of Fife, Duke of Clarence and about a dozen more and you come to the end of the list. It has been my object for some years to introduce variety into collections of these lovely plants both in the border and conservatory, and so far with great success, and I have the pleasure of sending you herewith specimens of a dozen that I have cut this morning (Christmas Day) in my conservatory. They are for the most part French and

German, and would be far finer but that so much air has been kept on the house for the benefit of the white *Chrysanthemums* required at this season.—H. W. WEGUELIN, F.R.H.S., *Shaldon, Teignmouth, Devon*.

** To our taste too much variety, too much of the bizarre and the wire and stripe and slaty hue, and very little of the splendour and intensity of the Carnation. We have always had too much of these frivolous aberrations, while no one was taking much notice of the more precious qualities.—ED.

OBITUARY.

Mr. W. C. Drummond.—This well-known nurseryman in the west of England, the proprietor of the Bath and Park Lane Nurseries, died recently at Bath at the age of 77 years. Nearly a half century ago he made a considerable reputation as a cultivator and exhibitor of Dahlias, though he was not the raiser of them. One of the earliest flowers to bear his name was *Beeswing*, which was distributed in 1845, and became much grown for exhibition, being a decided advance upon some which had preceded it. One of his greatest hits was with *Bob*, a deep scarlet flower of a bright hue, which was widely distributed and much exhibited. This was sent out about the year 1850. In 1852 two flowers were distributed, viz., *Sir Richard Whittington* and *Alice*, both of which were considered so good, that they were figured in the March number of the *Florist* of that year, then conducted by the late Mr. Charles Turner. Other flowers distributed previously or about the same time were *Felix*, *Utilis*, *Meion*, *Sarah*, *Minn*, &c. In 1853, British Queen, Robert Bruce, and Queen of Whites were put into commerce; and in the following year, *Miss Susan Sainsbury*, *Dhawala Giri*, *Miss Mary Sainsbury*, and others. He was a constant exhibitor of plants and flowers at the leading west of England shows, and up to the last year or two I used to meet him regularly at the exhibitions of the Trowbridge Horticultural Society. Mr. Drummond was one of the original supporters of the old National Floricultural Society, which was founded in 1851, and was the forerunner of the Floral Committee of the Royal Horticultural Society.

The weather in West Herts.—Another very mild week and the third in succession. On Friday the temperature in the shade rose to 51°, and on Saturday and Tuesday to 50°, while on no night did the exposed thermometer register more than 7° of frost. The temperature of the ground at 2 feet deep now stands at 41°, and at 1 foot deep at 40°, or respectively 3° and 6° warmer than at the same time last year. Some rain fell on Friday and again on Sunday, but the total measurement for the week only amounted to about a quarter of an inch. The winds have again mostly come from some southerly point of the compass and have been of about average strength. On four days of the week the sun shone for four or more hours, and on two of these (Thursday and Monday) the record exceeded five hours.—E. M., *Berkhamsted*.

Dogs in the garden.—To condemn these faithful animals is not in any sense my intention, but merely to point out a case in which the blame for the non-success of several shrubs was attributed in a most decided manner to the person who had charge of a plot of ground connected with a public building adjoining a very frequented highway. For the moment this puzzled me. I could not see why the shrubs should dwindle away and die until I made a close inspection of the wall and iron railings, as well as the piece of lawn. The traces of dogs were apparent not only upon the enclosure, but so repeated had been the visits that the tracks were plainly visible upon the stone coping. The only remedy prior to planting afresh was to fix a light wirework against the iron railings. It may be asked how it is that dogs do

not do more harm in gardens. To this my answer is that they do quite enough. It is, however, amongst newly-planted shrubs and in such positions as the example just given where most injury is done. To attempt to establish shrubs with this disadvantage to contend against is almost useless.—SOUTHTRON.

Destroying tree stumps.—Tree roots are often very expensive to uproot with only the grub axe and wedges, but with the new explosive mentioned by A. L. Y. Morley in *THE GARDEN* of last week the destroying of tree stumps will become an easy matter. Dynamite and gunpowder I have used extensively, but I prefer the dynamite. In practised hands it does its work more quickly than gunpowder, and is as safe to handle. A small charge of dynamite as it is made up in packets 2 inches long by 1 inch is quite sufficient to blow up a strong root of, say, 12 inches or more in diameter if a little judgment is used in boring the hole. Dynamite requires no tamping like gunpowder. When the charge is put into the root, the hole may be filled up with water, and the bursting of the root will be all the same.—J. MILLER, *Ruxley Lodge, Esher*.

