As most amateurs delight in propagating and growing their own Roses from the initial stage, and as the season for striking stocks is so near, a few practical notes may be of service. Owing to the forwardness of the season, the latter end of this month is about equivalent to the middle or end of September, and although the majority of large growers do not commence the propagation of Rose stocks until October and November, it is quite as well to begin earlier where only a few are wanted. The Manetti, Brier, De la Greferaie and any strong-growing varieties of the *Polyantha* section can be treated as I will describe in this article. The great advantage in doing this early lies in the fact that cuttings will thus be able to callus and make roots before winter. Under these conditions they will stand the winter and its drying winds much better, while the few roots made will also hold the young stock in its place and prevent the injurious lifting of it by frost. Choose wood that is about three parts ripened. It is not necessary that the whole of the shoot be in this condition; indeed, it will be difficult to find it so and still retain the amount of activity in the sap that is so essential to early autumn rooting. Fairly strong wood, without coarseness or pithiness, should be selected. By all means avoid choosing the short side growths so much recommended when

propagating Roses upon their own roots. In the latter case the numerous suckers that are certain to emanate from the base or heel of such shoots are particularly valuable, because suckers of Rose growth are most essential to the vigour and longevity of dwarf Roses; not so, however, in the case of stocks. Here we must try all we know to keep down suckers. For this reason it is better to select a fairly long rod of growth and cut up the riper portions into suitable lengths. These will generally contain from four to six eyes only, and which will be sufficiently prominent and developed to be cut out clean before the cutting is inserted. Remove all but the two top eyes, and make the cuttings from 9 inches to 12 inches long. In striking Roses a shorter cutting is preferable, but when it comes to stocks a longer one facilitates the process of budding later on.

When writing upon budding Roses a few weeks back I advised that the stocks should not be cut or mutilated in any way just previous to or after the operation of budding. But after the bud is set, no harm will be done by removing some of the wood for stocks. The shady side of a wall or hedge is an excellent site for propagating Rose stocks. If you can afford them a sandy compost, so much the better. Insert the cuttings fully three-fourths of their length. The following is a good method of operation: Turn over a portion of the ground deeply with a spade or spud, and having got say a breadth of a foot or so from the edge of your plot, set a short line across it about 3 inches from the edge of the newly-dug soil. Now cut this down with a spade, pulling the loose soil forward into the slight trench. This will leave you a firm bank against which to stand the cuttings. It is a great advantage to have a little prepared soil, such as worn-out potting material, and to place a small quantity of this in the bottom of the trench, so that the base of the cutting may be certain to rest upon a suitable compost. Slightly press the cuttings into this, placing them from 2½ inches to 3 inches apart. When the row is full, turn over some more soil and tread the cuttings up firmly. When about 18 inches of more soil has been turned over set your line again, allowing a distance of 15 inches from where it was before. This will give a suitable distance from row to row, and at the same time allow of a little soil being cut down in the preparation of the second trench similar to the first, and so on until you have inserted enough cuttings.

Cuttings rooted thus early are very serviceable to pot up for grafting upon during the following winter. They root freely, and may be lifted by the end of November, when they will be ready for grafting by the time the sun has turned—a much better period for the amateur to graft Roses than during November and December. A twelvemonth's saving of time is also another advantage of early striking, although where one roots a few Rose stocks annually it is better to leave them in the bed all through the following summer. However, where no stocks were prepared last year, those rooted now may be lifted and transplanted early in the spring, but in the case of such an exceptionally dry time as we experienced last March it will be necessary to give them one or two thorough waterings at the time of planting.

PLANTING THE STOCKS.

This is of great importance, because if done too deeply it is impossible to insert the Rose bud near enough to the base of your stock, and in this case a much larger percentage of suckers would naturally result. We must also bear in

mind whether our Roses are to remain where the stocks are planted or not. The preparation of the soil, the distance apart, and the variety to be cultivated must be considered if the Roses are to remain in the same spot after their maiden stage. This is very evident when we consider the immense difference between the size and strength of many varieties. But if they are all to be transplanted, the stocks may be placed about 9 inches apart in the rows, and the rows be 3 feet from one to the other. When transplanting is contemplated, it is only necessary to plant the stocks in ordinary garden soil, as a coarse, or what some style a rich growth is not wanted. On the other hand, should it be proposed to keep the plants where they are budded, we must provide a much better subsoil than exists in the majority of cases, as this can never be improved upon when once the stocks or Roses are permanently planted. We do not want the stocks to grow strong, only just sufficiently so to ensure healthy growth. But the Rose itself may grow as much as possible provided coarse wood is avoided, and this is best secured by transplanting after the maiden stage. R.

Rose Duchesse d'Auerstadt.—Fresh experience with this Rose growing in cold heavy ground shows that it loves a warm soil best and can hardly be relied upon in cold districts, at any rate away from a wall. The great heat of the past ten days, however, has opened out some of the finest flowers I ever saw of the kind, full of substance, of a rich deep yellow hue surpassing *Maréchal Niel*, and deliciously scented. In vigour it is all that can be desired, but, of course, one wants flowers in succession, and to have them the plants must be on a wall or in a hot place.—A. H.

A fine Rose bush.—A few evenings since I was passing through a rather new portion of a very old town, and suddenly came upon a huge Rose tree from 5 feet to 10 feet high. It had a clear stem of the common Brier or Dog Rose from 3 feet to 4 feet high, as thick as the arm of a strong man, and several of its sub-divisions were as thick as walking-sticks. But nothing of this was observed at first, for the long framework of boughs, branchlets and leaves was crowned with Roses of abnormal size and unusual brilliancy. Each fully-expanded bloom seemed like a flat vase crowded to overflowing with petals of the richest shades of salmon, fawn, orange, purple; while buds in singles, twos, and even clusters almost covered the ample foliage, such a beautiful feature in many Tea Roses, with their rich harvest of flowers in succession up to Christmas or afterwards. At first sight I felt sure I had found a novelty of rare excellence, but a closer inspection only raised my admiration of my old favourite, *Gloire de Dijon*.—D. T. F.

Rose Marie d'Orleans.—One of the many lovely Tea Roses now full of bloom is this. It is a most distinct and striking kind, and quite one of the best of those that incline towards shades of red. It has much the same tint as *Mme. Lambard*, but in other respects differs greatly. It is very vigorous and hardy, making a large stout bush. It flowers profusely. The blooms, whether singly or in the cluster, are borne on long stalks, and are of a soft rosy pink colour, large and full in the bud. When expanded the flower has a delightful starry look owing to the petals reflexing, the tips being quite pointed. *M. Nabonnand's* Roses are mostly unpopular, but this is quite one of his best. It was sent out about 1854.

The finest red Tea Rose.—Liable to correction, I shall select *W. F. Bennett*. On first seeing it, I longed to christen it the red *Niphetos*. It would probably have sold faster and been more grown under the latter name. As it is, this finest of red Teas is but seldom seen compared with other Teas. Even the colour has something to do with the scarcity. Had it been yet another cream,

golden, white, or even light pink Tea, it might have become more suddenly popular. But red Teas have not yet become fashionable; when they do, no doubt they will be largely grown. *W. Bennett* will match well with such chaste forms and colours as are found in *Lady Mary Fitzwilliam*, *Princess of Wales* and the two *Countesses Falmouth* and *Folkestone*, the last, however, having a dash of cream and salmon in it, and fully filled with the most exquisite fragrance.—D. T. F.

CLIMBING TEA AND NOISETTE ROSES.

The climbing varieties are now much grown for early forcing. It has become quite a new feature within the last few years, and some of the leading growers devote large houses exclusively to the culture of the climbing varieties. They are treated much in the same manner as young Vines are grown. *Maréchal Niel* takes the lead, and it is perhaps owing to this variety requiring exceptional treatment. When started early in the season and grown trained to the roof of a house, *Maréchal Niel* makes very long growths, which, if not checked or stopped, do not make lateral shoots. The wood gets well ripened, and when started in the forcing house if trained horizontally, nearly every eye will produce a flower-bud. Among the more recent additions to this class is the climbing variety of *Perle des Jardins*, which seems likely to become a general favourite. *Mr. G. Paul*, of Cheshunt, first brought this variety under my notice. It has a remarkably vigorous habit, and the flowers are even finer than those of the ordinary bush form. I have seen it growing in several nurseries, and in each case it seems to fully maintain the climbing habit, though I believe that stunted or cut-back plants revert to the normal bush habit. This is also the case with *Climbing Niphetos*, which, under fair conditions, is certainly as much a climber as any Rose grown, but once get it stunted, it will not start and make the long vigorous growths again. I refer more particularly to this variety, as I have often heard it questioned whether it was really distinct in habit from the old variety, and my experience fully confirms the claim it has to being a climber. *Reine Marie Henriette* is another which deserves note. It is only when treated as above that it will flower well, and I may here mention that I have seen shoots which have flowered from nearly every joint, and after these have been cut, taking them off nearly back to the old wood, a second crop of bloom has been produced, though, of course, the flowers have not been quite so large or good in colour as the first blooms. *W. A. Richardson* is grown extensively. Though the flowers are small, the peculiarly rich amber shade secures for it many admirers. Among other sorts, *Rêve d'Or*, *l'Idéal*, *Mme. Berard* and the old favourite *Gloire de Dijon* must be included. A. HEMSLEY.

Perennial Sunflowers in the Chiswick Gardens.—The collection of *Helianthus* at Chiswick is in full bloom, and those interested in the plants will find that they are classified, *Mr. Dewar*, of Glasgow Botanic Gardens, having given careful attention to this point. His notes published in the journal of the society are of value, and will be found in vol. xv., p. 26. This class of perennials comprises the gayest flowers of the garden, and the taller kinds, such as *H. occidentalis*, *H. orgyalis*, and *H. giganteus*, are delightful to plant amongst shrubs, over which they throw their flower-laden stems. They might be more used thus in gardens, and colour would be got in positions where it is often sadly needed. But guard against getting too much yellow, which frequently happens at this season, as all the *Helianthus* bear flowers of strong yellow colour. At Chiswick the showiest and most useful plants are *H. multiflorus* and its forms. *H. m. Soleil d'Or* is a very fine kind, the plant very vigorous in habit, and bearing a mass of rich yellow flowers, deeper in colour through association with dark green leafage. Worthy of

note also is *H. m. Peter Barr*, a tall, strong growing variety with a large yellow flower. This would make an excellent variety to form a large mass of in the garden, although we think the best for this purpose is the great perennial Sunflower (*H. m. maximus*), which attains considerable height, fully 6 feet or 7 feet. The flowers are very large, rich golden yellow and single. If only one kind is grown, this should be selected for its tall, robust growth and bold strikingly handsome flowers.

STOVE AND GREENHOUSE.

NERINES.

This family of bulbous plants is closely allied to the *Amaryllis*. They are Cape, or at least South African plants, but, like many other beautiful bulbs from the same region, they are not nearly enough grown. Now and again one meets with them in a thriving condition, and when they are well managed there is hardly anything to surpass them in their way. The brilliant colours and sparkling appearance of such as *N. Fothergilli* and *N. sarniensis* will at once commend them to the notice of all true plant lovers. Where, however, the chief cause of non-success in their culture has arisen is in the fact of their requirements not being properly understood. It is fairly easy to get them to grow well, but to flower them equally as well is oftentimes another matter. Before going further, let us for a moment consider the conditions as nearly as we can under which they naturally thrive best. Being bulbous plants of a deciduous character, they naturally have a resting period; this occurs during the hottest weather, when the ground is parched up, oftentimes almost to a cinder. Hence the bulbs become thoroughly matured, and are thereby well fitted for future flowering. When the cool and rainy season comes on, then the plants are excited into growth, first throwing up their flowering spikes and afterwards their foliage. This should be the mode of procedure adopted in this country by those who grow them, or at any rate as nearly as possible. Methinks, however, that this is not the case to that extent which is necessary to ensure freedom in flowering. The plan that is in some instances adopted is this: to look after them fairly well during growth, when probably they will get a favourable position, but as soon as the foliage dies down any place is considered good enough for them—under a stage, perhaps, or in some other out-of-the-way place. This is totally wrong, for as the growth dies down they should be well exposed to the light and air, with warmth also, for instance, such as would be afforded by a vinery shelf, where they could remain undisturbed with the sun shining upon them for at least a part of the day, no water being given them until the growing season again comes round.

I am inclined to think that it is the unnatural treatment that they receive which causes them to be less popular than they are. Instead of being kept cool whilst resting, that is actually the time when they should be the warmer of the two; being almost roasted, in fact, will not hurt them. Some years ago I used to grow *N. sarniensis*, and flower it every year without any trouble. The plan adopted was to leave the plants all the year in the vineries. The flower-spikes used to appear towards the end of August, being followed soon afterwards by the leaves. The vineries in question not containing specially late Grapes were not kept warm from that time until again closed

for starting; by that time the foliage would be dying off, the plants going to rest when the houses were the warmest, as they stood immediately over the hot-water pipes and upon a slate shelf. I give this explanation so that others who have not succeeded in flowering this variety may adopt the same methods as nearly as they can. It is an easier matter as a rule to flower *N. Fothergilli*, but the same treatment if accorded to it will give very satisfactory results. Another, and also a common mistake in some instances, is that of disturbing them too frequently at the roots. This they do not in any sense require, for, as in either of the species already quoted, they flower more freely when left for years in the same pots. I have seen the best results with *N. Fothergilli* when the bulbs have been almost on top of each other, so much crowded, in fact, that hardly any of the soil could be seen. When left thus in pots of about 9 inches or 10 inches in diameter, and a dozen or more spikes at the time, they are a grand sight. Too frequent potting and disturbing of the bulbs only result in an increased leaf growth and more offsets, which is not what is most desired when a good and sufficient stock has been obtained. The Guernsey Lily (*N. sarniensis*) is annually imported from the Channel Islands in September (early); this is the best time to obtain a stock of this variety. The flower-spikes are usually showing when received, or very soon after. *N. Fothergilli* is easily increased by offsets when further increase is needed, but only a part of the stock should if possible be operated on at one time for reasons already given. The soil best suited to their requirements is good loam with nothing added to it other than sand or road scrapings. Anything in the way of manure should be avoided. Insects are rarely any trouble I have in one or two cases seen *N. rines* attacked with what was apparently the *Eucharis* mite, or something of the same kind. In such a case a few applications of soot water would be a good remedy.

The best kinds to grow are:—

N. FOTHERGILLI, brilliant vermilion-scarlet; *N. Fothergilli major* is an improved form with more vigour. This species is also grown under the name of *N. curvifolia*.

N. SARNIENSIS in colour is more of a salmon tint; this does not, however, quite describe it correctly, as it is darker. This species is not of so strong a growth as the preceding.

N. CORUSCANS is considered to be only a form of the preceding; in colour it is much brighter, being more of an orange-scarlet.

N. FLEXUOSA is a very bright coloured species and somewhat scarcer than some kinds; in colour its flowers are intensely bright.

N. CRISPA is not such a showy variety. When grown in large masses it is very effective; in colour it is a dark rose.

N. MANSELLI.—This ought to find many admirers, not only for its late flowering character, but for its large umbel of brightly coloured flowers. The flowers are more of a rich carmine than those of *N. Fothergilli*. The scape is sturdy, of considerable length, the leaves long and strap-shaped. It was raised by Mr. J. L. Mansell, Somerset Terrace, Guernsey, and received a first-class certificate from the R.H.S. on December 13, 1887.

GROWER.

Agapanthus Mooreanus.—I note your remarks on this (p. 131). It may be hoped that a little more variety in the family may secure rather better culture for the old favourite *A. umbellatus*. One so often meets with it in pots, baskets, beds and borders in a half-starved condition. The most effective masses I have ever seen of the old *Agapanthus* were grown in 18-inch pots—huge masses of leaves and flowers of abnormal length

and size. The soil was rich loam with a fourth part of well-rotted cow manure. These plants were grown on a long, broad terrace wall alternated with the old scarlet *Tom Thumb Pelargonium* grown and treated in a similar manner, and the effect was rich and pleasing, the delicate graceful scapes of the *Agapanthus* toning down the scarlet of the *Pelargoniums*. How is it that the white and the variegated-leaved *Agapanthus* are so rarely seen? The latter, well managed, is a charming variegated plant out of doors or under glass.—D. T. F.

Crinum Moorei as a window plant.—This, though by no means the grandest, is assuredly one of the most delicate and graceful of all the *Crinums*. *Crinum amabile* well done furnishes a feast of beauty and fragrance not likely to be forgotten. But then it needs a semi-tropical temperature to develop its huge spathes of bloom; whereas, as you point out (p. 115), *Crinum Moorei* is as hardy as *Agapanthus umbellatus*—that is, it will endure the winter under a few inches of coal ashes or a foot or more of Bracken at the feet of a south or west wall, or it may be wintered safely with the Onion plant in a cottage window, or in garrets or cellars free from frost. A little more protection and warmth are by no means lost on this fine *Crinum*, as becomes obvious to those who have seen such masses as you have described. The very day after reading your account of the groups of this plant now in bloom at Kew I ran against it in window gardens in several directions, and I know from experience that there are few plants more easily managed or more beautiful in window gardens. This *Crinum* not only bears much rough treatment with impunity, but with positive advantage so far as blossoming freely is concerned. Hence it may even be potted up from the open bed or border after the spathes show without injury to the beauty and size of the flowers. Strong plants need rather tall windows to do them justice, as the fine leaves require space to develop to the full the gracefulness of their curves. The flower-stems, too, are tall and the individual blooms long. Plants grown partially in the open air have a sturdier habit and shorter spathes.—D. T. F.

GLOXINIAS FROM SEED.

NAMED varieties have almost become a thing of the past, and it is hardly worth while to propagate and preserve stock from year to year when such splendid varieties can be raised from seed. Seedlings are generally more vigorous and give far less trouble to the cultivator. They will flower within six months from the time the seed is sown, and will produce from six to ten or perhaps more blooms on each plant. The second year they will flower more profusely, that is if the corms are properly preserved during the winter. Any extra fine or distinct varieties appearing among the seedlings may be propagated from the leaves. If well matured leaves are taken off, a cut made through all the main ribs of the leaf, and laid on moist cocconut fibre refuse with a little sand on the surface of the leaf where the cuts have been made, they will form a corm at each cut. If the leaves show signs of premature decay the affected part should be cut away; but if successfully treated the leaves will gradually ripen off and dry up; the corms may then be taken out of the fibre and placed in sand with just sufficient moisture to keep them from shrivelling. If only just covered with sand they may remain until they begin to start into growth, which will be early in the year. If required to flower early in the spring they may be started in the stove, but for later flowering an intermediate temperature will suit them better.

In the culture of *Gloxinias* a great mistake is often made in giving them too much shade and a high temperature; the two combined induce weakly growth and thin, flimsy flowers. *Gloxinia* seed should be sown early in February, and care should be taken that the compost used is quite free from worms or other insects. If the pots are filled and the surface left rather loose, no extra

covering will be required when the seed is sown. The seed pots should be placed in a light position, but not exposed to the full rays of the sun. I always recommend pricking off the seedlings as early as possible. The plants should be potted off singly as soon as large enough. If potted in a good loamy compost, which may be mixed with some leaf-mould and well-rotted manure, they will make much better growth than when potted in peat and leaf-mould, which is sometimes recommended. Gloxinias are by no means such delicate subjects as are often supposed. Potted in a good rich compost with careful attention to watering, and grown in an intermediate temperature with just sufficient shading to prevent the sun from burning them during the hottest part of the day, vigorous growth and flowers of good substance will be ensured.

By raising a batch of seedlings every year and selecting the best to grow on, a grand display may be kept up from May until September, and during the summer they will last well in the cool conservatory. To preserve the corms during the winter the tops should be cleared off as soon as they are well ripened in the autumn and the pots be laid on their sides under a stage in the stove, but not so near to the hot-water pipes as to dry up the corms. A very small species of thrips is sometimes troublesome. It is hardly visible to the naked eye, but its presence may soon be known by the brownish appearance of the midrib of the leaves. If only a plant or so should be affected, it is best to throw it away, and then use less heat and more moisture to prevent any further attacks of this insidious enemy.—F. H.

These do not require the amount of heat that is by many considered necessary for their well-doing, that is if their blossoms are not needed till late in the season. I recently saw a good batch of pretty flowering plants, the result of last year's seedlings, which formed plump, well-ripened tubers. They were wintered in boxes of dry sand under exactly similar conditions to the tuberous Begonias, that is in a cool greenhouse from which frost was just excluded. When potted they continued to be treated in the same way, and were removed to an ordinary garden frame without any heat whatever. They were shifted into pots 5 in. and 6 in. in diameter, and are now flowering well. Of course, during a cold, damp season such favourable results could scarcely be anticipated, but even then I have seen some very nice examples grown in this way. The plants alluded to were without any heat whatever, but a slight hotbed will, of course, hasten growth considerably earlier in the year. Where the flowers are required for cutting only, or the plants needed for the production of tubers, the best results are obtained by planting them out on a gentle hotbed in a frame. So treated young seedlings will make good roots and flower well. As Gloxinias have increased a good deal in popularity within the last few years for cutting from, this system of planting them out will often save a good deal of trouble. Treated in this way the soil does not dry so quickly as when in pots, and consequently the water-pot should be used very sparingly when the season is nearly at an end.—H. P.

Cyrtanthus angustifolius.—This pretty little red-flowered species of *Cyrtanthus* will bloom out of doors under similar conditions to *C. Mackeni* and *C. lutescens*, noted in THE GARDEN (p. 132). It is, however it may be situated, not so continuous blooming as they are, as it usually flowers but once in the year, while the other two keep up a succession for some time. Some pots of it here that in previous years had flowered under glass were plunged in the open ground about the end of May, and very soon afterwards they flowered beautifully. One result of this treatment was that the blooms were of a much brighter colour than when they expanded under glass. Another species that succeeded well with the same treatment was *C. Macowani*, the showiest of all the smaller species of *Cyrtanthus*, as the flowers are so brightly coloured. All of these small-growing kinds of *Cyrtanthus* can be recommended as very

satisfactory subjects if placed under anything like favourable conditions. All they need is to have the pots well drained, and the soil, principally consisting of good loam, lightened by an admixture of leaf-mould and silver sand. Such compost will remain fresh for years, which is a great advantage, as all the species are very impatient of being disturbed at the roots. Treatment such as is given to *Pelargoniums* will suit them well—that is a greenhouse temperature and careful watering during the winter months; but at no time, not even during the winter, must they be allowed to become too dry. They flower best when thoroughly established and the bulbs are tightly packed together in the pots.—H. P.

Roechea falcata.—This bright-flowered succulent is blooming this year with great freedom, probably to a certain extent owing to the weather we have experienced. It is a plant of easy culture, needing simple greenhouse treatment, with exposure to full sunshine except when in flower. The large closely-packed heads of scarlet-crimson coloured blossoms, which, though individually small, are very numerous, make a goodly show at this season of the year. It is quite an old-fashioned plant, and though generally known under the above name, it is by the latest authorities included in the genus *Crassula*, which has also swallowed up the once popular *Kalosanthes coccinea*, from which, however, in general appearance the *Roechea* differs widely. The principal care in its cultivation is to guard against an excess of moisture, especially during the winter months.—T.

NOTES ON FUCHSIAS.

The *Fuchsia* has become within recent years one of the most popular plants for bedding and the greenhouse. It is well represented in all the principal parks, and a collection is at present in bloom in the Royal Horticultural Society's gardens at Chiswick. A separate house is devoted to them, and amongst the several kinds are many that we should like to see more grown in gardens. The majority are medium-sized plants, but a few are sturdy specimens that show the beauty of the *Fuchsia* when it gets a good age.

We looked carefully through this collection a few days ago and made note of several kinds that deserve mention. It is a pity that the rage for double flowers has resulted in some quite monstrous forms that are more curious than beautiful. One variety is named *Phenomenal*, the flowers of a huge size, perfectly double, but exceedingly coarse, the colour purple, and the segments crimson. Such types should be rejected as not in the least beautiful nor desirable to get. Charming is well named. It is a very free kind both in growth and bloom, dwarf, and the flowers, of dark colour, if not very large, are bright and attractive. A dark variety of great merit is *President*, which has large flowers, deep violet, the tube vermilion. It is well represented in the Chiswick collection. We admire that well-known and pretty variety named *Guiding Star*, quite a gem, the corolla violet-purple, and the sepals white. It is free, graceful, and in every way worthy of culture. *Mons. Thibaut* is conspicuous for its fine dark leaves and purple-violet flowers, a rich contrast of colour, whilst *Minerva* has crimson sepals and purplish corolla. *Aurora superba* is one of the most distinct *Fuchsias* ever raised. It is very free, of excellent habit, and the flowers are distinct in colour, the sepals salmon, whilst the corolla is light orange-scarlet—a pleasing shade. *Spitfire* we made note of as a very handsome variety. The sepals are of a bright red tone, whilst the corolla is rich magenta-purple. *Desideratum* belongs to the double-flowered section. It is a variety well worth growing, the flowers very double, but not so coarse as in some kinds, the whole purple-violet and the segments crimson. There is in this collection a fine plant of *James Welch*, a vigorous grower, with flowers of rich colour, the petals reddish rose and the corolla maroon. Surprise is a distinct and pleasing kind. The sepals are white, set off with a rich purple corolla.

It is a pity that the *Fuchsia* is not more grown for greenhouses. We see it in the flower garden, but not so much as one might in pots. The plant is remarkably graceful and very free-flowering when a good selection is made. In addition to those already noted, also worthy of remark are *President Thiers*, purple corolla and crimson sepals, the old *Rose of Castile*, still one of the best in cultivation, and *De Mirbek*, which has crimson sepals and purple corolla. It is a very useful kind.

Cyrtanthus sanguineus we recently noticed in bloom in the Cape house at Kew. It is a beautiful species, introduced in 1845 from Caffraria by Messrs. Backhouse and Sons, of York. A coloured plate of it is given in THE GARDEN, April 12, 1890. It is a pity that we do not see more of these fine kinds in gardens, as even now *C. sanguineus* is practically unknown. One might go into many gardens without seeing a specimen. The leaves are about 1 foot long, and the scape, which is 9 inches in height, bears about three flowers, which are rich scarlet in colour, large, and not unlike in general expression those of *Vallota purpurea*. As it may be grown under similar conditions to this plant, only requiring a little more heat, there is no reason why it should be scarce.

Babingtonia Camphorosma.—This little New Holland shrub, which has recently been shown in good condition by Messrs. Laing, is both pretty and interesting, while it also attracts attention from the fact that the flowering season of most hard-wooded plants is past before this. It is a somewhat Heath-like shrub with small linear leaves, while the flowers, which are closely packed on long slender shoots, remind one to a great extent of some of the *Leptospermums*. They are pink in the bud state, but become paler—in fact, almost white—after expansion. In its native country it is said to reach a height of 7 feet, but the plants shown were about 18 inches high and flowering profusely. It belongs to the order Myrtaceae, which is so largely represented among Australian flowering shrubs. The *Babingtonia* in question was introduced into this country in 1841, but it is now-a-days a very uncommon plant.—H. P.

SHORT NOTES.—STOVE AND GREENHOUSE!

Cobæa scandens.—C. Findlay asks if the fruits of this plant are eatable. The plant belongs to the Phloxworts. There is nothing hurtful in the fruits, but whether they are tasteful enough to be eaten is a matter of opinion.—W. H. G.

Tacsonia fruits (C. Findlay).—These are splendid ornamental climbing plants, which are too much neglected. *T. van Volxemi*, *T. speciosa* and *T. exoniensis* are very fine kinds. The fruits are about as palatable as those of the *Passiflora* or *Guanadilla*.—W. H. G.

Vallisneria spiralis (J. Elms).—This is the name of the grass-like green leaves you enclose, and the long spiral growth is the stem of the female flower which floats upon the top of the water. It requires to be planted in stiff yellow loam and to have a quantity of large pieces of stone put on the top; this assists in binding the soil and making it firm and hard, which suits the plant well.—W. H. G.

The Elephant Apple Tree (J. Ridley).—This plant is called *Feronia elephantum*, and there are no trees in this country simply from the fact of their not being sufficiently hardy to withstand the climate. It belongs to the same family as the Orange. The fruit contains a soft pulpy flesh, surrounded by a hard rind; it is beneficial in cases of dysentery. It is a native of Burmah and other parts of India.—W. H. G.

Wax-flower (Hoya carnosa).—This plant, if trained round a balloon-shaped or any other kind of trellis, can be well grown in a pot. A mixture of turfy loam and peat, with a dash of leaf-mould and enough sharp sand and bit of charcoal to ensure porosity, will grow it to perfection. The pot must have free drainage. Very little water will be required in winter.

TREES AND SHRUBS.

DEUTZIAS.

ALL the Deutzias are deciduous moderately-sized shrubs, and remarkable for their showy flowers, which, under favourable conditions, they produce in great abundance. From the facility with which Deutzias may be forced into bloom, they are extensively used, and form an important feature in the winter and early spring decoration of greenhouses and conservatories.

D. SCABRA (the Rough-leaved Deutzia).—This species is indigenous to mountainous districts in Japan, and was first introduced in 1832. In that country it is a favourite ornamental shrub, and is frequently seen not only in gardens but as a hedge plant. In our shrubberies it forms a strong-growing broad bush of about 6 feet in height. The

Deutzia parviflora. Engraved for THE GARDEN from a photograph sent by Mons. V. Lemoine, Nancy.

starry snow-white flowers are produced in compound panicles, in May or June, and when in perfection have a splendid effect. It requires a light, well-drained soil, and a sheltered situation—open, however, to the full sunshine, that it may be enabled to ripen its growths thoroughly before the winter sets in.

D. GRACILIS (the Slender Deutzia).—This superb little shrub is also a native of Japan, and was introduced about 1835. It is of a dwarf bushy habit of growth, rarely seen higher than about 3 feet. The pure white flowers are produced in axillary panicles, and in ordinary seasons are in perfection in May. Though quite hardy if planted in a light dry soil and in a sheltered situation, and though naturally the most profuse-flowering of the genus, it is only in exceptionally favourable seasons that its full beauty is developed in the open air in this country. It is, therefore, chiefly as a greenhouse plant or for forcing that it is now so extensively grown; and it is one of the best known and most popular of winter and early spring conservatory flowering shrubs. For this purpose it is usually kept in pots, plunged in a sunny border out of doors during the summer months, and freely watered during the growing sea-

son, the supply being gradually diminished as the shoots begin to ripen and the leaves show signs of decay. On the approach of winter the plants are stored under glass, to protect them from frost, and transferred into the forcing house from time to time, thus securing a succession of bloom, if desired, from January till May. As they are easily excited into growth, a gentle heat is all that is either necessary or desirable, unless, indeed, they are required very early, in which case it is best to put them into a warm temperature as soon as possible after the leaves fall. While growing freely, and immediately before the blooms expand, a dose of weak liquid manure will be found very beneficial in assisting the free development of both foliage and flowers. For pot culture a compost of three parts fresh light loam and one part well-rotted leaf-mould, with a liberal allowance of sharp sand, is found to suit admirably. A well-managed specimen of this lovely plant, with its fresh, warm, green leaves and graceful blossoms, has a charming

fibrous roots stands them in good stead when potted up for forcing.

Mons. V. Lemoine, who sent us the photograph from which the annexed engraving was made, thus writes concerning *Deutzia parviflora* here figured:—

Anyone who visited the quinquennial exhibition at Ghent last April might have seen some flowering branches of *Deutzia parviflora* side by side with an exhibit of cut flowers of double Lilac. These *Deutzia* flowers were produced by a plant which, after passing the winter in the open ground, had been taken up and potted and then forced in a temperate house. This forcing proved a complete success, all the buds shown by the plant having grown well and produced flowers of the usual size—a result which leads us to expect that, when flower fanciers and growers for market treat *Deutzia parviflora* in the same way as they do *D. gracilis*, they will be rewarded with results equally satisfactory. The hardiness of *Deutzia parviflora* is beyond question. We had some young plants of it put out in the open ground last year, and these did not suffer in the least from the very severe winter which followed, while *Deutzia crenata*, *D. crenata flore-pleno*, &c., were badly hit, their stems being frost-bitten to the extent of one half.

The two photographs which we herewith send you represent a plant grown in the open air and were taken from two points of view. This plant passed the last two winters in the open air, and a glance at the profusion of flowers which it now bears will enable anyone to form a good estimate of its hardiness. *Deutzia parviflora* grows in clumps or tufts seldom more than 5 feet high, the rather thick, rigid stems standing bolt upright and bearing lanceolate-elliptical dark green leaves, which are toothed at the margin and strongly veined and wrinkled on both sides. The flowers are disposed along the stems in erect corymbose panicles, presenting an aspect quite characteristic of the plant. The petals are five in number, round, narrowed towards the claw, as in the Rosaceae. The well-opened-out blooms standing stiffly on their stalks and having a horizontal direction remind one of the effect of Hawthorn flowers. They are of a creamy white colour without any tinge of pink or purple on the exterior of the petals. It is the earliest to flower of the genus, and in the open ground comes into bloom some days before *D. gracilis* and about a month earlier than any of the other species. It is a native of the northern parts of China and of the region of the Amoor River. It was first of all introduced to the Imperial Botanic Garden at St. Petersburg; thence it was sent to the Arnold Arboretum, Cambridge, Massachusetts, from which it was distributed amongst some American nurserymen. The Museum of Natural History at Paris also possesses specimens of it. It was for the first time put into commerce in Europe by our own firm in the beginning of the year 1891.

The late Alphonse Lavallée grew in his Arboretum Segregranum five species of *Deutzia*, viz.:—

DEUTZIA SCABRA (Thunb., Japan) and its variety with variegated leaves.

D. CRENATA (Siebold and Zucc., Japan) and varieties, flore-puniceo, flore-purpureo pleno, flore-albo pleno=candidissima plena, foliis variegatis, Fortunei, Sieboldi.

D. GRACILIS (Sieb. and Zucc., Japan) and its variety with variegated leaves.

D. DENTATA (Hort.).

D. STAMINEA (R. Br., East Indies).

M. Lavallée did not possess a specimen of *D. parviflora*.

effect in winter, and is not only invaluable for decoration, but supplies very beautiful sprigs for hand-bouquets.

THE DOUBLE FLOWERED DEUTZIA (*D. crenata* fl.-pl.).—This *Deutzia* flowers naturally so much later in the season than *D. gracilis*, that as a matter of course it cannot be induced to bloom even when forced as early as *D. gracilis*. Still, for all that, it is very valuable for greenhouse decoration, as good-sized bushes full of bloom are very pretty, and they retain their beauty a considerable time. There are a couple of distinct forms of this *Deutzia*, one in which the flowers are pure white, and the other with the outside of the blooms tinged with pink. A good white form is candidissima, between which and the variety known as Pride of Rochester there appears to be little, if any, difference. As outdoor shrubs, too, these *Deutzias* are wonderfully pretty, and the fact that they do not bloom till the majority of spring-flowering shrubs are past their best is an additional point in their favour. They are thoroughly hardy and by no means particular in their requirements, though the finest display is, of course, obtained from plants favourably situated. These *Deutzias* strike readily enough from cuttings, and their dense mass of

To the crenata group may also be referred *Deutzia Watereri* (single-flowered) and *D. Wellsi* (double-flowered), which have been erroneously represented as having been obtained by intercrossing *D. gracilis* and *D. crenata*; also *Deutzia Pride of Rochester* (double-flowered), raised by Ellwanger and Barry, of Rochester, N.Y., United States of America. In the tenth volume of the "Mémoires de l'Académie des Sciences de St. Petersburg," seventh series, Maximowicz has published a "Revision of the genus *Deutzia*," in which he describes nine species, all of Asiatic origin. Of these, three species belong to the region of the Himalayas, two species to Northern China (of these, a species named *D. grandiflora*, which has not yet been introduced into cultivation, is said to be one of the finest kinds) and four species to Japan.

Bambusa Ragamowski.—Among the dwarf Bamboos this stands out as a fine and distinct species. The leaves are very much larger than those of any other dwarf kind; indeed, so massive is the foliage that an inspection of it alone would suggest that it belonged to one of the largest-growing forms. A notable feature of this Bamboo is the habit of pushing up especially vigorous shoots at some distance from the parent plant. It is, as a rule, on these shoots that the finest leaves are produced. In grouping hardy Bamboos, such a species as this, with large massive leaves, yet dwarf in habit, is especially valuable. *B. Ragamowski* is a native of China and Japan, and besides the above name is also known as *B. tessellata*.—T.

Barberries in flower.—Two of the evergreen Barberries—*B. Darwini* and *B. stenophylla*—that bloom naturally in the spring are in some cases flowering again with great freedom, and very welcome their bright-coloured blossoms are at this season. Some individuals seem a good deal more prolific than others in the production of a second crop of bloom; indeed, so great is the difference between them in this respect as to suggest the possibility, by a course of continuous selection, of obtaining an autumn-flowering group of Barberries. In some seasons blossoms of *Berberis Darwini* may be found till the near approach of winter. The present hot season may have had something to do with the second display of blossoms, that is, in districts where the plants have not suffered from the drought. Among plants influenced by the unusual season must, I think, be included the hardy *Hibiscus* (*H. syriacus*), which, where the soil is moist, is flowering in great profusion, while on dry soils it has scarcely a leaf left.—T.

Wistaria sinensis.—A note appeared at page 93 as to this plant producing a second crop of bloom in the same year. I have a tree of immense size some seventy years old, that blooms profusely the second time if the first bloom is poor, and *vice versa*. If it fails to flower freely in May, I get a heavy bloom in July from the young wood. What a lot of drought the *Wistaria* will stand! I consider it one of the best of creepers for a dry exposed position, especially if allowed to grow naturally. I do not advise training during the growing season, I never touch it with a knife, and in such tropical weather as we are now experiencing the ample foliage forms a delightful shade to the dwelling. The plant I refer to is planted under the wide projecting eaves of the dwelling-house, and is a lovely object at all seasons, as even when devoid of foliage its ample growth presents a pleasing appearance.—W. S. H.

Bambusa pygmaea.—One of the most interesting of the numerous Bamboos introduced of recent years from Japan is this pigmy *Bambusa*. Its stems are only from 3 inches to 6 inches high, and it is therefore the smallest of any in cultivation. It has narrow linear leaves, tapering

to a fine point and of a vivid green on the upper surface. Underside they have a slightly glaucous tinge and are covered with small hairs. As this little plant may be rapidly increased by dividing the tufts into pieces consisting of two or three stems—especially if taken indoors and given a little bottom-heat—a large patch may soon be obtained. It suggests itself for use in a variety of ways, especially to form a green carpeting in moist situations. It is perfectly hardy at Kew, and retains its leaves throughout the winter. It is accepted as a good species by Munro in his "Monograph of the Bambusaceae," the standard work of reference on this order. The only other Bamboo near this in diminutiveness is a form of the variegated *B. Fortunei*; it is called *compacta*, but has to be grown in small pots. If planted out it gradually reverts to the ordinary form, which is 2 feet high.—B.

FERNS.

VARIEGATION IN FERNS.

THE natural green colour of Ferns, although very beautiful, presents a rather sombre appearance unless associated with a little colour; therefore, the variegated and tinted varieties should be cultivated as much as possible. The variegated varieties are not numerous, and any new additions are welcome. *Pteris Victoriae*, introduced a year or two ago, was a distinct acquisition, and from it other varieties have been raised, notably a good crested form, also *P. tremula variegata* and another which has all the characteristics of *Pteris serrulata*, except that it has a distinct linear marking of white. I am at present unable to say if these come true from spores, but hope to be able to say more about them a little later on. The following are among the best variegated kinds:—

PTERIS VICTORIAE.—Some months ago I referred to this distinctly variegated Fern, and mentioned that many of the seedlings produced imperfect fronds. I now find that as the plants grow older this deformity is not seen. The plant is altogether of a more robust habit than I imagined when first I saw it, and grown on freely it makes a splendid plant for decoration. I should not recommend potting into larger than 5-inch pots, but where a larger mass is required, several plants may be put together into a large pan. The clear white linear markings through the pinnae are much more distinct than in any other variegated Fern, and I think eventually it will become one of the most popular market Ferns. Spores are produced in great profusion and they germinate as freely as any of the *Pteris serrulata* type. Young plants are a little slow, perhaps, but when they once get a good start they soon make nice plants. This Fern succeeds best where potted in a light loamy compost; plenty of drainage should be used and care should be taken not to over-water the plants, especially when first potted on. An intermediate temperature, with sufficient ventilation to prevent damp settling on the fronds, will ensure the fronds keeping a bright, fresh appearance. I should mention that seedlings vary somewhat in character, and where a large number of seedlings is raised, the most distinct should be selected for growing on.

PTERIS TRICOLOR.—This is the most beautiful of all the variegated Ferns, yet we rarely meet with it in a condition to recommend it. It is undoubtedly more difficult to manage than most of the *Pterises*, yet with a little care plants may be grown on to a good size and kept in character. Change of temperature and damp on the fronds are great drawbacks. A little moisture on the fronds will do no harm unless the temperature falls low or the sun strikes them before they are dry; either will cause the fronds to become discoloured. The fronds not being produced so freely

as in most of the *Pterises*, it is of the greatest importance to preserve every one until natural decay takes place. The best way to treat this beautiful Fern is to pot it in a good porous compost, consisting of rough fibrous loam, leaf mould and peat, with a good sprinkling of sharp sand. Plenty of drainage should be used and care taken not to over-pot. In repotting, only one size larger pot should be used. Repotting from time to time is beneficial, but in case of plants not being healthy, it will be better to reduce the balls and pot back into the same size again, taking care to keep the crowns of the plants well down. I find this Fern succeeds best when kept well up to the light in a moderate stove temperature. A regular temperature is more desirable than excessive heat.

PTERIS CRETICA ALBO LINEATA.—This old favourite has come to the front again lately. It has been grown extensively for market this season and has been much appreciated. When grown on freely the basal fronds entirely cover the pots, and by the time the first fertile fronds (which are thrown up well above the barren ones) are well developed, fine plants are formed. The first plants I remember of this useful Fern were grown from spores, and as at that time it was considered a very choice variety, great care was bestowed on the plants. They were grown in a cool lean-to house with a northern aspect, potted on as they required it until they were in 7-inch pots, the barren fronds entirely covering the surface, and when the fertile fronds, which grew from 18 inches to 2 feet high, were well developed they made very handsome plants. It is one of the best Ferns for house decoration. The fronds, being of good substance, will stand a dry atmosphere even better than those of the ordinary green form of *cretica*, which is now such a general favourite. It must be remembered that for Ferns to stand well they must be well exposed to the light while they are making their growth and not kept too close. Plenty of room, light, and air will ensure good growth and symmetrical plants.

PTERIS ARGYREA.—This well-known favourite, though a little tender, is a grand Fern for decoration. It requires a little more warmth than some during the winter, but during the summer the cooler it can be kept the better. Some of the best plants I have seen of this useful *Pteris* have been grown in cold pits, and have made shorter and more stocky growths than those grown in heat. Although it will do well until late in the autumn without warmth, it must not be exposed to very much cold or the fronds will be discoloured. As a decorative plant the above-named *Pteris* may be grown together with other sorts. *P. straminea* is one of the best to associate with it. If one of each is potted in the same pot they grow up together, and the two distinct shades of colour form a nice contrast. *P. serrulata*, *P. tremula*, and *P. cretica* may also be grown in association with *argyrea*, but *P. straminea* is certainly the prettiest combination I have seen, the one filling up just the naked part which the spreading habit of the other leaves bare.

PTERIS NEMORALIS VARIEGATA.—This is a very distinct Fern. The linear variegation is somewhat after that of *P. argyrea*, but the young fronds have a distinct rosy tint, which is quite absent in the better-known *P. argyrea*: the plant is also of a more compact habit, and the marginal or green portion of the fronds has a glaucous shade. Like *P. tricolor*, it requires some care to establish good plants. It may be treated as recommended for the last-named, but will make a good specimen more quickly.

ADIANTUM CUNEATUM VARIEGATUM.—While writing of variegated Ferns I may say a word about *Adiantum cuneatum variegatum*, which is certainly a novelty. Although Ferns with the striped or irregular variegation are generally inconstant, yet, judging from plants I have received, this is an exception. Three plants which had the appearance of being seedlings were all regularly marked with white through all the pinnales. It is doubtful, however, if it will ever rank very high

as a plant for decoration. The variegated form of *Adiantum macrophyllum* is another attractive Fern which seems likely to retain its character. Those who have seen *macrophyllum* in its best condition can imagine the striped variegation through the broad tinted pinnules as forming an additional charm.

LASTRIA ARISTATA VARIEGATA.—This should be included among the best variegated Ferns. Seedlings are a little slow at first. The bright fresh green with a distinct linear marking of yellowish white through the fronds makes them very effective. It is also one of the best to stand, the fronds being of a peculiarly hard texture. This is a cool house Fern, but while plants are making growth they will develop larger fronds if grown in a warm and rather moist atmosphere. I find it succeeds best in a good loamy compost, and will stand more hardship than most Ferns.

Among hardy Ferns the only distinct variegated form which I am acquainted with is

ATHYRIUM GORRINGIANUM PICTUM.—In this the variegation is almost as distinct as in *Pteris tricolor*. Grown under glass it makes a very pretty plant, and should be found in all collections of hardy Ferns. It may also be recommended for decoration during the early part of the summer, for when the new fronds are first developed their colour is very bright. Being deciduous it is only during the summer that its beauty is seen, and when grown in pots it must be kept quite free from heat and not too dry during the winter.

A. HEMSLEY.

KITCHEN GARDEN.

SPINACH FOR WINTER AND SPRING.

GARDENERS, where Spinach is in demand throughout the winter and spring months, know the value of a good breadth of it. In very many instances the crop of winter Spinach is not very satisfactory. The grub of the Spinach moth is for the most part answerable for these failures, which are more prevalent in some seasons than others. The best preventive is to have the ground fallow at least a month before sowing, during this time well forking it over, thus exposing it to birds and the pulverising influence of the atmosphere. With soil nicely fined down the seeds germinate much more kindly. With winter Spinach there is generally a difference of opinion as to the date of sowing for the main winter crop. The danger is, that if sown too early and the autumn should turn out warm and dry, it may run to seed, and if sown too late there is not sufficient time for it to become large enough to be of use for gathering during the winter. A week or two often makes all the difference one way or the other. For late districts the first week in August is none too early, but for earlier and warmer parts the end of the second week or throughout the third week is the most suitable. It is a good plan to make two sowings, the first during the early part of the month and the other at the time stated. In this case the earlier sowing may be gathered from in the autumn, the other not being gathered from upon any account until the winter season. The chances are if the winter crop should be gathered from in the autumn the growth will be checked. This may appear a simple matter, but it is best to be prepared if Spinach is expected to be forthcoming at all seasons, or at any rate when the weather will allow of its being gathered. Another sowing should be made at the latter part of September. This commences to turn in just as the winter crop is going over. It is well known how quickly the winter crop runs to

flower upon the return to sunny and more genial weather. With the sowing under notice, the seedlings grow but very little before hard weather sets in, but at the turn of the day they commence to start nicely into growth and bear long before any sown in the new year. The commencement of the present year was a notable exception, as on account of the weather being abnormally mild, the early sowings grew freely. For the main breadth of winter Spinach there is nothing like having the plot in an open position, as here the plants are not likely to be attacked by grubs. Spinach follows well after Potatoes or even Peas, and as these latter, with the second early Potatoes, have been cleared off earlier than usual this year, there should be suitable space at command. The soil having been well forked over, should, previous to having the surface broken down, receive a fair dressing of soot and also burnt refuse. This, besides stimulating growth, also has a deterrent effect upon grubs.

For providing the supply for the winter season the Prickly-seeded is the variety generally grown, but *Victoria* is now having many advocates, it being considered much superior on account of the larger leaves and not running to flower-stem so quickly in the spring. But whatever merits this latter may have, the older Prickly-seeded will continue to be largely grown, as on suitable soils the leaves of this even will grow surprisingly large. The drills should be drawn quite 18 inches apart, as crowded rows are not very desirable, the seeds also being sown thinly, as if at all crowded the young plants become unduly disturbed in the thinning. Thinning should be gradual, or an attack of grub may lessen the number of plants considerably. Although winter Spinach likes a moderately firm soil, yet surface hoeing is very essential, this promoting a healthy and free growth, and, besides, if grubs should be present this will disturb them; in fact, hoeing should be practised as long as possible. In gathering, a leaf or so should be taken off each plant, as then the plants are more likely to keep on giving a supply, weather permitting.

A. YOUNG.

HARDY CABBAGE LETTUCE.

AT this date the seed should be sown for the next spring supply. In the matter of hardy kinds I do not consider we have made much progress. We certainly have plenty of new kinds, but none so hardy as the old Hammersmith Hardy Green and Lee's Hardy Green. These varieties have been grown for many years, but the beginner need not fear any evil consequences by selecting the above kinds, as they are the most reliable and are the hardiest of all. I have of late years when sowing my last lot of Lettuce always given a trial to some new kind, but none succeed like the old kinds. I admit in early spring varieties we have made considerable advance, as there are some valuable additions. In the Cos section the same remarks apply. If a good Cos Lettuce is wanted to follow the Cabbage variety I prefer the Brown Cos on account of its hardiness. During the past two severe winters the Hardy Hammersmith was the best, followed by Lee's Immense, a larger form of the former and much like it, but scarcely so hardy with me. Sowing should not be deferred after the first week in September in cold districts. I prefer a south sloping border, as this allows of excessive moisture draining away, as it will be found too much damp is more injurious than cold. After a prolonged frost a slight shelter from cold winds will do good. Of course, frame protection is of great service, but all cannot afford it, and much may be accomplished by drawing the largest plants and planting rather thickly at the foot of a south wall.

I have in cold districts sown a row thinly at the base of a wall, and by this means secured good material for early spring use. The great drawback is slugs, but by close watching and applying soot they can be kept away. Another simple way is to protect by boards and thatched hurdles, only using the latter in severe weather. Large weak plants are the first to suffer in severe weather, so that too rich land for winter Lettuce is not required. I plant on ground from which another crop has been cleared without digging or forking it. When sowing the seed on dry soil, it is necessary to water and afterwards to cover the seed-bed with mats to get a quick germination, taking care to sow thinly to allow of a robust growth.

S. H.

FRENCH BEANS FOR AUTUMN AND EARLY WINTER.

WHEN the choicer summer vegetables are scarce, anything which may be grown to form a variety in the usual run of autumn vegetables will be highly appreciated. To fill this void, French Beans are most useful, for although a little extra time will be taken up in the preparation of the pots, yet at the season when the Beans are in full growth the weather is more often than not very dull and wet, consequently watering is not a laborious operation. Useful crops may also be grown in heated pits. Of the two methods, growing the plants in pots is the better of the two, as then the pots may be removed to suitable quarters in which to finish off the crop. If the weather should remain for a time longer in its present fine and dry state, the Beans will succeed best in a cold frame. The fault I find with French Beans when the pots are stood in the open—a course sometimes recommended—is that upon being placed in warmer quarters upon the approach of colder weather, the sudden change causes the leaves to fall. I have also noted that this evil is sometimes apparent if the weather should be dull and wet when the pots are in cold frames, therefore, if possible, I like to place them in a pit where a little warmth can be turned on in case such a period should ensue. This season is likely to be an exception, therefore I should not hesitate to place as many pots as possible in cold frames, these being removed into a warmer structure when the time comes for housing.

After giving some of the most approved varieties for pot culture a fair trial, I have fallen back upon the old Osborn's Dwarf Forcing. Syon House and Ne Plus Ultra are also good, but for early winter work the variety named above is valuable. It is dwarf, sets freely, and moreover, is very prolific. It may also be necessary to add that new seed is the best. Large pots are not needed for this season of the year. Moreover with the pots well filled with roots they are in a condition to take feeding more plentifully. Half-filling the pots with soil is no gain whatever, in fact, it entails a deal of extra labour. Some good loamy compost should be used, the seeds being covered to the depth of 1½ inches. Six or seven seeds should be sown in each pot, as I find with Osborn's Bean that it may be sown thickly with advantage. Being placed in the frame the soil should be syringed over-head daily if the weather should be bright and sunny, when the plants will soon appear. No coddling must be allowed or the plants will not prove at all satisfactory, being drawn and spindly. Ventilation must also be freely applied on fine days, and the daily sprinklings must not be neglected, that is, unless the weather should be dull, when the drier foliage is kept the better. If the soil be kept fairly moist, good plants will be provided suitable for producing a good crop of late Beans.—A. Y. A.

—To get a supply of late French Beans is not often attempted, but they are valuable at the end of the year, as at that period choice vegetables are none too plentiful. To get a supply through September and October or even later is an easy matter provided frames can be spared for protection, sowing on a warm

border from the 15th to the end of August. Syon House, Mohawk, or Ne Plus Ultra are good kinds. A sowing should be made on a south border, and in proportion to the space that can be covered with frames or sashes. These will be required at night in September if frost is likely to set in, but in all cases the plants should be exposed as much as possible during the day. In mild autumns I have gathered Beans from this late sowing well into November, and as the pods keep good for some time when gathered, they are valuable. Of course it is essential to get a good growth and the first set before frost appears. I allow 2 feet between the rows, and mould up before the frames are placed over the plants. Beans of all kinds being gross feeders, I do not let them want for either food or moisture. Care should also be taken not to have the lights or sashes too close or touching the tops, as this latter prevents a free circulation of air, and often causes damping in wet weather. It is also important to keep the pods gathered, as if allowed to get old they prevent the younger ones growing. I have tried the larger Canadian Wonder, but it requires mere room, and must be stopped if required to come in at a certain time; besides it takes longer to come into bearing and is not so useful as the smaller kinds. By sowing in the way described a much larger crop will be secured than if sown later in pots, as often we get a sharp frost or two early in the autumn and a spell of fine weather afterwards, during which time the late-sown Beans will set freely, and with protection at night a good supply for a considerable period will be had.—G. WYTHES.

Mildewed Peas.—How is it that with all the information with respect to the mould-destroying properties of the Bordeaux mixture, these whose Peas suffer from mildew have not utilised this mixture? If here and there some Peas or some special varieties escape, it is perhaps more due to accident than to any other cause. However, it is evident that even if the sulphate of copper be poisonous, at least it cannot at all injure the pod products of the Pea plant. But it is not of much use to apply the dressing after the mildew has got a footing. It is far wiser to apply the mixture at an early stage of growth in almost vapour form, and at intervals of from ten to fourteen days. The application costs a mere trifle, for it may be used with the aid of a very fine syringe, and a small quantity would suffice to dress a good length of staked Peas.—D.

The Potato disease.—This fungus is reported to have made its appearance in Ireland, but even there, whilst the weather keeps so hot and dry, it can do very little harm. The early varieties at home are now all ripe, and the sooner they are lifted the better. They seem everywhere to be absolutely sound, and as nearly all our later sorts are of the accepted disease-resisting section, even did the heat and drought change to rain and cloud, it is very doubtful whether any material injury would result. For that reason it seems doubtful whether much, if anything, is to be gained this season by dressing Potatoes with the Bordeaux mixture, for the crops are rapidly ripening, and there is every reason to believe that we shall have an abundant produce of tubers.—A. D.

MARKET GARDEN NOTES.

RASPBERRIES are this year a short crop, and have been making 6d. per lb. Where the land is of a holding nature they have done fairly well, but on light soil the yield has been very poor and in many places the foliage shrivelled from the intense heat and drought. Where this occurred the growth of new canes has, of course, been very weak, so that next year's crop will necessarily be much below the average. Carter's Prolific seems to be the favourite variety, but a kind called Norwich Wonder appears likely to come into favour. The Strawberry season cannot be said to have been satisfactory. Prices ran higher than has been the

case for some years, but the yield of fruit was much below the average, in some localities not being more than one-fourth of what it is in ordinarily favourable years. In spite of its earliness, Neble is by no means a favourite with growers in this locality. It has obtained a bad reputation for quality, and is the worst eating Strawberry in cultivation now grown for market. A large grower here, who has many acres of Strawberries, has already reduced the area occupied by this kind to a quarter of an acre. It is not only in the London markets that Neble is disliked—it is equally unpopular in the great northern towns. Sir J. Paxton and Stirling Castle are the favourite kinds here. The latter does remarkably well on our light sandy loam, with gravel at about 2 feet from the surface. It holds out to the third year better than any other kind, and the fruit being so firm travels well in the peck baskets in which a great bulk of it is sent away. Beetroot is dear, making about 5s. per dozen bunches, and is not likely to be much cheaper. On heavy lands there was much difficulty in getting the seed in, and owing to the drought much of it failed to germinate. Turnips and Carrots are making about the same price, which is more than double the ordinary rates either at this time of year or in the winter. Good succulent Turnips are indeed rare. One may go through 20 acres of them and not find an acre fit for market. The dust-dry condition of the soil causes the roots to turn yellow and become tough and rank before they are one-third of their proper size, and the fly in many places takes off the young plants as soon as they come through the ground. Here and there one may come across a breadth of Carrots that have got well held of the soil and are doing well, but most of the crops of this vegetable are thin and the plants very small. Parsley in good condition is not too plentiful, making ninepence the peck—a rather long price for this time of year. J. C.

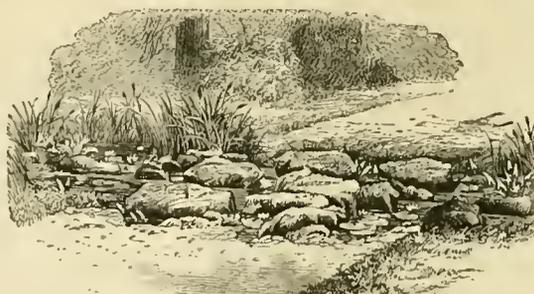

Byfleet.

THE ROCK GARDEN.

ACCESS TO ROCKS AND PLANTS.—III.

(3) BRIDGES.

ROCK GARDENS containing water will generally require one or several bridges in order to make them as easy of access as would be

No. 1.—Stepping-stone bridge, with Water Lilies and other aquatic plants.

desirable. Especially is this the case when a streamlet traverses the grounds and is used to advantage. Where such a streamlet crosses a path of any kind, no matter whether it be a gravel walk, a grass path, or a mere rocky passage, a bridge of some kind would certainly be desirable, and might be made so as to be not only useful by providing a safe and convenient means of crossing the water or other parts of the work, which otherwise would be inaccessible, but it might also be made decidedly ornamental by being constructed in such a way as to enhance the picturesque beauty of the scene. On the other hand, bridges are repul-

sive when introduced where not really wanted, and when several bridges of the same kind occur in the same work. I recently saw a garden where no less than five rustic bridges, all of the same pattern and all within the space of 50 yards, had been introduced. When abused in this way bridges appear ridiculous, reminding one more of the eccentricities of a toy-shop than the delights of a rock garden. Bridges must always appear out of place when their usefulness is not plainly evident—for instance, when they occur in a position where they would constitute not a short cut, but a detour; or when they are placed near a point where the water vanishes from view, and a bridge therefore would be quite unnecessary.

BRIDGES OF STONE.

In the rock garden itself a stone bridge, besides being the most substantial and lasting, would, perhaps, be also the most effective and practical. The size and shape must, of course, depend on circumstances. When speaking of a bridge of stones, I do not mean a bridge formed by masonry, in the shape of a stone or brick arch. The latter kind may be desirable and practical enough in a park or pleasure ground, and, if the stonework is decorated with suitable plants, might be made quite a picturesque object. But in the rock garden such a bridge is not desirable unless a natural stream of considerable width runs through the rocks and the bridge is connected with a more or less regular path. Bridges in the rock garden would, as a rule, have to be of smaller proportions.

THE NATURAL ARCH.—In the boldest part of the rocks a very effective bridge can often be formed with the rocks themselves, in the shape of a natural arch on either a large or small scale. Especially desirable is such a bridge when by this means access can be had across a deep ravine with or without water. In this case such a bridge might often constitute a point of vantage from which the sides and bottom of a glen or ravine may be viewed with safety, and present at the same time, perhaps, a more effective picture than could be obtained from any other position. To look perfectly natural such a bridge should have the appearance of having been formed either by water, which undermined the rocks, and by constant abrasion washed away the softer parts of the stone, or by violent volcanic action which caused the rocks to fall in such a position as to form a natural bridge. The hints given in a previous chapter on the formation of the roof of a cavern may be found of service to those wishing for further information with regard to construction.

SINGLE STONE BRIDGES.—A practical and often very effective mode of introducing variation in a rock garden consists in forming a bridge by means of one single stone. But, while a natural arch, as a rule, would form the means of transit at a considerable height above the level of the water, or, as the case may be, the bottom of a ravine, a single stone, if forming a bridge, appears generally most natural and effective when placed at a lower level or close to the water. Of all bridges this is the easiest to construct, requiring nothing more than a large flat stone, which for safety should have a good bearing at each end, and might be embedded in cement, but so as not to look in any way stiff or artificial.

STEPPING STONES.—For crossing a shallow streamlet, even if this should be of consider-

able width, a stepping-stone bridge can often be made most attractive, while affording at the same time a very safe mode of access. The illustration No. 1 shows such a bridge, with Water Lilies and other aquatic plants growing between the stones. In constructing a stepping-stone bridge, care must be taken to place the stones so as to afford a free passage to the water and appear at the same time careless and irregular. It is, of course, also necessary to have due regard to comfort by not keeping the stones too far apart and fixing them so securely that they can never shift when trod upon. If the bed of the streamlet were constructed with cement, as recommended in a previous article, the stepping-stones should not be placed in position until the bottom is quite hard and water-tight, when an additional layer of cement

through decay. There are, however, positions, especially in rock gardens on a large scale, where we could not well dispense with them and where a stone bridge of any kind would be far too heavy in appearance. Such a case is illustrated in the engraving No. 2, showing a rustic wooden bridge spanning the rocks above a waterfall. Lightness combined with strength is the great desideratum in a bridge made of wood. To avoid a clumsy appearance, I generally use for bearers the stems of crooked Oak, from which all the bark has been removed.

The railing of a rustic bridge can, unfortunately, not be made in the same substantial manner—at least not with wood—without looking too clumsy and heavy. It would be best, therefore, to make them of light pieces of crooked Oak or thin Larch stems with bark

fix in such a position, a chain stretched tightly across or a single rail of iron securely fastened might be found serviceable for the purpose.

Exeter.

F. W. MEYER.

(To be continued.)

FLOWER GARDEN.

CARNATION NOTES.

THE flowering season of 1893, although a brilliant one, has been of short duration, and now in the middle of August a great many kinds are flowerless. One aim we should have in the

No. 2.—Example of rustic bridge made of wood.

may be spread and the stones embedded in it. The remaining surface of the bottom is then covered between the stones with river gravel and small pebbles, so as to look perfectly natural.

As a rule, the use of stepping-stones should be limited to shallow water. If used for deep water, it is more difficult to fix them so as to be quite safe without looking more or less stiff and artificial. Especially is this the case when the water is so clear that the foundation of the stepping-stones under water would be visible. But where it can be so arranged that the stepping-stones appear like natural rock projecting here and there above the surface of the water, their use for deeper water would be quite commendable.

BRIDGES OF WOOD.

Wooden bridges, like wooden steps, have one great drawback; they soon become unsafe

attached. But it must be borne in mind that every few years this railing will require to be renewed, though the bridge itself may last for a generation if made of heart of Oak. In speaking of railings I would once more draw attention to the successful imitations of Birch, Beech, and other wood in iron, as mentioned under the heading of "Steps," and recommended as being light and durable.

Before concluding my remarks on the subject of bridges, I would like to mention another kind of wooden bridge suitable for occasional use, but more adapted for a rocky Fern glen shaded by trees than for a rock garden constructed for alpine. This consists in the stem of a large tree thrown carelessly across the stream or ravine, as if it had fallen there naturally. As a wooden railing would here look out of place and would, moreover, be difficult to

future is to develop and encourage that charming successional blooming habit so characteristic of Countess of Paris and several other French selfs, but this one notably. Someone recently sent me flowers of a promising seedling that is to be infinitely superior to the Countess of Paris, and the sender remarked that the Countess looked poor beside his seedling and was quite out of flower; whereas the seedling was promising a succession of bloom for several more weeks. No Carnation that I have ever grown out of doors can compare with the Countess in this respect, and the finest flowers it produces are really those upon the secondary spikes. I have them now perfect in form and delightful in colour. I believe a fictitious value is often placed upon seedlings, and their real value is only found out and known after they have been grown again one season at least

from layered plants. Seedling plants invariably have extra vigour, in part the result of their long season of growth previous to their first flowering; and as to successional blooming, they often promise this in the seedling state, but discontinue to do so entirely when grown on and layered from year to year in the usual way. A great number of seedlings appear at the shows in competition for the prizes offered for outdoor kinds, but I think a restriction should be placed upon this to some extent. It would not be well to insist upon named varieties alone, but if seedlings are permitted, there should be some means of knowing whether the blooms were cut from layered plants or from seedlings blooming for the first time.

EARLY PLANTING.—All the details of culture have in this extraordinary year been performed from three weeks to a month in advance of the usual date, and as a consequence there is nothing, so far as the state of the plants is concerned, to prevent the all-important early planting being carried out. I began to-day (August 14) by putting out a group of more than 100 plants of the best white self I ever grew, namely, Alice. There was no attempt at trying to begin on the first possible day, but the layers are furnished with large balls of roots such as we usually find upon them from the middle of September onwards. From now and henceforward as early summer things fade away, ground will be immediately prepared and planted.

YELLOW CARNATIONS.—I am pleased to read on page 147 that yellows are no longer "scarce, weak and disappointing," but I do not find full assurance in the facts that Mr. Weguelin proclaims. In the first place, I spoke of selfs, or at any rate if not clear on the point, these were uppermost in my mind. But Mr. Weguelin is obliged to borrow assistance from the yellow grounds, which I admit are numerous and fine, but they are beside the question altogether. From the standpoint with which we regard outdoor Carnations, these yellow grounds are too much alike. I do not wish to imply that they are not distinct from each other, but firstly, by reason of their varied colours and then by their subtle differences of shade, they have not that distinctive character and individual charm that are the most precious qualities of the true selfs. If the other yellow selfs Mr. Weguelin mentions are as fine as Germania and Leander, I hope they may soon be plentiful and cheap; but meanwhile my contention is true, and take any colour you will in Carnations, yellows are decidedly in the minority.

As to Leander and its raggedness, these terms of ragged and rough that are often given to flowers not quite up to the false standards of perfection, are, to say the least, absurd. If the flower is perfectly formed and clear and good in colour, why should some well-marked individuality or characteristic of the kind be set aside as depreciating its worth? If Leander does not spread each petal out flat and regularly disposed, it can find but scanty recognition amongst those who are bound more or less by the tenets that destroy the charm of individual distinctness, through setting up a false and formal standard which if not unreal is certainly too exclusive.

CAROLUS DURAN AND MRS. REYNOLDS HOLE.—These are both first-rate Carnations, but the former is, all points considered, the better of the two. I have had them both under close observation, Mrs. Reynolds Hole since 1887 and Carolus Duran since 1889, when it was sent to me from M. Hochard as a nankeen self, which it really is. Almost everyone who sees it makes an unfair comparison

between it and Mrs. Reynolds Hole, and the usual remark is, "It is so much paler." Of course, that is one of its points of distinction. No one ever said it was the same in colour as Mrs. Reynolds Hole, but it has some of the same brilliant apricot tint, although paler in the outer petals. In form, however, it is quite superior, and has never burst with me; whereas in some seasons I have not had a perfect bloom of Mrs. Reynolds Hole, although it should be admitted that it is not the persistent burster that some kinds are. Last, but far from least, after the Countess of Paris, Carolus Duran is the next best successional bloomer I know, and though its first blooming is past, there are now many flowers and spikes developing which as yet do not show their terminal buds. No doubt Mr. Weguelin will see its fine character better as his stock increases and grows stronger, for it is not two years since in correspondence with me he said he only then had it in a weak state. If it were more generally distributed there would be more said in its praise, but in all probability it has never been sold in the country unless Mr. Weguelin may have disposed of a few surplus plants. I have given it to a few, and among them Mr. Tallack, who speaks well of it in THE GARDEN of August 5.

A. H.

NOTES ON HARDY PLANTS.

Eryngiums.—Your correspondent at page 99 speaks deservedly well of these, and, indeed, it would be hard to over-praise them. One part of his note, however, struck me as what I think I may term exceptional, viz.: "It is unfortunate that these hardy plants cannot be propagated freely, but that seems to be impossible." This I cannot understand, and surely another experience than this must be the more common. They are got freely from seed, from crowns, and from root-cuttings. They have also a way of propagating themselves if you dig near to them, for every rootlet severed from the old plant and left in the soil will grow to a young plant even if 1 foot deep in light soil. It is true the plants are partial to light land, as may be readily concluded from a glance at the length and form of their roots. If the roots of a plant escape through the hole of a pot and you break them off, the parts left quickly grow into a tuft of plantlets. If you dig up the long liquorice-like roots of an old plant in spring, you may cut it into a number of pieces each 1½ inches long, and by keeping the natural upper ends correct and so inserting them 2 inches below the surface in sandy soil, you may confidently expect every one to make a plant. I know a place where the Eryngiums do well in deep sandy stuff, and the quarter cannot be cleared owing to the bits of roots left behind sending up growths long after the stock proper has been cleared, and this applies to all the best and better known sorts. This property of the vitality of the roots is further to the advantage of propagation when we find that all make very long tap roots, some as much as 3 feet, and none perhaps less than 1½ feet in the case of mature plants.

Gentiana gelida.—To see this name quoted as a blue-flowered species (July 15, p. 48) must bring to mind to many GARDEN readers the difficulty of getting the wrong (and once frequent) name put down. I hope, therefore, your correspondent will pardon this intervention. I only do it from a vivid recollection of the great trouble and annoyance the error caused when it prevailed about eight years ago. The name was given to the variable species septemfida, but, variable as that species is, none of its forms ever, in the double sense of the term, could give the least colourable excuse for the name gelida. *G. gelida* is really a yellow-flowered species, on the authority of "M. B.," and is reported as occurring at Arrat (Adams) and Iberia (Fisch.), but there is not

known to be any living specimens existent. There is no other species or even variety bearing the name gelida that is authorised; hence, we see at once the fragrance and well-defined nature of the error. I for one do hope the use of this name will not creep in again.

Aster Thomsoni.—A person once might have sought for this half a lifetime without getting hold of the right thing, owing to the muddled state of the nomenclature and the more mixed condition of both plants and names in commerce. The name can yet often be seen in lists, but the true thing is not at all plentiful. This is regrettable, because it is one of the Asters that nobody can fail to admire. There is, however, this to be said for it: When once seen, no one could easily mistake it, it is so markedly superior as well as distinct in its features. Now that the perennial Asters are being more cultivated and studied, this along with other types is more generally recognised. It is, therefore, to be hoped that this will soon become widely known, for that is only needful to ensure its wide cultivation. It has been said of it that it is not quite hardy and scarcely perennial. This is only another proof that the true plant has been confounded with some other for its hardness is perfect and it is a reliable perennial. You can sometimes get seedlings that flower the first year, but such precocious examples give but a partial idea of the habit of plant or quality of the heads. Seed, Mr. Wolley Dod tells me, is not a certain crop, but I have got a nice batch from some seed he kindly gave me. I have also been otherwise fortunate. It has been my practice for six or eight years to try every Michaelmas Daisy from every available source that seemed to suggest itself as a possible untried kind with a view of getting hold of the finest flowers of the genus, and I have been rewarded by finding this lovely species in quantity, and, oddly enough, under a much commoner name than its true one. I only mention this to show that some plants may not be so scarce as we have been apt to think when hunted up. It may be said with a measure of truth that it is not true to date as a Michaelmas flower, for it begins to bloom in August, but it continues a long time, and certainly the buds, which slowly develop, promise a succession of heads well into the Michaelmas season. These are 2 inches to 3 inches across and of a delicate glistening mauve; the ray florets, which are narrow and stiff, give a distinctly starry effect. The whole plant is pubescent, and has a forked or branching habit.

Jeffersonia diphylla.—"J. C. L." refers to this (p. 33), and supposes its flowers were destroyed by birds or something. I have noticed that the flowers are so fugacious as to scarcely offer the chance of their being seen more than once, or one day, especially if sunny and dry at the season, which is usually the case. Its enormous wiry roots enjoy a light, but moist sandy or silky loam, and I think better if free from lime.

Lilium candidum.—We cannot afford to despise this Lily because of late years it has suffered and failed from some cause in hundreds of gardens, neither any information that has a bearing on what might prove a remedy. My friend Mr. Weaver, of Crouch End, again favours me with his experience of the results of his experiments in shallow planting in the following words: "Lilium candidum has been good with me, but only where planted as I advocate—shallowly. The clump I referred to last year (planted shallow) was even more successful this; every spike flowered well, and the offset on the rockery developed twelve blossoms. Others planted only last summer did nearly as well." As this is the best month for planting this Lily, it seems this mode is worth a trial.

Lubinia purpurea.—This is a notable example of a species true to its specific name. Its flowers are red-purple, also its stems, its roots and fruits, or at least the fleshy capsules. This is what I consider an interesting plant, though neither showy nor beautiful.

Amianthium muscætoxicum is a bulbous plant fond of damp places and a covering of half-rotten peaty and other vegetable matter. It has

elegant foliage of a succulent and glaucous character like that of the *Tritomas*, but not so strong. The flowers appear in July and August in this climate, and they are in dense spikes, small, creamy white, and wax-like, with a powerful perfume resembling that of the Elder flowers. Now this is just such a subject as we want for the damp retreats of the garden in late summer when flowers are sparse. Given the above-mentioned conditions, there is nothing to hinder this North American species from flourishing, and it may be left alone for years to form natural groups, which alone can show off its many merits.

Iris lacustris.—This gem with generous treatment is, I find, coming into flower a second time. Likely enough the exceptionally warm summer may favour flowering, but under no circumstances can it be considered otherwise than free flowering, and certainly it is a good doer. It is a most dainty Iris of about 3 inches or 4 inches in stature.

Primula rosea.—A timely note about the planting of this may be useful. There is not much difficulty with this robust and distinctly beautiful Primrose, however or whenever it is set, but for the best results plant it by all means whilst there are yet plenty of leaves on it. Then, if you like, plant more later when the foliage has all died off, and you will then see the difference in the flowers in spring. It is better to deal with all the Himalayan species in August; they need transplanting when in a leafy state.

Lewisia rediviva.—Another timely note about this, too. As I pointed out in early summer, the leaves all suddenly wither and die when the flowers are open, and the plant seems to die totally in another day or two. It is not so. The roots, if left alone, begin to grow in August or September. This year they are sending up tufts of rigid foliage in early August, and by the time winter sets in may make a fair show of vegetation. This stands the winter in the open ground with me without the least injury, and this has been my experience of the plant for at least ten years.

Jaborosa integrifolia.—I used to grow this without any other care than providing for it deep and light soil, and for the first year with newly-moved specimens giving a handful of dry Bracken. The roots are injured by frost, but in the second year they naturally go deep down into the light soil, and are then safe.

Arnebia echioides is surely doing its very best this year, flowering freely and strongly for the third time in the case of the stronger specimens. Though many, perhaps most, of the Borage-Worts may be partial to a little shade, I grow this fully exposed to all possible sunshine, and I do not see any reason why I should do otherwise. Of course, the position should be moist and the soil deep, and by preference light as well. The rainy weather of the past three weeks or more has doubtless helped on the present crop of flowers.

Helianthemum pulchellum.—This is a gem of the first water. The plant, only 1 inch or 2 inches high, has rigid, short, forking and spreading branches. Leaves grey, almost silvery, and nearly as small as Thyme leaves. Flowers bright yellow, well imbricated, and about the size of a three-penny-piece. A very lovely plant for the rockery.

Woodville, Kirkstall.

J. WOOD.

Lilium Leichtlini and Batemannæ.—Though greatly dissimilar from each other—for *L. Batemannæ* is an erect-flowered species and bears a good deal of resemblance to *L. elegans venustum*, while *L. Leichtlini* is nearly related to the Tiger Lily group—yet it is very difficult to distinguish the bulbs from each other; in fact, it is in many instances quite impossible to speak positively on that point. They are both natives of Japan, from whence such quantities are sent to this country during the winter months, and this fact, combined with their close resemblance, at times causes a certain amount of confusion. The bulbs of *L. Batemannæ* are as a rule larger than those of the other, and when large they generally present the

appearance of a fusion of two or more bulbs and produce a corresponding number of stems. In addition to the bulbs of *L. Leichtlini* being as a rule smaller, they are also generally less flattened, but this is a feature which varies somewhat. One item of difference, not, however, always infallible, is that *L. Leichtlini* starts into growth earlier than *L. Batemannæ*; indeed, so noticeable is this, that when the balls of clay (in which the bulbs are hermetically sealed when sent here from Japan) are broken, *L. Leichtlini* will often be found starting into growth, while *L. Batemannæ*, on the other hand, is one of the latest to commence growing.—II. P.

The Pentstemon is one of the principal flowers of the season, and at Kew there are large beds of it which have a bright aspect by reason of the excellent selection of varieties. Care is essential in choosing Pentstemons for effect, as so many of the kinds have flowers of a purple-magenta or allied shades, which do not show to the best advantage in the garden. The plant is so graceful and free, that it deserves to be well grown, and more use should be made of it for boldly grouping on the outskirts of the lawn. A few good kinds are Norma, a very charming flower, soft pink and white throat; Marjolaine, pinkish purple, white centre; Thos. Traddle, deep crimson; Archibald Anderson, rose-crimson; Countess of Tarbat, similar shade; Henry Cannell, also of a rosy shade, the throat deep crimson; Mrs. S. Walker, scarlet; Rosy Gem, rose; and Rob Roy, brilliant scarlet. These are better for effect than the more delicately coloured kinds.

DAHLIA PROSPECTS.

THERE is every probability that we shall have a remarkably fine Dahlia season, for not only are the plants very clean, but they are flowering early. There can be no doubt but that most interest, after all, centres round the Cactus section—the prettiest of all the purely decorative varieties, for these are now being developed in the best direction, and whilst the big, flat-petalled or purely quilled flowers that have hitherto been classed as Cactus varieties are now lightly esteemed, the true Cactus forms are becoming more and more popular. It is pleasant to find that the production of such beautiful forms as Delicata, Robert Cannell, Panthea and similar pointed-petalled forms have led raisers to see that they have been wrongly directed previously, and that only real Cactus varieties, not large, but diversely coloured and of perfect form, will command popularity. That we have got added to these newer varieties some more compact habit of growth there can be no doubt, although there is much room yet for improvement. Plants that average 3 feet in height are tall enough for any purpose; the flowers are readily seen, the plants need less staking and are less susceptible to harm from rough winds. Already the show or large-flowered varieties are as dwarf as is desirable. Plants that are, when properly extended, some 30 inches across should be at least 3 feet in height; some, however, begin blooming at 2 feet, but their average height by the close of the season is about 3 feet. That is very good. We may hope to see some of the newer pompon section also materially dwarfed, but all these are so wonderfully free to bloom, that the height may be excused; however, even now some are moderately dwarf. As to the singles, these are more under control. Whilst so many of the older named varieties are so very tall, we have some dwarf ones, and as all are so readily raised from seed, it is obvious that intercrossing dwarfs with the best of the tall ones will soon remedy their defects as to height. That the singles are by no means so popular as they were cannot be doubted. The better Cactus and the pompon forms are rapidly displacing them. Then the flowers are of so fleeting a description, whilst the others when cut are so lasting, it is no wonder that public taste is greatly in favour of the more enduring varieties. The present condition of the plants is almost one of rude health. Whilst the hot, dry weather did somewhat cramp or check

growth, yet it was fairly firm and much more conducive to the production of early flowers than might have been anticipated. The frequent and very refreshing showers which fell since the end of June have done wonders to improve the plants, and although both watering and mulching have needed close attention, yet everything seems to be singularly satisfactory. Growers have now to attend to thinning—a great necessity with almost every section, but especially with the show varieties. Even in gardens where the show forms are grown for decoration only, it is wise to thin out.

A. D.

FLOWER GARDEN NOTES.

THE propagating season seems to have come upon us quickly, all too quickly in fact, for in all gardens where an abundant supply of water was not ready to hand growth was very slow, and cuttings will not be easily obtained. The cutting business, however, is not what it was in the old days when *Pelargoniums* of every colour went in by their tens of thousands. Seedlings, of which *Begonias*, *Verbenas*, *Petunias*, *Marigolds*, *Centaurea*, and *Crimson Beet* may be cited as examples, have in a great measure taken their place and very much reduced the August propagating. Nursery beds of seedling *Begonias* that were planted in June should be gone over occasionally to mark any specialities in colour and habit; these beds, by the way, are satisfactory where they were well mulched and watered, but they have not relished the prolonged drought where left entirely to its mercy. In the flower garden beds, too, note should be taken of the 1892 seedlings, and any that have not quite borne out the expectations formed respecting them may be shelved for more satisfactory varieties. *Begonias* certainly are grand summer plants, but all are not adapted for bedding, and, to my thinking, a type occasionally encountered with Cabbage-like foliage and flowers that drop on to the bare earth or dwarf carpet, as the case may be, are quite out of place in good flower gardening. In like manner beds of seedling *Verbenas* will want careful looking over to see if there are any good things worth propagating. It very often happens that this is the case so far, at any rate, as a thoroughly good flower is concerned; after-experience must decide if the variety is equally worthy of continued propagation from a constitutional standpoint. Continuing the subject of plants from seed adapted for bedding, I may mention that one or two new *Calendulas* seem likely to prove good things for the backs of borders and for large beds. Dying flowers must be promptly removed if a constant supply of bloom is required, and they like copious supplies of water. In the ornamental-leaved plants of that particular colour and size there does not seem anything to beat Dell's *Crimson Beet*—a trifle stiff and heavy, no doubt; but this, when it is in a mass, can be relieved by the sparing introduction of a few lighter plants.

Beds of scented plants, of which we make a speciality and to which we devote consequently a little extra attention, are looking well, thanks to a slight mulching and copious supplies of water. An idea for two large beds was occasional clumps of three plants of *Eucalyptus citriodora* surrounded by a nice band of *Heliotrope*, filling in the remaining more central portion of the beds with such sorts as *Lady Plymouth*, *quercifolium*, *filicifolium*, *tomentosum* and *Lady Scarborough Pelargoniums*, with an edging of dwarfier varieties. The *Heliotropes* were autumn-struck, grown on in 5-inch pots and lightly staked to keep them well above the heads of the scented *Pelargoniums*.

VASES AND WINDOW BOXES.—It has not been an easy matter to keep these going satisfactorily this year. A surface mulching and plenty of water were absolutely necessary for a time, and then rather more stimulant than usual. Free-flowering *Fuchsias* and Ivy-leaved *Pelargoniums*, with seedling *Petunias* and one or two good *Tropaeolums*, hold their own as among the very best plants for the purpose. One of the most effective

large boxes I have seen was planted with a strong-growing, light-flowered *Petunia*, faced with *Clebra's Gem Tropæolum*. Aided by a few twigs, the *Petunias* had climbed to a considerable height, and also drooped over the sides of the box and mingled with the flowers of the *Tropæolum*. Another very good box is a capital dark flowering *Fuchsia* faced with *Jeanne d'Arc* Ivy-leaved *Pelargonium*. This same dark *Fuchsia* also makes a capital plant for the centre of a vase, with *Heliotrope* and the trailing *Sedum* as edging plants.

I do not know how the majority of THE GARDEN readers have fared in the matter of earwigs. They have been a perfect pest here, and I think are worse enemies than the wasps (also very numerous before a raid was made on their nests), for the wasp confines its attention to fruit, but the earwig preys on both fruit and flowers. Traps, consisting of small pots with hay, also Bean-stalks, have for some time been in and about Dahlias and outdoor *Chrysanthemums*, with the result that the enemy has had its numbers considerably reduced. Dahlias, especially the *Cactus*, decorative, and pompon sections, are likely to be very valuable this season as cut flowers, and, aided by well-prepared borders and a good surface mulching, are now doing well.

E. BURRELL.

Claremont.

A border of annuals makes a charming picture in the garden. Unfortunately, however, annual flowers this year are by no means satisfactory, but at Kew skirting the wall in the herbaceous ground they are as fine as we have seen them this year, the more conspicuous kinds being *Poppies* in variety, the bright *Coreopsis tinctoria* bicolor, *C. coronata*, *Malopes*, *Lavatera trimestris*, *Phacelia viscida*, blue, *Cosmos bipinnatus*, and *Argemone mexicana*, very interesting with its Thistle-like leaves, veined with white, and pale yellow flowers. This border is filled with the best kinds of *Daffodils*, and when these have died down we get a succession of annuals that carry on the season of flowers until the autumn.

Double Violets.—In a Middlesex garden I saw some 10,000 very strong plants of double *Violets* growing so well, in spite of the season, that they have made big plants already, and probably there are few better anywhere. The varieties are *Neapolitan*, *Comte de Brazza*, blue and white, *King of the Blues*, and others, and doubtless the chief secret of their robust condition is the free use of the water-pot, for there is plenty of river water close at hand. The plants were raised from runners trimmed from off the stock of last year, usually in October, then dibbled thickly into frames and near the glass, where they make root, and are then early in April lifted and dibbled again out into the open ground in rows 12 inches apart. Now the plants make almost a mass of leafage. The process of production is so very simple in this case, that it leaves little more to be said about it.—A. D.

Tiger Lilies.—In common with all *Lilies*, these are flowering during the present season somewhat earlier than usual. As border *Lilies* they make a good show, but for pot culture there is only one variety that will succeed. This is the variety *splendens* or *Leopoldi*, which differs from the ordinary form in the leaves being fewer in number, broader, less woolly, and of a deeper green, while the stem is quite smooth and almost black, but in the other forms it is more or less clothed with whitish wool. The flowers of *splendens*, too, are larger and of a brighter colour, with the spots less numerous, but larger than in the others. Where there is space for but a single form of the *Tiger Lily* this should be the one chosen. Another merit is that it is less particular in its requirements than the others; at all events, I am acquainted with two places where all the forms except this soon die out and the variety *splendens* improves year by year. These different *Tiger Lilies* by no means flower simultaneously, the first as a rule to bloom being the typical *L.*

tigrinum, followed by the double-flowered variety, then *splendens*, and after that in a general way the variety *Fortunei* or *sinense*, a bold-growing, very woolly form with rather pale-coloured blossoms. Nearly allied to the *Tiger Lilies* is that known as *Lilium Maximowiczi*, *L. jucundum*, or *L. pseudotigrinum*. This is altogether a more slender-growing plant, and one without the bulbils in the axils of the leaves to be found in all the others. The flowers of this are red, dotted with black. The straw-coloured *L. Leichtlini*, dotted with red, is in shape and general appearance a good deal like the preceding.—H. P.

Clove Carotation Gloire de Nancy.—I think this beautiful white-flowered sport from the old crimson *Clove* suffers very much here from its French appellation, because so few persons seem to understand that it is the old *Clove* with a new colour after all. I saw a remarkable batch of this the other day in a small nursery in Middlesex in perfect health, and so abundantly layered, that if all take well, there should be at least 3000 rooted plants to lift presently. Even then the old plants were carrying numerous pure white and deliciously perfumed flowers. The owner seemed to think that it would pay him better to keep all his stock and grow it to produce flowers, for, said he, "I made 6d. per dozen of them in the season, and from a few thousand plants that would mean a good sum." Of course, it is the delicious perfume which the flowers give that adds so much to their value. There is no other white variety that can equal it for sweetness.—A. D.

Auricula-eyed Verbenas.—These represent a strain of *Verbenas* of various colours from maroon to pink, all having conspicuous white centres, and very striking and attractive because of the contrast between the marginal colours and the centres. Beds of these on the terrace at Dropmore are just now in full bloom, and it was pleasant to see the *Verbena* taking its place once more as a prominent bedding plant. Mr. C. Herrin raises the plants from seed, and they appear to come remarkably true to character. They are also of good habit, and it is almost superfluous to say they are very free blooming. I think, notwithstanding what is sometimes said to the contrary, that flower-beds of mixed colours are to be preferred for general effect to those of one colour, but on a terrace garden, where a large number of beds has to be planted, there is ample space for both, and one pleasingly diversifies the other. A bed of mixed colours of tuberous *Begonias*, for instance, is much more attractive than one formed wholly of crimson, scarlet, rose, &c. A bed of mixed large flowered *Phlox Drummondii* is one of the prettiest which can find a place in the garden.—R. D.

A note on Cactus Dahlias.—We have lately seen in gardens the so-called decorative *Dahlias* grouped in large beds, but the flowers are too coarse, although in a sense effective. Some of the kinds produce blooms of immense size, but not in the least pleasing through want of refinement. It is a pity that more use is not made of the true *Cactus Dahlia*, avoiding the coarse creations that certainly remind one of the show *Dahlia* spoilt. The *Cactus Dahlias* that have been raised within the past two or three years are very beautiful, the flowers neat, yet not too formal, the segments pointed, and in expression like *Juarezii*, the origin, so to say, of this group. Perhaps the varieties are too expensive to plant freely as yet, but when they get cheaper more should be seen of them in the garden than is at present the case.

Montbretias.—The note on page 114, whilst calling attention to the rich beauty of these, conveys the impression that they need a light, favourable soil. I do not think this is the case, and in consequence they become all the more valuable. One of the brightest things we have in the garden at the present time is a great spreading mass of *Montbretia crocosmiiflora* in a bed of poor, stiff soil beneath large bush *Azaleas*. The ground must be full of the bulbs, and there is a perfect forest of leaves and flower-spikes. *Montbretias* are so pretty in many ways, that they

deserve every encouragement and are worthy of careful trial, as new kinds have come rather freely of late, but are not altogether distinct. For cutting, the flowers are very charming. I do not think *Montbretias* are nearly so tender as supposed to be, and need not be confined to gardens in the south.—A. H.

SHORT NOTES.—FLOWER.

Monarda didyma alba is an interesting form in bloom on the Kew rockery. It is similar to the type, but differs in the colour of the flowers.

Native Water Lilies.—In reply to "A. H.," the tinted pink form is the larger of the two varieties, in fact, more approaching the dimensions as stated by "A. H." himself. Another season I hope to be able to send him some blooms.—A. YOUNG.

Heuchera sanguinea.—A friend of mine who thinks much as I do about *Heuchera sanguinea* has mentioned one thing to me which perhaps should not be forgotten. He says that it should be divided and planted in July if it is to blossom the following year. Of course, this is now out of the question, but it would be well for anyone who thinks of acting on the advice I have given to lose no time about it.—H. E.

Pompon Dahlia White Aster.—This is perhaps the most widely grown of all *Dahlias*. The variety, whilst a true pompon, is perhaps the earliest to bloom, and one of the freest. It has pure white flowers, which are highly prized for decoration. The flowers have somewhat pointed petals that give to them an appearance less stiff and formal than is the case in other varieties.—D.

GARDEN FLORA.

PLATE 924.

NEW TRUMPET DAFFODILS.

(WITH A COLOURED PLATE OF GOLDEN BELL.)*

I REMEMBER the assertion being made with some confidence a dozen years ago by a high authority upon *Daffodils*, that in *Emperor* and *Empress* the extreme limit of size had probably been reached. But Messrs. de Graaff, of Leyden, have considerably passed it in their *Glory of Leyden* and some bicolor seedlings, and it would be rash to prophesy that we shall not have even larger flowers, whether they are desirable or not. It is doubtful whether any raiser could give a recipe for producing giant *Daffodils*; certainly I cannot. Seed can, of course, be saved from the largest varieties, in hopes of enhancing their size. There is little doubt that *Emperor* is a seedling from the older *N. rugilobus* or *lorifolius*, and that *Glory of Leyden* was in turn a seminal enlargement of *Emperor*. But raise a hundred seedlings from *Emperor*, and there is every chance that fifty will bear flowers no larger than the parent and fifty miserably smaller. In my own experiments I have of late years tried the scientific Darwinian plan of having pollen sent from a distance, or letting one of the parents be the offspring of bulbs freshly imported into my garden the previous season. But the result of thus differentiating the parents seems much less marked in bulbous plants than in some other families. No doubt there are laws, if we could only

* Drawn for THE GARDEN by H. G. Moon, from flowers sent by the Rev. G. H. Engleheart, April 27, 1892.

NARCISUS GOLDEN BELL

master them, which govern the improvement from seed of all seed-bearing plants, but of Daffodils my own experience justifies me in saying that only some one individual plant out of some hundreds may be predisposed to yield enlarged progeny, or that there may be a fortunate moment of growth or season when fertilisation may secure unusual results, or that a particular flower needs pollen of some one other particular variety to gain such results. The hybridist not seldom finds that a chance seedling has secured the required conditions which have eluded his painstaking industry. The trumpet Daffodil Golden Bell, the subject of the coloured plate here given, grew from a seed of Emperor not artificially fertilised. The pollen parent was probably some such kind as Countess of Annesley. This flower was more than once nearly discarded, but four or five years after its first blooming suddenly developed both size—in which it runs Glory of Leyden hard—and characteristic beauty of form and colour. Its trumpet is rich yellow, the perianth primrose. The boldly-expanded and deeply-toothed mouth catches the light conspicuously, and the somewhat drooping, bell-like attitude of the flower marks it off from other large Daffodils. Golden Bell obtained a first class certificate R.H.S. in 1892, and the medal for the best flower of that year.

G. H. ENGLEHEART.

Appleshaw, Andover.

THE WEEK'S WORK.

THE KITCHEN GARDEN.

SOWING CAULIFLOWERS.—Sown earlier than the latter part of August or the first week in September, the plants are apt to become much too large before winter, and when this is the case they rarely if ever succeed satisfactorily. This possibly is the reason why sowing in the autumn is not so much adopted as formerly, but, taking all points into consideration, good plants may be raised, and which, if wintered carefully, will produce good and early heads. Another advantage in raising the plants now is, that where glass accommodation is scarce and labour also lacking at the busy season of the year, there will be the certainty of having a supply of plants at hand. A suitable seed bed should be provided, so as to ensure the germination of the seeds evenly and well, as if at all lumpy, the seedlings appear very irregularly, so for this reason a little fresh soil will be a decided advantage. The seeds are also the better for being sown in drills, as the plants are thereby enabled to have a circulation of air about them. If the soil should be dry, water the drills before sowing, and as a safeguard against the depredations of birds, a net should be stretched over the bed. The plants must not be allowed to grow too large before pricking off, and as success will depend largely upon this proceeding, the rooting medium must be suitably prepared. The frame should be in an open position, and be placed on a level and firm surface so as to prevent the roots from striking deeply. Over the bottom must be spread a layer of rotten manure to the depth of 2 inches or 3 inches, and over this the same quantity of holding soil. The plants should be pricked out 4 inches apart, and also be left exposed, the lights only being replaced when cold rains and frosts appear. Instead of pricking out the plants, they may also be potted, using 5 inch pots. The varieties

adapted for sowing now are Early London, Early Dwarf Erfurt, Walcheren, and Large Asiatic. For producing large heads of Autumn Giant during August, the seeds may be sown now.

OPEN-AIR TOMATOES.—Where these have been kept well supplied with water the recent tropical weather has been all in their favour, large clusters of fruit swelling off and ripening freely, and this without the least sign of disease. After this time the shoots must not be allowed to extend, the whole resources of the plant being given up to the finishing off of the fruit, and which must be freely exposed to the sun. To assist this, all overhanging leaves should, if they cannot be tied on one side, be promptly removed or partially shortened in, and in the case of over-vigorous plants not well burdened with fruit, all the leaves may be shortened in, also seeing that no side laterals are allowed to grow. Even now water must not be withheld from the roots, especially if the weather should remain bright and sunny, and in the case of plants growing in confined borders, liquid manure may be advantageously applied. With a fine and bright September there is every likelihood of heavy crops being ripened off without having recourse to ripening them up under glass or in warm kitchens, as under this process the flavour is not nearly so well developed.

TOMATOES UNDER GLASS.—There has been a heavy strain upon Tomatoes growing under glass. In some cases they will be almost exhausted, but much might be done to renovate them, as if the space could be spared, these old plants would produce fruit until late in the season. If there is not room for the leading shoots to extend, these might well be shortened back, younger and healthier growth following. At the same time, some of the old surface soil should be removed and be replaced with some loam, horse manure, and wood ashes in equal parts, this being pressed down firmly. Fresh roots will soon take possession of this, when the plants should be well fed up with liquid manure. Plants in pots or boxes must be kept well fed, or they will quickly give out, the curled state of the foliage showing plainly that the plants are not having adequate support.

GLOBE ARTICHOKEs.—These have done good service this season, and with a little attention are likely to do so. Although very often left to take care of itself, yet the best results are obtainable by looking after the plants' requirements, as the larger the heads the better the flavour. All old heads as well as stems should be promptly removed. All old rubbish having been removed, a soaking of liquid manure in which a little salt has been dissolved will swell out the late and smaller heads. As seedlings are apt to produce many spurious ones, take care as the heads are formed to mark only those which are of a good type, these being reserved for increase of stock. Those which have prickly scales are of no use whatever, being very poor in quality. By marking the plants now, much disappointment will be avoided another season.

A. YOUNG.

ORCHIDS.

WE will soon be into the month of September, when we may expect cooler nights and a more congenial temperature for cool Orchids. I fancy cool Orchids and Auriculas require similar treatment as regards repotting them. In fact when cool Orchids were first introduced we were so fearful of their being injured by excessive heat in summer, that all schemes were tried to keep them cool, and I placed my first lot of plants of *Odontoglossum crispum* and *Masdevallia Harryana* in frames on the north side of a high wall with the Auriculas. *M. Harryana* had not flowered in England at that time, but we knew it was a good thing, and those who had plants were anxious to see them flower. The plants did well in the frames, and were kept there until the end of September. I do not care to repot Auriculas during excessive heat in summer, nor is it well to repot the cool Orchids, of which *Odontoglossum crispum*

and *O. Pescatorei* may be considered the leading species, when the weather is very hot. The bulbs are apt to shrink a little, owing to the check caused by repotting and the heat combined. In September the outside air is very much what cool Orchids require, and if any plants really require repotting, it is better to make arrangements to have it done as speedily as possible, for the plants will quickly become re-established at this time of the year and will form roots freely. I believe the best time in the growth of the plants to repot them is soon after they have flowered. I like the plants to be allowed to recover themselves after flowering before repotting them. The bulbs are often much shrunk, and it is better to wait until they plump up again and start to grow from the base of the last formed bulb. Most of the cool Orchids seem to be always making new roots, and they soon run into the new compost. All the plants should be looked over, and if the system which I have recommended of recording the date of the previous shift on the label has been followed out, it will be easy to determine whether the plants should be repotted or merely surface-dressed. For *Odontoglossums* and *Masdevallias* I think it is better to have about two-thirds Sphagnum Moss to about one-third of good fibrous peat, with a fair sprinkling of broken pots and pieces of charcoal. I fear that slugs will be numerous in the Moss this year; they must have been driven into the damp places where the Moss grows from the dry ground surrounding it. At any rate it is always desirable to look over the Moss to clear it from all extraneous matter, slugs included. Besides the preparation of the compost, it is also necessary that flower-pots be rather more than half full of drainage, and if they are of large size two-thirds full, as masses of decayed peat and Sphagnum cannot but be injurious, as they very speedily decay when always kept in a moist condition. I pot rather firmly, and the potting material should be above the rim of the pot in the middle, but a little below it at the margin. Vigorous plants well rooted should have a good shift without disturbing the roots much. It is too much to expect that all will be vigorous and well rooted; some of them will be exactly the opposite of this. Badly rooted and weakly plants should have the soil washed from the roots and be repotted in much smaller flower pots. Such plants require very careful management to get them into good condition again. Choice varieties of *Odontoglossums* may be divided by cutting through between the bulbs. A plant may continue to make one bulb annually for many years, and if it is undisturbed no growth will be formed, but when a portion of the back bulbs is severed from the parent plant a new growth will be produced, weak at first, and it may not form a very large bulb, but in time the growths will be stronger, and spikes will be produced as vigorous as those of the parent.

I was looking through a choice collection of cool Orchids recently, and saw some of these severed-back bulbs suspended from the roof of the cool house, and was informed that they were from choice varieties, which were left in this state of suspended animation until some signs of growth were apparent, when they were planted in small flower pots to start on an independent growth. I observed that two bulbs were cut off from the parent plant. It takes a long time to get up a stock of a distinct variety of *Odontoglossum*; on the other hand, *Masdevallias* are very free, as old plants may be broken up into numerous small pieces, which very speedily grow into flowering plants. Some Orchids seem to do best when cultivated in small pots, and some of the *Masdevallias* may be included in this category. I believe it was owing to this characteristic that the system of making up large specimens for exhibition became so common at flower shows. A better formed specimen could be made up of small plants than if it had been grown as one specimen for many years, but the system once begun, exhibitors planted a dozen or more plants of one species together in a large pot or tub, and exhibited the make-up as one Orchid. This is not now so much done as it used to be. Any large specimens of the freer growing *Masdevallias* of the *M. Harryana*,

igneae, or Veitchi types should be broken up and repotted when they get too large into small flower-pots. Only the summer flowering species and varieties should be repotted now if they need it. *M. tovarensis* should be repotted in February or March, and *M. Davisi* or any autumn-flowering varieties may be repotted either before they pass out of bloom or soon after. If the plants are to be divided, it will be better to let them pass out of bloom before interfering with them. I ought to add as information to the inexperienced that it is better to divide *Masdevallias* by pulling the parts carefully asunder, as in this way they break off at the joints; whereas if a knife is used, the joints may be severed and the division be made at the wrong place. Plants that have been divided should be kept in a part of the house which is closer than usual. Keep moderately cool with plenty of moisture about them. Of course it will be necessary to see that the plants are quite clean before repotting them. In fact, now is a good time to remove all the plants from the stages and clean the wood and glass-work, being careful to surface-dress all plants if they need it and do not require to be repotted. I am writing on the assumption that we may soon have a change of weather, for the temperature both by night and day has been very high for the latter part of August. Even at night we gave up the use of fires, as the outside minimum temperature varied from 60° to 65°. If the plants are dipped to destroy aphids or thrips, lay them on their sides so that the solution may not run down amongst the roots. I tilt the pots so that the water may drain off at the end of the leaves, leave them for a few hours, and sponge the leaves over with clean rain water.

J. DOUGLAS.

FRUIT HOUSES.

VINERIES.—Another spell of exceptionally hot weather is proving very trying to Grape growers. The foliage, previously much weakened by fierce sunshine and red spider, now burns badly, and nothing short of shading rather heavily saves white Grapes from shrivelling and the black varieties from losing colour rapidly. During hot weather the houses ought to be set as widely open as possible, wasps notwithstanding, and be kept so during fine nights. This applies to those containing ripe Grapes, as well as all that are cleared of the same. Outside as well as inside borders will once more require attention, especially where no mulching material is applied. When approaching dryness, give water freely. In the case of well-established Vines that have borne heavy crops, something should be done towards reconquering their wasted strength. Directly the crops are cleared off, give either a good dressing of special, easily dissolved manures and well wash in or, better still, apply liquid manure rather freely, that obtained from a cesspool answering well. Any Vines that it is desirable should go to rest early should have all sub-laterals cut off, and if the laterals are somewhat long, these also ought to be shortened to about the fourth or fifth leaf. Any that are to be partially lifted should not be thus pruned, the aim being to keep green leaves on these for as long a time as possible. Not till the hot, dry weather is well over should any severe renovating measures be attempted, but if only about a third of a border is broken up, this may be done when next the weather is dull. Everything, that is to say, a good fresh compost, should be got ready before the old border is interfered with, and, seeing that the object of lifting in the autumn is to promote the formation of many fresh root-fibres before the leaves fall, the greatest care ought to be taken not to needly expose the old ones to hot sunshine and drying winds.

LATE VINERIES.—This season it is not a question of forwarding late Grapes, with a view to having them perfectly ripe by the end of September, but rather whether it is not a wise practice to retard ripening as much as possible. *Alicante*, *Lady Downes*, *Alwicks Seedling* and *Mrs. Pince*

are all colouring very rapidly, and most probably will be too early ripe to keep so long as desirable. Even the slow ripening *Gros Colman* is laying on colour faster than usual, and *Muscat-flavoured* Grapes are colouring well under quite cool treatment. Instead of nearly closing the houses containing these late varieties during hot weather, abundance of front air and a fair amount of top air should be left on all night, all being increased to its fullest extent in the daytime. Whenever the weather is dull, cold and damp, rather less air should be given and the fire-heat turned on, the aim being to keep up a good circulation of warm, dry air. Under this treatment the Grapes will colour perfectly, also laying on a thick bloom, the quality and keeping properties of the different varieties being considerably enhanced accordingly. If red spider is troublesome, paint the hot water pipes with flowers of sulphur mixed with milk and turn on the heat rather strongly in the evening occasionally, avoiding, however, completely closing the house more than a few hours during the night.

PEACHES AND NECTARINES.—Hot weather is trying the trees of these, red spider being especially active and injurious to them. In the case of early and successional trees, much of the thinning-out that is frequently left till the winter pruning is completed may well be done now. Cut out all that can be spared of this season's fruiting wood, but do not shorten much of that which is reserved for fruiting next season. Root-lifting and a change of soil have a most beneficial effect upon trees rooting in partially exhausted borders, and this should be done before the leaves fall, though not before September. In anticipation of this work, a heap of good loamy compost should be prepared. While hot and dry weather lasts, the borders must be kept uniformly moist and the mulching material be damped down at least once a day. In the later houses the fruit, in spite of being shaded, is ripening much earlier and more rapidly than desirable, and both Peaches and Nectarines will very probably be scarce when most wanted. All that can be done is to keep the borders moist and the houses as cool and airy as possible, shading also being applied during clear days. If enough whitening is mixed with water to make it no thicker than can be applied with a syringe, this will afford the necessary shade and the first heavy rain will wash it off again.

POT STRAWBERRIES.—Plants that were early placed in their fruiting pots have grown rapidly, and in many instances will most probably require to be spread out more in order to prevent them from becoming drawn and weakly. They ought always to be set in a sunny position and either on boards, slates, or ashes, or otherwise worms will find their way into the pots and clog the drainage badly. Those early established in 6-inch pots are usually the most reliable for forcing, but late potted plants not unfrequently succeed remarkably well. The former are apt to become divided, removing all but the central strong crown being necessary accordingly. Not so those late potted. Use clean, well drained pots and a fairly rich loamy compost. See that the plants are well moistened at the roots before turning them out of the small pots they are now in, and repot firmly. Arrange them in a sunny spot and attend carefully to the watering. During hot and dry weather overhead syringing every morning should be practised in the case of Strawberries in pots generally, this serving to keep them free of red spider.

PRACTICAL.

PLANT HOUSES.

PLANTS AND THE WEATHER.—In this department of the garden there will now be need of most constant attention to plants in pots of all kinds. No one will dispute the fact, I think, that this unusually hot weather is as trying (more or less) to plants under artificial cultivation as it is to human beings. It may not be just at present that any ill effects will be so fully evident, but in the course of a

few weeks the state of things will in all probability be different where due care and attention have not been bestowed upon the plants in general. True, it may be favourable to the ripening of growths in many instances, but adventitious ripening even is not always desirable.

WATERING.—This will, as long as this phenomenally hot weather lasts, be the most important of all work (in conjunction with ventilation) and a close observation should be kept to it from morning to night. Such hot weather casts aside, so to speak, all ideas of morning and afternoon waterings sufficing where the plants are in any way exposed so that they dry up rapidly. For instance, where the plants are out of doors in warm or sunny spots and their root-action in a good state, it is in the case of free-growing subjects quite astonishing what an amount of water is needed. But this increased supply has also its faults in that the soil becomes all the sooner exhausted of its good properties, and the plants thereby in a measure weakened in due course. To remedy this, partial or entire plunging can be adopted; partial in the case of permanent plants and those with the most delicate roots, and entire plunging with others of more rapid growth. When dealing with Cape and New Holland plants of the hard-wooded section, the better plan is to screen the pots with others of smaller growth and of less consequence, or to hang some shading around, or in some way to shade the pots upon the sunny side. It is not only to save watering in these cases, but also to prevent injury from the intense heat to the very delicate and minute roots which most of them possess. Plunging of these plants is hardly advisable save with experienced hands, otherwise the watering may easily be too excessive, particularly towards the lower part of the balls. These remarks apply also to *Indian Azaleas*, which, if they should be in pots of uniform, but not large size, could be shaded by means of a long board resting against the pots just for the time being. By either of these methods a deal of watering may be saved, causing less labour and anxiety also. Another good plan which I had almost omitted to advise is that of dropping pot-bound plants into larger pots, this double protection to their roots saving watering, as well as keeping them cooler. To stand plants in the shade out of doors, which delight in sunshine is not advisable if it can in any way be avoided.

INSIDE WATERING.—This requires quite as much attention as that just alluded to, and it must be given even if other work for the time is postponed. It is useless to grow plants and then spoil them from want of water in hot weather. Close observation as to their requirements and a knowledge of the real needs of separate kinds go a long way towards giving confidence to those in charge. Speaking generally, it will be in the cool houses, where ventilation is freely given, that the greatest need of extra watering will be apparent. In stoves or in ferneries, where the atmosphere is charged with more humidity, there will not be the same degree of watering in proportion. Of course, at such times as the present it can hardly be said that fires are essential; in fact, it is resting time to the plants when nearly approaching the dew point, which is more easily done without a fire than with it. It has hardly been possible lately to keep a fire alight with the outside glass so high all night without the thermometer registering too high a temperature inside. In the case of Palms, more particularly is it necessary to give increased attention to the watering now; so also is it to Aroids and other plants known to thrive with plenty of moisture at the roots. Palms in particular that are in airy and lofty houses will absorb a deal of moisture.

SYRINGING AND ATMOSPHERIC MOISTURE.—The syringe should be used now more freely than usual, it will not only do the plants good, but keep in check all insect pests which thrive in hot and dry weather. Not only does this apply to plants indoors, but outdoors also. As the sun leaves the plants that are outdoors, a good damping overhead will do them a lot of good. This can be done either with a syringe or with a fine rose

on the water can; the latter will answer well when no insects have to be dealt with. In lofty houses with climbers and large plants the garden engine should be brought into use; this will reach those parts which it is hardly possible to do with the syringe. Increased atmospheric moisture in houses with air on by night as well as day will not do any harm, but even now in stoves it will not be advisable to damp down after 6 p.m. with no fires alight.

SHADING.—Additional shading will in many cases be desirable, and the blinds may be let down earlier and be left down later just for the time, but do not carry this advice to any great excess. A good plan of giving extra or temporary shading is by means of whitening only, mixed with water. This can be quickly syringed upon the glass whenever it is found necessary, and it will be removed easily enough by the first rainfall. In some cases the usual shading, if light, will be hardly sufficient, but whitening applied thus will remedy it as long as it is needed. Where no roof shading is used, the whitening is a ready method for the time being.

JAMES HUDSON.

ORCHARD AND FRUIT GARDEN.

THE APRICOT IN FRANCE.*

The Apricot, which appears to be a native of Western Asia, has been known in France for several centuries, its introduction dating as far back as the year 1450. In the north and north-west of France it must be trained on a wall or on a fence, but under these conditions its fruits are, as a rule, only slightly appreciated. They ripen very unevenly, the portion of the fruit against the wall always remaining more or less green, whilst that exposed to the sun becomes more or less mealy. From bushes or standards in the open air the fruits are far better; but, in order to ensure success, great attention must be given to details. The trees require a warm and rather calcareous soil, and should be sheltered from the north and north-east winds. In less favoured localities the Apricot will give good results if sheltered by other fruit trees or by some ornamental trees. Unlike other fruit trees, it will succeed in the gardens of large towns, and even those of small dimensions, as in them shelter is always to be found. The great abundance of Apricots in some seasons does not influence the selling price to any great extent, and they are generally very remunerative. The varieties most largely grown in France are very few in number and to a great extent localised. By simply inspecting the wood it is difficult to distinguish one variety from another. Sometimes confusion may be avoided by noticing the distance—more or less great—between the leaves. In Apricot "Peach" and its sub-varieties, for example, the leaves are very near to each other, and the young wood consequently short-jointed, whilst in other kinds the wood is longer-jointed, and the leaves, therefore, perceptibly farther apart. By means of the foliage Apricots may be divided into three great classes. First, the varieties with large leaves, the blade of which forms a right angle with the petiole, as in Apricot Royal, Commun, &c.; second, those kinds in which the blade of the leaf is rather tapering and forms a sharp angle with the petiole, as in Montgamé, Luizet, &c.; and, thirdly, the varieties in which the leaves are flaccid, wavy, and partly folded, as in Peach, Moorpark, Viart, &c. The stone is also of some assistance in classification. It is generally of a bitter taste,

* Paper read before the Royal Horticultural Society by Mons. F. Jamin, August 24, 1892.

but has a sweetish flavour in the following varieties, viz., Montgamé, Hollande, Bleenheim, Luizet, &c. In Apricot Peach and its sub-varieties the stone is perforated—that is to say, it presents on one side a small orifice through which a needle may be passed. This is a characteristic which is not to be found in Commun or the Royal and many others. The Apricot is cultivated in many parts of France. The locality in which the fruits are chiefly ripened in spring is at Solespont, in the department of the Var. Here the fruits, though only of ordinary quality, are ripe by the 1st of June. When sending to market, about a dozen are packed in a small light box, and, notwithstanding their somewhat inferior quality, they readily find purchasers at a comparatively high price. In La Limogne d'Auvergne a larger number of Apricots are grown, and these represent for the most part a variety with large white fruits bearing the name of the province. The entire produce is almost entirely utilised by the manufacturers of Apricot preserves, into which an appreciable quantity of Pumpkin pulp finds its way. It is easy to imagine the enormous profits realised by the manufacturers who were the first to direct their attention to this particular business. In the valley of the Rhône, in the departments of the Rhône and the Isère, there are several places in which the Apricot grows remarkably well. For several years the variety Luizet—raised by M. Luizet, of Ecully-Lyon—seems to have excelled all others. The fruit is of good quality and ripens rather early, while the trees present a vigorous and fruitful appearance. The average income derived from Apricots in these three departments is said to exceed £4000. The Saumurois, in the department of Maine-et-Loire, is another part of the country remarkable for the culture of Apricots. The variety Peach, and to some extent the less known Précoce de Saumur—closely related to l'Alberge de Montgamé—are the principal ones grown. The last-named is a good early sort, and is superior to the Apricots of the Var. Unfortunately, however, owing to the latitude of the district, the fruits reach the Paris markets rather late for realising very high prices. The average yield in this district is only estimated to return 8s. a tree when in full bearing, and the number of trees seems to be about a thousand. Under the Apricots, Strawberries are grown with great success, and in the full season of their ripening two vans are daily loaded on the railway at Saumur Station for the Paris markets. About twenty-two miles to the west of Paris, and along the banks of the Seine for a distance of about five miles, is to be found some remarkable land, which for centuries has been utilised for the culture of Apricots. This highly favoured locality extends in a circle as far as the parishes of Triel and Vaux, sheltered from the cold winds of the north and north-east by the heights of Hautil. In this region the soil is warm and calcareous, and everyone grows Apricots. Spring frosts rarely make themselves felt there, so that the crops ripen with great regularity. The trees (often more like large bushes) are planted from 12 feet to 15 feet apart each way. The stems are never very tall, 3 feet to 4 feet at the most, and oftentimes the branches bear fruit on a level with the ground, and thus the trees assume, more or less regularly, a globular or pyramidal form. The method of pruning back the fruiting branches to three or four eyes is the same as that used for Peach trees, and it is, speaking generally, the only method to which cultivators attach any importance.

Three years after planting, the trees generally bear fruit, the quantity increasing year by

year, and the trees thrive without any particular attention being given them. Of course poor trees will be met in this locality occasionally, but it may generally be concluded that such are quite the old trees of the neighbourhood, veterans two hundred years old being occasionally met with. It may be said that the trees are at their best for fruit producing between the ages of ten and fifty years. In spite of the favourable conditions referred to, it cannot be said that the yield of fruit is at all uniform in quantity or quality. Sixty pounds weight of fruit may be considered about the average yield per tree, and estimating the price at an average of 24s. per 100 lbs., each tree will at this rate produce an income of 14s. 6d.; but it almost invariably happens that besides fruit of ordinary size there are a certain number of first-class fruits, and even some few extra choice samples, which without the least trouble will realise half a franc per pound. It follows, therefore, that without any exaggeration one may consider the sum of 16s. to be the average value of the fruit produced by a tree in full bearing. Growers who sell their crops on the trees, which is very often done, of course do not realise such a large income as this; but, on the other hand, they do not incur the expenses of gathering, nor of other items which tend to lessen the profits of those who pick and sell their own fruit. The annual sale of Apricots grown in this district is said to amount to a sum of £3000 sterling. The common Apricot is almost the only one cultivated, and although the fruits are not of the finest flavour, they are largely used for culinary purposes. Choice preserves are made from the ordinary qualities of fruit, while the better samples are naturally reserved for the table. In the above-named parishes (as well as throughout the whole neighbourhood of Paris) Apricot trees are worked upon the stock of the St. Julien Plum. The plantations extend in a straight line along the banks of the Seine, which at this point is at an elevation of about 90 feet above the sea level. They occupy a narrow band or border along the river side of only 40 feet or so in width, and are then far from reaching the top of the hill behind. A remarkable fact is that the soil does not appear to become at all exhausted. Every year the trees which perish from old age or other causes are replaced by new ones, which always seem to grow in a very satisfactory manner. The severe winter of 1879-80, however, played great havoc in the orchards of Triel and Vaux, but the majority of the trees have now recovered their usual healthy condition. Descending the river Seine, and more to the west, is a small locality known as Tripleval, belonging to the parish of Bennières. Here some equally fine plantations are to be met with, and so favourable are the climatic conditions that the inhabitants are enabled to even cultivate the Fig with great success.

At my own place, Bourg-la-Reine, the Apricot grows satisfactorily, but rarely produces anything like a good crop of fruit. Some trees planted twenty-five years ago in my nursery produce an abundance of fruit—at least every alternate year. They are planted in the midst of other fruit trees, and are protected from ill-favoured winds by a screen of Elm trees a little distance away. Some other specimens, however, of the same age and vigour, and only a few hundred yards distant from the preceding plantation, are almost entirely exposed and all but sterile—a fact which serves to emphasise again the necessity of growing the Apricot under particular conditions if it is to yield a satisfactory crop of fruit.

WASPS AND THE FRUIT CROPS.

WASPS are more abundant this year than I can ever remember them before, and their attention to and destruction of choice fruits cause very great inconvenience and loss. What would have happened had their nests been left undisturbed is not very difficult to imagine; heavy crops as there are of Plums, Apples, Pears, Peaches, and Nectarines would have disappeared quickly. We have destroyed about ninety nests with cyanide of potassium in solution, and whatever may be said of gas tar and its value in destroying their nests, cyanide of potassium is much easier of application and is not required in the same large volume as tar; hence does not occasion the same amount of labour in carriage from one nest to another. Mr. Tallack's estimate of the quantities required in gas tar speaks pretty plainly of the amount of work in dealing with a large number of nests. Two single pound bottles of the cyanide is the quantity we have used for the ninety nests dealt with, and another one is already in preparation by dissolving in cold water for many others recently found. Its effects are not found strictly uniform, because of the varying positions of the nests. In some cases there is a very small entrance, which makes no difference if it takes a downward course, but if it should take an upward one, then the fumes of the deadly fluid do not act as speedily on the wasps. My plan in preparing and applying the chemical is to dissolve about one-third of a pound in three pints of water in a wide-mouthed bottle holding that quantity. In dissolving it, I find it requires to be stirred briskly, the hard lumps remaining a long time in the water without some aid in this manner. When ready, I take a small tin canister with the bottle, so that a small quantity can be poured into this for applying it to the nest entrance. About a tablespoonful is sufficient, but we vary the amount according to the strength of the nest. Some are much deeper in the ground or bank than others, and I find by the aid of the small tin it can be thrown into the hole pretty easily. In most cases the wasps die almost instantly as they pass over the cyanide. Rarely do they come out once they pass in. If the nest is a very strong one and the entrance small, it becomes blocked with the dead and dying insects so much, that they all cannot get in. In this case a spade or hoe would be useful in making a free passage for the remainder; and a small quantity poured in the next day will destroy all those on the wing. Unless the nest happens to be in a public thoroughfare, where the wasps are subject to annoyance, there is no disposition on their part to sting, for the reason that when they return from their journey they go straight to the nest without taking note of anyone, and once within the nest, they have no opportunity of interference afterwards. Although I have destroyed so many nests, not one attempt has been made by a single wasp to sting, so that there would appear to be no occasion for nervousness on the part of anyone in attacking them with this convenient, but deadly poison.

A bright sunny morning is the best time to choose for an expedition, because then they are stronger on the wing and the sunshine makes their whereabouts more easily ascertained, as they can be seen often some distance ahead. There is no difficulty in finding them in dry banks, but there is a very small wasp which makes its nest in the open field, which, unless it is traced by watching its departure from fruit trees, or is come upon accidentally, is not easy to find. Some of the largest nests must be a home for thousands of wasps, and

it is really surprising the quantities that find their way into comparatively small ones.

Although so many have been destroyed, their numbers do not seem diminished as regards their attacks on fruit. Plums, Peaches, Nectarines, early Pears and Apples all claim attention from them. We have kept them from the wall fruit fairly well by applying Scott's wasp destroyer to the already attacked fruits and on the foliage here and there about over the trees. Its effect is clearly perceptible a few hours after, for no wasps will come near it for a time once they taste it. They commenced an attack on a house of ripening Peaches and Nectarines, but immediately it was observed, the remedy under notice was applied, and no further trouble was experienced. Outdoor Nectarines and Pears they eat while yet hard, and they turn their attention to these latter more when they are driven from the walls by Scott's. It is very singular what a magical effect it has in clearing them from vineries, Peach houses and wall fruit outdoors; very rarely do we find any dead ones resulting from its use. Davis' is looked upon as a superior article to Scott's, but whichever may be used, it would be a profitable investment where fruit of any sort is grown to keep a bottle in hand. W. STRUGNELL.

Road Ashton Gardens.

BERDIANSK GRAPES.

BERDIANSK is celebrated in Southern Russia for the size and sweetness of its Grapes. The British Consul in Southern Russia in a recent report speaks of Berdiansk town as formed by Prince Woronzoff in 1842 on the low ground adjoining the steppe, and was originally probably washed by the Sea of Azof, the soil being entirely sand and shells, with brackish water everywhere within a foot of the surface. Plans were drawn up for the formation of gardens, and about 800 acres were offered to peasants and German colonists on condition that they planted not less than 120 fruit trees or 2400 Vines per desiatine of 2.7 acres. Sole ownership was granted upon condition that, in case of default, the land would revert to the town. Every available plot was soon taken up, and in a few years the entire space was transformed into well-arranged and profitable gardens. During 1888 this experiment was repeated by the Town Council. A quantity of land—about 500 desiatines—was sold by auction, and averaged £10 to £50 per desiatine, the terms being an annual payment of 6s. per desiatine for ten years, and the same conditions as to cultivation. No difficulty occurred in finding purchasers, and the necessary Vines and fruit trees were planted, and the gardens now present a very favourable aspect. The Vines thrive well, and already bear fruit, large quantities of ordinary garden produce being also grown. The descriptions of Vines principally grown here are the Chassla or Bernska, Chaons, Isabella, Black and White Muscat, Burgonski, Arcitinski, and the Alexandra Muscat. The Vines give a greater yield on the low, sandy soil, but the more delicate kinds thrive better on the slopes in a clay soil. About 3000 Vines occupy a desiatine of land, and no manuring is practised, although, where experiments have been made with old Vines, manure has been found advantageous. The average yield of Grapes of the common kinds is about 10 lbs. per Vine, 36 lbs. producing about two gallons of wine. The superior kinds give a smaller yield. Prices of Grapes average from 1s. 8d. to 8s. per 36 lbs., and new wine from 3s. to 10s. per two gallons. The crushing is carried on in a primitive manner, and little attention is paid to sorting or cleaning. Bulgarian and German colonists go in from the country districts during the early autumn and buy up the wine, none being as yet exported. There are several large private growers, who take special care in the cultivation of their Vines and preparation of wine, and some good sound wine can be

generally found in their cellars. The bulk of the wine being of a light character (8 to 10 per cent. of alcohol), does not bear keeping; but where the superior kinds are properly cleared from the stalks and sun-dried, a good strong wine is obtained, which keeps well, and can be bought at 12s. to 16s. per two gallons. No phylloxera or other Vine disease has yet been experienced at Berdiansk. It is estimated that some 1500 desiatines of land are under Vine cultivation amongst the various colonies and villages in the district, in addition to the quantity belonging to the town. Probably in a short time an outlet will have to be found for the surplus wine, as the quantity produced will be doubled, and the supply will be greater than can be consumed in the surrounding districts. The Vines seldom fail to give a good yield. The cultivation, therefore, is found to be lucrative; but it is five years before the Vine is in full bearing. The present production of wine at Berdiansk amounts to about 300,000 gallons per annum. The Vines during the autumn are bent down and well covered over with earth to provide against the attack of the severe frosts. In the spring this is removed and the Vines cut down to 2 feet and 3 feet from the ground, and not more than five stalks or branches are allowed to remain, and these have necessarily four or five buds on each.

Raspberry Superlative for late fruit.—I

have for some time grown the above and advised its culture, and this season am much pleased with it on account of its free bearing qualities during a hot, dry summer. At a recent R.I.S. meeting this variety was staged by Messrs. Veitch in splendid condition, and, considering how small fruits have suffered owing to the drought, they were wonderfully fine. If the canes are cut down in the early spring they produce late fruit, so that a row or two treated in this way will do much to prolong the season. It may be thought preferable to grow the autumn fruiting kinds for a late supply, but Superlative will give larger and much sweeter fruit, and being such a heavy cropper it is always reliable. For late fruit a north border under a wall will be a good position for the canes, and as the fruit is produced on the newly-made canes, tall stakes are not wanted, and being dwarf the plants do no injury to wall fruits if grown in front of them.—G. WYTHES.

Cherries and moisture.—No doubt many fruit trees fail through lack of moisture. I have some trees which do grandly in a wet season—at least as far as swelling up the crop is concerned; but, of course, with a wet season there is a serious drawback in the way of cracking, as it is impossible to keep cracked fruits for any length of time, and what is gained in one way is thus lost. There is no difficulty in throwing off heavy rains by planting on sloping banks or by using some conductor to throw off excessive rains and prevent cracking. In dry, gravelly soils the Cherry is short-lived if not well attended to in the way of moisture. If these trees are now suffering at the roots the mischief is soon seen; the leaves droop in hot weather and do not assume an erect growth after a night's shade, and, what is worse, the trees frequently break into new growth early in the year, or even in midwinter if the weather is mild. This growth is soon destroyed, and the result is canker and in time total loss. I am well aware the Cherry does not like a very heavy soil, but feel sure a very light, dry subsoil will not tend to a healthy growth or long-lived trees. I am obliged to mulch very heavily, and in such weather as we are now experiencing to water at least twice a week, this entailing a lot of labour. In no case do I advise a south wall in hot or exposed places, as with a tropical summer the fruits are nearly wasted before they are ripe, as they are much exposed on one side and hard on the shaded side. At p. 92 "Dorset" points out the importance of moisture for Cherries even on a north wall, and it is far more essential on a wall more exposed. I lost several trees years ago through drought, hence my anxiety as to a good supply of moisture. With

plenty of the latter there will be less decay, as a robust growth will result and little canker. I am alive to the importance of ample drainage in heavy land, but deep planting is not to be recommended, as if the fibrous roots can be kept near the surface, there will be little canker provided there is an ample supply of moisture.—S. H. B.

THE AUTUMN PRUNING OF PEACHES.

Mr. WYTHES' remarks on this (page 131) are as opportune as they are valuable. The more thoroughly ripened the wood of this year, the finer the crop, weather permitting, the next. Now, maturity of wood is often less a matter of weather than of treatment. Overcrowding of shootlets and leaves is the chief cause of green, sappy wood in the autumn. Such wood, again, is crowded with immature buds, mostly wood ones, which are tender in the ratio of their size. The few fruit-buds among them that escape freezing develop into weakly fruit hardly worth growing. On the other hand, where all the wood is grown up to perfection, wood and buds alike resist almost any amount of cold, and the fruit-buds yield fruit equal if not superior to that grown under glass. The latter is specially so this year, thanks no doubt chiefly to the abnormal heat and drought.

To return to summer pruning, I wish especially to corroborate Mr. Wythes' views as to doing this tentatively, a little at a time. Not only fruit trees in the open, but also under glass, and especially Grape Vines, are often most seriously crippled by wholesale onslaughts of summer pruning. The check to the flow of sap on the heels of such wholesale slaughtering is simply disastrous. But not a few go to the opposite extreme, and instead of having a few field days for wholesale summer pruning, leave all pruning until the winter or spring. The latter resent time and force by growing what is worse than useless, viz., a redundancy of wood in their Peach, Plum, or other fruit trees.

Want of time for summer pruning is often urged to cover other objections. Of course, where the trees are numerous and the walls of great height the labour is heavy. Nevertheless, skill of head and nimbleness of fingers get over quantities of such work in a short time in summer weather, and there is little or no labour in the garden that yields quicker or more profitable returns. All the labour expended in summer pruning is also saved in the winter and spring pruning. Summer pruning properly practised lays the basis of fertility. Winter and spring pruning at the best but remove useless or sterile wood out of the way.

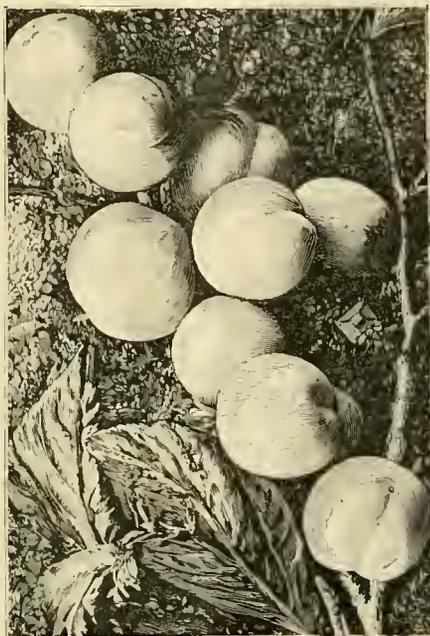

D T. F.

Melons and the hot weather.—I believe complaints have been pretty general this season as to the early collapse of Melon plants, the recent hot and sunny weather having been very trying to the foliage. Melons being lovers of bright sunshine, this season should have been more in their favour than otherwise. This early collapse must, therefore, be attributed to other causes than the bright weather. My opinion is, and this is further borne out by facts, that it is on account of a sluggish root-action. For the last few years I have grown a portion of my Melons in a structure where there is a pit filled with leaves, this having previously been used for forcing. On these leaves small hillocks of soil are placed, in which the Melons are planted, and I must say that I never saw Melons thrive better than these have this season. The foliage was of a very dark green colour up till the time the fruit was cut, and without an insect of any kind being seen, and this without any syringing to promote this end, as this latter is a practice I do not believe in with Melons. There being such a body of leaves, the inference might be drawn that this would favour a strong succulent growth for the time being, and predispose the plants to canker and gumming. This, however, does not happen, as the leaves keep up a healthy and continuous root-action. A large body of fermenting material composed principally of horse litter might be against such good results,

but not leaves, as I am certain these are a good aid to the Melon's healthy progress. The leaves by generating a gentle warmth promote root-action, and this being the case, healthy foliage follows, and such as will withstand hot sunshine and dry weather with impunity.—Y. A. H.

THE BEST PLUMS.

This has been a very extraordinary Plum year, yet it is doubtful if anything like good representative collections will be forthcoming at the principal fruit shows. Already many of the best are nearly or quite over, and those that follow will be principally produced by trees trained against walls with a cool aspect. These remarks, however, apply more particularly to the more southern parts of the country, and should the northern growers come south to

Plum Green Gage.

compete at the great fruit show that is to be held under the auspices of the Royal Horticultural Society at Islington, they will very probably have matters much their own way with Plums. If we cannot compare fruits, there is nothing to prevent comparing notes. In addition to be very plentiful, or far more so than at one time thought possible, Plums have also been of exceptionally good quality. So well have they ripened, that the immense quantities that have been eaten do not appear to have injured but few people, this further confirming the well-recognised theory that it is only unripe fruit which is very injurious to those who partake too freely of it in a raw state.

As far as early dessert varieties are concerned, there are none in my estimation to equal Oullin's Golden Gage. To do justice to this fine Plum a fairly warm site or a wall facing south-east should be accorded it. It is of sturdy growth, the wood as well as leaves being very distinct. With me it rarely fails to bear good crops, the fruit being large, roundish oval in shape, of a rich yellow colour, and in flavour not far behind a Green Gage. It usually ripens about the second week in August, but was fully a month earlier this season. Oullin's Golden should find a place in the most limited collec-

tions. The best purple companion for the last named that I have yet tried is De Montfort, a variety but little known, yet a very excellent Plum all the same. In growth it is totally the opposite of Oullin's, being of a thinner habit altogether. For the past six years the tree has not failed to produce a fairly good crop of medium-sized fruit in form somewhat resembling Coe's Golden Drop, only a little smaller and a dark purple in colour. It has a yellow flesh, rich, and is improved rather than otherwise by keeping. Transparent, or as some prefer to name it Early Transparent Gage, is always a very attractive variety, but this summer it is better than I have ever seen it before. The tree is of a fairly strong and productive habit of growth, the fruit being somewhat flatter and also larger than the Green Gage, and when ripe the skin is transparent yellow and prettily coloured on the exposed side; quality first-class. Transparent Gage forms a good succession to Oullin's Golden, and actually pleases better than Jefferson, good as the latter is. The last-named has long been popular, this handsome richly-flavoured yellow Plum succeeding well in most gardens, always provided the trees can be trained against a wall of some kind. With me it colours beautifully on a south-east wall, but the finest fruit is gathered from a tree trained against a wall with a north-west aspect. Kirke's is still the best purple companion for either of the two yellow Plums just commented on, this also being of a good productive habit of growth and the fruit large, handsome, and richly flavoured. If a tree or trees of Jefferson are planted against a wall with a cool aspect, the supply of choice fruit will usually be maintained till Coe's Golden Drop is ready for use. The latter is, perhaps, the most valuable variety in cultivation, and this season, thanks to its long keeping properties, will be particularly appreciated. It is a good grower, yet never fails to flower and, if the season is favourable, to crop heavily, the fine, handsome, richly-flavoured fruit frequently keeping till November. In Guthrie's Late Green we have another good late variety. On walls it is a sure bearer, and the large, round, green-coloured fruit, though not particularly attractive in appearance, are of good quality and keep remarkably well. The Gage family—I mean the true Gages—is somewhat disappointing. Only the ordinary Green Gage (here figured) can be termed reliable, and the trees even of this are more crippled by red spider this season than any other varieties. But for their superior quality not many Green Gages would be grown by me, and both the Purple Gage and Reine Claude de Bavay have been discarded owing to the fruit cracking so badly.

All the foregoing are dessert varieties of superior quality, but they are equally valuable for making into preserves or for pies. Why, therefore, so much good wall space should be devoted to second-rate varieties is to me somewhat of an enigma. It is true some of them are available for either dessert or cooking, but they are a poor substitute for the genuine article, and if grown at all should be more in the form of standards, pyramids, or bushes. Early Orleans, of which Grimwood's Early is the best form I have come across, and a tree of Victoria are about all that should be given wall space in the majority of gardens, and if an extra early variety can be found room for, plant Morocco in preference to the flavourless Rivers' Prolific. The Czar, Sultan, and Washington are of fairly good quality only against walls, but the two former are among the best for growing in the open. Quite recently I passed

through a rectory garden where no less than four large trees of Prince Engelbert are trained against moderately warm walls. It is true they rarely fail to produce a crop of extra large purple fruit, but the quality is simply execrable. Those other extra large varieties—Pond's Seedling and White Magnum Bonum—are equally worthless, but they have their share of wall space in many gardens in spite of their poor quality. Goliath, again, is not of much value, and Diamond is sour and of but little good, though there are plenty of well-grown pyramids of it to be seen in different gardens. Prince of Wales and Mitchelson are suitable for growing as low standards, and so also are Czar and Sultan, both of which I have just previously alluded to. If a really good preserving or cooking Plum is wanted in quantity, then plant standards of Gisborne's, this being an improvement on Pershore, a small, yellow-fruited, heavy-cropping variety much grown in Worcestershire. Coe's Golden Drop should also be tried as a standard, as I have seen it doing well in orchards near London, and no variety surpasses it for making into preserves. Winesour seems to be going out of cultivation, yet the fruit of this variety is considered very superior for cooking or preserving, the flavour being quite distinct from that of any other Plum I have yet tried. The tree is of erect, but not very strong growth, and from what I can remember of it not much fault can be found with it as regards productiveness.

FRUIT GROWER.

STRAWBERRIES ON LIGHT LAND.

THIS has been a trying season for this fruit when panted on light, gravelly soils; indeed, in some cases there has been a total collapse of plants if the latter were poor or had occupied the same ground for any length of time. There is considerable advantage in adopting the yearly system with such soils, especially if special means are taken to plant early and thus secure a good growth before the winter. The runners require as much care as if layered for forcing. It may be thought best on dry, poor land to allow a freer growth somewhat like the alpine Strawberry. By allowing the runners to root and fruit between the rows there is less chance of failure. No doubt this is a good plan on light land where the necessary attention to secure first-class fruit cannot be given, as I have seen crops obtained in this way that would otherwise have been utter failures. Often small fruit in abundance is required for preserving, so that the last-named answers admirably, especially for such kinds as Black Prince, King of the Earlies, and the old Scarlet Pine. I have had abundance of fine fruits from plants put out in February, these having been wintered in $\frac{1}{2}$ inch pots, but I do not recommend it for general practice. My reason for doing it was that some of the new varieties that came to hand were badly rooted, but by potting up, keeping plunged up to rim in the open or in cold frames, they well repaid special means to get strong plants. There is often considerable loss by planting badly-rooted runners. Again, why, it may be asked, is it necessary to get special soil when the plants occupy it such a short time? There are several reasons, and one more important than others is to prevent failures in seasons such as we have just passed through. By planting in suitable soil a greater size of fruit and a heavier crop are secured in favourable seasons. Some varieties almost refuse to grow on poor gravelly soils, but by the use of heavier soil few failures occur, and the old Strawberry bed when cleared is just the place for such crops as Broad Beans, roots of various kinds and many other green crops. It well repays the cultivator to give his Strawberries some heavy soil, and where it cannot be done thoroughly, that is, by carting clay or marl into the quarters, a few barrow-loads of this

material placed along the rows or round the plants give the latter a firm root-hold, as well as secure them against drought. If a few rows are planted every season in the way described, there will be as much weight of fruit as from double the quantity of plants on poor, light soil. It is surprising to see the progress the plants make when first planted in such soil. Often heavy soil may be had at a small outlay and would cost less than a large quantity of manure; it may not always be ready to hand just at the time required, but those who can store a good heap will find it of great value at this season when planting. I find it invaluable, as it comes in for other fruits, such as Melons, Vines and hardy fruits. There are several varieties of Strawberries which refuse to do well unless special means are taken to secure a good root-formation. If close observation is made with pot Strawberries, it will be found a large proportion of heavy soil is used, this being made very firm. I would also advise a thorough treading, or even ramming the bed before planting. I do both and pass the back of the rake over the surface after treading, planting carefully with a trowel and leaving a cavity round each plant to hold the water. By attention to details at this season there is less anxiety as to the plants next year, indeed failure rarely occurs. The individual fruits will be much finer, the flavour improved and a very heavy crop secured.

Y. T. II.

OUTDOOR GRAPES.

WHILST we are having one of the most favourable seasons ever known for the maturing of outdoor Grapes, and there will be found still in diverse parts of the kingdom immense quantities of the common varieties, there is little probability that we shall see even the best samples fetching in the markets more than 2d. per lb.; whilst the worst of Spanish and Portuguese imported Grapes will sell readily at 4d. and 6d. per lb. This fact is due to two things: first, our average summers are distinctly unfavourable to the production of good outdoor Grapes, and second, because our outdoor varieties are of such inferior merit. Then, even when conditions are so favourable, as is the case this year, practically nothing is done to improve the quality of the Grapes by thinning either bunches or berries. Probably did anyone take so much trouble, it would not pay in a pecuniary sense; but it would pay were the Grapes consumed at home, as whilst the number of bunches or berries would be reduced one-half, the loss in that way would be more than compensated for by the superior size and quality of the berries. If we have so few Grapes that are worth cultivation outdoors, we have our own inaction somewhat to blame, but more, of course, our unfortunate climate, which gives us absolutely so little encouragement to improve our hardy Grapes, that the present season stands out literally as but one in ten; indeed, it is almost a rarity in a lifetime, and in such case how is it possible to expect that anyone would care to undertake work which would meet with such poor encouragement? If we take stock of outdoor Vines now all over the kingdom, setting aside, of course, those planted in vineyards, as at Castle Coch, Cardiff, we shall doubtless find that White Sweetwater is almost exclusively the one variety grown. Mr. Fenn used to grow Esperione and Royal Muscadine at Woodstock on the best aspects of the old rectory house, but even there the berries could never be said to ripen, although they answered the purpose of the grower for wine-making. Some fifty years ago, and before glass was so cheap, a large portion of the population had to be dependent upon such fruits as they could obtain from the outsides of their dwellings and from walls. I remember

well as a boy Clement Hoare's earnest and well-meant effort to form a vineyard on a hill slope at Shirley, near Southampton, for I just then lived close by. He erected low walls at moderate intervals from each other, and rising one above the other on the slope. But in spite of the warm position and the undoubted special knowledge of the planter, the attempt failed absolutely. The best hardy varieties of that time were August Muscat, Early Black July, Royal Muscadine, White Sweetwater, White Dutch, Esperione, Black Prince, Parsley-leaved, Ciotat, and a few others. So far as my recollection serves, the best for the production of good-sized berries was the White Dutch, but the bunches were small. The Sweetwater is perhaps the next best white, whilst the best blacks are the Ciotat and Black Cluster, although these are poor enough. I often wonder whether amidst all the efforts made from time to time to secure improved tender Grapes anything has been done towards obtaining better hardy or outdoor Grapes. Not that anyone, if he did with ever so much success, would reap any pecuniary benefit. It would have to be a matter of pure liking or of fondness for the work of hybridising, for, after all, let the results of such labour be ever so good, there could be no actual benefit unless we had seasons that would fully mature Grapes outdoors. One of the special needs is found in varieties that will break into growth earlier than is usually the case, but even then, so tender are the young shoots, that they may be all killed by late spring frosts. Then Vines outdoors have formidable rivals in other fruits. How much more can be made on south aspects from Apricots, Peaches, Pears, or the best Plums. How much more regularly do these crop, and how invariably does the fruit ripen fully. A good Marie Louise or Pitmaston Duchess Pear on a north wall would probably give a ten times better return than would the best cropping Vine. I should never think of advising the clothing of a cottage front with any Vine now, although it was common about fifty years ago. Happily, whilst seasons have so largely given the *coup de grace* to outdoor Grape culture, they have not materially injured the production of other fruit, and so long as we can purchase fairly good Grapes—much better indeed than we can grow outside—for from 4d. to 6d. per pound, we need not want for Grapes, whilst other fruits rarely are too plentiful, especially of the fine quality that walls give. A marked feature on outdoor Vines this year is the absence of mildew.

A. D.

THE FRUIT CROPS.

SOUTHERN.

Cassiobury Park, Watford—Apples under average. Pears bad; only a few set. Cherries good. Plums good. Peaches and Nectarines average. Apricots average. Black and Red Currants good. Raspberries average. Strawberries under average.

Vegetables in every case a very light crop. Early Potatoes small, but of good quality. All seeds sown early stood this dry season best.—CHAS. DEANE.

Gaddesden Park, Hemel Hempstead, Herts.—The fruit crops in these gardens and neighbourhood, I think, in general have been with few exceptions very satisfactory. Apples a fairly good crop, and the fruit swelling very well. Apricots a heavy crop, the fruit set in clusters like Grapes. Pears a very fair crop, not heavy. Plums a fair crop. Peaches and Nectarines a good crop; the Peaches have ripened off very early this year,

three weeks before the usual time. I began picking Early Alexander June 21, Hale's Early July 3, Early Rivers July 5, a heavy crop, fruit well coloured, and not split at the stone, as it usually does here; Early Beatrice July 14. The only protection the trees receive in the way of covering is a double net in the spring and a board for a coping 16 inches wide. Cherries have been very plentiful, especially Morellos. Strawberries have been fairly good, but smaller than usual, and in many places were over very soon. In these gardens they have done very well. I have them planted on borders with different aspects. I began picking on May 28, on south border, Noble, then Vicomtesse H. de Thury and La Grosse Sucrée; then followed on with the same sorts in the open, President added; then the same sorts on north border, Sir Joseph Paxton added; the last turned out very fine. I picked every day from May 28 until July 17. Gooseberries, Black, White, and Red Currants have been a very good crop, the fruit not so large as usual.

The vegetables have been very good considering the long spell of dry weather we have had. Early Potatoes turn out very small, not more than half the usual crop. The late ones look more promising. The Onion crop is had in places, especially with the cottagers. Several of them have lost the crop entirely with the maggot. Peas have done fairly well. All winter stuff got in early is looking very well.—HENRY FOLKES.

Holly Lodge, Highgate.—Strawberries and Raspberries good on the whole. Bush fruit full average crop. Morello Cherries a heavy crop and well finished. Peaches and Nectarines good. Plums and Damsons partial. Apples and Pears a full crop. The foliage of Apples and Plums has suffered severely from the drought and insects; consequently the fruit is below average size. All fruit crops up to the present have been nearly a month earlier than last year and of shorter duration. Present appearance is a falling off in bulk of Apples, Pears, and Plums. The foliage of Apples and Plums is much damaged.—J. WILLARD.

Wonersh Park, Guildford.—We had no rain from March 2 till the first week in July, with the result that nothing would grow, our time being fully occupied in keeping things alive by continuous waterings. The fruit crop was rather disappointing after such a good show of bloom. Strawberries were a poor crop and deficient in flavour. Red and White Currants were above the average, but Black was the poorest crop I have ever known. Raspberries much below the average. Gooseberries rather above. Apples are a good crop, especially such old standard varieties as Blenheim Orange, Ke-wick Codlin, Hawthornden, &c. Pears are rather better than last year, a few varieties carrying good crops, both on walls and standards. Plums an average crop, such varieties as Cee's Golden Drop, Victoria (Denyer's), Diamond, White Magnum Bonum, and most of the Gages being fairly well loaded. Morello Cherries were a good crop. Peaches and Nectarines outside are carrying an average crop, though very small, the sorts doing best being Royal George, Alexandra Noblesse and Diamond, and in Nectarines, Murray and Violette Hâtive. Apricots were above the average, though rather small.

Peas were a poor crop, Telephone and Duke of Albany doing best with us. Broad Beans were a complete failure, flowering about 6 inches from the ground, and being completely smothered with black fly; the early sowings of dwarf Beans were spoilt by red spider, but later sowings are doing well. Cabbages, Cauliflowers, &c., were rendered unfit for use by blight. Early Potatoes were an average crop, but I find that the late varieties, such as Magnum Bonum, are growing out very much. Carrots and Beet have failed altogether. Onions where free from maggot a medium crop. One thing I noticed particularly, and that was the superiority of the Cabbage varieties of Lettuce over the white Cos in standing the drought.—A. HORSELL.

Brickhill Manor, Bletchley.—The year 1893 will long be remembered for the exceptional

drought and great heat. With the exception of a slight shower, no rain fell in this district between March 18 and June 28. In consequence of the want of rain between the dates mentioned, many crops have suffered. Strawberries set well, but could not swell to full maturity, and I found them wanting in flavour; the plants have suffered also. We gathered in the open air, May 21, Keens' Seedling, and by the end of the month the whole crop was ripe. All sorts of Apples are bearing heavy crops, the trees healthy and free from caterpillar. Plums abundant, especially on pyramids, and the trees free from blight. Pears moderate crops. Apricots and Peaches do not succeed here. Gooseberries heavy crop, but the foliage was devoured by the caterpillar in spite of all remedies we could apply. Red, Black and White Currants good crop, but smaller than usual. Walnuts, Filberts and Cobs are good crops.

Vegetables have suffered from the dry weather. Veitch's Selected Early Pea did well. We gathered from this variety May 20; American Wonder and William I. followed. Stratagem and Autocrat stood the heat better than other varieties, and I consider these two of the very best Peas that are grown, and especially adapted either for large or small gardens. Carrots are good in gardens, but field crops are poor. Among Turnips for early use, I find nothing so useful and reliable as Early Milan. Onions, spring-sown, are almost a failure all round this district. Potatoes look well in the top, but I find the yield is small, and unless all early sorts are lifted, second growth will take place. Magnum Bonum and such late sorts require a good rain. All are very healthy and no disease.—G. BLOXHAM.

Stowe, Bucks.—There has been an abundance of fruit this season here. We have quantity, but not quality. Apples plentiful, but small. Pears plentiful in places; crop varies. Plums abundant. Currants and Gooseberries the largest crop for years, but on light soil the strain upon the trees and dryness have killed many.

Around here this season has been an unfavourable one for vegetables. The dry season has caused the seeds to germinate at different times. Thus on the Beet bed I have seen here and there a very fine plant, with others just coming out of the ground, and also find good seed not yet germinated. This has also been the same with the Onion and Carrot beds. Cauliflowers have been quite a failure, while Peas sown in trenches have been very good, as also have been French Beans. Potatoes which were not in a sheltered situation were cut down by a frost we had in June. Since then they have done no good, although the haulm has grown more than usual. Very few Potatoes are found on the roots of these. From Potatoes not cut by the frost I have fine crops, but the tubers are now growing. On the lighter soil I find many of the Potatoes covered with a dark substance, which gives them a scabby appearance, while on the heavier lands they are perfectly clear.—G. HASKINS.

Binsted Wyck, Alton, Hants.—In this district Apples are over average and the trees clean. Pears are very good. Not many Plums or Damsons, and trees have suffered from blight. Peaches and Nectarines are plentiful. Bush fruit has been very plentiful. We have a plague of wasps, which are eating all ripe fruit they can get at. Strawberries were plentiful and good. Morello Cherries plentiful.

Vegetables rather short on account of the dry season. Broad Beans are a complete failure. Early Potatoes are poor. The late ones are looking well; no sign of any disease as yet.—JOHN ROGERS.

Cowarth Park, Sunningdale.—This has been a trying season in many respects, fruit and vegetables being greatly affected by the long spell of drought. Fruit is much below average. The great heat did not suit the Strawberries. I commenced gathering from the King of the Earlies on a south border May 19, followed by La Grosse Sucrée, Noble being a few days later. Sir Joseph

Paxton and Sir Charles Napier were by far the best with me, the fruit not large, but of good flavour. Latest of All to-day (July 26) is flowering freely, and if weather permits I hope to gather some nice fruit yet. Gooseberries, Raspberries, and Currants are very plentiful, but far from satisfactory as regards flavour, all ripening very early and soon over. Caterpillar, red spider, and wasps have been great enemies to the fruit. Very early also were the dessert Cherries, Morellos likewise being ripe fully a month earlier. Plums and Apricots an average crop. Peaches plentiful, but small. I gathered from the outside June 23. Nectarines of medium size, colour good, but flavour poor. Apples are far below an average, although at one time they looked promising. Pears are abundant, every tree being loaded. Nuts are plentiful.

This has been a bad season for all kinds of vegetables. I commenced gathering Chelsea Gem Peas on a south border on May 25, followed by the Pioneer and William I. Cauliflowers and Lettuces have been a complete failure. Potatoes were never better, not large, but good and free from disease.—H. ATFIELD.

Westbury House, Petersfield.—Strawberries were all quite a fortnight earlier than usual, Noble, Vicomtesse Héricart de Thury, and Sir J. Paxton having been nearly all in at once, each having an abundance of fruit, well coloured, and well flavoured, though deficient in size. I have no late Strawberries at all this year; Frogmore Late Pine, Laxton's Latest, and Loxford Hall Seedling all came in before Sir J. Paxton was quite over. The three late varieties just named are comparatively new, or at least they are not yet very widely grown, and this is the first year that I have been able to test their relative merits, each variety having borne a large crop of the most splendid fruit I have ever seen. Gooseberries quite average crop, but small and not well coloured. Red and White Currants plentiful, but small; Black Currants under north wall abundant, and nearly full sized. Raspberries small and short stemmed, but fair average. Peaches on walls where covered in spring plentiful and of good flavour, though under-sized in spite of thinning, watering, and mulching. Apples with me very plentiful. Walnuts with me a failure, the frost having destroyed the blooms, but trees a few miles out on higher ground are heavily laden. Filberts and Cobs well fruited just here, but I believe rather partial.

I have Carrots of four or five different sizes and heights on a bed from one sowing. Parsnips the same. Beet the same. The most sorry spectacle of all is the Onion bed. I sow over 1 lb. of seed annually, and usually store from 10 to 15 bushels of bulbs. This year I cannot store one half-bushel. This is quite accountable, and if we are beaten we at least know how it has been done. For seventy clear days, viz. from March 7 to May 16, not one drop of rain fell in this neighbourhood. The small seeds were sown and found just sufficient moisture under ground to cause them to germinate, after which came a long succession of burning hot days, and no more moisture being forthcoming in any shape, the germ dried up and the seed died. The seeds which have been coming up lately and formed a succession were those which at sowing were left nearest the surface, and never got damp enough to start them till the rains came. We have had a very harassing time fighting red spider, wasps, &c., which have almost mastered us here, and from what I read my friends at a distance are quite as badly plagned.—C. LANE.

Wyfold Court, Reading.—We have had good crops of all kinds of fruit, but Strawberries had to be watered to prevent berries shrivelling. Currants and Raspberries suffered worst of all; the fruit could not withstand the scorching sun, consequently only half came to perfection. Gooseberries finished off well. Apricots, Peaches, Plums, Pears and Apples have all done well, the crop of the three last being very heavy and clean. This being a Cherry county, large quantities are grown, the crops heavy. The absence of rain caused the fruit to finish off without splitting. All fruit was ripe three weeks earlier than usual. I have ob-

served that plants of all kinds with long roots withstood drought best, and, again, only on well-cultivated ground have plants done well; therefore we must bear this in mind and dig and plough deep.

Among seeds, Carrots, Beet, Parsnips and Salsify took much longer to germinate than usual, but it was noticeable after a while, when the roots had penetrated the soil, that growth was rapid. Onions did well; good crop and large considering no water was applied. Peas have been bad; although the haulm quickly grew up, only half a crop of pods followed, which quickly filled. The haulm of all early varieties was cleared off by first week of July. Out of eight varieties I found Laxton's Supreme was the best. Early Potatoes, such as Myatt's Ashleaf, were good crops and of fair size, but Early Rose, Beauty of Hebron, and other second earlies were very poor and haulm all dead by July 10.—ARTHUR LONG.

Englefield, Reading.—The Apple crop in this neighbourhood, I believe, is an average one, but in these gardens it is very poor, Keswick Codlin, Alfriston, and Cox's Orange being the only varieties which are fruiting this year. Pears are pretty good. Apricots good. Plums good. Peaches good. Gooseberries good. Red and White Currants good. Black Currants very poor, which I attribute to very late frosts when in bloom. Raspberries were nearly a failure owing to the long-continued drought. Strawberries the early part of the season were good, but the late varieties were poor on account of the dry weather.

Early Peas were good, but later crops have suffered much from the dry season. All crops in the kitchen garden have suffered much from drought. It was difficult to get many seeds to germinate.—JAMES COOMBES.

East Sheen.—The Apple and Pear crop in this district is very thin, although there was abundance of bloom and a heavy set. Owing to the drought the fruit dropped badly. The best Apples here are Lord Suffield, Lord Derby, Bismarck, Worcester Pearmain, Kerry Pippin, Baumann's Red Reinette, Pott's Seedling, the best Pears being Clapp's Favourite, Williams' Bon Chrétien, Beurré Fouquieray, Duchesse d'Angoulême, Pitmaston Duchess, Fondante d'Automne. Plums are a failure. Cherries, except Morellos, are a failure. All kinds of bush fruit are good. Wall fruit is very good. The best Peaches are Royal George, Condor, Grosse Mignonne, Alexander, Sea Eagle. The best Nectarines are Elruge, Lord Napier, Pineapple, Rivers' Early Orange, and Prince of Wales.—S. OSBORN.

Syon House, Brentford.—The year opened with every promise of an abundant crop of fruit, the protracted frost early in the year keeping the blooms later than otherwise would have been the case. Apples are under average. There was plenty of bloom and a fair set, but owing to the long drought a great portion of the fruit dropped. Such kinds as Lord Derby, Alfriston, Lord Grosvenor, Manks and Keswick Codlins—indeed, all of the Codlin type are bearing freely. Lane's Prince Albert and Stirling Castle, the latter on Paradise stock as a cordon, are bearing very heavy crops. Choice dessert kinds are very scarce, our best bearers being Cox's Orange, Cockle, and Kerry Pippin. Pears are a very thin crop, the best croppers this season being Louise Bonne of Jersey (which rarely fails to bear), Beurré Bachelier, Beurré Diel, Pitmaston Duchess, and Easter Beurré. Though we devote a large wall space to Pears on various aspects, the pyramid trees are our best bearers this season. Plums may be termed a failure. Cordon trees have invariably done well, but we grow only a few cordon Plums. Our best Plum this year is Czar, a valuable variety. Peaches and Nectarines promised well; there was abundance of bloom and a free set upon such kinds as Hale's Early, Early Silver, Stirling Castle, Royal George, and Noblesse, but many fruits dropped during the stoning, our soil being very light. Lord Napier Nectarine is bearing a good crop of large fruit—indeed, in my opinion this is our most reliable Nectarine, equally good inside or out. Much

labour was entailed in keeping these trees in a healthy condition. Red spider and aphid were most troublesome during the hot, dry weather. The trees are now making a vigorous growth, having been mulched heavily to protect from drought. Apricots are an enormous crop, fruits smaller than usual and much earlier. We gathered Early Frogmore end of June. Hemskirk, Moorpark, Shipley, and Large Red are our best bearers. Moorpark suffered most from the drought, losing some wood, although receiving due attention in the way of mulching and moisture. Cherries bore well, but were smaller than usual. Governor Wood, Early Rivers, several of the Bigarreans, and Black Tartarian bore grand crops. Morellos are very heavily laden, and others of the Kentish or Morello type are all bearing freely. Strawberries were exceptionally early and much under average. Some varieties suffered badly from the drought. Those kinds with a soft and hairy foliage got infested with red spider despite all remedies to prevent it spreading. Our crop would have been poor, but by early mulching and a thorough soaking weekly we had fruit for nearly six weeks and of good quality, Vicomtesse, La Grosse Suerée, Keens' Seedling, British Queen, Elton Pine, Jubilee, and Latest of All giving a good return. Raspberries suffered badly from the hot, dry weather, the fruits being smaller and soon over. Superlative was our best kind and of good quality. Small fruits, especially Gooseberries, dropped badly, and the trees were infested with spider, taking a lot of time and trouble to preserve the few fruits left. Currants did better, the crop being good and the berries of fair size. Damsons are a failure, the trees being very dirty.

Potatoes are under average, the tubers of the early kinds small and not numerous. Sharpe's Victor was dug from the open ground the second week in May, and Veitch's Ashleaf came in early and good in quality. Many of the American varieties are of good quality this season, not so watery, owing to the drought. So far there is no disease, and late kinds promise well. Peas were very early, but soon over. We mulched heavily all our mid-season and late varieties, and thus secured good crops. Cauliflowers were scarce early in the year owing to the loss of plants in winter. Cabbages very early, but most of the Brassica tribe have suffered badly from fly. Our best Spinach is Victoria; this is valuable in hot weather. Roots, such as Carrots and Turnips, have done fairly well. Succession crops are making good headway and will be valuable.—G. WYTHES.

Nash Court, Faversham.—The fruit crop here and in this neighbourhood may be put down as exceptionally heavy. Pears and Apples very heavy crop, but small owing to the long drought. Peaches, Nectarines and Plums abundant and good. Cherries never better. Strawberries a fair crop, but soon over. Of bush fruit Black Currants were but half a crop; Red Currants and Gooseberries heavy crop; Raspberries fair average. Nuts are plentiful, especially Walnuts, which are the heaviest I ever knew.

Vegetables with me have been almost a failure. Potatoes are of good quality and no disease. Most of the crops here had no rain from planting till lifting.—G. HUMPHREY.

Denbies, Dorking.—Considering the dry season the crop of fruit here has been very good, especially Strawberries, Gooseberries, Red and Black Currants, Cherries, Plums, Apples and Pears. Raspberries were very small owing to the drought; also the Apricots from the same cause, and the same may be said of Peaches.

Vegetable crops, with the exception of Cabbages and Potatoes, are very inferior both in quantity and quality.—J. BEESLEY.

Woodhatch Lodge, Reigate.—Apples and Pears over average. Plums slightly under average. Morello Cherries, Peaches and Nectarines average. Strawberries under average. Gooseberries, Raspberries, Currants, Nuts average. Apples and Pears where the trees have not been watered are very small. With us the fruit is swelling very fast owing to having been watered, and the

showers that have fallen lately have moistened the atmosphere; in fact, Pear Marie Louise is as good now as when gathered in October. The season, owing to drought, has been a short one for small fruit. Strawberries promised well, but late fruit failed to swell. Trees have suffered from black-fly, especially Plums and Cherries.

Early varieties of Potatoes are a failure, but later varieties promise well at present; the haulm is green and sturdy in growth. It has been a most trying season for vegetables. Early Peas and Ellam's Cabbage have been good, but later Cabbage has failed. Everything in the Brassica tribe, also French Beans, are smothered with black-fly. Main-crop Peas have been covered with thrips.—C. J. SALTER.

Hamstead Park, Newbury.—Peaches, Gooseberries and Apples are plentiful; also Black and Red Currants; but Strawberries, Raspberries, Damsons, Cherries and Apricots are poor crops. Plums and Pears are fair crops. Roses have been very poor, and the herbaceous plants have suffered very much.

This has been the most trying season for all kinds of seed I ever knew. In many cases I have had to sow four times. All the early kinds of Potatoes are very poor indeed, a little under half a crop, but Magnum Bonum is looking well. I am in hopes we shall get a full crop. Early Peas and Cauliflowers have been almost a failure.—ROBERT GAMMON.

Claydon Park, Winslow.—The fruit crops, speaking generally, are very good in this district with the exception of Strawberries, which were very light and soon over. Caterpillars, aphid, and red spider have been very troublesome. I have noticed the Gooseberry trees in many of the cottagers' gardens have been literally stripped of their foliage, though bearing heavy crops. Apples especially are above the average, trees on the Paradise stock that have been kept mulched have borne very firm fruit of excellent colour. Mr. Gladstone and Beauty of Bath have been exceptionally early this season. Pears are scarcely up to the average; the trees have suffered from the ravages of the red spider. Plums are above the average. Gooseberries and Currants very good, though the fruit is small. Our Peach crops as a rule are good; this year they are very abundant and quite a month earlier, owing no doubt to the almost tropical heat we have had during the summer. The fruit is very firm and the flavour excellent.

Vegetables, especially Cauliflowers, have suffered very much from the drought. Peas and Spinach have suffered very much from the intense heat. Potatoes are very good, and up to now there is no sign of the disease.—I. MILSOM.

Luton Hoo, Beds.—In this neighbourhood Apples and Pears are very abundant, the fruits being of first-class quality. Peaches are a good crop, so also are Apricots, but rather small. All kinds of bush fruits are good. Strawberries I never saw looking better than they did in the spring. We had a good set, but the fruits turned out very small owing to the drought, the best being gathered from Sir J. Paxton, President, and John Ruskin. Plums are a good crop, and though great numbers fell off through insufficient moisture, there is still plenty left. Early Potatoes are good, but the crop will be lighter than usual. In some parts of Bedfordshire caterpillars have been very troublesome, but fortunately not so here, green and black-fly being our worst enemies, with red spider on the Damsons.—G. H. MAXCOCK.

Waresley Park, Sandy.—Fruit crops with me and in this neighbourhood are with a few exceptions below the average and fully a month earlier than usual. I gathered some Jargonelle Pears to-day (July 18) of good quality. This Pear in ordinary seasons is not ripe before the end of August or beginning of September. Apples are a fair crop. Pears and Plums are very thin. In some parts of this district there are good crops of Green Gages. Cherries are light, but good. Apricots are splendid, the best I have had for years. Peaches and Nectarines are below the average. Strawberries were

good, but of short duration. All sorts of bush fruits are fairly good.

Vegetables in this dry district are very poor unless the land is in a high state of cultivation and abundance of water been used. Beans, Marrows, Cucumbers, and Onions are grown largely in this district for market, and in most cases they are a failure.—R. CARTER.

NOTES OF THE WEEK.

Solidago serotina is a splendid Golden Rod. Its flowers are of the richest yellow colour, produced in a dense mass, and make a fine show of colour in the border at this season. We recently noticed it in bloom at Long Ditton.

Zinnias from Surrey.—I have sent you some double Zinnias and Gaillardias. The Zinnias are planted in masses, each colour separate, and give a grand effect.—J. GUYETT, *Broadlands, Ascot.*

*** These Zinnias are fine in size and superb in colour, owing no doubt in part to the hot Surrey soils. In some cold soils Zinnias never show their fine qualities.—ED.

A beautiful Funkia which we noticed in bloom a few days ago with Mr. Barr at Long Ditton is *F. subcordata grandiflora*. It is flowering freely in the open, the spike sturdy, and supporting large pure white deliciously fragrant flowers. If the soil is not well drained, moderately light, and the position sunny, it will not bloom. A good mass of it is a distinct gain to the garden, the flowers being larger and more fragrant than those of any other kind. It is more often called *F. japonica*.

Hedychium Gardnerianum.—A bed of this species in the Chiswick Gardens is interesting, as the plants are blooming freely, and the fine green leafage, even without flowers, is conspicuous. The *Hedychium* is, of course, a greenhouse plant, but it may be used with advantage for beds, the best soil to use being light loam. In especially favoured spots it will be safe in the open if the crowns are protected with coal ashes or cocoa-nut fibre refuse; otherwise the roots should be lifted and treated similarly to those of the *Dahlia*.

Lilies at Tottenham.—Many Lilies are in bloom with Mr. Ware at Tottenham, and amongst them there is the new *L. Henry*, which we recently made note of as in bloom in the Kew collection. We are pleased to see that this beautiful kind is getting spread, as it will doubtless become in a few years' time a largely grown type. Very charming also were the tall-growing *L. superbum*, *L. speciosum* in variety, *L. auratum platyphyllum*, *L. a. rubrum vittatum*, and the forms of *L. tigrinum*, the best being the very fine variety *splendens*.

The Flame Nasturtium, as *Tropaeolum speciosum* is familiarly called, is one of the finest flowering creepers. It was very beautiful a few days ago in the garden of Mr. G. F. Wilson at Wisley, the graceful shoots coming through a dense hedge and lighting it up with colour. It is strange that such a creeper should be comparatively rare in gardens, although in moist, fairly rich soil it will thrive to perfection. It is perfectly hardy, and the trailing shoots covered with rich vermilion-coloured flowers are brilliant in the extreme.

Magnolias at Washington City, D.C.—The species and varieties of *Magnolia* indigenous to the States, as well as those from China and Japan, succeed admirably in Washington. Our warm, dry autumns mature the wood and perfect the flower-buds for spring. These plants are perfectly hardy. Our winters, in which the temperature occasionally goes down to 10° below zero, never injure wood or bud if the cold is uniformly steady. What we have most to fear is mild weather in January or February, followed by a cold snap. This injures the flower-buds. The past winter has

been unprecedentedly cold, yet on the return of spring our *Magnolias* were very fine. I sent by mail yesterday some photographs of *Magnolias* in bloom. Should you consider any of the same of sufficient interest to use in *THE GARDEN*, they are at your service.—JOHN SAUL, *Washington Nursery, August 12, 1893.*

*** Excellent photographs, showing well both habit and bloom, and which we hope to have engraved for *THE GARDEN*.—ED.

Sedum Ewersi.—Our gardens lose much in interest through want of variety in the plants used for edgings. A bed in the Chiswick Gardens is edged with this *Sedum*, and it is a perfect mat of rosy purple flowers, so densely produced as to hide the silvery or glaucous leafage. A broad edging of it might be planted freely without introducing a monotonous effect. It is quite hardy in light soils, and bees have a special fondness for the flowers.

Annuals in a dry season.—Among those which which have flourished well during this dry and hot summer are the following: *Viscaria cardinalis*, *Linum grandiflorum rubrum* (never saw it so fine), *Phacelia campanuloides*, *Agrostemma cœli-rosa*, *Calliopsis*, mixed; *Larkspur*, mixed; *Lupine*, mixed; *Lasthenia californica*, *Bartonia aurea*, *Sweet Sultan*, *Phlox Drummondii grandiflora*, *Shirley* and *Mikado Poppies*, *Nemophila*, *Salpiglossis* and *Cannabis*.—M. A. R., *Liphook.*

Carnation Mrs. Reynolds Hole.—I was surprised to note that some correspondents write rather disparagingly of the constitution of this variety. It does very well here. To make sure that there is no falling off, in this exceptional season, from a constitutional standpoint, I looked carefully through our bed of this variety, and found we had been able to put down an average of seven strong layers from each plant. It bloomed very freely, but some of the flowers were inclined to split.—E. B., *Claremont.*

Pentstemons are blooming remarkably well this year, and this is evidence that they are capable of withstanding a long spell of tropical weather, whilst tuberous *Begonias* and zonal *Pelargoniums* are almost burnt up. The *Pentstemon* is becoming slowly, but surely, a popular garden flower. A few kinds noted in bloom may be mentioned as being of very fine colour: *Cythere*, purple; *Wm. Scott Watson*, deep crimson; *Mrs. Hemans*, white, flushed with rose; *Emperor*, crimson; *H. Stadler*, purple; *Longfellow*, crimson; and *Norma*, which is one of the finest of the crimson-coloured varieties.

An interesting Tigridia is *T. Van Houttei*, a native of North America, and of extremely beautiful colouring. Unfortunately, however, the various shades are rather dark and the flowers comparatively small, so that this acquisition is far less valuable to the garden than the brilliant *T. pavonia*, the familiar Tiger flower. The growth is slender, the leaves narrow, deeply ribbed, rich green, and the flowers clear yellowish as regards the ground colour, richly striped and suffused with deep crimson in rich association with the yellow stamens. *T. Van Houttei* is certainly a most interesting type, and is in full bloom in the Long Ditton nursery.

Early-flowering Asters.—Several early-flowering *Asters* are in bloom, although they usually do not flower until quite September. But when recently in Messrs. Barr and Son's nursery at Long Ditton we made note of several varieties in beauty. One of the best of all this section is *A. acris*, a dwarf, vigorous growing kind, which we should like to see more popular in gardens. The flowers are of a soft and pale purple-lilac, produced in a dense head, and the plant when in a mass makes a great show of colour. A bed of it presents a fine effect in the autumn. Also in bloom were *A. ptarmicoides*, *A. umbellatus*, *A. corymbosus Perseus* and *A. Shortii*.