Flora of South Arabia.—Mr. Theodore Bent, the well-known archaeologist and traveller, having arranged an expedition to Hadramant, in South Arabia, the director of Kew has obtained permission for a plant-collector to accompany him in the interests of Kew. Hadramant is one of the four ancient kingdoms of Southern Arabia which formerly supplied the world with its more important luxuries. It is practically unknown, but is reported to be rich in ruins and inscriptions. Frankincense, the product of *Boswellia Carteri*, is obtained almost exclusively from this part of Arabia. There are good reasons for believing that the flora of that part of Arabia is exceptionally interesting, both botanically and horticulturally. The small island of Socotra, off the coast of South Arabia, proved a rich mine both to botanists and horticulturists when visited by Professor Bayley Balfour thirteen years ago. Mr. Bent's party will be away about six months.

Iron roofing for sheds.—I am not at all surprised that iron roofing for sheds should be condemned. In this material for roofs we have the two extremes of intense heat in summer and extreme cold in winter. Light houses (or sheds for that matter) may look all right with iron roofing upon them in the opinion of those who do not think the matter out. Such have a neat appearance if that counts for anything, and it may do in the eyes of some people. Has it occurred, however, to anyone that through the iron being non-absorbent it is not calculated to be the best roofing material? In the editorial remarks in the issue for December 16 (p. 570) this fact is touched upon—"iron roofs weeping drops" in reality. This would not occur either with a slate or tile roof to anything like the same extent, if it did at all, simply because both of these are absorbent; hence the moisture on the underside is taken up instead of having to be dispelled in other ways, as by trickling down the roof to the base. This fact has no doubt occurred to those who in erecting iron roofs take as their shape nearly half a circle, so that the moisture upon the underside passes away more quickly than would be the case upon a comparatively flat roof with an inclined, but straight plane.—H. G.

I quite agree with every word your correspondent "J. C. B." says on this subject. I can go further. He speaks of ten years; whereas I have had nearly 25 years' experience in Australia, where the majority of the houses are roofed with corrugated galvanised iron. Certainly, with us, it is hot, but not hotter than slates or tiles, and cools more quickly. To obviate this heat we whiten our roofs with a preparation which lowers the temperature at least 10 degrees, and, in the case of sheds, will keep out the frost. This preparation requires renewing every two or three years, but it is very

cheap, looks picturesque, and is a great relief in our hot summers. The iron is infinitely cheaper than slates or tiles, more easily and quickly laid on, and, in my long experience, requires no further outlay.—HENRY DUTTON, *Anlaby Estate, Kapunda, South Australia*.

** *We are sorry for the beauty of a country in which the houses are roofed with corrugated iron. We would not willingly roof a pig-stye with it. Even an iron bridge is rusting and rotting away every day of its life. We have put up iron roofs within four years which are rusting away now, and the iron piping we have put up is rotten as a wet blot sheet. The defects of iron from a builder's or an artistic point of view are more than we have time to enumerate.*—ED.

PUBLIC GARDENS.

A new open space at Fulham.—On Tuesday afternoon Mr. John Hutton, chairman of the London County Council, formally opened Bishop's and West Meadows, an area of over twelve acres, bordering the river at Fulham, and hard by the Bishop's moat. In 1884 the Ecclesiastical Commissioners, as Lords of the Manor, at the instance of the late Bishop Jackson, conveyed it to the local authorities to be maintained as a public recreation ground, but the work of laying it out has for many reasons been delayed until the present time, when, at the instance of the present bishop, West Meadow has been added to the gift. A magnificent river wall has been constructed at a cost of £12,617, and it is estimated that the total expenditure in connection with the open space will be £19,000, towards which the London County Council has promised £5000. In declaring the Meadows open, Mr. John Hutton pointed out that since the Council came into existence it had added 1000 acres to the open spaces of London.