Hardy Cyclamens.—These charming flowers are in full beauty in the Broxbourne nursery. They are represented by large masses, which make a gay display of varied colour. At Kew also, near the

Cumberland mound, clumps of them amongst Ferns make a pleasing picture, and it is a pity that they are not more grown in English gardens. They are not difficult to establish, but should be left alone to form bold masses. There is beauty not only in the flowers, but also in the marbled and variously coloured leafage; whilst the shelter from Grass, Ferns and similar things protects them from storms of rain. At this season of the year the flowers are most welcome, and in mild weather continue in beauty more or less throughout the winter.

Plumbago capensis planted out.—It is surprising that this beautiful plant is not more used as it is at Chiswick for bedding. In the larger London parks large specimens are grouped on the turf, and they have a distinct aspect, but Mr. Barron uses small examples in beds, with the result they are as pretty as anything we have noticed this season. In one case a bed is filled with it, the edging an *Echeveria*, whose tall flower-stems are in delightful contrast to the profuse display of delicate blue flowers. *P. capensis* is blooming exceptionally well this year, and a good mass of it makes a distinct feature in the garden. It is an easy matter to lift the plants before they are injured by frost; pot them up, keep over the winter under glass, and plant out again in the following May.

Primula Poissoni is flowering in the rock garden at Kew, but it is better as a pot plant. It does not seem very happy in the open, although it is early yet to tell what this fine species is capable of. *P. japonica*, to which *P. Poissoni* bears much resemblance, is now planted largely in the open. We hope that it will prove as easily grown as the older species. The coloured plate of it in *THE GARDEN*, October 17, 1891, will show its character; the flowers, however, vary in colour, those of the plant figured being of a rosy shade. *P. Poissoni* was first introduced to France by a French missionary named Abbé Delavay, who found it in Yunnan (China) about eight years since. Seeds of it were forwarded to Paris, and from thence to Kew. It was found at an elevation of between 5000 feet and 7000 feet.

Nymphæa Marliacea—A specimen of this beautiful Water Lily has for several weeks made a pretty picture in a recess at the far end of the lake in the pleasure ground at Kew, and on the morning of August 19 seven flowers were fully expanded on the plant. This Water Lily was first brought into notice about six years ago by M. Latour Marliac, a well-known cultivator of *Nymphæas* and *Bamboos*. The flowers are of a beautiful soft yellow and about the same size as in our native *Nymphæa alba*. Its affinities, however, are with the North American species, *N. tuberosa*, and it is said to be the same as the variety named *flavescens* by Professor Oliver. However that may be, there can be no doubt as to its value as a hardy Water Lily, being extremely free-flowering and distinct from any other thriving out of doors. A coloured plate of it appeared in *THE GARDEN*, March 31, 1888.—B.

Vanda Sanderiana.—On its first flowering under cultivation nine or ten years ago, this *Vanda* was at once recognised as the finest species known, and this position it still holds. Its pre-eminence is shown yet more strongly by its flowering during August and September, when few of our showiest *Orchids* are in bloom to compete with it. It is a native of Mindanao, one of the largest of the numerous islands of the Philippine group. It is erect in growth, with stout, strap-shaped leaves a foot long. The racemes proceed from the axils of the leaves, and have been known to carry more than a dozen flowers. But with even half that number, the effect produced is not easily surpassed, for not only are the flowers unusually large, but they are remarkable for their striking contrasts of colour. The upper sepal and the two petals are of a pale rosy lilac, tinged towards the base with yellow, where also numerous crimson dots occur. The lateral sepals are 2 inches in diameter, the fawn-coloured ground being overlaid by a conspicuous network of brownish crimson

lines. The lip is proportionately small and in colour dull crimson and greenish yellow. The full diameter of the flower is 5 inches, its somewhat flat appearance suggesting a resemblance to *Miltonia vexillaria*. There is a good example at Kew now carrying a raceme of seven flowers.

An interesting race of double *Begonias* we made note of a few days ago in the Chiswick gardens. A large bed is planted with several varieties, each of which is better adapted for bedding than the ordinary double-flowered kinds. The plants are compact, neat and dwarf, the flowers being produced well above the leafage. Louise Robert is white, touched with rose, the flowers very neat; Mme. Louis Urban, rose-crimson; multiflora l'Avenir, deep crimson; multiflora rosea, rose-pink; multiflora Mme. Courtois, pale yellow, a very charming kind, very free and pretty; multiflora gracilis, crimson, and Soleil d'Austerlitz, deep crimson. These varieties represent a class of *Begonias* which will be doubtless much used for bedding in the future, as they are blooming freely this year, when double-flowered *Begonias* in the open are scarcely satisfactory. A bed might well be formed of such a kind as Mme. Courtois, of a peculiarly soft and attractive colour. The plants are useful also for forming a margin to beds filled with larger growing things.

Vanda cœrulea.—First introduced in 1849, this beautiful *Vanda* remained for many years one of the rarest of its class. Like many other Orchids sent home about that time, which although natives of tropical latitudes, yet grew at such high elevations as to be practically temperate plants, it was sweated to death in hot, close stoves. Its cultivation is now, however, pretty generally successful. It is usually grown in the Cattleya house, where it obtains abundance of fresh air and light, and is rested in winter by keeping it on the dry side from December to February. During the period of active growth it likes copious supplies of water. The colour of the flower is one of the most rarely seen in Orchids, being a lavender-blue on the outer segments, whilst the lip is almost pure blue. The sepals and petals are oblong, the ground colour prettily tessellated with darker lines. In large-flowered varieties the blossoms are 4 inches in diameter, the parts overlapping each other. The species grows on the branches of trees on the Khasya Hills in localities where slight frosts are occasionally experienced.—B.

The Sorrel Tree (*Oxydendron arboreum*).—Although one of the oldest of American ericaceous plants introduced to Britain, this species appears at present to be one of the rarest. *Oxydendron* is now its accepted name (by Professor Sargent amongst other botanists), but it is more frequently known in gardens as an *Andromeda*. In an adult state it is, as the specific names implies, a small tree, and is found in the South-eastern United States in the valleys of the Alleghany Mountains. It carries a cluster of racemes at the end of each branch, the flowers being white and cylindrical. The leaves are dark green, oblong, tapering to a point, and slightly serrated; they differ from the somewhat similar foliaged *Vaccinium arboreum* by being smooth underneath, whilst the latter is slightly hairy. A fine old specimen grows in Mr. Anthony Waterer's nursery at Knap Hill, and there is one flowering at the present time near the Water Lily house at Kew. The leaves have an acid taste, on account of which the tree is known in the United States as the Sorrel Tree. The species sometimes figures in trade catalogues as a *Lyonia*. It is believed to have been introduced in 1752, and is altogether an interesting as well as a beautiful tree.

Ailanthus glandulosus is a noble tree, beautiful at all seasons both when leafless on account of its varied outline, and when adorned with its large pinnate leaves, toothed at the base with the glands from which it takes its specific name. It was introduced from China in 1751. It is quite hardy in this neighbourhood and attains fine proportions. Its special recommendation is the beauty of the seed-vessels, which resemble those of the Ash after a warm and sunny summer, such as the pre-

sent and that of 1887. During the past four or five weeks the parts of the trees exposed to the sun have been brilliant, the elegant keys, of a bright red colour, hanging in profuse masses. The large trees thus emblazoned form very striking objects. This year, from the prolonged and powerful sunshine, the trees have been unusually bright and conspicuous, but not so brightly coloured as in the Jubilee year, the seed-vessels not being so large, but more numerous than in 1887. The mode of fructification is very interesting. The male trees this year were so laden with pollen, that when shaken by the wind it fell as a cloud, and the ground beneath was thickly covered. The pollen thus dispersed alighted on the female inflorescence at considerable distances. The area over which the pollen was spread was large, and the topmost branches of some trees a furlong distant and apparently in face of the prevalent wind have been fertilised, but none so markedly as that in the accompanying photographs.—J. S. B., Bath.

* * With these notes were sent excellent photographs, one showing well the form of a fine tree and the other a fruiting shoot.—ED.

NOTES FROM NEWRY.

ONE of the most charming of dwarf alpines which flowered here last spring was *Mathiola valesiaca*; it has narrow grey foliage, and forms a perfect hillock of the softest mauve. *Hesperis violacea* is similar in colour, but the flowers are larger. It is blooming again now in August. *Myosotis lithospermifolia*, distinct and good, forms an upright little tuft, and is of a peculiar shade of blue. *M. Welwitschi*, now in full flower, is a very good and free-growing plant, and where Forget-me not is required in plenty in the end of summer, is quite a valuable introduction. *Micromeria montana* is a charming little shrubby plant, the spikes quite 6 inches long, the flowers pinkish. *Thymus comosus* is a very fine plant, and quite the best of the *Thymes*; the rosy spikes, 4 inches long, produced in great profusion, continue long in flower. *Pentstemon atropurpureus* is a delightful plant, in habit erect, in height about 9 inches, with clean, glossy, ovate leaves and purplish crimson flower-tubes. *Gentiana alba* will become quite a front rank plant; it grows freely in an ordinary soil not too wet, attains a height of 12 inches to 18 inches, and bears terminal heads of very large pure white flowers, and is in full beauty now. *Sagittaria gracilis flore-pleno* is one of the most chastely beautiful aquatics which has flowered this season. In foliage it is by far the most graceful of the Arrowheads; the flowers are full, double and snowy white. *Liatris callilepis* is the handsomest of all the introduced species. It grows about 2 feet high, has large (for a *Liatris*) leaves, and the individual heads are 2 inches across; it is far and away larger than any species I know. *L. callilepis alba* is a gem, indeed; the species is a very graceful and handsome one; the flowers are pure white and remain a long time in beauty. *L. callilepis alba rosea* is the first instance I have seen of a bicolor, and in habit it is similar to the last; the flower tubes are white and the tips and anthers pink; it is very charming. *Coreopsis grandiflora* is a well-named plant; its flowers are the largest and the colour superb. The gem of gems in flower just now is *Linaria alpina alba rosea*; the flowers are pale flesh colour with a rich orange throat. The warm summer weather has suited the *Callirhoes*, and *C. involucreta* is and has been very fine, its colour closely similar to that of *Calandrinia umbellata*, which has also been a good 1893 plant. The distinct *Lithospermum canescens* was beautiful in June, with its fine orange flower-heads. Here at any rate it is not a difficult plant to manage, but it is quite eclipsed by the rarer *L. hirtum*, which is more orange. *Fuchsia myrtifolia* is a very valuable garden plant in appearance, much like a miniature *F. gracilis*, foliage and flowers being similar, but in height it is only about 18 inches, forming quite a perfect pyramid, the flowers being produced in the greatest profusion. *Chrysanthemum maximum filiforme* has been one of the most admired plants

here this season, the flowers full size, with the florets cut into thread-like divisions. As a decorative subject it is quite the best of the *Marguerites*. *Coris monspessulanus* was charming in a sunny wall pocket; it appears to live on sunshine. *Aletris farinosa* has been very good in several different aspects; on the top of a stone-supported bank in full sun, in a boggy place in full sun and in a wet shady place. In the last, however, its leaves keep greener and do not take on the bronzy hue they do in the exposed positions. *Baptisia tinctoria* is a really valuable late summer plant. Here it is a dense mass of yellow; it grows about 1½ feet high, finely branching. *Roscoea purpurea* in a sunny border is beautiful. *R. sikimensis* in a shady border is more beautiful; it is a more leafy and robust plant, with flowers twice the size of those of above and of a soft mauve colour. *Nerine cornucans* in a sunny border close beside the *Roscoea* is and has been in full flower for nearly a fortnight, and despite the pelting rain showers which have prevailed more or less during the whole of that period, it remains fresh and uninjured, brighter and better than on is accustomed to see it in the greenhouses. *Vallota purpurea* in the same border is vigorous and all but in flower. *Hedysarum multijugum*, as a distinctly interesting late-flowering shrub, will be hard to beat; in growth free, the flower-spikes 6 inches to 9 inches long produced in the upper axils, colour purplish crimson. I have been much interested in a miniature bog formed in a stone trough. Some peaty soil was put in nearly filling it, then a quantity of *Lophiola aurea*, *Lobelia*, *Kalmia*, *Lysimachia longifolia*, a few Arrowheads, and some tufts of *Gentiana bavarica*. It has been quite a success. Two very fine cold house climbers are in flower now—*Mutisia retusa* with pink rays, and *Convolvulus californicus*, the latter a very beautiful plant. It is evergreen, the growth slender and free, the flowers, milk white, produced in the freest manner for months.

T. SMITH.

BOOKS.

CLASSIFICATION OF CHRYSANTHEMUMS.*

WE have long been hoping to see some tangible evidence of the existence of this society, and are pleased to record that we have just received a small paper-covered pamphlet of thirty-seven pages bearing the above title.

In general appearance this report resembles very closely the National Chrysanthemum catalogue of this country, but its scope is somewhat more restricted. There are four divisions corresponding to the select lists in the National catalogue, and these are devoted to incurved, Japanese incurved, Japanese and reflexed varieties, the whole of which are the product of American seedling raisers or importers. The names of the raisers and distributors, with dates, are supplied, but, as was the case with the catalogue issued by the New York Horticultural Society seven years ago, the descriptions given are rather meagre and confined to the colour only. There is a very lengthy alphabetical list printed in double columns at the end, in which the choice of varieties has been of a more cosmopolitan nature, such well-known European varieties as Alberic Lunden, Amy Furze, Baron Beust, Belle Paule, Carew Underwood, Etoile de Lyon, Eynsford White, Fair Maid of Guernsey, Hero of Stoke Newington, Isabella Bott, the Christines, the Queen family, &c., finding a place there. In this list a short description, with the section, follows the name, and is probably all that will be required by American growers.

Considering the very great interest that the Chrysanthemum has excited in America, it is somewhat surprising that its literature does not increase there to a greater extent than has hitherto been the case, but this at any rate makes the

* "Report of the Committee on Classification of Chrysanthemums." American Chrysanthemum Society.

little book now under review all the more acceptable. In England there is so keen a desire among a certain section of cultivators to know exact particulars concerning the varieties in their collections, that the publication of such a work by an authoritative body in America may greatly help to facilitate the acquisition of such knowledge. It has long been a most difficult matter to trace the origin of many Chrysanthemums that have reached this country through America, and we would without critically examining the new work simply observe that its value depends wholly upon the absolute accuracy of such particulars. The price is not stated, and we cannot say whether the report is only supplied to members or not.

CHRYSANTH.

Chrysanthemums.*—This is a small-sized illustrated brochure of thirty pages, forming one of a series issued by Mr. John Lewis Childs, of New York. There are in all eleven short chapters dealing with such subjects as the different types of Chrysanthemums, Chrysanthemums as outdoor plants, as house plants, as greenhouse plants, propagation, growing plants from seed, &c., are of course treated from the American grower's standpoint, and with due regard to the difference in climate. There are nine little illustrations of the average American catalogue type, and the work itself is a creditable volume, and will, no doubt, be of service to beginners in Chrysanthemum cultivation across the Atlantic, although from its unpretentiousness it is not likely to compete seriously with a book like "Chrysanthemum Culture for America," by James Morton, which was reviewed in these pages at the time of its appearance two years ago.—CHRYSANTH.

SOCIETIES AND EXHIBITIONS.

GARDENING AND FORESTRY EXHIBITION,
EARL'S COURT,
AUGUST 23 AND 24.

THE schedule on this occasion was not framed for plants, although a few miscellaneous groups were shown. It was chiefly for Gladioli and Dahlias, which were shown exceedingly well. The large marquee was filled as full as it should be, at any rate for the comfort of the visitors, there being neither spare tabling nor vacant spaces, but, on the other hand, not overcrowded in any part. A more interesting show in all respects has hardly been held at this resort this year, whilst the winning exhibits were all first-rate. The Dahlias were the most numerous of any, but Gladioli were shown in the finest condition. A quantity of excellent fruit was also staged, chiefly from outside, although some fine Melons were likewise exhibited.

Dahlias.

In most of the Dahlia classes there was an extra strong competition. For twenty-four shows and fancies in variety, Mr. Mortimer, Rowledge, Farnham, was placed first with blooms of first-rate quality and in good selection of colour. The best of these were John Walker (fine white), Buttercup, Mand Fellowes, Muriel, Nugget, David Saunders, and Major Bartelott. Mr. Chas. Turner, Royal Nurseries, Slough, was a remarkably close second, there being little to choose between the two exhibits. His best flowers were Primrose Dame, J. Bennett, Mrs. Slack, Prince Bismarck, and Colonist. Mr. Vagg, Bedford, Havering, Essex, was first for twelve kinds with even blooms, the best of which were Prince of Denmark, Rev. J. B. Camm, and James Cocker. Mr. Ocock, Havering

Park, was a poor second, his best blooms being Dazzler and Harry Keith.

Cactus and decorative Dahlias were exhibited as usual in bunches, and they made a fine display, all four of the competing exhibits being excellent. Messrs. J. Cheal and Son were first with a fine selection, consisting of Countess of Gosford (extra fine), Beauty of Arundel (a rich colour), Kaiserin, Marchioness of Bute, Duchess of York, orange shaded with crimson, new; Lord Rosebery and Bertha Mawley. Mr. W. Seale, Vine Nursery, Sevenoaks, was second with fine blooms, forming a showy stand. Messrs. J. Cheal and Son were also first for twenty-four bunches of single Dahlias with the best kinds, Lowfield Beauty, The Bride, Aurora (new), Eclipse, Miss Linnaker and W. C. Harvey being the best half-dozen. Mr. Seale was second again with a good display of flowers. The latter exhibitor won the first place with pompon varieties with typical kinds, the best being Leila, Lillian, Eva, Whisper, Mary Kirk and Red Indian. Mr. C. Turner again followed very closely in this class, having a fine selection. Rowena (new), rich orange-scarlet; Darkness, Ariel, Fairy Tales and Irene being the best and most distinct. Messrs. J. Cheal and Son also showed well in this class.

Gladioli.

The finest feature here was the magnificent array of 100 spikes in the open class shown by Messrs. J. Burrell and Co., Cambridge. These were of superb quality, the spikes large and the individual flowers large. Of the older sorts, Baroness Burdett Coutts, light pink; Grand Rouge, fine red, with dark feather; Atlas, bluish; Iolanthe, pale salmon; Conquerant, dark cerise, and Pasteur, terra-cotta-pink, were the most distinct; and of newer kinds, particular note should be taken of Tessa, light salmon-pink; Castilda, pale straw colour; Muriel, dark red, with white centre, and Fiametta, a pale salmon-pink, all decided improvements. Mr. D. Whitlaw, Brechin, N.B., was first in the amateurs' class for twelve spikes, all of which were of good quality, Enchantress, Soleil, Couchant and Pyramid being, however, the finest. In the class for fifty spikes, there was no competition. This being exclusively for amateurs was rather too large a class; twenty-four spikes at the most would have been ample.

Miscellaneous Exhibits.

These were very numerous as well as of excellent quality in nearly every case. Messrs. W. Paul & Son staged autumnal Roses of the best kinds. Of these note should be made of the old Malmaison, a fine late Rose; also of Niphotos, l'ideal, Marie van Houtte, General Jacqueminot, Duke of York (new China), a fine button-hole Rose, darker than Homère; W. A. Richardson, La France, White Lady, and Maréchal Niel (a gold medal was awarded). Messrs. Kelway and Sons staged a fine bank of Gladioli in excellent varieties, the light sorts amongst which were extra good. Note should be made of Sir Michael Culme Seymour, a vivid crimson-scarlet, with violet feathering; Boston, pale cerise-pink; Kate Marsden, a fine light kind; Duchess of Edinburgh, Stanley, Hemon, pale buff. Gaillardias and hardy herbaceous flowers in season were also included (a silver-gilt medal was awarded). Mr. Hudson, Gunnersbury House, Acton, staged a dozen specimens of scented-leaved Pelargoniums, and received a silver-gilt medal for the same. Mr. Wythes, Syon Gardens, Brentford, had an attractive and well-grown group of Nepenthes in the best sorts, as N. Mastersiana, with large pitchers, N. Curtisi, N. Amesiana (after N. Rafflesiana) and N. Hookeri, a fine form; N. Dicksoniana and N. Morgania. With these were grouped Crotons, well coloured, Ferns, and Grasses, the award being a silver-gilt medal.

Messrs. Barr and Son had a fine and showy display of hardy flowers and bulbous plants, the former including Funkia grandiflora (extra pure in colour), Liliiums in variety, and Penstemons also, with an excellent assortment of other hardy flowers in variety. Messrs. J. Cheal and Son had some additional boxes of Dahlias, so had Mr. W.

Seale (a fine lot) and Mr. Mortimer, each receiving a silver medal for their exhibits. A showy mixed collection of hardy flowers was staged by Mr. Salmon, West Norwood, the flowering and fine-foliaged plants of Mr. Walborn, Cedars Nursery, West Kensington, making a pretty group. Mixed hardy flowers (annuals and biennials) were shown by Mr. Welsford. A silver medal was awarded in each case. A bronze medal was given to Mr. A. W. Young, South Norwood, for Begonias (tuberous, cut blooms) and Gloxinias. Mr. Such, of Maidenhead, sent early Chrysanthemums. A well-grown lot of Zinnias was staged by Mr. Slogrove, Gatton Park, Reigate, the blooms very good, but lacking the darker shades of colour.

Fruit.

In the class for twelve dishes of fruit, some fine fruit was staged. For twelve dishes of hardy fruit, there were five competitors. Mr. J. McIndoe, Ilton Hall, Guisborough, Yorks, was first, having very fine Pitmaston Duchess and Souvenir du Congrès Pears, Crawford and Violette Hâtive Peaches, good Jefferson Plums, Byron Nectarines, Swedish Reinette and Cox's Pomona Apples, Apricots and Morello Cherries. It is only fair to the other exhibitors to add that the class stated hardy fruit, and in the first prize lot there were certainly three dishes grown under glass—the Pears and Apples. The other exhibitors kept to the schedule. Mr. G. Wythes, Syon House Gardens, Brentford, was second, with very fine dishes of Bellegarde, Grosse Mignonne and Royal George Peaches, Spencer Nectarines, very good Williams' Bon Chrétien and Louise Bonne of Jersey Pears, Duchess of Gloucester and Worcester Pearmain Apples, Magnum Bonum and Denyer's Victoria Plums, Mulberries and Cherries. In the miscellaneous class, Messrs. W. Paul and Son, Waltham Cross, secured the highest award—the gold medal for fruit trees in pots, having very fine Peaches, the best being Exquisite, Chancellor, Grosse Mignonne, Sea Eagle and Noblesse, good Elruge and Stanwick Nectarines, Washington, Kirke's and Blue Imperatrice Plums, very fine Apples and Pears and a dish of the Dartmouth Crab. Mr. T. J. Stacey, Caversham, Reading, staged 150 very fine fruits of The Countess, Conqueror, and Golden Perfection Melons, also two seedlings, which were past their best (silver medal). Messrs. Spooner and Sons, Hounslow, had a nice collection of fruit, including a dozen baskets of Apples, among which Duchess of Gloucester, Cellini Pippin, The Queen, Nonsuch, Col. Vaughan, and Duchess Favourite were very fine. They also showed some good Pears (silver medal). Mr. A. H. Rickwood, Fulwell Park Gardens, Twickenham, staged twenty dishes of Peaches. This was a fine exhibit, and consisted of such kinds as Sea Eagle, Noblesse, Goshawk, Alexander, Barrington, Royal George, Princess of Wales and Teton de Venus (silver medal). Mr. Hoar, West Molesey, had a very fine lot of fruit, chiefly Peaches, Apples, Pears, and Plums. Mr. Slogrove, Reigate, had three very fine dishes of Williams' Bon Chrétien, Beacon, and Brockworth Park Pears. A seedling Apple came from Mr. W. Vaughan, Crowlands. Mr. W. G. Rickard, Ealing, sent a collection of fruit (bronze medal).

A full prize list will be found in our advertisement columns.

NATIONAL CO OPERATIVE FLOWER SHOW.

AUGUST 18 AND 19.

THIS annual gathering was, as usual, held at the Crystal Palace, and it is fortunate for the executive that they have such an amount of floor space at their disposal, for were it otherwise the exhibits would have to be unduly crowded together. No better place for such an immense display could well be chosen within a reasonable distance of the metropolis, nor could the exhibitors wish for a more suitable position wherein to display their exhibits. The Crystal Palace is still the most popular place of amusement and recreation with the

* A book of practical information regarding Chrysanthemums and their culture (Child's Horticultural Literature).

masses; when, therefore, such a show as that now under notice is held, and which is mainly for their benefit, it would be next to impossible to choose a better place. The entries on the present occasion were larger than at any previous show, these amounting in the aggregate to 4077 as against 4038 last year—the increase being chiefly in fruits, cut flowers about the same, and vegetables somewhat less than usual. The increase, however, was such as to require sixty additional tables, the whole length of which was five-eighths of a mile.

Vegetables.

Classes were provided for collections from different districts, which is an excellent plan, in that it affords more encouragement to those not so favourably situated as others. Eight classes were in this way provided for members of industrial co-operative societies throughout England, Wales, Scotland and Ireland. The best of these collections were most decidedly from the south. Considering the drought has been more severely felt in the south than the north, this is highly creditable. It should be mentioned that the southern district includes Oxford and other counties contiguous thereto. Class 6, for the south of the Thames, produced, on the whole, the best competition, two very excellent collections being staged by Mr. W. Thayer (Crawley Soc.) and Mr. Ward (Horsham); the former included extra fine Carrots, Potatoes, Tomatoes and Cauliflowers. In the other southern class, Mr. G. North (Banbury) was a capital first, with fine produce. In the metropolitan class, Mr. C. Luff, Bromley, had another good collection. In the midland and eastern class the produce was much under the average of that previously instanced; Mr. J. Adams, West Haddon, had the best. The same remark applies to the north-western, where Mr. A. Griffiths, Sawley, was first. From the western district and Wales the produce was again of the very best description, Mr. Nicholls, Chippenham, being first, all his dishes being extra good; these were Tomatoes, Peas, Cauliflowers, Onions, Potatoes and Beans. In the Scotland or Ireland class, Mr. Thomson, Penycuik, N.B., took the first prize; the exhibit a rather small one.

In the single classes of this section the competition was very keen in nearly every instance. The classes for Scarlet Runners were as fine as one could well wish. For Giant Scarlet, Mr. Cripps, Oxford, was first with a dish that could not be beaten in the whole show; for any variety the first still went to Oxford, this time to Mr. Green, with extra good pods. The best French Beans came from Horsham, Mr. Ward winning in a keen contest. Beetroot, both Turnip-rooted and long kinds, is evidently very popular, the best being from Mr. Powell, Norwood, and Mr. Leabourn, Wilton, respectively. The classes for Cabbages were well filled; so were those for Cucumbers, Leeks and Lettuce. Carrots were remarkably fine, the finest in the three classes coming respectively from Mr. East, Maldon, Mr. Nunn, Maldon, and Mr. Leabourn for Early Horn, Intermediate and Long Surrey. Celery was very fine; the best red, large and good, was from Mr. Boole, Mansfield, and the finest white (extra fine) from Mr. Mears, Peterboro'. Onions were remarkably fine, the bulbs large and well ripened. The finest Improved White Spanish were shown by Mr. Turner, Aylesbury; the best spring sown, any variety, by the same exhibitor; and the finest autumn sown (immense bulbs) by Mr. Nunn, Maldon. Peas and Parsnips were excellent, and the Potatoes decidedly first-class, the tubers clean and even, with that appearance denoting excellent quality. For four white kinds Mr. North, Banbury, was first with Snowdrop, Defiance, Windsor Castle, and another of the Magnum Bonum type. The prizes for single dishes of vegetables were closely contested; in each instance Tomatoes again stood out prominently, the best coming from Mr. Richard, Hereford. Turnips, Vegetable Marrows, and Shallots were well shown.

In the section for gentlemen's gardeners and others who prefer to compete therein in preference to the former, Mr. Waite, Glenhurst, Esher, showed in his usual excellent style, having the best collection in this section for vegetables with grand

produce, rather larger, perhaps, than he usually shows, but good all the same. The two first prizes for Runner Beans again went to the Oxford Society, Mr. Holton winning in each class. Mr. Waite was the most successful exhibitor in the single classes for Potatoes (extra fine), Broad Beans, Longpod Beans, Beetroot, Carrots, Cauliflowers, Cucumbers, Leeks, winter Onions, and Tomatoes. Messrs. Mossman, Martin, Holton, and Osman also showed well in these and other classes.

Agricultural Hall show.—On Tuesday, August 29, the great show of plants, flowers, fruits, and horticultural sundries will be opened at the Agricultural Hall, Islington, by the Royal Horticultural Society, and will remain open to the public until the night of September 1. The members of the fruit, floral, and Orchid committees will meet on the 29th inst. at 11 a.m. precisely, but will be admitted at the Barford Street entrance as early as 10 o'clock. They are particularly requested to wear the badges given out at the last Temple show, and to have their Fellow's pass and tickets with them. As the catalogue of the show must go to press on Monday, it is hoped that all exhibitors will have given particulars as to their exhibits by that date to the superintendent of the R.H.S. Gardens, Chiswick, as otherwise they cannot possibly appear in the catalogue.

Senecio pulcher.—This is flowering well in the Broxbourne nursery, where it is grown in quantity. When a large group of it is seen, one gets the full richness of the bold flowers. *S. pulcher* is one of the finest species of the family, but is usually seen singly, whereas the best effect is got from a large group. The flower-stem branches freely, and the large fleshy leaves are of a very deep green colour. Being perfectly hardy, one need fear no mishaps from frost, although the flowers often appear late in most years and get touched. This season, however, through the drought they are in full beauty much earlier than usual. The soil for it must be deep, not too dry, and the position not too exposed, otherwise the stems will get broken about with winds. Cuttings of the roots taken in the spring will strike readily.

Cassia corymbosa planted out.—A short time ago I noticed this plant doing grandly in beds in the Royal Horticultural Society gardens, Chiswick, its bright yellow flowers being very effective, and lasting a long time. Of course it is not hardy, but if treated somewhat like Cannas or Fuchsias, that is, taken up in the autumn and placed in a cool house, cutting the growth back and keeping on the dry side, it gives little trouble and is readily started in the spring. I have old plants that flower profusely, and these stand under a stage in a cool house during the winter, being pruned hard just before they begin to break. After starting, they are repotted and grown on for house decoration. When planted out if the soil is clayey I would advise a mixture of peat or light loam and plenty of leaf mould. The great beauty of this *Cassia* consists in the bright flowers and continuous bloom, as the corymbs of bloom do not open all at once. Though an old plant it is a beautiful one, easily increased by striking the shoots in the early autumn or as soon as they get a little matured in the early spring.—G. WYTHES.

The weather in West Herts.—On Thursday and Friday in last week the temperature in shade rose respectively to 89° and 91°. Both these readings are higher than any I have yet recorded here. Since then the weather (although above the average for the time of year) has been much cooler. During the week the temperature of the ground at 1 foot deep has fallen 7°, and at 2 feet deep 3°. Rain has fallen on each of the last four days, and to the total depth of nearly three-quarters of an inch, and during a heavy shower on Wednesday at 12:38 p.m. was falling for four minutes at the mean rate of nearly an inch an

hour. Thursday, the 17th inst., proved exceptionally dry, the difference between the readings of an ordinary thermometer and one with its bulb kept constantly moist amounting at 3 p.m. to as much as 20°.—E. M., *Berkhamsted*.

Death of W. Whittaker.—William Whittaker, for many years foreman of the plant houses, and the principal salesman at the Royal Nursery, Slough, died lately, aged 75 years. He entered the nursery sixty years ago when quite a boy during the proprietorship of Messrs. T. C. and E. Brown, and was connected with it until 1891, when increasing infirmities compelled him to retire. He was a most skilful soft-wooded propagator, and during his long term of service at Slough many millions of cuttings and plants must have passed through his hands.

Caterpillars destroying Ferns (*J. B. Harp-ham*).—The caterpillars attacking your Ferns are those of *Phlogophora meticulosa*, a very common insect. You might syringe the plants with extract of quassia chips, soft soap and water. But by far the most satisfactory method of destroying them is to pick them off by hand, though it is a tedious process. If the fernery is under glass turn out or kill any moths you may find in it.—G. S. S.

The Butcher's Broom.—A plant of the male Butcher's Broom (*Ruscus aculeatus*) would be thankfully received by Mr. Milburn, superintendent of the Royal Victoria Park, Bath, for planting in the Botanic Garden.

Names of plants.—*E. Walker*.—*Oncidium crispum*, fair variety.—*E. B.*—*Periploca græca*.—*W. A. G.*—Apparently *Lælia Dayana*; 3, a *Pendrobium*; cannot determine which, specimen insufficient.—*J. M. L.*—They are two *Stapelias*, but cannot name without flowers.—*J. B. H.*—1, *Cattleya Dowiana aurea*; 2, *Cattleya pumila*; 3, *Onidium pulvinatum*.—*G. Newbold*.—1, *Chenopodium ficifolium*; 2, *Jasione montana*; 3, *Isatis tinctoria*; 4, *Thalictrum alpinum*.—*J. Britton*.—1, *Miltonia spectabilis*; 2, *Oncidium sphaecelatum*; 3, *Oncidium Lanceanum*; 4, *O. Lanceanum Louvrexianum*.—*B. H. L.*—2, *Litob ochia spinulifera*; 2, *Elaphoglossum rubiginosum*; 3, *Pleopeltis excavata*.—*E. Hammill*.—1, *Hypoderris Brownii*; 2, *Lastrea strigosa*; 3, *Hypolepis repens*; 4, *Neottopteris australasica*; 5, *Gleichenia Spelunca*.—*Rosa*.—*Saccolabium Blumei*; 2, *Cyrtopodium Pollettianum*; 3, *Selenipedium Sedeni candidulum*.—*T. M.*—A very good form of *Cyrtopodium oenanthum superbum*.—*F. W. Harmer*.—*Allium senescens*.—*F. Hand*.—1, *Helonium pumilum*; 2, *Pyrethrum parthenium*; 3, *Rudbeckia hirta*.

Names of fruit.—*F. Hand*.—1, New Hawthornden; 2, Hoary Morning.

"The Garden" Monthly Parts.—This journal is published in neatly bound Monthly Parts. In this form the coloured plates are best preserved, and it is most suitable for reference previous to the issue of the half-yearly volumes. Price 1s. 6d.; post free, 1s. 9d. Complete set of volumes of THE GARDEN from its commencement to end of 1892, forty-two vols., price, cloth, £30 12s.

"Gardening Illustrated" Monthly Parts.—This journal is published in neatly bound Monthly Parts, in which form it is most suitable for reference previous to the issue of the yearly volumes. Price 5d.; post free, 8d.

"Farm and Home" Monthly Parts.—This journal is published in neatly bound Monthly Parts, in which form it is most suitable for reference previous to the issue of the yearly volumes. Price 5d.; post free, 8d.

"Hardy Flowers."—Giving descriptions of upwards of thirteen hundred of the most ornamental species, with directions for their arrangement, culture, &c. Fifth and Popular Edition, 1s.; post free, 1s. 3d.

"The Garden Annual" for 1893.—Contains Alphabetical Lists of all Branches of the Horticultural Trade. The Lists of Gardens and Country Seats (containing over 9000) have been very carefully and extensively revised, and are admitted to be the most complete ever published. Price 1s.; by post, 1s. 3d.

All of our readers who are interested in the improvement of cottage homes are invited to help us to make Cottage Gardening known. It is published at the very lowest price to meet the wants of those for whom it is intended, and copies will be sent for distribution free, by the publishers, Messrs. Cassell and Company, La Belle Sauvage, Ludgate Hill E.C.

No. 1137. SATURDAY, September 2, 1893. Vol. XLIV.

"This is an Art
Which does mend Nature: change it rather; but
THE ART ITSELF IS NATURE."—*Shakespeare.*

ORCHARD AND FRUIT GARDEN.

THE GRAPE SEASON.

With so much sunshine during the ripening period it might reasonably have been expected that Muscat of Alexandria, Buckland Sweetwater, and Foster's Seedling would have been seen at the various early August shows, if not still earlier, in extra good condition. Whatever might have been expected, however, it is very certain that particularly well coloured white Grapes have been by no means plentiful. I will go further and assert that quite as many well-finished bunches have been seen quite as early in the season in most other and, presumably, less favourable seasons. This, let me add, is being written before the great Shrewsbury show takes place, and, it may be, the quality of white Grapes to be seen there will be considerably ahead of that of former exhibits. It has always been my contention that white Grapes want no more sunshine to ripen them to perfection than do black varieties. Light and heat they must have, but a fierce sunshine beating directly on the bunches and a very thin covering of leaves are far from being good aids to colouring. At the Co-operative show, held on August 18 and 19, there was only one good stand of white Grapes, these being two comparatively small, but pretty bunches of Muscat of Alexandria. The berries were not large, but were perfect amber in colour and quite plump. At some of the leading west of England shows Muscats were shown fairly well by one or two exhibitors in each instance, but for one well-coloured bunch there were six that presented a decidedly green appearance. This failure to colour Muscats properly in time for the shows would not so much matter if only perfect ripening would take place later on. Unfortunately, there is little or no likelihood of this happening, for the simple reason that shrivelling has already commenced in several cases. There is no hiding the fact that if Muscats are either over-cropped, and duly stripped of leaves, over-run by red spider, given too little moisture at the roots, or are rooting too deeply, colouring will be faulty and shanking very prevalent. Why Muscat-flavoured Grapes, notably Muscat of Alexandria and Mrs. Pince's Muscat, should shrivel prematurely is a mystery that no one seems capable of elucidating. As many or more reasons are given for it than there are days in the week, but nothing short of very high culture will prevent it. I shall not be surprised to learn that high culture, even, is no remedy in some cases. It cannot be a want of heat that is responsible for either shrivelled or badly coloured berries, or how is it that so many are to be seen this season? With me well-coloured Madresfield Court promises to keep plumper and better than Muscat of Alexandria in the same house, and yet the latter has been admired for its well-ripened appearance.

Much that has been advanced concerning the faulty colouring of Muscats also applies to the two other white varieties that have been named,

and which are among the most popular forcing varieties. If Buckland Sweetwater and Foster's Seedling started in February or early in March were not well coloured by the first week in August this season, it is very doubtful indeed if they would greatly improve by being left on the Vines any longer. The berries of neither will be fine or assume a clear amber colour if over-cropped, while exposing to strong sunshine has the effect of discolouring rather than improving their appearance. Buckland Sweetwater is invariably grandly shown at the Bath show held at the end of August, or much better than it is usually seen in any other parts of the country. At its best it is a noble Grape and very refreshing, though not richly flavoured. I hold that early ripening, is essential in the case of Mrs. Pearson, and fully expected to see Golden Queen in better condition than usual this summer. Very fine bunches have certainly been shown, but the berries still present that muddy appearance that mars this otherwise excellent late Grape. Trebbiano, Syrian, and Calabrian Raisin are all comparatively green, though the first-named has been considered ripe enough to cut for show. The question is, Is either of them worthy of house room?

Curiously enough, the very hot summer experienced has not been attended with unfavourable results as far as black Grapes are concerned. For instance, there have been more really good, well-coloured Black Hamburgs grown and shown than I ever remember to have seen. Of Madresfield Court, however, the same cannot be said. This noble Grape most probably suffered during the dull, wet weather that we had late in July, cracking of berries being difficult of prevention in mixed vineries. It would seem to be almost impossible to colour this variety properly, that is, when the berries are large. If only partially coloured they become redder the longer they are kept; whereas, the small blue-black berries retain their colour as long as they hang. Which is best, medium-sized to small berries, or large berries faulty in colour? Some judges prefer the latter, but are they right in their decisions? It is much the same with Black Hamburg. Only berries blue-black in colour hang without changing to reddish black or even a foxy red, and early ripening has left its mark on a great many bunches that were to have won prizes. Gros Maroc is very fine everywhere, and only those who have been in too great a hurry have failed to colour the berries perfectly. Its attractive appearance, the berries being extra fine, is its principal recommendation, and if badly coloured, then is it of little value. Alicante is rarely seen so plentiful and good in August, several growers staging faultless bunches. Being subjected to a freer circulation than usual of warm dry air has doubtless been the cause of such perfect colouring, accompanied by a thick bloom, and the quality, too, should be better than is the case when the ripening takes place under less favourable conditions. How will this early ripening affect the keeping properties of this late Grape? It is not wanted for use now, nor will be so long as Madresfield Court and Black Hamburg are available, but it is doubtful if the bunches will hang after, or even up to mid-winter. Lady Downe's has also coloured very early, but is not nearly ripe, and it is to be hoped it will keep better, instead of worse, for being ripened under natural conditions. Gros Colman, again, though far from being black in late houses, is yet ripening earlier than I have ever had it before, the same report coming from other parts of the country. In this instance I am in hopes the berries will be more

solid, better in flavour and keep longer than is the case when ripened, as too often happens, under too cool conditions. Should early ripening prove fatal to long keeping, then there will be a blank in the late winter dessert, for which there is no remedy. Gros Colman is now rightly considered the most valuable late Grape in cultivation, being by far the most extensively grown accordingly, and it is to be hoped the bulk of the crops will not have to be placed on the markets prematurely. It is what is taking place and will continue in the case of all other fruits, and I am afraid many Grapes, too, will have to be sacrificed.

The less generally grown Gros Guillaume is behaving strangely this season. In one famous vinery out of about forty bunches not one is of any value, small bright red berries being the order of the day. In the same neighbourhood another fairly heavy crop of bunches has finished remarkably well, the berries being large, as black as Sloes, crisp and pleasing to eat. Why there should be such a contrast is somewhat of a mystery unless the credit of an improved state of affairs can be given to the Black Hamburg stock, the Vine with red berries being on its own roots. I wish I could say something in favour of Alwick Seedling. This season it has coloured admirably, as usual, but what a poor thing it is when the flavour test is applied. I. M. H.

Strawberries and Peaches.—When visiting a walled-in garden recently I observed that on a particular portion of a south wall the Peach and Nectarine trees had been almost denuded of their leafage, and on inquiring the reason was told that the border, which is a broad one, was planted with Strawberries, on which the excessive drought had generated spider, and this had, in spite of frequent washings, so taken hold of the trees, that the result I mention followed. When I saw the border the Strawberries had been removed, but the mischief seems to have been done prior to that. It was most interesting to note that up to the margins of the Strawberries at either end the trees on the wall were not merely quite untouched, but were in perfect health. What is here referred to indicates a by no means improbable trouble in many cases, and perhaps may help to open the eyes of some other gardeners who have found spider more than usually troublesome on wall trees this season where Strawberries have been grown close by. Possibly Strawberries are not in all cases alone to blame, as some other crops may be equally harmful. Possibly, however, Strawberries may be more exacting of the moisture of a border, and thus render the wall trees less capable of withstanding an attack of spider.—A. D.

Blister on Apples.—Although Apples here and in this neighbourhood are an abundant crop, of fair average size, and in some cases beautifully streaked by the sun's rays, I observe that this year, and in several previous years, many of the earliest varieties, such as Ecklinville Seedling, Lord Suffield, Hawthornden, Kerry Pippin, &c., are much deformed by a blister or scab over the eye of the fruit, and varying in size in a circular form from a sixpence to a penny-piece. It is chiefly on the sunny side of the tree that it occurs, and the finest specimens are affected. I believe it is due to a sudden outburst of the sun's rays upon frosty or wet petals when the fruit is setting, and might be prevented by a light shading. It spoils the fruit for exhibition or for the dessert table. I shall be glad to have the opinion of your fruit-growing correspondents on the subject in question.—P. DAVIDSON, *The Gardens, Iwerne House.*

Apple Devonshire Quarrenden.—This Apple has been very plentiful this year; in fact, up to within the past few years, when planting of fruit trees has been more general, it was in danger

of becoming very scarce. This variety must be grown on the Crab stock to see it at its best. The two trees I used to see as a boy were old standards—a form under which it thrives well. This season it has also fruited freely on free-growing bush trees as well as standards. As regards quality, it is first-rate, being tender and full of sparkling juice, which during the past hot weather has been very refreshing. My advice to those people with whom it has hitherto fruited very sparingly is to let it have an unrestricted growth, merely thinning out crowded branches. By growing it on the Crab stock, success with this good old Apple will be assured.—A. Y.

Gage Plums and the hot summer.—This has been a splendid season for the ripening of this, the very best class of dessert Plums. Everyone knows the value of the true old Green Gage. In some parts the trees bear enormous crops as standards. Useful as the above kind is, there are several other kinds of Gages I consider of more value for dessert. First, they are larger in size and of quite as good flavour; added to this they are later in ripening, seeing we have a number of kinds that come into use during August. It is in seasons like this that their true flavour is brought out. I have not seen a cracked fruit on the open walls this season; whereas two years ago I had three out of four cracked and many were quite useless. I grow several kinds of these late Gages. The old Green Gage is from our first, from a west wall, followed by McLaughlin's from east wall, next Lawrence's Gage. By the time this is over we have Guthrie's Late Green, Reine Claude de Bavay, Transparent Gage and Jodoigne Green Gage. These kinds keep us supplied till Coe's Golden Drop comes in. I also grow the old Woolston Black Gage and Ickworth Imperatrice; as a very late kind for cooking I grow Coe's Late Red. From these we get a continuous supply till the middle of November. To obtain the best results from all these late Gages, the trees should be grown against an east or west wall, allowing the fruit to hang as long as possible. To do this it is necessary to protect it from wasps, birds, &c. At the present time (end of August) I am covering a large quantity of fruit in a simple way, namely, by putting one or more fruit into muslin bags; this answers well in dry weather, but the fruit is apt to crack in wet weather. Some cultivators complain of the trees growing too strong when young, but this defect can be overcome by root-lifting, keeping the roots near the top and in good soil. If treated in this way, there will be no cause for complaint on this score.—DORSET.

STRAWBERRIES FOR NEXT YEAR.

STRAWBERRY plants suffered badly during the fruiting season, but during the past week, with the thermometer at 90° in the shade, the plants in light gravelly soil nearly gave out if due attention had not been paid to watering and feeding. I prefer young plants, and even these looked bad till watered. Watering such plants as Strawberries means increased labour, never any too abundant in the garden. A great deal of trouble may be avoided by early clearance of runners, as the runners greatly rob the plants of sustenance. Some may think that by leaving the runners the roots are shaded, but such is not the case. I have this season left the mulching as late as possible to protect the plants. This chiefly concerns those which have been grown to provide runners for forcing. These I grow doubly close from plant to plant, but this season, since removal of stock, I have been afraid to sacrifice every other plant owing to drought. These plants only fruit one year. It is not too late to examine the quarters for the main crop next season and to boldly root out and replant if they are at all sickly, as many plants that have suffered from drought and red spider will not pay for the ground occupied. Runners secured from heavy land will be in a vigorous condition for planting, and, I feel sure, will well repay for increased cost and labour if

now planted and given ample attention in the way of moisture. The sooner the planting is done the greater chance will there be of a heavy crop. Pot Strawberries will show at a glance the secret of high culture. Here we have strong runners with plump crowns a mass of roots and abundance of fruit, thinning heavily being resorted to on account of the confined root space being insufficient to mature all the fruit. The question of clearing off old foliage is also important. As concerns next season's crop, I prefer to remove old leaves, thus giving the young growth room to harden and develop. With young plants this is not necessary if the plants are destroyed after the fruit is gathered. Of course, a few kinds do best the second year, but, fortunately, they are few, and in such cases it is preferable to grow those kinds which are sturdy growers and give the best fruit at the least cost. All may not be able to secure good runners, but there is no excuse for growing weak or exhausted plants, as if runners are secured late, these may be planted in rows 18 inches apart and 6 inches from plant to plant and again transplanted into their permanent quarters the following March. Though little fruit will be produced the first summer, there will be no failures or lack of fruit of a large size fifteen months from the time of planting. In severe winters a little leaf-mould or short litter between the rows of these young plants will do much to prevent loss of root and thus favour an early start.

G. WYTHES.

Ripening Vines.—There need be no complaint this season as to the wood being soft if means are taken to expose and ripen up the wood. Those who grow pot Vines and young Vines for hard forcing will have found out that it is not the hottest summers which produce the best rods; indeed, the reverse at times is the case, as in houses much exposed or deficient of moisture, growth is arrested unless extra moisture can be maintained during excessive heat. It will be observed that the wood of the young cane at the base hardens up before the final swelling unless care is taken to stop and feed during growth. I never saw Vines grow more rapidly than they have this season. I planted a house that had given us a crop in May early in June. The new border was made inside, and at this date the growth is as robust as may often be seen in Vines planted early in the year. Owing to the excessive heat, Vines may have lost a few of the bottom leaves, but no injury will result if growth or extension is allowed as long as the rods are swelling. In the London area there is greater difficulty in perfecting the growth of Vines, but we cannot complain this season. Now is a good time to stop pot Vines at the required length if this has not been done. I would also advise pruning in the lateral growths of very early Vines, as if these are stopped only a short time before the foliage falls, the Vines bleed badly when placed in heat and are much weakened in consequence. After stopping, free exposure in fine weather to mature the canes will do much towards next season's success.—G. WYTHES.

ORCHIDS.

REED-LIKE EPIDENDRUMS.

This is a genus which in the Western Hemisphere appears to be akin to the Dendrobiums in the Eastern. The majority of the kinds included in this section of the genus are of great beauty and well worth extended cultivation. The flowers continue in beauty a long time, those of some species lasting two and three months in full perfection. The majority of the species succeed best in the cool house, so that no one need hesitate to grow them because of want of heat, as they thrive

well with the Odontoglossums. If exception be made to them that they are too tall for the low-roofed houses usually devoted to these plants, then train the shoots upon the roof, where their gay flowers will serve to enliven and set off the pale colours of the Odontoglossums beneath. All of these plants, which have Reed-like stems, are not cool house plants, for I have seen some growing and flowering in the temperature of the Cattleya house, and recently I saw that fine Veitchian hybrid, E. O'Brienianum, growing luxuriantly and blooming in the East Indian house. This was a far higher temperature than that in which I had grown and flowered both its parents. In answer to my inquiries, the grower of this hybrid said, "I do not know whether this hybrid would thrive with less heat than I give it, for I have never tried it. The plant was set down there when I first purchased it, and there it has grown magnificently, and as my other houses are low, there is nowhere else that I could find accommodation for it, so that I am well satisfied to allow it to remain where it is." It may be that the very fact of its being a garden hybrid has given it a stronger constitution, and so it is not so very particular in its requirements. Generally, these cross-bred plants are endowed with a better constitution than the species from which they were derived. Epidendrums require to be potted in peat fibre and Sphagnum Moss made sandy. The pots also should be well drained, for during the growing season the plants require a considerable quantity of water to their roots and overhead from the syringe. At no time of the year should these plants be allowed to suffer from drought. The following are amongst the best kinds that I know, and all are worthy of the most careful cultivation. The lowermost flowers on the raceme open first and the others expand slowly, maintaining a good head of bloom for months:—

E. ARACHNOGLOSSUM makes a slender stem between 5 feet and 6 feet long, terminating in a many-flowered raceme. The flowers are of a deep rich crimson, saving the orange-coloured tubercles of the lip. This plant is a native of the mountains of New Grenada, at considerably above 6000 feet elevation, and does well in the cool house, where it proves an almost constant bloomer.

E. CATILLUS.—This also thrives well in the cool house; the stems are tall and somewhat stout, clothed with dark green sheathing leaves; the flowers are numerous and showy, being rich bright cinnabar, the middle lobe toothed. It comes from New Grenada.

E. CINNABARINUM is an old species which was grown by the Messrs. Loddiges, of Hackney. It is a slender plant, growing about 4 feet high and producing large bright scarlet flowers, the lip being rich orange-yellow, spotted with red. It continues flowering for between two and three months. It blooms in spring and early summer, and does best in the temperature of the Cattleya house.

E. CNEMIDOPHORUM.—This is a tall and stout-stemmed plant, growing to upwards of 6 feet in height. It is found in the deep ravines of Guatemala at an elevation of between 6000 feet and 7000 feet, but appears to be a rare plant even there. It thrives best in quite a cool house, and is really one of the handsomest of the genus with its long, glossy green leaves and its pendent many-flowered raceme. The flowers are large and very fragrant, china white behind, yellow in front, blotched with deep reddish-brown; the three-lobed lip is deeply cleft in front, soft white, flushed with rose, the long pedicels being pure white. The plant flowered for the first time in this country in the spring of 1867.

E. COOPERIANUM.—This is a stoutish plant, growing about 3 feet high, clothed with long sheathing leaves and a nodding many-flowered raceme. The sepals and petals are yellowish-

brown, the three-lobed lip being of a bright rose colour. It is a handsome species from Brazil, and requires the temperature of the Cattleya house. It appears to be somewhat rare.

E. ELONGATUM.—We have here the original plant of this section. True, other kinds come very near to it, if they are not identical. These are *E. crassifolium*, which, however, is a stronger growing plant with larger racemes of bloom of a somewhat different colour, and *E. ellipticum*, a smaller plant, more slender than the last-named, and bearing a correspondingly smaller raceme. The stems of *E. elongatum* are from 18 inches to 2 feet long, furnished with thick coriaceous leaves of a deep green. The raceme is many-flowered. The flowers, produced in the spring and early summer months, are bright rose. It comes from the island of Jamaica and likes the Cattleya house.

E. FREDERICI-GULIELMI is a lovely species from Northern Peru, originally discovered upwards of forty years ago. Living specimens were not forthcoming at this time, but some time afterwards Wallis obtained some plants and sent them to M. Linden; one plant alone survived the journey. Some three or four years ago Mr. Shuttleworth, of the Clapham Park Road Nursery, had the good fortune to receive a good lot alive, so that now the plant has become somewhat widely distributed, as it well deserves. It is a very robust growing plant, attaining some 5 feet or 6 feet in height. The flowers, of good size and of a bright rosy purple, are numerous on the raceme. It must be grown in the cool house.

E. IBAGUENSE.—A species that appears to be widely spread in New Grenada and Peru. For its introduction we are indebted to the Messrs. Backhouse, of York; the stems are slender, leafy, and surmounted by a large raceme of rich orange-coloured flowers with a yellow lip. It requires to be grown cool.

E. MYRIANTHUM.—This is one of the handsomest of these slender-stemmed kinds. It attains to some 5 feet in height. Its stems are leafy, terminating in a branching panicle of flowers of a bright purplish rose. I have heard of a pure white-flowered form of this plant, but have not yet seen it. The plant thrives best under cool treatment; indeed, I believe its failure to flower must be attributed to its being kept too warm. Lindley gives M. Klee the credit of finding it in the high mountains of Guatemala, but to Mr. Skinner the credit of sending the plant to England in a living state. It flowered first nearly thirty years ago, and is still very rare.

E. O'BRIENIANUM.—A hybrid raised by the Messrs. Veitch, of Chelsea, between *E. radicans* and *E. evectum*. It is a very strong grower and a profuse bloomer—in fact, it appears to be never out of flower. The flower is larger than that of either of its parents, the colour bright carmine.

E. PSEUD-EPIDENDRUM.—This must not be passed over in my notes on these plants. It is a winter flowerer, and the contrast of its colours is very singular. It is a somewhat stout growing plant, some 2 feet to 3 feet high, the flowers large, the sepals and petals apple-green, lip large and spreading, frilled at the edge, colour deep orange-red. It is a native of New Grenada at some 4000 feet elevation, and thrives best at the warm end of the *Odontoglossum* house.

E. PANICULATUM.—A species not often found in collections at the present day. Its stems are slender, growing to a height of about 4 feet, and producing at the top a large branching panicle, which is densely laden with rosy lilac flowers, which are gratefully perfumed. It is one of the most charming species that I know, and is found at from 7000 feet to 8000 feet elevation in various parts of South America.

E. RADICANS.—Another old species, having been introduced upwards of half a century ago. Mrs. Lawrence, of Ealing Park, first flowered this, the most beautiful of all the orange-scarlet *Epidendrums*. This plant used to bloom freely in the late Mr. Partington's garden at Cheshunt under the care of Mr. Sewing, with whom it seldom appeared

to be out of bloom. In its native country it seems to grow amongst the long Grass, where its long white roots, which proceed from the sides of the stem, find an abundance of moisture, and this should afford ample evidence that water is essential. The slender stems are terminated by a dense many-flowered raceme, which lasts many weeks in full beauty, the flowers being rich orange-scarlet. It requires cool treatment.

E. SCHOMBURGKI.—This is another old species, originally found in British Guiana, but it has since been found in many parts of Brazil and other places in South America; consequently it varies considerably. The plant grows between 2 feet and 3 feet high, and bears a many-flowered raceme of brilliant vermilion-scarlet flowers. It likes the warmth of the Cattleya house.

E. SYRINGOTHYRSUS.—This species has been known nearly fifty years. It is a native of Bolivia, growing at from 7000 feet to 9000 feet elevation, but it was not till about twenty-five years ago that Pearce sent it to his employers, the Messrs. Veitch, with whom it flowered soon after its introduction. It is a slender plant, growing some 4 feet or more high. The colour of the flowers is rosy purple tinged with a shade of red. The disc of the lip is white, on which are situated several yellow calli. It unfortunately still continues to be rare in collections.

E. WALLIS.—This species is another almost perpetual bloomer. The slender stems grow some 3 feet or 4 feet in height, and are terminated by a raceme of large flowers, which after being open some little time are supplemented by lateral spikes from the base of each leaf. The flowers frequently measure 2 inches across; the sepals and petals bright golden yellow dotted with crimson, the lip white, having feathery lines of bright purple. It is found on the mountains of New Grenada at 6000 feet to 7000 feet elevation.

E. XANTHINUM is a very beautiful plant from warm parts of Brazil. It grows about 2 feet high, the stem slender, leafy, and surmounted with a globose head of clear yellow flowers, the lobes of the lip being prettily toothed and fringed. This plant requires the heat of the Cattleya house.

WILLIAM HUGH GOWER.

Dendrobium Phalaenopsis Schroederianum.—The specific name of this fine *Dendrobe* is very appropriate indeed, as a fully expanded spray reminds one very much of a spike of *Phalaenopsis*. And what a range of beauty there is in the colour of the flowers, some being very pale, whilst others are quite dark and very handsome. Another of its fine characteristics is its wonderful freedom of growth. I can quite bear out the observation made in THE GARDEN a week or two since as to its freedom of growth under cultivation, this even being stronger than in its native home, that is if one may judge from the old pseudo-bulbs. To all appearance much pot room is not needed, as quite large plants may be grown in comparatively small pans.—A. Y.

Odontoglossum houses.—Thos. Castle asks for information respecting these structures. He says, "I have just completed an *Odontoglossum* house 50 feet long with the intention of adding to it. It is a lean-to with a northern aspect, and just as I had put the finishing touch to it a friend that has the reputation of being a good Orchid grower condemned it, saying I would never have a plant fit to look at in such a structure." The cool system of growing Orchids originated with myself in a north house, and the plants did well and were a perfect surprise to everyone who saw them, even the late Mr. James Veitch, of Chelsea. The finest collection of *Odontoglossums* and other cool Orchids which has ever been seen was that of the late Mr. J. Buchan, of Wilton House, Southampton. These were grown for years by Mr. Osborne in a north house. I advise you to continue your plan, and you will be able in twelve months' time to convince your friend that he knows nothing of the

wants and requirements of cool Orchids. Keep the house properly ventilated and a fair amount of moisture in the air, and do not allow the temperature to fall below 45° or 48°, and all will go well with you.—W. H. GOWER.

NOTES OF THE WEEK.

Aster corymbosus.—This is worthy of note among the early Asters, although one hardly appreciates them so much when they come in the heat of summer days. It is tall and graceful, bearing at the top of its slender shoots large flat corymbs of white flowers. In a mass among shrubs it has a pretty effect.—A. H.

Eryngium planum.—This is one of the best Sea Hollies, and though we have most of the good kinds, none of the others last like this. One reason for this perhaps is that the plants seed freely, the seedlings appearing at long distances from the parent. Whilst established plants were flowering well in June, other self-sown seedlings are just now at their best. Except *E. giganteum*, which of course is not a perennial, no other kind grows so freely from seed as this.—A. H.

Fruit crops.—We learn that fruit is so plentiful in Lincolnshire this year, that growers are experiencing the greatest difficulty in disposing of the produce of their orchards. The markets are so glutted, especially with Apples, that the sales in many cases have not realised sufficient to pay the expenses of sending to market. Plums also have been a bad trade, and those that were damaged at all by wasps have been practically rendered unsaleable. The average price of Apples is about 2d. per stone.

Tropæolum speciosum and Clematis flammula.—The Flame Nasturtium is noted on page 197 as being very beautiful in Mr. Wilson's garden. At one time it was popularly, but quite erroneously, supposed to be a plant for cold northern gardens alone. Happily, it promises to succeed in many places in the south. In trying it, care should be taken to plant it where there is no risk of spade or hoe being used. We are enjoying the beginning of pretty effects that may go on for years, the Flame Nasturtium and the sweet Virgin's Bower climbing Holly trees and hanging in graceful festoons. If the Flame Nasturtium is a plant for special places, the Virgin's Bower should be largely planted, and it never looks better than when left to itself.

A good town tree.—The Mountain Ash would appear to be an excellent town tree, but I do not know whether it would stand the smoke and fog well. Many times this season, however, I have greatly admired some large trees in small gardens by the side of the station road at East Grinstead. They have been laden with immense clusters of beautiful berries which quite weighed the branches down, and untouched by birds here they look splendid for a very long time. In the country the birds usually take these berries very early. I might mention what promises to be a fine form of the Mountain Ash. It is named *asplenifolia*; the leaves, no mean ornament in the ordinary species, are in this kind beautifully cut like the fronds of a Fern.—A. H.

A good red Tea Rose.—Princesse de Sagan is to me the most pleasing of all the red Teas I have seen. W. F. Bennett, which "D. T. F." would place at the top, I do not know much about, but certainly I know of nothing richer than Princesse de Sagan. I have just been admiring some splendid flowers of wonderful colour—a rich velvet-like crimson overlying deep red, giving them a striking appearance. Souvenir de Thérèse Levet, Charles Legrad, and others I could name are dull and dreary in tint with me. I hope red Teas will not become fashionable, because they come too near the Monthlies when in that colour. The Teas will lose by the

importation into them of a lot of red hued kinds. We have this shade in sufficient variety in the great class of summer Roses, and, considering that there is still room for more first-rate all round Tea Roses of the Marie van Houtte and Anna Olivier type, I hope all who raise Roses will try to preserve the race of Teas in its present delicacy and refinement of form and hue.—A. H.

Two forms of *Lathyrus azureus*.—The Sweet Pea is so deservedly popular, that the other annual Peas are rather overlooked, but *Lathyrus azureus* has come into favour with many of late no doubt because of the lovely shade of blue which its flowers have. We have no such shade of blue among the so-called blue Sweet Peas. The late Mr. T. Laxton sent us two forms of *Lathyrus azureus* for trial this season along with other Sweet Peas, and they will both be welcomed by those who like the typical kind. One has pure white flowers, and those of the other are of a pretty shade of soft pink. Such graceful trailing things as these should be freely used.

A fine water plant.—A colony of the double Arrow-head in the water on the margin of the lake has been a very pretty feature during the past two or three weeks. This is an old, but far from common plant. The roots, which are much like pigeons' eggs in size and shape, were merely pushed into the mud last April, and a good growth has been made. The plant merits cultivation for its leafage alone. When in flower it is striking and showy; the spikes stand up boldly like a great double Rocket, bearing many large double white rosettes. Our native Arrow-head is a plant not to be despised, but this double kind is worthy of a place among the most select hardy water plants.

***Bambusa Ragamowski*.**—I agree with all that "T." says in favour of this splendid dwarf Bamboo on p. 182 except the last remark that it is synonymous with *B. tessellata*. What I know as *B. tessellata* is, in comparison with *B. Ragamowski*, a poor thing. Whilst one is always good, the other, but for the first few weeks of its fresh growth, is a seedy-looking plant. I have had leaves on *B. Ragamowski* 18 inches long and 4 inches wide. The leaves of *B. tessellata* are less than 6 inches long and rather ovate, with rounded tips. It is a dwarf, dense grower, and when full of fresh leaves looks very well, but as soon as growth is completed the edges of the leaves begin to die. This partial death of the leaf occurs as a regular margin, and I have seen this mentioned as a characteristic point in favour of the kind and suggestive of variegation. With me, however, it always bore too plainly the semblance of death. It mattered not whether the plants were in sun or shade, and I came to the conclusion that of all the dwarf Bamboos this kind was of the least value as an ornamental plant.—A. H.

Alabama Snow Wreath (*Neviusia alabamensis*).—At page 408 of your May number I read of this shrub, "This is decidedly an over-rated shrub, and proves once more that the glowing descriptions of some of our American friends savour somewhat of exaggeration." Were the writer of the foregoing to see this lovely shrub on its native mountains, or grown in any of our middle States, he would have a very different opinion as to its beauty. Large bushes of it in my nursery about the time the above was published were covered with flowers of the purest snow-white. The small flowers, from their immense number and purity and their light airiness, could be likened in justice to waves of flickering snow. No *Spiraea* or any other shrub can approach it. No writer in Great Britain who has not been in a drier and warmer climate than his own can have any conception of the beauty of *Spiræas*, *Forsythias*, *Weigelas*, *Magnolias* and other beautiful shrubs—natives of China, Japan and the United States—when grown in our warm, dry climate. The summer and autumn of 1892 in the United States were warm and very dry; this ripened up the wood and buds. An intensely cold winter followed, ranging at times 10° to 15° below zero, yet comparatively few shrubs were injured, not even the power-buds on *Magnolias* and other shrubs. In the

spring of the present year our trees and shrubs bloomed in great profusion—literally covered with flowers of the clearest and purest colours; no white flower on *Spiræa* or other shrub is ever tinged with green in this country, as is frequently the case in Britain.—JOHN SAUL, *Washington, D.C., U.S.A.*

Another race of Carnations.—I send you a few blooms of some of Mr. Herbert's hybrid Marguerite Carnations, seedlings of this year. The three blooms tied together are small flowers of the first batch of seedlings of 1892 from a cross between the Margaret Pink and pollen from Robert Houlgrave, scarlet bizarre, a grand exhibition variety raised by the late Samuel Barlow. In the first batch much more of the Carnation character was obtained, and the seedling plants from seed sown in February were strong blooming plants the following August. Further crosses made last summer were with a view to get still more of the Carnation character, and a large number of plants are now blooming, some of them since the end of July, from seed sown in February of this year. The photos sent represent the seedling plants from seed sown in February last. Mr. Herbert is crossing blooms again, and this new race of Carnations will become very popular by-and-by because of the rapidity with which they become strong blooming plants. They are wonderful bloomers, several of them having from forty to sixty buds and flowers on each. They are also of stout dwarf habit, and, as you will see, are not very small plants.—WM. DEAN.

The Californian Poppy (*Eschscholtzia*).—Spring-sown annuals have had a trying time this year, and few of them have made any display worthy of notice. The Californian Poppy in its varied forms, however, is one striking exception, and probably it hardly ever fails, no matter what the season is like. Graceful in growth and remarkably brilliant when in flower, it has a telling effect if sown in bold, broad masses and the plants thinned, so that each may have ample room to spread over the ground. The typical kind has been in our gardens quite 100 years, and the varieties we now grow have doubtless all sprung from it. Of these there are at least half a dozen well worth growing, one of the very best being that named Mandarin. Its flowers are very rich in colour, being of a deep orange with a crimson exterior, showing well in the bud state. *E. crocea* has flowers of a distinct and rich shade of yellow, and then there is a white variety with flowers of a delightful creamy hue. A double-flowered form, too, exists, and is a pretty and lasting variety. The rosy form named *rosea* is the least reliable, as it generally shows a tendency to revert to the white form from which it sprung. *E. tenuifolia* is a little gem, and looks quite like another species, but probably is a tufted diminutive form of the original Californian. As a choice, yet attractive plant for a little nook or to grow upon the site occupied by some choice spring bulb there are few prettier annuals. It makes a close tuft of the most graceful leafage, and bears on slender stalks the soft yellow flowers, each about 1 inch across. These annuals may be sown now for spring blooming, being quite hardy, and they usually flower longest and best when sown at this time.—A. H.

Fine groups in Hyde Park.—Three of the finest between Hyde Park Corner and the Marble Arch are composed of the Australian Gum Tree, *Heliotropes*, and the purple-leaved Castor-oil plants. Each is separate and distinct and of considerable size. The first is formed of well grown plants of pyramidal form and each from 5 feet to 7 feet high. The plants are not crowded together, so closely as to prevent each single plant from being thoroughly seen and its entire beauty appreciated. The Gum trees have the whitest leaves of any I have ever seen, and their quivering motion in the sharp wind added greatly to their effect. The *Heliotrope* used was President Garfield, one of the best and most striking for grouping either out of doors or in. It blooms very freely, the flowers being more compact than in most of the *Heliotropes*. The odour, though not so full as that of most of the

lighter varieties, filled the air far and near, though a gusty day is not favourable to the production or enjoyment of such sweet fragrance. These two groups combined grace and dignity in a very pleasing manner. The Castor-oil plants, which occupied the third bed, could hardly be said to have either, and yet their colour and massiveness of stem and leaves told powerfully in their favour. Close by there is a fine group of new *Cannas* in full bloom, the flowers reminding one more of the size and glowing colours of those of the *Gladiolus* than of the Indian Shot plants of the olden times.—D. T. F.

FERNS.

THE ELEPHANT'S-EAR FERN.

(*HYMENODIUM CRINITUM*.)

The fronds which come from W. O'Brien of this plant show by their brown and shrivelled edges that they have been grown in far too dry an atmosphere, and in such a state the plant is anything but attractive, whilst their size is under 4 inches in length. When grown with fronds some 18 inches long and 9 inches broad the name has a significance, and the specimen is a bold and handsome one, worthy of all commendation. Two other species are included in this genus by J. Sm., *H. pachyllum* from Peru and *H. reticulatum* from the Sandwich Islands, neither of which is known to me. The present plant appears to be somewhat rare in cultivation now, although two or three decades back it was eagerly sought for by lovers of Ferns. It is found in Mexico and the West Indian Islands, and in Jamaica it appears to be very frequently found in the cracks of the mountains which had got filled up with soil. It makes a superb specimen when well grown, potted in a well-drained pot, using for soil peat and turfy loam made sandy, the whole pressed down firmly. It should have strong heat and moisture in the air. It is a very distinct and singular Fern, having fronds from 1 foot to 2 feet in length. The rhizome is densely crinite, the whole surface and the edges covered with long black hairs; the venation is uniformly reticulated, colour dull green; the fertile fronds are contracted, being less than half the size of the others. The stem is densely clothed with long black hairs, and the whole of the under side is occupied with the sori. It belongs to the *Acrostichum* family.

WM. HUGH GOWER.

***Cheliantes capensis*.**—This pretty plant, as its name implies, comes from the Cape of Good Hope, and is somewhat rare in cultivation with us, although it succeeds under warm greenhouse treatment. When at its best the fronds are nearly a foot in height, the edges of the segments toothed, the colour being rich bright yellow.

***Woodsia mollis* (W. O'Brien).**—This is the name of the Fern which you send, asking if it is an *Aspidium*. It is a native of Guatemala, Mexico and various other parts of South America. It is a handsome cool house species, with fronds from 1 foot to 18 inches long. It belongs to the section of the genus which is called *Physematium*; some authors make a genus of it. It is distinguished from the true *Woodsias* in not having the main stems jointed.—W. H. G.

***Mesochlæna javanica*.**—H. Baker sends this, asking for the name. He says it was bought from the Messrs. Rollisson's at Tooting. It makes fronds from 2 feet to 4 feet long; these are pinnate, the lower part of the frond furnished with abortive pinnae, the colour a bright green. The plant is nearly related to *Nephrodium*. I think at the present moment it is somewhat rare in cultivation. It is a native of Java, &c.—W. H. G.

TREES AND SHRUBS.

AZALEAS.

THERE are few shrubs which flower so profusely and with such a range of soft colours harmonising well with each other as the different varieties of garden Azaleas, and one is surprised at not seeing them planted to a greater extent in large gardens. It is possible that many people may be deterred from attempting to grow them by the idea that peat is necessary for their welfare. That which really is essential is the absence of

the greatest profusion every year. After a certain age the bushes assume a distinct character, having flat spreading branches (somewhat like those of the Cedar), the surface of which during the flowering season is a mass of colour so dense, that the foliage can scarcely be seen beneath it. The forms of *A. pontica* have a much more upright growth and are not so good in outline, but, on the other hand, they have the merit of the gorgeous tones assumed by the leaves in autumn, for which alone, had they no other recommendation, they are worth growing, and a neighbour of mine has planted no less than 10,000 during the last twelve months

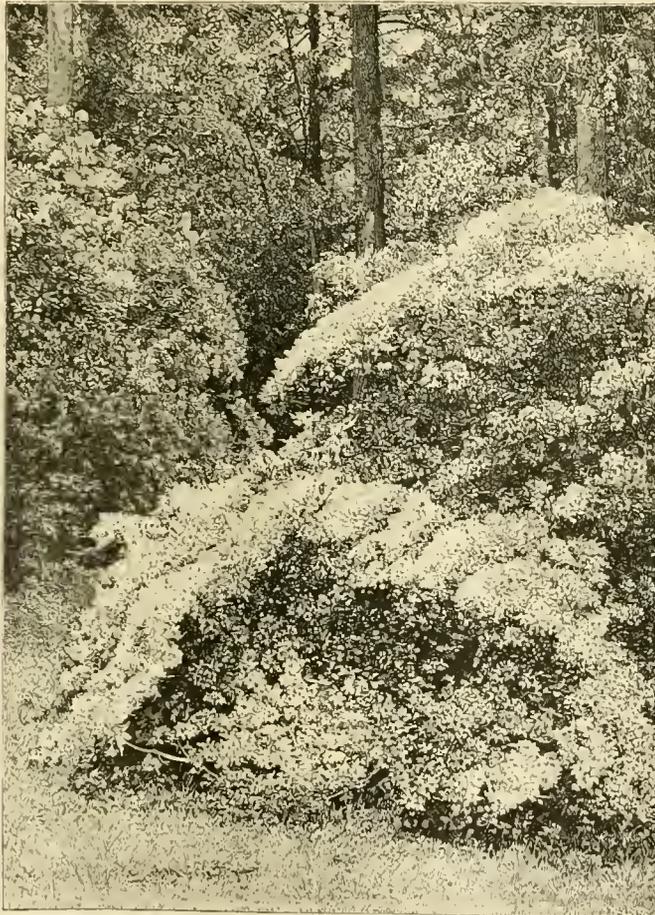

colour, there seems little reason why grafted plants should not be rejected. This class of shrubs is worth planting for the sake of the immediate effect which they give, and for the number of years during which they will remain a source of pleasure to those who live amongst or see them in their beauty.

C. R. S. D.

FREMONTIA CALIFORNICA.

My garden has just now suffered an eclipse of the greatest possible magnitude. It is owing to the unusual heat, and I shall always have reason to remember the abnormal season of 1893. But it does seem a pity that the very best of all its treasures should have been the one to go, and yet this sort of thing is far from being uncommon. The tender and pathetic words of Moore, which begin with "I never loved a dear gazelle" and end with "it is sure to die," are *mutatis mutandis* quite as applicable, I fear, to a botanical as to a zoological garden. My threnody of regret refers to what I have for some time considered the finest specimen of *Fremontia californica* in the kingdom. I have so often heard that said by one and another of my visitors, that I have come insensibly to believe in it myself, though I daresay if any pains had been taken to investigate the matter, some other claimants for the highest honour would have been found. Mr. Noble, of Ascot, will, I daresay, remember how he noticed this shrub some three or four years ago, and he said then that he thought it distanced any other of a like sort he had either heard of or met with. Mr. Elwes was much struck with it when he paid a visit to the island towards the end of last year, and he called Mrs. Elwes' attention to it as having been last seen by them on the mountains of Mexico. It runs in my head that a dangerous rival to it, and possibly a superior, might be found somewhere in Dorsetshire, and I can only say that if it be so, it must be a very fine specimen indeed.

My *Fremontia californica* was bought by me with another between twenty and twenty-five years ago. It was then, so far as I remember, about 2 feet high, and the thickness of the main stem was about that of my forefinger. I had two of them of about equal growth. The one I planted in the open border, and it very soon succumbed to the rigours of winter. The other I put against a western wall, and it has lived and gladdened me till now. From end to end at each side it covered a space of more than 25 feet; in height it was about 13 feet or 14 feet so far as I can judge, and the girth of the main stem was 1½ feet just above the ground. It was very strong and thick. In point of height it has never had justice done to it at all. The wall against which it stood was in the direct line of the furious south-west winds which so often prevail here, and the tree has had to fight hard against them as soon as it reached above the top of its 6-foot protector. Had the wall been higher, my *Fremontia californica* would have been very much higher than it is. I think, from the size of the trunk, it would have attained to a height of not less than 25 ft. or 30 ft., but it has been hard work for it to make much upward growth, as it has been decapitated so often. The 7 feet or 8 feet to which it has attained in point of height above the wall are the survivals after endless battles with the wintry gales. Latterly it has never failed to blossom, and nurserymen have been provided with seed from it which they could not get elsewhere. Two years ago it was rather extensively layered,

Azaleas at Coolhurst. Engraved for THE GARDEN from a photograph sent by Mr. C. R. Scrase Dickins.

lime in all its forms, and it is possible to secure this in some of the poorest soils and barest districts in this country. Most of the Azaleas may be transplanted with greater success than the Rhododendrons, but it is desirable to guard against the rays of the sun striking directly on the roots near the surface of the ground either by planting in the shade of other things, such as deciduous trees or near low-growing evergreens, or else by mulching the surface until the plants are large enough to shade for themselves the ground in which they grow.

The variety, from a photograph of which the engraving was made, is one of the fiery orange-scarlets, which never fail to flower in

chiefly with a view to the effect of the autumn foliage. It would take more space than I could hope to occupy, and more patient interest than I could hope to arouse, if I were to attempt to catalogue the merits or demerits of the different species, their admixtures and varieties, but I should like to call attention to the way in which, with one or two exceptions, the different shades of colour in the flowers harmonise with each other when planted in sufficient masses. The evils of grafting may be noted in the case of Azaleas, with the consequent annoyance and trouble caused by suckers breaking up from the stock, and as seedlings are generally obtainable classed under different headings of

and the layers should have been able to make a start for themselves in life in a very short time. In fact, it has had quite a run of prosperity save only in its hard-fought contests with the wind, and it never was beaten in them. In June last it perhaps attained to the zenith of its success. As one after another of my visitors at a garden party passed through the gate and immediately set eyes on its myriad golden blossoms, each one of nearly the size of a five-shilling-piece, studding the wall with a blaze of beauty which it would be very difficult to excel, and also mounting high above the wall in the richest profusion; when they saw this outspread of most beautiful colour set off by a dark glossy green foliage which exactly befitted it, and the branches trailing on the ground, which were wreathed to the very tips with the blossom they carried so well, not a few of them said that they had never seen or dreamt of such a sight in this country, and they would scarcely have believed it to be possible. But how little did I then think that all this was for the last time, and that it would soon be over, or at any rate for many years to come. My "dear gazelle" was bound very soon to die, or to come quite near to it. I went away for my holiday in the summer, and though I had fears about many things, I never felt the smallest anxiety as to how *Fremontia californica* would get on. Did not its very name speak for itself? Would not the bright summer glow be only a reminder of its own native habitat? It was a certainty to me that, though other things might fail, this at all events would revel in the almost tropical heat and think nothing of it. I could have fancied its going down before the frosts of December or January, and I have often thrown a friendly net over its head in the rigour of winter, but surely nothing could injure it in July and August, and it would be its season of triumph. And yet what has happened! It is always the unexpected that takes place quite as much in horticultural as in political affairs. My gardener (and I can now say that I have a very good one indeed) passed it without misgiving during my absence from home; he saved innumerable other lives by the anxious solicitude with which his watering was carried on, but it never once struck him where most of all it was required, and no wonder, for he was comparatively new to the place and to the tree, and he might well take it for granted that it had all which it required. But I could be under no such illusion as that. I saw at once on my return home a sort of ominous curl in the leaf, which told me that the tree was ill; its radiance of happiness seemed quite to have gone from it. I looked at it and was startled when I looked, and more than ever so when a quick glance over it took a lower sweep than before, and I saw immediately that the sap was exuding copiously from the stem and running down in thick resinous streams, and, in fact, its very life's blood was passing away from it and leaving it a sort of monument of distress. The tree was labouring in its adversity, and as though some dreadful malediction had come on it like that of which we are told in the Gospel, it shuddered in the fierce sunshine which was pouring on it without any pity at all. The level rays of the western sun seemed to bring death upon their wings; the days of *Fremontia californica* appeared to me to be numbered without hope or remedy. But it is never the part of a gardener who treats his garden as the very home of his favourites, which he watches over with unremitting care, to give up too soon, or to give up at all if there be the slightest chance of bringing relief to some suf-

ferer in a crisis that has occurred, and drastic measures were not long in being applied. We deluged the border where *Fremontia californica* had been lately growing so well with can of water after can. We applied thick coatings of rotten stable manure as a mulch to its feet, so as, if possible, to keep them cool. We worked up some clay till it had become ductile as putty in our hands, and then, with all the tenderness possible, we swathed the main stem with it just above the ground, where it is $1\frac{1}{2}$ feet in girth, and then most carefully we bound it all round with straw, because we thought it would be a non-conductor of heat, and then we only felt regret that there was nothing more that we knew of to be done. We had to wait some little time to see what would be the end of it all, and if the destroying hand could be stayed even at the last moment after much sad havoc had taken place, or if Ichabod, and nothing short of that, was to be written on a bare and empty wall which had been lately clothed so well. I am thankful to be able to say that while about six-sevenths of my tree are utterly gone and hang down now in hopeless and piteous dejection, I quite believe that the remaining seventh part will be saved. Of course, at the best it will take many long years for those who see it before the former splendour of *Fremontia californica* is restored, if that ever be the case. But it is a blessing to think that it is not quite lost, and if it can be saved by any amount of attention, it will be saved, so as to spread and some day to blossom again. It all depends, of course, on the state of the roots, and about that I can tell very little at present, nor have I looked at all; but the battle has not ended yet in complete and utter defeat, though the struggle has cost me dear. Its *in memoriam* may yet have to be written by another hand than mine. For the future I shall go upon the principle that prevention is better than a cure with this glorious shrub, and I shall dig a trench round it and fill it up with rotten manure and keep it cool and moist in summer-time, and I advise all owners of *Fremontia californica* to give heed quite as much to the heat as to the cold regarding it, and if it has been put against a western wall, I should offer it some slight protection of straw around the stem, for it is worth while to keep it well, and yet this does not by any means come of course. Some half dozen *Magnolias* have braved the wave of heat and seem uninjured by it. In the very same border where *Fremontia californica* stands *Xanthoceras sorbifolia* has laughed at the very worst which could be done against it. *Poinciana Gilliesii* at no great distance off seems to be in quite cherubic happiness. *Pomegranates*, *Roses*, &c., have not suffered to any extent. The only shrub in my garden, save *Rhododendrons*, which has nearly slipped through my fingers is the one for which I would have done most of all with alacrity. It would be an immense pity if the Dorsetshire specimen—unless it be apocryphal—were to suffer as mine has suffered. I hope *Fremontia californica* will continue to be represented there. But it is the way of a garden very often, as it is the way of all human affairs, to endure loss, and it is no wonder that my tree has come to grief—*sic transit gloria mundi*.

St. John's, Ryde.

HENRY EWBANK.

P.S.—I have just now received a letter from a friend in Switzerland which throws some light on the difficulty I have had to meet. My impromptu measures were in the main suggested by what I have seen them do abroad with a bleeding Vine, and though it was rather like shutting the door when the steed had been

stolen, I had recourse just now to a well-known Vine-dresser and horticulturist to see what he would say. His answer may perhaps be useful to others and save them from the disappointment which I have to bear. I therefore append an extract from the letter I have received, and I only wish I had seen it myself a few weeks ago. It runs as follows:—

The tree should be bound up to prevent bleeding. Care should be taken not to pour water on the trunk and bleeding part when watering it, and if it stands against a wall, straw or a plank should be put between it and the tree. That often the hot wall produces such bleeding. Anyway, no water should be poured against the trunk of the tree, especially when the sun is on it or after a very hot day. I hope the tree will yet be spared.—
August 28, 1893.

Stuartia virginica.—This has long been introduced into this country, but very few really fine specimens exist. I never saw the above variety more beautiful than it has been this season. Our plants thrive well and bloom profusely. One, some 15 feet high, faces full south, and the other is on a western aspect. Of course, the former does best, but the one in a colder position never loses any wood by severe weather. *S. virginica* is a lovely object when in bloom. The flowers are white, somewhat like those of a single *Camellia*. I have also noticed the plants bloom best after a wet winter, thus showing the roots like a fair amount of moisture, provided the wood is well ripened. Our soil is very light and well drained. Heavy, wet land would not suit the *Stuartias*, and in the latter they would require a certain amount of peat soil and free drainage. *Stuartias* are compact growers and give little trouble, but they soon get spoiled if at all crowded. At the same time they require a certain amount of shelter from the east winds, which seem more destructive than severe dry frosts.—G. WYTHES.

SHRUBS AND THE DROUGHT.

SAD havoc has been played amongst shrubs during the summer months, and at no time was such destruction seen as during the period from Aug. 13 to 19. During that time shrubs which had been transplanted two and three years succumbed. The worst sufferers are undoubtedly *Rhododendrons*, as some very fine bushes are killed, and in light gravelly soil they have been kept alive with great difficulty, no moisture having reached them for a long time except by watering. No doubt the reason why these plants are suffering so much is on account of their being called upon for extra moisture to supply the new growth. Being moisture-loving subjects, they soon suffer by prolonged drought. Being shallow rooters, shade to a certain extent does no injury, but when the plants are overhung by tall trees then injury is caused. The value of a mulch in such seasons will be very great, and there is no better material than decayed leaves, and the value of allowing these to remain year after year to enrich and protect the roots in preference to the annual clearing out and forking over which are at times practised will be evident. Of course, in heavy soils or in loam of good depth it is not so important, but on thin, gravelly soils more food and moisture are required. Digging and forking give a neat finish, but this may be effected by merely removing broken wood and allowing the leaves to remain, as these soon decay and may be covered or placed underneath the finer soil to support the surface roots in such seasons as we have just passed through. Leaf soil placed as a mulch over shallow rooting shrubs is of great advantage, as after a thorough watering it retains the moisture for a long time. This is a great saving of labour, as the leaves keep the roots cool and moist, so necessary with evergreen and surface-rooting shrubs. Water applied indiscriminately to shrubs on hard baked ground with cracks and fissures in various directions is useless, as it all runs away, but with a mulch it is retained for a long time

Shrubs which are valuable will well repay extra attention this autumn by mulching and thoroughly watering them. If feeding is necessary, I do not know of any better food than cow manure. This if mixed with loam or leaf-mould and well watered in will soon create increased vigour. For conifers and trees with dense foliage it is invaluable.

G. WYTHES.

Japanese Acers and the drought.—On light soil the Acers have had a bad time of it. It would be interesting to know the rainfall these plants get in their native country, as in a wet summer they thrive amazingly, and though they lack the brilliant shades of colour they assume in hotter seasons, I have noticed the foliage is brighter after a wet winter than otherwise. I have tried these plants in very dry sheltered corners and they do not grow freely. I note at this time there is abundance of rain in Japan and drought is not very common, thus showing that the Acers require plenty of moisture. If Acers, when cultivated in pots, are allowed to get dry and flag, the leaves assume a rusty tint, which spoils the appearance of the plants. On heavy soils Acers may not have suffered so badly, but in these they do not stand such severe weather as when growing in light and well-drained land.—S. H. B.

Pterocarya caucasica.—I consider the above one of our most ornamental deciduous trees, and of great beauty when planted near a lake or by water, as in such a position it thrives luxuriantly. The foliage of *Pterocarya* is so distinct that it is easily recognised even at a distance, and when planted at the water's edge it assumes a graceful drooping habit, and being of such noble proportions, it should find a place in all collections where a moist position can be given it. Along the Thames valley it grows grandly. We have noble specimens nearly 50 feet high. This is much above the average height. The leaflets average nineteen to twenty-three, and are much longer and broader than is usually seen. In the autumn months the foliage assumes a rich colour. The plant is readily increased by suckers from the base. The trees are lovely objects when in bloom, the flowers, of a greenish white colour, hanging in long pendulous spikes. See 1 ripens in favourable seasons.—G. WYTHES, *Syon House*.

CHRYSANTHEMUMS.

SEASONABLE NOTES.

"TAKING" the buds will now occupy the time and attention of the cultivator of large blooms, whether they be intended for home decoration or exhibition. The plants that made a second break about July 20, as noted on page 126 in *THE GARDEN*, are now (August 19) forming another flower-bud at the point of growth. I am just now referring to plants of the Queen type. This family, owing to the many distinct varieties that have emanated from the original Queen of England, raised by J. Salter during the year 1847, or from its direct sports, is an important one in the exhibition tent. The plants composing this family have behaved somewhat strangely this season in the matter of premature bud-formation, owing presumably to the effects of so much hot and dry weather during the early part of the year. Where the plants received constant attention as directed in the matter of daily syringing to maintain a less arid atmosphere about them, and where growth was forced, as I might term it, by one or two doses of nitrate of soda given cautiously, with a view to the elongation of the sap vessels, the plants are now in a satisfactory condition, in spite of their unpromising appearance earlier

in the year. By the time these lines appear in print the buds will be sufficiently developed to enable the cultivator to "take" them safely. Directly they are sufficiently developed to discern that no deformity exists, owing to the work of insect pests, of which there is a plentiful supply this year, the shoots which cluster around the buds should be promptly removed, so as to concentrate the whole vigour of the plant into the buds selected. If the removal of the shoots is delayed for a few days longer than it ought to be, they appear to rob the bud of its powers of development so much, that it does not swell in proportion to its requirements, and consequently does not make so fine a bloom as it should and would do under the correct cultural conditions. Early in the morning, when the foliage is laden with dew, or in the evening is the most suitable time to "take" the buds, not only because the work can be carried out so much more expeditiously, but because it is much safer to remove the shoots when they are succulent. If done during the middle of the day, the heat renders the leaves and shoots limp, and the danger of injury to the bud is increased. By holding the shoot firmly in the left hand and giving the shoots a downward sharp bend, they snap off easily and quickly. Blooms of the Queen family developed from buds "taken" as directed are certain to be of that uniform shape, colour and substance so desirable in this family. In close competition it is the adherence to the quality noted in this family that places one exhibitor before another. No variety in the whole incurved section tests the cultivator so much as does the Queen family. Those persons who select buds of these varieties known as "crowns," irrespective of the time they are produced, simply because they are regarded as producers of the largest blooms, will have much cause for regret this season. True, they obtain size as far as diameter is concerned, but it is at the expense of quality. After a season like the present we hear loud complaints of the blooms having reflexed petals instead of incurved ones; this defect is entirely owing to the anxiety of the cultivator to ensure the early-formed buds. Experienced exhibitors, however, seldom commit such an error.

I never saw the plants of the Princess of Wales family look so promising as at the present time in all collections that have come under my notice. They are tall. In this section I firmly believe the finest blooms invariably come from tall plants. I do not mean, however, that those plants that are rendered abnormally tall by faulty methods of culture, as crowding them during the early stages of their existence and allotting them a position unsuitable during the summer. The present appearance of the plants denotes blooms of the finest quality. The cultivator should pay daily attention to all varieties in the matter of bud-formation, as it will not be wise to allow any variety in either of the large flowered sections to "run on," as it is termed. If buds are now lost, the blooms resulting from the next formed growth will be small and indifferently developed compared with others produced from earlier selected buds.

Pompons, Anemone pompons, and single-flowered varieties are now many of them setting a bud in the point of each shoot, while the bulk will not do so for several days. Where exhibition blooms are required, and these to be set up in threes in the orthodox manner, whether pleasing to the general public or not, these buds must also be "taken." If this method is not in favour, rub out the bud and

allow the shoots to "run on;" the next formed buds will be the terminals, and from these the best results are obtained in these sections. Whether the plants themselves are required for decoration or the shoots are to be cut, a wealth of blossom is obtained. Rich food should now freely be given to those plants that have their flower-buds partly developed. The present hot and dry weather is all in favour of a liberal employment of stimulants, and especially of a liquid kind. In any case care is necessary to avoid too strong doses of any kind; far better give two weak ones than one double the strength. Another caution appears necessary, that of allowing the soil to become quite dry before applying stimulants. It should never be in that state when artificial food is given, the roots are so liable to be burnt, and thus receive a check which is not desirable. During dry weather like the present the plants are in a better state to receive aid from artificial means than during a wet season, and where applied with discretion I expect to see good results emanating from such practice. The plants are all the better when they receive what I term corrective treatment, *i.e.*, supplied with nothing but clear water for a couple of days about every fortnight. Stimulants have a greater and more beneficial effect afterwards. Where lime does not exist naturally in the soil in which the plants are growing, it is a good plan to occasionally well soak the soil with lime water, adding as much lime to a canful of water as will be held in suspension. When the lime in bulk settles at the bottom of the vessel the water is strongly enough impregnated with lime. Not only is this treatment beneficial to the plants themselves, but the lime rids the soil of worms. Surface roots should be encouraged as much as possible, for these have a decided effect upon the flowering of the plants. It is not that a limited few roots on the surface derive so much benefit from the food given, but it is the multiplication of roots that is to be encouraged. A cool and moist state of the surface soil will increase the stock of roots in that particular spot. When the plants are allowed to become dry too often, seldom can ever a fair quantity of surface roots be found. Now is a good time to set about the increase of surface roots. Plants that have their buds taken are in greater need of assistance from the roots than at any other period of their existence, because of the extra strain of supporting both leaves and developing the buds also. A top-dressing of some rich food is obviously the best means of affording additional food and encouraging surface root action at the same time. There are so many kinds of top-dressing materials recommended, that it is difficult to individualise them. No one can err in employing fresh turfy loam sufficiently decayed to destroy the grass; two parts of this to one of bone-meal or dissolved bones will form a good rooting medium if laid on about three-quarters of an inch thick and pressed down firmly. It is a good plan to well soak the loam in liquid manure before using it. Freshly gathered cow manure mixed with maiden loam in equal proportions provides a good rooting medium. Many of the growers around Liverpool are staunch believers in top-dressing their plants in this manner. Some of them build up small mounds around the edge of the pot with the top-dressing material to give additional space for water. In cases where but little space is left for top-dressing, owing to the pots being filled too full at potting time, if a thin layer of soil is laid on the surface and partly covered with pieces of potsherd, it is surprising what a number of roots quickly form on

the surface underneath the crocks, showing their value in maintaining moisture close to the surface. No matter in what way surface roots are obtained, they must benefit the plant, and should be encouraged as much as possible.
E. MOLYNEUX.

CHRYSANTHEMUM NOTES.

WITH what extreme rapidity the weather is causing prognostications with respect to the blooming time of Chrysanthemums to vary. Not long ago the bloom must be a month earlier than usual, then came the showers and clouded skies, and it was then found so robust were the growth and leafage, that flowers might be rather late than early. Even "E. M.," I observe, says that in low-lying districts it may be needful to pick off some of the leaves to allow the wood to ripen. Since that was written we have been having a couple of weeks pretty well of intensely hot weather, and the hardening process has been going on so rapidly that already there is fear again bloom will be unduly early. Certainly the recent heat has done more to mature wood and develop buds than an entire month can often accomplish. Even now we feel that Chrysanthemums must be chiefly contingent upon the weather of September, and what that may be remains to be seen. When I was in the Reigate district, where there are many good growers, on August 5, I was informed that there was no special reason to think bloom would come unduly early. Since then a change has taken place, as no one then contemplated the tropical heat which began on Bank holiday. Nevertheless, Chrysanthemums everywhere look wonderfully well. I saw 1000 fine pot plants at Woodhatch, Reigate, recently, and they were in the finest possible condition. I saw a smaller collection in a Teddington garden some time ago, the plants in 9-inch pots only, three parts full of soil, and they looked very poor and weak. Then I saw them a few days since, and they had done wonders, their thin weak-looking stems having put forth stout shoots that delighted the grower as much as they surprised me, for the pots still remained one-third empty. The rains so far had provoked a remarkable change, but this grower, who always produces some capital blooms, prefers to rather starve than feed his plants at the first, then gently stimulate later, filling up the pots with fresh soil, and feeding when buds are swelling. That is, however, a rare method, as almost everywhere I note that the flowering pots are filled right up at the potting time, and apparently very much the same results are obtained whichever plan may be adopted. That after all shows how easily the Chrysanthemum adapts itself to diverse forms of treatment. Given plenty of moisture at the roots, it would seem as if the plants revelled in ample air and sunshine. I have sometimes thought that plants standing, as is so frequently seen, in very long rows on each side of a garden path, the plants touching each other, lost very much of sunshine when the sun's rays ran longitudinally along the walks, as one plant materially shaded another. At Woodhatch I observed that Mr. Salter had nearly all his plants standing in rows, one a little above the other on a rising space, so that every one obtained a maximum of light and air. No doubt such a position is the very best, if at the same time somewhat sheltered from rough winds. So far there has been little trouble on that head, but because the great heat may generate wild thunderstorms at any moment, it will be well for growers to be prepared for eventualities by having every shoot securely tied.
A. D.

Early Chrysanthemums.—Last year at a meeting of the Royal Horticultural Society, held on August 25, Mr. McMillan, of Trinity College, Edinburgh, exhibited some splendid blooms of Chrysanthemums, consisting not only of the varieties usually associated with summer blooming, but also of the ordinary November flowering forms.

This season at Earl's Court, on August 9, the same exhibitor was to the fore with beautiful blooms of the following: Elaine, Stanstead Surprise, Mlle. Marie Hoste, Mrs. Irving Clarke, Mme. Leroy, Puritan, Stanstead White, Mrs. Hawkins, Venus, Admiral Symonds, Annie Clibran, Mlle. Lacroix, Edwin Molyneux, C. Wagstaff, W. W. Coles, and Mary Anderson. The blooms of all were very fine, and some of them would occupy a prominent position much later in the season than this. Four varieties, viz., Edwin Molyneux, Annie Clibran, Mlle. Lacroix, and C. Wagstaff, were shown in the shape of good sturdy plants about a yard high, the first mentioned three carrying four good blooms and the last three. The foliage on the plants exhibited was in good condition. Apart from the question whether Chrysanthemum blooms are needed at the present season, such an exhibit was a very noteworthy one, and it would be very interesting to many to learn how such results are achieved.—T.

KITCHEN GARDEN.

PRESERVING TOMATOES.

MISS LAWRENCE will be greatly obliged if any reader will tell her what are considered the best ways of preserving Tomatoes for winter use.

* * * There are extra heavy crops of fine Tomatoes ripening in the open both against and clear of garden walls and fences, and as yet all are free of disease. This being so, the question naturally arises, Why not make some attempt to store some of these for winter use? As it happens, there are several ways of utilising not only the ripe fruit, but also quite the smallest green Tomatoes, these latter being more sought after by those who know their value than are ripe fruit even. Bottling or canning Tomatoes is an industry principally confined to America, and of this I have had no experience. I fail to see, however, why private growers should not try to imitate the practice on a small scale. Cans, it should be noted, are fast going out of favour from their tendency to spoil their contents to the extent of rendering them positively injurious, owing to the effect of acids upon the metal, and it is either wide-necked jars or bottles that should be used in preference. Another recommendation these latter have over cans is to the effect that they can be effectually made air-tight without any assistance from a tradesman, soldering down being necessary in the case of cans. For bottling, the preference should be given to sound medium-sized to small ripe Tomatoes, these being separated from their stalks and sponged quite clean if need be. These should then be packed closely and tightly, but not crushed, in the bottles or jars, afterwards filling up with clear water. Supposing it has not been possible to obtain bottles provided with rubber rings and screw tops, though, unfortunately, I am unable to state where these can be procured, the bottles or jars must next be very tightly corked and then placed in a stock pot or deep stewing pan, filling this with cold water and setting over a fire to very gently boil for the space of about twenty minutes. In order to render ordinary bottles or jars perfectly air-tight, new corks soaked for a short time previously in hot water should be used, and after the boiling has taken place and all are cool again, cut off the corks even with the tops. Make a cement or bottle wax by melting 2 ozs. of resin and 1 oz. each of beeswax and gum shellac, inverting each bottle or jar in this, repeating it when the first coating is cool. Store in a cool, dark

place, where the Tomatoes ought to keep admirably for many months.

The foregoing is the best recipe for storing Tomatoes that I am acquainted with, but there is an older and more simple, if less to be commended, practice that I will next give. Select perfectly ripe Tomatoes and pack them closely and without pressing in a stone or glazed earthen pot, and completely surround with a brine of salt and water strong enough to support an egg. Cover with a deep plate in such a manner that it presses upon the fruit and set in a cool dark room or closet. Fruit thus treated will keep a year without further attention, but must be soaked in fresh water for several hours prior to being cooked.

There are several methods of making Tomato ketchup, or sauce as it is often erroneously termed, and a few bottles of this might be found very serviceable during the coming winter. The first of these recipes, and which I can strongly recommend, is as follows: Take Tomatoes when fully ripe, bake them in a jar till they are tender, strain them, and rub them through a sieve. To every pound of juice add a pint of chili vinegar, an ounce of shallots, half an ounce of garlic (both sliced), a quarter of an ounce of salt and a quarter of an ounce of white pepper finely powdered. Boil the whole till every ingredient is soft; rub it again through a sieve. To every pound add the juice of three lemons, boil it again to the consistency of cream. When cold, bottle it; put a small quantity of sweet oil on each, tie bladders over, and keep in a dry place. Another recipe that might also be tried with advantage is rather simpler. Slice the Tomatoes, put them in layers into a deep earthen pan, and sprinkle every layer with salt. Let them stand in this state for twelve hours. Then put them over the fire in a preserving kettle and let them simmer till they are quite soft. Put them into a thin linen bag and squeeze the juice from them. Season the liquor to taste with grated horse-radish, a little garlic, some mace, and a few cloves. Boil it well with these ingredients, and, when cold, bottle it for use. There is yet another good recipe for Tomato ketchup, and it is this: Slice the Tomatoes and sprinkle them with salt, boil them, and strain through a coarse sieve. Slice two good-sized Onions to every gallon, add a small spoonful of ginger, two of pounded cloves, two of allspice, and one teaspoonful of white pepper. Boil twenty minutes after the spices are in. Keep it in a jar closely covered.

Although no mention was made of green fruit by the lady who asked for information as to the best methods of storing Tomatoes, I am enlarging upon the subject for her benefit, and I hope for that also of many other readers of this paper. So well have Tomato plants grown and so freely have the crops set, that there are extra large quantities of green fruit that will not have an opportunity of attaining anything like their full size, colouring being as a consequence quite out of the question. Even if green fruit can be kept after being cut long enough to colour, the quality is as a rule wretchedly bad, and the fruit in a fresh green state might well, therefore, be put to a better use. Tomato pickle made principally from the green fruit and Onions invariably finds favour with most people who have an opportunity of trying it and believe it to be quite wholesome. There are only two recipes for pickling Tomatoes that I am acquainted with, and these I will give. The first, and which is most popular, is as follows: Take two pounds of green Tomatoes, pull them to pieces (they must not be cut), add two or three Onions sliced and six chillies.

Scatter salt over them, letting them stand fifteen hours, then strain away the liquor and cover the remainder with good vinegar. Place this in an earthenware jar, bake in an oven for one hour and then press pulp into jars. Now take a dessert-spoonful of mustard and half a tea-spoonful each of pepper, spice, sugar and cloves, a little cinnamon and four chillies, adding sufficient vinegar to make this quite thin; boil it and pour over contents of jar while boiling hot. If spiced vinegar is used, this may be brought to the boiling point and used without the addition of the raw spices. When cool, closely cork the jars and cover with bladders. This pickle is found to be rather hot, especially if not well stirred prior to use, the hot spices collecting on

SHORT NOTES.—KITCHEN.

Celeriac is cultivated here to a great extent. It is used as a winter vegetable, boiled and afterwards cut into thin pieces for salad.—*LOUIS KROPATSCU, Vienna.*

A seedling Pea.—I send some pods of a Pea raised by Dr. Froud, of Feltham. I wish to call it *Oceana*, after his namesake, the travelled and charming historian. It has a good constitution, catches no mildew. The haulm has borne Peas for quite two months, these being off the one row I have. I also send some ripe seed which I have been gathering for three weeks past. One row of this Pea does the work of three rows of any other. It is, I should think, a step in the right direction, and though the haulm dries up a good deal, still it

it may be worth while if in judging Tomatoes it be made a rule to cut them transversely and then give the prizes to those which best present the above-mentioned features. Some of the varieties have in them rather hard cores; others lack solidity, having far too much seed room and soft juicy pulp rather than firm, yet soft, smooth flesh. Of course solid fruits will weigh the heaviest; hence, apart from their greater favour with consumers, they would be more profitable to growers. I do not learn that there is any diverse form of culture adopted to secure this solidity. It seems to be a characteristic of the sort. Generally, Tomatoes seed too freely. That may be a virtue with those who grow for seed production, but still we have far more of Tomato seed than is required, especially that the bulk of growers for market or private use save their own. To get rid largely of seed and its surrounding pulp, therefore, would be a good feature when it is replaced by solid flesh.—*A. D.*

ROSE GARDEN.

ROSES IN POTS.

IN order to secure a display of cut Roses during the winter months, it is necessary to look forward and commence operations at once. There are two plans that may be adopted. We may secure ripened wood to start with during October or November, or we may keep the plants growing steadily on the cool side of a wall until colder nights warn us that they must be housed, and so succeed in realising the last crop of bloom from the Tea-scented and Noyette varieties. But where the same plants are to give a second or third crop of bloom during the early spring months, I would prefer to start with those that have had a fair amount of rest for six or eight weeks. When a batch of plants has once been used for early forcing, they naturally come to hand better for the same purpose another time, because the earliness of their growth allows of a corresponding earliness in ripening. Plants that were under pressure all through the winter and early spring may well be stood out of doors by the middle or end of June, especially if a sheltered position can be afforded them. During the two or three months they are in the open it is necessary to be particularly careful as regards watering. If given too free a supply, growth will not cease in the gradual manner so essential in building up ripened wood for the following winter's forcing. On the other hand, almost as much harm may accrue from a little neglect, it taking but a short time for the soil to become so parched as to ruin a large number of the Rose roots. They may be allowed to get dry without being sufficiently so to show the effects, and it will be found much better to give a thorough soaking occasionally. I prefer to have the pots about half plunged, and if this can be arranged upon a concrete bottom, so as to avoid worms, it will be still better. Standing the pots upon pieces of slate does not recommend itself to me, for a very little soil being washed to the bottom will cause a stoppage. Worms, &c., may be kept out by sprinkling a layer of soot over the ground and standing the pots upon this. By partially plunging the pots, we avoid that sudden and injurious drought which comes on so unexpectedly after a few hours of dull weather, and as the most important roots of pot Roses are usually in the lower half, it behoves us to take due care of them. My own plants in pots that are intended for winter forcing are in two batches, one of them being about in the stage I have endeavoured to describe above.

Tea Rose Niphetos in a pot.

the top. The other recipe alluded to is also worthy of being given a trial. Scald and peel green Tomatoes, lay them on dishes and strew salt thickly over them. Let them stand twenty-four hours, occasionally pouring off the liquor that the salt extracts. Drain them and gently squeeze them, as it is this juice that weakens the vinegar and makes them spoil. Take a large jar, put in a layer of Tomatoes, then a layer of sliced Onions, mustard seed, cloves and white pepper or whole black pepper, or two pods of red pepper may be broken up and put into the jar. When the jar is full, pour very strong vinegar over, and in a few days the contents will be ready for use. Stored in a cool dry place, this pickle will keep all the winter.—*W. I.*

goes on bearing nice Peas of a thoroughly good flavour.—*A. DAWSON.*

Solidity in Tomatoes.—A friend recently gave me a few good-sized, handsome Tomatoes. I did not learn what sort they were supposed to be; indeed he did not know, for he had the fruit from which the seed was originally taken without name. When I cut these fruits transversely I found they gave the smoothest and most solid flesh I had ever seen, and they contained very few seeds. I hope to have more of these later to see how far the character thus given is sustained. Now I think it is in this particular direction we should look for further improvement in the Tomato. So far as beauty, colour and productiveness are concerned, it will be hard to excel what we have, but there is room for improvement in solidity of flesh. For that reason

By the time these notes are in print I shall probably be overhauling this batch and repotting the plants that require it. What pruning may be needful will be done at the same time and the whole batch stood back again, care being taken to keep the newly-potted plants by themselves. This is more necessary than might generally be imagined. In the first place, they will not need so much water until the new roots are well at work, nor will they receive any liquid stimulants nearly so early as in the case of the established plants. Those plants that do not need a shift will have a portion of their top soil removed, the drainage looked to, and be mulched with a rich turfy compost. It is not necessary to turn all of the plants out of their pots to ascertain if the drainage be sound or not; one can generally see by turning the pots on their sides. When a pot is full of healthy roots, turning the plants out must necessarily injure and disturb them more or less, and I would avoid it as much as possible. By the middle of October it will be well to take a few of the most forward looking under cover, but not to introduce them to any artificial heat. A deep pit or frame, where they could be kept close without heat, will be found much better than taking them into the greenhouse direct, the end of November being quite early enough. Should a bright and late autumn set in, the plants must be sprinkled over-head occasionally, or red spider, &c., is almost sure to attack them. The steadier and stouter the new growth breaks, the better and more numerous will be the flowers. The pruning necessary will be very slight, and simply consist of shortening back strong shoots and removing as many as possible of the weaker lateral growths. This last sentence refers to ordinary growers like Catherine Mermet, Mme. Falcot, Niphotos, &c., and not to those of the climbing section.

Reine Marie Henriette, Maréchal Niel, William Allen Richardson, l'Idéal, &c., may be used for early forcing with every prospect of success, provided a thoroughly matured rod or rods of growth is available. As the blooms are practically stored in the ripened eyes of these varieties, we see how necessary it is to have well-matured wood. It is easy to get rods of these ranging in length from 6 feet to 12 feet and 15 feet, and where they can be trained upon the roof, say about 18 inches from the glass, a quick and certain crop may be expected from all ripened wood. It is a good plan to have a dozen or so plants of this class and to train them cordon fashion, as you then get a more uniform break of young growth. It is useless to attempt forcing these extra strong growers unless they bear rods of considerable length and are well matured. Given this most essential point, I think they are the most certain to please of all early forced Roses. When this class of Rose has done blooming, no time should be lost in securing good rods for next winter's use, and as little good can be had from the old growth, it is well to cut away freely and so induce a healthy break or two from the bottom. This may be grown on as rapidly as possible, feeding liberally with liquid manure. Where repotting is necessary, this should also be done before the young growths have made much progress. What we want is a good growth attached to roots established in good soil, and which will ripen all the more effectually from being pot-bound. Never attempt to repot this section until you have secured your crop of bloom.

The second system of getting winter Roses will need but very few words, it simply being the judicious continuance of late autumn growth. Almost all of the dwarfier growing

Teas and Noisettes may be readily encouraged to make late growth in the autumn. Perhaps the worst foe to contend against in this case is mildew. This is very prevalent during some autumns, the clear bright days with chilly nights and mornings having much to do with its rapid spread. The form of dwarf Rose most suitable for pot cultivation is undoubtedly that worked upon the dwarf cutting or seedling Brier, or the plants may be upon their own roots. The cut accompanying these notes is a plant of Niphotos growing on the short hedge Brier. This also is a most excellent stock, but perhaps more suitable for outdoor culture. Although a few standard and half-standard Roses are of much value in pots, they are not so suitable for general cultivation as the dwarfs.

With a reminder that it is absolutely necessary to keep the plants clean from the very first, and also a further hint that a temperature of from 55° to 65° is quite sufficient until the days have turned, I will close these notes with a list of twenty grand Roses for pot culture. The first six are climbers. Maréchal Niel, l'Idéal, W. A. Richardson, Climbing Niphotos, Climbing Perle des Jardins, and Reine Marie Henriette. Dwarfier growers: Perle des Jardins, Catherine Mermet, Niphotos, The Bride, Edith Gifford, Jean Ducher, Francisca Krüger, Sappho, Ernest Metz, Augustine Guinoisseau, Mme. Falcot, Cleopatra, Anna Ollivier, and Mme. Hoste.

RIDGEWOOD.

EARLY PLANTING AND POTTING.

OWING to the excessively hot and dry weather since the few showers of last month, many Roses, especially those of the Hybrid Perpetual section, are rapidly ripening, and will soon be ready for transplanting. I am a staunch advocate of either very early or late planting of Roses. In the former instance they commence rooting again immediately, and are, therefore, in much the same condition next spring as plants that have been established a season. Indeed, plants put out extra early this season are likely to be more than equal to those transplanted early this spring, as, owing to the excessively dry summer, these have made little or no growth. When a plant ripens so early as many Roses are likely to do this year, late autumn rains often cause a fresh growth, which, owing to the approach of winter, is often of little value; rather the contrary, because it weakens and exhausts the plant, as well as renders many of the best and strongest eyes useless for another year. This is especially so among strong growers that are usually selected for pegging down. With the Tea-scented and Noisette sections this does not so much matter, as they very seldom finish their long growths until quite late in the season. My object in writing is to call attention to the great advantage of potting up Hybrid Perpetuals as early as possible. By doing so, and standing them on the north side of a hedge or wall where they are free from mid-day sun, we get root-action almost equivalent to that of spring, and avoid the injurious drying properties of the bright autumn sun. Plants that are denuded of foliage can be potted up under these conditions at any time, and are sure to be almost if not quite as satisfactory as those established for a season.

A few weeks gained in planting will be a great advantage next spring and materially assist the Roses during mid-winter, when we frequently get sharp, keen and exceedingly drying winds. In this case, the roots, being surrounded with a younger set of feeders, will be able to convey a far greater amount of sap to the wood than could otherwise be the case. Mid-winter or very late planting does not mean such immediate action of the roots as when this operation is taken in hand while the soil is still comparatively warm. Lift a

plant in mid-winter and lay it in by the heels in a shed, and you will find the roots respond in almost the same way as if planted early; but lay it in in the open ground, and you will find root-action considerably retarded. There need be little fear of new growth being made from early lifting; in fact, not so much as when a plant is allowed to remain in the bed after getting comparatively ripe previous to a late and genial autumn. Teas and Noisettes continue in growth until very late in the season, and if we were to wait until all of their wood was ripened, we should oftentimes find ourselves too late for any but spring planting. I would not hesitate to lift these during October, however full of growth they might be. True, they would present a sorry and woeful spectacle for a few weeks, but frost would also soon have had the same effect. By October almost all of the wood upon ordinary growers that is of any particular service for next year will be quite sufficiently matured to allow of successful lifting. The early roots pushed out would supply enough sap to keep the best of the wood plump and sound, and as winter approached we should find the eyes in a much better condition than upon late-planted bushes, and very little pithy wood would be found at pruning-time in the spring.

A. P.

Rose Climbing Perle des Jardins.—Sent out by Mr. Henderson in 1891, this new Rose has already shown that it has a grand future. In every way it is equal to the type; indeed, I think there are if anything fewer cracked or divided blooms produced. It is one of the strongest growers we have, and may be relied upon to produce blooms as freely and certainly as Maréchal Niel. The foliage is far more handsome than that of the last named variety, while the colour of the flower is considerably deeper in tone and more constant, never coming pale. I note on p. 173 A. Hemsley mentions that this and other climbers which have originated from shorter growers will rarely produce strong shoots from stunted plants. For some time I had the same idea, but find that if the plants are cut down hard and an eye encouraged to break as a sucker, the climbing habit is again produced. No doubt it is better to propagate from those plants which show the greater tendency to grow vigorously. One of my original plants of the above variety and also a climbing Niphotos hung about and only produced the normal growth until I treated them as described. But a few may revert to the original type, as is the case with many sports of other plants.—R.

Some good old Roses.—Alba carnea, blush-white, and alba mutabilis, rose tinted, with alba rosea, a flesh white Tea of about the same period, would form good telling groups either separately or together. Alexandre Dumas, dark crimson; Alfred de Rougemont, fiery crimson; and Alsace-Lorraine, deep crimson, were among the more vigorous and striking of the Hybrid Perpetuals in the 60's, and would be of great value for grouping on lawns and shrubberies to-day. In such fine sorts as Alfred Colomb, Auguste Neumann, Auguste Rigotard we have reds of the brightest that would not fail to give a good account of themselves in the garden or landscape. The following oldish garden Roses should be inquired for, found and grown in quantity wherever distinctness of colour and sturdiness of constitution are desired: Ecchus, H.P. (1855), crimson; Baron de Bonstetten, H.P. (1871), velvety crimson; Baronne Gonella, B.P. (1859), rosy pink, almost as useful and beautiful as Coupe d'Hebe and Charles Lawson, two of the finest Roses for the garden and the house; Baron Haussman, H.P. (1867), bright poppy-red; Baron de Rothschild, H.P. (1862), carmine-red; and, of course, the more modern Baroness Rothschild, which is as showy on a pillar or in a group as it is successful on the show table. Its light rose also contrasts pleasingly with the bright red of Baron Rothschild. Perhaps the old Aimée Vibert, introduced in 1828, was never seen to greater advantage than during the past summer. Its sheen of pure white was specially welcome in the baking sunshine and

drought of the past summer. The old and common variety continues still to be by far the most popular, though the climbing variety, which many have thought to be a sport and which is said to have been raised and sent out by Curtis in 1811, has very substantial merits. The variegated variety did not appear until 1878, and is all too seldom met with. Beautiful as each is by itself, those that have room grow all the three—the climbing variety over an arbour or arch and the others in masses near by. Exquisitely beautiful as the forms of Aimée Vibert are, their full effect has seldom been developed through grouping them into masses entirely by themselves or near enough to form sharp contrasts with such brilliant coloured Roses as Turner's Crimson Rambler. These would not only be extremely beautiful, but would also link the new and the old Roses together in the production of some of our richest landscape effects.—D. T. F.

Rose Duchesse de Caylus.—I was pleased to rote "R."s praise of this fine old Rose (p. 164). It has always been one of my special favourites since its introduction. Even its size commended it to me, while there are few brighter, more beautiful, and exquisitely fragrant Roses. I also note that some of our modern rosarians describe it as large. I did not used to think so, but anyhow it is good most seasons, and it will gratify many to hear that it has been extra fine with me and others in this year of drought.—D. T. F.

MANURES FOR ROSES.

DURING the past few weeks several queries have reached me relating to the above. When discussing the suitability or otherwise of any manure, we must take into consideration the class of soil to which it is to be applied. Roses like almost any kind of manure. What we want to aim at is to give the soil the properties it is deficient of. In many cases Roses are considerably over-manured under the impression that they are exceedingly gross feeders. This idea is wrong. The Rose enjoys a generous and rich treatment, but is quite as easily surfeited as other plants. In more than one instance I have known Roses planted in what was little more or less than a manure heap. In selecting ground for a rosery, it is well to know how it has been manured and cropped during the past two or three seasons. If manured so heavily as many do wheo growing vegetables of the Brassica tribe, there will be little need to do more than thoroughly trench it and apply a small portion of suitable manure to the subsoil. Let us imagine that the soil is naturally of a somewhat stiff and close nature, and that much farmyard manure has been used during the past few years. Under these conditions, unless such ground has been very heavily cropped with gross-feeding subjects, there will still remain a considerable amount of humus. To add to this by applying more of the same manure would not be beneficial to Roses. These being an entirely fresh crop to the ground, would not need more of the same class of manure. Should the soil be very stiff and close, a dressing of fresh lime would be of great service and would bring it into better order, besides releasing much of the stagnant humus. If stiff and not too full of humus, then a manure having a light and opening tendency should be chosen. Soot is a grand fertiliser and also has the desired effect. Liquid manures should seldom be applied to Roses growing upon stiff soil, as it does not drain away freely enough to avoid stagnation. At any rate, it should never be applied except when the plants are in full growth and their roots hungry and ready to absorb it at once. Upon light and naturally well-drained soils the same precautions are not so necessary.

From these few remarks it will be seen that it is not so much a question of what manure is best for Roses as it is to what is best for the soil they are to be cultivated in. I would not recommend the application of what are styled green manures, that is those of a very fresh nature. A heap of rotted weeds, vegetable refuse, old potting soil,

&c., that has had a little night so and other sewage emptied upon it, turned over frequently, and during the last turning had a little fresh lime intermixed with it, is my ideal of a suitable compost to enrich almost any soil for Roses. To sum up, apply heavy manures to very light soil, and the reverse to that of a close and heavy nature. The class or kind of manure employed does not matter in the least so long as it answers to the above, and the soil is not already over-charged with the same. Having got our soil well turned over and manured according to the above, the plants should be put in as early as possible. Do not, however, hurry this operation to the extent of planting when the soil is too wet. Dryness at planting time is a factor that scarcely needs consideration, as it so seldom happens that the soil is too dry. Should such be the case, I would still plant, and water the soil around their roots, not finishing the planting and then applying enough water to penetrate to their roots, but watering around them immediately the first small portion of soil has been placed upon them. Sufficient moisture will thus be conserved around the roots, and the soil will not be in a close or sodden state, such as would happen if planted when excessively wet. It does not want much rain upon newly-moved soil to make it harsh and stiff if trod upon at this time. If you can manage to plant directly it is prepared, by all means do not miss the opportunity.

A most important item in planting Roses is the depth at which to put them. This depends upon whether they be worked as dwarfs or upon standard Brier stocks. The former, with such plants as are cultivated upon their own roots, need to be fully 2 inches below where the bud was inserted. Those on their own roots having no such guiding mark, may be planted the same distance below their base. In this case suckers are more freely produced, the softening influence of the soil tending to develop what would otherwise often be dormant buds for a long period. As the season goes on and the plants are mulched, the soil may be slightly drawn up around them, thus encouraging more eyes to break from a point slightly higher up their base. This is, in fact, the secret of growing dwarf Roses, they producing their most valuable wood in the form of suckers. Before planting, should they be worked upon any stock, great care should be taken to overhaul them and cut out any dormant eyes beneath the point where the Rose was budded or grafted upon the stock. When this precaution is taken, and the Roses are well worked, i.e., as low as possible, there is very little need to fear stock suckers being produced. With own-root Roses this is not necessary. In planting standards, depth is not needed. Only cover the collar of the Brier about 3 inches, and do not draw any soil around them in the way advised for the dwarfs. But it is equally necessary to search well for any eyes upon the collar, or even strong roots of the Brier. This stock not unfrequently produces roots which push away and develop eyes freely, resulting in suckers appearing through the soil from 1 foot to 3 feet away from the plant. In a wild state the common Brier reproduces itself more freely in this form than from seed.

R.

A USEFUL FORAGE PLANT.

In the protracted drought of the present season it may, perhaps, be permitted to horticulture to come to the aid of the farmer, just as, twenty-five years ago, the gardener's art helped the Vine-grower out of his difficulties by showing him how to make use of the remedy of grafting.

The remedy in the present case is a robust and vigorous-growing perennial plant, which is equally unaffected by excessive heat in summer and extreme cold in winter, namely the Sachalin Knot-grass (*Polygonum sachalinense*), belonging to the same natural family as the Sorrel, the Buckwheat, the Rhubarb, &c.

Since its introduction into France we have been growing this plant merely as an ornamental subject in gardens, although its young shoots when blanched are as edible as Asparagus, if not of quite so high a quality, and the fine foliage might be utilised in garnishing desserts, and also in packing fruit for market. We certainly had pointed out to bee-keepers the fact that its flowers, which are produced in great abundance, are much frequented by bees at the close of the summer; but the writings of M. Doumet-Adanson on the qualities of this *Polygonum* as a forage plant which were brought under the notice of the Académie des Sciences by M. Duchartre, and the reports which we have made on the same subject to the National Agricultural Society of France have brought the plant more prominently into view and claim for it the earliest attention of farmers.

This Sachalin Knot-grass was discovered by the Russian botanical explorer Maximowicz in the island of Sachalin (or Saghalien), which is situated in the sea of Okhotsk, between Japan and Siberia. This island is of large size, and was ceded to Russia by Japan in exchange for the islands of the Kurile Archipelago. In the year 1869 my friend M. Edouard André, meeting with this lately-arrived plant in the Jardin d'Acclimatation at Moscow, was struck with its highly ornamental character, and brought back specimens of it to France. In speaking of it to us he dwelt very strongly on the great vigour of the growth exhibited by the plant both at root and at top, the roots sending out horizontally on all sides rhizomes which are capable of penetrating the stiffest ground—even that of old, well-trodden roadways—and pushing up fresh shoots in all directions, thus largely extending the area occupied by the plant when first put in the ground. The stems, which are numerous and grow close together, soon attain a height of 3 feet or more, even when the early frosts may have nipped their extremities. From the middle and top of the stems issue long, slender, curving ramifications. The foliage is pleasing in its effect, the leaves being alternate, distichous, oblong-oval in shape, each leaf measuring from 1½ inches to over 1¾ inches in length, and about an inch in width. The leaves are also perfectly smooth or without the least trace of down or tomentum. The leaf-stalk is of a carmine-red colour, and the stem, as it ripens, takes on a reddish tinge on a green ground. The flowers, which are of a dull white colour, are borne in small axillary clusters, together forming long, paniced, closely-set fascicles, which droop slightly with their weight. The bees frequent these flowers in the autumn, but it must be borne in mind that when the plants are regularly cut for forage, there will be no flowers.

The experiments carried out at Baleine are quite conclusive on the subject of forage. A young plant when planted out does not take long to cover an area of a yard square or more with its leaves. The first cutting is made when the stems have grown from 3 feet to 5 feet high, and if the second growth of the first year is strong enough, a second cutting is then taken. In the following years three or four cuttings are taken annually. In the green state the weight of the grass varies from 44 lbs. to 88 lbs. per square mètre, so that the yield per acre of green fodder would amount to from about 60 tons to 120 tons, according to the calculations of M. Doumet. Horned cattle are very fond of this green fodder.

M. Edouard André, M. Gustave Huot (president of the Comice Agricole de l'Aube) and some farmers have made trial of the plant with similar satisfactory results.

As the Sachalin Knot-grass does not yield seed here, we propagate it very readily by division of the rhizomes, and in this way we have raised thousands of plants for distribution amongst the agricultural schools and to enable us to meet the demands for it which reach us daily. The proper time for planting it is in August and September or else in spring. Any ordinary soil will suit it; however, a moderately moist position would help to retain the sap and be conducive to obtaining a leafy final cutting at the close of the season. After planting, no further cultural attentions are required, and the plant may be left entirely to itself during the winter, whether this may turn out dry, or damp or snowy. In the ensuing spring any stems that remain standing should be cut away before the new growth pushes. At planting time, if the plants are set out a mètre (3 feet 3 inches) apart in every direction, the surface of the soil will soon be covered with an abundance of nutritious forage.

Troyes.

CHARLES BALTET.

GARDEN ENEMIES.

ALTHOUGH the fruit reports from different sources seem unique in their partiality, places only a few miles apart differing greatly as to quantity and quality of crop, there would seem to be an almost unanimous verdict on one subject connected with fruit-growing, viz., that insect enemies were never more numerous or more troublesome. Possibly under such circumstances a lengthy correspondence may arise as to battles fought and won against the enemy. At any rate, I should like to chronicle a little experience in this direction.

AMERICAN BLIGHT.—In all gardens where this has obtained even a slight hold, it will have increased during the summer of 1893 at an alarming rate. About the only sure remedy known for it up to a very recent date—paraffin in a neat form—is a dangerous thing to employ at this season of the year; indeed, any attempt to check the insect with this agent on and about buds that have to be reserved for another year is likely to result in a case of a remedy worse than the disease. Fortunately, experiments have found an efficient antidote in the shape of Murray's electric insect destroyer. This was what I may call a lucky discovery. Having tried and proved its efficacy in the case of mealy bug, it struck me that this woolly aphid, being of a somewhat similar nature, would be equally susceptible to its influence. This is certainly the case. The insecticide in the proportion of one part to four parts water will turn the cocos into a brown pulpy inanimate mass.

EARWIGS.—It is a hard matter to say whether these or wasps have been the more troublesome, but I think the earwig the more mischievous of the two, and the more difficult to dislodge even in the case of fruit. It does not confine its attention to fruit, Dablias and Chrysanthemums being peculiarly subject to its attack. There was an old idea that in the case of fruit walls it was a good plan to take away the soil to the depth of an inch along the base of the wall early in the season and substitute fresh soil, but this is not of the slightest use. Traps, whether of Bean or Artichoke stalks, or small pots with hay propped away slightly from the wall on short stout sticks, are the only remedy, and this must be attended to early in the season, as soon as the perforation of the leaves indicates the presence of the enemy. The traps must be set to change, for the earwig does not take kindly to traps when it can pass its time in a luscious Peach, Nectarine, or Apricot.

WASPS.—When a short fruit report was written about the middle of July, some thirty wasps'-nests had been taken within a radius of half a mile, taking the garden as a centre, and the number has been increased up to the present date (August 16)

to over a hundred. I notice in a daily paper that a correspondent takes up the pen on behalf of the wasp to such an extent that the extermination of the gentle insect would almost seem in his opinion to come under "the cruelty to animals act." Possibly his ideas in this direction would be somewhat modified if circumstances necessitated his mounting a ladder and gathering a basket of Plums and Apricots where a swarm of his friends were in and around the fruit. So serious has the wasp plague been this year that I think the principle of a little remuneration both for queens and nests should be enforced in every garden throughout the kingdom.

RED SPIDER.—As in the case of earwigs and wasps, this pest has been exceedingly troublesome, and from the season when the leaf of the Gooseberry was just bursting from the bud up to the present time an incessant war has had to be waged against it; nothing in the way of foliage at all susceptible to its attack seems to have escaped. As recorded in fruit report note, one particular stretch of old Peach wall at the back of a Strawberry plantation was very bad, and no ordinary method of occasional syringings with an insecticide seemed to have the slightest effect in reducing the numerical strength of the enemy. So soon, however, as I was able to get rid of the Strawberries, the desired end was effected by mixing on the first dull cloudy day a strong solution of paraffin oil insecticide, rather over half a pint to two gallons of water, and giving the worst trees repeated doses at intervals during the day; literally, in fact, keeping them dripping all day and finishing in the evening with a vigorous application of clear water. What with the spider and the continued drought, a considerable portion of the foliage went wrong, but I saved the greater part of the crop, and the trees are now healthy and clean. Perhaps healthy is hardly the term to apply; what I mean is that the foliage is clean, and the growth now being made indicates a healthier state of things. Peaches, dessert Cherries and all Plums on walls with a southerly aspect have had several soakings of water. Our old walls are answerable in a great measure for the difficulty in dealing with spider unless they get a thorough dressing at least every third year.

BLACK OR CHERRY FLY.—In a note arising from a short paragraph that treated of the liking of the wasp for the substance exuded by this aphid, a correspondent was answerable for the opinion that it was very easily dislodged. Is it so? "Not in a season like this," I fancy, will be the verdict of the great majority of gardeners. The great difficulty has been the necessity for an early covering with nets to protect from birds consequent on the very early ripening of the fruit. Several good drenchings were given prior to this, but we have had to partially remove the nets and continue the dose on two occasions, so persistent was the attack of this particular form of aphid, and I do not know if its cousin, that displays a marked partiality for Plum and Apricot foliage, is dislodged much more easily than black fly. Pear foliage has suffered considerably from the voracious appetite of the Pear slug or leach, as it is occasionally called. The Pear sawfly, which is answerable for the appearance of this slimy insect, would seem to be partial to the foliage of particular varieties, as I find some appear peculiarly subject to its attack. The grub wants checking as soon as seen, or it will quickly spoil the appearance of the foliage. Powder insecticides, as tobacco and Hellebore powders, will effect its destruction, so will a pinch of finely powdered salt. Speaking of Pears, it is time to keep a sharp look out for the attack of birds; they had started tapping Louise Bonne, Marie Louise, and Clapp's Favourite, so these sorts with others have been already netted.

Claremont.

E. BURRELL.

Shrubby Spiræas in clumps.—How well these plants have bloomed this season, and though the later growth is less than usual, owing to drought, there will be no lack of bloom next season if the plants are not starved by being

planted in poor soil. Of late years I have tried various kinds which are often given pot culture, and with excellent results. For instance, *S. media* or *confusa* is a lovely object when planted in clumps. *S. prunifolia* fl.-pl. is also beautiful when a whole bed is devoted to it. This we have with an edging of a dwarfer form, *S. decumbens*, the latter giving a nice finish to the group. *S. Thunbergi* is a choice plant and looks well edged with a small-leaved variety of Ivy. As single specimens, *S. aræfolia*, *S. discolor aræfolia*, *S. Lindleyana*, *S. lobata*, and the taller species are charming objects. They never fail to bloom profusely, and well repay good culture. When mixed in shrubberies they only present a one-sided appearance, but given room they are much more effective.—G. WYTHES.

GARDEN FLORA.

PLATE 925.

CHIRONIA PEDUNCULARIS.

(WITH A COLOURED PLATE.*)

THE Chironias, of which fourteen species have been described, may aptly be called Cape Gentians, as they are the representatives of the Gentian family in South Africa, to which region the genus is restricted. About half of them have been in cultivation, and two of them, viz., *C. ixifera* and *C. Fischeri*, are still—or were a few years ago—included among choice greenhouse plants in England. I think we may call the species here figured the best of them; at any rate, I have seen it grown into a much handsomer pot shrub than any of the others. It is widely distributed over the eastern side of South Africa, forming a trailing or spreading bush and preferring moist, sandy ground. It was introduced into English gardens many years ago. Dr. Lindley described it in 1835, stating then that it was a garden plant known as *C. trinervis*, and that its native country was unknown. It does not appear to have remained in cultivation long after Lindley drew attention to it, which is all the more curious from the fact that, as he stated, nothing could be more easily grown, for it will grow in any kind of soil, thrive out of doors in summer, and survive the winter without suffering in an ordinary greenhouse; also that it is easily propagated from cuttings, and that it is covered with a succession of purple flowers from July to October. It was again introduced in 1887, when I brought seeds of it from Algoa Bay to Kew, where it has since been grown as a greenhouse plant, flowering most freely in autumn. In a wild state it grows amongst Grass and small Sedges wherever there is water, and usually close to the sea. The rosy purple, star-like flowers, mixed with the Grasses, looked very pretty, and they were as abundant in some places as its British relation, the yellow Centaury (*Chlora perfoliata*), is in our chalk pastures. Grown in pots and kept stubby by pinching and tying the stouter shoots to a stake, it

* Drawn for THE GARDEN in the Royal Gardens, Kew, by Champion Jones, August 26, 1892. Lithographed and printed by Guillaume Severeys.

VERBENA PEDUNCULATA

forms a bush 18 inches high, with rich green leaves and long stalked flowers of a bright rosy purple colour, the largest being fully $1\frac{1}{2}$ inches across. Planted on a sunny border in summer and kept watered in dry weather, it forms a loose trailing shrub a yard across and flowers freely in August and September.

Growing along with *Chironia peduncularis* and almost as effective in flower, I found a second species, of which I gathered good seeds and afterwards raised plants at Kew, which flowered and were named *C. palustris* by Sir Joseph Hooker, who described it as a handsome addition to cultivated *Chironias*, adding that, although the district where I had seen this plant had been well explored, it had never been found so far southward by several hundred miles. *C. palustris* differs from that figured, and indeed from all the others of the genus, by its tufted habit, long spatulate, fleshy green leaves and fleshy roots. It grows to a height of 18 inches, with erect branching cymes, bearing numerous bright rose-red star-shaped flowers, each 2 inches across. It blooms in autumn and remains in beauty several weeks. We have not had much success in propagating this plant, cuttings of it having always failed, and when the tufts have been carefully divided, the pieces are not easily established. This and *C. peduncularis* deserve to rank with first-rate greenhouse plants and ought to find favour with anyone who can admire other plants than those that have flowers as big as *Dallicias* or as numerous as tuberous *Begonias*. Other species of *Chironia* cultivated at Kew are *C. ixifera*, *C. Fischeri* and *C. dianthiflora*.

W. W.

THE WEEK'S WORK.

THE KITCHEN GARDEN.

LETTUCE FOR SPRING.—The earliest Lettuces from the open air during the spring are secured from a sowing made in the early part of September, but whether these will eventually become too large to winter safely will depend upon the state of the weather, as if the autumn should turn out very mild the plants from the seed sown now will grow very rapidly, and if the winter should prove severe they will be killed. To guard against this, two sowings should be made, the first now and the second in about a fortnight. Directly the plants are large enough prick them out on rather firm ground, the position being open and sunny. As a safeguard against frost in case this should be exceptionally severe, plant a portion on a west border, this position not catching the early morning sun after a severe night's frost. Hick's Hardy White and Black-seeded Brown Cos are the best of the Cos section, the former turning in quite a fortnight earlier than the Brown Cos. Of the Cabbage section, All the Year Round, Hammersmith Hardy Green and Stanstead Park are the best. This last is a very hardy Lettuce, and if the winter should prove mild it keeps on growing and turns in very early.

CARDOONS—There is no necessity to commence blanching Cardoons thus early in the season, as the flavour is not nearly so good as when this operation is performed a month hence. The blanching is done all at one time. Altogether this has not been a good season for the perfect growth of Cardoons, that is unless planted on deep and rich soil and kept well watered. Any that have run

to seed should be pulled up, the remainder being kept well watered and fed up with liquid manure in which a little salt has been dissolved. Feeding will prevent the plants running to seed.

CHARDS.—Some time since I drew attention to Chards, these being simply the blanched growth of Globe Artichokes, and if the Cardoons have partially failed through running to seed, Chards may be used to fill the gap. All that is necessary to secure Chards is to clear away all small suckers and old flower stems, leaving two or three of the stronger growths. To further assist a rapid growth, these should have a good soaking of liquid manure, when they will be fit for blanching at the same time as Cardoons.

EARTHING UP CELERY.—Although the season has been so hot, yet where the trenches were well prepared and the soil about the roots kept in a well moistened state, the growth has been very satisfactory. In all cases where Celery is sufficiently advanced in growth, excepting, of course, the later supplies, the first earthing may now take place. Where the growth is still backward, excepting a top-dressing to further encourage growth and to prevent the leaves from spreading out, earthing up is better left alone, and growth encouraged by keeping the soil in a well-moistened state, as it must be understood that to secure a free growth and plants that will eventually become solid-hearted, a good foundation must be laid before earthing commences. Before earthing up is attempted see that the soil is in a thoroughly moistened state. The soil must not be thrown roughly against the plants, for if so it will most likely get into the centres, which must be avoided, or early decay will be engendered. To prevent this, each plant should be drawn up with the hands and tied with a piece of matting. Afterwards clear away any sucker growths, also any small outer leaves. A little salt sprinkled on the surface will be of value, as besides being a stimulant, it will assist in keeping away slugs. The soil should be well broken up, as if at all lumpy the stems are apt to become bruised. A heavy earthing is not needed, about 3 inches being quite sufficient for the time being, as it will be another three weeks before earthing is again necessary. In all cases the hearts of the plants must be in advance of the soil. Directly the soil is added, cut away the matting or the hearts will be crippled.

GARDEN REFUSE.—At this season of the year rubbish is apt to accumulate rapidly. Leaving vegetable refuse on the ground to be dug in is very well in principle, as some soils are undoubtedly benefited by its application, but on the other hand it is a harbour for slugs and other root-eating insects. All vegetable refuse I burn, the ashes proving very valuable for many crops.

A. YOUNG.

HARDY FRUITS.

APPLES.—At present there are extra large quantities of fruit on the orchard trees, but the ripening period of very many of the varieties is far earlier than usual, and there is every likelihood of Apples being scarce when most wanted. Garden trees are more variable, the crops in some instances being anything but satisfactory. The fruit on the garden trees also appears to be the most preyed on by birds and wasps, the latter following upon attacks of the former. Not a fruit that has had a small hole pecked in it by birds will keep long after it is gathered, and all such ought, therefore, to be kept apart from that which is sound and good, being also used very soon after gathering. It would be a mistake to drag Apples from the trees before the pips are nearly brown or the fruit comes away somewhat readily, but, all the same, there must be no undue delay in gathering, and no waiting for the usual time to come round. All the trees should be frequently gone over, and the varieties that are fit for storing be unhesitatingly gathered. The longer they are left for the birds and wasps to prey on, the less there will be fit for storing. After they are gathered, and all unsound or damaged fruit separated from that which is

good, store the latter in a cool, sweet-smelling dark place with a view to retarding ripening as long as possible. If stored in a warm, dry room there is every likelihood of maturation taking place rapidly—Cox's Orange Pippin, for instance, being fit to eat early in October instead of a month or six weeks later.

PEARS.—Much that has been advanced concerning Apples also applies with equal force to Pears. Now that Plums and other fruit are getting scarce, wasps will be even more troublesome than formerly. As a rule, however, they do not start on a fruit that is unripe unless birds have previously made small holes in it, and the precaution should have been taken ere this of netting over the trees to keep away the tomits, these being the worst offenders. In some instances it may be found necessary to double the nets, nothing short of this deterring the bold little tits. What fruits have had holes picked in them should be left on the trees. They are of no value for storing, premature decay being inevitable, and left hanging they may be the means of saving sound fruit from being also eaten. Pitmaston Duchess, Beurré Superfin, Louise Bonne of Jersey, Marie Louise, Doyenné du Comice and Conseiller de la Cour already give signs of very early maturation, and in the more southern counties, at any rate, will need to be very carefully gathered and stored by the end of August, if not still sooner. Duchesse d'Angoulême, Beurré Diel, Beurré Clairgeau, Knight's Monarch, Glou Morceau, Beurré Rance and other late or comparatively late varieties look green enough at present and are not fit for gathering; but these also should be watched closely, not leaving them on the trees till dropping commences. Heat, accompanied by a fair amount of moisture, has had the effect of considerably increasing the size of some varieties, and if the trees of the later sorts are kept constantly moist at the roots, the fruit may be both finer and better in quality than usual. While there is yet time, take particular note of the qualities of different varieties, with a view to weeding out any that scarcely pay for the room they occupy. There is a fair number of good varieties that ought to be grown in most orchards and gardens, and if any trees are found to be either unproductive or the variety valueless, then should these be either re-grafted with a superior sort, or else fresh trees of better varieties be planted next season to replace those to be cut out as being no longer worth retaining.

PLUMS.—The sunshine has been too strong for some of the late-ripening varieties, shrivelling taking place accordingly. On cool walls Coe's Golden Drop promises to be fairly late in ripening and extra fine. This season enemies to the fruit crops, and Plums in particular, appear to be extra troublesome. Rats, squirrels, birds, wasps and slugs have all to be reckoned with in some gardens. The gun and trapping are the best remedies for the two first-named, while birds and wasps can be kept out by means of wasp-proof netting, common scrim canvas answering very well. Slugs collect on both sides of a wall, and are quick to discover the whereabouts of Plums. Hunting for them after dark with the aid of a candle is advisable, and they can also be caught in great numbers on heaps of brewers' grains, or anything else saturated with beer. If Golden Drop is gathered when fully ripe, all the sound fruit wrapped separately in squares of tissue paper, and then packed away in a drawer in a cool, dry place, it will keep much longer than if exposed to light and air.

STRAWBERRIES.—Young plants are growing strongly this season, and if kept free of runners, the ground about them also being lightly hoed occasionally, they will attain a size and strength equal almost to what happens in other years to spring-planted stuff. Strong plants, well rooted in pots or else lifted from the open ground, may yet be put out with a prospect of their fruiting fairly well next season, and even should newer varieties not grow very strongly, they will yet do good service next summer in the way of producing early runners in quantity. Runners from such late sorts as Lex-

ford Hall Seedling and Latest of All are naturally late in attaining a size fit for planting where they are to fruit, but it is astonishing what good clusters of fruit are produced by quite small plants put out late on cool borders. Forced plants of Vicomtesse Héricart de Thury and Noble duly turned out or plunged in the open and kept well supplied with moisture during the summer are now producing fruit freely. The fruit, however, keeps badly, and is with difficulty saved from birds, wasps, and slugs. It pays well to prop up the clusters of fruit with crutches made from either Birch or Hazel spray, as thus treated ripening of the later fruit takes place more surely, and slugs do not get at it so easily. Birds must be kept away by means of fish nets, and wasps are not very troublesome if either Davis' or Scott's wasp-killer is used. Fruits that have already been partially eaten should have a little of the poisonous syrup dropped on them and be placed where children cannot get at them. Those plants still in flower or with only green fruit on them can be readily lifted and potted before cold weather sets in and the crops ripened under glass.

W. IGGULDEN.

PLANT HOUSES.

GREENHOUSE PLANTS OUT OF DOORS.—In all cases avoid by every means that can be devised the too common evil of overcrowding plants when stood out of doors. They are frequently dropped down, as it were, at random and allowed to stand thus to their evident injury, if looked at in the proper light. Added to overcrowding is that of not being stood upright; this in itself is a decided evil, causing more watering, with the top of the ball much moister than the bottom thereby. Worms must also be guarded against; these after the rains will be nearer the surface, being also at all times attracted to the bottoms of pots by reason of the moisture found there. In the case of permanent plants, each of the foregoing mistakes in cultural detail should at once be looked to and remedied. In special cases it will be found better to stand the plants upon bricks or slates rather than trust to a bed of cinder ashes, although these are good.

ERICAS AND EPACRISSES FOR WINTER FLOWERING.—These should now be fully exposed to light and air, shading in no case being entertained for one moment. In the case of the Ericas there may be a disposition to mildew with the rains and heavy dews, but it may be easily stopped with sulphur. Look well to the watering and do not let the plants suffer from drought at the roots. If permitted to get dry only a few times, the earlier kinds will inevitably lose their first flowers either by deformity or blindness. Where no potting has this year been done, an inspection should be made as to the state of the plants. Probably a few may be sour-looking upon the surface. This inert soil should be removed lightly and some sand and peat be used to take its place, this being pressed down firmly. It is not advisable to pot now unless compelled to do so in extreme cases; the time has gone by when any appreciable gain would be manifest.

OTHER CAPE AND NEW HOLLAND PLANTS.—These on the whole require a similar treatment. Of course in all cases the locality must be duly considered. In the north, for instance, these plants would not in some gardens be allowed to stand out of doors at all. If the plants be specimens, some considerable amount of care will now be needed in the case of a heavy rainfall to see that they are not too wet at the roots, more particularly those that have been but recently repotted. Where there are any symptoms of red spider, as in the Pimeleas, the Chorozeas and plants of similar texture in the foliage, the syringe should be plied freely until it is exterminated. Thrips in some cases will give trouble, particularly to Indian Azaleas; these will not be dislodged by heavy rains. In any case where the plants stand

in such a way as to grow in a one-sided manner, turning should be resorted to.

CARNATIONS FOR THE AUTUMN AND WINTER.—These invaluable plants must receive every attention needful to their successful flowering in due course. I have just noted that a few plants have been attacked by caterpillars rather badly. As soon as this was seen the plants were closely examined, and then removed to a more open position. Other growers may have been troubled in the same way; it will be well, therefore, to keep an eye on the plants about now, for they are too good to lose just for want of an inspection or two. I find that the caterpillars eat through the flower-spikes just as they commence to push up; this of course throws the plants back. A dusting of soot was also given; it is hoped, therefore, that no more trouble will be caused. The earliest of the spring-struck Winter Cheer are already opening a few of their flowers; these must be housed soon in case of injury from rain. In any case where another shift is needed from a 4½-inch to a 6-inch pot, it may yet be done with advantage; it will, however, benefit those the most that are not too much advanced.

BOUVARDIAS IN POTS AND PLANTED OUT.—The young stock of the former has just got the last shift into 6-inch pots; these will make useful plants in due course. I hope to keep them outside yet for a week or two with a slight protection on cold nights. If housed too soon they come on very rapidly. The last stopping for later flowering should now be given. Where planted out this same advice applies; this stock should be potted up by the end of the next week, or at the most by the middle of the month. Owing to the long drought the growth of these has not been so vigorous as usual, nor have the plants, on the whole, done so well. Where there is any difficulty in striking cuttings early in the spring, I would advise that an experiment be now made instead. I am disposed to think it would be found an advantage.

CALLAS.—These if not yet potted after a resting period should have attention as soon as possible. I do not consider it a good plan to be constantly pulling such a stock to pieces every season; a part one season and a part another will be found better. This will give different sizes of plants as well as (in all probability) a difference in the season of flowering. Planted-out Callas should be lifted soon, even if they afterwards stand outside for a time with a trifle shading when it is needed. It is never advisable to transfer a stock immediately after potting to a close and damp house; it has a tendency to draw the foliage up too tall with no corresponding advantage in its favour. More exposure and a free use of the water-can are better.

JAMES HUDSON.

ORCHIDS.

I WROTE a good deal about the cool Orchids last week, and need not say more except that we seem now to have passed through the hottest month of August I ever remember. Brilliant sunshine and high winds followed towards the end of the month, with much calmer weather and refreshing showers. The cool Orchids have not suffered in the least, but I fancy this is owing to our being careful not to allow the east winds to blow through the house, for instead of opening the ventilators wide and shading heavily, we do not open the ventilators at all in the front, not even at night unless the weather is cool, with the air calm and moist. Owing to the change in the temperature it has been found necessary to start the fires again for the warmest house, for as soon as the rain came I noted the temperature early in the morning, and the warmest house had fallen to 60°. This is too low, and although no harm would accrue to the plants for a few nights, it is better to keep the minimum temperature to 70°. We seldom let our fires go out even in hot weather, but this season has been an exception. As a rule it is better to keep up a little heat in the hot-water pipes both in the Cattleya house and the warmest divi-

sion all through the summer months. Where Phalaenopsis are grown, they require a high temperature at this season of the year and a moderate degree of moisture. Many cultivators seem to have an idea that Phalaenopsis require a very moist as well as a very high temperature, and they keep the ventilators shut, so that the temperature may be kept up at night to 70° or 75°. An over-close and over-moist atmosphere is positively injurious to the Phalaenopsis family. If the above temperatures can be maintained all night, with a little air on in favourable weather and the hot-water pipes not over-heated, no harm will be done; but if the conditions are such that the leaves do not develop healthily, the probabilities are that there will be losses in the winter of many back leaves, and, what is worse, spot may develop amongst the plants. When Mr. Searing grew the Phalaenopsis so well in the late Mr. Partington's garden at Cheshunt, I frequently saw them, and always found the atmosphere rather on the dry side and the house never close and even stifling, as it sometimes is in places where these plants are grown. Twice a year in the spring and autumn Mr. Searing used to give the stages and the floor of the house a good salting. The stages as well as the floor were covered over with clean gravel. The salt was also supposed to have some beneficial effect upon the plants. The well-known Phalaenopsis amabilis is always found growing close to the seashore, sometimes high on tall trees, and also in low positions almost within reach of the salt spray. The knowledge of its habitat might have given the idea of salting down the floors, stages, &c., but chemists would tell us that salt would have no effect upon the plants one way or the other applied in this manner. It would kill slugs and other depredators, and where it is used the gravel is kept very clean; and certainly if it does no good it is evident that it does no harm. The collectors also tell us that the temperature is seldom below 70° and 75°. There is also much moisture, but the plants must have plenty of fresh air around them. The Cattleya house may now have as much sunlight as the plants will stand, and they enjoy an airy atmosphere at this season. The house should be well damped down in the morning and again in the afternoon; that will be enough at this season, besides what moisture is obtained from the watering of the plants. When the plants are freely exposed to the sunshine it may be necessary to look over them daily. It will still be necessary to shade in the hottest part of the day, and care must be taken not to let any of the plants get burned owing to bad places in the glass. Scalded leaves have a very unsightly appearance, and the marks are there year after year, bearing witness to our carelessness. Plants in flower should be shaded well, as the blossoms should be kept perfect for as long a period as possible. *Odontoglossum grande* is a useful Orchid in the Cattleya house in September. The plants which have been kept rather dry during the resting period should now have a good supply of water to sustain the massive spikes of bloom. They must have sufficient ventilation to correspond with the sun-heat, as well as water. *Vanda cœrulea* should also at this season be placed where the spikes now showing get enough sunlight to bring out the colour in the flowers. The plants can stand as much sunlight at this season as any Cattleyas.

The majority of the Dendrobiums have now completed their growth, and at that stage they are likely to start away into growth again unless they are removed into a cooler house with a drier atmosphere. Our latest plants of *D. Wardianum* have just finished their growth, and as these have a greater tendency to start a second time than any others, they are carefully watched and gradually inured to quite a cool dry atmosphere. Some varieties or species have not this tendency to make a second start; indeed, it takes all the season with as high a temperature as we can maintain to complete their growth. The tall-growing species, such as *D. moschatum* and *D. Dalhousianum*, do not complete their growths until October; indeed, in some late seasons they have been kept growing in

a high temperature until November and have flowered superbly the following season. It has been difficult to keep some of the small-growing species, such as *D. Devonianum* and *D. Falconeri*, free from red spider. The use of the syringe has not been spared, and our plants are clean and have made good growth. They, like the others, require a rather cool decided rest in winter. *D. chrysotis* is not often seen in collections, but it is a splendid species to produce its large golden flowers in September on spikes a yard or more in length. I grew it for years in a rather shady part of the intermediate house. The *Dendrobiums* will stand fumigating with tobacco smoke, and they should be kept quite free from the aphid tribe and thrips by this means. I need not say more about the temperatures of the various houses. It does not take much artificial heat to keep the temperatures up to the higher summer minimum.

J. DOUGLAS.

FLOWER GARDEN.

HARDY WATER LILIES.

WITH the advent of so many fine hybrid Water Lilies to supplement the few, but good kinds long known, but more or less existing in obscurity, a new era dawns in water gardening, offering glorious possibilities to all who have water at command. From henceforth *Nymphæas* must be the centre of attraction—the chief feature wherever water is present and permits of their culture. In fact, they need no culture but to be planted. It is hardly possible to name another flower, or family of flowers, that will give so much enjoyment. The newer kinds are becoming better known, and I hope public gardens will lead the way in showing what splendid pictures may be made.

A visitor calling recently noticed the beauty and size of the flowers of *N. Laydekeri rosea*, and at once remarked that the flowers were larger than those of the same kind in the Lily house at Kew. This brings me to the point that rather astonishes me in "F. W. B.'s" interesting article on page 153 in THE GARDEN of August 19. He speaks of *N. Laydekeri rosea* as "the finest in colour of all the pigmy *Nymphæas*." Is it a pigmy kind at all? I have grown the little white *Nymphæa pygmaea*, but its flowers are scarcely larger than a half-crown. It is a pretty gem in its way, but one needs to see it near at hand on the margin of the pond. Not so with *N. Laydekeri rosea*. I only planted it this spring. There are two plants, and the flowers certainly are not smaller than those of our own common white Water Lily. All the coloured kinds that I have hitherto seen are of pale, though distinct shades, and are rather for close inspection, but the kind in question is simply brilliant, whether looked at from the shores of the lake or seen, as is quite possible, nearly half a mile away. I planted a whole collection this spring. They were put into flat hampers and tubs filled with soil, and now the lake is full there is at least 2 feet of water over the crowns of them all. As "F. W. B." says, *N. Laydekeri rosea* can be grown in a tub or large bowl with a foot of water and 6 inches of mud; it is evidently regarded as quite a pigmy kind. The flourishing condition of my plants, their vigour, and abundant succession of blooms prove beyond doubt that the right thing to do with it is to put it into a good depth of water. It is then no

pigmy, but a sterling kind, which when plentiful will make a brilliant effect such as we never expected to see and enjoy on water in the open air. "F. W. B." mentions many kinds, but not all. There is another of the *Marliacea* series named *N. Marliacea rosea* of the same character and line form as *albida* and *carnea*, though, as the name implies, deeper in tint. A plant and flowers of it recently were sent by M. Marliac, but I planted it and all the others at Shrubland two years ago, and noted its merits last year. Then in the *odorata* series there is *rosacea*, which should not be confounded with the Cape Cod form of *odorata*, as they are distinct. It is a charming kind with full starry flowers, and possessed of a delicious odour. Then there is *odorata sulphurea*, another yellow, and distinct from *Chromatella*, a little deeper in tint, having a very long bud, and when fully out often 8 inches across. *N. odorata exquisita*, too, is another kind not mentioned, but having had weak plants of this, I have not been able to form a decided opinion as to its merits. It is very deeply coloured.

Possibly, as "F. W. B." says, Water Lilies are slow in establishing themselves without a deep rich bottom. A great many plants we grow are the same. I have had some Tea Roses taken up to ascertain the cause of their stunted habit, and find them in barely a foot of soil with their roots trying to penetrate the inert sub-soil below. So with Water Lilies; it is not enough to give them water alone, and a pond with a stony or gravel bottom will hardly support them, much less be adorned with flowers. But give them soil of some sort—the mud deposit will do if there is any—and no hardy flower that I have ever dealt with gives so good a return the same season. I have had them all flower within three months of planting with the exception of the variety *Chromatella*, and this, though growing as strongly as the rest, did not flower till the second season. I had this experience with this particular kind three times. After it once begins, however, it flowers as freely as the others.

As to the enemies of Water Lilies, I unfortunately made the acquaintance of another this season, and one capable of much mischief when plants are newly put out. Of the collection I put out in April of this year, three parts of the plants fell a prey to this new enemy, and I thought they might possibly be even killed. Fortunately, they have grown up again, but the check they had was so great, that whilst those that escaped, as *Laydekeri rosea* and *Marliacea albida* and *carnea* have been giving flowers for a long time, many of the injured ones have only recently thrown up leaves to the surface. All the plants had leaves upon them when planted, and my suspicions were aroused by seeing leaves detached and floating. On the water becoming clearer, I could see what appeared like small bits of stick an inch or so long attached in numbers to the leaf-stalk. It was the grub of the caddis fly, with its house upon its back. In the hollow stick it was safe from the fish, and, fastening itself upon the young and tender leaf-stalk, it fed away, or rather several of them did, till the stalk was eaten asunder, and away went the leaf. This was quite a new experience and, happily, of temporary duration, for the grub has changed its state and is now no trouble. I think strong established plants will hardly suffer in this way, but it is well to know what may happen to those newly planted. Water rats must be kept down, or they will have half the flowers. I do not think they touch the leaves. I notice with special satisfaction that these fine hybrid Lilies are becoming cheaper, and therefore

within the means of all who wish for them. Some of them are less than one-fourth what they were three years ago. A. H.

Fuchsias.—The hardy Fuchsias are this season very fine and are all flowering in the greatest profusion. That new dwarf variety, *Dunrobin Bedder*, has proved itself to be a decided acquisition among the smallest members of the genus. The different Fuchsias of this class certainly show signs of becoming more popular than they were a few years ago, and this is not to be wondered at, as with very little trouble they will yield such a display of bloom as to be equalled by but few other classes of plants. Some of the original species, too, that cannot be classed with the hardy varieties are also very showy, notably *F. fulgens*, noted in THE GARDEN as recently as August 12; *F. corymbiflora*, a tall-growing species with large pendulous clusters of bright-coloured blossoms; *F. boliviana*, a good deal in the same way, but dwarfed. Of this there are some examples flowering freely in pots in the temperate house at Kew. *F. triphylla*, that requires nearly the heat of a stove to get it at its best, must always be included in any selection of the different species; while the tiny-flowered *F. microphylla* and *F. thymifolia* are both very pretty.—T.

The dwarf Antirrhinum.—Several fields crowded with the yellow *Antirrhinum* predispose me to write in support of Mr. R. Dean's advocacy of the great merits of some of the improved strains. For wild gardens, rock gardens, and masses in woods or meadows, there are few more striking than the common yellow, the single white, the double white (now comparatively rare); the crimson, scarlet, purple, sulphur, and variegated are also striking. The small double white that I used to bed out years ago had, of course, to be propagated annually, and was kept in store in quantity with *Verbenas* and other bedding plants of the period, including a *Bouvardia* now seldom seen and quantities of Fuchsias, such as *F. microphylla*, *globosa*, *fulgens*, and others.—D. T. F.

Lilium superbum.—This is one of the most beautiful of all Lilies. We recently noticed it very charming in a Surrey garden, where it was planted amongst *Rhododendrons*, which are in perfect harmony with the tall stately stems, that rise over 5 feet in height when in a suitable soil and position. Those who have large gardens and woodlands should make good use of this lovely species and plant it in colonies. We should like to see such Lilies planted more freely in gardens, but one rarely sees much of them, although very hardy. The secret of success with this kind is to choose a moist, partially shaded spot, such as in a clearing amongst trees. These positions are most suitable and the profusion of bold flowers is in contrast to the green colouring of the leaves. The flowers vary in colour from brilliant crimson, and in some there is a larger proportion of orange enriched with numerous shades.

African Marigolds in beds.—These are flowering fairly well this season, and we like them when a small bed can be devoted to the two chief varieties, *Prince of Orange* and *Lemon Queen*. One gets a very poor idea of these showy autumn flowers from their aspect in the exhibition, where they are treated similarly to the show *Carnation* the flowers gathered with little stem and stuck on the box. *Prince of Orange* has bold, intense orange flowers, while these of *Lemon Queen* are soft lemon-yellow, a peculiarly refined and pleasing shade.

Herbaceous Phloxes at Broxbourne.—A very fine collection of herbaceous Phloxes is grown in Messrs. Paul and Son's nursery at Broxbourne. When there recently we made note of a few of the best varieties. One can judge of their fine aspect in gardens when grouped boldly, as in this nursery, and the great point is to reject those kinds having flowers of dull or uninteresting colours—purple

magenta, and so forth. The following are in every respect first-rate, and should be noted by those who require only a small collection: Avalanche and Amazon are two beautiful white-flowered kinds, quite the best of this class. The plants are dwarf, compact, and bear large heads of pure white flowers. Flambeau, Le Soleil, Hirondelle, Henry Murger, Eclairer, Etna, Neptune, Boule de Feu, Eugène Dangainvilliers, one of the finest of all Phloxes; Eclatant, and John Forbes, pink, the eye crimson, are all of much merit.

SEASONABLE NOTES ON FAVOURITE GARDEN FLOWERS.

THE AURICULA—I wrote a few remarks for THE GARDEN upon this favourite old flower, which were published in the number for April 29, 1893; since that time the plants have passed through the hottest summer they have ever experienced. I made an experiment this year with the repotting of the show Auriculas. A frame full of plants was repotted in May and an equal number was reserved to be transferred to new flower-pots in August. They were repotted in the first week of that month, and at that time the plants that had not been repotted were much stronger and had produced a greater number of offsets than those that had been repotted. This might have been expected, as the repotting of the plants in May would be sure to give them a check, from which they would take three weeks or more to recover. Now the others will be thrown back a little, and it is possible that the plants repotted in spring may not overtake those which have just been done. One point I have found out this season worth noting is, that the plants stood upon an ash bottom were much freer from the woolly aphid (*Trama auriculae*) than those placed upon staging or inverted flower-pots. I had not observed this before, but the reason is obvious. The insect does not seem able to exist unless the air can reach it. It does not like moisture and detests soot, which we also mixed amongst the ashes. We sowed the seed saved this year early in July, and already there is a very numerous progeny of fine young plants. Some of them are already large enough to be picked off into small pots. We plant a dozen or so into a 3-inch pot, and when the leaves touch each other, it will be time to replant them again; three this time in a 3 inch pot. I see some amateurs plant a considerable number of seedlings in pans or boxes; they are planted 3 inches or 4 inches asunder and are allowed to flower there. By this system much labour is saved and the plants are put into less space. The Rev. F. D. Horner plants out his seedlings in the open garden during the summer months and lifts them about the middle or towards the end of the month of September, each plant being large enough for a 4-inch or 5-inch flower-pot. They get established in the Auricula house and are strong enough to flower the following season. I grow all my seedling Auriculas and flower them singly in 3-inch or 4½-inch flower-pots, for I find that the seedling plant is more likely to produce a finer truss the first season than it will afterwards.

The alpine Auriculas are generally left to be repotted last. I like to see them finished in August, but more often our plants have been repotted in September, and they generally flower very well the following spring. Except that they are more hardy than the show Auriculas, the treatment they need is much the same, and they may be left freely exposed to rain during the summer months.

CARNATIONS AND PICOTEES.—Layering has been completed for some time, and the favourable weather has caused the layers to form roots very freely. As soon as the plants have become sufficiently rooted they may be removed from the parent plants, and should be planted out where they are to flower. The soil ought to be well prepared previously by trenching it, adding some rich manure, and if the ground has grown Carnations previously it should have an addition of good loam added to it. I place a layer of manure about 6

inches under the surface, and over the manure a layer of virgin loam; it must be free from wire-worms, for this voracious pest will soon destroy the finest specimens. We have planted out the principal lot of seedlings which have been produced from seed sown the first week in April. They are growing very freely, but have needed a good deal of attention as regards watering. A considerable number have not yet been planted out, but they have twice been planted in boxes, and are now stronger than those put out two months ago. We are now preparing ground for them, and they will be planted out probably before this is in print. The plants have been checked in their growth this year by thrips, the Carnation maggot, and green-fly. All these depredators have had to be disposed of one after the other, but the plants were much crippled, and have now only started into good growth. I like to see good strong specimens, so that the layers may be abundant the year following. We have layered seedling plants this year with as many as sixty strong layers upon them, which gives one a good start for next season. Weakly plants will sometimes give less than a dozen layers.

PINKS.—These are very choice garden flowers, and much valued by those who are unable to purchase glass frames or build greenhouses. Pinks may be grown in the garden of the cottager, and are so sweet and lovely, that the wealthiest amateur should not lack a bed of them in the flower garden, or a colony of plants in the pleasure grounds. To have Pinks in a high state of perfection with perfect lacing, they ought to be grown on rich deep well manured soil. This ought to be prepared at once, and much in the same way as I have advised for Carnations. I observed when travelling in the north that some of the growers layered the Pinks in the same way as Carnations. I never take the trouble to do this, but merely slip off the growths and plant them in a moist shady place out of doors or under hand-glasses, as being safer if these are available. The plants should be ready to set out where they are to flower by the middle or end of September. The earlier they are planted out the better chance have they to stand the winter. When planted late, alternate frosts and thaws throw them out of the ground to their serious injury. If the flowers are intended for exhibition, it is best to plant them together in a prepared bed or border. Plant them in rows about 9 in. asunder, and allow the same space between the plants. A light mulch of decayed manure should be spread over the surface of the ground, especially if the weather continues hot and dry. This admits of water being freely applied without causing a hard surface almost impervious to the air.

FORCING PINKS should now be strong specimens if the slips were taken off and planted in March or April as I have advised to be done. They should grow into clumps large enough to fill 6-inch or 7-inch flower-pots by the end of September, which is a good time to lift them, to be planted in the flower-pots. The plants form each a mass of fibrous roots, and if carefully lifted from the ground, planted in flower-pots at once and stood in a close garden frame for a time, they soon become established and are ready to be placed in the forcing houses in December. The forcing Pinks are quite distinct from the laced or florists' Pink; the latter when forced is mostly out of character, the lacing gone, and the flowers of poor quality. The white Pinks are all excellent for forcing, as also are the coloured ones of the old Anne Boleyn type.

PANSIES.—Notwithstanding the excessively hot weather our Pansy bloom has been altogether very satisfactory, and where good growers have exhibited their flowers the standard of excellence has been very high. I think I never saw a better lot of fancy Pansies than those exhibited in July at the great show of plants and flowers at Newcastle-on-Tyne. Our own have continued to flower freely since early in the year until now, but it is time to put in the cuttings for next year, as the ground is wanted for the seedling Carnations. We are putting in the Pansy cuttings and removing the old plants; as they have flowered so long the flowers

are necessarily of poor quality, and it will be more interesting to watch the progress of the young Carnations than to note the gradual decline of the Pansies. The cuttings have been planted in boxes of fine soil, and will be placed under a north wall until they have formed roots. When they are well rooted they will be planted out a few inches asunder in fine soil. We do not plant them out where they are to flower until the spring.

THE HOLLYHOCK.—This stately plant has flowered admirably this season, but the plants have been very dwarf. No disease was apparent until the end of July when it appeared, and has spread rapidly since that time. This insidious parasite seems to lie in wait for suitable weather, when it spreads over the plants, destroying the leaves very rapidly. Condy's fluid applied to the affected part will destroy it. See that the young plants propagated from eyes or cuttings are kept clean, and replant each when well rooted in a 3-inch flower-pot. Remove all decaying flowers, else they will cause the seed-pods to decay. Plants for late flowering should be freely watered and syringed if the weather continues hot and dry.

JAMES DOUGLAS.

Abutilon chrysostephanus grandiflorum is planted out in a bed in the Chiswick gardens. The plant is vigorous in growth, the leaves deep green and the flowers rich yellow, whilst they are produced with great freedom. It seems to be especially suitable for planting out.

Marguerite Carnations.—From seed sown in the spring Mr. Burrell has now at Claremont two or three beds filled with Marguerite Carnations, which are about to bloom profusely. One admirable feature of these Carnations is that they run so even in height; also they have stiff, erect stems and do not want to be tied up. The chief objection to Carnations in the mass is that they must have supports and, of course, be tied, thus giving at once an artificial or formal aspect to the plants. That objection does not apply to these Marguerite Carnations, and it is thus negatively a great recommendation. I expect that these plants will supply flowers in great abundance up to the end of October. Only apparently 5 per cent. produce single flowers. These are, however, not altogether objected to and may be tolerated. It is a good plan to have a successional sowing of these so-called annual Carnations planted out later in the summer for lifting into pots in September, allowing them to bloom all the winter in gentle warmth. They do not of necessity displace the true winter-blooming Carnations, but those who cannot have good stocks of these will find that it is very easy to have a good quantity of Marguerite Carnations from late sowings as advised. Some few may be so good as to be worth propagation, but plants either from pipings or layers will hardly give the same floral results as seedling-raised plants. After all, with seed so cheap and the product so reliable, it seems hardly worth while to trouble about other means of propagation. In such case a sowing may be made in a pan in September, housing the seedlings during the winter and planting out early. One or two sowings may also be made in the spring.—A. D.

Nymphæa odorata gigantea.—Mr. J. L. Childs, of New York, sent us recently plants of the above Lily, and they are already well established in the lake. A large form of the American Sweet Water Lily will be an acquisition even with the splendid hybrids we already have. Little attention has hitherto been given to these flowers, but this will all be altered now, and we hope those who have Water Lilies wild will observe them closely and select distinct forms.

White Tobacco (*Nicotiana affinis*).—Very disappointing is *Nicotiana affinis* as a sunshine flower; indeed, it wears then almost a repelling appearance, especially when in the brilliant sunlight all other flowers seem to be so bright and beautiful. But let the sunshine become shade, the

daylight change to the softer glamour of evening, then is a transformation wrought; the masses of greenish white tubes with petals closed up come nearly erect, the flowers expand and exhibit their snowy whiteness, the rich perfume is liberated, and anything sweeter or more lovely than a mass of the white Tobacco can hardly be found.—A. D.

E. Burrell, in his remarks on this sweet-scented Tobacco, mentions that it has not stood the winter with him in the open (except under a south wall) as well this season as in previous years. He may be interested to know that in our garden it has stood just as well this year. We have a good-sized bed of hardy Fuchsias, and among these we grow some of this white Tobacco. Every autumn we cover this bed with rotten leaves to protect the Fuchsias, allowing the roots of the Tobacco to remain, and every year we get a large number to live through the winter. I have observed that plants put out in the spring do not come into bloom so early by several weeks as those that have lived through the winter. I grow a good quantity of this under a south wall in front of the abbey. In this position it stands through the winter without the least protection, and comes very early into bloom.—J. Crook, *Forde Abbey, Chard.*

A SKETCH OF AMERICAN WILD FLOWERS

THE Pines are lovely now with great masses of Partridge-berry, often several yards in extent, starred thickly with delicately perfumed flowers, and matted so thickly over the ground that it is difficult to find places for one's feet without stepping on the pretty blossoms and the scarlet berries which still cling among the shining evergreen leaves from last year's setting. The luxuriant growth of this handsome plant in its native wilds is a puzzle and mystery which I cannot understand. Like the trailing Arbutus and our charming Pyxie, it languishes amid civilised surroundings. Pyxie and the Arbutus are out of flower, but their thick masses of foliage are always suggestive and attractive. Large beds of both the Chimaphilas here in the woods are putting to shame my efforts to establish them in the garden; still I succeed better with these plants than with the other trailers I have named, but, after all, they do not compare with those in the Pines, which have much larger umbels of waxy, fragrant flowers. All of these little evergreen trailers are handsome in the Pines the whole year through.

The airy Columbine is scattered among the Partridge-berries, and gracefully nods its scarlet flowers over the white and green carpet beneath; and this, too, is much more delicate and handsome here than in our gardens. In a damp place is a great mass of the Lizard's-tail (*Saururus cernuus*) standing so thickly that it excludes almost everything else. The small white flowers are crowded in long, slender, terminal spikes. These spikes are not stilly erect, but they nod gracefully under the swaying of the breeze. In striking contrast is *Aletris farinosa*, or Star Grass, which stands erect and unbending, with a naked flower-stem 2 feet or 3 feet high, terminated by a spike of tubular white flowers, rough on the outside. The roughness is caused by numerous small mealy points or prominences, which, with a low magnifying power, assume quite gigantic proportions. And here is *Coreopsis auriculata*, with handsome yellow flowers on long peduncles, and also two or three species of *Rudbeckia*, our bright Coneflowers, lighting up the waste places with brilliant yellow rays and purple cones. A good many Orchids abound in the Pines. The handsome *Arethusa*, with its fragrant rose-coloured flower, has passed away, and so have the pink and white flowers of the Lady's Slipper (*Cypripedium acaule*), but there still remain *Listera australis*, with a single pair of leaves and a spike of purplish flowers; *Microstylis ophioglossoides*, with only one leaf and a raceme of small greenish flowers, and *Liparis liliifolia*, with two root-leaves, which are large compared with the

small bulb that produces them. Between the two leaves arises a small scape of purple flowers. The Coral Root (*Corallorhiza multiflora*) grows in the dry woods. It has a purple stem, which arises from a cluster of coral-like roots, without any leaf whatever, and yet it supports quite a long spike of small, pretty, light-coloured flowers, the lips of which are spotted with crimson. In more damp, rich soil is the Rattlesnake Plantain (*Goodyera pubescens*), with its tuft of white-veined thickish leaves lying snug to the ground, and from the midst of the little rosette of foliage arises a flower-stalk with numerous small white blossoms. Two or three species of Ladies' Tresses (*Spiranthes*) are also in bloom, some of them with flowers deliciously scented. *Pogonia divaricata* is now blooming in wet places, and *P. verticillata* as well. *P. ophioglossoides* is almost everywhere in the damp Pines, with its ever-present companion, *Calopogon pulchellus*.

Ursinia pulchra (Sphenogyne speciosa).

And the charming fringed Orchids are just coming into bloom. The white fringed *Habenaria blephariglottis* is strikingly handsome, with its scape of pure milk-white fringed flowers; and the yellow fringed *H. ciliaris* is very abundant; the flowers, however, are more orange than yellow. The pale yellow *H. cristata* is here, too, with smaller flowers than those of the other two. Some of the *Asclepias*, or Milk-weeds, are beautiful now, especially *A. rubra*, with umbels of rose-coloured flowers, and *A. pauperula*, with long slender stems terminating in small umbels of large, bright orange flowers. Both of these species grow in the wet woods and are more abundant quite near to the coast. *A. tuberosa* is almost everywhere in the more dry Pines. The Meadow Beauty (*Rhexia virginica*) is brightening up all the moist places with its purple flowers, while the *Roses* are everywhere, and such *Roses* as one never sees further inland. Near the coast they are much more thrifty and far more handsome than the same species a few miles from the shore. When the salt spray can reach them,

the foliage is perfect and of the deepest richest green. May not this give a hint for the treatment of our *Roses* at home?—MARY TREAT, *Finland, N.J.*, in *Garden and Forest*.

URSINIA PULCHRA.

U. PULCHRA, better known, perhaps, under its old name of *Sphenogyne speciosa*, is a very charming hardy annual, introduced, it is said, about 1836, and ever since it has been a general favourite in gardens. It seems to have been almost unknown to botanists, having been first described and figured by Knowles and Westcot in the "Floral Cabinet," 1838, vol. ii., p. 131, fig. 77, and by Paxton, "Magazine of Botany," 1839, vol. vi., p. 77, both of which works give the name of *Sphenogyne*. It is, perhaps, a pity that botanists did eventually find it, as it has had to go through the fire, and have the name changed from *Sphenogyne speciosa* to *Ursinia pulchra*. Its native country is not known with any certainty. It is not mentioned in Harvey and Sonder's "Flora Capensis." Paxton states that it is asserted by some to have been introduced from South America, and by others from South Africa; the latter is doubtless nearest the mark. The plant under cultivation proves one of the prettiest and most useful of border flowers. Paxton in his remarks, 1839, says that "it cannot prove otherwise than an acquisition to any collection; whether in its finely cut foliage, graceful and undulating, or its large and handsome blossoms, it is eminently worthy of admission to all well-arranged flower borders." It fully merits now all that may be said in its favour, standing out, as it does, conspicuously amongst all the later introductions. The flowers of the type are of a rich orange, with a circle of black at the base, and a dark purple disc. *U. anthemoides*, introduced in 1795, and figured in the *Botanical Magazine*, t. 544, as *Arctotis anthemoides*, differs from *U. pulchra* in having the under side of the florets purplish instead of yellow. Though an exceedingly large and varied genus, these are the only species to our knowledge in cultivation at present. D. K.

ORNAMENTAL GOURDS.

It is a matter for wonder that some of the handsome small-fruited varieties of the Pumpkin Gourd are not more grown for garden decoration. They are mainly of moderate growth, and if planted out and supported by means of a few branches, upon which their trailing shoots can rest, they are uncommon and full of interest, the fruit lasting for a long time when fully ripe. One peculiar form is known as the Warty-skinned, the shape of a small Melon, the creamy skin covered with warts; the seeds are small. The white egg-shaped is a very distinct variety, the fruit resembling a large white egg, and if the shoots can be trained along some branches at a height of 4 feet or 5 feet, the fruit hanging down from the stem is highly ornamental. The seeds of this also are quite small, smaller than those of the preceding. Another is the Orange Gourd, the fruit when ripe being so like an Orange, that a pleasant practical joke can be played in the family circle at Christmas by placing one or two among some Oranges in a dish and handing them round to the company. The puzzled look which follows the taking of one of the Gourds is quite diverting. The seeds of this

variety are rather larger than those of the two already mentioned. The Pear-shaped bicolor is in the form of a small shapely Pear, dark green in colour, with longitudinal bands of very pale whitish green running longitudinally, the seeds quite small; and so are those of the Pear-shaped Striped, a singularly handsome form, green near the stem, the thicker part striped with yellow and green, but the marking varies somewhat upon the fruits. The Pear-shaped varieties are among the prettiest which can be grown. The Flat Striped is in the form of a small flattish Melon, the fruit deep green, banded with white, and quite distinct; the seeds also small. The season having proved so dry has not been favourable to these Gourds, but they have all fruited and the fruits have proved very true to character. Seeds should be sown in early spring, and the plants grown on and hardened off so as to be planted in the open as soon as the weather permits. R. D.

FLOWER GARDEN NOTES.

THE spell of exceptional heat we have just experienced dealt rather severely with many inmates of the herbaceous borders, especially those things that were moved early in 1893. This late moving is always bad policy; all work of this description should be finished by the end of November before there is any danger of continued frost, but in this particular case we were not able to do it until the breaking up of the frost in January. With the view, therefore, of rendering a little assistance to many such sufferers, various members of the Phlox, Pyrethrum, Lychnis, Veronica, and Spiræa families, we shall get around them towards the latter end of September as deeply as may be consistent with non-interference with good roots, and remove a portion of the soil, substituting for the same a compost consisting of a bit of good loam and well decayed rather holding manure in equal proportions. This work, if finished before the heavy rains of autumn are over, should benefit the plants wonderfully and set them up for another season.

Violas on our rather light soil have cut up badly the last week, bright sheets of colour being transformed into rather unsightly patches; the only remedy is to remove all seed-pods as quickly as possible. A soaking of water may encourage growth, but is hardly likely to be productive of any further bright floral display so far as this season is concerned. Among the best dry-weather plants, the varieties of Japanese Anemone and most of the Starworts stand out very prominently; they go deep and wide in search of moisture, and consequently are less affected by prolonged drought and intense heat than almost any border plants. An extremely good hot-weather, dwarf plant is the old double Chamomile. I saw a charming bed the other day in which it was used as a carpet to a dark, free-flowering Fuchsia, possibly Abundance. The Chamomile had completely covered the bed and was quite at its best, and in addition to showing off the Fuchsias to the best advantage, was a decided help because of the effectual manner in which, with its dense carpet of foliage, it kept the sun from penetrating the soil. Succulents are revelling in the hot, dry summer and are flowering finely.

Except in very favourable cases, this has been an exceptionally poor season for the trial of novelties. Many things, especially somewhat tender annuals, succumbed quite early in the season, and in no case has anything shown its true form unless special facilities have been afforded in the way of heavy waterings and mulchings. It will soon be time to think about the winter housing of Violets, and preparations for the same, so far as the plants are concerned, may be put in progress early in September, viz., to run the spade round the roots to ensure lifting with a ball. I like to do this work at twice, at intervals of a week. If Violets for lifting were planted on any southerly aspect, they will have required a considerable amount of attention through the summer in the way of mulching and watering, and even with this, al-

though they may have made good growth, they will likely be suffering from the attacks of red spider, as this pest is more than usually troublesome, and very partial to Violet foliage. With buds beginning to show prominently some insecticides are hardly safe; probably one of the safest would be quassia extract in the proportion of half a pint to four gallons of water. All foliage may be safely soured in this, and it will effectually settle most of the spider if the operation is thoroughly performed. The pit or frame should be prepared for the reception of the plants as soon as possible; a good heap of road sidings will furnish a suitable compost.

The nice rain of the 23rd has enabled us to break down and pulverise the quarter intended for border Carnations, and as these with early layering are making nice plants we shall be able to get them out early in September. The prolonged drought seemed to have no prejudicial effect on Carnations except that the flowering season was nearly three weeks earlier than usual, nor did the intense heat seem to limit its duration so much as one would have supposed. Of the varieties grown, Ketton Rose has this year made least grass, and as strong rooted layers of this variety (ready October 1) have been advertised in THE GARDEN at the decidedly high, I had almost written prohibitive, price of one guinea per dozen, it would seem that others have had a similar experience to myself in securing a stock of this particular sort. Beds of pompon Dahlias are now good, and furnishing a plentiful supply of cut bloom. Nearly all varieties of recent introduction throw the flowers well above the foliage and may be cut if required with quite 1 foot of stem, a decided boon for tall vases. Achilles, Catharine, Darkness, E. F. Jungker, Martial and Camelliæflora are a useful half-dozen in various shades of colour.

Claremont.

E. BURRELL.

SALPIGLOSSIS GRANDIFLORA.

THE *Daily News*, in alluding to the co-operative flower show at the Crystal Palace on the 19th last, mentions the Salpiglossis as representing some of the highest achievements on the part of the working man exhibitor, and states that "flowers of this kind were objects of general admiration on Saturday," and it was remarkable how often the question was asked, "But what are they? Their fame is not equal to their deserts." It may be stated that the Salpiglossis is a native of Chili, introduced about three quarters of a century ago. By some termed a herbaceous perennial, by others biennial, the Salpiglossis is now regarded and treated as an annual, as it is found plants come readily from seeds sown in the open and flower finely the same season. Our popular strain is known as Salpiglossis grandiflora, in all probability a large-flowered improvement of *S. variabilis*; the flowers white, rose, crimson, lilac, violet, maroon, yellow, orange, &c., or more generally some combination of these colours, and in not a few cases they are conspicuously veined with some striking tint. The flowers, borne on terminal panicles, are generally very viscid. The forms of Salpiglossis may be regarded as the Orchids among hardy annuals, as there is no annual which presents to view such rare and striking combinations of colour—rich, indeed, and startling in regard to their unusual beauty. Of late years considerable improvement has been made, and yet the possibilities of further development are unlimited.

They, Phlox Drummondii and Sweet Peas were shown in fine bunches from many parts of the country, and they formed the most effective of the many varieties submitted for competition. In the case of light, warm sandy soils the seeds of Salpiglossis can be safely sown in the open ground in March and April when the weather is favourable. In the case of heavier soils, it is perhaps best to treat this subject as half-hardy, raising the seeds in a cold frame or greenhouse, and planting out in the open as soon as sufficiently hardened off. To have fine flowers handsomely marked the plants

should be grown in somewhat rich, warm or light soil in which they can root freely, and the individual plants should have abundant room. They grow to a height of 18 inches or 2 feet, and need protection from sweeping winds. Judging from what was seen at the Crystal Palace, the flowers stand well in water, as at the close of the show they appeared to be among the freshest of the cut flowers shown in water. The viscid character of the foliage makes the stems a little disagreeable to handle, but this characteristic is more than atoned for by the rare beauty of the blossoms. There seems no reason why the Salpiglossis should not be treated as a biennial, in the same way as the Schizanthus, sowing the seeds at the end of August or early in September, and growing the plants on in pots to flower in the greenhouse in early spring. In this way fine and striking examples could be obtained. R. D.

Crocoshia aurea var. imperialis.—The superiority of this variety over the typical form of the old *Crocoshia* (*Tritonia*) *aurea* is strikingly shown by three or four groups of plants which are growing on one of the side stages of the Cactus house at Kew, and are now beautifully in flower. They are, of course, at the cool end, and are planted in beds of loam where they have been for three years. Some of the plants are nearly 4 feet high, and carry large spikes of flowers, the colour of which is a fiery orange-red. The flowers are also as proportionately large as the plant itself, and are, in fact, about twice as large as those of the commoner forms. This variety was introduced from South Africa about five years ago. The Royal Horticultural Society has recognised its value so far as to give it an award of merit. Another equally fine variety of this species is one named *maculata*, which was introduced from South Africa by Mr. James O'Brien five or six years ago. It also grows to a height of 3 feet to 4 feet, and its flowers are close upon 3 inches in diameter. The distinguishing mark of this variety is a reddish-brown blotch near the base of the three inner petals, which, contrasted with the orange-red, adds greatly to the effect. Both for greenhouse decoration and for autumn flowering out-of-doors these two plants promise to become very useful when more generally distributed.—1.

THE FRUIT CROPS.

SOUTHERN.

Burcombe Place, Lewes.—The fruit crops are very good with me this year. I have had splendid crops of Strawberries where others have failed close by. I have never known the Peaches to ripen so quickly as they have this year. The Currants are rather scarce, especially the Red and White; the Black have turned out very good and are very plentiful in this neighbourhood. There are splendid crops of Apples, especially on such sorts as Lord Suffield and Stirling Castle.

The vegetable crops have done fairly well; the Asparagus and Bread Beans have been the best. Peas have been nearly a failure on account of the long dry season. Beetroot, Carrots and Turnips are looking well.—F. HAYLER.

Caversham Park, Reading.—Apples are most abundant. Pears also a grand crop, fine and clean. Apricots quite a full crop. Peaches and Nectarines, both indoors and out, are a good average crop. Grapes are good, especially Lady Downe's, Gros Maroc, Muscats, and Alicante, but the late Grapes are very forward, it being difficult to keep them back. Strawberries were a very heavy crop, but came in a month earlier than usual, and did not last long. James Veitch, Noble, and President very fine. Black Currants an enormous crop. Red Currants and Gooseberries only half a crop. Raspberries a full crop. Morello Cherries most abundant. Nuts poor. Medlars

most abundant. Plums of many varieties are in clusters; although we thinned a good deal, they are much too thick. Tomatoes are very good.

Peas have not been at all plentiful. Cauliflowers early sown, such as First Crop, Early Forcing and Magnum Bonum, were very good; the later kinds such as Walcheren are not good, and since the rains Scarlet Runners and Vegetable Marrows are good. The dwarf Beans, especially Ne Plus Ultra, are very good and came in early. Onions, Parsnips, Carrots, Shallots, &c., are very good, and all winter Kales and Broccoli are now looking promising. Broad Beans after the first and second crops were quite a failure. The Beet gave us some trouble, but it is now growing fairly well.—C. LOTT.

Aston Clinton, Tring.—Apples and Plums, including Damsons, are the principal fruits grown in this neighbourhood, and the crops of all are heavy. Apples are fairly clean and swelling well, but the Damsons are much blighted. I notice the orchards now have a very sickly look, and much of the fruit is falling. We have had but few showers since early in March, and not a single thunder-storm to cleanse the trees. Filberts are a heavy crop, but badly blighted. Walnuts none. Gooseberries, Red and Black Currants are good crops, the two former slightly blighted. Strawberries at blooming time promised to be heavy, but the extreme heat lessened the crop.

Potatoes are a poor crop; they have been cut down several times by frost, the last time on June 1. Victor suffered more by the last frost than other sorts, and can hardly return the seed. Magnum Bonum is looking the most promising. The rapid growth it makes no doubt has prevented the ground being dried up. Late Peas are very poor, being covered with mildew and thrips. Nearly all vegetables are very poor and a short crop consequent on the severe drought and the multitude of insect pests. There is yet seed in the ground that was sown last March; also Potato sets still dormant.—J. W. SHRIMPTON.

Addington, Winslow.—This certainly has been up to the present time a most exceptional season, one to be long remembered and often referred to in years to come. What with the long continuance of dry weather, the great amount of brilliant sunshine and high average temperature, vegetation of all kinds was brought forward in a rapid manner and everything was very early. Fruit trees of all kinds were covered with fine healthy blossom, and there was a fine set of fruit, but a sharp frost of 11° on May 14 did much damage. The Plum crop was seriously injured even where protected. Pears suffered in like manner. Apples, not being so far advanced, did not suffer and they are a heavy crop. Strawberries were plentiful, early, and very soon over. Gooseberries, Red, Black and White Currants very heavy crops. Raspberries poor.

Owing to the excessive dryness of the surface of the ground, seeds of all kinds came up most irregularly, some lying in the ground so long, that when they did vegetate they were of no use at all, causing much disappointment. Those seeds that did vegetate at the proper time have done very well, and kitchen garden crops as a rule are very good. I never knew such things as Peas, Broad Beans, French Beans, Scarlet Runners come into use so soon. The same may be said of all kinds of bush fruits and Strawberries. The drought that set in on March 3 was not fairly broken until May 15, when we had a heavy rainfall, rather local I believe; after the 20th another long spell of dry weather, with many very high maximum temperatures. Total rainfall from January 1 to July 1, 8.24 inches. That is more than we had during the same period in 1892, which was only 6.40 inches. What made the difference to the dryness of the ground was that in 1891 the last three months (Oct., Nov., and Dec.) gave us 12.26 inches, whereas the same months of 1892 only gave 6.82 inches.—JOHN MATHISON.

Elvetham Park, Winchfield.—In the garden here and surrounding district the fruit crops, generally speaking, are under the average. I never remember to have seen such a profusion of Pear

and Plum blossom. The greater part was, however, destroyed by frost, 13° having been registered during the time the trees were in full bloom; consequently the crops are very light. Apples being later fared somewhat better and will be a fair crop, but small in size owing to the long drought. Peaches and Apricots, where protected with double blinds, are average crops. Cherries, Morello, May Duke, Bigarreau Napoleon, Downton and Emperor Francis, a new late variety of great excellence, are good. Strawberries under average, good in quality, but soon over, President being the most reliable kind grown here. Raspberries and bush fruits average crop of fine fruit.

Potatoes light crop, plenty in number, but small, quality, good and so far free from disease. The past spring has been the most trying in my experience; fortunately, we are well supplied with water, and it is needless to say it has been liberally made use of.—T. JONES.

Fulham Palace, London, S.W.—Apples set remarkably well, and held on for some time, but with the continuous heat and dry weather, both leaves and fruit began to fall, leaving only a poor crop. Pears blossomed and set very well; the excessive dry weather not taking much effect on them, there is a fair average crop. Plums flowered well, but did not set freely. Peaches blossomed very well, but did not set. Some very sharp frosts occurred about the time of setting. Only a fair crop on some late kinds. Bush fruits, such as Black Currants and Gooseberries, set remarkably well, and have been a very good crop, large and clean, with the exception of some trained bushes on walls. Some fruits were left to get ripe, and these were, you may say, roasted; the leaves on these trained bushes dropped also very much. Strawberries were a good crop, very clean, but not quite so large as in past years. By the time the picking of the fruit was finished the plants were almost burnt up. Tomatoes were planted out very early; the fruit set well up to the time of the change in the weather, but now, with occasional rain and cold nights they are not setting at all well, and the growth is now getting sappy.

Potatoes show every signs of an excellent crop. Early Puritan stands first on the list as a good early, being a good cropper, the tubers of good size and colour, and excellent quality.—A. J. BALL-HATCHET.

Ham House, Richmond.—Apples and Pears are a fair crop, especially on old trees, young trees on the Paradise having suffered very much from the extreme drought. Morello Cherries promised fine crops, but dropped wholesale at stoning time. Plums are thin, especially on standards. Green Gages are good crops on walls. Strawberries were not up to the average. Red Currants and Raspberries plentiful. Black Currants none, flowers killed by frost. Peaches and Nectarines in the open, good crops and very early.—G. H. SAGE.

Betteshanger Rectory.—Fruit of all kinds is plentiful and good, except Black Currants. Red Currants in the market gardens have been almost given away. Standard Pear and Plum trees and many of the Apples are bent down with the weight of the fruit. A small Morello Cherry which grows here freely has a splendid crop. The crop of Apples promises to be exceptionally heavy.—W. HERRINGTON.

Mereworth Castle.—Considering the long spell of drought the fruit crop generally is very satisfactory. Strawberries were among the worst; although plentiful, the berries were small and soon over. To secure a fair crop next year heavy mulching and an abundant supply of water to build up strong fruitful crowns must be given, otherwise next season there will be a great percentage blind. Noble was fine, but wanting in flavour; Vicomtesse Héricart de Thury good, and for many purposes one of the best, while the plants stood the drought better than some others; Sir C. Napier fruited well, but being later than the two kinds above noted, did not ripen at the tips. Raspberries good. Black and Red Currants fair. Gooseberries heavy, but smaller than usual, while red spider did much harm to the leaves, and the caterpillar was also very destruc-

tive. Stone fruits are good, and I think Apricots are better than I have ever seen them, plenty of fruit and fairly good in size. The old Moorpark, still one of the very best to crop, has been very good. Peaches and Nectarines very fine indeed; Waterloo, Alexander, Amsden June are over, the fruits of fair size and better in flavour than usual. The best way to get flavour in these early kinds is to gather the fruits a few days before they are ripe and put them in the fruit room; this gives more time and the flesh gets ripe through. Later sorts are looking well; all are three weeks earlier than in previous years. Black-fly appeared early in the season, but with a few dressings of quassia and soft soap matters were quickly put right. Cherries good. The wasps are very numerous; we have destroyed 120 nests within half a mile radius, and still they come. The queens came out early, and the weather was dry and warm, so that they (up till now) had matters their own way. Pears of some sorts good and plentiful, others thinly cropped. Apples very good, and although in some instances the fruit has dropped, there will be a good average crop. Plums and Damsons are fair, but the trees were fairly crippled with aphid and red spider. Nuts the best and heaviest crop we have had for years, while the clusters are marvels in size. Newly-planted trees have made very scanty growth.—H. MARKHAM.

Moor Park, Rickmansworth.—Apricots, Apples, Pears, Cherries are heavy crops in these gardens. Peaches, Nectarines, and Plums heavy crops on walls. We escaped the sharp June frosts. Much of the fruit, also Potatoes, suffered very much in the low districts. Bush fruits have been plentiful. Raspberries lasted but a very short time, and much under the average yield. Strawberries that were well supplied with water have been good. Oxonian has proved one of, if not the best late Strawberry we grow. We never had such a crop of Apricots as this year; after two or three severe thinnings the trees are crowded with fruit. I should think we shall be able to gather a quarter of a ton.

On trenched ground Peas have done well through the hot weather. Carrots and Onions are a failure in many places. Vegetables have improved very much since the rain. We have lifted all the early Potatoes; the yield has been good, but tubers rather small. The flavour is splendid. The Ashleaf, Sharp's Victor, and Early Puritan are the best earliest; the late varieties are promising.—J. C. MUNDELL.

Roehampton House, Roehampton.—The fruit crop in this neighbourhood taken as a whole is very good. Apples and Pears are very promising. Plums are abundant. Peaches, Nectarines, Apricots, and Green Gages on walls are very good. Bush fruits were plentiful, but small and dirty. Morello Cherries are almost a failure; they fell off in stoning, and those left on are dirty. The Strawberries with us were very good, and we had a fairly long season. We began picking Noble on May 30, and left off with Waterloo on July 14.

All sorts of vegetables with us are below the average both in quantity and quality.—EDWARD BERRY.

Aldenham, Elstree.—Generally speaking the fruit crops in this district may be said to be satisfactory. The most important of all, the Apples, are quite an average crop, and in most cases the trees are quite free from the caterpillar that has done so much damage during the last five or six years. The fruit is of good size and very promising. Pears a good crop. Plums average, but fruit small. Cherries of all kinds abundant. Apricots good, but ripened very early. Gooseberries and Currants of all kinds very fine, also Filberts and Cob Nuts. The most disappointing of all are Raspberries and Strawberries; fortunately we had a number of the latter on a north border which did well, and kept us supplied for a long time. Our principal beds, in spite of heavy mulching and watering, were completely scorched up. Never in my experience have I seen such quantities of wasps. We have destroyed considerably over 100 nests within a small radius here, using cyanide of potassium, the best

and simplest of all methods for destroying them I am acquainted with.

All kinds of kitchen garden crops, except Turnips, are excellent. Potatoes quite free from disease and of first-rate quality.—E. BECKETT.

Titness Park, Sunninghill.—In the early spring all fruit trees and bushes were well furnished with bloom-buds, and the blossoms expanded from a fortnight to three weeks earlier than usual and were healthy and vigorous. On April 13 we had 6° of frost, on the 14th 11°, and on the 15th 6°. These frosts did great damage to the Pear and Apple blossoms, cut off the newly set Plums, and thinned the Gooseberries and Black Currants. Some gardens suffered more than others. Apple blossoms were not expanded and seemed to be all right, but on being examined the centres were found to be blackened. Pears and Green Gages on the walls escaped here and are a good crop, but most of the pyramid and standard trees are blank, or nearly so. Plum and Apple trees have suffered much from blight. Strawberries in general were a short crop, but where they were well watered before the straw was put on the ground they bore a good crop.

Vegetables have been stunted and blighted all the season from lack of moisture. Peas came in three weeks earlier than usual, but have been a very short crop all the season. Where the ground was deeply worked the supply was kept up till the end of the first week in July, but that hot week finished them; on shallow ground they were all dried up before then. Early Cauliflowers turned in fairly well, but all succession crops were and are very unsatisfactory. Broad Beans have been a failure. French Beans are all blighted and of very little value. All sorts of vegetables have been and are scarce.—THOMAS DUNCAN.

Sewardstone Lodge, Chingford.—In this part of West Essex on a clay subsoil the fruit crop is good with the exception of Strawberries, which were only moderate. Gooseberries, Currants and Cherries have been plentiful. Apples good average crop. Blenheim Pippin, Manks Codlin, Alfriston, Stirling Castle, Keswick Codlin, Irish Peach, and Lord Suffield are carrying fine crops. Pears are over average and remarkably clean and well shaped. Louise Bonne of Jersey, Durondeau, Marie Louise, and Beurré d'Amanlis are promising. Peaches and Nectarines on walls are smaller than usual, but the flavour is good. Plums, on the other hand, are not so plentiful. In some neighbouring gardens with a higher level the crop is both plentiful and good.—J. NICHOLSON.

Shirley, Croydon.—In this neighbourhood the soil is mostly of a light gravelly nature; therefore most crops have suffered through the long drought. Fruits of all kinds are hardly up to the average in size. Apples are plentiful. Sorts having good crops are Stirling Castle, Lord Grosvenor, Lord Suffield, Warner's King, Pott's Seedling, King of the Pippins, and Cellini. Pears are a fair crop, but, where the trees have not been watered, small. Plums of all kinds are an excellent crop. Strawberries were plentiful, but the season exceedingly short. Raspberries good. Peaches, Nectarines, and Apricots are capital crops. In one garden here is a tree of Peach Thames Bank, a fine yellow-fleshed variety of good flavour. It is rather late, but has such excellent qualities as an outdoor Peach, that one wonders why it is so seldom met with. Gooseberries were scarce. Currants an average crop, but in all cases much spoiled with aphides. Cherries, especially Morello, are abundant.

It is yet rather early to speak of Potatoes. They appear free from disease, and in regard to other vegetable crops, all that have not been watered are very poor.—H. SHOESMITH.

Albury Park Gardens, Guildford.—All kinds of fruit here and in this locality have been plentiful this season. Apples and Pears are a very fine crop; also all stone fruits. Plums of all kinds are extra fine. Damsons are in my case one of the finest crops I have ever seen. Currants, Raspberries, and Gooseberries have been very fine. Strawberries also were a very fine crop, but owing

to the drought (nearly five months without rain) soon over. I depend on deep cultivation instead of pouring so much cold water on plants in hot weather; besides, gardeners in nine cases out of ten have no water laid on in the garden, and cannot find labour to carry water for growing crops.

In spite of the drought I have had vegetables in quantity and of the highest quality. Potatoes, Onions, and Carrots are very fine, the last being large and free from grub. There is no trace of disease in Potatoes.—W. C. LEACH.

WESTERN.

Moreton Court, Hereford.—Apples and Pears will be a thin crop. The frost on April 7 did much mischief, and the caterpillar attack on the Apple trees after nearly stripped them of leaves in some places. The trees have withstood the drought on deep land, and since the rain both trees and fruit have improved very much, although Apples and Pears will be this year smaller than usual. Peaches, Plums, and Apricots on walls with me are a very poor crop, fruit small and of poor flavour. The Peach and Nectarine has suffered more than any other from the attacks of red spider. Small bush fruit and Strawberries are a plentiful crop, fruit small and of poor flavour.

Peas are good. Broad Beans a failure here from want of rain. Onions, Parsnips, and Carrots where watered are looking well.—THOS. PARKER.

Hardwick Hall, Chesterfield.—Apples and Pears abundant. Plums exceptionally heavy. Damsons heavy crop. Cherries good crop. Abundance of small fruit except Strawberries, which suffered from the drought. Cob Nuts light. Walnuts good crop.

Early Potatoes abundant and good; late Potatoes are promising. All kitchen garden crops doing well after the rains.—E. WILSON.

Wilton House, Salisbury.—Apples fair crop, trees much infested by insects and the fruit by maggot. The crop of Apricots is the best I have had during the past thirty years, the fruit unusually large, exquisite in flavour and brilliant in colour. Cherries moderate crop, trees much blighted. Currants heavy crop. Gooseberries abundant crop. Peaches and Nectarines good crops, trees much infested by aphids and red spider. Alexander Peach ripe on south wall with glass coping only June 25, Early Louise July 15, Hale's Early July 20; the two latter varieties large in size and exquisite in colour and flavour. Nuts heavy crop. Pears medium crop, Doyenné d'Été ripe June 30, Citron des Carmes July 10, Jargonelle July 20. Plums good crop on walls, poor crop in the open garden, except Rivers' Prolific, on which there are heavy crops. Raspberries heavy crop, fruit small. Strawberries poor crop, especially Noble, Auguste Nicaise, Sir Joseph Paxton, and President.

Potatoes, early, light crop; many of the sets did not commence growth in consequence of the lengthened drought till the end of May, and the late varieties suffered severely, making but little progress till the first week in July, when rainfall sufficient to penetrate the ground produced a marvellous change. Should the autumn prove favourable there will be excellent crops. Very little disease has shown itself up to the present time. Cauliflowers and all the Brassica tribe were with difficulty kept alive. All bulbous and tuberous-rooted crops suffered from attacks of wireworm and grub except where heavy dressings of soot had been applied in the previous autumn. Peas, especially the first crops, were a failure except in deep, rich ground; no amount of watering seemed to benefit them during the extreme heat and drought. Total rainfall for four months 2 895 inches, equal to one month's fall on an average of thirty years. The average temperature during these four months was unusually high. In April the thermometer in the shade indicated 70° and over on thirteen occasions, and on two days it indicated 82° and 83°. In May it exceeded 70° on twenty days, and on two days it reached 80°. In

June it indicated 70° and over on twenty-six days, 80° and over on eight days, and 90° and 91° on two days.—T. CHALLIS.

Glewston Court, Hereford.—In this neighbourhood Apples are about one-fourth of a crop, much of the fruit having fallen from the drought. Lane's Prince Albert, Yorkshire Beauty, Frogmore Prolific, and Worcester Pearmain are bearing the heaviest crops. Many of the cider Apple trees are heavily laden with fruit. Pears in the open quarters are a failure; on walls they are a fair crop. Flemish Beauty, Clapp's Favourite and Beurré Superfin are the best. Plums on walls are a very good crop. Out in the open, bush and standard trees are half a crop. Strawberries have not done well this season. Sir Joseph Paxton and Commander produced the heaviest crops and finest berries; Waterloo has been a complete failure. Sweet Cherries were a fair crop; Morellos are a good crop and the fruit fine. Apricots are the heaviest crops we have ever had, Musch Musch being particularly good. Peaches and Nectarines are excellent in every way, fruit being plentiful, large, and highly coloured. Nuts promise a heavy crop. Raspberries have been a comparative failure, the fruit being small and dry. Currants of all kinds have been an average crop. Gooseberries a very heavy crop, but the fruit is a little smaller than usual. Medlars are an average crop, and the same may be said of Damsons, but red spider has made sad havoc with the trees.

Owing to our system of deep cultivation, the drought has not seriously affected our vegetable crops, with the exception of Peas. These have not been a good crop, and the pods quickly became too old. Cauliflowers have been very good, especially Autumn Mammoth. From seed sown in heat early in January we have been cutting large and tender heads since the middle of June. Cabbages have been much troubled with grubs, otherwise they have done well. Dwarf Beans and Scarlet Runners are excellent crops; of the former Sir Joseph Paxton and of the latter The Czar have been the earliest and most productive. Root crops of all kinds look well, including Onions. Globe Artichokes were seriously crippled by the past winter. Vegetable Marrows have grown vigorously, but so far have not cropped well. Of Lettuces Paris Green and Continuity have succeeded the best, both hearting freely and not running to seed. Celery put out early looks very healthy.—S. T. WRIGHT.

Clarendon Park, Wilts.—The fruit crop in this locality cannot be described as any other than a thoroughly good one. Apples, if not universally abundant, are plentiful in most cases, and the only cases of light crops with us are where the trees were overtaxed last year. Among the kinds of these bearing exceptional crops may be mentioned Stirling Castle, Dumelow's Seedling, Lord Suffield, Worcester Pearmain, Golden Noble, Cellini, Loddington, Keswick Codlin, Cox's Orange Pippin (very heavy), Potts' Seedling, Duchess of Oldenburg, Ecklinville Seedling, King of the Pippins, and Blenheim Pippin. Many of the local kinds, such as Prophet and Ducat, are carrying heavy crops. The fruit of almost all kinds up to the last few days had the appearance of being very small, but thanks to the recent heavy rains things have improved. Pears, again, are all that could be desired, and nothing that I have seen looked happier under the influence of the excessive drought and bright weather. Almost all kinds have set very heavy crops, so that in many cases thinning had to be resorted to somewhat heavily. Amongst others that look exceptionally well may be mentioned Marie Louise, both on walls and in the open; Pitmaston Duchess, Duchesse d'Angoulême, Doyenné d'Été, Doyenné du Comice, and Doyenné Boussoch. Glou Morceau, Williams' Bon Chrétien, Beurré d'Amanlis, Beurré Bosc, Beurré Rance, and Beurré de Capiaumont are all very good, as also are Van Mons, Flemish Beauty, Gratioli of Jersey, and Hacon's Incomparable. Plums are also a full crop both on walls and in the open, and so far as our own garden is concerned, have never been more plentiful for the

past twelve years. Rivers' Early Prolific and The Czar are excellent early Plums, and were they more plentifully grown would prove formidable rivals to the French fruits now having such a run in our towns. Pershore, Victoria, Pond's Seedling, Green Gages of all kinds, Kirke's, and many others are carrying heavy crops, as also are the Farleigh and Shropshire Damsons. Peaches are everywhere abundant, and except for a little red spider where water has been insufficient the trees generally look well. Apricots seem everywhere more than usually abundant, and the trees on all sides are laden with fruit almost to excess. Here it is the best Apricot season I have known for years. Early Moorpark, Moorpark, and Hemskirk are alike heavily cropped, and most of the fruit has swollen to a good average size. Strawberries have not fared so well as some other fruits owing to the excessive heat and drought, but where strong plantations were well mulched early in the season fairly good gatherings have been the result. Cherries have been plentiful and good, May Duke and other early sorts being quite up to the average in quality, and the Morellos with us have not been affected in the least by the drought, and are cleaner and finer than usual. Raspberries have been very plentiful, though the fruit was somewhat smaller, but most of it finished up well. Black Currants have been an enormous crop, while Red and White have been somewhat lighter. Nuts of all kinds, except Walnuts, are plentiful. Gooseberries have been a very heavy crop.—C. WARDEN.

SOCIETIES AND EXHIBITIONS.

ROYAL HORTICULTURAL SOCIETY.

AUGUST 29, 30, 31 AND SEPT. 1.

ANY doubts that may have existed in the minds of horticulturists in general as to the success of this exhibition, which was held at the Agricultural Hall, would soon be dispelled upon taking even a cursory glance of the products shown. The show, taken as a whole, is an undoubted success; some prominent exhibitors, it is true, are conspicuous by their absence, but others have more than made amends for this by their extra exertions, and to these the Royal Horticultural Society is in a large measure indebted for the fine display on this occasion. One conspicuous feature in this show, as in those held at the Temple, is the large number of miscellaneous exhibits. These occupy of themselves a large amount of space and are thoroughly representative of each branch of the profession. Orchids are proverbially scarce during August and September, whilst after the intense heat of late it is a matter for surprise that any are shown at all. There are, however, a few good things. This is certainly the weakest part of the whole show, affording quite a contrast to the Temple show. Plants in flower are not plentiful, it is true, the chief redeeming features being the groups of Lilies. On the other hand, there is an enormous display of hardy herbaceous flowers, finer than which has very rarely, if ever been seen. These do not, in some quarters at least, appear to have suffered from the drought. The Dahlias also contribute largely to the floral section, these in the various classes being shown extremely fine. The Roses amongst other cut flowers stand out most prominently, and the method of exhibiting them *en masse* in baskets and otherwise is a new and improved idea. Many fine blooms are to be found amongst them, the Tea-scented kinds standing out conspicuously. Groups in the competing and miscellaneous classes are grand features in the show. These have been disposed through the centre of the hall with the best effect. A few breaks occur, which is entirely the fault of the intending exhibitors who did not keep to their promises and fill the spaces allotted to them, otherwise the effect of this part of the show would have been perfect. Fruit, competing and otherwise, is of remarkably even quality, lacking in the

number of collections in the large mixed classes, but otherwise of uniform excellence. The large trade exhibits in this department speak well for the enterprise of our nurserymen who make fruits one of their specialities. Vegetables are likewise shown well, the Tomatoes amongst which are as fine as one could wish. Exhibits of horticultural appliances and sundries are numerous, and will be alluded to next week.

Orchid Committee.

A first-class certificate was awarded to—

HABENARIA CARNEA.—A lovely variety with pale flesh-coloured flowers, which as regards size are three times as large as those of *H. militaris*, so finely shown from the Burford Lodge collection last year. The foliage of *H. carnea* is shorter and more in the form of, and resembling that of an *Anæctochilus*. It is a distinct variety. From Messrs. Sander and Co., St. Albans.

Awards of merit were given to—

CYPRIPEDIUM SANDERIANUM SUPERBIENS.—A lovely hybrid (*C. Sanderianum* × *C. superbiens*); the blooms are large as compared with those of most kinds, and being of a light yellow ground colour, with chocolate veins and blotches, are very distinct. From Mr. N. C. Cookson, Oakwood, Wylam-on-Tyne.

AERIDES BALLANTINIANUM AUREUM.—A very distinct form with the lip and central portion of the flower of a clouded golden yellow colour, the sepals and petals of a pale flesh colour. The spike upon the plant shown was long, and bore very fine flowers. From Messrs. Sander and Co.

CYPRIPEDIUM EDWARDI.—A hybrid which, speaking from memory, has a decided resemblance to the Veitchian Niobe. It is a fine variety, the wings long and drooping, being spotted with chocolate, and the flowers generally suffused with purple. From Mr. T. Statter, Stand Hall, Manchester.

Only two groups of Orchids were exhibited, and to each of these a silver Banksian medal was awarded. One came from Messrs. Sander and Co., and comprised choice and new kinds only. Of these *Aerides Lawrenceæ* was one of the best; the plant bore one spike with immense flowers, which are best described as gigantic ones of the old *Aerides odoratum* in form and colour. Several new *Cypripediums* were also shown, the best of which were *C. picturatum*, extra large, with purplish flowers; *C. radiosum*, with yellowish green flowers, and an extra large dorsal sepal. *C. Maynardi* was also shown again. Another good thing was *Calanthe Sanderiana*, a major form of *C. masuca* in every respect.

The other group was from Messrs. Lewis and Co., of Southgate, and was composed of small fresh looking plants in good condition. *Oncidium Jonesianum* (a fine form), *Cattleya guttata* in several varieties, darker than usual, some bordering upon *C. Leopoldi*; *Cattleya bicolor*, with *Oncidium*s in variety were included. Of these latter *O. prætextum* and *O. tigrinum* were the best. This exhibit was finished off with small plants of Maiden-hair Fern, which always give a finish to a group of small Orchids. A few Orchids included in other groups are noted under the several exhibits in the miscellaneous classes.

Floral Committee.

First-class certificates were awarded to the following:—

WEIGELA EVA RATHKE.—A very decided acquisition to flowering hardy shrubs. Its flowers are of a dark red self colour, of good substance and in large trusses; but its chief value is the fact that it is a perpetual summer-blooming plant. From Mr. Anthony Waterer, Knap Hill, Woking.

AGAVE LEOPOLD II.—A hybrid raised by the exhibitor. In general appearance and character it is much after *A. filifera*, but quite distinct and in every respect superior; the leaves are narrower, of a dark green shade and very flexible. The chief ornament of the plant is the long hair-like filaments, which are densely set upon the edges of

the leaves; these filaments are of a silvery shade and 3 inches or 4 inches in length. From Mr. Kellock, Stamford Hill.

AGAVE UNIVITTATA.—A variety of Yucca-like growth and of sturdy, compact habit; the leaves have a stripe of yellowish green down the centre, the rest of the leaf a dark green, with a silvery white margin. Also from Mr. Kellock.

LILIUM HENRYI.—This appears to be a distinct species, the nearest to it in the colour of the flowers being *L. tigrinum*, and in form those of *L. pardalinum*. The colour is rather paler than in the former, and a few small spots of a dark orange shade are seen here and there; the foliage is of a dark green shade and lanceolate in shape. Two plants were shown, one taller than the other. From Messrs. Wallace and Co., Colchester.

EXACUM MACRANTHUM.—Not a new plant, but one that is well worthy of the very highest award. The flowers are of a deep rich blue and about 2 inches in diameter; the stamens of a rich golden yellow. The combination and contrast in colour being so decided make it a very showy plant. The example shown bore eight trusses of seven or eight flowers each, and had been grown in a 4½-inch pot. From Sir Trevor Lawrence.

CORNUS BRACHYPODA VARIEGATA.—A fine acquisition to hardy variegated shrubs. The colouring is as in the variegated *Negundo*, but better. A very showy plant. From Messrs. Veitch and Sons.

CLERODENDRON TRICHOTOMUM.—A valuable hardy autumn-flowering species introduced from Japan. It is of free growth, and attains the height of from 8 feet to 10 feet. The foliage is dark green; the flowers of a creamy white, with a purplish calyx, and delightfully fragrant. From Messrs. Veitch and Sons.

Awards of merit were given to—

GLADIOLI BERNICE. pale straw colour with long spike; Gertrude, pale soft blush shade with extra fine flowers suffused with rose; Orlando, dark salmon-red with darker veining; Cassandra, pale creamy yellow, extra fine. These were all from Messrs. Burrell and Co., Cambridge, and are marked advances.

CACTUS DAHLIAS GLORIOSA. bright scarlet with large flowers and twisted petals, a rich colour; Chancellor, dark crimson shaded with purple, an extra fine variety and quite distinct; Lady Penzance, a pale lemon-yellow, unlike any other variety of the true Cactus type, one of the best new kinds. The foregoing were from Messrs. Keynes, Williams and Co., Salisbury.

CACTUS DAHLIA ERNEST CHEAL. a dark orange-crimson, very full, and quite a distinct kind. From Messrs. Cheal and Son, Crawley.

POMPON DAHLIA ROWENA. a dark orange tipped variety with pale yellow base. From Mr. C. Turner, Slough.

FANCY DAHLIA MRS. MORTIMER.—In colour decidedly distinct the flowers large, pale yellow, tipped with pale lilac, which fades to white. From Mr. Mortimer, Rowledge, Farnham, Surrey.

ROSE DUKE OF YORK (China).—A valuable autumnal-flowering variety with some resemblance to the well-known *Homère*, but much deeper and richer in colour. From Messrs. W. Paul and Son, Waltham Cross.

HELIANTHUS RIGIDUS MISS MELLISH.—A fine acquisition to these valuable hardy border flowers. This plant is quite distinct from the ordinary form of *Harpalum rigidum*, which this season is only 2½ feet high, the semi-double form 3½ feet, and Miss Mellish 5½ feet. This new form has a double row of petals, and is a showy kind, possessing good powers of endurance when cut. From Rev. W. Wilks, Shirley Vicarage, Croydon.

CARNATION MRS. LEOPOLD DE ROTHSCHILD.—This received an award of merit first at the Chiswick show last year, and which award is now again given, proving its value. It is of free growth and also free-flowering, the colour rather deeper than in Miss Jolliffe, the perfume at the same time being delicious. From Mr. Reynolds, Gunnersbury Park, Acton.

PENTSTEMON CLEVELANDI.—This, if not a distinct species, is nearest in its resemblance to *P.*

barbatus, but the colour is deeper, in this instance a rich orange-scarlet, the flowers being more densely set on the spikes, and rather narrower but longer—a fine border flower. From Sir Trevor Lawrence.

PINK (PERPETUAL) ERNEST LADHAMS.—A profuse flowering variety of vigorous growth with large pale pink flowers and dark bases to the petals—an acquisition to its class. From Mr. B. Ladhams, Shirley Nurseries, Southampton.

Fruit Committee.

There was a very large number of exhibits before this committee, the fruit trees in pots from Messrs. Rivers, Bunyard and W. Paul and Son making a grand display. The very fine fruit from Messrs. Veitch, Bunyard, Paul and Cheal was worth a higher award. Seedling Melons, Apples, Tomatoes, and some of the largest Onions ever staged were shown. Messrs. Rivers, Sawbridge-worth, had an extensive and varied collection of fruit trees in pots. The Vines were a grand feature, being trained flat and laden with bunches of well-finished fruit. The varieties were Dr. Hogg, Black Hamburgh, Gros Maroc, Gros Colman and Golden Queen. Some very fine bushes of Exquisite Peach, a showy yellow-fleshed variety, also Albatross, Princess of Wales and some seedlings were also shown. Souvenir du Congrès, Louise Bonne of Jersey, Williams' Bon Chrétien, Beurré Superfin, Pitmaston Duchess and Conference Pears were also shown in pots. There were some fine Plums and Apples, including Rivers' Codlin, The Queen, Ribston, Emperor Alexander, and Peasgood's Nonsuch (gold medal). Messrs. Bunyard, Maidstone, had a very large group of fruit trees in pots, 150 dishes of fruit, thirty-six flat baskets, also a number of plants of forcing Strawberries and Tomatoes. Apples were fine, the fruits of Worcester Pearmain, Lady Sudeley, The Queen, Baumann's Reinette, and Grenadier being specially good. Some extra fine fruits of Dr. Jules Guyot Pear were staged, and a number of dishes of Melons, Grapes, Damsons, Nuts, Plums and Crabs (silver-gilt Knightian medal). Messrs. Veitch, Royal Exotic Nurseries, Chelsea, had a very large number of dishes of fruit. A few Peaches and Figs in pots formed the centre of their extensive collection. The fruit staged was gathered from pyramids and bush trees in the open. There were some very fine Apples, Warner's King, Cellini, Lord Suffield, Seaton House, Frogmore Prolific, Lane's Prince Albert, Albury Park Nonsuch, Schoolmaster, Bismarck, Ribston, American Mother, Jefferson, King Harry, and Duchess Favourite being grandly coloured and of great size. Pears were also shown well. There were some very good Pitmaston Duchess, Marie Louise, Beurré Superfin, Triomphe de Vienne, and Thomson's Pears, with Plums, Morello Cherries, John Downie and Siberian Crabs, and Raspberry Superlative (silver-gilt Knightian medal). Messrs. Wm. Paul and Son, Waltham Cross, staged a group of fruit trees on the ground, and this is certainly a better way to see fruit in its natural condition, as when raised on stages 4 feet high the pots are the most prominent feature. Some extra good bushes of Figs were staged; also good varieties of Peaches, Pears, Apples, Plums, and 100 dishes of fruit (silver-gilt Knightian medal). Messrs. Cheal, Crawley, had a varied collection of fruit, there being also a nice background of trees in pots, chiefly the best kinds of Apples and Pears, heavily laden with highly coloured fruit. There was also an interesting collection of Gourds, Cobs, and Crabs, and some grand dishes of Apples, Pears, and Plums, the varieties consisting of those named in the preceding collection (silver-gilt Knightian medal). Messrs. Spooner, Hounslow, staged a smaller collection of good fruit in dishes, their dessert Apples being very good, and the Pears large and clear skinned. Some baskets of Tomatoes gave the collection a bright appearance (silver Knightian medal). Mr. Bythway, Llanelly, Carmarthenshire, had a good collection of Apples consisting of well-known varieties (silver Knightian medal). An interesting exhibit was staged by Mr. Trotter, Broomsbarrow Gardens, Ledbury. This consisted of two cases

of dried fruits, one of conserved and one of evaporated fruit, dried by the Mayfarth process; also Apples, Plums, Cherries, Damsons, Apricots, and Pears with a few vegetables (silver Knightian medal).

Messrs. Peed and Sons, Norwood, S.E., had a collection of fruit, chiefly well-known kinds of Apples and Pears (silver Banksian medal). Mr. J. Clarke, Albion Nursery, Farnham, staged thirty-three well-finished bunches of Grapes grown without heat (silver Banksian medal).

Mr. Hudson, Gannorsbury House Gardens, Acton, staged the new Lady Hutt and Appley Towers Grapes from Vines inarched on Muscat; also Appley Towers on own roots in nice condition. Bunches of Gros Maroc on Muscat stock were also shown. Mr. Fitt, Panshanger Gardens, Herts, had two good clusters of Lady's Finger Banana, a variety certificated recently. Messrs. Carter, Holborn, staged good fruits of Tomatoes in variety. Mr. Thomas, Royal Gardens, Frogmore; Mr. Smith, Fairlawn, Totteridge, and Mr. Gilman, Ingestre, sent seedling Melons. Seedling Peaches came from Messrs. Veitch, Exeter, and Mr. Divers, Ketton Hall, Stamford. Good fruits of Barrington and Chancellor Peaches from open walls came from Mr. Miller, Ruxley Lodge, Esher. The Currant Grape was sent from Chiswick Gardens.

Mr. T. Wilkins, The Gardens, Inwood House, Blandford, staged twelve grand dishes of Onions, the best being Inwood Favourite, a red-skinned variety of great weight (silver Knightian medal). Messrs. Cannell, Swanley, had a varied collection of Onions from the open ground, the best being Anglo Spanish (silver Banksian medal).

Some specially fine clusters of a Tomato named Allsop's Selected came from Mr. Allsop, Dalton Hall Gardens, Yorks. A seedling Potato (George Dickson) came from Mr. Mackereth, Ulverston, and also one from Mr. Young, Barton Court, Kintbury. These two varieties were asked to be sent for trial to Chiswick. Mr. South, Neasdon, sent a new Potato, nearly black, a long tuber, not at all handsome, having a lot of eyes. Messrs. Dobbie, Rothesay, had some grandly grown Leeks, the useful Golden Ball Turnip, Red Celery and Invincible White Celery, good Beet, Parsnips, and Parsley. Messrs. Cross, Glasgow, had some fine bunches of Grapes, Tomatoes, and other fruits, and Messrs. Harrison, Leicester, a representative collection of roots, seeds and vegetables.

A miscellaneous collection of foreign vegetables grown in the open was sent by Mr. Emerson, Broadstairs, the Pe Tsal Cabbage being requested to be sent for trial to Chiswick (bronze Banksian medal).

In the competitive classes there was no really fine indoor fruit, whilst the hardy fruit, Apples, Pears and Peaches, were specially fine. For twelve dishes, amateurs only, one collection was staged, and that a very medium one. The Grapes were poor, and a huge Melon was out of all proportions to the other dishes. The Pears (Beurré d'Amanlis) were good, and there were some nice Brown Turkey Figs. Mr. J. McIndoe, Hutton Hall Gardens, Guisborough, was the exhibitor, and the Veitch Memorial medal was not awarded. For six dishes there were three lots staged, and none remarkably fine. Mr. Ocock, Havering Park, Romford, was first, showing Muscat of Alexandria and Alicante Grapes, a good dish of Osprey Peaches, Elruge Nectarines, and Williams' Bon Chrétien Pears and good Melons. Mr. Masterson, Weston House Gardens, Shipston-on-Stour, was second. He had good Muscats, but poor Madresfield Court Grapes. For three bunches of Muscat of Alexandria Mr. Reynolds, Gunnersbury Park, Acton, was an easy first, having medium-sized bunches, but grandly finished (the Turner Memorial cup was awarded to this exhibit). Mr. Winter, Walk House, Barrow-on-Humber, was second, the berries being small and the bunches thin.

For three bunches of Black Hamburgh, Mr. W. Elphinstone, Shipley Hall, Derby, was first, with good-shaped, grandly coloured bunches, berries being large and even and bunches well shouldered. Mr. Reynolds was second with smaller bunches,

but of perfect finish. For three bunches of any other white variety (Muscat of Alexandria excluded), there were only two exhibitors, Mr. Reynolds being first with medium-sized Buckland Sweetwater, good in berry and very bright; Mr. Osman second, with good bunches of Mrs. Pearson, but hardly ripe. In the class for any other (Black Hamburgh excluded), there were five competitors. In this class were undoubtedly the best Grapes in the show. Mr. S. T. Wright, Glewston Court, Ross, Hereford, had perfect bunches of Alicante of great weight and good finish; the only blemish was a few berries rubbed in travelling. Mr. Howe, Park Hill Gardens, Streatham, was second. For eight varieties of Grapes, distinct, two bunches of each, the first prize went to Mr. Reynolds for large bunches of Trebbiano, Chasselas Napoleon, very good and of taking colour, Mrs. Pearson, Gros Maroc (very good), Alicante, Madresfield Court, Black Hamburgh and nicely finished bunches of Muscat of Alexandria, the second prize going to Mr. Barry, Tewkesbury Lodge, Norwood, Gros Guillaume, Alicante, Alnwick, Gros Maroc, and Trebbiano being remarkably good. For four dishes of Peaches, Mr. Divers was first with large fruit well coloured, but not quite ripe; second, Mr. Woodward, Barham Court, Maidstone, with riper fruit a trifle smaller. For two dishes, Mr. Tidy, Stanmore Hall, Great Stanmore, was first. For four dishes of Nectarines, Mr. McIndoe was first with nice fruit of Byron, Spencer, Humboldt, and Pine-apple; these were evidently orchard house fruit. Mr. Woodward, Barham Court, Maidstone, staged outdoor fruit more highly coloured, larger, but not so ripe. There were grand examples of Stanwick Elruge, Humboldt, Rivers' Orange, and Pine-apple. For two dishes, Mr. Divers was the only competitor. For two Melons, distinct, Mr. Ocock was first with a seedling and Countess; second, Mr. Messenger, Woolverstone Park, Ipswich. For four dishes of Plums, Mr. McIndoe was first. For the larger collection, only Mr. McIndoe staged. In the class for six dishes of Apples there was a spirited competition, and Mr. Woodward was first, having the best dish of Apples in the show—Peasgood's Nonsuch, magnificent fruit, his other fruits being Warner's King, Lord Suffield, New Hawthornden, Washington, and Emperor Alexander. Mr. Chambers, Beech Farm, Mereworth, Maidstone, had smaller fruit, but a good half-dozen dishes. For six dishes of Pears, Mr. Woodward took the second place, the premier award going to Mr. J. Gibson, Draycot House, Chippenham, with very large fruits. For a collection of Lardy fruits, the prize being given by Mr. Watkins, Hereford, Mr. Woodward was far ahead of the other two competitors, staging Triomphe de Vienne, Pitmaston, and Jules Guyot Pears in grand condition, good Nectarines, Peaches, Plums, Apples Alexander and Yorkshire Beauty; second, Mr. McIndoe, with smaller fruits, he having Gooseberries, Cherries, Currants, and Nuts in addition to the fruits named in first lot. For a collection of Apples, Mr. Bunyard, Old Nurseries, Maidstone, was first, staging no less than 120 dishes, consisting of leading varieties, large, and of good colour, Messrs. Cranston (Ltd.), King's Acre, Hereford, being second with 100 dishes, little inferior to the first. For Mr. Bunyard's prizes, three dishes dessert and kitchen Apples, to include his Lady Sudeley, Mr. Woodward was first, having Ribston and Washington; second, Mr. Chambers. Messrs. Woodward and Chambers took the awards for three dishes of kitchen Apples in the order named. Mr. McIndoe was first in the collection for orchard house fruit, Peaches and Nectarines excluded, having a splendid dish of Peasgood's Nonsuch Apple, Plums, Figs, Lemons, Passion fruit, Guava, and others. For nine orchard house trees in fruit there was only one lot, Mr. Bunyard taking first with good trees well laden with fruit, Apples, Pears, Plums, and Peaches being staged.

Vegetables

brought out little competition. For the silver cup presented by the Turner Memorial trustees, Mr. Wate, Glenhurst, Esher, was first, having good

Mammoth Cauliflower, Veitch's Early Rose Celery, Scarlet Intermediate Carrot, Silver Ball Turnips, Satisfaction Tomatoes, Pragnell's Beet, Student Parsnip, Ailsa Craig Onion, good Lyon Leeks, Potatoes and Artichokes. Mr. Wilkins, Inwood House, Dorset, was a very close second; indeed, he had a fine collection, but not put up so well, the Potatoes and Onions being superb. For six kinds, Mr. Payne, Neasdon, was first with a moderate half dozen. For Messrs. Carter's prize Mr. Waite would have been easily first, but included Potatoes, which were not allowed. Mr. Payne took second, the only award given. For twelve dishes of Potatoes there was a brisk competition. Mr. Chopping, Sittingbourne, took first with clear even tubers, Mr. Waite second with larger and well-grown tubers. For a collection of salad there was only one exhibitor. This was shown crowded in a round plate by Mr. Waite. Tomatoes were a nice lot and good. Mr. Howe, who was first, had very fine Ladybird, Perfection, and Silver's Invincible. Mr. Ryder, Orpington, Kent, was second with a fine dish of the old, but good Trophy and Ham Green. For Messrs. Deverill's prize for pedigree Onions Mr. Wilkins staged grand Lord Keeper. The competition was spirited for Messrs. Dobbie's prize for Leeks. Mr. Gibson, Lyminnton, Ayrshire, staged perfect specimens of Dobbie's Champion. Second, Mr. Watson, Lanark.

Plant Classes.

These are, as afore stated, chiefly noteworthy for the various groups. Three classes were provided for groups as usually shown, one of 800 square feet, to consist of fine-foliaged plants only, in which Mr. H. B. May, Dyson's Lane Nursery, Upper Edmonton, alone exhibits; another of 300 square feet, in which Mr. Hudson, of Gunnersbury House, Acton, is likewise the only competitor and another of 150 square feet, in which Mr. Mellis, Sewardstone Lodge, Chingford, occupies the same position. These groups left nothing to be desired as to the plants' general effect, or as to the quality of the material employed in each instance. It is to be regretted that there were not more entries, but the season has been a trying one, more particularly as regards flowering plants; this is to be clearly seen throughout the show in all the miscellaneous groups as well. In the class for a group of Lilies, the only exhibit is that of Messrs. Bunting and Sons, Lexden Road, Colchester, but it is an excellent one both in quality and culture. It is comprised of fine forms of *Lilium auratum*, as *platyphyllum* and *virginale*, of *L. tigrinum splendens*, *L. speciosum album*, and *L. sp. roseum* in the best varieties of each, and very dwarf plants of *L. longiflorum* and *L. Bate-mannianum*. Dwarf growth throughout characterises this exhibit.

Strange to say, no one competed in the class for tuberous Begonias, the well-known exhibitors each being conspicuous by their absence. The same applies to Cannas, to early Chrysanthemums, and to China Asters. In the two first-named classes and that for Begonias this is a matter of surprise and regret. There was only one entry of Pelargoniums (of any class or of various classes); this was from Mr. Hudson, and consisted wholly of sweet-scented kinds, large specimens and otherwise, in twenty varieties. One entry only was made of Coleus; this was from Mr. Mellis, the plants being well coloured, dwarf, and good; larger never need be encouraged. There were two exhibits of two Palms, these were grand plants in each case, the best pair being that from Mr. Howe, Park Hill, Streatham, the kinds *Scaforthia elegans* and *Kentia Fosteriana*, and the other from Messrs. B. S. Williams and Son, Upper Holloway, of *Areca sapida* and a fine *Kentia australis*. In the class for two Tree Ferns, Messrs. B. S. Williams and Son alone competed, and the same exhibitors had the only collection of eight Crotons, well coloured and healthy plants of moderate, but useful size, and of twelve Palms, excellent examples of decorative plants, not too large, but in the best of health.

For twelve exotic Ferns there were two entries. The best of these by far were those from Mr. Howe, who staged really fine plants, all in good

health, the most noteworthy being *Adiantum Weigandi*, *A. concinnatum latum*, A. Williamsi, A. tenerum, *Gymnogramma schizophylla gloriosa*, *Marattia elegans*, a fine plant of *Nephrolepis exaltata* and another of *Goniophlebium subariculatum*. Mr. P. McArthur, Maida Vale, W., was second. In Fuchsias, again, there was no entry. In the classes for zonal and Ivy-leaved Pelargoniums and Achimenes there was no competition.

Miscellaneous Groups of Plants.

The best of these by far, as regards quality and quantity, was that staged by Messrs. B. S. Williams and Son. This group was a fine feature in the centre of the hall. Two grand Tree Ferns and a large *Kentia* were the central objects, around which were arranged other Palms, with *Dracenas*, *Anthuriums* (*A. Warocqueanum* in fine health), *Phyllo'anium Lindenii*, well-coloured Crotons and several Orchids at intervals, as well as *Nepenthes*. Among the Orchids were *Cypripedium Morganii*, *Odontoglossum Alexandrae*, *O. vexillarium*, *Oncidium incurvum*, and *Coleogyne Massangeana* (silver gilt Flora medal). Messrs. Shuttleworth and Co., Peckham Rye, had also a large group of Palms and other fine-foliaged plants, many of the Palms being of large proportions and in rude health; this group was well finished off at the base (silver-gilt Flora medal). Messrs. Cutbush and Son, Highgate, had a large group. This again consisted largely of Palms, but was brightened up by flowering plants around the front and sides, making altogether a fine feature (silver Flora medal). Mr. Hudson showed scented-leaved Pelargoniums, standard *Aloysia citriodora* (Lemon Plant) and *Campanulas*. Amongst the Pelargoniums were two large specimens of *P. radula* trained as window screens, each one being 7 feet in diameter at the base, forming an exact semi-circle (silver Flora medal). Messrs. Paul and Son, Cheshunt, had an exceedingly interesting and attractive exhibit in Bamboos, large plants in tubs, and other Grasses, as *Eulalia japonica*, *zebrina* and *variegata*, *Typha minor* and a few excellent plants of *Cannas* in flower (silver Flora medal). Mr. P. McArthur had a capital group of decorative Palms and other fine-foliaged plants, with a few good Orchids intermixed, forming a good bank (silver Flora medal). Messrs. W. and J. Birkenhead, of the Fern Nursery, Sale, Manchester, showed an extensive group of Ferns in great variety, the plants of decorative and medium size, affording practical information as to the many kinds which are suited for culture in a small state other than those usually seen. To enter into names would require much space; the tinted forms of *Adiantums*, however, should be alluded to (silver Flora medal). Messrs. J. Peed and Sons, Roupell Park Nurseries, S.E., had a showy group of small plants of *Caladiums* in the newer varieties, those shown having very novel and distinct variations in the colours of the foliage (silver Banksian medal). For large specimen Tree Ferns and *Dracenas*, Messrs. B. S. Williams received also a silver Banksian medal. Messrs. Cannell and Co., Swanley, had a novel and interesting exhibit of succulent plants, the best kinds for general culture being shown in fine health (silver Banksian medal). Mr. C. Turner showed well-grown *Liliums* and *Hydrangea paniculata*, forming together a capital group (silver Banksian medal). Mr. H. J. Jones, Lewisham, staged a showy group of zonal Pelargoniums, including Mrs. W. Wright, a shade of dark magenta, very distinct; also early Chrysanthemums and a new pompon Dahlia with real pompon flowers, the plants of this in pots showing it to be thus a capital pot plant for the autumn. With these were included well-grown tuberous Begonias from seed sown this past spring (silver Banksian medal). Mr. Anthony Waterer, Woking, showed four fine plants of *Abies* in *A. pungens glauca* and *A. p. argentea*, the former being the more distinct, the glaucous or grey-green shade of which is exceedingly fine. It is a grand conifer without doubt (silver Banksian medal). Messrs. W. Barron and Sons, Borrowash, Derby, showed a large and varied collection of cut specimens of foliage of orna-

mental deciduous trees, affording a good guide to future planters (silver Banksian medal).

Cut Flowers.

These formed, next to the fruit, the most important feature of the exhibition, but, unfortunately, quickly faded. A four-day exhibition is too long where cut flowers are concerned. The classes, as a rule, were remarkably well filled. Dahlias were splendid, and about nine classes were set apart for them. The chief class was for a collection arranged for effect, and there was a sharp contest for the first prize, which went to Messrs. J. Cheal and Sons, Lowfield Nurseries, Crawley, for a somewhat flat arrangement, well put together, however, but quite different from the bold style of that of Messrs. Keynes, Williams, and Co., The Nurseries, Salisbury, who were second. In both cases Cactus, show, single, and pompon varieties were freely used, the centre feature in the exhibit from Salisbury being a fine mass of the variety Harry Freeman, which is of purest white. The displays by these firms were a feature of great interest and beauty. Another great class in Dahlias was that for sixty show and fancy kinds in not less than thirty varieties. There was good competition, and the winner of the first prize was Mr. John Walker, Thame, Oxon, who had very fine blooms, smooth, even, and of exceptionally good colour. We picked out a few of the best, and their names are Harry Keith, Prince of Denmark, Burgundy, Mrs. Gladstone, Colonel, Majestic, T. J. Saltmarsh, J. T. West, Wm. Rawlings, James Stephens, Mr. Harris, John Standish, and Walter Campbell. A good second was Mr. G. Mortimer, Rowledge, Farnham, and he showed especially well the kinds Mrs. J. Downie, Rev. J. Good'ay, William Garrett, Mrs. Gladstone, Muriel, Glow-worm, and Rebecca; whilst the third place was occupied by Mr. Charles Turner, Slough.

It is a pleasure to see so much encouragement given to the Cactus or decorative varieties, which are very beautiful when not too coarse, and embrace now a striking variety of colours. The finest eighteen bunches came from Messrs. Keynes, Williams and Co. They were remarkably fresh and of fine colour. Especially worthy of note were *Lady Perzance*, yellow; *Countess of Radnor*, *Delicata*, *Countess of Gosford*, *Chancellor*, crimson-purple; *Bertha Mawley*, and *Lady Skelmersdale*, primrose. The second prize was won by Messrs. J. Cheal and Sons, who had the crimson coloured *Duke of Clarence*, *Kynerith*, one of the brightest of all, scarlet; *Robert Cannell*, *Marchioness of Bute*, white tipped with reddish colour; and *Duchess of York*, rich terra-cotta; Mr. C. Turner, third. The next important class in the open division was for eighteen bunches of pompons. Here the premier place was occupied by Messrs. Keynes, Williams and Co., who had charming varieties, some highly promising seedlings, others being such well-known favourites as *White Aster*, *Bacchus*, *crimson*, &c., whilst Messrs. J. Cheal and Sons were placed second, with Mr. Turner third. The class for single Dahlias brought again into competition those two great Dahlia growers, Messrs. Cheal and Sons and Messrs. Keynes, Williams and Co. In the present instance the former were first, and had a very fine collection of eighteen bunches, the kinds comprising *Annie Hughes*, rose-purple; *Gulielma*, white edged with buff; *Duchess of York*, scarlet; *Evelyn*, rose; *Formosa*, crimson; and *Miss Glasscock*, white edged with pink; Mr. E. F. Such, second.

The Dahlias exhibited by amateurs were remarkably fine. The chief class was for twenty-four show and fancy kinds, not less than twelve to be distinct, in which one of the most successful amateur growers, Mr. West, gardener to Mr. W. Keith, Cornwalls, Brentwood, was first. His flowers were very good, particularly those of Harry Keith, Alice Emily, J. T. West, W. Rawlings, Dorothy, Ethel Britton and Sunbeam, whilst Mr. T. Vagg, gardener to Mr. J. Theobald, M.P., Bedford, Havering, was second. Mr. West was again the principal prizeman for twelve Cactus kinds, many of those exhibited being his own seedlings. They were excellent, especially the flowers of St.

Catherine, Harry Freeman, Duke of Clarence, Glory of Brentwood, Mrs. Keith and Kynereith. Mr. J. Hudson, Gunnersbury House Gardens, Acton, was a good third. Prizes were offered for twelve bunches of this section of Dahlias by Messrs. Keynes, Williams and Co. Mr. J. T. West was also first for twelve bunches of pompons, and we noted that there is less desire to get them of abnormally large size than a few years ago. Very charming were the varieties Eva, Fair Helen, Achilles, Eurydice and Gipsy. A very good second was Mr. Hudson.

The hardy flowers were excellent. They were exhibited in bold masses and, as a rule, in good variety, showing how many beautiful hardy things are in perfection at this season. The principal class was for a collection, distinct, including also bulbs, and the first prize of £5 was given by Messrs. F. D. Shuttleworth and Co., Ltd., Albert Nurseries, Peckham Rye. There were several fine exhibits, and the first prize was well won by a comparative stranger to London shows, Mr. B. Ladhams, Shirley Nurseries, Southampton, who had a mass of *Liatris pycnostachya*, *Rudbeckia purpurea*, *Heliopsis major*, the blue-flowered *Stokesia cyanea*, *Platycodon grandiflorum*, *Phloxes* in variety, *Helenium grandicephalum striatum*, red and yellow striped, *Gaillardias*, *Centaureas* and Pink Ernest Ladhams, which is referred to elsewhere. Messrs. Paul and Son, The Nurseries, Cheshunt, were a good second, and Messrs. Cocker and Son, of Aberdeen, third. Two amateur classes were those for twenty-four bunches and also for twelve bunches respectively. In the first case the winner of the premier award was Mr. Sage, gardener to the Earl of Dysart, Ham House, Twickenham, who had splendid bunches, the chief kinds *Eryngiums*, perennial *Sunflowers* and *Coreopsis lanceolata*; the Rev. F. Page-Roberts, The Rectory, Scole, Norfolk, a good second. For twelve, Mr. Hudson was a good first. We may mention that Messrs. Kelway and Son, Langport, Somerset, offered prizes for a collection of herbaceous plants. Messrs. Paul and Son had the best herbaceous *Phloxes*; bright colour was contributed by the annual and perennial *Sunflowers*. The first place was taken by Messrs. Burrell and Co., whose exhibit comprised also *Rudbeckia purpurea*, *Helenium pumilum* and a great variety of perennial *Helianthus*; Mr. Sage, second. The tufted *Pansies* look extremely well as sprays. This was shown by the twelve sprays from Mr. A. J. Rowberry, The Crescent, South Woodford.

The *Roses* were delightful, although they soon faded, this being due to the drought of the present summer. There was good competition in the open class for a collection arranged for effect, and the first prize was awarded to Messrs. Paul and Son for a fine arrangement, but there was some discussion as to whether pot plants were admissible, as the *Rose* classes were placed in the cut flower section of the schedule. In the first prize collection well shown were the varieties *Augustine Guinoisseau*, *Dowager Duchess of Marlborough*, *l'Idéal*, and *Marie van Houtte*. Messrs. Cocker and Sons were a very close second; in truth, there was little to choose between the two collections. Their finest flowers were those of *Gloire de Dijon* (finely represented), *Alfred Colomb*, and *Viscountess Folkestone*, whilst the third place was occupied by Mr. Geo. Mount, Canterbury. These comprised the chief *Roses* in competition in the show.

The *Gladioli* were a feature of much interest. In the competitive open class for twenty-four, the first prize was awarded to Messrs. Burrell and Co., Cambridge, for a splendid collection, many of them seedlings. Two very beautiful varieties were *Cassandra* and *Bernice*. The former has large, light buff flowers, remarkably distinct, and the latter of a paler tint, more of a yellow shade. Many others were shown, but want of space prevents further enumeration.

Stove flowers were well shown by Mr. Gibson, Halstead Place Gardens, Sevenoaks. We noticed a fine bunch of *Dipladenia Brearleyana*.

Amongst miscellaneous exhibits of cut flowers Messrs. Barr and Son, Covent Garden, had a fine collection of hardy perennials, comprising a mass

of the too little seen *Belladonna Lily*, *Colchicums* in variety, *Lilies*, the sweetly-scented *Funkia grandiflora*, *Rudbeckia purpurea*, *Pentstemons* in variety, *Gaillardias*, a large bank of *Gladioli*, and many other things in bloom now (silver medal). Messrs. Cutbush and Son, Highgate, had a splendid collection, and were given a silver medal; whilst from Messrs. Dobbie and Co., Rotheray, Scotland, came one of the largest displays we have ever seen. It was of very large extent, and comprised a large assortment of tufted *Pansies*, including all the leading varieties, *African Marigolds*, *China Asters*, early *Chrysanthemums*, and a collection of every section of *Dahlia* (silver-gilt med l.). Another superb exhibit was that from Messrs. Kelway and Son, Langport. It is impossible to deal at length with the various things, but the *Gladioli* were remarkable for beauty, culture, and variety, whilst *Gaillardias*, *Dahlias*, and *Asters* were shown in quantity (silver medal). We may also mention that hardy flowers were shown by Messrs. E. D. Shuttleworth and Co., Peckham Rye (silver medal). *Dahlias* came from Mr. A. Rawlings, Old Church, Romford, Essex, and Mr. E. Such, but want of space prevents mention of the best varieties. Messrs. H. Cannell and Sons, Swanley, had *Begonia* flowers and a large group of *Cactuses*. Of *Roses* special note must be made of the group from Messrs. Wm. Paul and Son, Waltham Cross, which was given a silver medal. The varieties *l'Idéal*, *Grace Darling*, the *Polyanthas*, and such *Teas* as *Ernest Metz* and *Corinna* were well shown; also the *China Rose Laurette de Messimy* and the *H. P.* Mrs. John Laing.

Nerines.—The brilliant umbels of flowers of the different species of *Nerines*, notes on which appeared in THE GARDEN of August 26 (p. 179), are now unfolding, and at this season of the year are invaluable. Those who may be in possession of large specimens know their value, and although when they reach this stage they are rather expensive subjects to purchase, yet this should not deter their being grown, as single bulbs may be purchased at a comparatively cheap rate, and if well cared for, in a few years they increase in size when all the offsets are allowed to develop. The culture of *Nerines* is very simple, yet each detail must be rigorously attended to, as there is both a decided season of rest and of growth, the former being during the summer months. At this time the soil must be kept perfectly dry, or otherwise the roots and bulbs are apt to decay. I find the most successful results follow when either the pots are placed in a sunny part of an airy greenhouse or in a well ventilated, cold frame. This is much better than storing the bulbs away in some shed or out-of-the-way corner, as here they do not receive that thorough rest which is essential to success. As soon as the flower-scapes show, the soil must be just kept slightly moist, the foliage appearing immediately afterwards. At this time the growth is freer if the plants are placed in a little more warmth, a warm greenhouse or intermediate structure fully exposed to the light being just what is needed. Although over-potting must be strictly guarded against, yet I find the bulbs increase more rapidly when repotted about every other season or up till a 7-inch or 8 inch pot is reached. At no time must *Nerines* be repotted unless the roots have taken full possession of the soil. Potting must take place immediately after flowering. The *Guernsey Lily* (*Nerine sarniensis*) is well known, but it is to such beautiful kinds as *Nerine coruscans*, *flexuosa*, *Fothergilli*, and *Fothergilli major* that I wish to draw attention.—A. Y.

How to destroy wasps.—Wasps have been very numerous and troublesome here, but, thanks to a gentleman residing near, Mr. G. F. Lyndon, who set about destroying their scores of nests, we have now scarcely a wasp about. I asked for the recipe and he very kindly gave it me. It is as follows: cyanide of potassium about ten per cent. solution—a gill is enough for a nest—which should be poured in at the mouth of the nest in the daytime. It will not only kill all in the nest, but every

one flying to the hole will drop dead. I thought daytime dangerous, but Mr. G. F. Lyndon considers it the best time, and says wasps will not sting unless disturbed. If a nest be situated in a building, it is without doubt the safest and best form of taking it. Cyanide of potassium being very poisonous, great care is necessary in dealing with it.—W. EARP, *Highbury Gardens, Birmingham*.

Wasps.—In addition to the many complaints that have been made in various parts of this country concerning the prevalence of wasps this summer, it appears that they are not confined to England alone. In France these insects have been exceptionally numerous and have caused much damage to the fruit.

Retirement of Mr. Manning.—Many gardeners and others interested in horticulture will regret to hear that Mr. Thomas Manning is about to retire from the management of the well-known Royal Exotic Nurseries, Chelsea. For some time Mr. Manning's health has been far from satisfactory. We sympathise with him in his trouble and trust retirement and rest will benefit him and that he may long be spared. After between forty and fifty years' faithful service, he leaves, carrying with him the respect of both employers and employés.

The weather in West Herts.—During the past week the weather has been, on the whole cooler than at any previous time this month, and low temperatures were on most nights recorded. On Monday night a thermometer exposed on the lawn fell to within a degree of the freezing point, making this the coldest night since June 3. On the other hand, the maximum reading in shade to-day (Wednesday) has been 74°, which is the highest for ten days. At both 1 foot and 2 feet deep the temperature of the soil now stands at 62°. No measurable quantity of rain water has come through either of the percolation gauges for four days.—E. M., *Berkhamsted*.

Spiranthes Romanzoviana.—Mr. Burbidge in his review of Mons. Correvon's book (p. 173) is wrong in stating that the illustration of this is from a sketch supplied to Dr. Masters. The original sketch is in my possession, and was sent to me from Dublin in 1885.—A. D. WEBSTER.

Names of plants.—*J. B.*—*Catascum Russelianum*.—*T. Ridge*.—1, *Cypripedium superbium*; 2, *Cypripedium Fothergilli*.—*J. Scaton*.—*Cattleya granulosa*.—*J. Goutler*.—1, *Ononis arvensis*; 2, *Leonurus cardiaca*; 3, *Salicornia herbacea*.—*J. Todd*.—All are varieties of *Laelia crispata*; will notice them next week. — *J. Phillips*.—*Spathoglottis aurea*, sometimes known as *S. Kimballiana*; 2, *Vanda cœrulea*, poor form and out of season.

Names of fruit.—*H. Lea*.—1, *Winter Hawthornden*; 2, not recognised.

"The Garden" Monthly Parts.—This journal is published in neatly bound Monthly Parts. In this form the coloured plates are best preserved, and it is most suitable for reference previous to the issue of the half-yearly volumes. Price 1s. 6d.; post free, 1s. 9d. Complete set of volumes of THE GARDEN from its commencement to end of 1892, forty-two vols., price, cloth, £30 12s.

"Gardening Illustrated" Monthly Parts.—This journal is published in neatly bound Monthly Parts, in which form it is most suitable for reference previous to the issue of the yearly volumes. Price 5d.; post free, 8d.

"Farm and Home" Monthly Parts.—This journal is published in neatly bound Monthly Parts, in which form it is most suitable for reference previous to the issue of the yearly volumes. Price 5d.; post free, 8d.

"Hardy Flowers."—Giving descriptions of upwards of thirty hundred of the most ornamental species, with directions for their arrangement, culture, &c. Fifth and Popular Edition. 1s.; post free, 1s. 3d.

"The Garden Annual" for 1893.—Contains Alphabetical Lists of all Branches of the Horticultural Trade. The Lists of Gardens and Country Seats (containing over 9000) have been very carefully and extensively revised, and are admitted to be the most complete ever published. Price 1s.; by post, 1s. 3d.

All of our readers who are interested in the improvement of cottage homes are invited to help us to make **Cottage Gardening** known. It is published at the very lowest price to meet the wants of those for whom it is intended, and copies will be sent for distribution, free, by the publishers, Messrs. Cassel and Company, La Belle Sauvage, Ludgate Hill. E.C.

No. 1138. SATURDAY, September 9, 1893. Vol XLIV.

"This is an Art
Which does mend Nature; change it rather; but
THE ART ITSELF IS NATURE."—*Shakespeare.*

KITCHEN GARDEN.

PREVENTION OF THE ONION FLY.

ACCORDING to reports from different parts of the country, the larvæ of the Onion fly have caused much havoc this year. Generally the plot intended for the Onions is that which was previously occupied with Cabbage or some of the Brassica family. Very likely it will have the refuse of the previous crop left on it for the purpose of being dug in. If there has hitherto been a difficulty in securing a clean crop of Onions, this is a very questionable proceeding, as amongst such refuse the pupæ are apt to harbour, and the better method is to clear it off. The soil should be dug deeply with forks and thrown up roughly, and immediately afterwards have a light dressing of gas-lime—not a heavy dressing by any means, as this might have as bad an effect upon the Onions as the grub, but just sufficient to colour the surface. The soil should now be forked over, and if possible again during the winter. This forking over will bring the pupæ to the surface to be acted upon by frost. If gas-lime is not procurable, use freshly slaked lime. More surface will be exposed if the soil is ridged, the frost also working right through it. The fault with trenched soil for Onions is that it is apt to favour thick necks and late maturing, especially if the season should be wet. If trenching is intended, rather depend upon bastard trenching, which should be done in the autumn. The manuring should take place about a month before the time intended for sowing, at which time the spring precautions should commence. These will consist of dressing with wood ashes, soot, and a little salt, each of which, besides being of great value in combating the fly, is also a capital fertiliser. Lime should not be used at this time; not that it would prove injurious, but it would counteract the influences of the soot and salt. Soot undoubtedly appears to be very distasteful to the fly, and I am sure that a freer use of it would prove highly beneficial in those gardens where these insects cause such destruction. With salt more care is needed, but a little used judiciously is of great benefit. Before the soil is broken down after being laid up to the action of frost, the burned refuse should be first spread on and then a good dressing of soot, the whole being now knocked over with a coarse rake, this operation working the ingredients into the top 2 inches of surface. The whole surface having now been equally trodden over, a mere sprinkling, or about an ounce to the square yard, of salt should be applied. The drills having been drawn and the seeds sown, nothing more will be necessary until the young Onions have grown 2 inches or 3 inches. At about this period the fly emerges from its pupa stage, and soon commences to look about for a suitable place to lay its eggs. This is just within the outer edge of the skin of the young Onions and close to the ground. When attacks are known to have previously taken place, it is a very unwise policy to wait until the effects of the injury are visible before applying a remedy.

It is better by far to adopt the same tactics as with Celery, viz., dusting the foliage over with soot, or syringing with well-diluted petroleum. A decoction of quassia and a suitable insecticide mixed with it would also be useful. I have seen gas-lime used for the same purpose, but the other remedies would be the safest, as with these there would not be any likelihood of injury. By syringing the whole quarter over at weekly intervals, the flies would not care to settle. There is no mistaking the presence of the grub when once the work of destruction has begun, for the young Onions take on a yellow cast and the tops fall over. When this occurs, although there is not much likelihood of making a clearance, it may be checked considerably by carefully digging up all affected plants and burning them. If merely pulled, the grubs are apt to be left behind. As there are two or three generations until the season occurs for them to enter the pupa stage, remedial or preventive measures should be persisted in up till midsummer. As the Onions are harvested, take care that all trimmings are cleared away and burnt.

Transplanted Onions are seldom, if ever, affected, and this has led to the plan, where the grub is such a pest, of sowing the seed in a prepared cold frame, and as the plants become large enough they are transplanted. Onions treated in this way are very likely to grow to a large size, and there is also the advantage of their ripening up well. A. YOUNG.

Large Cabbages.—The hot, dry summer has done much to shake general confidence in large varieties of the Cabbage family. Really good ones have been few, and breadths usually grown for a summer supply have been rendered valueless by combination of drought, aphid, and caterpillars, so that they have only furnished food for pigs. I cannot see what good it is to encourage the production of big Cabbages at any time in private gardens. They may do for the market grower, but they are, however produced, strong and gross, and the reverse of nice however cooked. Size has now to give place to quality, and although the progression is slow, it is sure. Very much blame for this, however, is due to the somewhat absurd fondness of judges at vegetable shows for size, and especially so is this noticeable at exhibitions of cottagers' produce. All the same, in a few years we shall see bigness as an element banished, and quality, as marked by beauty, refinement, and moderation in size, made a primary factor in judging.—A. D.

Tall Peas and mildew.—This has been a trying season for Peas. During the seventeen weeks of dry weather I was able to keep up the supply by heavy mulchings and giving them good soakings of liquid manure water. Although the plants never attained their usual height, they kept free from mildew; but as soon as sufficient rain came to soak the ground, the mildew set in. Fortunately, I had sown several rows of my old favourite *Ne Plus Ultra*. This has stood the mildew better than any other kind, has given an unbroken supply, and now (August 20) I can still gather good dishes. Several other kinds have succumbed. Just before the rain came early in July I sowed several rows of different kinds of dwarf-growing sorts; they came up well enough, but will be of little value. The tomtits are injuring late Peas very much. So bad were they, that I found it necessary to cover the rows with nets. I have heard the same complaint from neighbouring gardeners.—DORSET.

Autumn Cauliflowers.—I have often found that such early sorts as *Snowball* sown in February has been in before such sorts as the *Early London* sown in August or September. No doubt Mr. Yeung (p. 160) hits off three of the most potent causes of failure with autumn-sown Cauliflowers. They are sown too early, coddled too

much, and pricked out in unsuitable soil. Most of us have grown good Cauliflowers autumn-sown. With infinite patience, care and skill, the result has been satisfactory, but the labour has been out of proportion to the result. I began gardening in November, and one of my duties was to ventilate and cover a plantation of Cauliflowers under handlights, and I will never forget the work and the worry of it, and having saved most of them from frost and fogging off, fully 50 per cent. bolted instead of mellowing into full, sweet flowers. The mixed experience of this partial success has haunted me ever since. I have seen very many worse examples of autumn sowing. It is not necessary either to gain time or quality. It may, if successful, give better results. We can wait till the *Snowball*, *Early Erfurt* and *Early London* sown in succession from January to March will afford a sufficient supply of early Cauliflowers. First sowings of *Autumn Giant* and *Walcheren* may also be made under glass in April, to be succeeded by others in the open. By this simple means I shorten the period of Cauliflower care by four or five of the most trying months of the year and may cut just as early and as fine heads, as Mr. A. Young will probably admit.—CALEDONICUS.

BLANCHING CELERY.

IT matters little how well Celery may have been attended to previously if the blanching is not well carried out. It must also be borne in mind that, although blanching is all-important in the production of good edible Celery, yet there must be the foundation laid beforehand to ensure good solid hearts pushing up. It will therefore be seen that if the plants are small or undersized for the variety, however carefully blanching may be done, good solid-hearted Celery will not be obtained. For this reason if the plants should be now undersized, it will be much better to encourage growth as much as possible before any soil is added unless it should be as a top-dressing, by keeping the trench in a well-moistened state with an occasional application of liquid manure or a light sprinkling of salt. Nitrate of soda will also hasten on the growth of backward Celery. With the growth in a free state and well up to time, clear water will be ample, as with a free use of liquid manure or of nitrate of soda the plants become coarse. Over-feeding Celery leads to inferior quality, and is also against its keeping well after earthing up has been completed. Huge sticks may certainly eventually be had, but on the approach of winter they quickly suffer from damp, and when this sets in, the leaf-stalks decay wholesale. Moisture being a necessity for the securing of high quality in Celery whether in a forward or backward condition, this must have attention before earthing commences, for although it is possible to water Celery after the first earthing, yet with the soil in a well-moistened condition prior to this operation, it invariably keeps moist enough afterwards to lead to a satisfactory after growth. The first earthing must not be confounded with an ordinary top-dressing, after which water may be applied as often as before. Before blanching proper commences the trenches should be well watered, giving sufficient so that the soil is thoroughly moistened. Earthing up Celery with the soil about the roots in a dry state, if it does not exactly lead to bolting, renders the quality poor, the heads being tough and insipid instead of crisp, sweet, and nutty in flavour. There is also the danger of being in too great a hurry with the blanching. A good guide is to have sufficient well in hand for use, the blanching of what should be needed for the main winter crop being left some time longer. This latter lot I like to have well top-dressed, as this, besides

keeping the outer leaves well up together, encourages a free growth, and there is also the certainty of its receiving the benefit of the rains direct to the roots. Without this top-dressing, the plants, if left to themselves, will, if the growth is free, take on a spreading habit, the outer leaves falling out, when there is a difficulty of forming symmetrical heads.

Some growers have their favourite methods of blanching, such as surrounding the stems with stout brown paper, or collars purchased for the purpose. Others go to the trouble of surrounding the stems with sand, ashes and burnt soil, but whatever advantages these may have, well-worked soil is the most generally used, and, besides being the most convenient, invariably results in securing well-blanching produce. Whatever extraneous aids are used, the brown paper, in conjunction with the soil, will prove the most suitable, but I only recommend its use where hitherto clean Celery has not been secured through the aid of soil alone. Heavy soils are supposed to be the worst to deal with, but with a free use of lime and burnt refuse mixed with the staple in the ordinary course of cropping, I have not had any difficulty in this respect. If, on turning up the soil for earthing, it should prove lumpy, the best addition I find is to wheel some burnt refuse along the sides, this being worked in with the soil as it is being thrown up, of course taking all ordinary precautions to get it as finely divided as possible. As fresh soil is added, the plants should be drawn up together and tied with a piece of matting, as this will prove a much more convenient method than having one person to hold each up separately whilst another adds the soil. Three earthings are generally sufficient, and these at intervals of a fortnight. After each earthing, take care that the matting is cut away, for if this were allowed to remain, the hearts would become crippled. To ensure a clear growth after earthing, the hearts, except at the final earthing, must be kept in advance of the soil added, or there will be danger, if the stems should be heavily weighted with soil and the hearts thereby enclosed, of the stems bulging; consequently the heart growth would be crippled. At the final earthing I like to use plenty of soil as a protection from frost, taking care, however, that the sides of the ridges are brought up sharply and made smooth, this being an excellent protection from wet. It is when the soil is thrown up loosely with a rough outer surface that the wet penetrates. As a safeguard from slugs, I have found salt a good antidote, a little being sprinkled over the soil at the first earthing. Lime may also be used for dusting over the soil at each earthing, or even soot may be used.

A. YOUNG.

Ordinary exhibition Onions.—Whilst there is such a tendency on the part of many persons to favour big Onions simply because they are big and no more, it will not do to lose sight of the fact that under no conditions can bulbs produced under the somewhat artificial system of culture needful to grow them be ever profitable or useful, except where they are either capable of winning valuable prizes, or may be sold to seedsmen for stock or exhibition uses. These big Onions can only be produced on soil that is over-manned, deeply cultivated, are planted very thinly, and are from seed sown quite early in the year under glass. The rule is to put them out into rows 18 inches apart and some 15 inches apart in the rows, so that the average product per rod cannot be high. Then these huge bulbs will not keep. Very often one half of them are rotten by the end of November, and only the very firmest will keep sound in the spring. It would be a good plan to demand of competitors that all Onions exhibited should, like Carrots,

Parsnips, Beet, Turnips, &c., be sown in the open ground. That would help us to get rid of Onion monstrosities, and induce gardeners to take greater interest in the production of profitable and useful crops. There has been a very interesting trial of Onions at Chiswick this year, and we have there seen the numerous varieties sown, grown and displayed in their true form. The result is, therefore, far more instructive as well as useful than would have been growth under the artificial conditions now employed to produce the giant bulbs that are of so little service when obtained.—A. D.

Celeriac blanched or green—"S. H. B." in praising this as a winter vegetable is silent on this vital point. It is only a Turnip-rooted Celery fit for soups if grown on the surface, as it mostly is with half starveling culture, as your correspondent describes, but with good feeding and a final earthing up or blanching, Celeriac may be made tender and nutty, and as useful for salad or cheese as Celery. Neither can there be any doubt of its excellent keeping qualities. Doubtless fish manure, salt, and guano prove valuable stimulants. Celeriac also does well planted in shallow trenches filled with rotten manure exactly in the same way as Celery. In households where there is a great demand for stewed Celery, as well as Celery for soup, Celeriac would prove a most valuable relief. Some also prefer Celeriac to Celery to their cheese, as it is firmer in texture and more nutty.—D. T. F.

The hardiest winter Lettuce.—In these days of novelty and change it is refreshing to find "S. II." still recommending the Hardy Hammer-smith as the best winter Cabbage Lettuce, and the Brown Cos as the hardiest Cos. I presume he means the Black-seeded Brown Cos, that is the orthodox variety, though I believe this is almost the only known example in which such a quality as increased hardness is associated with the colour of the seeds. In the case of Spinach, for many years a similar quality was associated with the roughness or prickliness of the seeds. But that is now found to have been a fallacy, the smooth-seeded or so-called summer Spinach being proved to be just as hardy as the Flanders or prickly. Has any reader fairly tried the White-seeded Bath Cos Lettuce as against the black for winter?—D. T. F.

SHORT NOTES.—KITCHEN.

Pea Autocrat.—Although the season has been so unfavourable for late Peas, this variety has succeeded the best of any. This being so, we may well look forward to its succeeding grandly under more favourable conditions in future seasons.—A. Y.

French Bean Ne Plus Ultra.—What a splendid Bean this has been this season—in fact, I never remember seeing any variety so free in producing pods. Judging by the reports now appearing in THE GARDEN, French Beans even have not been a success in all cases, whilst with me they have never been better.—A. Y.

Onion Veitch's Main-crop.—When at Taunton show I was pleased to see a splendid dish of this fine main-crop Onion taking first prize, showing it still holds its own. I doubt if many of the large, soft-growing kinds are ever worth the trouble from a keeping point of view. It may be worth while asking how long many of the enormous-sized bulbs will keep.—J. C. F.

Potentilla fruticosa.—We have a plant of this shrubby Cinquefoil which has been in flower for several weeks, but is now, at the beginning of September, brighter in its profusion of yellow flowers than ever it has been. Resting on the deep green foliage they make quite a charming picture. The shrub itself is of neat rounded habit, and is 2 feet high by about 3 feet in diameter. The flower is an inch across. The species is spread over the Northern Hemisphere, and occurs wild in the north of England, in Scotland, and in several localities in Ireland. It is certainly worth growing more extensively than at present it appears to be, especially as it is not very particular as to soil,

one of medium richness being the best for obtaining abundance of bloom. So few shrubs are in flower at this season, that it deserves consideration on that account alone. Two other shrubby Potentillas are in cultivation, *P. Salesovii* and *P. glabra*, both similar in character to *P. fruticosa*, but with white flowers.—B.

ORCHIDS.

LÆLIA CRISPA.

THIS has been grown in our gardens for between sixty and seventy years, and I remember that some thirty years since it was despised on account of the lip being so closed up, that its fine dark purplish colour was completely hidden. I am now in receipt of a dozen flowers of this species from J. Todd, asking me to give him my opinion respecting them. Beautiful although they all are, I do not see anything out of the usual run of varieties, saving in Nos. 3 and 7. There does not appear to be any one of them with the closed lip which I have spoken of, but this may be accounted for by the treatment which the plants now receive, being so much more in accordance with their requirements. No. 3 appears to be the same as the variety known as *purpurea*, having the sepals and petals slightly flushed with rosy purple, the lip wide, open in front, and of a rich deep velvety purple, with radiating veins of a darker hue, which run out on to the white margin. This is a magnificent variety and worthy of all care. No. 7 is also a good form, but nearly all the rich colouring is obliterated. It has broad sepals and petals, the latter undulated at the margins and of the purest white. The lip is longer than in the last-named variety, well open in front, crisped at the edges, throat stained with pale yellow and having straight veins of rosy purple.

These are the only flowers in the batch worth special recognition. The others are all very fair forms, excepting No. 9, which I would advise "J. T." to destroy. *Lælia crispa* was named *Cattleya crispa* by Lindley, but more modern authors, having found that it had eight pollen masses, changed it to *Lælia*. It is, however, best known to Orchid growers as *Cattleya crispa*. The plant appears to be somewhat widely spread in Brazil, mostly in the southern portion. It is found at some 2500 feet to 3500 feet elevation, and consequently should be grown in the cool part of the *Cattleya* house. It begins to grow in the winter months. Care must be taken not to wet the young growths at this season. In fact it requires exactly the same treatment as *Lælia purpurata*, but it must be borne in mind that this latter plant is finishing up its growths through the winter, while *L. crispa* is just beginning them at the latter end of the dull season. It does not like its roots to be overloaded with soil, which should consist of good brown fibrous peat fibre and chopped Sphagnum Moss, which should be made firm. The pots should be thoroughly well drained, and water to its roots must be given sparingly.

W. HUGH GOWER.

Waillesia paludosa.—"W. T. W." sends me flowers of this plant. They appear to have been open a very long time, but there is sufficient colour left to see that it is the ordinary variety I noted some time back as in flower at Mr. Williams' nursery, Upper Holloway, where it is named *Dipodium paludosum*. I can see nothing to connect this species with that genus at all, for it is not a leafless plant, neither is it terrestrial, and so, follow

ing Lindley and Reichenbach, I must consider this plant a *Wailesia*. Griffith appears to have been the first to discover it in Malacca and named it *Grammatophyllum*, but I cannot see what resemblance there is in this plant at all to that genus. It requires a very moist place, but I do not think so warm as many imagine.—W. H. G.

Lælia elegans Turneri.—T. Jennings sends me a flower of this plant, asking if it is true, and from the spatulate shape of the lip and its rich deep colour, I have not the slightest hesitation in pronouncing it quite the true form. The flower now before me measures fully $6\frac{1}{2}$ inches across; the petals are slightly broader than the sepals, both of a deep purplish rose; lip three-lobed, the side lobes white towards the base, suffused with rose colour at the tips; front lobe spatulate, the entire surface deep purplish maroon; the flower is thick and fleshy in texture and was cut from a scape bearing six blooms. I have seen eight flowers produced from a single peduncle, but in this case the plant was very strong and one growth only was flowering. It requires a good rest through the winter months, but not over-drying, or the bulbs are apt to shrivel, and when this occurs the plant requires a good deal of management to restore it to its accustomed health. Give rest rather by reducing the temperature, only giving enough water to maintain the bulbs in a plump and healthy condition.—W. H. G.

Miltonia Schröderiana.—A very nice flower of this plant comes to me from Mr. Dorman, of Laurie Park, Sydenham, under the name of *Odontoglossum Schröderianum grandiflorum*. The flower is a very fine one, but I and many others appear to have been led astray in some manner with these two plants, and I must confess never to have known, and do not at the present know any other *Odontoglossum Schröderianum* but the plant named above. I first saw it some few years ago, and I then expressed the opinion that the flower more certainly resembled that of a *Miltonia*. I also saw this plant flowering with Mr. Measures at The Woodlands a short time afterwards under the same name, and in several other places, and now this fine form comes from Mr. Dorman. It is a very handsome species, introduced about eight or ten years since by Mr. Sander from Central America. The dorsal sepal and the petals are erect, the lower sepals divergent, white at the base, the rest dark chestnut-brown, tipped with light yellow; lip almost pandurate; the base of the lip is bright rosy purple, the upper portion pure white. The flowers are very fragrant.—W. H. G.

Cypripedium Sedeni.—Mr. Rapley, of the Gardens, Harrow Weald House, Stanmore, sends me a flower of this beautiful hybrid having two distinct lips or pouches. These do not improve either its symmetry or its beauty, and such freaks are not desirable. This plant, which is a cross between *C. Schlimi* and *C. longifolium*, is one of the most lovely Lady's Slippers that I know. When it gains strength, the number of flowers it will carry is quite surprising.—W. H. G.

Cypripedium spectabile.—Noticing in your valuable paper some correspondence concerning the difficulty of growing successfully *Cypripedium spectabile*, leads me to state that it is native here in our shady ravines. The banks of the latter average from 50 feet to 90 feet deep. On slightly shelving spaces, generally 15 feet to 20 feet below the top, the species thrive. The surface soil is, of course, leaf mould, under which lies a rather stiff yellow clay. The situation is rather moist from the time of the April thaws until July 1. By this time the bloom is nearly over. By August the ground is extremely dry, and remains so until the autumn rains in October. I gather plants while in bloom, cutting deeply around them with a spade and thus obtaining blocks of soil some 6 inches square and 8 inches to 10 inches deep. On the upper edge of a ravine bank bordering my summer home I excavate irregular shaped beds to a depth of 18 inches, filling partially with leaf-mould. The blocks containing the plants are then put in closely, like paving bricks; sifted leaf-mould is then worked into the interstices, and a

2-inch layer spread over the whole surface, when a good watering completes the work. After then, no more attention is paid to the group. Being beyond the border of the lawn proper and amid the precincts of Nature's garden, I allow anything to grow up among them, they having to fight for existence, as they did in their habitat. Strong-growing imported weeds are alone demolished. One bed of some thirty plants has held its own for the past three years, and is a marvel of beauty when in bloom; colonies of two or three plants leading to another group planted two years ago do well. No artificial water is given them; no winter protection save what leaves naturally fall from the overhanging boughs. They get the direct sunlight up to 10 a.m.; after then they are in the shade.—W. C. EGAN, *Egandale, Highland Park, Illinois.*

Oncidium Wheatleyanum.—This is one of the most beautiful Orchids I have ever seen. The flowers, thickly set upon the spike, are each nearly 2 inches across. The spike carried upwards of thirty flowers, making a most imposing display; the sepals and petals are spreading, nearly equal, of a rich, bright brownish crimson bordered with yellow; lip somewhat uniform, rich golden yellow, with a marginal border of deep chestnut-brown or crimson, the whole surface regularly and distinctly corrugated; at the base are two golden yellow auricles, and the claw and for some distance upon the blade is a large stain of deep maroon-crimson of a velvety appearance. These flowers were sent to me by Mr. F. Wheatley, of Ringmore, Teignmouth, to whom I have dedicated it, accompanied with the following particulars: "The plant which produced these flowers was purchased as an imported specimen with one or two others as *Oncidium Gardneri*.—W. H. GOWER.

FERNS.

CHOICE STAG'S-TONGUE FERNS.

(ELAPHOGLOSSUMS.)

THIS family includes many beautiful plants, but I have usually found them ignored because they have simple fronds, many people forgetting the fact that a simple fronded Fern makes an agreeable and effective variation. *Elaphoglossums* are widely distributed throughout tropical countries, and one species extends to Madeira in the northern hemisphere. They are called *Acrostichums* by many authors, but in my estimation they have little in common with these, and their free venation compared with the reticulated veins of *Acrostichum aureum*, the typical plant in that genus, is in itself at once sufficient to distinguish them. These *Elaphoglossums* being all simple fronded, many of the so-called species resemble each other very closely, but the fertile fronds, which are entirely covered with sori on the inside, render them distinguishable. *Elaphoglossums* are easily grown, requiring only a mixture of light turfy loam and peat, the whole made sandy. The drainage, too, must be good, as they like an abundant supply of water through the growing season and a moist atmosphere. I dislike the use of the syringe for overhead watering, for some of the kinds have scaly fronds, and these chaffy scales hold the water, to the great detriment of the plants. To those kinds having smooth and shining fronds, syringing apparently does no harm. I will here mention a few of the most beautiful and distinct kinds which I have myself grown, some as specimens for surmounting a pedestal, some as basket plants, and others in a Wardian case.

E. CALLEFOLIUM is a fine species, which has been known in English gardens for upwards of

fifty years. It has fronds some 12 inches or 18 long, proceeding from a creeping rhizome; the fertile frond is about 1 foot long, narrower than the barren one, deep shining green above, covered with sori beneath. On account of this being a smooth and shining surfaced plant, it may be syringed with impunity and thrives well in the Wardian case. It is also known in gardens as *E. brevipes*.

E. CRASSINERVUM.—This is another smooth-fronded form. The fronds attain to 18 inches in length by $2\frac{1}{2}$ inches in breadth, waved and undulated in the way of *Scolopendrium crispum*. The fertile frond is much shorter and also narrower.

E. CONFORME is a dwarfier species, with plain shining green fronds, which are thick and leathery in texture, the barren ones about 1 foot long, the fertile ones about half that size. This plant appears to be widely spread in its native home, and may be used either in the fernery or in the Wardian case.

E. CUSPIDATUM.—This does not like water overhead. It is a handsome dwarf plant, the fronds from 7 inches to 8 inches in length; the fertile fronds about half the size of the barren ones. It makes a handsome small specimen for the front row in the stove fernery.

E. GARDNERIANUM.—A somewhat rare plant, and I do not remember to have seen more than two specimens. The fertile frond is in some cases longer than the barren one, which is from 7 inches to 8 inches long and about 1 inch broad. The fertile frond is less than a quarter of an inch in breadth, dark green above, clothed with sori on the under side. It makes a handsome specimen.

E. HERMINIERI.—This is a beautiful species, and makes a handsome basket plant. The fronds are from 18 inches to 3 feet or more in length, thick and leathery in texture, the upper side of a bright lustrous blue. The fertile fronds are quite small, never more than 5 inches or 6 inches long, but broad in proportion. The first living plants that came to this country were sent by my friend Mr. Prestoe from Trinidad, and Sir William Hooker told me that it was the first time it had been found in that island. Its bright metallic blue colour renders it very distinct.

E. PILOSELLOIDES.—This is a small, but elegant species. It seldom makes fronds more than about 3 inches high, more than half of which is naked. It is a most interesting plant, but it is also very rare.

E. SCOLOPENDRIFOLIUM is a handsome kind, having fronds some 12 inches or 18 inches long, fringed at the margins with long hairs, the colour pale green. The barren fronds are spreading, the fertile ones small and erect.

E. SQUAMOSUM.—This is a most interesting and remarkable plant, but rare in cultivation, although it grows so near to us as the Azores and Madeira. The fronds are narrow, about 8 inches or 9 inches long, densely covered with large reddish brown scales, and in a specimen which I received from Capt. Toppin gathered in Jamaica the stipules are thickly covered with black scales.

E. UNDULATUM.—The fronds of this are each about a foot or 18 inches long, from $2\frac{1}{2}$ inches to $3\frac{1}{2}$ inches wide, and light green in colour. The fertile frond is much smaller. It comes from the island of Dominica, and makes a remarkably handsome pot specimen in the stove.

WM. HUGH GOWER.

Hypericum patulum.—This species and the now well-known hybrid *H. Moserianum* are amongst the gayest of our outdoor shrubs at present in bloom. *H. patulum* is a native of Japan, where it is said to grow to a height of 6 feet, but I have not heard of it being more than half that height in this country. With us, at any rate near London, the shoots are killed back nearly to the ground in winter, but push up vigorously again the succeeding spring. This year the annual growths are shorter than usual, measuring little more than 1 foot in length; they are quite slender and somewhat arching, bearing ovate-lanceolate leaves which are pale green above and glaucous

underneath. The flowers are produced in terminal cymes, each one measuring nearly 2 inches across, the petals being nearly round and of a bright yellow. The hot summer has no doubt helped to produce an unwonted abundance of bloom this year, more especially in positions where sufficient moisture has been available for the roots. Our plants commenced to bloom early in July, and at present are as bright as ever. For furnishing the front of a border of shrubs, this *Hypericum* planted in groups proves very useful. It should, however, be always given a sunny sheltered position and treated liberally in the matter of soil and moisture. It was from this species crossed with *H. calycinum* that the beautiful hybrid *H. Moserianum* was obtained.

NOTES OF THE WEEK.

Zephyranthes candida.—It is not often one sees this charming flower flourishing in gardens, and many consider it too tender, but in a favourable spot at Kew, warm, sunny and sheltered, it has withstood recent severe winters which have killed many supposed hardier things. It is now in full bloom.

The Colchicums are commencing to bloom freely, and the beautiful *C. autumnale* is very pleasing dotted about the Grass, as on the Cumberland mound at Kew, where the autumn *Crocus* makes a shimmering of soft purple. In a border several kinds are in bloom, comprising *C. autumnale* and its double varieties, *C. byzantinum*, *C. variegatum*, finely marked, and *C. Parkinsoni*.

Solanum Jacquinii.—This is a bold and distinct type for sub-tropical bedding. The leaves are deep green, spiny, and the flowers plentifully produced, whilst individually they are large and tinged with lilac, the stamens rich yellow. It is a very charming kind, but should be either kept by itself or used as a margin, so to say, to beds filled with larger growing things.

A border of the Belladonna Lily.—We have never seen a finer mass of colour than is presented by a border of the familiar Belladonna Lily (*Amaryllis Belladonna*) that skirts the Orchid house in the Royal Gardens, Kew. The specimens are large and the flowers delightful—rich pink—against the chocolate-coloured stems. The position here exactly suits the plant, as it is sunny, sheltered, and the soil light.

Pentstemon barbatus coccineus.—A mass of this is in full bloom near the Palm house at Kew. It is a *Pentstemon* that requires grouping to get the full effect of the graceful spikes of flowers, each of a tubular form and bright scarlet colour. The stems rise quite 3 feet in height, and have a distinct and graceful aspect. A succession of bloom is maintained, so that throughout the autumn this fine plant is attractive. It is fairly hardy, not difficult to grow, and is better known as *Chelone*.

Tea Rose Mme. Joseph Schwartz.—We recently noticed a group of this beautiful Tea-scented Rose in full bloom. It had given handfuls of flowers for many weeks past. One does not hear much of this fine variety, but it is very charming, especially when planted in a good group. The flowers are white, tinged with yellow in the centre, and those much exposed to the sun take on quite a peach shade. They are very strongly scented, full, and well shaped.

The Portulacas enjoy a warm season, and they have certainly had everything in their favour this year, although it has been almost too dry for them, as in the case of annuals in general. A bed of *Portulacas* makes a brilliant display of colour, and at Kew they are in full beauty now, the flowers showing a great range of colour from carmine to crimson, through shades of rose and pink. The seed should be sown in heat and treated as for half-hardy annuals. It is advisable to pot off

the seedlings singly, as then they bloom more quickly, and certainly more strongly. Raise the beds a few inches above the level to throw off rains, as wet is fatal to this brilliant annual.

An Apple from Ireland.—I send you here-with a specimen of a little-known south of Ireland Apple called Gibbon's Russet. About Cappoquin and Lismore in old cider orchards it used to be called Cherry Brandy. It was the favourite Apple of my grandfather. I remember my uncle Richard, long since dead, also prized it for mid-winter use above all others. Put this fruit in a drawer for two or three days, close it up, and you will get a whiff of perfume from the fruit or drawer the third day. I should like it known in England.—W. B. HARTLAND.

Aster Amellus.—One of the most beautiful effects in the Royal Gardens, Kew, is got by planting bold groups of this fine Starwort, which is, with *A. acris*, the best of the early-flowering kinds. The flowers are rich violet-purple, large, and produced in great profusion, being in excellent contrast to the Sunflowers and other perennials that are in perfection at this season. One might see still more of the Starworts in gardens and less of the *Helianthus*, which are much alike in colour, and if overdone, the result is a surfeit of yellow.

Hydychium coronarium.—Few stove plants are more beautiful than this old favourite. There are several specimens in bloom in the Water Lily house at Kew, and one in particular is a picture of luxuriant growth and pure white flowers. Each stem bears a large crowded head, the individual flowers of the purest white, except a suffusion of pale lemon-yellow at the base of the upper segments, and they exhale a powerful fragrance like a *Gardenia*. This fine species was introduced from the East Indies as far back as 1791, and *H. flavescens*, also in bloom, in 1822. The latter has smaller and yellow flowers. It is not so beautiful as *H. coronarium*.

Lilium speciosum album.—One of the finest masses of this we have seen is in the Royal Gardens, Kew, where it is now in perfection. No other Lily is associated with it, and one sees a mass of purest white, the plants rising from a groundwork of the white Calluna, also in bloom now. This Lily is succeeding remarkably well at Kew, and such bold groups of one distinct kind give much pleasure. It flowers later than the type, which is practically over, although all plants, Lilies included, are blooming very early this year. A delicate fragrance is exhaled from this beautiful white Lily, very agreeable in the cool of the evening.

Dried fruits and vegetables.—The exhibit of dried fruits before the fruit committee of the R.H.S. at the exhibition recently held at the Agricultural Hall, Islington, proved extremely interesting. It must be remembered that this process of preserving fruits and vegetables is only in its initial stage in this country, so I expect we shall progress slowly, for the present at any rate. The only faulty kind amongst several appeared to be the Peas. These certainly had a very discoloured appearance, and the question is, Are these when cooked equal to those which are bottled, as these latter when well done, turn out almost equal to Peas fresh gathered?—A. Y.

Fuchsia gracilis.—Compared with the popular type of *Fuchsia* in regard to size, the individual flowers of this species would be considered poor indeed, yet they are borne in such great profusion and accord so well with the foliage and habit of the plant, that one could not wish them other than they are. This species is of tender growth, and is admirably adapted for covering pillars and rafters in the cool greenhouse. In the conservatory at Kew, as well as in the large temperate house, it is used for this purpose, and just now the plants are very delightful in the remarkable profusion and grace of their blossoms. Some of the plants are 12 feet and 15 feet high, and the flowers being pendent, such a position above the level of the eye

shows their bright jewel-like character to best advantage. The petals are purple and the sepals scarlet. The leaves of the ordinary form are green, their small size according with the dimensions of the flower, but there is also a variegated form which will be found useful for lighting up shady corners of conservatories, where an unrelieved mass of greenery is often apt to prevail. This plant also flowers quite well in shade. The green form may be used out of doors; it is almost as hardy as *Riccartoni*, and although killed to the ground every winter, sends up during summer luxuriant shoots to a height of 3 feet or more, which, as the season advances, become crowded with flowers. An effective combination may be obtained by planting the white-flowered *Galtonia candicans* in a bed of this *Fuchsia*.

New Water Lilies.—Flowers of more new Water Lilies come to us from M. Latour-Malliac, who evidently has fresh surprises in store. The flowers sent show wonderful advances in colour. *N. Marliacea ignea* is an addition to that remarkable series, and has deep purple-red flowers. Another kind, *N. M. rubra punctata*, is very interesting and striking, the colour, rosy red over a lighter ground, being laid on, as it were, in innumerable little dots. A third kind is very charming, a soft salmon and rose tint with a rich yellow centre. These Water Lilies are by far the most important things that have been raised in latter days, and henceforth water gardens may be very delightful and beautiful.

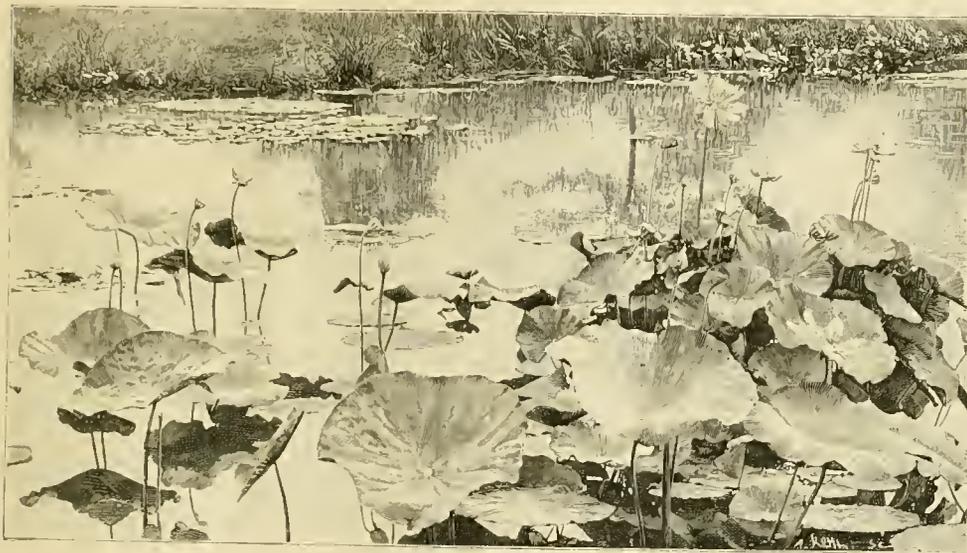

Nerines.—I hope that "Grower" will allow me to rectify a slight mistake in his statement about *N. Manselli*, but which error is likely to cause confusion. The raiser of this variety is Mr. O'Brien, who was at the time with Messrs. E. G. Henderson and Son. He raised several fine varieties. Among his seedlings was a special batch, which looked all alike, and a bulb or two having flowered, it was sent out as *Nerine atrosanguinea*. Mr. Mansell, as he himself in a letter to myself stated, ordered a bulb of this, and hereafter it turned out a very distinct late-flowering *Nerine*, which, as he was a great amateur, and by the help of his gardener, Mr. Peters, an excellent cultivator of the genus, very appropriately had his name. The colour of the flowers is not a deeper shade of *Fothergilli*, but a bright, deep rose colour. My statement is based on a bulb which was presented to me by Mr. Mansell at a time when it was still extremely rare.—MAX LEICHTLIN, *Baden-Baden*.

Tecoma radicans (the Trumpet Flower).—The other day at Hampton Court I noticed a fine old example of this North American climber growing against a wall and flowering very beautifully. Although it is always best when given a place in full sunshine on a south wall, it is hardy enough to dispense with even that protection. For the sake of greater freedom in flowering, the former position should, if possible, be selected; we have, however, a plant growing in an open border without shelter or other support than a stout stake, which is now very nicely in flower. In the matter of sunshine, the past summer has been one that especially suited it, approximating more nearly what it obtains in its native home in the States of Carolina, Florida, &c., than it will very frequently experience in this country. I am told by a friend who has just returned from a visit there that, as seen in its native condition growing over trees, the long festoon-like shoots, with their terminal clusters of orange and scarlet flowers, make a marvellously brilliant sight, the beauty of which is heightened by the crowds of humming-birds that flock to the plants when in bloom. When grown on a wall, the shoots should be allowed to assume their natural mode of growth as much as is convenient; when closely nailed in, the grace of its pendent habit is destroyed. Our plant is cut hard back each winter, its main stem being now as thick as a man's arm. The flowers are of the shape suggested by the popular name of Trumpet Flower, the tube being 3 inches in length, the mouth of the corolla expanded and recurved. The species is said to have been in cultivation in England 250 years ago.—B.

FLOWER GARDEN.

THE SACRED BEAN IN NEW JERSEY.

THE engraving here given illustrates more clearly than the recent woodcut in THE GARDEN the habit of *Nelumbium speciosum*. This plant is a rambler, and except when the runners are confined or have become much intercrossed on an old plantation, it does not form the compact mass as figured. It will be noticed that there is a clump in this picture, this being formed by the confinement of the plants in a sunken frame in which the tubers were originally planted. At the base of the clump may be noted the floating leaves, which are the first expanded on the commencement of growth. The various other growths show clearly the habit when unconfined. These proceed from underground runners or stolons, which are round and

The ways of growth of the Sacred Bean. Engraved for THE GARDEN from a photograph sent by Mr. J. N. Gerard, Elizabeth, New Jersey, U.S.A., August 7, 1893.

tipped by the immature leaf enclosed in a spathe and curled to form a conical point enabling it to pierce the loose soil. When the stolon has advanced a foot or more, a cluster of roots is formed, the point turns upward, and a stem expands carrying the gradually maturing leaf. Another stem and leaf will follow, and usually two flowers in succession, while from the base one or two new stolons will soon proceed, and later on tubers form.

This picture, which represents a plant in a pond of my friend, S. C. Nash, Clifton, N.J., clearly shows it in all stages, and illustrates also the charm of its foliage and the decorative value of one of the noblest of hardy plants.

J. N. GERARD.

Elizabeth, N.J.

Cockscombs and Celosias in Regent's Park.—Very beautiful just now are these flowers in Regent's Park, and many good contrasts are got by judicious association. A bed of crimson Cockscomb and the same coloured kind of Celosia is

remarkably rich, the latter breaking the flatness of the arrangement. In another bed three things are mixed together, a Cockscomb with flowers of a pinkish shade, a yellow-coloured Celosia, and the familiar *Verbena venosa*. The three subjects mentioned make a distinct and beautiful bed, very free, not to say graceful.

Helianthus rigidus Miss Mellish, shown by the Rev. W. Wilks at the recent Royal Horticultural show, is a distinct and very handsome form of this well-known species. It is distinct from the ordinary semi-double form of *H. rigidus*, taller in growth and with richer coloured flowers. They are broad, intense yellow in colour and remarkably showy, with blackish centres. A good group of this fine kind in the garden would make a splendid break of colour. There are a large number of *Helianthus*es, and, unfortunately, the more weedy varieties are most common.

A note on Cactus Dahlias.—It is evident that the Cactus Dahlia is getting more popular each year, and it is important that encouragement should be given to varieties of the Cactus type—not the coarse blooms represented by the so called decorative section. At the recent show at Islington we made note of a few of the best Cactus

course they do not represent the many beautiful shades in the flowers of this firm, but were as distinct and pleasing as any exhibited. Duchess of Edinburgh has a bold bloom, the colour delicate rose, with a central line of white down each segment; Princess Beatrice, white, crimson at the base; Maid of Orleans, white, striped and blotched with rose; Herkomer, crimson; and James Kelway, crimson, passing to white, with a white line down the centre of each segment.

THE ROCK GARDEN.

GENERAL HINTS ON PLANTING.—I.

I NOW come to the most important part of these articles, viz., the adornment of the rock garden with suitable plants. In my opinion it is most essential that the planting of the principal part—if not of the whole of the rock garden—should be done, or at least supervised, by the same person who designed and constructed the rocks. Not only for the sake of particular effects, but also for the well-being of the plants, it is of the utmost importance that the person entrusted with the planting should know exactly how the rocks were composed. Whether there are narrow crevices formed below the surface of the soil, whether the stones mixed with the soil are limestone, granite, or any other kind, whether the place is well drained, and whether the situation is dry or wet—all these are vital questions, which can be solved satisfactorily only by the person who has carefully watched every inch of the work during its progress, and who, perhaps, even when building this or that particular rock made special preparations to suit the requirements of certain kinds of plants. I have frequently constructed rocks and prepared them with the greatest possible care for the reception of the choicest alpine, but at the special request of the owner left the planting to be done later on. When visiting the same spot a year or two later, I was horrified to find the places that I had taken such great pains to prepare for choice alpine occupied by some coarse weedy-looking plants altogether out of place, and for which all the special preparation of crevices, &c., would have been quite unnecessary, and was, therefore, only so much time and labour wasted. Nothing is easier than the spoiling of a rock garden by bad and unsuitable planting, and nothing is more difficult than remedying the evil effects thus produced.

I have in an earlier chapter on the requirements of alpine plants pointed out the desirability of setting apart at least a portion of the rock garden to the almost exclusive use of the smallest and choicest kinds of mountain plants, which might for many years occupy the same position without overcrowding and killing each other. This select part of the rock garden should be the portion which is most easily reached and admits of access to every plant. Unless the work should be of very small proportions indeed, there would probably be also parts devoted to larger plants, and the portion of the work requiring the most knowledge of plants and at the same time the most artistic taste is the effective blending and amalgamating of groups of plants of a different character, so as to be practical, i.e., suited to the requirements of the plants and also perfectly careless and natural in appearance. The system of putting plants of the same kind together so as to form large or small irregular groups is much to be preferred to the system (if such it can be called) of letting all the plants in the rock garden form a sort of general mixture. In a

kinds, in which the flowers resemble the old Juarezi and are of refined aspect. The following were shown by Messrs. Keynes, Williams and Co., and are well worth a place in the garden: Lady Penzance is a neat, shapely flower, rich self yellow, and of much beauty; Countess of Radnor, salmon-rose, the centre yellow; Chancellor, crimson-purple; Bertha Mawley, crimson, shot with magenta, a very distinct kind; and Countess of Gosford, one of the most distinct of the section, the flowers comparatively small, reddish brown in colour, the centre yellow. We hope to see more kinds of this character raised, as here we get the true shape.

Rudbeckia purpurea.—It was interesting to note at the recent R.H.S. show how often this fine hardy perennial was exhibited. It is welcome as much as anything for its colour, which is very distinct, and a relief to the preponderance of yellow from the perennial Sunflowers at this season. A good break of *R. purpurea* in the garden makes an interesting feature throughout the autumn months.

Good varieties of Gladioli.—In looking through the remarkably fine collection from Messrs. Kelway and Son at the recent exhibition of the Royal Horticultural Society, we made note of the following Gladioli for their colour. Of

well-arranged rock garden, however, this planting in groups requires the greatest care and circumspection, as the plants must be judged by what they will be, and not by what they are when planted. If the sizes and shapes of the groups do not vary sufficiently, or if the outlines are too stiff, the arrangement will look more like a nursery garden than like a piece of idealised Nature. When, therefore, groups of plants are of considerable size, it would, I think, be well to keep the irregular outlines so loose that plants of adjoining groups can protrude here and there, or, in other words, to amalgamate one group of plants with another so gradually, that no discernible line of separation exists between the two, which is exactly as we would find them in Nature. Thus we may join a group of *Gentians* to a group of *Edelweiss*, a group of *Androsaces* to a group of the neatest gems among *Saxifrages*, and so on. Or between taller plants in the bolder part of the rock garden we might form a carpet with *Aubrietia*, *Arabis* and *Alyssum*, or with *Sedums* and mossy *Saxifrages* covering the ground in irregular groups, without detracting in any way from the beauty of the taller plants forming the principal feature of such groups.

The question of arranging the plants with a view to successive blooming and harmony of colour, too, is a most important one. Late-flowering as well as midseason and early-flowering plants would have to be distributed with the greatest care if we would prevent certain parts of the work from looking dull and uninteresting during the greater part of the year. Sometimes plants flowering at different periods of the season can be grouped together with good effect, not only on the rocks themselves, but also where comparatively level places suitable for large irregular beds or groups occur between the rocks at intervals. We might, for instance, plant a large group of *Primula Sieboldi* or other spring-flowering plants and intermix them with *Spiraea filipendula*, which would bloom in summer, introducing into the same group also a few late-flowering plants like *Plumbago Larpentæ*, or others. The result of such an arrangement would be that we would have a gay and cheerful looking group of plants blooming from early spring till late in autumn.

I will now discuss the operation of

PLANTING CHOICE ALPINES.

By choice alpine I mean the neatest and smallest kinds of mountain plants, mostly from high altitudes, which are suitable for the select part of the rock garden and require being planted more carefully than plants of coarser growth. If at all possible, only well acclimatised and established plants in pots should be used for this purpose. I find it an excellent plan to have all plants available close at hand and plunged with their pots into a bed of ashes, sand or soil until wanted, keeping not only all the sorts distinct, but separating also the shade-loving plants from those requiring a sunny position. When thus brought together, the plants can be easily selected as most suitable for the various situations. Plants in pots have another advantage, and that is, that they can be planted at almost any time of the year, though early autumn and spring are, of course, the best time of all, as the plants would probably have the chance of being benefited by more rain.

The planting operations in the select part of the rock garden may be divided into three parts, viz.—

- (1) *Planting choice alpine on elevated level spots,*

- (2) *Planting on gently sloping ground,*
- (3) *Planting abruptly sloping or vertical fissures,*

and in this succession I will now discuss the best methods to be employed.

(1) PLANTING CHOICE ALPINES ON ELEVATED LEVEL SPOTS.

Level spots among the rocks are generally devoted to plants requiring a considerable degree of moisture; but it is absolutely necessary that such spots should be well drained. I cannot here enlarge on the formation of proper crevices, but if these were made on the principle explained and recommended in the chapter entitled "Construction of rocks for choice alpine" (see THE GARDEN of April 1, pp. 253 and 254, where my method is fully described and illustrated by sketches), there could be no doubt about the drainage being perfect. My plan is not to fill up the crevices entirely with stones and soil during the work of construction, but to leave the upper part open, so as to be able to fill this during the operation of planting with any particular soil that may be required. If the rocks were built during dry weather, I always find it an excellent plan to pour an abundance of water into these crevices several days before planting. The projecting stones will help to keep in the water, and enable us to give the ground such a soaking as it could never receive after the completion of the work. This watering has the additional advantage of causing all stones to settle firmly to their proper bearing, and also of causing the mixture of small stones and soil with which the crevice was filled to settle firmly against the sides of the stones and fill out any vacant spaces that might have been left during the general construction of the work.

The hints here given can apply, of course, only in a general sense to the planting of the select part of the rock garden, and any particular treatment of the plants will be considered in a later chapter, when the plants themselves will be enumerated. Generally speaking then, the plants are knocked out of the pots, the roots are loosened, and the plant is then inserted in the crevice. If this crevice should be too wide to enable the roots of the plant to "feel the stone," more stones must be added and pressed edgewise into the soil. In surrounding the roots of the plants with the mixture of small stones and soil prepared for them, a small stick will be found most useful for ramming the mixture firmly around the roots and making sure that no hollow spaces are left, as probably would be the case if the planting were done with a trowel in the ordinary way. When the crevice has been thus filled up, a little *Sphagnum Moss* might be spread around the plant, and the ground is then covered with small stones, which would not only prevent a too rapid evaporation of moisture from the ground, but would also help to surround the plants with a damp atmosphere by evaporating, especially on sunny days, the moisture previously accumulated. These small stones are best pressed firmly into the ground if this can be done without injury to the roots.

If the plants used are from very high altitudes, they would in some cases require to be kept cool at the roots, and though we cannot give them the cool streams flowing from the glaciers of their native mountains, we can at least protect their roots from the influence of such scorching rays of sunshine as we have had in this country during the present summer by covering the ground around the plants with white silver sand or very light-coloured stone chippings or gravel. It is a well-known fact

that white or very light colours repel the rays of sunshine whose heat would penetrate all substances of darker colour. *Gentiana bavarica* and other plants accustomed to have their roots immersed in the icy cold liquid that saturates their native haunts may thus be protected successfully in this country. A year or two after planting, when the roots have penetrated so deeply into the crevices as to be out of harm's way, this protection can be dispensed with, but until the plants have become established, this method of protecting the soil around them against drought and heat cannot be too strongly recommended.

Delicate plants which are exposed to a hot sun immediately after planting may be slightly shaded by putting a loose stone on the south side in such a way that its shadow would fall on the plant at least during the middle part of the day. As soon as the plant begins to feel at home, this stone would be, of course, removed, for abundance of light is in most cases absolutely necessary. F. W. MEYER.

Excerpt.

(To be continued.)

CARNATION NOTES.

IT seems clear, from the persistent way that "A. H." continues to advocate the growing of self-coloured Carnations, that there is likely to be a large demand this season for varieties of that description. I cannot say that I quite agree with him myself. I admit that masses of colour are always more beautiful and more effective than spots, but we most of us have to put up with what room our garden affords, and have not the space to set out 100 plants of one variety in a single border. If that is so, and you cannot plant in masses, what becomes of the supreme advantage of the self Carnation?

I am glad to see that this well-known authority agrees with what I have so often endeavoured to impress upon amateurs of Carnations, that many of the French varieties exceed in strength and vigour of constitution anything that we have in this country. He refers to Countess of Paris and *Carolus Duran*. To these two first-class French selfs I should like to be permitted to add the names of a few more equally good, thereby making up the dozen, any of which will grow well in the open air from Land's End to John o' Groats, as I have good reason to know from the reports of the last six years given me by my numerous correspondents. I am now only treating of selfs, but I have grown hundreds of others, all French, bizarres, flakes, fancies, yellow grounds, &c., all equally good and strong growers in the open air all the year round. The dozen is as follows:—

Countess of Paris	creamy white
<i>Carolus Duran</i>	orange
L'Eden	heliotrope
Merveille des Roses	immense, rose
Baron von Thuyll	violet
Lord Simorel	crushed strawberry
Eliasion	pink
Centenaire de Bergeman	rich plum
Duchesse de Lavalière	pure white, fringed
Du Roi	bright scarlet
Mme. de Senevière	dark red
Député Rambourgt.	yellow

Sha'don, Teignmouth. H. W. WEGUELAN.

Varieties of Montbretia.—We are pleased to see in our visits to nurseries and gardens that the *Montbretias* are grown well in several places and in good variety. When at Long Ditton recently we made note of several excellent kinds, the colours rich, distinct, and the plants very free. One of the most conspicuous was *Gerbe d'Or*, which has a small yellow flower of much beauty, a change from those in which orange-scarlet enters largely. *Pyramidalis* is worthy of mention, the flowers rich

orange-scarlet; and also of note is Fiery Star, the flowers not large, but very bright. The Montbretias are not only valuable for massing boldly in the garden, but also for cutting. The graceful spikes last well in water, even during very hot weather.

Tiger Lily in the London parks.—Lilies are not good town flowers, but they make very fine beds when they can be coaxed into respectable growth. In Regent's Park one of the finest beds at the present time is planted in the centre with *L. tigrinum splendens*, *Asparagus plumosus* and *Verbena venosa*. We do not remember to have seen such a combination before, but it is extremely happy.

Aster acris.—This is one of the best early-flowering Asters, but little is seen of it in private gardens. Few things are more interesting in the garden in September than a bed of this form mixed with the *Chrysanthemum Mme. Desgrange*. They are of similar height, the Aster being very dwarf, compact, bushy and smothered with pale purple flowers. It would be worth while to make a bed of it even, or of that charming kind named *linariifolius*, also in bloom, which has flowers of a similar shade of colour, but the petals droop in a characteristic way.

WAYS WITH WATER LILIES.

THE present season with its sub-tropical heat and sunshine has, indeed, been an ideal one for these lovely flowers. Never before have they bloomed so vigorously and continuously with us as this year, a fact largely to be attributed to suitable atmospheric conditions, but partly to the rhizomes being now well established in deep rich mud, leaf soil and cow manure. Another little secret in the culture of all the *Nymphæas*, so far as a long and continuous season of flowering is concerned, is the constant removal of all flowers when they close on the evening of, say, the fourth day after the bud opens. I have this year pulled or cut off all the old flowers, and as one result of this practice there has been a constant supply of fine flowers every day for over twelve weeks from the date the first blossoms opened (about the middle of May) until the present time.

In removing old Water Lily flowers, I have learned how to distinguish the old flowers from the newly-opening buds, which is not quite so easy in practice as in the case of other flowers. The old flowers close up for the last time on the third to the fourth day, and the plan in case of doubt is to pinch the closed flower, and if it really is a faded one, some discoloured water will be pressed out and the flower may be cut away; but if, perchance, it should prove to be an unopened flower-bud, then there is no water inside to be squeezed out, and, of course, it is left on the plant to open.

A practical word to intending *Nymphæa* planters and beginners in their culture may well be given here. The best time to start these flowers is in April and May, and April is by far the best month in which to divide old plants. Shallow water answers very well at first to start new rhizomes, and they are best planted in loosely-woven Osier hampers or wicker flats. In order to succeed with Water Lilies generally in a cold water pond, the water should never be less than 3 feet deep in the winter, but in summer such a depth is not so necessary even if desirable. If the water is shallow during severe and protracted frosts, there is danger of the growing points of the rhizomes becoming frost-killed, in which case they will rot away, and the subsequent breaks are weak and do not flower well. When *Nymphæas* are well established it is almost impossible to give them too much cow manure,

and guano mixed with rich mud may be thrown amongst the clumps with advantage after the leaves appear.

As cut flowers these Water Lilies are very lovely, but they require a little special management. The flower-buds should be cut just as the perianth segments begin to open in the sunshine for the first time, and may be arranged three, five, or more together in a shallow bowl, tray, or tazza of water and placed in full sunshine if possible near an open window. So treated, they will open for two or three successive days just as they would do upon the plants. In this way bowls of the different species and varieties are most attractive. I have tried both the pigmy varieties as well as the larger kinds in this way, and they were much admired. Most of the hardy Water Lilies, however, are essentially flowers of the hottest and brightest hours of the day, opening at ten or eleven and closing about three or four in the afternoon. On very hot, sunny days they have opened at eight in the morning and did not close until nearly six in the evening; but, on the other hand, on dull, rainy days or on dull, windy days they scarcely unfold their petals at all. They close so early, that many have been disappointed with them as flowers for the dinner-table, but they may be used for night effects if opened mechanically with the fingers before they are floated in clear fresh water amongst their own exquisite leaves. This must be done gently, turning each segment of the perianth from its naturally concave to a convex position, beginning at the sepals and turning each segment inside outwards as it were in turn. Some large bowls of *N. candidissima* (pure white) and of *N. Mariacea alba* so treated quite puzzled some friends, who persisted in mistaking them for night-blossoming Cacti, notwithstanding that they were floating amongst their own great pads or leaves.

I can quite believe the prophetic drift of "W. R.'s" recent note in THE GARDEN about these most exquisite flowers and the fertile potentialities of the water garden. But we are never satisfied. Some of us are now longing for M. B. Latour-Marliac to give us a hardy blue Water Lily. He has done much for us all, but "much would have more."

F. W. BURBIDGE.

NOTES ON HARDY PLANTS.

Veronica Hectori.—This is at once one of the rarest, hardiest, most distinct and beautiful of the new and peculiar shrubby species. These pretty little shrubs have curious ways. If you change them about in different soils and positions and temperatures, as you are apt to do when propagating and trying to afford them the best accommodation, you will get foliar developments so varied, that you can hardly believe the specimens are all of one stock. The general effect of this species has a resemblance to *Andromeda tetragona* and *A. fastigiata*, only that the arrangement of rudimentary foliage is without angles. This has now stood with me fully exposed and without the least protection at any time of the year unharmed for three years.

Daffodils.—It is true that to the eyes of the ordinary gardener scores of separately named kinds are very similar, practically the same for garden effect. It has been said by a Daffodil authority that not only are the Daffodils as distinct as kinds in other large families, but that were one to seek to reduce the numbers, it would be hard to know which should be more fittingly discarded, or even where to begin. It may be so, but I rather imagine that practically the questions will be depth of

purse and garden space. My own view is that those who become enthusiastic may grow large collections or selections and find few flowers to afford more pleasure and interest. But that the generality of gardeners might well reduce the number of varieties, including even the poetical section, to say a score kinds, and these might be selected to represent the more distinct types. I consider that the greatest mistake of the Daffodil grower or planter is in leaving the planting undone until the cold and wet season sets in, and the one and most common excuse made for the delay is a very sorry one at the most, viz., that the planter has a few flowers in his borders and does not like to disturb them yet to plant Daffodils. In many ways an objection of this kind might be obviated, and the Daffodils would then have a full and fair chance of doing their best.

Brachycome Sinclairi.—This little beauty sustains our interest in it in the best possible way by keeping on flowering all summer till quite late. It seems to be tender, and yet I have kept it without any effort at all for many years, or, in other words, it takes care of itself. Its earlier flowers produce good seed, which sows itself and comes up freely about the old plants. Nothing can be more dainty than its tiny Daisy-like beads, and still it makes itself attractive as an uncommon form of a common order. I think very sandy soil is best for it, because I never fail to find seedlings where there is plenty of sand and sunshine.

Lotus peltiorrhynchus.—I would simply notice this plant at present, as I have grown it but one winter. I believe, however, it is hardy if a place somewhat dry is selected for it. Its slender branching habit is most striking, and the silvery foliage even more so. Without its flowers it might almost be described by comparison as a silvery *Asparagus*. For stony ledges in a sunny aspect it is likely to do well as a permanent plant.

Onosma albo-rosea.—The propagation of the woody Borageworts is a pleasing and edifying study. It is delightful to see how some will root in just their one particular way, and how others resist with deadly stubbornness every form of coaxing, unless it be that the one mode or set of conditions is adopted to suit them. The "how to do it" with these subjects has special reference, I think, to quality of material or stock, season of operation, and especially position and subsequent treatment of the cuttings. Much indeed could be said about this matter generally by taking note of the different species in the relative sense, but the present note must deal only with the plant named. Having a strong plant to deal with that had previously had its points picked out, I got rather long branches, each with a number of laterals of a year's growth, consequently woody at their junction with the main branch. The whole of the main branch had been layered for a year, simply pegged to the surface. This, I supposed, would so tone the wood as to make it callus quickly and surely when made into cuttings. Each lateral was so cut as to take the inch or so of the older wood, and the older wood in its turn nicked on the underside so as to open up more callus surface. I had tried for several years to root cuttings without some such preparation of the wood, but never seemed to be successful. In this way the cuttings taken in early summer and placed in a bed of moist sand in full sunshine made long roots and plenty of them in a fortnight. I find it much easier to deal with such things when the days are longest and warmest, and the Borageworts especially resent being what we usually term "kept close." It seems as if their glandular surfaces become disarranged or destroyed when subjected to a sweating process, and it is important, I think, that every leaf should be retained as long as possible, as doubtless the foliage facilitates root-formation. When placed in exposed situations as here advised, the cuttings may sometimes seem shrivelled and doubtful, but as soon as a little root has been developed, it is pleasing to see how the leaves begin to prick up, and in a very short time most of them near the apex assume the normal state. This somewhat rare and beautiful plant is worth

more than ordinary care. A word of caution may here be given: do not let down the constitution of young plants by making their little branches into cuttings, or you may lose all. Only strong specimens should be cut from, and besides it is the larger specimens alone which are capable of giving an idea of the beauty of the plant when in flower.

Woodville, Kirkstall.

J. WOOD.

FLOWER GARDEN NOTES.

WE have taken advantage of a little spare time to overhaul and thoroughly reconstruct where necessary those home-made frames that come in so handy for hardening off plants in spring, and which are now filled with pot Strawberries, *Viola* cuttings, and a good batch of potted-up border Carnations. They are 2 feet high at back and 18 inches in front, giving just sufficient slope to throw off the rain, and are formed, as stated in a previous note, by fastening boards on either side uprights of 4-inch quartering. I find an application of gas tar to both posts and boards more than pays for the time and labour bestowed. The woodwork lasts sound much longer, especially if the space between the boards is packed with Fern, straw, or Heather. Continuing the short list of good dry-weather plants mentioned in last week's notes, I find *Tropeolum Vesuvianum* an extremely good thing, as it flowers with great freedom, and the season has been all against an undue development of foliage. Associated with plants of silvery foliage, as *Centaureas*, *Gnaphalium*, with a groundwork of *Veronica incana*, or as a broad band to a centre of white Snapdragons, it is very pretty and effective. It is a variety of close, compact habit, not a trailer, and should be planted thickly if a mass of colour is required. Cannell's dwarf *Ageratum*, little more than 3 inches in height and throwing large trusses of flower, forms just now a very bright bed associated with clumps of Chelsea Gem *Pelargonium*, a variety with bright variegation and double dark pink flowers. These things are good despite the difficulties of the season, and without having received any aid in the way of watering and mulching. Perhaps some correspondents who have grown tuberous *Begonias* rather largely and were unable to lend them a helping hand through the drought will say how they have fared. They are certainly not generally up to their usual form by a long way where they have had to weather the drought without help, but I think extra good where they were well mulched and received for some time after planting liberal supplies of water. Seed of East Lothian Stock must be sown at once if an early supply is required for another season, and the plants, so soon as they can be handled, be pricked out into a frame or into boxes and receive the shelter of a frame with the advent of bad weather. Such autumn-sown plants have been a great success this year; they were early planted, and consequently were well established by the time the effects of the dry weather were beginning to tell on more susceptible things. Borders or beds that are to be occupied by these Stocks another season will pay for doing well, for the Stock is a gross feeder, and not only gets a very firm grip of the ground, but draws therefrom every atom of goodness.

If more Carnations were layered than are likely to be required for beds, it is a good plan to pot up a few in 6-inch pots unless there are ample facilities for a plentiful supply of Tree Carnations, and even then the experiment can be tried, for these border varieties give no trouble all through the winter months, except an occasional supply of water and the protection of pots from frost. If transferred to a cool, airy house so soon as signs of growth are apparent in spring, the flowers will come in very useful for cutting before they are available out of doors. Only a word of caution: if the old crimson Clove is included, a sharp look-out must be kept on the foliage to see that the disease to which it is so susceptible does not make its appearance. We are quite free from the pest this year at present, and I hope shall remain so; but potting up the old Clove is a risky business, and so that par-

ticular colour must be represented (as near as we can get it) by Murillo. From more than one source I hear that batches of Margaret Carnation potted up in the autumn of 1892 were very quickly badly affected by the fungus, mildew, or blight. What is the proper term for the mysterious visitation?

The same cause which rendered most of our summer flowers stunted in growth and sickly in appearance has told heavily on ornamental trees and shrubs, especially 1892 transplanted stuff; many failures are noticeable, and we shall have a very early ripening of foliage and leaf-shedding. We have not as yet, I fancy, seen or realised the full effect of the drought, for looking through a large collection of shrubs the other day on a south hill, I found in many cases not only this early ripening of foliage, but a general absence of the plump, firm wood and buds one usually finds at this season. *Kalmias* and *Andromedas* with many Belgian *Azaleas*, and among deciduous shrubs *Hydrangea paniculata*, show in wood and bark what may be termed a drawn-up, shrivelled appearance. A few of these plants were mulched with short lawn Grass, but it proved of little use, being little better than powder after a couple of hot days. Among the different things used for special situations in autumn planting operations the ornamental Grasses *Gynerium* and *Arundo* often find a place. From one point of view, that of grace and elegance in the plume, the *Arundo* claims pride of place, but I should like to specially note as a warning to intending planters that the Pampas Grass is a long way the harder of the two. I should never in fact again plant *Arundo* conspicua in any special position, for although not actually killed, severe winters have reduced fine plants to little more than skeletons, although after a first experience they have been brought up and tied to rods and protected. The Pampas Grass, on the other hand, passes unharmed through the most severe weather. Other work of the week has been the overhauling of winter window and balcony boxes which will be required about the end of the month. There is nothing better for such boxes than small conifers with an outer edging of *Periwinkle*. I have tried several evergreen shrubs with either green or variegated foliage, but, with the exception of *Aucubas*, the majority succumb in sharp winters, leaving gaps in the boxes. The inmates of the boxes want cutting over slightly to keep them within bounds, surface soil pricked over and removed, and a bit of good stuff substituted if such work, by the way, was not performed in spring. That is really the better time to do it, as it leads to density of growth and bright rich foliage.

TREES AND SHRUBS.

SUMMER TRANSPLANTING OF CONIFERS.

ON September 11 of last year, when visiting for the first time the celebrated nurseries of MM. Honoré Defresne et fils at Vitry-sur-Seine, and more particularly inspecting that part of their grounds which lies near Villejuif, and is specially devoted to the culture of conifers, I was surprised to find that the transplanting, or, more properly speaking, the tubbing of these trees had just been completed.

Now, the period which has always been recommended as the best for transplanting conifers is during autumn (October and November) in the case of light soils, and during spring (April and May) in the case of heavy soils. The latter period is that which is most usually selected, for the reason that, as growth is then commencing and the sap circulating actively, the trees are less likely to suffer from being removed from the soil. It is undoubtedly an ascertained fact that the success of a plantation

of evergreen trees is more certain when the sap is actively at work than when it is at rest or dormant. But, as one can never be sure how the weather may turn out afterwards in the course of the spring, it is easy to comprehend that if a spring planting is succeeded by a mild, moist time, all will go well; but if, on the contrary, a dry, scorching season sets in, as happened this year, everything will be in jeopardy.

From these considerations I must say that the period for transplanting conifers which has been adopted by MM. Defresne appears to me to be in every respect deserving of recommendation. The operation should be commenced during the last fortnight in August, for it will be too late to set about it if this is delayed to the early part of September, and the reason for this is that at the time first mentioned (the last fortnight in August) conifers will have ceased making fresh growth over-ground, but their sap is still sufficiently active, after the main roots have been trimmed or shortened, to produce an unending and abundant growth of fibrous roots, by which the trees will be nourished. These new fibrous roots will have taken firm hold of the soil during the succeeding months of September and October, and the trees will thereby be enabled to withstand the rigour of the winter and come out in the following spring equal to subjects that have been transplanted a year previously. I must add that if the weather at and after the indicated time of planting is set fair, as it generally then is, the transplanted trees must be frequently watered either from fine-rosed watering-caus, or, better still, with a garden engine. In watering, care must be taken to give the leaves a thorough drenching, as the main object of the watering is to prevent, or at least to diminish the amount of evaporation from the leaves and thus to powerfully help the trees to strike root. In the morning or the evening is the proper time to administer these waterings, but never in the middle of the day.

This period of transplanting conifers will also be very advantageous to nurserymen in another way, as at that time the operation of shield-grafting with a dormant bud will have been almost completed, and then, being less pressed upon by other work than they would be in spring, they can proceed to the important work of transplanting conifers under the most advantageous conditions.

But as there are conifers for all kinds of soils, and as the most of them succeed well in siliceous-clayey or clayey-siliceous soils, it may be objected that in the latter part of the month of August soils of this kind after a short period of dry weather become so hard, that the work of transplanting or lifting the trees would not be easy. In this particular and very possible case it would be necessary either to wait for a propitious fall of rain, or else, if the means of doing so are available, to water the ground before commencing operations.

The foregoing remarks are especially applicable to conifers raised in the open ground, and which have already attained a sufficient size for planting out at once in parks and pleasure grounds, but they are also applicable to the youngest conifers raised in pots as well as generally to any conifers that are to be transplanted or repotted.

In transplanting conifers in the open ground, it is very essential to avoid a practice which is very commonly followed, namely, that of dipping the roots of the trees in a thick mixture composed of one-half pure loam and one-half cow manure, tempered with water into such a consistence that it will adhere firmly to the

roots. This operation (commonly termed "pralinage") is an excellent one for the deciduous-leaved forest and ornamental trees, but an equally bad one for conifers, which, as well as Rhododendrons, generally speaking, and all peat-loving plants, do not like or thrive on nitrogenous manures. This fact or truth, which was communicated to me by Professor Cornu, of the Muséum, has been proved to me clearly by the fate of a batch of young Yew trees which had had their roots dipped in this mixture at the time when they were transplanted, and made no growth whatever for two years afterwards. This spring they have given the first indication of making any fresh growth, that is, in the third year after they were transplanted.

In conclusion, I will summarise as follows: Plant or transplant conifers during the second fortnight in August, and never give them any kind of nitrogenous manure.—C. GROSDEMANGE, in *Revue Horticole*.

To the foregoing is appended the following note by M. Edouard André:—

The practice recommended by M. Grosdemange, and which he saw so judiciously carried out in the

enormous crops of fruit nearly every year, and is then a sight well worth seeing.—A. D.

Hypericum Moserianum.—We have previously made note of this hybrid St. John's Wort in THE GARDEN, but it deserves mention again, as it is of great beauty in the Royal Gardens, Kew, where both small and large beds are carpeted with the dwarf growth enriched with yellow flowers. It is a hybrid between *H. calycinum* and *H. patulum*, and is a very useful and ornamental kind for planting in distinct beds, as it blooms from early summer until quite late in autumn, whilst it is in perfection in full summer, when few shrubby things are in bloom.

CISTUS FORMOSUS.

This is an erect, much-branched, bushy shrub, with leaves greenish when old, but covered with a whitish tomentum when young, and large bright yellow flowers with a deep purplish brown blotch near the base of each petal. The species thrives well in any rich, dry soil, but is apt to succumb to the cold and wet of English winters. It is, however, such a beautiful plant, that it is well worth the trouble of putting in a

Cistus formosus (Helianthemum formosum):

nurseries of MM. H. Defresne, was many years ago highly recommended by M. André Leroy, the celebrated nurseryman at Angers, where the practice of transplanting conifers in the latter part of August is still carried out, as it has been in other places also for the last thirty or forty years.

In my own practice of forming plantations in parks and gardens, I frequently transplant conifers at the end of summer and always with success. I therefore feel bound to add my testimony to that of M. Grosdemange, and to congratulate him for having so opportunely directed the attention of planters to this admirable practice.

The Siberian Crab.—Mr. Hooper may well express surprise that this beautiful tree is not more frequently found on lawns. There is no more fruitful or handsome deciduous tree in cultivation than is the Siberian Crab when in bloom or in fruit. With this Crab should be planted Quinces, Medlars, Morello Cherries, Duchess of Gloucester Apples, Mulberries, indeed any fruiting tree that gives beautiful bloom in the spring and rich colour when in fruit in the autumn. Mr. Molyneux has at Swanmore a grand Siberian Crab tree that bears

pot of cuttings each autumn in a cold frame, planting these out in the open the following spring. It is one of the largest-flowered species and one of the most distinct and handsome of all the Sun Roses. If raised from seeds, which in ordinary seasons ripen in abundance, a considerable range of variation in the depth of the yellow colour and in the size and intensity of the purplish blotch is obtained. Seedlings also vary a good deal in foliage characters, so that any especially desirable variety should always be increased by cuttings, which root readily if made of half-ripened wood and inserted in a shaded cool frame in autumn.

CONIFERS AND MOISTURE.

In no place that I have visited, where conifers are grown in the most successful manner, have I ever seen them planted upon raised mounds. This system is an utter mistake; of this I am fully convinced, and many will have cause to regret its having been adopted after such a phenomenally dry spring and summer as that of the present year. Not only will this be the case in newly-planted examples, but it will also seriously affect others

which have been planted several years. Where mounded up it will be quite impossible for the rainfall, during many months to come, to thoroughly penetrate the soil. It is not only at the present time, but during another season also, that bad results will ensue, for where there is a semblance of drought at all it is only a question of time, by a process of slow starvation, that those permanently established will quite succumb. I have seen the finest of our imported coniferæ from Japan, from North and South America, and from other quarters of the globe, thriving amazingly well in different parts of England and Wales, all seeming to be in perfect accord. In each of these places, where found growing most luxuriantly, the rainfall of the district has been above the average. Take, for instance, the lake district of Cumberland and Westmoreland, and that part contiguous to Windermere in particular. Here the rainfall is always noted as being excessive, but conifers of all kinds luxuriate in the district.

They do not show any symptoms of suffering from the effects of the more severe frosts of the winter season. In the south, with several degrees less of frost as a rule, many examples will be found that are not nearly so healthy. One might naturally assume that in the case of the Japanese coniferæ, which come from a country milder, on the whole, than Great Britain, they would suffer more from frost than anything else. That this is not the case can be abundantly verified in many instances in the localities already quoted. The cause of non-success in several districts must be rather traced to a weakened constitution brought about by want of moisture during the growing season, this being afterwards hastened or made more apparent by the effects of a severe winter and easterly winds. Some might think that, where the rainfall was so excessive, the growth would be too vigorous and that each kind would grow out of character; this, however, is not the case, but rather the reverse follows. I have never seen such compact growth anywhere in the coniferæ as in the lake district and North Wales, notably the former. There are, I am fully aware, other causes that contribute to the success already indicated. One is the fine quality of the loam, which is sound and enduring, being full of fibre, not of light texture, nor, on the other hand, heavy; another is, without doubt, the rocky character of the subsoil, the rocks cropping up here and there in most of the gardens where these plants thrive so well. This latter fact points undoubtedly to a natural system of drainage. That this is essentially needful cannot be disputed, for, in spite of these conifers thriving so well, they must not be designated marsh or aquatic plants. Herein comes the mistake, on the other hand, of planting upon mounds of raised earth, thinking to avoid the evil of excessive moisture, therefore falling into the opposite evil of drought instead. How, then, it may be asked, is the fact of water-logging the soil around the roots to be overcome upon retentive land in localities where a rocky stratum does not exist near enough to the surface to be of any real service in draining the soil? The answer to this is, provide drainage either by means of pipes, or brick bats, or any suitable refuse to effect this, and then plant upon the natural level of the ground, so that each plant receives its fair share of moisture. Upon what are termed light soils, or where the subsoil is gravelly, these precautions would not be necessary. In these cases, however, artificial watering should be resorted to in all such seasons as the present one, and even in others more favourable to healthy growth. The reason why coniferæ do not receive attention in the way of watering is without doubt the fact that they do not show signs of distress at the time in such a plain and unmistakable manner as do many other trees and shrubs. In what are termed dry localities, it is incumbent to guard against this suffering in one way or another by watering, and syringing also in the case of newly-planted trees. In doing this it may be urged that labour is scarce and time cannot be spared, or that proper conveniences are not available. Having to purchase and replant fresh examples will in a short time involve more expense,

however, with the same disadvantages to be fought against.

I have furthermore noted that the best results have been apparent where at least a partial shelter has been obtainable from easterly winds. In some districts these prevail more than in others, or, at any rate, are more injurious in some localities than in others. Protection, therefore, from easterly winds as experienced in many parts of this country should be duly considered when fixing upon a spot for fresh planting. I do not for one moment think that an easterly wind in either the lake district or in North Wales, or in some parts of Scotland for all that, would be nearly so injurious as in the more level districts, where it gains force and the atmosphere is less laden with humidity. In the case of conifers in general all due consideration should be given to soils and situations so as to avoid in some measure disappointment in the future. Conifers in general are wind-resisting subjects, but it is the easterly wind that tries them most. On the south-west coast of Anglesea (N.W.), for instance, where fully exposed to the westerly gales, the *Retinosporas* thrive surprisingly well, the moisture of the atmosphere, although largely laden with saline matter, not harming them in the least. On the other hand, where the sooty fogs prevail, the greatest difficulty is experienced in keeping them alive and at all presentable. This, in my opinion, might in some measure be obviated by having recourse to the garden engine more frequently to wash them, and that even in the winter season. In Scotland it is the purity of the atmosphere, combined with the large rainfall, that is so conducive to that splendid growth of the various forms of the *Abies*, of the *Picea*, and of the *Pinus* families. In North Wales the same conditions obtain more or less, the severity of the frosts not appearing to have any effect upon the growth. It is rather from drought, I am fully convinced, that failure to succeed with these splendid subjects in general must be anticipated.—H. G., in *Field*.

THE SELECTION OF RACES OF CULTIVATED PLANTS.*

THE subject on which I intend to address you may seem at first sight to be a rather special and limited one. I trust, however, that upon consideration you will see with me that it is one of great importance and of the deepest interest. I claim for it a constant and all-powerful action in the life of garden plants when we are seeking the most improved races.

It is a well-established fact that the life-work of plants is to make the mineral wealth of the earth fitted for the use of animals and of man. Now it is clear that the plant's work can be done well or ill according to its more or less perfect fitness to its functions. It is, moreover, within the power of man to consider, and to some extent control, the efficiency of plants in regard to their work, to select and to increase the best only, and by continued selection to develop more and more the good qualities of each kind. In this way man raises races and varieties of plants which do their work best and quickest. Heredity is the lever by which the results of the study and care and perseverance of the raiser are fixed, so to say, into the most valuable of the plants grown for man's use or delight. We have no more powerful means of improve-

ment of vegetable forms. All the care, food and protection given to plants may make them larger and finer, but only selection among many of the same kind, with the help of heredity, can fashion an enduring race of plants with special good qualities for our farms, gardens or orchards. Chance seedling may yield some very good finds, as sometimes a good hit is made by shooting at random. But no good marksman will, even after the luckiest of chance shots, dispense with the use of his eyes and judgment for the rest of the day! In the same way no experienced raiser will trust to chance in the choice of the seed from which he expects some precious results. He will gather it from one plant seen among many, and will have good reasons to show for his choice.

It is plain that selection was not at all times done with such thought and skill as it is now; but ever since plants have been cultivated an evident improvement has been going on for our benefit, and fixed and valuable races of field plants, vegetables, flowers and fruits were known to the oldest nations and are mentioned by the oldest writers. Since the settlement of America a new field was opened for good work, which yielded a splendid crop of honour and profit to American as well as to European cultivators, and through them to their respective countries. Let anyone who doubts the high value of selection look at our fine races of Cabbages, Kales, Cauliflowers, Kohl Rabi and Rutabaga and compare them with the wild Cabbage of our western shores of Europe; let him compare our fine garden Beets and our Mangolds to the wild Beet of the Mediterranean shores; let him compare the Tomatoes and Potatoes of to-day with the wild South American plants, and he will see proof that only human thought and skill have brought about such wonderful changes—many of them in our own day, many, on the other hand, some hundreds of years in existence. In the Tomato and Potato we have two distinct examples of garden races, viz., (1) those which are increased from seeds, as the Tomato, and (2) those which are increased by division of a plant, as the Potato. Even where we divide the plant itself, heredity is of some importance, as new varieties can be raised from seed only, and it is by no means indifferent to gather seeds meant for the purpose from one variety of Potato or from another. Distinct groups of races are seen in the Potato, as the Rose tribe, to which the Early Rose, Late Rose, and many more can be referred. Just in the same way a nurseryman who sows Pear pips in search of new varieties will take good care to take them from some old sort the parentage of which gives good hopes of success. It follows then that even where increase by division is the rule, the knowledge of the quality and history of a plant may be of essential importance.

WHAT HEREDITY IS.

Where selection is done with skill and care the improvement of many kinds of cultivated

plants effected by its means is invaluable. The large Pansies, the huge hybrid Gladioli, the large-flowered Cannas were all brought from the state of small flowers to their present excellence in our own day by careful observers, who, watching every variation and keeping an exact record of the descent of all their plants, turn to the best account the wonderful action of heredity.

That plants are endowed with the power of changing to some extent under altered and varying conditions no one will deny who knows even a little natural history. Such changes will occur in wild Nature as well as under cultivation, and by the action of heredity will be transmitted more or less faithfully to the next generation.

But an all-important fact must be recognised and remembered. It is that in the wild state only such variations have a chance of enduring as give the plant in which they occur some advantage in its life. Many variations appear every year which soon disappear, because they are a loss, not a gain to the plant. Suppose in the wild state a Potato plant with short stems and late sprouting tubers in a mass at the base of the stem. Such a plant would not have any chance against rank-growing and early shooting varieties, and it would soon perish. Still, some such characters belong to some of our best Potatoes. This is owing to the action of man, who throws his power into the balance when cultivating plants which are useful or pleasant to him, and who gives the weakest plant, if it is for some reason a favourite with him, all the advantage he can to make it thrive and answer his purpose. Most of the variations induced in our garden plants are not in favour of the plant if in a "free fight" with its kind in Nature. All our improved roots, as Carrots, Turnips, Beets, make an early and succulent growth for our own benefit, but not at all for their own good. If left to their fate to struggle with their own wild forms they would soon have to take a "back seat," and very likely soon perish. It follows then that varieties improved from man's point of view must receive kind treatment and richer food than wild forms of the same plant. The cultivated plant, like the domesticated animal, yields in a measure its powers of self-defence to adapt itself to our service. Man must in return provide for its safety and nourishment. In the improvement of plants the action of man, much like influences which act on plants in the wild state, only brings about slow and gradual changes, often scarcely noticeable at first. But if the efforts towards the desired end be kept on steadily, the changes will soon become greater and greater, and the last stages of the improvement will become much more rapid than the first ones.

I may relate here in a few words an unpublished experiment which I have been conducting for more than twenty years—from 1872 to the present year. It has consisted in cultivating one of our Parsley Worts (*Anthriscus sylvestris*), a European weed, in order to change its slender and

* Paper read by Mons. H. L. de Vilmorin, Paris, before the Seedsmen's session of the World's Fair Horticultural Congress, Chicago.

much-forked roots into fleshy, straight, and clean roots, say like those of the Parsnip. Amongst the first batch of roots raised from wild seeds a dozen were selected with a tendency in their roots to larger and straighter bodies. Each root was planted separately and its seed harvested separately. Of the dozen lots obtained, eight or nine were discarded at once, and roots were selected only in such lots as exhibited some trace of variation. Again a dozen roots or so were chosen, a drawing made of each root, which was afterwards planted separately. I have sketches of all the roots selected, so that it is possible to follow all the stages of variation of each plant living at this day. For the first ten years the changes were slight, but now they are more and more marked with every generation, and in some of the lots the straight and smooth roots are the most numerous.

My object was not to create a new vegetable, as the roots of *Anthriscus sylvestris* have such a strong taste of camphor as to be quite uneatable, but simply to show that careful and continuous selection could transform a wild plant in years that do not equal a quarter of the span of many human lives. Like results had been shown by my grandfather with the wild Carrot, only its results were open to controversy as to possible crosses between garden varieties and the wild strain. No such objection can be raised in the case of my wood Parsley Wort.

HOW IT WORKS.

Although heredity is an ever-present and active agent in the transmission of qualities and characteristics in organised beings, its mode of action is not so simple as at a first glance it might seem to be. That like breeds like is a commonly admitted fact, but there like must be taken in a rather broad sense, and the fact that some differences may occur between the parent and the offspring is at the bottom of all improvement of plants by selection.

A being born from one or two of the same kind will be like his parent or parents. But if the parents, although of one kind, were not exactly like one another, how will the descendant look? Will it take after the one or after the other, or blend the features of both? And again, if each of the parents comes from two different ancestors, which of the four will take the lead in the form and character of the new being?

The network of lines of attraction which would induce a living organism, plant or animal, to be like every one of its ancestors can scarcely be unravelled. Still, the consideration of the various influences acting on an incipient organism can be pretty accurately summed up in direct heredity, which tends to make the new plant or animal to resemble its immediate progenitors, and atavism, which induces it to be like the mass of its removed ancestors. I omit for the present the idiosyncrasy, which is the tendency in the new plant to combine the inherited characteristics in some special manner

adapted to its own particular wants. If the parent was like its progenitors, then all the influences work the same way, and there is every chance of perfect fixity in the series of beings born in succession. But if the progenitors for one or more generations has swerved from the characteristics of the ancestors, heredity and atavism will come into conflict, and the outcome cannot be predicted surely.

Some hints on probabilities may be had from an experiment conducted by my father on two varieties of the *Lupinus hirsutus*, the one with blue and the other with pink flowers. The conditions were in this case very well adapted to the study of the action of heredity, the flowers being in the *Lupine* not only hermaphrodite, but also cleistogamous, so that a seed is the produce of only one bloom of one plant. Two lots of seeds were sown to begin with, some of the blue and some of the pink strain. Most plants turned out true; still a few with pink flowers were found in the lot of blue, and conversely some blue amongst the pink ones.

In the following year seeds of the true plants were sown again, and along with them seeds of the "rogues" found in each lot. In the latter the greater proportion of plants followed the colour of the parent plant, but a great many more showed the alternative colour than was the case in the original lots. Seed from blue and pink-flowered plants of the third generation were sown again, every possible combination in the relations of the ancestors as to colour and distance being tried as much as possible and the number of blue and pink-flowered plants being carefully noted in each case, and the experiment was carried on for several years. Though no exact rules can be arrived at from experiments with living things, from the tabulated results of the experiment the following inferences can be drawn:—

1. The tendency to resemble its parents is generally the strongest in any plant.
2. But it is notably impaired if coming into conflict with the tendency to resemble the bulk of the ancestors.
3. This latter tendency (called atavism) is constant, though not very strong, and scarcely becomes impaired by a series of generations passing by without a reversion to the ancestral type having taken place.
4. On the contrary, the tendency to resemble a near progenitor (two or three generations only distant) very soon becomes obliterated if the said progenitor be different from the bulk of the ancestors. From this it will be seen that choice new races can be raised quickest and with the smallest amount of labour where all needless conflict in the hereditary powers is avoided.

HOW THE ACTION OF HEREDITY CAN BEST BE TURNED TO ACCOUNT.

But it may be rightly remarked here that it must be shown how variations can be obtained before we are shown how they can be made permanent.

It is admitted by all observers that plants being immovably fixed in the ground by their roots, and consequently prevented from seeking favourable and from avoiding untoward circumstances, are endowed by way of compensation with the power to adapt themselves to some extent to different conditions as to soil and climate. The manner in which plants so adapt themselves is most admirable, but it is not here the place nor the time to consider it. Suffice it to say that the changes in the size, position, and anatomy of their various organs appear to be much called up by than produced directly by the changed conditions. The important point in the present case is that variations in the special characteristics of a cultivated race may and do occur occasionally, and that such variations can be made permanent and still magnified by the process of selection. To wait for them to appear among seedlings is the simplest and most ordinary process. But their appearance can be hastened and made more probable by the selection of seeds from a plant showing already some trace of variation, or by means of a cross with some other variety of the same species. As soon as a distinct variation has made its appearance, the work of selection begins. The essential thing is to secure a deviation from the old type of the plant under experiment. It matters little whether such deviation takes place in the desired direction or not. Some authors even advise the experimenter to look for any change at the first stage, and at the next one for the greatest possible deviation from the first change in any direction except a reversion to the old type. This may be useful as far as the appearance of new forms is concerned, but if adhered to too long, it might make the fixation of the new forms rather difficult and slow by breeding continuity out of the new race.

Whatever the cause of the original variation was, action of the plant's own tendency to vary, or some external cause, or a cross of pollen, the next thing to be done is to make the variation permanent by selection. This is sometimes very easy, the new form becoming at once perfectly true and fixed. A case in point occurred several years ago in my trial grounds at Verrières. One plant of *Clarkia elegans* with pure white double flowers was discovered among a number of the same species with double purple flowers. It was singled out of the seed sown the next year, when every plant raised gave only double white blooms, and it has never since been known to give any but pure white flowers. If such cases were of common occurrence, they would make the task of the breeder of new varieties a very easy one. Unfortunately, they are very rare exceptions, and the tendency of new seedling forms is rather to revert frequently and rapidly to the original type. Great attention and vigilance must be exerted to counterbalance this tendency to reversion. The best and most useful plan is not to mix together the seeds of the selected plants in case several were singled out, but to sow the seed of each separately, as the several plants selected may

be endowed in a very unequal degree with the power of transmitting their own characteristics to their progeny. Now the principal object and the principal effect of selection if well conducted is to effect a complete transmission of the qualities we seek of any given race. Its aim must be in consequence to eliminate any plant which is not fit to reproduce itself "true."

It is often observed that in such cases when the seeds of several plants selected in the same batch of seedlings are sown side by side and separately, the one will come up true with only a very few or no "rogues" at all, while others will give a very medley of plants. If further selection be made only from the lot that came up true, the new variety may be considered as already fixed; whereas many years of cultivation and "roguing" may be required to bring it to anything like purity if progenitors be taken from the lots in which numerous variations occurred. Fixity of character is of great importance to garden and field plants grown from seed, and the tendency to fixity should be inbred in plants just as the tendency to curliness or to hardness. The power of transmitting their own qualities to their progeny is just as hereditary as any other qualification, and no effort should be spared to make it one of the points of a new race. Breeding from single progenitors appears so far to be the safest and shortest way to the proposed end.

Cross-breeding greatly increases the chance of wide variation, but it makes the task of fixation more difficult. It, however, gives the raiser the only means in his possession to unite in one the qualities of two different plants while discarding their weak points. All the different qualities of the two parents seem to unite in the most varied combinations in the cross-bred products. In this way plants are often found which inherit most of the good points of both parents, while some others sum up the defects of both. This I repeatedly observed in rearing cross-bred Wheats. An occurrence not unfrequently observed in cross-bred plants is that some character belonging to one of the parents is magnified in the progeny. For an instance M. Charles Naudin observed in crossing *Daturas* that the cross of a slightly prickly variety with another kind which had smooth stems resulted in the raising of a decidedly prickly hybrid.

In framing the character of the progeny, the action of each parent is often very unequal, according to the power of each in transmitting its characters. The one that is better endowed in that respect stamps its features more firmly on the cross-bred plant. Discussions have arisen on the influence of the male and of the female progenitor on a cross. I believe that the stronger organism of the two, the one rather which is better endowed with the power to transmit its characters, will predominate in the progeny whether it comes from the male or the female parent.

One trait that makes the fixation of cross-bred plants difficult is in some characters of

both parents breaking out in different parts of one and the same plant, instead of being, as we could wish, blended together. In cross-bred Peas, for instance, which were raised from a white seeded and a green-seeded parent, it often occurs that at the second or third generation pods are produced which contain mixed white and green seeds. In the same manner round and wrinkled seeds are found in the same pod. This is a great difficulty, and an almost sure sign of further variation, as a plant showing such breaks cannot be depended upon to give rise to a uniform progeny. In many similar instances recorded in my books of experiments the green Peas gave plants with white seeds, and the white ones with green. You can scarcely expect a plant which is not constant in its own parts to be constant in its progeny.

The unity in character of any single plant is the main factor in the work of pedigree or grade breeding, and I wish to lay especial stress on that point, which I think of paramount importance. The consideration of the qualities or defects of a plant taken as a whole, not of minor parts, should guide the raiser in his work. Of this I am convinced from experience, and I may be permitted to give a few facts in support of my opinion.

The advice is often given in horticultural books to take the seeds from some particular portion of the seed-bearing plant in order to secure a better result. In German Stocks, for instance, it is a common belief that the seeds of pods taken from the middle or from the base of the main stem will give a larger proportion of plants with double flowers than if taken from the top of the same or from side shoots. I many times tested the idea, and it always proved a fallacy. All the pods on a plant give an almost exactly equal proportion of plants with double and single flowers, no matter what part of the plant they may be gathered from.

A real difference is in the percentage of single and double flowers from various plants of the same variety. In this way very wide differences sometimes occur, but not in the case of seeds taken from various parts of the same plant. I tried an experiment with seeds of *Chrysanthemum carinatum* gathered on double, single, and semi-double heads all growing on one plant, and found no difference whatever in the proportion of single and double-flowered plants. In striped *Verbenas* an unequal distribution of the colour is often noticed; some heads are pure white, some of a self colour, and most are marked with coloured stripes on white ground. I had seeds taken severally from all and tested alongside one another. The result was the same. All the seeds from one plant, whatever the colour of the flower that bore them, gave the same proportion of plain and variegated flowers. No more proof, I think, need be given that selection, which is all-important in the case of seeds from different plants, is of no importance as regards the different parts of any one plant on which seeds may be borne.

No limit can be fixed as to the improvements which may be expected from care, thought and selection. The gains of the last dozen years may usually be taken as the forerunners of better things. It is clear that no very important additions to our cultivated plants are to be expected now from the discovery of new species, but an unlimited field opens before the raiser of new and improved forms in all our garden flowers and in fruits and vegetables. The recent success of European raisers of new *Begonias*, of hybrid *Gladioli*, and of large-flowered *Cannas* are equalled by the gains of the American raisers of *Chrysanthemums*, of garden *Beets*, and of *Tomatoes*. I may add by way of conclusion that much good may be expected from the more and more frequent exchange of strains between the Old and the New World. Such complete changes of soil and of climate frequently give rise to variation, and so, either by subtle changes one cannot see the cause of or by well-considered crosses, American and European varieties of our useful or beautiful plants may give rise in their turn to more numerous and useful variations than would have occurred had these races been confined exclusively to the country of their origin.

GARDEN FLORA.

PLATE 926.

CALANTHES.

(WITH A COLOURED PLATE OF *C. GIGAS*.)

CALANTHE in its natural state is one of the most widely spread genera in the Orchid family, belonging to the few that are represented on both the Eastern and Western Hemispheres. The greater number of its species are concentrated in India and Japan, but others are found in South Africa, in Australia, and in Central America. Sir Joseph Hooker in his "Flora of British India" enumerates thirty-four species, so that with the representatives of other regions the genus altogether embraces about forty-five. It is with only a small proportion of these, however, that Orchid growers are concerned; most of them (including the whole of the American species) have never been introduced, so that it is probable scarcely more than a dozen species are at present in cultivation, and some of these are extremely rare.

For garden purposes *Calanthes* may be resolved into two well-marked groups—the evergreen and the deciduous. Numerically, the former is much the larger, but from the horticulturist's point of view the deciduous species are by far the more important. Although not more than three, or perhaps two, species are in cultivation, they and their varieties have been used to such good effect by professional and amateur hybridists, that *Calanthes* may safely be said to include some of the finest work done in this branch of horticulture. Of the two or three deciduous species alluded to, only one is generally cultivated; this is the old and well-known *C. vestita*, perhaps the most popular of

* Drawn for THE GARDEN in Messrs. Veitch's nursery at Chelsea, by Gertrude Hamilton. Lithographed and printed by Ben George, Hatton Garden, London.

all Orchids, taking the country through. This, however, is more especially the case in country gardens, the increasing prevalence of fogs in the neighbourhood of London having in a great measure rendered its cultivation useless there. The fact of its flowering from November onwards makes it exceptionally useful where the atmospheric conditions are favourable, but this, unfortunately, is the time when London fogs are worst, and, so far as I have seen, it is rarely indeed that the flowers escape. This applies more particularly to the typical form of *C. vestita*. The varieties of it known as *C. Regnieri* and *C. Turneri* flower well on into spring and escape, as does also the fine variety known as *gigantea* (or *oculata gigantea*), which is noteworthy because it retains its foliage during the flowering period. Its flowers are very large, the sepals and petals creamy white, and the blotch on the lip of a bright orange-red. Two other varieties which deserve mention are *Sanderiana*, with rosy carmine flowers, and *Williamsi*, in which the petals are pencilled with rosy pink and the lip is rosy crimson. The characters of *C. vestita* itself are so well known, that a description of them is unnecessary; it will suffice to say that it was first discovered by Dr. Wallich in Tenasserim in 1826, but not introduced to cultivation until twenty-two years after, when it was sent to Messrs. Veitch, of Exeter.

The species next in importance to *vestita* is *C. rosea*, but its importance is chiefly historical, and due more to the hybrids which owe their origin in part to it than to its own intrinsic merit. It was introduced to the Exeter Nursery in 1850 by Thomas Lobb. As *Calanthes* go now-a-days, it is not a striking plant, its spikes being about 1 foot high and the few flowers generally of a somewhat washed-out rose colour, although occasionally flowers of a brighter and more decided shade may be seen. It is now scarcely grown except in botanical collections. Another species which may be briefly mentioned is *C. labrosa*. It is of about the same size and strength as *C. rosea*, and was introduced by Messrs. Veitch in 1878. They describe the flowers as scarcely an inch in diameter and of a rosy purple colour. Like *C. rosea*, it is chiefly interesting on account of the hybrids raised from it.

The origin of the first hybrid *Calanthe* in the deciduous section dates back to 1856, in which year Dominy crossed *C. vestita* with *C. rosea*. Three years later this cross resulted in the flowering of *C. Veitchi*, which is, so far as general garden purposes are concerned, probably the most valuable and important hybrid ever raised. This is not owing so much to its beauty—for although that is great, there are others which surpass it—but rather to its capability of being rapidly propagated and to the long start it had. It was not until 1878 that the next hybrid *Calanthe* flowered, and by that time *C. Veitchi* had become a common garden Orchid. Since then, however, many more—named and unnamed—have been raised, amongst the most beautiful of which are those of Sir T. Lawrence, who has on several occasions made a most delightful exhibit of them at the Drill Hall.

But the crown of all the hybridist's labours, so far as this genus is concerned, is the beautiful Orchid here portrayed, *C. gigas*. It made its first appearance in public on January 17 of this year at the Drill Hall, when a first-class certificate was awarded to it. It had been raised by Messrs. Veitch, who gave the parentage as *C. Sanderiana* var. *gigantea* × *C. vestita* var. *gigantea*. (The *C. Sanderiana* here mentioned is a Cochin China plant, a variety of *C.*

vestita, and must not be confounded with the new East African species of that name described last year by Mr. Rolfe.) *C. gigas* when exhibited bore a spike which was 4 feet high and carried thirty to forty flowers. The sepals and petals were nearly pure white, whilst the large lip was of a lovely shade of rose, passing into crimson at the base. Of the size of the flowers and the substance of the different segments, the accompanying plate gives sufficient evidence. This hybrid has the additional merit of retaining its foliage in a fresh and healthy condition during the flowering season, a character previously pointed out as belonging to one of its parents, *C. vestita gigantea*. Altogether, it is the finest hybrid *Calanthe* yet raised.

Several very fine hybrids have been raised by using *C. Veitchi* as a parent. From it and *C. vestita rubro-oculata* *C. Sedeni* was obtained, the flowers of which are like those of *C. Veitchi*, but deeper in shade. It was raised by the famous hybridist after whom it is named, and first flowered in 1878. From the same hand came *C. lentiginosa* (*C. labrosa* × *C. Veitchi*). Reichenbach described it as a "lovely thing," with white flowers flushed with rose. Its variety *carminata* has, according to Messrs. Veitch, the richest coloured flowers of all the hybrid *Calanthes*. Amongst the hybrids of more recent origin may be mentioned *C. Mylesi* (*C. Veitchi* × *C. Turneri* var. *nivalis*), with pure white flowers; *C. Veitchi* var. *alba*, also pure white, raised by Sir C. Strickland from the same parents as *C. Veitchi* itself.

THE EVERGREEN SPECIES.

Whilst the flowers in this section of the genus possess the same leading features as those of the previous division, especially in regard to the prominence and distinctive character of the lip—which is attached to the base of the column, and is divided into four conspicuous lobes—the species differ considerably in other respects. The foliage is not only evergreen, but is of stouter texture and of a deeper green; the large variously-shaped pseudo-bulbs of the previous section are wanting, whilst, on the other hand, the flowers are represented in much greater variety of colour. Some of this group flower during the summer, so that by growing them as well as the deciduous species *Calanthes* may be had in flower during every month of the year. Their cultivation in most respects approximates that of the *vestita* group, one important exception being the necessity of keeping them fairly moist during the late winter months, when the others are quite dry. *C. vestita* and its allies are usually grown in a brisk stove heat, but with few exceptions (duly noted below) the evergreen kinds like intermediate temperatures. They require a compost consisting of two parts loam and one of peat (both of the best fibry kind with a large proportion of the loose earthy particles shaken out), lightened by the addition of a little chopped Sphagnum and coarse silver sand. When well established, dry cow manure may be used in the compost for repotting and top-dressing. I have found it a good plan to use broad shallow pans in preference to ordinarily shaped pots. In the former the compost is less liable to become sour, and the roots can push horizontally near the surface, which they prefer.

C. BREVICORNIS.—This is a Himalayan species, and occurs at elevations of 6000 feet to 8000 feet. It was introduced to Kew only a few years ago, although known long previously. As long ago as 1838 a figure of it made from a wild plant appeared in Lindley's *Sertum Orchidacearum*, t. 9. Its flowers are quaintly, yet handsomely coloured, the sepals and petals being brownish

purple with white margins; whilst the lip is of a deeper redder purple, also margined with white. The spikes are erect and carry eight to twelve flowers, each nearly 1½ inches in diameter. It is a rare species and flowers during early summer.

C. CURCULIGOIDES.—I have not seen more than three or four plants of this species altogether, and only one in flower. It is not easy to cultivate, and being a native of the Malacca Straits, requires tropical treatment. Its flowers are small, measuring scarcely more than half an inch in diameter, but they are crowded thickly on the top of a scape 18 inches high. The colour is orange-yellow, and the species is therefore unique amongst cultivated *Calanthes*.

C. MASUCA is a useful and well-known species that has been in cultivation more than fifty years. Its flowers are usually of a purplish mauve and are numerous borne towards the top of a scape 1½ feet to 2 feet high. It is a variable Orchid, some forms having pale purple or pale rose flowers, whilst in a variety known as *fulgens* the sepals are almost crimson and the lip purple. It was originally found in the Himalayas of Nepal and Sikkim, but was later discovered on the mountains of Ceylon.

C. NATALENSIS is undoubtedly one of the most charming of this group. As the name implies, it is a South African species, and it was introduced to Kew eight or ten years ago from King William's Town. The scape is about 1 foot high and carries several extremely pretty flowers, the colour of which is pale lilac on the sepals and petals and deep lilac on the lip. As a rule, it flowers in summer, but sometimes in autumn. It is at present a very scarce species, but with the first-rate communication now existing between this country and Natal, there is no reason why it should not be more plentiful; this, however, applies to several other South African Orchids of equal merit.

C. PLEIOCHROMA.—A Japanese species which, flowering in July and August, makes a succession plant to *C. brevicornis* and *C. natalensis*. The flower-spike is 18 inches high and the flowers are pale mauve, with a spot of violet on the centre of the lip; the flowers are 1½ inches in diameter. This species was introduced by Messrs. Veitch in 1891.

C. STRIATA.—This is a plant of considerable historical interest, having been figured by the naturalist Kempfer during his stay in Japan, where he went in 1690, but it was not until 150 years after that living plants were introduced. The following description is taken from the last plant I had in bloom. The scape was 15 inches to 18 inches high, and bore on the upper part sixteen flowers, each 1½ inches across. The sepals and petals were brownish red, more or less distinctly striated with yellow; the lip wholly yellow. *C. striata* flowers in February and March, the flower-spike and the new growth pushing simultaneously. When the flowers are past it should be placed in the Cattleya house, removing it to the cool house when growth is completed.

C. VERATRIFOLIA.—Handsome as all the previous species are, there is no question of the superiority of *C. veratrifolia* above all other *Calanthes* of this group. Its foliage alone would entitle it to rank as an ornamental plant, and when this is accompanied by the stout erect scape of pure white flowers, there are few Orchids which surpass it in all-round excellence. The plaited leaves in strong, healthy plants are 1½ feet to 2 feet long and of deep vivid green. The scape is about as much in height, with the flowers crowded in a dense raceme at the top. It has a remarkably wide distribution in its natural state. First met with in Northern India, it stretches through Cochin China and the islands of the far East away to Queensland. It is the one representative of *Calanthe* in Australia.

There is only one hybrid in this section to be mentioned; this is *C. Dominii*, which was raised by Mr. Dominy, after whom it was named. It was raised from *C. furcata* (now unknown in cultivation) and *C. masuca*, flowering first in 1856, three years after the seed was sown. It is

like *C. masuca* in habit and shape of flower, the colour of the latter being a light mauve-purple suffused with white. It flowers from June to August.

W. J. B.

THE WEEK'S WORK.

ORCHIDS.

THE present season seems to be quite as exceptional as regards Orchids as it does in reference to most other plants, which are quite three weeks earlier than usual. A striking Orchid now in flower is *Miltonia Moreliana*, a remarkably high-coloured form of *M. spectabilis*. The deep purple-maroon sepals and petals form a striking contrast to the reddish purple lip. The plant was first known under the name of *purpureo-violacea*. The yellowish tinge of the entire plant is not a sign of bad health; it is peculiar to it. The plants succeed best in pans, with an inch or two in depth of peat and Sphagnum. *Cattleya Loddigesi* var. *Harrisonæ* is also to the fore in the *Cattleya* house at this season, and it is interesting in one sense, because *C. Loddigesi* was the first *Cattleya* introduced to European gardens, and was grown under the name of *Epidendrum violaceum* until Lindley founded the genus *Cattleya* upon *C. labiata*. The mention of this species reminds us that it will soon be making a very fine display in the *Cattleya* house, and those who have recently purchased imported plants will be looking out for the development of the flowers. Those who have plants of the distinct little *Cattleya luteola* should now see that the plants, which are usually grown in small teak baskets, do not suffer from want of water, as the flowers may be expected to appear two months hence. We are now finding a good deal of work that wants attending to in the *Cattleya* house. Small seedlings which were repotted in the spring have grown so much, that they need repotting again. They do not grow quite so fast as *Cypripediums* for instance, but when of small size they need repotting every year, and sometimes twice, as in the present instance. I find the small plants which have not yet grown beyond the 2-inch and 2½-inch pots do best if, say, six or a dozen of these small pots each containing a *Cattleya* plant are stood upright in a teak basket and some potsherds put between the pots to keep them in position; I also pack a little freshly gathered Sphagnum over the potsherds. If this is kept in a moist and growing condition the young seedlings generally do well. *Cypripediums* may be treated in the same way. The long-bulbed *Cattleyas* and *Lælias* require some attention at this season; some of them are now making their growths, and care must be taken to keep water from getting into the half-grown sheaths. If water does get in, or it is even suspected of being there, much the best way is to turn the plants upside down, holding the fingers over the surface of the compost, and gently shake the water out. A valuable plant may be much depreciated in value by the loss of its leading growth. Keeping the plants too wet at the roots is also a cause of decay at this season.

Lælia elegans, *L. purpurata* and the numerous distinct varieties nearly allied to the former are not only impatient of too much water at the roots, but they also suffer from a low temperature sooner than the *Cattleyas* of the *C. labiata* section. Some of the *L. elegans* type have passed out of bloom and some are yet in flower. This is a good time to repot any plants that need it, as the roots are either pushing from the base of the flowering growths, or will soon do so if the plants are in good condition. It always pays to do this work carefully. The roots generally cling so tightly to the inner sides of the flower-pots, that to knock the plants out in the usual way, by turning them upside down and tapping the rim on the edge of the potting bench, would wrench the best roots from the plants. I break the flower-pots in pieces gently with a hammer and remove the pieces one

by one carefully with the fingers. It is not necessary to remove every bit of broken flower-pot, as the compost itself will contain a fair proportion. The potting material for these should be the best fibrous Orchid peat and clean chopped-up Sphagnum Moss. The small-sized pots should be filled half full of drainage, and the larger ones rather more than this. I like to use quite fresh Sphagnum, at least for the surface. They seem to do best when the Sphagnum is encouraged to grow between the pieces of peat and potsherds, but not so much as to overspread them. Plants well rooted may not need any support, but any that are inclined to be shaky should have neat sticks placed to the bulbs, for they must be kept firmly in position. These tall-growing species seem to do best on the centre stage of the house, or at least they ought to be where draughts of cold air cannot touch them, for I have seen plants both of the *L. elegans* and *L. purpurata* types much injured by cold winds passing through badly-fitted sashes. The treatment of *L. purpurata* is much the same, except that it makes very much more roots and may have a larger shift. The growths are now starting from the base of the last-formed bulbs. Large specimens have a tendency to become bare at the centre, owing to the bulbs creeping gradually out to the rim of the pots. Back breaks may be obtained by severing the rhizome with a sharp knife at a place where the bulb is likely to break. Some old plants get out of condition and need to be broken up. That may now be done, carefully repotting the portions in suitable sized flower-pots. It is better to take the opportunity to cut off any old yellow bulbs that have lost their leaves, and with them the part of the rhizome to which they are attached; the roots at this part are mostly dead and the compost decayed to a fine black powder. All this must be cleared away and the plants given a good start in the best potting material. No plants better repay the care of the cultivator than this glorious old *Lælia*; it will always be a popular plant in collections. I may also add once more that before repotting, all insect pests should be removed by sponging or fumigating. I have found that plants which have been recently repotted are more easily injured by tobacco smoke than those firmly established. More care must now be taken in watering the occupants of the various houses; shorter days and colder nights must be thoughtfully considered.

J. DOUGLAS.

THE KITCHEN GARDEN.

MAKING UP MUSHROOM BEDS.—To succeed with Mushrooms it is of the greatest importance that the material for forming the beds be in a suitable condition. The preparation of the manure having been referred to in a former calendar, the material should now be in condition for making up. This when ready should be sweet to the smell, and be neither too wet nor too dry. It matters little where the beds are made up at this season, as any position which may not be open to too great fluctuations of temperature caused by draughts or exposed to too much heat is suitable. The position of the beds even very often makes all the difference between success and failure, as a genial atmosphere is of as much importance as the material used for their formation.

FORMATION OF THE BEDS.—The position having been fixed upon, proceed to make up the beds. It is advisable to point out that the more open the position is the greater need is there of not making the beds too small. I do not like to make the beds of a less depth than 20 inches, width 4 feet, length being immaterial. Firmness being another essential detail, this must receive due attention. If the material was in the right condition for making up, the temperature will not rise much above 100°, but if it rises rapidly above this there is danger of the bed becoming spoiled. To obviate this holes should be bored all over the bed. A temperature of 80° or 85° is none too high for inserting the spawn, which should be placed 9 inches apart equally over the bed and be fixed firmly. If there is no likelihood of the tempera-

ture rising above 80° after the spawn has been put in, the bed should be soiled over. In sheds or other not very confined places, a thin covering of hay should be laid over the beds so as to conserve both moisture and warmth. In the Mushroom house an old mat is the most suitable covering.

OPEN-AIR BEDS.—This is a good season for making up a ridge-shaped bed in the open, but a sheltered position is highly essential. The site of the bed should be marked out by inserting corner sticks, so that the bed should be evenly made. The width of the base should be from 3 feet to 4 feet, the sides being brought up to a width of a foot across the top. The material must be well beaten with the back of a fork, so as to secure the requisite degree of firmness. Over-heating is not likely to occur, and the spawn must be inserted equally over the bed, which should be afterwards soiled over. A sprinkling of long litter must be spread over the whole bed. At this season an inch would be sufficient, but later on more will be needed so as to maintain the right temperature. The state of the weather in all cases is the guide, as if too heavy a covering is placed on whilst the temperature of the atmosphere is high, the bed would become much too hot.

TOMATOES FOR WINTER.—Extra care is needed with these, for although good Tomatoes are comparatively easily secured up till Christmas, yet after this time they are more often conspicuous by their absence. If previous instructions have been attended to, the plants will now be established in their fruiting pots, and be growing in a light and airy structure which can be heated during the night. Up till now plants have succeeded well without heat, which now that the nights are cooler and moister is certainly necessary to solidify the growth so as to keep away disease. A good position now for the pots is along the ridges of soil in structures cleared of Melons or Cucumbers, the growth being tied to the trellis. The soil may be levelled down and the pots stood on the surface, or they may be plunged partially in leaves, this keeping up a healthy root-action without causing grossness. The growths must be kept thinly trained, no side shoots being allowed to smother up the main stems, or the flowers will fail to set through exhaustion. As these open attend carefully to the setting. By keeping the plants carefully watered and the atmosphere in a warm and buoyant state through careful ventilation, a good set should be secured.

A. YOUNG.

FRUIT HOUSES.

PINES.—Fruits of Smooth Cayenne or other varieties that are to ripen in October and onwards ought now to be swelling rapidly, and the plants should be kept well supplied with guano water varied with diluted drainings from a farmyard. No strong doses ought to be given, the better plan being to give it them well diluted with water each time. Avoid over-watering, only enough being given to keep the soil uniformly moist. A night temperature of from 70° to 75° is suitable, a bottom-heat of from 85° to 90° being maintained. Close the house early enough on warm days to raise the temperature to 85°. Keep the air well charged with moisture, and on sunny afternoons lightly spray the leaves, but avoid wetting the crowns, especially in the case of Charlotte Rothschild, or otherwise they may become disproportionately large and ugly. Those plants with fruit not far advanced in growth may well have a few of the smaller lower leaves removed and then receive a top-dressing of horse-droppings and turfy loam in equal parts, or the former alone. This will prevent a loss of moisture from the soil and afford some support to the plants. Pines that are colouring should be placed at the driest and airiest end of the house, the flavour not being so good when the ripening takes place in a moist atmosphere and strong heat. Any fruit that is nearly ripe, and which it is desirable should keep for some time longer, may be transferred to cooler, drier quarters, such as a fruit room or a vinery,

and no water be given the plants. The most forward Queens, and which it is intended to fruit early next year, ought now to have less water given them, the atmosphere also being kept drier. Only enough water should be given to prevent the soil becoming excessively dry and the foliage limp. There must be no more overhead syringing and the night temperature should be reduced to about 65°. Plants to afford a succession should be kept growing strongly for another month, the heat and moisture being kept up during that time. Suckers may still be put in, the strongest being given 7-inch pots, and for the rest 6-inch pots are quite large enough. Use fibrous loam and a sprinkling of bone-meal only. Supposing the soil is in a moderately moist state, no water will be needed till roots are forming, and which soon takes place if the pots are plunged in a brisk bottom-heat of from 85° to 95°, the top heat being from 65° to 70°. During hot days very gently spray the plants overhead, ceasing to do this after they have formed roots.

BANANAS.—Late formed clusters of fruit will ripen readily enough in an ordinary stove temperature, and prove very acceptable during November and December. Bananas revel in rich food and plenty of moisture, and they ought always to be fed very highly from the time the clusters first show till near the ripening period. Rich top-dressings are also quickly taken possession of by the coarse hungry roots. Cut off the unsightly ends of the inflorescence just beyond where the last whorl of pods promises to swell to the full size, and remove any scales or dead flowers that are starting to decay. Those fruits that are ripening should, if possible, be subjected to a rather drier atmosphere, and when the uppermost have changed to a yellow colour and commence to crack, cut them and place in the fruit room to further mellow. This will be found a better plan than cutting whole clusters at one time, as any that are cut when quite in a green state and ripened similarly to those imported will not be any better than the latter; whereas they ought to be much superior. Plants that are to fruit early next year ought now to be growing very strongly, being already well established in either large pots, tubs, or small brick pits. Continue to keep them well supplied with water, varied with liquid manure if at all root-bound, the resting during the winter being brought about by the ordinary method of lowering the temperature so as to not greatly exceed 60° by night.

PEACHES AND NECTARINES.—This season the wood has matured very early and the leaves will fall probably three weeks or a month sooner than usual. It is after the wood is fully matured and the buds well plumped up that root-action is briskest, this going on all the while the leaves remain in a green or semi-green state. It is of the greatest importance, therefore, that the borders be kept in a thoroughly moist state, liquid manure being given to those somewhat impoverished, this tending to promote a stronger break next season. Unmulched borders frequently crack badly after overhead syringing ceases, but this must not be allowed to go on, or very many roots will be broken and a severe check be given to the formation of fibres. The surface of hard cracking borders should be lightly broken up, though not to the extent of damaging many surface roots, and a good soaking of water be given for two days in succession. All Peach houses are not favourably situated for the perfect ripening of the wood, and should there be any signs of backward maturation, more especially in the case of strong young trees, fire-heat, where possible, ought to be turned on and a good circulation of warm, dry air be constantly kept up. Continue the cutting out of exhausted wood or any old fruiting shoots that would otherwise have to be cut from the trees at the winter pruning, and the wood reserved will be all the better for the additional light and air that will reach it.

ROOT-LIFTING AND TREE-MOVING.—As root-action is briskest after the crops are cleared from the trees and the wood hardened, any root-lifting and tree-moving that may be thought desirable

should be done, this giving the trees a chance to recover from the check before the leaves all drop. Those trees that are rooting most strongly near the surface prove the most profitable, these also presenting the healthiest appearance throughout the season. Deep root-action is very frequently plainly denoted by the sickly yellow colour of the points of the branches. Now is a good time to open a wide deep trench at a distance of 5 feet or rather less from the stem of the trees, following this up by well undermiring so as to reach all the deep running roots. In many instances it is necessary to raise the ball of soil and roots saved considerably, the collar of the stem being brought fully up to or even well above the level of the border. In any case the roots saved, after having their broken ends pruned, should be brought up much nearer the surface than heretofore, and if the old soil is at all exhausted, substitute a good loamy compost. Trees may also be safely transplanted from early houses to successional compartments or *vice versa*. No attempt should be made to save a very large ball of soil with the roots, especially if hot-water pipes are in awkward positions or doorways have to be passed through. Take good care of the best of the roots, and make some allowance for sinking when the trees are replanted. Keep the roots within easy distance of the surface—they will strike downwards readily enough—and well distribute them through the soil. Keep the old ball of soil thoroughly moist, but avoid badly saturating the new soil. Syringe all newly-moved trees very frequently; they must be kept constantly wet in fact if disposed to flag badly, and they should also be shaded from bright sunshine and kept rather close. Partially lifted trees that give signs of flagging should be similarly treated.

PRACTICAL.

PLANT HOUSES.

GREENHOUSE PLANTS PLANTED OUT IN OPEN BORDERS.—**SOLANUMS.**—Those who are short of labour (and they are a good many), and consequently plant out these and other plants which are grown in quantity, must not much longer postpone the potting up. Solanums, when required larger than the trade size of plants in 4½-inch and 6-inch pots, are much easier grown by planting out. These will then later on be first-rate plants for large houses. Any secondary shoots made since the last stopping should be pinched back so as to expose the berries as much as possible and to assist them towards perfect maturation. In any case where the growth has been luxuriant, a spade should be worked round the plants to check the growth and to induce the roots to break afresh in that part of the ball which will be retained when potted. When this is done, a few moistenings overhead should be given, and a good supply at the roots also. Keep down any attacks of spider either by renewed syringings or by the use of sulphur.

SALVIAS.—To these the same remarks mainly apply. The latest stopping of such as *S. Heeri* and *S. gesnerifolia* for early spring flowering should now be given. Both of these sorts are disposed to run away in growth if not stopped a few times, besides which, by stopping now and at the same time checking the root-growth, the plants will lift all the more satisfactorily. Before lifting, the shoots should all be secured by ties to prevent breakage. Other kinds for late autumn and winter flowering, as *S. splendens* and *S. Betheli*, if they have been planted out should be the first to be lifted, and no more stopping should be allowed.

CHRYSANTHEMUMS, &c.—Where these come under this heading it will not be advisable to postpone potting many days longer, otherwise there will not be sufficient time for fresh root-action before the flowering season. If only wanted for cutting, a ready method is to lift with large balls and stand them in cold pits, empty orchard houses and the like, with plenty of covering to the roots for moisture. The late kinds, or at most the mid-season varieties, are the best to plant out for lifting. All other plants upon which any future store is set and which are expected to

retain their foliage and freshness should not be left out in the open ground much longer. The after treatment for a time in all of the foregoing cases must be rational if the best success is to be attained. By this, I mean that a close house or pit is not the right thing; it induces a soft and weakly growth, which is easily encouraged with a close treatment and too much moisture. See to it that the plants do not suffer from want of water, and let them have two or three syringings during the day. In most or even all of the foregoing cases the plants should be able to withstand any serious check without any coddling. If in the worst cases they do suffer more than is desirable, keep them close during bright sunshine, and give air more freely from the afternoon until the following morning.

WINTER-FLOWERING PLANTS IN POTS.—This month should be one of hardening to the growth of such as *Poinsettias*, which ought now to be well established in their flowering pots. Too much heat and moisture only tend to lengthen the stems of the plants to no good purpose. A light, rather dry and more airy house or pit should now be accorded them. With this treatment, however, they must not suffer at the roots. For a few days it may be needful to watch the plants against burning if previously any shading has been in use. *Euphorbia jacquiniæflora*, on the whole, does best with rather more warmth than the *Poinsettia* at this stage. I prefer for my own part to keep this plant in the stove, but fully exposed to the sunshine to ripen its growths. In both instances these plants should have occasional doses of liquid manure when the pots are well filled with roots. If there are any scale or bug on either, use every means to keep the same down and the foliage healthy and clean.

Winter-flowering *Begonias*, as *B. insignis* and its allies, should now be kept cooler and in plenty of light and air. Never mind if the foliage, as compared with plants in heat and moisture, does look less healthy; it may assume a yellowish green, but this is no indication of being out of health. The advantage will be apparent later on when the plants are in flower. *Eranthemum pulchellum* should by this time have made a good growth. This plant can be grown along now with the *Poinsettias*, but I prefer to give it a little more warmth, not so much, however, as that accorded to the *Euphorbia*. A pit to themselves or a shelf near the glass in an intermediate house would suit them. *Centropogon Lucyanus*, *Conoclinium ianthinum*, and *Reinwardtia tetragyna* will each do well treated like the *Begonias* aforesaid, the ripening being favourable to future flowering. *Scutellaria Mocciniana*, *Justicia carnea*, and *Thyracanthus rutilans* will each be at home with the *Poinsettias*; so also will *Plumbago rosea*, *Amasonia punicea*, *Aphelandra aurantiaca* *Rozeii*, and the *Jasminum* ought not to be out of the stove proper. If these are allowed to remain in a temperature much lower than the stove, there will be a risk in their losing their roots or in receiving a check in other ways. Let the watering now in any case be done early in the day, not nearly so much atmospheric moisture being needed.

JAMES HUDSON.

A new China Rose.—An acquisition to a charming class is named *Duke of York*. It is in bloom now in the Waltham Cross nursery of Messrs. Wm. Paul and Son, and deserves mention for its distinctness and bright colour. It reminds one in general aspect of the popular *Ideal*, the flowers of a crimson shade of colour passing to white towards the base of the petals. We noticed it also in the large collection of *Roses* from this firm at the recent exhibition of the Royal Horticultural Society at the Agricultural Hall. A good, free, and bright coloured *China Rose* is always welcome, and we are pleased to see that so much interest is now taken in those classes of *Roses* that were until comparatively recent times frowned upon. The rosarians of old seemed to have considered the *Ilybrid Perpetual* perfection and alone worth consideration.

ORCHARD AND FRUIT GARDEN.

COARSE FRUIT.

DURING the last six years I have noticed a tendency in judges to favour great size in fruit rather than quality. This has been the guiding principle of fruiterers and market salesmen very much longer, and even owners of large gardens have a similar weakness, so that, all things considered, it is not to be wondered at if gardeners generally adopt the same ideas. What individuals may think and say has little or no effect upon the different classes alluded to. Now-a-days it matters but little how good the quality of the Grapes exhibited at a flower show or displayed in a shop window may be if great size be wanting. Such varieties as Madresfield Court, Black Hamburg, and Foster's Seedling are frequently so badly treated, that they are fast going out of cultivation, or at any rate the Vines of them are being very greatly reduced in numbers. I have frequently seen the first-named in excellent condition passed over in favour of Alicante, and that, too, in August. Certainly the latter was shown in good style, but it ought to be remembered that it is of easy culture and, as a rule, not of first-rate quality; whereas Madresfield Court requires a lot more doing, and, as far as quality is concerned, is immeasurably superior to the Alicante. So long as a separate class is provided for Black Hamburg it will be seen at flower shows, but when it has to be pitted against Gros Maroc in good condition, it must be considerably above the average to take a prize. Gros Maroc is even frequently shown in collections of fruit where, if anywhere, we look for good quality, and yet it is only one remove from another coarse, badly flavoured variety—I mean Alnwick Seedling. At Shrewsbury extra fine and very ugly bunches of the latter were shown in a winning stand, but all the while judges favour such monstrosities there will be no attempt made to either select better shaped bunches or else to trim the rough ones into shape. At the same show and, if I remember rightly, on the same stand Alicante was shown equally rough and ugly. I readily admit that the berries were also large and well coloured, but that is no excuse for such unsightly clusters. Vines that produce the latter would also give bunches both large and handsome, and it is these that ought to be saved and the great branching clusters cut away. In another instance, large, though not badly formed, clusters of Gros Guillaume so caught the judges' fancy as to quite drag six other very moderate bunches along with them, yet they were neither ripe nor even well coloured. What will be the consequence of all this? Simply a general resort to the cultivation of varieties and the production of bunches that will best please the judges. The pretty bunches of choicer varieties will not be seen in competition for big prizes, and the scales will decide who shall take the prizes.

It is not black Grapes only that are wrongly judged, and this several exhibitors of Foster's Seedling, as well as disinterested onlookers, must have felt. No matter how well this variety may be shown, very mediocre bunches of Buckland Sweetwater will beat it. At Shrewsbury, for instance, there were three grand bunches of Foster's Seedling shown from South Wales, but they were passed over in favour of second-rate Buckland Sweetwater. Why should looseness of bunch and unevenness of berry be tolerated in Buckland Sweetwater any more than in the case of black Grapes? If only the half of the berries are larger and all

not exactly green in colour the prizes go to them, and the better flavoured and probably more perfectly ripened Foster's Seedling is nowhere. Muscat of Alexandria still holds its own against all comers among white Grapes, but the judges, as a rule, do not seem capable of appraising the merits of this variety properly. In a big class the bunches must be large and the berries of good size or they will not be looked at, some of the best ripened Muscats shown this season not being noticed other than by experienced critics.

Pine-apples are not very numerously shown anywhere, but enough are to be seen to prove my argument that coarseness is the order of the day. All must admit that a well-grown Queen is superior to all other varieties in point of flavour, but unless the fruit is nearly or quite equal in size to Smooth Cayenne it stands a good chance of being beaten. I hold that a well-formed, perfectly ripened Queen shown in August, and weighing say four pounds, should score over, or be considered equal to, a Cayenne or any other variety shown against it, no matter how heavy the latter may be. A Smooth Cayenne weighing six pounds is more easily grown than a Queen weighing four pounds, and there is no comparison as far as quality is concerned. Huge Melons as yet are not in great favour. A fruit weighing four pounds is quite large enough for a collection, and one weighing not more than one pound not unfrequently takes a prize when the fruits are judged by flavour. With Peaches, however, the case is very different. Great size would appear to be all that is necessary, little or no weight being attached either to the form, colour, or known good quality of the varieties staged. Fortunately, Sea Eagle is both large and good, but ought certainly to have some colour when shown. But for the introduction of this variety we should soon see Lord Palmerston, Pavie de Pomponne, Prince of Wales, Exquisite, and such like once more brought into prominence; in fact, unless I am very much mistaken, a "washed-out" dish of Pavie de Pomponne did recently take premier honours in the Peach class at a leading show. I am averse, as a rule, to cutting and hacking exhibition fruit, but would always test coarse Peaches. With such handsome richly-flavoured varieties as Bellegarde, Crimson Galande, Royal George, Grosse Mignonne, Dymond, and Barrington to select from there ought to be no necessity to either award prizes to or cultivate the coarser sorts. With Nectarines there are few or no causes for complaint, good dishes of Pine-apple or Pitmaston Orange being rarely or ever passed over in favour of less richly flavoured varieties.

It is among Plums where the greatest confusion exists, no two sets of judges apparently being able to arrive at similar conclusions. Some give the preference to good dishes of varieties of known excellence, and some cannot get away from great size only. Sometimes we see them compounding, as it were, the first prize going to a dessert variety and the second to a cooking sort. In one instance Jefferson was rightly placed first, but somewhat smaller, though good fruit was passed over in favour of White Magnum Bonum, this being, as a good fruit grower remarked in my hearing, "a descent from the sublime to the ridiculous." Pond's Seedling, Prince Englebert, Diamond, White Magnum Bonum and Goliath are poor, coarse things compared with Jefferson, Oulliu's Golden, Transparent Gage, Kirke's and such like; yet at the great Shrewsbury show some of the former were most favoured by the judges. A few years ago medium-sized to small dessert

Apples were preferred, good form, rich colour and known good quality of the varieties most affecting the decisions. Now-a-days dessert varieties cannot well be too large. It is true evenness and colour greatly recommend them, but there is no getting away from the fact that they must be comparatively coarse to win prizes. Are these big fruits most appreciated on the dining-table, or is it not the case that medium-sized, well-coloured Apples still find favour? Pears have been grown to huge proportions of late years, sensational dishes being seen at most autumn shows. Among some judges, however, there is a tendency to favour the less coarse fruit, the preference being rightly given to moderately large, well-matched and brightly coloured Pears. This is as it should be, and it is to be hoped the same rule will be once again applied to the Apple classes.

Not many mistakes are often made with respect to Apricots, the finer varieties, notably Moorpark and Hems Kirk, being also the most richly flavoured. The coarsest Fig I am acquainted with is the Castle Kennedy, but, thanks to the habit this variety has of cracking badly, it is not grown much, and most of the others are of good quality. Very little can be said in favour of the largest varieties of Strawberries; whilst big Gooseberries are poor things compared with the smaller varieties.

FRUIT GROWER.

Deterioration of Melons.—No sooner is a new Melon certificated, than in all directions attempts are made to use it for cross-breeding. It is quite evident that this in-and-out cross-breeding is weakening the constitution of the Melon, and no doubt may be another reason for the early collapse of plants before the fruit is perfected. Considering the number of years that attempts have been made to improve the Melon, the ideal should have been reached long ere this, but instead of going forward, it is just the opposite. In no introduction of late years is the flavour better than in some of the older kinds. The flavour of the Melon depends upon the grower, but for this to be perfect, the plants must be well grown and the fruits ripened on the plant.—A. YOUNG.

Crab trees in fruit.—These are certainly well worth the attention of the planter for their ornamental features alone, but in addition to this the fruits can be made into a very superior jelly. Where hardy fruits are exhibited in quantity, after the fashion so popular at some of the large shows, the different Crabs are very effective, and in this way some of them were especially noticeable at the Agricultural Hall. The variety John Downie, with its bright red and yellow fruits, is, perhaps, the finest of all where there is only space for one, but it by no means stands alone, as there are others that well merit a place. A very distinct form is Dartmouth Crab, a good deal larger than any of the others. This is, when ripe, of a bright purplish crimson tint and covered with a bloom after the manner of a Plum. The Fairy, a small red and yellow form, is very pretty, and so are the Siberian Crabs, some with red and others with yellow fruits, while that known as the Transparent is quite distinct from the others.—T.

Plums on north walls.—As I have previously recommended the growing of some of our choicest Plums against north walls, my reference to them now is to further emphasise the statements then made, from a close observation again this season. This season certainly has been more in favour of the production of good fruit from such a position than some previous years. I never had finer fruit from any position than from the trees against a north wall during the past few weeks. Jefferson, Kirke's and also the Green Gage were very fine. It is surprising how well this last succeeds against a north wall, the fruit this season from trees grow-

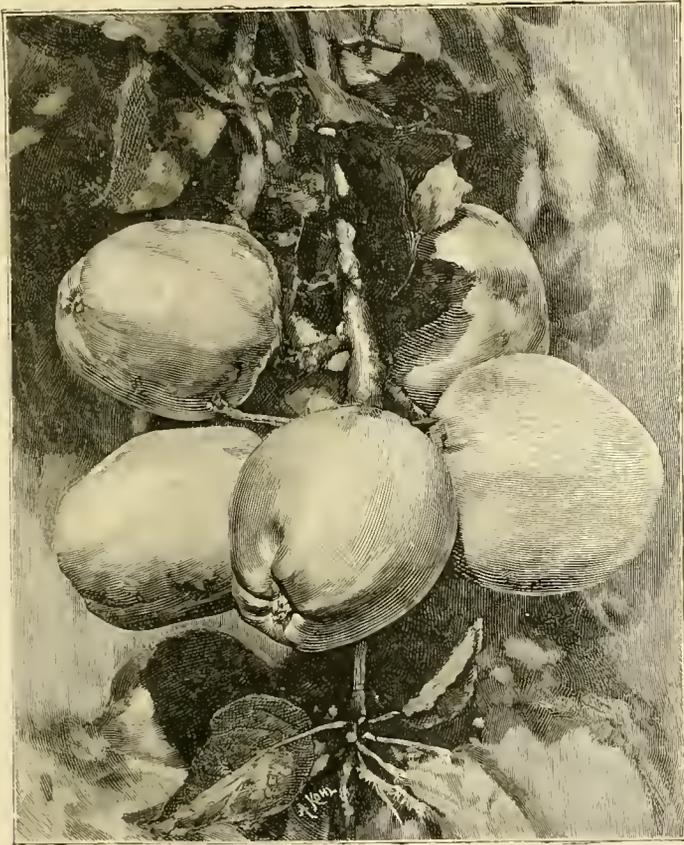

ing in the open not being nearly so finely flavoured. It is quite evident that other fruits, as well as Morello Cherries, Currants and Gooseberries, can be grown with advantage on north walls.—Y. A. H.

APPLE LORD SUFFIELD.

GIVEN the right soil and situation, where vigorous growth and freedom from canker can be ensured, this variety should take the lead. As an early cooking Apple and valuable market fruit it cannot well be beaten. Lord Grosvenor, frequently recommended as a substitute, although in some few soils succeeding where Suffield will not, is second to it in earliness and regularity of cropping; at least, that is my experience. Having made the culture of this Apple a speciality both in the form of

my five-year-old bushes, large enough to bear one and a half bushels of fruit each, have not hitherto given a good crop. Although Lord Suffield does not grow into a large tree, owing to its heavy cropping propensities, it is really a vigorous variety; at least, a young tree which will produce a bushel of large fruit and throw up shoots 2 feet in length in a season like the present cannot be called a weak grower. In grafting especially is the vigour of Lord Suffield seen. The grafts take better than those of any other kind; even the smallest wood is certain and soon swells and heals over the stock, so that it is possible to utilise all wood of proper length cut off in pruning. The grafts also keep sound in the soil longer than those of most varieties. Some object to growing these large Apples on standards on account of damage by wind, &c.; but as regards Suffield, not only is

good unless treated better than orchard trees generally. Grass and weeds should be kept clear at the least 2 feet or more round the stems. By grafting on to various stocks, some early and some late, there will be a better chance of some fruit escaping when frost comes with unusual severity. In 1891 my best crop was from grafts put on a tree of a specially early cider kind. Suffield trees generally were just in bloom on that terribly destructive morning of May 17, but on this one the fruit was set and comparatively uninjured. The time the fruit is ready for market does not seem to vary much, whether the stock be early or late. No doubt one chief reason that Lord Suffield is so good and regular a cropper is its tendency to profuse blooming and setting of fruit. The fruit will set in such abundance that even the various forms of blight cannot destroy it all. Kinds that bloom only moderately have stood no chance of a crop, for this has been a particularly trying season for Apple trees. Caterpillars of all kinds were very destructive here, and the Apple crop generally is very light indeed. Drought is one of the chief inducements to blight. When a plant or tree is suffering from want of sufficient moisture at the roots or the reverse, some form of parasite is sure to attack it, and hot weather with the entire absence of cleansing showers exactly suits the progeny of the winter moth, the lackey moth, the small ermine moth, and other caterpillar pests. Caterpillars are to be found every year as sure as the spring comes, and although in some seasons the weather is not favourable to their development, more or less damage is always done. Fruit will not grow without leaves, and the healthier the foliage the larger and more perfect the fruit. There is a marked advance in the size of early Apples on trees where the forward leaves are allowed by unassailed growth to draw a full share of nourishment from the atmosphere. Nitrogen in some form the tree must have, and the broader the leaf the greater its absorptive power.

A fruiting branch of Apple Lord Suffield.

I am not an advocate for much pruning: the heads of grafted trees will occasionally require thinning, and pruning is beneficial to Lord Suffield to a certain extent. In the case of bush trees on a rich soil, pruning is quite necessary the first few years, or a good deal of propping and tying will be needed. One of the chief objects in pruning these should be to enable the tree to carry a heavy crop without artificial support. This is best done where the annual growth is long by cutting back about one half, though where the shoots can be supported, as in the case of young espaliers or trees trained to a fence or arch, I believe in extension where there is room, and in any case to prune back all the young growth to a stubby head, as is done so frequently in gardens, is not the way to secure a full crop of this or any other Apple. Bushes and espaliers which have been served in this way year after year will generally be improved by cutting right away at least half of the head (and the present is a good time for doing this), thereby letting in more sunlight and allowing more extended growth. A taller and larger bush need not necessarily cause more injury to other garden crops by its shade, for you should be able to see through an Apple tree in the summer, then there is a chance for the direct sunlight to play on the fruit, a matter of the first importance with Red Astrachan, Worcester Pearmain, and other varieties, the chief value of which, as market Apples, lies in their superbly rich colour.

bush trees and as standards, I can recommend it as the most profitable Apple to grow, and every year I look on it with more favour. Of course, we must have variety. Really good dessert Apples are likely to be always in demand, though the reliable, free-cropping, and profitable early dessert Apple is yet to come.

There are, no doubt, soils on which such varieties as Cox's Orange Pippin succeed well, and we are not likely to be over-done with fruit of that description. Here ten bush trees of Cox's Orange planted five years have not yet produced a peck of fruit. I have found Stirling Castle a heavy cropper and grand for bush culture, but not well adapted for standards. I certainly have young standards which have borne a heavy crop of fine Apples every year since they were planted, but they require propping and tying to save the tree and fruit. Ecklinville Seedling is recommended as a first-class cropper, but

the fruit, as a rule, marketed before rough weather sets in, but the stem sprays have a natural tendency to enlarge and bend to the weight, enabling the fruit to hang on much firmer than that of many kinds, and it is surprising what a weight of fruit a three or four-year-old graft will carry. Only the other day I gathered some fine fruits from grafts put in in April last. At present (weeks after Lord Suffield has been gathered) the ground in the orchards is strewn with late Apples, such as Blenheim and Wellington, though drought and codlin moth are as much the cause this season as the prevalence of high winds.

If for standards on grass land, the young trees after being purchased from the nursery should be grown a few years on some good land, where they can receive special cultivation, for you cannot, as a rule, procure trees of sufficient size and strength to go directly to the orchard. If planted small on turf Suffield will do little

There need be little fear of overcropping Suffield if the tree has plenty of nourishment and the fruit is not too thick to grow to the fullest

size. The tree has a long season in which the recuperative process is going on to give strength for its next effort in bearing. This is one of the chief reasons no doubt why fruit-buds are so freely produced in this variety. As a rule I do not find thinning the fruit necessary, but this should be attended to where needful.

Holmer, Hereford.

E. W. BEAVEN.

LIFTING PEACH TREES.

THE beginning of September may be considered rather early to lift or transplant Peach or Nectarine trees, but it must be taken into account that we have had a tropical summer, and that most of the trees inside will have finished their growth sufficiently to allow of their being moved with safety. I am aware that this early lifting of trees is not favoured by some, but I am fully alive to its value, as it is useless to wait for the leaves to fall if the best results are expected next season. I do not think any stone fruit repays for lifting better than the Peach and Nectarine. No matter how carefully one plants Peach or Nectarine trees, with good culture gross wood results, and this grossness is better counteracted by lifting than any other plan, that is if due attention is paid to extension. In good loam the trees invariably run to wood, and as one is anxious to fill a large space as early as possible, a check during the growth of the trees is not given by stopping. In such cases lifting may be prescribed as the remedy. I do not advise extreme measures, but care and a certain amount of time to the work. By proceeding cautiously there need be no fear as to loss of crop, and the health of the tree will be assured for the next four or five years. To show the good resulting from lifting, I have for the past three autumns annually moved a Nectarine tree of large size. This tree has borne very fine crops yearly, thus showing that if care is taken to preserve the fibrous roots, no harm will follow. Cherries thrive much better the following season if lifted or planted early in October in ordinary seasons, and in such a one as this I would advise a fortnight earlier. This early lifting or transplanting is more difficult when the trees have to be conveyed some distance, but even then I would prefer to plant early, provided the trees are well furnished with fibrous roots. In lifting, care should be taken to keep at a good distance from the trees, and in the case of Peach trees in early houses lifting should be done early in September. It is a very good plan to damp the lifted trees overhead in the evening, as this keeps the buds plump and enables forcing to be done more readily the next season. With large trees it is not necessary to remove every particle of soil. Allow that adhering to the fibrous roots to remain, provided the weight does not break the latter. The preservation of fibrous roots is an easy matter if there is room allowed at the start to get round them. All large roots may be cut clean off at a fair distance from the tree, and if the roots are inclined to descend, planting higher is beneficial. Manures of any kind should be omitted, good turfy loam well rammed or trodden being essential, and in clayey soil some mortar, brick rubble, or road scrapings is a valuable addition.

By this early lifting, severe cutting back, often the cause of canker later on, is avoided, and the trees can be forced the next season if not subjected to excessive night temperatures at the start. In the case of trees on open walls and that are required to fill up gaps I still advise early lifting, as by so doing the root action continues as long as the leaves remain, if these are assisted by frequent dampings to preserve vitality and encourage new root growth. After lifting no tying should be done till the trees have well settled down.

G. WYTHES.

Frogmore Prolific Apple.—This variety has done wonderfully well this season, and though not so much grown as some large Apples, on a heavy

clay soil in warm seasons it is a first-rate fruit and of high quality. I consider it one of our best flavoured kinds for kitchen use, and it frequently crops when others fail. The tree is very hardy and a constant bearer. In some catalogues it is described as a dessert and cooking variety, but I consider it most suitable for kitchen use. I recently saw some very fine trees in pots, and was informed that this variety never fails to crop when grown thus, and to give fruit of high quality. At the Islington show of the R.H.S. it was staged in fine condition in several collections, some nice trees in pots also being shown.—S. H. B.

THE FRUIT CROPS.

Abberley Hall, Stourport.—This garden is situated at a high elevation; in fact, it is much the highest cultivated point in Worcestershire; therefore one might naturally expect that we should have suffered greatly, but such has not been the case. As regards the fruit crop generally, Apples are abundant, but rather small, the dry weather being answerable for this. Pears are a fair average and clean, and will, no doubt, swell to a fair size. Plums are better than I expected at one time. Victoria and Jefferson are the heaviest cropped; the majority of other kinds are carrying a good half crop, and since the rains they have improved immensely. Damsons, where not attacked by aphides, will bear a crop. Strawberries a very heavy crop, but rather smaller than usual. Cherries of the dessert kinds, both on walls and in the open, a fair average crop and the trees clean. Morellos a very heavy crop, both against north walls and on bush trees in the open. Apricots very good, but the fruits rather small. Peaches and Nectarines are also excellent. Other small fruits have borne heavy crops.

The vegetable crops have also not suffered to such an extent as on lighter and gravelly soils. A fair amount of manure and the surface kept well stirred have assisted crops immensely. Peas have been the quickest over, but we have not been without a gathering a single day. These latter were well mulched and also watered. Except the very earliest crops on south borders, the Potato crop is good, and so far perfectly free from disease. On well-cultivated farms the root and corn crops are very good, the hay crop being the only failure.—A. YOUNG.

Tortworth, Falfield.—Apples in this district set abundantly; the crop is over average and fairly good. Pears are much over average and very fine—better than they have been for at least ten years. Cherries somewhat smaller than usual, but a full crop. Peaches and Nectarines are very good where the trees have been properly cared for. Apricots very abundant. Small bush fruits good, but the caterpillar very troublesome. Raspberries and Strawberries quite an average crop and very good. Nuts abundant.

The early Potatoes are very good and quite free as yet from disease. The later crops look very promising. First early Peas very good, but mid-season crops are the worst ever known. Dwarf, also runner Beans fairly good. Broad Beans poor.—THOMAS SHINGLES.

Witley Court, Stourport.—In this locality vegetation has not suffered from the drought to such an extent as is the case in the more southern and westerly districts. Apples and Pears are fair average crops, the fruit and trees being clean and healthy looking, and much benefited by the recent rains. Stone fruits collectively are above average. Peaches and Nectarines are abundant, so also are Plums and Apricots; Damsons are only partial. Cherries were most abundant, the earlier kinds suffered somewhat from drought, but the Bigarreaus and other late ones came up well. Morellos are full crops of fine fruit. Small and bush fruits of all kinds are, and have been, most abundant. Strawberries suffered the most from want of rain,

but where water was available in quantity the produce was excellent. All kinds of Nuts, especially Walnuts, are plentiful.

Potatoes, early kinds, are on the whole deficient in size and quantity, the exceptions being on previously enriched borders where water could be applied copiously with the hose. Recent rains have ensured the crop of late and field kinds. Hops have been much benefited by refreshing showers, and where washing has been attended to, look remarkably promising. Roots are somewhat patchy, but are growing away luxuriantly, and will soon make up lost time.—J. AUSTEN.

Forde Abbey, Chard.—For upwards of eighteen weeks we had but little rain. We have plenty of water, and things have fared much better. In our case many fruit trees have been greatly benefited by a good watering. Apples bloomed most abundantly and promised a grand lot, but the weather being so dry, the trees became infested with insects. The following are very good: Royal Somerset, Cox's Orange Pippin, several of the Codlin type, King of Pippins, Frogmore Prolific, Lane's Prince Albert, and that valuable late kind Sturmer Pippin. Pears are variable; our best are Marie Louise, Louise Bonne of Jersey, Beurré d'Amanlis, Beurré Diel, Winter Nelis and Jargonelle. The fruit promises to be very early and extra large. Plums are extra good, Victoria, Green Gage, and several of the Gage type, Jefferson, and Golden Drop are all well cropped, the fruit swelling off to a good size. Trees are now clean, the heavy rains of late washing off the fly with which they were badly affected. Strawberries came on very early, and gave us a good crop of extra large fruit, thanks to being mulched early and having plenty of water. Our best kinds were Keens' Seedling, Héricart de Thury, Noble, Unzer Fritz and Elton Pine. Morello Cherries enormous crop and good. Apricots were the heaviest crop I ever had. Some shoots set as many as from thirty to forty fruit on a foot length of wood. To assist this crop we gave good soakings of water after applying guano, and now the trees are looking well. Our garden lying low has not suffered so much as many, and since the rain things have improved immensely.—J. CROOK.

Trelissick, Truro.—The phenomenal season of 1893 will long be remembered in this neighbourhood. From the end of February to the end of June we had scarcely enough rain to lay the dust. Crop after crop was sown both in garden and field, and the seed might just as well have been left in the bag, for it never germinated. Beet, Mangolds, Carrots, &c., sown first week in May only began to appear above the soil beginning of July. Peas and Broad Beans, sown in March and April, made a fair start, but were soon attacked and crippled with aphids and thrips. In many places the ordinary water supply completely failed, as was the case here, the only available water having to be carted from a long distance. Still, all kinds of fruit set well and gave promise of abundant crops. The Strawberries were burnt up before they had attained half their usual size, and thousands of the plants killed. Raspberries were abundant, but very small and poor in quality. Gooseberries and Currants gave exceptionally heavy crops, which matured well, a few syringings of hellebore powder having kept the bushes in perfect health and free from caterpillars. The bush fruits here are all grown under permanent wire netting, which protects them from bullfinches in winter and the ripe fruit from the birds in summer. The present is the sixth season our bush fruits have been so protected, and so far it has proved a perfect success. The trees are in excellent health, heavily laden with splendid fruit, while in the past it was very difficult to protect the berries till they were thoroughly ripe, so that wire netting has proved more satisfactory and cheaper in the long run than fish netting, which rots so quickly and through which the birds often manage to pass. Bush fruits do not appear to have suffered much from the prolonged drought. Apples are a very heavy crop, but will be very small, though the present genial showers will no doubt do much to swell them up before the ripen-

ing period, which will be abnormally early this year. Some of the earliest sorts began to fall quite ripe the last week in June. Apples, however, will be plentiful and cheap. Pears are abundant both on walls and standards. Fruits of Citron des Carmes and other early sorts began to ripen at the end of June. Plums are very plentiful. The extensive Plum orchards in this neighbourhood give promise of heavy crops, though in some the caterpillar has made great havoc. This is not a great district for Cherries, but they have been more plentiful this year than usual. Peach and Nectarine trees are carrying heavy crops. I never remember them cleaner or in better condition. They have, however, been plentifully supplied with water to both roots and foliage. The first Peach to ripen was Early Alexander on June 29, which is nearly a month earlier than our usual time. Tomatoes are doing splendidly both indoors and out, carrying immense crops of very fine fruit. Ornamental trees and shrubs, especially newly-planted ones, have suffered greatly from the drought. Several Rhododendrons and old-established plants of *Pernettya* have been completely killed, and many gardeners, I fear, will be at their wits' end to keep up their vegetable supplies during the coming winter.—WM. SANGWIN.

Compton Basset.—In these gardens we do not feel the drought as in others; in fact a dry time suits us to perfection, but, of course, not such an exceptionally dry season as the present. Our outlook here in the early part of this season was splendid for everything, and even now we shall get a good and abundant crop of fruit. Vegetables, such as Cauliflowers and Cabbage, &c., have not been very good. Peas have been short-lived. Lettuce have been grown with much difficulty, and until the rain came they were beginning to get mildewed at the roots. Deep-rooted things have done well. We have been obliged to water all growing crops, but latterly we have used up the supply of water after having only watered the small fruit trees. Apples are abundant; the quality will be good, and the fruit will be ready for storing early. We have gathered Red Astrachan and Juneating, Blenheim Orange, King of the Pippins, and Ribston have heavy crops. Pears are very good, the fruit fine and of good colour. We gathered Doyenné d'Été July 2, and Jargonelle on July 10, fully six weeks before its usual time. Marie Louise and Louise Bonne will be ready, I expect, the beginning of September. Gooseberries, Currants, and Raspberries are and have been excellent crops, fruit rather smaller than usual. Strawberries a good crop, but soon over. Peaches, Nectarines, and Apricots are good. I never saw such crops outside before. Had to thin very much. The Shipley Apricot has been excellent. Peach and Nectarine trees have become affected with spider in spite of daily washings with the engine, but have made splendid growth, and the early varieties have been cleared. We gathered Waterloo on June 27. Cherries, both the sweet and Morello, are very good and crops heavy. Plums are unusually heavy crops, and have had to be heavily thinned. Nuts are rather scarce. Medlars and Quinces are full crops.

The Potato crop up to the present is good. Birds have been very troublesome on account of the dry weather, and wasps are everywhere, although just round about the gardens we have destroyed over 100 nests.—W. A. COOK.

Rood Ashton, Trowbridge.—Fruit of all kinds is unusually abundant here, much the scarcest being Strawberries and Raspberries. These, although they were mulched heavily with strawy manure in the early spring months, were very poor. Of Apples, many sorts are so thickly set, that severe thinning was absolutely necessary to relieve the strain on the trees. Such varieties as Golden Noble, New Hawthornden, Lane's Prince Albert, King of the Pippins, Leyden Pippin, Cox's Orange Pippin, Stirling Castle, Rambour Franc, Reinette du Canada, London Pippin, Worcester Pearmain, Adam's Pearmain, Golden Pippin, Peasgood's Nonsuch, Ecklinville, Beauty of Buth, Warner's King, Lord Suffield, and Lord Grosvenor are conspicuous for heavy crops. Orchard trees

are similarly fruitful. Pears are almost as abundant as Apples, and there are but few trees which are not carrying some fruit. The early Citron des Carmes was all gathered by July 17. Williams' Bon Chrétien is extremely fruitful on standards, bush trees, and espaliers on walls. Beurré Clairgeau, Doyenné du Comice, Colmar van Mons, Emile d'Heyst, Comte de Flandre, Bezi d'Héry, Conseiller de la Cour, Délices d'Hardenpont, Andrew Murray, Amandine de Rouen, Gilgil, Dunmore, Beurré Hardy, Thompson's, Marie Louise, Seckle, Althorp Crassane, and Doyenné Boussoch are some among many others bearing full crops. Frosts occurred in this neighbourhood while the trees were in bloom, and although so many of the more forward flowers were killed, yet from their abundance sufficient for a full crop escaped uninjured. Peaches and Nectarines are above the average, but the trees have suffered from attacks of red spider through absence of rain and water to syringe with. Plums are a bountiful crop, and quantities were gathered for cooking as well as preserving in a green state. Apricots, too, are equally fruitful and ripened very early. Cherries, both dessert and Morello, are fine crops, and the fruits, considering the season, are of good size. Bush fruits were small owing to the severe drought, but all were extremely plentiful, as also was the Gooseberry caterpillar, which stripped the trees of their leaves rather freely. Figs have profited by the warm weather, more so than any other fruits, a wonderfully good crop resulting from the moderate growth and early maturity. Filberts and Walnuts are abundant. In the latter case, trees that have not fruited for years are bearing a good crop this season.

Potatoes are variable. In some instances the yield is not good enough for seed; in others a first-rate crop is produced. Early ones, including Sharpe's Victor, Sutton's Ringleader, Veitch's Ashleaf, Snowdrop, and Beauty of Hebron, were good average crops. A few of the midseason sorts had commenced protuberation, and where the tubers were found to be fairly matured the stalks were drawn. Magnum Bonum and other late Potatoes will be benefited by the recent rain, while in many cases I learn that among midseason ones much damage is already reported. Peas have been only half a crop, and the birds have done considerable mischief among these from scarcity of other food. Onions have improved considerably since the rain, and will now reach a good average. No attack of maggot has been experienced, although it is a common cause of complaint locally. Runner Beans have persisted in dropping their flowers, and will be late in consequence. Turnips from north borders very good; from warmer positions useless except for flavouring. On the whole the season has proved a very disappointing one, more particularly as regards vegetables.—W. STRUGNELL.

Pull Court, Tewkesbury.—Apples are extra heavy, fruit a trifle small, but very clean—much improved by late rain, so that we may expect a crop much over average in quantity and quality. Pears are just the opposite, and only a few varieties carry even a moderate crop. Marie Louise against west wall, Citron des Carmes against north wall, Pitmaston Duchess, Knight's Monarch, Beurré Diel and Winter Nelis are the only varieties worth mentioning as having a moderate crop. Apricots a very heavy crop, fruit clean, but small; usually two or three branches die off on one or other of my trees, but this year, so far, there are no signs of any going. Cherries have been a good crop; the Morellos are much smaller than usual. Other varieties were very good in size, and, what is more, we managed to keep the trees free from black-fly—a thing most unusual when the season is considered. Peaches and Nectarines are carrying good crops, but trees are badly infested with red spider. Plums are a fair crop. A local kind called Firelights is bearing very heavy crops; the fruit is small, but it commands a ready sale and is eagerly sought after by dealers, who mostly send it to Manchester. Raspberries and Strawberries have given a very limited supply, although both were well mulched and attended to. Currants have been good; season shortened by the weather.

Gooseberries are a heavy crop, fruit small and caterpillar very troublesome. I find nothing short of hand-picking of the grubs gets rid of them. Figs out of doors are showing and swelling fruit more freely than usual. All trees, except Peaches and Nectarines, are making good growth and are very clean.

Vegetables have suffered much more than fruit from the drought, and it has only been by constant mulching, watering, and frequently sowing and planting that Peas, Cauliflowers, Turnips and even Broad Beans have grown at all. Turnips even at the present time are not worth eating; they are only used in soups. William Hurst Pea is the best with me. I generally plant two borders with same variety (same time), one border facing south and the other north or east. The Sweet or edible-podded Pea has stood the drought well. It is a strong grower, and being planted in old Celery trenches found a good medium to grow in. I always grow a couple of rows of this; in other years it has often filled a gap. The cook finds the edible-podded Pea of great value for soups. It is also appreciated as a vegetable. Tomatoes in the open are both early and well fruited. Chancellor I consider the earliest and freest fruiting of four other leading kinds growing alongside. Potatoes (early ones) small, but clean and good; late ones look promising.—JOSEPH HINTON.

Knightshayes, Tiverton.—The fruit crops in general are exceptionally heavy, especially Plums, Pears, Apples, Morello Cherries, Gooseberries, and Raspberries. Peaches, Figs, and Apricots are also good. Strawberries, owing to the continued drought in the spring, were a complete failure, while Red and Black Currants were but a meagre crop, excepting those grown on the north walls with the Morello Cherries, which were good. I hear numerous complaints about fruit-dropping since we have had so much rain, and from my own observations I am of opinion that it is only where the fruit has not been thinned. Where that has been done judiciously little or no complaint can be made with regard to premature fruit-dropping.

Peas in many instances have been a complete failure. I have had several rows of Ne Plus Ultra and Duke of Albany that did not bear a single dish. Sharpe's Queen, Veitch's Perfection, and Magnificent stood the drought best, and from these I had a fair supply. Cauliflower has been also a very trying crop, Earliest Dwarf Erfurt stood the drought best. Late Carrots, Beetroot, Turnips, Lettuces, Chicory, and other small seeds it seemed almost impossible to get to germinate.—ROBERT GRIGOR.

Inwood House, Henstridge.—The crops in this neighbourhood are above an average. Most of the fruit is small except Pears, unless where the trees were heavily mulched, which no doubt is a great protection to the roots. I mulched all my crops with short litter, and no doubt saved a great many of my trees and vegetables from being burned up. We stand here on a hill, and had only rain once in four months, which was a thunderstorm, and lasted twenty minutes. I must speak in favour of a few things which have done well this dry season. Waterloo Strawberry is a first-rate one for a dry season. Superlative Raspberry has done remarkably well.

Peas Duke of Albany and Prodigy and Magnum Bonum Cauliflower have also been good. Potatoes are doing well in this neighbourhood, some fine tubers being among most of the sorts. Onions are splendid this season.—T. WILKINS.

Westonbirt, Tetbury.—The whole of the fruit trees in this neighbourhood were quite a month earlier in flowering than usual. Fortunately, we escaped frosts, the result being that Apricots, Peaches, Nectarines set so freely that hundreds had to be thinned out, especially the first. From March 17 till the end of June we only registered $1\frac{1}{2}$ inches of rain, and most of the days brilliant sunshine; this of course just suited the insect pests, and I never recollect a year when they were so numerous, but by constant syringing and battling with them, we were fortunate enough

to secure good crops. Strawberries were quite three weeks earlier, good what were gathered, but soon over. Bush fruit very plentiful, but small; these we could not assist. Pears a good moderate crop of all the leading kinds; these I thin well every year; by so doing I find I succeed in having some every year. Plums are abundant. Peaches and Nectarines average. Cherries under average, but fine. Apples everywhere abundant. We have not one of the best soils for Apples, so grow principally cider and cooking sorts. Annie Elizabeth does well, never failing to crop, and eats well when kept till March. Manks Codlin bears abundantly, and coming in before the American varieties reach here, usually fetches a good price. Wasps are a pest this year; already we have taken upwards of 150 nests. I fear a great deal of the fruit will be spoiled by them.—A. CHAPMAN.

Bricklehampton Hall, Pershore.—Apricots and Peaches very good. Nectarines half crop. Cherries very good. Apples very good, especially Blenheim Orange, Cellini, Keswick Codlin, Lord Suffield, Golden Winter Pearmain. Pears half crop. Plums half crop. Green Gage, Early Prolific, Pond's Seedling, and Cox's Emperor good against the walls. Figs look very promising. Currants, Gooseberries and Raspberries very good. Strawberries half crop, suffered very much from the dry weather. Tomatoes are doing very well outside, especially the old large red. Vegetables are poor.—E. LOTT.

Memland.—In spite of the great drought shrubs and trees suffered but little. February was a very wet month, rain falling on twenty-two days, giving us nearly 6 inches of rain. From March 2 to May 17 no rain fell; heavy storms on the 17th, 19th, and 20th gave us 2.85 of rain. The greater part of June was very hot, thermometer ranging between 70° and 91° in shade. About June 20 vegetation began to suffer; fruit trees, such as Apples and Pears with heavy crops of fruit on them, began to droop. Peas were checked in their growth by thrips; Broad Beans infested with black aphid. Notwithstanding these and other drawbacks, there has been no lack of good vegetables in this part. Of course, we had to attend to mulching and watering. All small fruits were a heavy crop and excellent, especially from the jam-makers' point of view. Apples are a heavy crop, and since the rain has well soaked the roots the fruits are growing to a great size. Gladstone Apple was ripe the first week in July, Irish Peach the second week, and to-day (August 3) I have gathered Braddick's Nonpareil from an espalier six weeks before its usual time of ripening. Pears are a good crop on walls and pyramids. Jargonelle was ripe on July 25, Williams' August 2. Peaches and Nectarines are a good crop, and trees are healthier than for years, although there was some blister early in the season. Plums are a heavy crop. In fact in South Devon it is the finest season for all kinds of fruit that has been for many years.

The Potato crop up to this time is satisfactory. Heavy storms began the first week in July, when the early Potatoes were fairly ripe. On the 7th and 8th I had the haulm carefully pulled, and now (August 3) I am taking up all the Ashleafs, Puritan, and Hebron. Potatoes are quite ripe and all that can be wished for. I find a few of the later sorts growing out very much, especially Bruce. I shall draw the haulm from all sorts as the skin becomes set. We have had a considerable rainfall the last few days with a rather high temperature. I fear the disease will make its appearance pretty soon. In the less open gardens I hear the disease has already affected some of the tubers. Late Peas are coming on, and I hope for some good gatherings for the next two months at least. I see my first gathering was made from Exonian on May 6; this sort with me is by far the best. I hear from some growers it is rather delicate. For very early sowing Chelsea Gem as a dwarf in this part is an immense cropper, suitable for market work. Turnips have been difficult to keep going; by the early use of soapy water we have Early Milan and Snowball in good condition. This garden being situated

within a mile of the sea we get very heavy dews.—GEO. BAKER.

Mount Edgcombe.—The fruit crop in this district is far above the average. Gooseberries, Currants and Raspberries a very heavy crop and fine fruit. Strawberries plentiful, but smaller than usual. Peaches, Nectarines, and Apricots a heavy crop and good. Plums heavy crop; not quite so large as they are generally. Pears and Apples are an enormous crop, and the rain of this month is making them grow well. With the exception of a few of the earliest sorts they will be quite up to the average size.

It has been a very trying season for gardeners. For three months (April, May, and June) we did not get half an inch of rain; some of my neighbours were favoured with a few thunderstorms. I have had great difficulty in keeping up a supply of salading. Broad Beans a complete failure, being badly attacked by aphid. Peas were a fair crop. I always use a lot of soot for them, throwing it over the plants while they are damp with the dew. I find sparrows do not eat them so badly; it also keeps away the thrips and, I fancy, tends to check mildew. Runner Beans are plentiful. Cauliflowers that were wintered in frames are very good. Onions are looking well and a good crop, but rather later than usual. Brussels Sprouts, Celery, Carrots and Beet are looking well. The early varieties of Potatoes were very small; if it were not for clearing the ground I would not have taken them up, and the late varieties are all growing out.—S. J. RICHARDS.

Kimbolton Castle, Hunts.—The Apples are an average crop. Pears very poor, also Strawberries, owing to the drought. Morello Cherries a good crop. Gooseberries and Currants a very good crop. Apricots and Peaches showed plenty of fruit, but it was cut off by frost.

Vegetable crops have suffered severely from the dry weather. Peas have been almost a failure. Potatoes are improving.—J. HEWITT.

Clevedon Hall, Somerset.—The Apple crop here is very good, quite above the average. Pears average crop, Marie Louise, Williams', Louise Bonne of Jersey, Chaumontel being heavily laden. Plums average crop. The sorts that we grow are principally Early Orleans, Jefferson, Kirke's, Golden Drop; trees of Victoria heavily laden. Damsons below the average, infested during the dry weather with the blight, which, combined with the drought, caused a quantity of the fruit to drop. Peaches and Nectarines average crop. Commenced picking Early Alexander from outside walls on June 14—a month earlier than usual. Apricots also average crop. No protection afforded to Peach trees in the spring, and we are successful in securing a good crop every year. Bush fruits a good crop. Gooseberries very heavy, many of the bushes having to be supported. Raspberries a good crop. Strawberries average crop; sorts we grow here are President, La Grosse Sucrée, Sir Joseph Paxton, James Veitch and Princess Alice. For pot work we rely on La Grosse Sucrée; for earliest and for succession, Sir Joseph Paxton. Walnuts a very heavy crop; trees literally covered with nuts, many in clusters of twelve and more in a bunch.

Early Potatoes half a crop and very small; later batches more promising. Runner Beans are looking extremely well. Broad Beans a complete failure. Carrots and Onions a fair crop. Roses a complete failure as regards the summer blooms, but a fair promise of a good supply of autumn flowers if rain continues.—W. POLLARD.

Canford, Wimborne.—The fruit crops in this neighbourhood are a good average where a supply of water was given during the drought, without which, in few exceptions, they are undersized and very thin. Plums are average. Apricots plentiful, and small fruit about average.

Vegetable crops have suffered a good deal, more especially Peas and Potatoes, the latter going a little diseased.—J. MCCORMACK.

Iwerne Minster, Blandford.—We have experienced three months (April, May and June) of perhaps the most trying heat and drought that

have been felt since 1826. Fahrenheit's thermometer has during the end of June and the beginning of July frequently indicated 90° and 94° in the open and 1 feet above ground, while the night temperature frequently stood at 70°. For over ten successive weeks we were without a drop of rain or dew to moisten a leaf or blade of Grass, while plants were withering under a tropical sun. It is a miracle that we have anything to record from the garden. It was only by dint of mulchings and excessive and incessant waterings that we could keep any plants alive. The spring months were chiefly mild, and brought forth an abundant show of all kinds of fruit blossoms, fat and fully matured, and which withstood the severity of 10° and 12° of frost. Apples, Pears, Plums, Apricots, and all bush fruits are, and have been, abundant, although the last were small and wanting in juice and flavour. Strawberries were also small and soon over. Fruits and vegetables as a natural consequence are nearly a month earlier than in ordinary seasons. We began to cut Melons April 28; we had May Duke Cherries in the middle of May, and ripe Apricots from the open wall the beginning of July. Many of the earliest sorts of Apples, such as Keswick Codlin, Hawthornden, Lord Suffield, Stirling Castle, Irish Peach, Kerry Pippin and Lemon Pippin, are now ripe. Pears Williams' Bon Chrétien, Jargonelle, and Thomson's are also ripe. Plums of all kinds are also abundant, mostly ripe, including Green Gage, Washington, Jefferson and Kirke's, and all have much increased in bulk since the glorious rain that we have been having since July 4. Wasps are a terrible plague.

Vegetables are now plentiful, Autumn Giant Cauliflower just turing in. Marrows, Beans, dwarf and running, also British Queen and Egyptian Marrow Peas, are also good. Potatoes are an excellent crop, of good flavour, and as yet free from disease.—P. DAVIDSON.

Longford Castle.—Trees of the Peach, Nectarine, Apricot, and Green Gage Plum which had their blossoms protected by glass coping set immense crops of fruit, which had to be severely thinned. The soil over the roots of these and other wall trees was slightly loosened in the spring and then covered to a thickness of about 3 inches with short manure, afterwards giving the whole a good watering, repeating the application several times during the season, with the most satisfactory results as regards the quality of the crop and the condition of the trees, which I may add were generally washed overhead every afternoon with clear water from the garden engine. The 6° to 12° of frost which we experienced every night during the last fortnight of the month of March severely thinned out the blossoms of non-protected trees of Plums generally, and reduced the chances of a good crop of Pears to a minimum. Still, the following varieties of Plums which received no protection when in flower are bearing good crops: Early Prolific (a sure bearing Plum of good size and fair quality), Orleans, Coe's Golden Drop, The Czar, Sultan, Belgian Purple, Diamond, Victoria, Pond's Seedling, Grand Duke, and Reine Claude de Bavay. Pear trees on the open walls and pyramidally trained of the following varieties are bearing fairly good crops of clean fruits, namely, Marie Louise, Beurré de Capiaumont, Williams' Bon Chrétien, Beurré Gris, and Grosse Calebasse. Trees of May Duke, Governor Wood, and Black Tartarian Cherries have borne good crops of fine fruits. Morellos are carrying good crops of fruit. Black-fly has been unusually difficult to dislodge from the points of the young growths this year. In addition to syringing the trees with a mixture of tobacco juice and water at the rate of one quart of the former to four gallons of the latter, the affected shoots had to be manipulated, afterwards washing the leaves with clean water. Gooseberries and Currants are abundant, some of the bushes succumbing to the weight of the crop, which, as regards Currants, is somewhat blighted through the long spell of semi-tropical weather and long period of drought which we were subjected to during March and three following months. Of Raspberries we have had abundance, but not without having mulched heavily between

the rows with short manure, afterwards giving good supplies of water at the roots and then netting the several ranks of canes overhead and at sides, keeping the net sufficiently high up to enable the fruit to be picked without having to remove and replace it each time the fruit was being gathered. Figs are a good crop, and the same may be said of Filberts. In low-lying districts, where the soil about the roots of the trees remained moist, notwithstanding the protracted spell (four months) of heat and drought, Apple trees are carrying good crops of promising fruit; especially is this so in the case of cider Apples. In our orchard, which is located some distance from the kitchen gardens in a rather light soil, resting on a substratum of gravel and some 12 feet above the ordinary water-line, the trees, through the abnormally dry state of the soil, gave out towards the end of April to such an extent as to involve a general flagging of the sheets of blossom with which they were clothed, and a large percentage of which were burnt by the sun's rays while in that unresisting flabby condition. Subsequently, the heat and drought continuing, many of the fruits which then "set" dropped off the trees; still, we shall have plenty of Apples for our own use from espalier-trained trees of Stirling Castle, Early Nonpareil, Worcester Pearmain, Northern Greening, Emperor Alexander, Keswick Codlin (a variety which has never failed to yield a good crop of fruit here during the last twenty-two years), Prince Albert and Kerry Pippin. The Strawberry crop was a good average as regards the yield, but the fruit was below the average size and of rather short duration. The crop would not have been up to much had we not watered the beds well two or three times while the fruits were swelling. Alexander Peach was ripe on June 16 on a west wall, and Waterloo six days later on the same wall, Amsden on a south wall coming in next towards the end of the month. The fruits of Alexander and Amsden having been thinned out to about 9 inches apart every way, they attained to fine size, being highly coloured and very good in quality. The periods of ripening indicated are a month or five weeks earlier than the usual time for gathering the above-mentioned varieties.

We began gathering regular supplies of early Peas on May 7 (exactly a fortnight earlier than in any previous year), and good supplies of the mid-season, large-podded varieties (Telegraph and Telephone) were secured on the 29th of the same and onwards, being a month earlier than usual. The plants from which the above gatherings were made were raised from seed sown in 3-inch pots early in January and duly hardened off prior to being transplanted out of doors at the end of February and early in March, when they were earthed up, staked and then mulched to the thickness and width of 9 inches on either side of the ranks with good substantial manure, thereby maintaining the soil in a uniformly moist and warm condition about the roots from start to finish and prolonging considerably the produce-bearing period.—H. WARD.

Killerton.—Peaches and Nectarines very good and trees healthy and vigorous. Apricots were the heaviest crop I ever knew; trees all healthy. Plums are one of the most abundant crops ever known on walls, pyramids, and trees in orchards. Cherries very good, especially Morellos. Pears are heavy crops, especially on pyramids, which have required to be thinned very much and supported, or they would have been broken down by the weight of fruit. Apples are abundant and fine. Figs are a fine crop. Raspberries, Strawberries, Black, Red and White Currants, and Gooseberries have all had fine crops. Filberts very plentiful, but Walnuts on old trees are a failure. Taken altogether, it is the most abundant fruit year I ever knew. All our fruit trees and Raspberries were well mulched with half-rotten manure and leaves from old hotbeds and Seakale covering. The fruit trees and Strawberries also were well watered.

Peas and Scarlet Runners were mulched and watered in the same way, and have afforded an unbroken supply.—J. GARLAND.

Batsford Park, Gloucester.—Most kinds of fruit are exceptionally plentiful in this neighbourhood, and but few of the blossoms sustained any

serious injury in the spring. Some frosts were experienced at the time the Apricots were in flower, but these did but little harm, the trees being protected with netting. Nearly all of the later blossoms, including those of Apples, Pears, Peaches, &c., were unharmed, our position being rather elevated on the south side of a hill, with protection from the coldest quarters afforded by large trees. The season, as in most districts, has been nearly a month earlier than usual, and in the early part insect pests of various kinds were very troublesome consequent on the extreme heat and prolonged drought. Apples, both on orchard standards and garden pyramids, are bearing very heavy crops, much too heavy in many instances for the good of the trees or quality of the fruit, which will, where unthinned, be rather small. Orchard standards of Blenheim Orange and Keswick Codlin amongst others are heavily laden. Amongst bush and pyramid trees in the garden the following are noteworthy for the amount of fruit produced and also good quality: Stirling Castle, Ecklinville, Warner's King, Tower of Glamis, Lord Suffield, Yorkshire Beauty, Irish Peach, Margil, Cox's Orange and Sturmer Pippins. Pears are somewhat partial, but, on the whole, are much more plentiful than for several years. Some pyramid trees, especially on the Quince stock, have needed support to prevent the branches breaking off. Of these, *Conseiller de la Cour*, *Beurré d'Amanlis*, *Clapp's Favourite*, *Soldat Laboureur*, *Emile d'Heyst*, *Vicar of Winkfield*, *Williams' Bon Chrétien*, *Durondeau*, *Thompson's*, and *Nouvelle Fulvie* may be noted, as also *Knight's Monarch*, *Pitmaston Duchess*, and *Fondante d'Automne* on the Pear stock. Apricots had to be severely thinned, as the fruit set in large clusters and equally thick all over the trees. A heavy crop, ripened splendidly, and the flavour was pronounced unusually rich. The foliage of the Apricot was not attacked so much by grubs as in late years, and this would naturally favour the fruit. Peaches and Nectarines are bearing good crops, and this applies to nearly all of the kinds cultivated. As the season is so early, some of the later sorts may ripen satisfactorily. Much of the fruit is rather small, especially on the early sorts, Alexander, Hale's Early, &c., a result probably of insufficient moisture. The following are bearing unusually well: *Stirling Castle*, *Royal George*, *Alexandra Noblesse*, *Bellegarde*, *Sea Eagle*, *Barrington* and *Dymond*. Much the same remarks apply to Nectarines, the best being *Elruge*, *Lord Napier*, *Violette Hative* and *Pine-apple*, all of which are bearing abundantly. The trees suffered but little from blister this season. Plums in the open were injured by bullfinches eating the buds; against walls the trees with few exceptions are producing good crops, including nearly all of the *Gages*, *Early Prolific* (excellent as a cooking Plum for early supply) *Orleans*, *Kirke's*, *Pond's Seedling*, *Nectarine*, *Victoria* and *Coe's Golden Drop*. Morello Cherries were much attacked by black fly, which it seemed impossible to remove effectually for a long time; the trees and fruit improved very much after the rains came, and the crop is much better than was expected. Sweet Cherries do not succeed very well, and there are not many standard trees in this immediate locality. Strawberries began ripening in May, and were nearly over by the end of June. Much of the fruit was small and had the appearance of being baked by the excessive heat. Many plants were quite dried up and killed. Four varieties on which we principally depend were again much better than any grown in smaller quantities for comparison. These are *Keens' Seedling*, *Vicomtesse Héricart de Thury*, *Sir Joseph Paxton*, and *President*. The last-named was if anything the best, but not of its usual size and quality; still this is scarcely to be expected with so little rain. Gooseberries were badly attacked by red spider and caterpillars early in the season, and the crop suffered somewhat. Handpicking was persisted in for destroying the caterpillars. Raspberries were good considering the drought, and Currants were very heavily laden with fine fruit, especially Red and White varieties. Black Currants rather small, but abundant. Filberts promised well, but were soon taken by squirrels.

Walnuts a heavier crop than for several years past.

Kitchen garden crops in some instances have proved failures in consequence of the exceptionally dry and hot weather. Peas have done very badly, not reaching their height nor producing many flowers; what they did produce never set well, and the supply has necessarily been irregular and indifferent. A second early lot, consisting of *Advancer*, *Gladiator*, and *Dr. Maclean*, have been the best of the season. All the early Cauliflowers were a complete failure. Carrot and Beet seed germinated at two or three different times, and Turnips could not succeed at all. It was difficult to keep a supply of salading, the chief thing (Lettuces) so soon running to seed in the hot weather. A good bed of spring Cabbage proved invaluable, as it stood the winter well and was available for use at an early date. The change experienced when the rains came was most remarkable, and most of the kitchen garden crops have grown well since. Peas, however, remain an exception. Potatoes were rather small when first dug from outside; the later supplies are good in quality and fairly productive. Late ones have been looking remarkably well. On the whole the great drought did not do quite the amount of harm here that it must have done where the soil is light or of a gravelly nature. Being dependent on springs, which gradually kept giving a diminished supply, we were unable to afford much water for outside crops or for fruit trees, all available water being required for Peach and Vine borders, &c., indoors. The rains have made but little difference, if any, to the springs, and probably will not do so until the autumn.—J. GARRETT.

EASTERN.

Culford Gardens, Bury St. Edmunds.—Apples, Pears, and Plums are under average. Figs (outdoors) promise better than for three years past, while Apricots, Peaches, and Morello Cherries are an abundant crop. Strawberries and Raspberries have been almost a failure. Bush fruits are a good crop, also Nuts.

Peas and Spinach have been very scarce; the same may be said of good Cauliflowers and Cabbage. French Beans and runners have done better, and are very early. Onions are an excellent crop, but rather under-sized. Potatoes turn out clean and healthy, but not very large tubers, and all root crops are looking well. The soil hereabouts is of a very light and sandy nature overlying gravel and chalk.—W. HARWOOD.

Gunton Park, Norwich.—This summer of drought and sunshine will be remarkable for the extraordinary heavy crops of Apricots, Pears, and Plums. These three surpass all others in weight of crop, although on the whole there is not much to complain of now the rains have come. A period of drought such as we have passed through, lasting from the 1st of March to the end of June, with only four light showers at intervals—just enough to lay the dust on each occasion—is trying to the gardener and the farmer. But the summer here of 1868 was far more so, with only one shower of rain in April and not a single drop more till the 6th of August. Brilliant sunshine every day and cool and cloudy nights, and two horses and water-carts going for three months, make one look on the past drought with comparative equanimity. There was no hay and very few Turnips and Mangolds grown in Norfolk in that year, but the corn crops probably were the finest sample and heaviest that this county ever produced. The corn crops this season in North-east Norfolk are everywhere full of promise, and those three or four light showers previously mentioned caused the Mangold and Turnip seeds to germinate, and I see on every hand fields covered with flourishing roots. Apples will be plentiful and clean. Currants small and early, inclined to drop. Gooseberries plentiful; bushes troublesome to keep clean; attacked with spider, aphid and caterpillar. Raspberries plentiful, but small. Cherries (dessert) good

Morellos plentiful. Strawberries, where well cared for, very good; early and short season.

Asparagus suffered from drought more than any other vegetable; was very small and scarce. Peas abundant. A glut of midseason and late kinds all rushing into bearing in July will make them scarce during August and September. Potatoes so far not large, but of excellent quality. It is to be hoped that the rains will not bring the disease. I have not heard of it yet. Cauliflower Veitch's Pearl has been excellent during the driest weather, and I never remember Lettuce to have been finer. Hick's Cos, my mainstay, has been very fine. This is an old variety, probably well known. I have tried many, but none give so much satisfaction where a really excellent crop of Lettuce is imperative.—W.M. ALLAN.

Sudbourn Hall, Wickham Market.—My crops on the whole are very good, and from what I have seen in this part of East Anglia they are the same. I have had a splendid crop of Strawberries, my favourite being Vicomtesse Héricart de Thury. Gooseberries and Currants very good. Raspberries fair. Cherries very good. Plums very good, but on account of so much dry weather the trees in some instances are blighted. Apricots on south walls very good. Nuts fair. Some kinds of Pears very good. Apples good. Peaches and Nectarines we grow largely, and have a splendid crop, but I am afraid they will be rather small; at any rate the early varieties are.

Vegetables on the whole are good. The Peas have gone off very quickly this dry weather.—W. COLLETT.

Livermere Park, Bury St. Edmunds.—Apples are generally a heavy crop, but irregular; many of the best kinds, such as Ribston, are almost without a fruit, the dry weather apparently preventing the good show of blossom from setting. Blenheim's are better than usual. Manks Codlin, Nonsuch, King of Pippins, Keswick Codlin and a few others are heavily laden. Devonshire Quarrenden will probably be in true character this year, this being quite an unusual occurrence in the eastern counties except where grown on walls. Pears taken all round are better than I have ever seen them in these gardens. The crop is not particularly heavy (just about as it should be), but the fruits are cleaner and finer by far than is usual, a cracked or spotted fruit being quite the exception, and the drought has not affected the size in the slightest degree. I shall expect to see many varieties that are usually only fit for stewing quite up to dessert form in their season. Apricots are a heavy crop and had to be very freely thinned and the trees well watered several times; they look very healthy and promise well for another year if the season is favourable. Mice have been a great nuisance to the fruits and cannot well be trapped while they have ripe fruit to eat; they scale the trees with the greatest ease. Plums are a very heavy crop and wall trees are fairly clean, but bush trees have suffered very badly from a plague of aphids, and we had no rain to wash these pests off, so that many trees are crippled. Victoria and Belle de Louvain are the two best market Plums grown here; the latter is not well known, but is very much liked for kitchen use by these who know it. Cherries, with the exception of Morellos, were slightly under average, but the fruits were fine. Morellos good average crop. Gooseberries were a heavy crop, the fruits of several kinds being rather under size, though Rosebery was finer than I have ever had it. Warrington and Crown Bob also are fine. Raspberries were a very heavy crop of good fruit, and, thanks to a heavy mulching, the new canes are fine, though in some places near they are very poor indeed. Strawberries were a fair crop, and the fruits exceptionally good where the beds were kept watered. Noble especially gave us magnificent fruit of fair flavour, and President was said to be equal to British Queen. The season was shorter than that of last year, but held out longer than could be expected in such weather. Black Currants were a very good crop and the fruits fine. Red and White Currants good average crop, but quite a drug in

the market, small fruits brought from cottagers' gardens having been sold as low as 9d. per peck, and many could not be got rid of at any price. Peaches and Nectarines are very good, and coming on rapidly towards ripeness. Figs did not show well for a first crop out of doors, but the second crop is getting so forward, that I think it probable that many will ripen if the weather is fine. The trees are making splendid growth. Grapes are a splendid crop and should ripen well, as Sweetwaters are already beginning to soften. Medlars are again a good crop, but Quinces a failure. Filberts a fair average crop, and already (July 30) quite full. Walnuts are heavy in the neighbourhood, but very scarce with us, probably owing to frost in spring, our trees being much exposed to east winds.

Tomatoes promise well; medium-sized kinds, such as Conference, have set freely, and the crop is heavy. Very few have yet ripened out of doors; dull weather and cooler nights have checked the rapid progress which was made earlier. Potatoes will be very unsatisfactory. Early and second early kinds have been already dug, and were a very light crop. Late kinds, such as Magnum Bonum, The Gentleman, The Bruce, and Stourbridge Glory, are growing out since the advent of rain, and the quality of these will be sadly impaired, though the crop promises to be fairly heavy. These who planted late are to be congratulated. Many people in this neighbourhood put off planting till the last week in May in consequence of the dry weather, and these Potatoes planted then are looking very fine indeed, and will escape the second growth. The general effect of the very fine and dry weather of spring and early summer was to bring crops very forward. Early Peas did remarkably well, as the ground was wet enough to carry them through. Later kinds have held out well with us, but the season is bound to be over early; the latest sown are now coming into bloom. Many seeds germinated badly or irregularly, Carrots, Beet, and French Beans especially so. Onions are better than we have ever had them and will soon be harvested, a very heavy crop, averaging at least a sack to a rod of ground. Celery is very fine and forward, with no sign of running to seed. Cabbages have been very inferior, and suffered badly during the drought. Late Cauliflowers and all kinds of winter greens are looking remarkably well. Early Brussels Sprouts are getting quite forward and buttoning well. There is sure to be a dearth of many things which are usually plentiful during the autumn unless extra late sowings have been made.—J. C. TALLACK.

Babraham Gardens, Cambridge.—The fruit crops here are very uneven. In some cases Apples are a full crop, but small; some sorts, such as the Codlins, Cellini, Norfolk Bearer, Ecklinville and Dumelow's Seedling, that seldom miss carrying a crop, are now carrying good crops. I find any other sorts that were exposed to the east wind that lasted all the time the trees were in blossom are quite a failure, but all sorts blossomed well. Pears are much worse than Apples. The trees were covered with blossom, but, with the exception of a few sorts on walls, such as Marie Louise, Louise Benne, Doyenné du Cœmic and Beurré Diel, there is no fruit at all. Plums are a heavy crop, especially Victoria; also Damsons. Cherries have been very good, Morellos carrying good crops. Apricots are remarkably good. The trees were very early in blossom and set soon enough to escape some late frosts that, together with the east wind, seemed to destroy the Apples and Pears. I believe if all fruit trees had bloomed with the Apricots, the fruit would have been safe. Peaches are very good; the crop, of course, has been regulated to suit the trees. Watering and syringing have been well attended to; in fact, Apricots, Plums and all wall trees have had occasional syringings overhead. Currants (Black and Red), Gooseberries and Raspberries are a heavy crop, but fruit small. Strawberries were much cut up by the winter and had no chance of pulling round before the dry weather set in, which was the end of February and lasted to July 12, with the exception of

a shower in June. Some sorts have been satisfactory, notably Noble and Sir J. Paxton. Nuts and Quinces are plentiful.

This season has been one that has required the greatest attention and skill in keeping up a supply or succession of vegetable crops, as well as keeping fruit trees in a healthy condition; one day's neglect meant ruin to everything, our soil being very light and chalky. I have found the greatest benefit from mulching, which was done before the middle of March. Chelsea Gem Pea sown on February 7 was ready for gathering second week in May. Waterloo Peaches ripe on walls June 20. Strawberry Noble ripe outside before the middle of May. Potatoes so far are quite free from disease; crops light; in some open places the haulm is quite burnt up.—J. HILL.

Kimberley Park, Wymondham, Norfolk.—Apples are variable; some trees are heavily laden with fruit, others have scarcely any fruit upon them. Cherries abundant. Pears good. Apricots over average. Peaches and Nectarines over average. Plums average. Bush fruits abundant. Raspberries abundant. Strawberries average; the two latter crops had a very short season owing to the severe drought. Walnuts and Nuts are abundant.

The drought has been very trying; Cauliflowers and Spinach have suffered very much. Potatoes are very good and free from disease. All other kinds of vegetables have done well with me and are abundant.—W. WAINWRIGHT.

Papworth Hall, Cambridgeshire.—The crops in this garden have been good with the exception of Pears, which with us are very scarce. Apples a fair crop; in some places in the neighbourhood they are abundant. Plums and Cherries good. Gooseberries abundant; also Currants of all sorts, but the dry weather very much affected the black ones. Strawberries promised well in the early part of the season, but fell very short at ripening time. Raspberries quite a failure. I have not heard of a good crop anywhere in this locality.—THOMAS SMITH.

Harkstead Rectory, Ipswich.—Strawberries a very good crop and very early. A splendid season for Laxton's Noble, the extreme heat suiting it admirably, as this variety generally is very acid. Cherries a splendid crop of all useful kinds; Morellos especially fine; in fact, the largest fruit I ever saw, which I attribute to the extreme heat. Apricots (outside) are abundant, but owing to the extreme drought were not properly developed. Plums of all kinds a grand crop, such kinds as Jefferson, Kirke's, Cœ's Golden Drop, Prince of Wales, and Pend's Seedling, also Green Gages, being very fine. Pears an average crop, the fruit being exceptionally clean and good. Apples most prolific crop; the young trees are laden with fruit of good size, while owing to the tremendous crop on old trees, the fruit is and must be rather small. Bush fruit very good all round; also Raspberries. Peaches (outside) a good average crop; also Nectarines.

Potatoes fairly good, but owing to the drought rather small. Peas (first crop) good, but main crop a failure; later varieties doing better. Beans of all kinds very good. Carrots, Marrows, Turnips, and Onions a very good crop. Spinach a failure. Lettuces soon ran to seed, making it very difficult to keep up a supply. The winter greens promise to be very good owing to the heavy rains experienced here lately.—G. JORDAN.

Shrubland Park, Suffolk.—Apples and Pears here are ever average. Some of the sorts were smaller than usual, but since the rain both Apples and Pears have improved in size. Kitchen sorts are more plentiful with us than table fruit; Ecklinville Pippin is one of the earliest and best we have; Lord Suffield and the Codlins are also a large crop; Peasgood's Nonsuch not a great bearer, but the finest looking Apple we have; King of the Pippins is a regular, good bearer, not equal in quality to Orange Pippin and Ribston, but always colours well; Court Pendu Plat, generally a good bearer, is very scarce this year; so is Devonshire

Quarrenden. Pears are smaller than usual from the dry season, and having too many on some of the trees; this is so with Marie Louise, Josephine de Malines and Bergamote d'Espereux; Williams' Bon Chrétien and Doyenné du Comice are of fair size; Catillac always bears well and keeps till June and is a most useful stewing Pear. Plums are a good crop, especially Victoria. We have very few Damsons. Apricots abundant, but very small. Cherries a moderate crop; Morellos were fairly good. Bush fruits have been plentiful, but small. Strawberries were a large crop and fine, but were soon over; Dr. Hogg and British Queen are still the best that I have seen for table; the Queen does not succeed everywhere; Vicomtesse Héricart de Thury is an excellent bearer and good for preserving.

Insects of all kinds were exceedingly troublesome all the first part of the season. Caterpillars had to be cleared off several times. Wasps are now the greatest pests we have to contend with, and are making havoc among all sorts of fruit. Apples and Pears that should not be fit to gather for a month or six weeks are badly damaged; some of the trees have scarcely a sound fruit left. Our men killed more than double the number of queen wasps this spring, and within a radius of half a mile of the garden they have already destroyed over seventy nests. Squirrels have also been more troublesome than usual; after clearing off all the Filberts, which were a large crop, they made free with Apricots, Plums and Gooseberries. The extreme dry weather was rather against some vegetables. Small seeds early in the season gave a good deal of extra work, but the late rains have improved them very much, especially Scarlet Runners and French Beans. The late Peas are not so good as the early varieties. Potatoes are a good crop, large and of fine quality, but within the last few days disease has appeared in several places.—T. BLAIR.

NORTHERN.

Ripley Castle, Yorks.—After the exceptionally dry spring and early summer we have passed through, the reports on fruit crops will be perused with more than usual interest by all gardeners anxious to know how their crops compare with those of their neighbours. All fruit trees flowered abundantly and at an earlier date than usual, which caused us some misgivings, as we are subject to visitations from late spring frosts. But though we had a few slight frosts, there was nothing to cause injury to the bloom. The weather was all we could wish for during the blooming period, consequently the "set" was exceptionally good. Then came plagues of insects, which, had they not been battled with, would have played sad havoc. In consequence of the drought, a number of Pear trees and the smaller trees among the bush Apples cast a great deal of their fruit. The drought ended the last week in June, since which time rain has fallen in quantity, and everything is recovering rapidly from the ill effects of the dry period. Apples on old standard trees are over an average crop; on bush trees thin; quality promises to be very good. The varieties bearing most heavily are Lord Suffield, Alfriston, Mère de Ménage, Nelson Codlin, and Keswick Codlin. Pears are much under average, but the quality is good. Marie Louise, Jargonelle, Althorp Crasane, and Louise Bonne are the best croppers. Apricots heavy crop, rather smaller than usual. Plums average crop; Angelina Burdett, Jefferson, Green Gage, and Golden Drop are the best. Strawberries, Red and Black Currants, Raspberries, and Gooseberries very heavy crops. The first covered but a very short season. Cherries average crop. Filberts under average.

Potatoes (earlies) excellent crop, quality superb. Late varieties growing well and so far free from disease.—J. TUNNINGTON.

The Gardens, Studley Castle.—The late spring frosts did great damage to the Pear crop in these gardens and the neighbourhood, leaving the fruit very thin. There are some trees with an

average crop, as Fondante d'Automne, Beurré Giffard, and Pitmaston Duchess. Apples are an average crop, fruit clean and of fair size; trees clean and free from caterpillars. There are some sorts with heavy crops, as Lord Suffield, Ecklinville Seedling, Duchess of Oldenburg, Emperor Alexander, Peasgood's Nonsuch, Dumelow's Seedling, Tower of Glamis, Beauty of Kent, Norfolk Bearer, and New Hawthornden. Dessert varieties: Cox's Orange Pippin, Worcester Pearmain, Emperor Napoleon, Transparent, Ribston Pippin, and Rosemary Russet. Plums are plentiful; Green Gage, Peach Plum, Morocco average crop on the wall trees, while Victoria, Early Prolific, Early Orleans and late sorts are good on standards and bush trees. Apricots over crop of Moorpark and Large Early. Although covered with double fish nets, all the first blooms were killed by frost, but there was sufficient left uninjured. Small fruits abundant, but under-sized. Strawberries under-sized. Vicomtesse Héricart de Thury and Noble were much better in flavour owing to the dry season. The crop was soon over.

Potatoes look promising; the early varieties were light, but sound and good. Second earlies, as Covent Garden Perfection and Snowdrop, are heavier. All later kinds are looking very promising and quite free from disease.—H. PORTER.

Sandbeck Park, Rotherham.—This has been an exceptional season, but the soil here being heavy on the magnesian limestone formation the crops do not suffer so much in a dry season as on some of the lighter soils. As an instance, I never saw Peas and runner Beans look better than they do at the present time. I have found no Pea better than Ne Plus Ultra to stand the dry weather. Early Potatoes are smaller than usual; late varieties are looking well. All small fruits have been very plentiful. Gooseberries and Currants were heavily cropped. The Strawberry season was short and quite a month earlier than usual. Vicomtesse H. de Thury did remarkably well; Sir J. Paxton did not crop as freely as usual. Apples, Pears, and Cherries are a good crop, but Apricots and Plums have exceptionally heavy crops.—GEO. SUMMERS.

SOCIETIES AND EXHIBITIONS.

NATIONAL DAHLIA SOCIETY.

CRYSTAL PALACE.

SEPTEMBER 1 AND 2.

THE annual exhibition of this society, which took place at the Crystal Palace on September 1 and 2, must, when the incidence of the season is considered, be pronounced a distinct success. It is true that some who entered found themselves unable to compete, and some big blanks were to be seen on the tables, but the blooms were in not a few instances very good, while the bold and striking bunches of the Cactus and decorative varieties, the pompon, and the single Dahlias were generally superb. It is true there is a certain amount of formality in the present method of exhibiting the show Dahlias, as they are termed, but it appears to be the only way in which the heavy blossoms can be seen to the best advantage, and their size, symmetry, and brilliancy of colour tell wonderfully despite their formal appearance.

SHOW DAHLIAS (NURSERYMEN).—There were three competitors with sixty distinct blooms of show Dahlias Mr. Charles Turner, Royal Nursery, Slough, took the first prize. Messrs. Keynes, Williams and Co., nurserymen, Salisbury, were second with a collection only just inferior, there being the difference of one or two points only. With forty-eight distinct blooms the positions were reversed, Messrs. Keynes and Co. being first with fine flowers. There were five exhibitors of thirty-six blooms, and here Mr. John Walker, nurseryman, Thame, was first, with probably the finest stand in the whole show. Of self flowers

he staged W. Powell, John Henshaw, Mrs. Gladstone, Duke of Fife (very rich in colour), Purple Prince, John Standish, Colonel, Crimson King, Shirley Hibberd, Prince Bismarck, Seraph, Willie Garratt, Dr. Moffatt, Arthur Ocock, James Cocker, Flora Wyatt, John Hicking, W. Keith, Mr. Glasscock, Arthur Rawlings and J. C. Bird; of edged flowers, Maud Fellowes, Mrs. D. Saunders, J. T. West, Majestic, T. J. Saltmarsh and Mrs. Geo. Rawlings; fancies: Dorothy, Hercules and Hartie King, orange, with crimson stripes. Mr. G. Humphries, nurseryman, Chippenham, was second. There were five exhibitors of twenty-four blooms, Mr. John Walker being again first; second, Mr. Geo. Humphries, also with good blooms. With twelve blooms, Mr. Arthur Rawlings, florist, Romford, was first, with self flowers W. Rawlings, George Rawlings, W. Keith, W. Garratt, Mr. Glasscock, R. T. Rawlings and Mrs. Gladstone; edged: J. T. West, Mrs. Langtry and Maud Fellowes; fancy: Rev. J. B. M. Camm; second, Mr. H. Harris, Writtle Road, Chippenham.

SHOW DAHLIAS (AMATEURS).—In the amateurs' division for twenty-four blooms of show Dahlias there were six competitors. Mr. J. T. West, gardener to Mr. W. Keith, Cornwalls, Brentwood, was first, with refined flowers of Willie Garratt, Mrs. Gladstone, W. Keith, A. Rawlings, H. Keith, Victor, W. Powell, E. Sherman, J. Walker, George Rawlings, J. Standish, W. Rawlings, Clara, Shirley Hibberd, J. C. Vaughan and Sunbeam, selfs; edged: Majestic, Maud Fellowes, Ethel Britton and J. T. West; fancies: M. Campbell, Frank Pearce, John Britton and Henry Glasscock; second, Mr. A. Ocock, gardener to Mrs. McIntosh, Havering, Romford. With twelve blooms, Mr. J. Vagg, gardener to Mr. J. Theobald, M.P., Havering, Romford, was first, with Geo. Rawlings, J. Rawlings, W. Garratt, Maud Fellowes, Duke of Fife, R. T. Rawlings, W. Rawlings, A. Ocock, T. J. Saltmarsh, Mrs. Gladstone, Mrs. W. Slack and Prince of Denmark; second, Mr. Thomas Anstiss, Brill, Bucks. With six blooms, Mr. G. Boothroyd, Chippenham, was first, with James Cocker, Ethel Britton, Mrs. Gladstone, Duke of Fife, John Walker and W. Rawlings; second, Mr. W. Wheeler, Henley-on-Thames.

FANCY DAHLIAS.—The fancy Dahlias are kept distinct from the show varieties only in two classes for amateurs. Three collections of twelve blooms were staged, Mr. J. T. West again being first with capital blooms of Henry Glasscock, John Britton, Salamander, T. W. Girdlestone, Frank Pearce, Matthew Campbell, Professor Fawcett, John Cooper, Mrs. J. Downie, Buffalo Bill, Egyptian Prince and Mrs. Saunders—a very good selection indeed; second, Mr. S. Cooper, Chippenham. There were eight collections of six blooms, Mr. T. Anstiss, who had capital blooms of Mrs. N. Hall, Rev. J. B. M. Camm, Buffalo Bill, Professor Fawcett, Mrs. Saunders and Matthew Campbell, being first; second, Mr. John Couzens, Langley Broom, Chippenham, who had, distinct from the foregoing, Duchess of Albany, Prince Henry, Edmund Boston, Lottie Eckford and General Grant; third, Mr. W. Mist, Ightham, Sevenoaks.

CACTUS AND DECORATIVE DAHLIAS (NURSERYMEN).—Very imposing stands of these were staged, and the mixture of rich colours with paler tints of cream, pink, yellow, &c., made them very effective. With eighteen varieties, six blooms of each, Messrs. J. Cheal and Sons, nurserymen, Crawley, were placed first, having in fine condition Beauty of Arundel, Sir Roger, Delicata, St. Catherine, Christine Cheal, Countess of Gosford, Professor Baldwin, Bertha Mawley, Countess of Radnor and R. Cannell, all true Cactus types, Delicata in particular being very beautiful. Of decorative varieties, there were fine examples of Duke of Clarence, Honoria, Lanclot, Duchess of York (new), Ernest Cheal (new), Black Prince, Josephine and Mr. Tait; second, Messrs. Keynes and Co., having of Cactus varieties Bertha Mawley, St. Catherine, Sir Roger, Lady Penzance (new), Lady H. Grosvenor, Countess of Radnor and Countess of Gosford; of the decorative type, Josephine, Rayn d'Or, Apollo, Kaiserin, Maid of Kent, Dawn, Black Prince, Avalanche, Countess of Pem-

broke and Lancelot. There were six exhibitors of twelve varieties. Mr. G. Humphries, Chippenham, was first with Professor Baldwin, Countess of Radnor, St. Catherine, Baron Schroder, Kynereith, Bertha Mawley, Juarez, May Pictor (clear yellow), R. Cannell, Amphion, Sydney Hollings and Duke of Clarence; second, Messrs. Paul and Son. Then came a class for twelve bunches of true Cactus Dahlias, and here Messrs. Keynes and Co. were first with Gloriosa, Kaiserin, Duke of Clarence, Countess of Radnor, Apollo, Delicata, R. Cannell, Miss Violet Morgan, Bertha Mawley, Countess of Gosford, Chancellor (new), and Lady Penzance (new).

CACTUS AND DECORATIVE DAHLIAS (AMATEURS).—There were two exhibitors of twelve varieties, six blooms of each, Mr. J. T. West being first with Marchioness of Bute, Charles Rolfe, Bertha Mawley, Mrs. Keith, Joseph Chamberlain, Glory of Brentwood, Blanche Keith, Duke of Clarence, and seedlings; second, Mr. J. Strudwick. There were eight exhibitors of six bunches. Mr. E. Mawley, Rosebank, Berkhamsted, was first with Duke of Clarence, Bertha Mawley, Juarez, Professor Baldwin, Delicata, and St. Catherine; second, Mr. Hopkins, Bristol, Messrs. H. Cannell and Sons offered special prizes for six bunches of varieties sent out by them, Mr. West being placed first out of five exhibitors with E. Mawley, Marchioness of Bute, Henry Cannell, Glory of Brentwood, Emily Girdlestone, and Mrs. Keith; second, Mr. E. Brown, gardener to Mr. M. W. Morris, Hockley, Surrey, with Lady Marsham, Favourite, Mrs. Douglas, Mr. Tait, Beauty of Eynsford, and Marchioness of Bute.

POMPON DAHLIAS (NURSERYMEN).—There were four collections of twenty-four varieties, ten blooms in a bunch, and they formed quite a show of themselves. The collection shown by Messrs. Cheal and Sons, who were placed first, and Mr. C. Turner, who was placed second, were so close together, that they might have been justly placed equal. Messrs. Cheal and Son had Fairy Tales, Arthur West, Geo. Brinckman, Ringdove, Martial, Tommy Keith, Marion, Isabel, Cecil, Phoebe, Goldfinch, Eva, Darkness, E. F. Jungker, Grace, Bonquet d'Or, Admiration, Lady B'anche, Sunshine, Iolanthe, Eurydice, Whisper, Favourite, and Rosalie. Mr. G. Humphries had the best twelve varieties, staging very good bunches of Arthur West, George Brinckman, Darkness, Little Duchess, E. F. Jungker, Red Indian, Mabel, Favourite, Whisper, Lorna Doone, Phoebe, and Lillian; second, Messrs. Paul and Son.

POMPON DAHLIAS (AMATEURS).—With six bunches of ten blooms Mr. J. T. West was again first, having in capital condition Arthur West, Mary Kirk, Winifred, Eva, Tommy Keith, and a seedling; second, Mr. W. Mist, who had Whisper, Grace, Dora, Prince of Liliputians, Admiration and Eurydice. With six bunches of six blooms Mr. S. Cooper was first, having White Aster, Phoebe, Juno, Whisper, Lillian and H. Molesky; second, Mr. C. Osman, Sutton.

SINGLE DAHLIAS (AMATEURS).—Mr. T. W. Girdlestone, Sunningdale, was the only exhibitor of six bunches of ten blooms each, and was awarded the first prize with Demon, Kitty, Ruth, Yellow Satin, Daisy, and Gwendoline, all his own seedlings. Mr. E. Mawley, Berkhamsted, was the only exhibitor of the same number of bunches, six blooms of each, having Yellow Satin, Rosebank Cardinal, A. Pery, Enchantment, Miss Roberts, and Duchess of York. Special prizes were offered by Messrs. J. Cheal and Sons for twelve bunches, six blooms of each, and again Mr. Girdlestone was the only exhibitor, having The Mikado, Little Frank, Prince of Orange, Dearest (a charming variety, white, with side edgings of yellow), Maize, Marion Hood, Demon (a very fine dark variety), Yellow Dwarf, Sunningdale Scarlet, Cinderella, Awdry, and Florence.

An interesting class was an open one for six varieties of fancy single Dahlias, ten blooms of each, meaning varieties whose blooms are tipped, striped or edged. Mr. T. W. Girdlestone was first with Splash, Houri, Tommy, M.C.C., Phyllis and Irene; second, Messrs. J. Cheal and Sons.

Then followed a series of open classes of an educational character. Six blooms of any dark Dahlia—Mr. J. Walker was first with Prince of Denmark, Messrs. Keynes and Co. second with Niobe, and Mr. G. Humphries third with William Rawlings. Six blooms of any light, not yellow—first, Mr. J. T. West; second, Mr. G. Humphries; and third, Messrs. Saltmarsh and Sons, all with Mrs. Gladstone, a variety unapproached for its chaste beauty. Six blooms of any yellow—first, Mr. J. Walker, with John Hlicking; second, Mr. G. Humphries, with R. T. Rawlings, undoubtedly the two best yellow selfs; and third, Mr. Mortimer, with John Hickling. Six blooms of any tipped Dahlia—first, Mr. S. Mortimer, with Mrs. N. Halls; second, Mr. Seale, with Mrs. Saunders, both fancy varieties. Six blooms of any striped Dahlia—first, Mr. G. Humphries, with Frank Pearce; second, Mr. J. Walker, with Matthew Campbell; third, Mr. Seale, with Henry Eckford, all fancy varieties. Six blooms of any edged variety—first, Mr. C. Turner, with Miss Cannell; second, Mr. J. T. West, with J. T. West; third, Mr. J. Tranter, Henley-on-Thames, with Florence Tranter. Mr. John Walker offered special prizes for his new white self John Walker, six blooms being required. First, Mr. S. Mortimer, with very fine blooms; second, Mr. G. Humphries; and third, Mr. E. F. Such. It is incomparably the best white self Dahlia.

Miscellaneous exhibits included a fine collection of cut Dahlias, &c., from Mr. T. S. Ware, Hale Farm Nursery, Tottenham; a fine lot of Cactus Dahlias with blooms of Orange Begonias, from Messrs. H. Cannell and Sons, Swanley; cut Roses in great variety from Messrs. Paul and Son, nurserymen, Waltham Cross; a bold group of Begonias and other plants, as well as a collection of cut flowers from Messrs. J. Laing and Sons, Stanstead Park, Forest Hill; and plants and cut flowers from Messrs. B. Peed and Sons, Lower Norwood.

But few seedling Dahlias of the show class were exhibited on this occasion, the most promising being Niobe (Keynes and Co.), shaded crimson, paling to bright crimson on the petal edges, and Nellie Tranter (Tranter), a pale ground flower, with slight edging of bright lilac-purple, very pleasing. Of new Cactus and decorative Dahlias there were several, first-class certificates being awarded to the following: Lilacina (Cannell and Sons), yellow ground, deeply suffused with bright purplish mauve, especially towards the petal edges; Mrs. A. Pearl (Ware), a near approach to a pure white Cactus Dahlia, creamy white, the centre bright citron, very distinct and a decided acquisition; Lady Penzance (Keynes and Co.), a lovely soft yellow Cactus of the finest quality; Lady Henry Grosvenor (Keynes and Co.), Cactus, delicate salmon base and bright yellow base, the best of the varieties in this way; and Chancellor (Keynes), Cactus, bright crimson, suffused and edged with purple, very fine; Beauty of Wilts (Pictor), Cactus, bright orange-salmon, distinct and pleasing; Mary Hillier (Hillier), Cactus, bright salmon, deepening to orange, very promising; Matchless (Perkins and Sons), Cactus, a very fine dark variety, maroon, paling to crimson on the petal edges; and Purple Prince (Perkins and Sons), Cactus, maroon centre, the basal petals maroon tipped with bright purplish crimson. To pompon varieties, Captain Boyton (C. Turner), deep maroon, of the finest shape, an excellent addition to the dark varieties; and Rowena (C. Turner), tipped with bright pale red on a yellow ground, very distinct. To single Dahlias, Demon (Girdlestone), rich bright maroon, fine shape; Phyllis (Girdlestone), pale ground, mottled and splashed with lilac round the centre and flaked with crimson; M.C.C. (Girdlestone), yellow, striped and flaked with bright orange-red; and Tommy (Girdlestone), yellow, striped and flaked with bright crimson, very handsome. To Scarlet Perfection (Perkins and Sons), very bright scarlet, of the finest shape and substance; Mary Sharpe (Cheal), buff ground, with reddish orange ring round the eye and flakes of orange-red, deepening to crimson; and Mrs. Harris (Cheal), blush, with side margins of bright rosy purple, small, excellent shape and very distinct.

Several other promising new varieties of Cactus, decorative, pompon and single varieties were staged.

A full prize list will be found in our advertisement columns.

NATIONAL CHRYSANTHEMUM SOCIETY.

THE Royal Aquarium was filled with flowers of various kinds on Tuesday last, the opening day of the first exhibition. Dahlias and Gladioli were the leading features besides the Chrysanthemums. At the meeting of the floral committee, Mr. W. Herbert Fowler took the chair, this being the first occasion since the reconstruction of the committee. We were rather surprised, considering the numerous additions to the early-flowering list, to find so little material submitted to the committee for adjudication. Mr. N. Davis, of Camberwell, and Mr. W. Piercy, of Forest Hill, staged several bunches of Gustave Grunerwald, a free-flowering, medium-sized Japanese variety of a light lilac-mauve colour. This would undoubtedly have received a certificate but for the fact that a plant was not forthcoming, the rule being very definite in cases where new varieties are submitted as decorative Chrysanthemums.

First-class certificates were awarded to the following:—

MR. E. ROWBOTTOM.—A new yellow Japanese, very pure in colour, and of perfect form. It is a seedling raised by its namesake, who was also the exhibitor.

SAMUEL BARLOW.—A medium-sized Japanese, raised from seed last year at Camberwell. The colour is a deep salmon-pink with centre shaded yellow, not unlike the later variety Margot. Shown by Mr. N. Davis.

The early-flowering Chrysanthemums are being added to each year, and a number of varieties with handsome blooms may be obtained; but still there is a lack of colour. About eleven classes were set apart for Chrysanthemums. The chief class was for twenty-four bunches, not less than three blooms in a bunch, and the first prize was awarded to Mr. E. Such, Maidenhead, who had a well set-up collection, in which the principal kinds were Early Blush, blush, white in the centre; Golden Gem, rich yellow; Mrs. J. R. Pitcher, rose and yellow; Alice Butcher, rich chestnut-crimson. The most interesting collection was that from Mr. Norman Davis, Lilford Nursery, Camberwell, who was placed second. His flowers were of great merit; the best were La Vierge, pure white; Alice Butcher, previously described; Samuel Barlow, salmon-rose, the reverse yellow; the well-known Mme. Desgrange and its several forms; Mrs. J. R. Pitcher, M. Pynaert Van Geert, Lyon, rich crimson; Blushing Bride, rose, and beautiful clusters of M. Gustave Grunerwald, a lovely early variety, the flowers white, yellow in the centre, the outer petals touched with rose. Very fine flowers came from Mr. H. Shoesmith, gardener to Mr. M. Hodgson, Shirley Cottage, Croydon, who was first in the class for twelve blooms of Mme. C. Desgrange, with Mr. W. C. Pagram, gardener to Mr. A. F. Hobbouse, The Whin, Weybridge, second. The next class was of interest. Twelve blooms of any large-flowering varieties were to be shown, except Mme. Desgrange, and excellent flowers were staged by Mr. Agate, Havant, Hants, who had the silvery white sport from Etoile de Lyon, Mrs. W. H. Goulden, white; Mr. E. Beckett, yellow; Puritan, white, broad petals; and W. Tricker, rose. In the second prize stand from Mr. A. McMillan, gardener to Mr. J. Currie, Edinburgh, were good blooms of Puritan and Mme. Lacroix. But yet throughout there is a want of distinct and telling colours, though many of the shades are very delicate and pleasing. Another class was for six bunches of Mme. C. Desgrange with foliage, the first prize going to Mr. W. C. Pagram, and in the corresponding class only yellow varieties were admitted. Mr. H. Shoesmith had the best, showing good blooms of Mrs. Burrell and Mrs. Hawkins, whilst Mr. W. Pagram was second.

Mr. A. McMillan won the first prize for six blooms, distinct, excluding Mme. C. Desgrange and its sports. The best kinds shown were M. Freeman, rose; Etoile de Lyon, Stanstead White, Mr. Irving Clarke, rose; and Puritan. Pompons were exhibited well by Mr. D. B. Crane, Archway Road, Highgate, who showed neat, well-developed blooms, particularly of Mrs. Cullingford and Piercey's Seedling, yellow.

In the classes set apart solely for amateurs, medals were given, and for twelve bunches, pompons allowed, the silver medal, equal to first prize, was awarded to Mr. D. B. Crane, who had a good collection, including a pleasing Japanese variety named Alfred Montibelli, salmon and white in colour. The best stand of Chrysanthemums came from Mr. W. Mole, High Street, Hemel Hempstead.

Dahlias.

These proved an important feature. The chief class was for sixty show and fancy blooms, and the first prize went to Mr. C. Turner, The Royal Nurseries, Slough, who had a remarkably fine collection of smooth, even, well-finished flowers. It is unnecessary to mention names, as all the leading kinds were included. Messrs. Keynes, Williams and Co., Salisbury, were a very good second. The Salisbury firm were first for thirty-six blooms, and showed very fine flowers, whilst Mr. J. Walker, Thame, Oxon, was second.

Amateurs showed fairly well. The principal class in this division was for twenty-four blooms, show kinds, the first prize going to that well-known amateur grower, Mr. J. West, gardener to Mr. W. Keith, Cornwalls, Brentwood, whilst Mr. Ocock, gardener to Mrs. McIntosh, Havering, Essex, was second. Matters, however, were reversed in the class for eighteen blooms, in which Mr. A. Ocock was first and Mr. J. T. West second. The premier award for twelve blooms was made in favour of Mr. T. Vagg, gardener to Mr. J. Theobald, Havering, near Romford, whilst Mr. J. Gurney Fowler, Glebelands, South Woodford, was second. Mr. Vagg had the best six flowers.

Three classes were devoted to pompon kinds. Twenty-four very fine bunches came from Messrs. Cheal and Sons, Lowfield Nursery, Crawley, comprising many of the older and more recent varieties, whilst Mr. Chas. Turner was second, and Messrs. Keynes, Williams and Co. third. In this collection was a new kind named Madge, a very neat flower, scarlet in the centre, the outer petals white. In the corresponding class for twelve bunches, Messrs. T. Burrell and Co. were first with excellent blooms, especially of the well-known White Aster, E. F. Jungker, salmon; Whisper, yellow, small crimson centre; and Fairy Tales, primrose; Mr. George Humphries, Chippingham, second. The best six bunches were from Mr. J. T. West, the most distinct kind being Little Julie, the flower scarlet.

Single varieties brought a good competition. As usual, the post of honour was occupied by Messrs. Cheal and Sons, whose collection included a brilliant scarlet flower named Duke of York, one of the brightest we have seen; Mr. F. W. Seale, Vine Nurseries, Sevenoaks, second. The best twelve bunches were from Mr. Geo. Humphries. A very charming kind represented was Florrie Fisher, the flower rose, white at the base of the petals. Mr. R. Burgin had the best six bunches, with Mr. Ed. Mawley, Rosebank, Berkhamsted, second.

The Cactus varieties are always the most attractive to us at the exhibitions. It would be difficult to eclipse the twelve superb bunches staged by Messrs. Keynes, Williams, and Co., who were placed first. Remarkably fine were Lady Penzance, a lovely soft yellow shade; Chancellor, crimson-purple; Countess of Gosford, Bertha Mawley, Gloriosa, brilliant crimson; Lady Henry Grosvenor, reddish tone, yellow in the centre; and Delicata, an exquisite salmon-rose shade, shot with magenta, and suffused with yellow in the centre. Messrs. T. Burrell and Co. were second, but their collection comprised too many of the decorative type, which are coarse. The best six bunches were from Mr. J. T. West, who had a very

charming kind named Blanche Keith, the flowers of a yellowish colour and pleasing shape.

Two classes were provided for Gladioli. In the open class a remarkably fine collection came from Messrs. Burrell and Co., comprising no less than twelve boxfuls of splendid varieties. Special prizes were offered by Messrs. Sutton and Sons, Reading, for a collection of vegetables. The first prize went to Mr. C. J. Waite, gardener to Col. the Hon. W. P. Talbot, Glenhurst, Esher, who had excellent produce, whilst Mr. C. Osman, South Metropolitan District Schools, Sutton, Surrey, was second.

Several miscellaneous exhibits were shown. A superb group of Dahlias came from Mr. T. S. Ware, Hale Farm Nurseries, Tottenham. The flowers, representing every section, were delightfully arranged and set off with plants of the graceful Eulalia gracillima. A silver-gilt medal was most deservedly awarded. Mr. Mortimer, Farnham, had an interesting collection of seedling Dahlias; also Messrs. Perkins and Sons, of Coventry. Messrs. Keynes, Williams and Co. had a collection of show Dahlias of leading varieties, and Mr. Piercey, Forest Hill, S.E., flowers of early Chrysanthemums M. Gustave Grunerwald and Arthur Crepey. Mr. Arthur Rawlings, Romford, Essex, exhibited a collection of show Dahlias (silver medal), whilst a most interesting group of hardy flowers came from Messrs. J. Laing and Sons, Forest Hill.

Fruit was chiefly represented by a remarkably fine collection from Messrs. J. Laing and Sons, to which a silver medal was awarded. The Pears most worthy of note were Louise Bonne of Jersey, finely coloured, Souvenir du Congrès, and Beurré Bosc; whilst Apples worthy of note were Cox's Pomona, Lord Derby, Lord Suffield, and Fearn's Pippin. Remarkably large fruits of Peasgood's Nonsuch Apple were shown by Mr. J. B. Payne, gardener to the Bishop of Bath and Wells, The Palace, Wells. The twelve fruits weighed 15 lbs., and the heaviest specimen 22 ozs.

— On Monday last the general committee held a meeting at Anderton's Hotel. Mr. Harman Payne took the chair, and after the minutes of the two previous meetings had been confirmed, the secretary read certain correspondence chiefly relating to the withdrawal of members and three of the affiliated societies. Mr. Geo. Gordon not being able to officiate as judge at the show on Wednesday was replaced by Mr. Geo. Stevens, of Putney. Mr. Payne read an invitation from the Bordeaux Society for members to exhibit at their show in November, and also intimated that there was a desire on the part of Antipodean growers to compete for a prize at one of the N.C.S. shows, sending their exhibits of six Japanese blooms and six incurred over to England free of expense to the society for the purpose. The suggestion, which met with some approval, was decided to be left in the hands of the schedule sub-committee for consideration at an early date. Reports by the secretary as to the financial position of the society and the reserve fund were satisfactorily received. Mr. Edwin Molyneux, of Swaomore Park, was elected a member of the floral committee in place of the late Mr. Sanderson. Ten new members and one Fellow were also elected, and a Cape of Good Hope Chrysanthemum Society admitted in affiliation. A vote of condolence with Sir John Llewelyn at his recent loss was passed, and the meeting closed at an early hour.

ROYAL HORTICULTURAL SOCIETY.

AUGUST 29, 30, 31, SEPTEMBER 1.

Horticultural Buildings, &c.

TAKING into consideration the large amount of space at disposal under the galleries where these exhibits were grouped, it must be taken as a very good representative display. Had the same things been all arranged together they would undoubtedly have made a better impression. As it was, however, there was plenty of room for inspection in comfort. One thing that no doubt prevented more

of these exhibits from being sent was that (in our opinion) high rate charged by the Agricultural Hall Company for space. According to what some at least paid, the receipts from this source alone must have been considerable, and have gone a long way towards paying the prize money in the schedule.

In horticultural buildings and heating apparatus, Messrs. Foster and Pearson have the most extensive exhibit. The erections of this firm are well known, and of good repute for their workmanship. Those exhibited were of this stamp, not having been worked up specially for the purpose. They showed a most useful erection in the Beeston greenhouse for amateurs, strongly built and ventilated on the best principles. This was heated by the Beeston boiler, which was for such a purpose as good as we could desire. There were also well-planned wall coverings, which, for exposed situations, will soon repay the cost of erection in the better crops of fruit and vegetables. Their larger boilers were also shown; these are quick in action and of good design. Another excellent exhibit was their well-known span-roofed frames (awarded silver-gilt Flora medal for general excellence), the last-named exhibit being highly commended. Messrs. Messenger and Co. also showed well in this section, their chief exhibit being a light, elegant and ornamental house, in which were shown interior fittings either for a vinery in the form of wires and trellis-work, for a plant house in the way of stages, or for forcing purposes in the arrangement (an excellent one) of slate staging—far more desirable than any wood or brickwork erections. The ventilating arrangement here commended itself, especially that in which the Archimedean screw was utilised, making the lights self-locking at any angle. The roof of this house was tightened by iron rods of light make. The same firm also showed boilers, valves, &c., of new and approved designs, as well as cold frames (awarded silver-gilt Flora medal for the house and its arrangements). Messrs. Sam. Deards and Co. showed their coil boiler, which has been proved in previous exhibitions to be a powerful and economical one. They have also a coil arrangement adapted to the interior of Walker's slow combustion stove, which adds greatly to its heating power. The arrangement for feeding this boiler by the addition to its top is a novel one, which, for amateurs at least, would be desirable. Award for this latter exhibit silver Banksian medal.

HEATING BY GAS AND OIL—As might be anticipated with the advances now made in this direction, there were exhibits of this character which are in every way commendable for the small grower as well as for heating entrance halls and corridors, &c. Messrs. Fenlon and Son had their patent gas boiler and piping attached in working operation; rapidity of action as well as economy of gas is claimed for this invention. Others are also shown. Awarded silver Banksian medal. Messrs. Tootle and Son had another exhibit in this section; this also is good for the purpose, the copper pipes in place of iron ones being noteworthy for workmanship, whilst for durability they should be all that one could desire. Awarded silver medal Banksian medal. Messrs. Clark and Co. show both oil and gas-heating arrangements in operation. In the use of the oil there is no appreciable smell. An excellent arrangement of this exhibit is the upright form, by which little room is taken up wherever the apparatus is stood. This exhibit was commended.

A new automatic damper was the most novel exhibit in the whole show. By means of a float in the expansion cistern the damper is opened or closed according to the temperature of the water. To amateur and small growers who do not want to be always watching the temperature this should be valuable. Shown by Mr. Lascelles, 97, Fleet Street, E.C. (award silver Banksian medal). Standard tree pruners were shown by the Standard Manufacturing Co., Derby; these were of further improved make, by which more power was imparted by leverage arrangements in the working. These were fully tested and found to be very powerful and efficient (award

silver Flora medal). Miscellaneous exhibits by horticultural sundriesmen and others were important features, occupying a considerable space. All conceivable wants of the garden were to be found shown here. The summer houses shown by Mr. Riley, Herne Hill, S.E., were of good make and design, of rustic character and not formal (award silver Banksian medal). Messrs. Osman and Co. had a large and comprehensive stand of sundries on which were to be seen light and well-made boxes for parcel post, garden cutlery and tools of all kinds, insecticides, manures, light iron stakes, exhibition boards and boxes, tying materials, &c., with a new trap for catching wireworm of simple make (award silver Flora medal). Mr. J. T. Anderson had also a large stand, on which could be seen a splendid sample of the old tying material, Cuba bast, which for durability is infinitely better than raffia, this also of good quality being set up beside it. Sacks, ropes and twines, with all sorts of mats and the most approved shadings were displayed here. Mr. J. George, Putney, had a representative stand, on which were to be seen first-rate samples of Orchid and other peats, very superior Mushroom spawn, artificial manures, bones, &c., as well as fumigating materials as now in use, and wood wool of the finest quality, now so much in request. Messrs. W. Wood and Son had a very novel and attractive erection over their large and comprehensive stand of Bamboos, which formed the outline of an improvised summer house, affording an excellent idea of the adaptability of Bamboos to garden purposes. This firm does a large trade in Bamboo sticks, these in various kinds being also displayed. Here also were to be found effective insecticides, artificial manures, tying materials, peat of the finest qualities, and the best kind of wood wool for packing, soft and void of smell. Mr. W. Cooper, Old Kent Road, had a large exhibit of sundries of various kinds, peats, loams, manures, and other requisites of the garden. The most noteworthy exhibit here was the small portable houses (for amateurs) of various designs; these were excellent for the purpose in small gardens. Messrs. A. Cross and Son, Glasgow, showed artificial manures and fertilisers, also their "insecticide and mildew-destroying compound," which is one of the most efficacious and safe in use of anything in its way. Messrs. Corry, Soper and Co. showed a comprehensive stand of sundries that included nearly every article in daily use. Messrs. B. Lawes and Co., the well-known chemists, had an exhibit of their "disinfecting compound," an article not nearly enough in use in gardens; no garden, in fact, should be without one or another effectual disinfectant. There were several other smaller exhibits, one of the most useful being the paper fruit and flower baskets of Messrs. Cooper, Denison and Walkden, St. Bride Street, E.C.; these are light and serviceable. A few other exhibits hardly pertained to horticulture, therefore need not be named.

— The next meeting of the above society will be held on Tuesday, September 12, at the Drill Hall, Victoria Street, S.W. Mr. Jas. Douglas will deliver a lecture on "Garden Phloxes and Pentstemons," and collections of these plants will be welcomed as a means of illustrating the lecture in a practical way. As the season for Gladioli is drawing to a close, we have been requested by Messrs. Kelway and Son, of Langport, to say that their prize of a silver medal will be offered at this meeting for the best twelve Gladioli *gandavensis* varieties raised from British seeds. Prizes are also offered by the society for twelve distinct Gladioli grown by amateurs.

The weather in West Herts.—All the day temperatures during the past week have been moderately high for the time of year, but on two nights the exposed thermometer indicated readings within 6° and 4° of the freezing point. With the exception of a slight fall of rain early on Friday morning, the weather has remained perfectly dry. The summer of 1893 proved very hot. On one day the shade temperature exceeded 90°, on eight

days 85°, on eighteen 80°, on twenty-eight 75°, and on fifty-five 70°. It was also a dry season, the total rainfall falling short of the average amount by about 2 inches. The number of rainy days was, however, about reasonable. The great spring drought left the soil and sub-soil extremely dry; in fact, notwithstanding the frequent rains in July, not a drop of water came through the 2½ feet of soil in either of my percolation gauges between the end of March and the beginning of August, or for four months.—E. M., *Berkhamsted*.

A note from Ireland.—One of the most interesting notes in THE GARDEN to me is that weekly from West Herts. I tried the soil here yesterday (4th) at 1 foot deep, and found it 64°; this is 2° warmer than a week ago, the rain having then reduced the temperature very quickly. On Tuesday, August 8, the sea temperature was 62°. This is the best year known for fruit in the south of Ireland, shy-bearing Apples having a full crop, and four to five weeks earlier than usual.—A. WHITE, *Waterford*.

Recreation grounds scheme.—The committee having purchased a site for carrying out the proposed recreation grounds in Smedley Street, Matlock Bank, and about a score of gentlemen having come forward as guarantors for the £1750 required, a meeting of the gentlemen concerned was held on Wednesday night at the Social Institute, Matlock. Dr. William Moxon was elected to the chair, and the meeting unanimously adopted a resolution approving of the purchase of land by the committee, and it also decided to form a limited liability company to carry out the project, under the title of the Matlock Pleasure Gardens Company, Limited. The shares were fixed at £1 each, but the amount of capital was deferred. The meeting adjourned until next week.

Two new Monthly Roses.—An amount of interest has been awakened in these during the past few years, and has led to the hunting up of not a few old and all but forgotten kinds. The next most desirable thing is the addition of new varieties if they have the essential distinctness. M. Guillot led the way with Mme. Laurette Messimy, sent out a few years ago, and at once recognised as of sterling worth, in lovely shades of rose-pink and copper-yellow. Two magnificent kinds in rich many-flowered trusses have come to me from Messrs. W. Paul and Son, of Waltham Cross, both being very distinct, of true Monthly character, rich in colour, and sweetly scented. Duke of York has a pretty well-shaped full flower of soft salmon-pink with yellow base, rich rose and crimson on the exterior. Waltham Bedder is very brilliant, a rich rose with copper-yellow at the base of the petals. Next to the Teas I should like to see the best Monthlies grown well in good groups, and whatever the advocates of non-pruning may say to the contrary, I have always got the best and most continuous display by cutting the bushes hard back in spring. It is a good thing that some of our nurserymen pay attention to other Roses than those merely which conform to exhibition standard.—A. H.

Pinus nobilis unhealthy.—I enclose a few pieces from the bark of a *Pinus nobilis* which are full of an insect. The same tree was affected in a similar way last summer, and was dressed with a mixture of lime and water on the trunk. I should be obliged by your informing me the probable cause of it, and if any treatment of the tree is advisable as a remedy. The soil is clay on limestone. The tree has a very fair amount of air, and a top-dressing once a year of decayed leaves.—W. CHAPLIN.

** In reply to the above, your *Pinus nobilis* is attacked by one of the Coccidæ. As I am away from my books at the present moment, I cannot give its name more definitely. The treatment, however, of the tree will be the same whatever the pest may be, which is the more important point.

You cannot do better than wash the tree with one of the following mixtures: 5 lbs. of soft soap, the extract from 5 lbs. of quassia chips well boiled, and 100 gallons of soft water; or, 12 lbs. of soft soap, half a gallon of paraffin oil, and 100 gallons of hot soft water, the hotter the better, as the soap and oil mix better with hot water than with cold. This mixture when in use should be kept well stirred so as not to allow all the oil to float on the surface. I will write again, giving the name of the insect as soon as I am in a position to do so.—G. S. S.

Grubs in Potatoes.—Would "G. S. S." kindly name enclosed gigantic grub, found in the soil of a Potato drill as it was being dug this morning? From the look of its mandibles, it appears to be a carnivorous species, and, if so, would be just the kind of friend and helper gardeners would like to have to keep down "leather-jackets."—W. M.

** The large grub you found is that of the common cockchafer. It is not carnivorous, but is a very destructive pest to a large number of crops. I am afraid I can suggest no means for the destruction of this insect but turning it out of the ground and destroying it.—G. S. S.

Spiranthes Romanzoviana.—In reference to what Mr. A. D. Webster says at p. 224 of THE GARDEN, I have to say that the original sketch made by myself of the above species was used in the *Gardener's Chronicle* for October 8, 1881, on page 465, so that it was not quite original when it reached Mr. Webster as a free gift in 1885. Anyone interested in trifles who may care to glance at the illustration in *Gardener's Chronicle* of 1881 will see that Mr. Webster simply used an electrotype copy of that block in his work "British Orchids," published in 1886, added to which we have M. Correvon avowedly publishing his figure in "Orchidées Rustique," 1893 (p. 191), as "après Webster."—F. W. BURBRIDGE.

Names of plants.—C. Johnston.—1, a very good form of *Aerides quinquevulnerum*; 2, *Platanops amabilis*, but not the *amabilis* of gardens, which is P. Aphrodite.—W. Mortimer.—*Saccolabium Blumei*.—Nemo.—Impossible to name from such a scrap.—C. L. V. A.—All the Roses seem to be *Rève d'Or*; the H. P. in bud we cannot name.—Lyrrium.—*Acer campestre*.—J. B.—*Chelidonium majus*.—Courtown.—1, *Rhamnus catharticus* (the Buckthorn).—H. May.—1, *Catalpa* sp.; 2, *Digitalis ferruginea*; 3, *Lonicera aureo-reticulata*.—J. F.—Apparently *Catasetum callosum*; should like to see the flower of the other sex when it has any upon it.—B. T.—1, *Adiantum formosum*; 2, *Aglaomorpha Meyenianum*; 3, *Asplenium formosum*.—L.—*Lilac flower*, *Crocus zonatus*; *rose flower*, *large*, *Colchicum byzantinum*; *small flower*, *Colchicum Szovitzianum*. In sending flowers or fruit for name please always affix numbers.—H. Prothero.—*Tecoma jasminoides*.—T. B.—1, *Nerine flexuosa*; 2, *Stapelia* species; 3, *Ophiopogon Jaburan variegatum*.

Name of fruit.—W. B. Hartland.—Cornish Gilliflower.

"The Garden" Monthly Parts.—This journal is published in neatly bound Monthly Parts. In this form the coloured plates are best preserved, and it is most suitable for reference previous to the issue of the half-yearly volumes. Price 1s. 6d.; post free, 1s. 9d. Complete set of volumes of THE GARDEN from its commencement to end of 1892, forty-two vols., price, cloth, £30 12s.

"Gardening Illustrated" Monthly Parts.—This journal is published in neatly bound Monthly Parts, in which form it is most suitable for reference previous to the issue of the yearly volumes. Price 5d.; post free, 8d.

"Farm and Home" Monthly Parts.—This journal is published in neatly bound Monthly Parts, in which form it is most suitable for reference previous to the issue of the yearly volumes. Price 5d.; post free, 8d.

"Hardy Flowers."—Giving descriptions of upwards of thirteen hundred of the most ornamental species, with directions for their arrangement, culture, &c. Fifth and Popular Edition, 1s.; post free, 1s. 3d.

"The Garden Annual" for 1893.—Contains Alphabetical Lists of all Branches of the Horticultural Trade. The Lists of Gardens and Country Seats (containing over 9000) have been very carefully and extensively revised, and are admitted to be the most complete ever published. Price 1s.; by post, 1s. 3d.

All of our readers who are interested in the improvement of cottage homes are invited to help us to make Cottage Gardening known. It is published at the very lowest price to meet the wants of those for whom it is intended, and copies will be sent for distribution, free, by the publishers, Messrs. Cassell and Company, La Belle Sauvage, Ludgate Hill E.C.

No. 1159. SATURDAY, September 16, 1893. Vol XLIV.

"This is an Art
Which does mend Nature: change it rather; but
THE ART ITSELF IS NATURE."—Shakespeare.

ORCHARD AND FRUIT GARDEN.

STATE OF THE FRUIT TREES.

A LONG spell of tropical weather, accompanied by prolonged drought, had the effect of maturing both the wood and buds of fruit trees generally before the month of August had arrived. Following upon the drought, we had a change to wet and dull weather, and once more the sunshine is remarkably powerful, the days being very hot, though the nights are cold, frosts having been experienced in some places. The effect of all this can scarcely be realised as yet, but to all appearances it will not be altogether in favour of the owners of very many fruit trees. We hear and meet with instances of Pear trees having actually flowered at three distinct times, ripening two crops, the third only just setting now. Many Apple trees are now flowering freely, a horizontally trained Warner's King in a town garden being heavily laden with fine fruit, among which are distributed numerous trusses of flowers, and with me Bramley's Seedling, Lane's Prince Albert and Cox's Orange Pippin are behaving very similarly. It is the young trees that are most addicted to this, to say the least, very unfortunate behaviour, the flowers, strangely enough, being principally produced at the points of young shoots. If, however, it was of only a few isolated cases that this abnormally late flowering could be written, there would be little or no need to complain, and it may yet turn out that the effect of so much sunshine on the trees will be of a beneficial and lasting character rather than otherwise. At present what we have most to fear is that very many fruit-buds on old trees will either burst before the leaves fall or else become so dangerously forward as to be incapable of standing the vicissitudes of our winter. Where wall trees are in a rather sunny position, the fruit-buds, in addition to being very numerous, are also remarkably forward, this being especially the case where rather hard stopping has been practised. Should we have a few days of warm showery weather, then I am afraid not a few of these forward buds will burst, though even then there are so many on the trees that plenty may be left to open in due course. It is not often that summer stopping leads to the formation of so many fruit-buds the same season, as proves to be the case this year, and, judging from the state of unpruned shoots on old Apple trees, many of these will, if left untouched, flower very freely next spring.

Raspberries are also showing the effects of so much dry, hot weather in a way that is not altogether satisfactory, and yet not without its bright side. Very many of the young canes have flowered or are flowering freely, and ripe fruit, where it can be saved from the birds, is fairly plentiful. In some instances a bunch of fruit is produced at the points of the canes only, while in others fruit is ripening nearly throughout their whole length. It is the sturdier-growing forms, notably Carter's Prolific and Baumforth's Seedling, that are behaving in this manner, the weaker growers presenting their

usual appearance. I need hardly add that those canes that are producing fruit throughout their length will be of little or no value next season, but all that have borne at or near the points only may be shortened next winter or early in the spring to below where they are fruiting now, with every prospect of their breaking and fruiting freely from the lower reserved joints.

Red spider has done great injury to a variety of fruit trees and bushes in innumerable gardens this summer, Peaches, Nectarines, Plums, and Gooseberries being the greatest sufferers. In some instances not a leaf could be seen on the trees and bushes as early as the second week in August, and seeing that the leaves cannot possibly have properly fulfilled their functions, a very feeble break must result next season. In some instances it would perhaps be the right practice next winter to hard prune wall trees that have suffered most from the effects of red-spider attacks with a view to forcing out a few strong shoots instead of numerous weakly growths that will inevitably ensue if the trees are pruned in the ordinary manner. This would, at any rate, be preferable to wholly rooting out the early defoliated trees, as intended in one case that has come under my notice. If the trees do start well after their severe pruning, they would, if rooting in a fairly good border, soon surpass newly-planted trees, though I would not rely too much upon this, but should advise planting young trees midway between those that are severely pruned. This proposal to either hard prune or root out trees that have been greatly injured by red spider may appear rather of a too drastic character, but exceptionally bad cases call for exceptionally strong remedies. In far too many gardens forest trees are growing within a few yards of the warmest garden walls, and it is these that are largely responsible for many failures of Peach and other trees. Not only do the roots of Elms, Beech, and such like penetrate beneath the foundations of the walls, find their way up into the borders and rob these of much food and moisture intended for the wall trees, but they also communicate red spider, thrips and aphides to the foliage of the latter. Undoubtedly poverty at the roots has much to do with bad attacks of red spider, but the remedies are scarcely so simple as at first sight may appear. Gooseberries have tried to make up lost ground already. Many that lost nearly or quite all their leaves owing to the work of red spider are now in quite a green state, but the bushes are in a very feeble condition, and they are likely to be found so next season. Fortunately, quite large bushes transplant readily, and those who have feeble bushes under wire netting-covered structures, and stronger, healthier ones in the open, will do well to arrange for some of these latter to take the place of the former.

As I fully expected would be the case, Strawberries have suffered very much from the drought, and the prospects for next season, as far as many growers for market are concerned, are anything but cheering. In the neighbourhood of Bath there are many hot sloping banks devoted to Strawberry culture, the plants on which at the present time are in a bad plight. Those newly put out remain almost stationary, while the older plantations are over-run by red spider and fast drying up. The owners have been afraid to do any trimming or clearing off of rubbish, those breadths that have been thus attended to suffering the most from drought. Where the Vicomtesse Héricart de Thury is still given a good position the rows are flowering and fruiting with great freedom. At Longleat there is quite a large breadth of this variety netted over, excellent dishes of fruit being now

available, and abundance of green Strawberries is swelling most satisfactorily. The rows were not planted out after being forced, but produced a heavy early crop of fruit where they now are. How far this second crop will affect next summer's prospects remains to be seen, but in any case the fruit is very welcome now. Vicomtesse would appear to be the most reliable autumn-fruiting variety, or much more so than Noble, and there is no mistaking the superiority of its flavour over all other varieties that ripen early or late in the season.

W. IGGULDEN.

GRAPES MILDEWED.

I HAVE a greenhouse facing the east and have had good crops of Grapes for many years till the last two years. The Vines and Grapes have been mildewed; nothing else in the same house has suffered. I have also a large Vine facing the south on a house 10 yards from the Grape house, which is 30 feet long and 8 feet wide; all the Grapes and Vine are mildewed also.—A. B.

* * Vines not in a healthy state at the roots, more especially if rooting deeply, are apt to form soft sappy growth peculiarly liable to be overrun by mildew, but more often than not the attack of the latter is brought about by faulty ventilation. In the first place, a house largely devoted to the cultivation of greenhouse plants is not the best place for Grape culture. Certain classes of plants, notably Ferns, Begonias, Cypripediums, and zonal Pelargoniums, might be, and very often are, extensively grown under Vines, but when to these are added Azaleas, large-flowering Pelargoniums, Fuchsias, Roses, Carnations and such like, then the chances are insect pests and diseases will be communicated from these to the other occupants of the house, and the Vines in particular. Judging from the letter before me, "A. B." does not blame the pot plants for the two successive attacks of mildew, but they had something to do with it all the same. Greenhouse flowering plants require, and usually get, abundance of air during bright spring and summer days, the front lights as well as the top ventilators being set wide open. When the young growth of Vines is beginning to mature is when mildew is most liable to affect it, and it usually follows in the wake of a rush of cold air. I have frequently made this assertion in these pages, and have never been contradicted. Had I been so, my experience this season would have conclusively proved me in the right. In houses of late Grapes much exposed to easterly winds, no front air was given, with the exception of at one end light, till June, and that in spite of the very hot weather we had in May. For two seasons previously mildew had shown itself all along the front of both houses. This year the only trace of it worth mentioning was where air had purposely been given with a view to testing my mildew theory. In that corner it started badly and spread rapidly, this happening soon after the bunches had been thinned out. The worst attack of mildew it has been my misfortune to contend with was distinctly traceable to a sudden opening of the front lights on a very bright day, the wind being in the east. A rush of cold air through the top ventilators will also bring mildew with it, the Vines on back walls sometimes showing traces of this.

The other extreme, or heat and stagnation, is undoubtedly most favourable to the spread of mildew when once it has effected a lodgment on the Vines, but it does not start it in the first place. By all means thoroughly cleanse the house, hot lime water being used in the case of walls, hot water and soft soap for the woodwork, removing all rubbish, loose soil, and such like from the beds, borders, or floors as the case may be. The rods, after pruning, should also be scrubbed with hot water, and then receive the usual dressing of Gishurst compound. Such preventive measures are wise, but they ought not to stop there. Attend more closely to the ventilation, giving a little top air extra early, gradually adding more as the

sun gains in power. It will then be found that there will always be a comfortable feeling in the house, no great quantity of air being necessarily put on at one time. So much can be done in the way of keeping the air genial by early and gradual ventilation, that it must be very hot indeed if there is any necessity to give front air in early and successional houses much before the berries are commencing to colour; while in the case of late vineries or any allowed to start naturally, no front air need be given till the time when easterly winds are not felt. Rather than open front lights in vineries or greenhouses containing Vines when easterly winds are blowing against them, I would sooner open doors at the sheltered ends. Once mildew is observed, the first remedial proceeding should be to thoroughly dredge the bunches on which it is seen and the rest near as well as the stem and leaves with flowers of sulphur. Mildew can make no headway against this, and a timely application, coupled with the maintenance of a good circulation of warm, dry air, will do much towards arresting the spread of the very insidious fungus. Much mildewed berries will hold the sulphur tenaciously, and may well be cut out when the bunch is required for use. The rest of the bunch can be cleared of sulphur by means of bellows or a tobacco powder distributor by way of substitute. Better still, either black or white Grapes may be cleared of powder or dust without prejudice to the bloom by being held under a tap and a force of clear water, a syringe answering the same purpose.—W. I.

APPLES KEEPING BADLY.

SOFT Apples, such as Duchess of Oldenburg, Keswick Codlin, Lord Suffield and Ecklinville, have kept or are keeping very badly indeed, and there is every prospect of Stirling Castle, Warner's King, Lord Derby, Lord Grosvenor and such like behaving very similarly. The tiniest hole caused by bird or insect leads to rapid decay directly the fruit is stored, while the sound fruits soon become spotted right through, this rendering them worthless. Owners of orchards are becoming nervous about their fruit, and instances have occurred where all the Apples, early and late alike, have been sold for cider making at the rate of 1s. per bushel of six pecks. As it happens, the later varieties are not maturing so rapidly as at one time thought most probable, and it may also prove that they will keep better than anticipated. Any way, care ought to be taken of all varieties that have the reputation of being good or fairly good keepers, and this whether the bulk is to be sold or kept for home consumption. Do not gather before the pips have changed to a light brown colour nor leave the fruit on the trees after they have so changed. Left too long on the trees the fruit does not keep so well when stored, and is also more liable to be blown down or otherwise bruised. On no account resort to the labour-saving, but bad plan of shaking down the fruit, and avoid bringing down too many from a tree at one time. Carefully sort over the fruit, throwing on one side for immediate use or cider-making all that are damaged in any way, as well as those which are small. In particular avoid mixing the varieties, as they vary greatly both in their keeping and cooking qualities. They must not be stored in very large heaps at first, as they are liable to heat and be quickly spoilt when stored so early, as they will have to be this season. After they have sweated and dried once or twice, there will be less likelihood of their heating unduly when placed in larger heaps, especially if stored in a cool, dark place. Warmth and air hasten ripening and also decay, and it will very probably be found that Apples will keep much the best in almost air-tight boxes, these being packed closely together or one above another in a cool dry room or shed. Judging from what has already taken place, it will be scarcely wise to pack direct into these boxes and store. After the fruit has sweated for a few days and before the heap becomes hot in the centre, each Apple should be wiped with a cloth and spread out for a few hours to become perfectly dry. A cer-

tain amount of moisture being thus got rid of, the fruit may safely be closely packed in paper or hay-lined boxes, finishing off with more paper and shutting the lid closely down on this. This plan is scarcely to be recommended for adoption on a large scale, as in this case proper cool storage quarters should be provided, but should commend itself to the owners of a few garden or orchard trees. Each box ought to be marked and so arranged that the worst keepers can be the first got at and used. They need not be examined if the precaution of storing none but perfectly sound fruit has been taken till November or later, and then very few, if any, decaying ones will require taking out, the hay, if used, also being changed, or it will become musty and taint the fruit. M. H.

Exquisite Peach.—Possibly it is because of its showy appearance that this Peach is grown; its flavour is about as bad as it well could be. This is my reason for just now calling attention to it, as anyone not acquainted with it would be apt to be led astray by seeing handsome fruits on the exhibition table.—Y. A. H.

Peach Walburton Admirable.—Although this Peach is said to be a bad bearer, yet during the past six or seven years with me it has not missed a crop. To bring out its high merits a warm season is needed, and this year has just suited it. It has ripened much earlier than usual. This is certainly an advantage, as no doubt this has much to do with its being of such high quality this season. People who only cultivate the comparatively early kinds have certainly missed a treat, as all late Peaches are this year exceptionally good.—Y. A. H.

The size of Vine borders.—Of late years there has been a considerable leaning towards forming small Vine borders, or at least smaller than they used to be. Although I do not wish to imply that such huge borders are necessary for the well-being of the Vines as was at one time considered requisite, yet I think there is too much of an inclination to go to the opposite extreme, and form the borders much too small, or at least too small to ensure the Vines producing good Grapes for a series of years. Vines with their rooting space limited to a width of 5 feet or 6 feet, and to the depth of 30 inches or thereabouts, require as much attention in watering and feeding as even pot Vines. To sustain Vines in good health for a series of years, each of the borders, inside and out, should not be less than 12 feet wide. With the soil placed in sections the roots do not ramble away, but form a complete mass of fibrous roots. I have noticed that the small borders which require watering so very often soon become sour; consequently after a time the root action becomes weakened and the Grapes shank.—A. Y.

Figs for forcing.—When visiting Syon House Gardens last year I was much struck with the health and fertility of the Figs grown by Mr. Wythes. His note on two good pot Figs for forcing on p. 168 is, therefore, deserving of special attention. I have not grown the varieties Mr. Wythes names either in pots or otherwise, but have no doubt they are all that he affirms of them. As he grows a good collection of sorts, a dozen or more, I should be glad of his next best from the older sorts, such as the Brown Turkey, White Marseilles, White, Blue, and Black Ischia, Hardy Prolific, and Early Violet for forcing in pots. I note especially this sentence in regard to St. John's and Pingo de Mel: "These varieties do not shed their first crop like many other kinds and swell up quickly." These are vitally important points, but are they not rather the outcome of careful culture than the result of constitution in Figs new or old? There may be a good deal in constitution, but as far as Fig dropping goes it is more the result of treatment. Further information would prove useful to many readers.—D. T. F.

Grape Mrs. Pince.—As this Grape succeeds well in these gardens, a short account of its behaviour this season may be of interest to those

cultivators who still retain a regard for it. Why it should have got into such bad repute I am at a loss to understand, for as regards its appearance it ranks amongst the handsomest Grapes in cultivation. In form it is second to none, while the flavour is superb, and what more is wanted in a late Grape? Colour is supposed to be its worst point, but with this I have no fault to find. Of course, it does not carry a heavy bloom, or if so it might rank in colour to well-grown Madresfield Court. I have seen it stated that to secure large bunches of this variety it requires to be grown on the long-spur system. The Vine growing here is pruned annually on the short-spur system, and I have no difficulty in annually securing bunches each from 5 lbs. to 7 lbs. in weight. This season there is no exception, the berries being large, well coloured, and as yet without the least sign of shrivelling. I consider it would be most unfortunate if this grand Grape should be elbowed out of cultivation. Like the Muscat of Alexandria, it must not be overcropped, and this probably is the reason of its downfall in many gardens.—A. YOUNG, *Abberley Hall.*

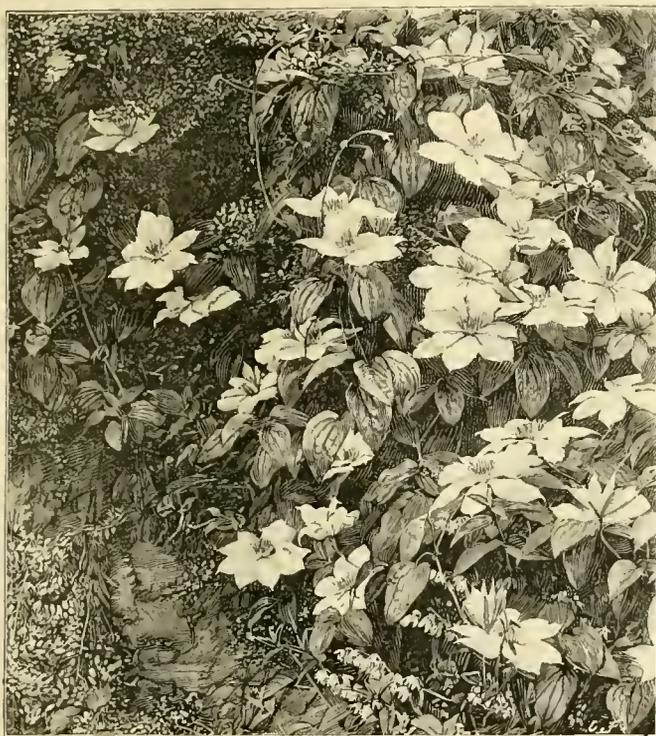

PROFITABLE GOOSEBERRIES.

WHEN at Messrs. Veitch's Langley Nurseries, Slough, a short time ago, I noticed a large number of Gooseberries trained as cordons. Cordons may often be planted in places where space could not be given to bush trees. The system of training two growths right and left at the base of a wall and allowing several upright growths to proceed from the base, is too well known to need description. I have in previous notes advocated this mode of culture for north walls to secure late fruit, and an excellent one it is, as by netting, nice fruit may be had for a considerable time after the fruit in the open is over. There is also another system of culture, namely, trellis training; this is an admirable system, and one specially adapted for gardens where the trees can be duly attended to in the way of pruning or spurring in. By growing trellis-trained trees there is a great saving of room, and more fruit can be grown in a small space with a greater certainty of a crop. When I say with more success I do so for various reasons, as how often has one to lament loss of crop through the ravages of birds when the trees are grown bush form; also the loss of fruit from caterpillar and red spider. These pests will attack trained trees as well, but cleansing is more readily performed. Where cordon or trellis-trained trees are grown, protection is an easy matter; whereas with bush trees netting is difficult. There is another system, viz., growing young trees in the open as single cordons. Having for several years noticed the grand growths of trees exhibited at the meetings of the R.H.S., I was interested in observing how these heavily-laden growths were obtained. At Langley, the trees, growing in heavy soil, subsoil clay, are trained to a strong stake, which is placed to them early in the year. These trees being grown for sale, a permanent support would be out of place, but when such fine fruit can be obtained at a trifling cost, I do not see why this system cannot be more widely carried out in private gardens when the cost is so small and the results so certain. When trellis-trained trees are grown, a quantity of stakes is not required, as if a few stakes support some three or four strong wires a fence is readily erected, and the cost of erection saved in a year or two by the quantity of fruit and the space gained for other crops, besides the great saving in protecting material. There is also another advantage with trees limited to a certain space, and that is size of berry, as these cordon trees give much finer fruit than bushes. Of course, some kinds do better than others, but so far as I have observed, most of the kinds thrive well so trained and give better results. Those who intend renewing their Gooseberry quarters during this autumn would do well to grow a few as cordons, and when a wall cannot be afforded late fruits, some of the better kinds grown as described would give a good return in a short time. G. WYTHES.

FLOWER GARDEN.

A HAPPY MARRIAGE.

SINCE Virgil's time there have been many happy marriages of the clinging twiner to its more stalwart support. Of such alliances the cut is yet one more example. *Clematis lanuginosa alba* has been allowed to ramble at its will through the deep green twigs of *Azara microphylla*, out of which the large white flowers shine like stars, forming a charming picture, a bit of double *Deutzia* below making a suitable finish to the whole. The *Azara* is a pretty evergreen wall shrub, having small polished leaves, and in spring it bears myriads of tiny inconspicuous yellow flowers, which possess a rich aromatic fragrance, especially in the evening. It is a native of

Clematis lanuginosa alba growing through *Azara microphylla*. Engraved for THE GARDEN from a photograph sent by Mr. Greenwood Pim, Dublin.

Chili. It grows freely in very heavy clay, and forms admirable green for cutting. The *Clematis*, as may be noticed, flowers profusely in the early season, and again, though less freely, in autumn. At this moment a tall branch of the *Azara* is crowded with its flowers.

G. P.

The white Aster Dahlia.—Too much cannot be said in praise of this little gem referred to by "A. D." (p. 188). The size, form and purity render it invaluable for room and table decoration. For weddings and funerals such Dahlias and a few other white flowers come in useful. The pointed petals make the flowers less Dahlia like than those of most others. Why so many should object to Dahlias for bouquets or other decorations as one of those freaks of fashion, it is not easy to understand.—D. T. F.

Carnation Countess of Paris.—In my case the best flowers of this variety were the very earliest and those appearing now, the cooler atmo-

sphere favouring this development. At what should have been the height of the flowering season the heat was too great, the flowers quickly taking on a faded appearance. This variety does not grow with me nearly so strongly as Mrs. Reynolds Hole, and the best results I have had follow from not removing the layers from the parent plant, this appearing to afford that support which it is evidently in need of. Very early layering and planting so as to become well established before winter might certainly overcome this difficulty.—A. YOUNG.

LILIUM SPECIOSUM ALBUM AT BALCOMBE.

THE old road from London to Brighton passes through Balcombe, and travellers who happen to pass that way may learn a fine lesson in Lily culture. A cottage garden is absolutely full of the above-named Lily, which grows, blooms, and in-

success, the very conditions under which they grow are astonishing, for there is a perfect canopy of leafage overhead in much of the garden. The occupier—I do not know if he is the owner—of the place is a tailor with plenty to do to look after his own profession. His two daughters do all the cutting, packing, &c., and generally attend to the whole thing except a little assistance for the actual manual labour. The origin of this Lily garden is one bulb, a gift from a friend some twenty years ago. For a time it was grown in a pot and regarded as a tender pot plant, but it increased and the stock grew till there were more Lilies than pots. To get rid of them, they were planted out to take care of themselves, and they soon manifested their happiness in freedom from restraint. Still, no special effort was made till nine years ago one of the two ladies that attend them conceived an idea of marketing the flowers, and finding it remunerative, the stock was increased. No bulbs have ever been bought, and they are lifted only when they become too thick. Owing to the drought, they are not more than about half their usual height, but I was assured that in most years they reach 6 feet or more, and as many as twenty-five flowers have been counted on a spike. I could see nothing special in the soil to favour the splendid growth of this Lily. It was of quite a medium character in consistence and apparent fertility. I have long thought that we do not make enough of Lilies in our gardens, and now that more attention is being rightly bestowed upon fine hardy plants, *Lilium speciosum*, the type, and its varieties are very important to the flower gardener who can use them well, and with them he can have fine colour, charming effects, and a sweet-scented garden through the autumn till the advent of sharp frosts.

A. H.

NOTES ON HARDY PLANTS.

Hedera minima.—This should not be confounded with *H. conglomerata*, though at a certain stage of growth there is some similarity. A three-year-old specimen, say, differs from the freer conglomerate form in that it grows more flat both as regards the twigs and the leaves on the twigs. It has more shining foliage of a deeper and more sombre green, with pleasing clouded tints, and further, as the name would suggest, it is a less plant in all its parts. It is a lovely creeper for positions on the rockery. It nestles sweetly in recesses, creeps over stone surfaces, and takes angles neatly. It is one of the best surface plants, as through it bulbs may spear their growth and flowers without mutual injury.

Cypripedium spectabile.—Not long ago in these columns someone took exception to what I said about this hardy Orchid being liable to hurt and hindrance from being blown over and broken at the thin junction of stem and rhizome. We have just had nearly a week of gales, and I wonder what my objector would say were my plants seen just now. They were a fair and comely group of about twenty plants in early summer and flowered well. Now the tops, many carrying seed-pods, in a yet green state are blown over and laid prostrate. These being the facts, may I not reasonably conclude that at least in some measure my plants are hurt and hindered? and as pretty well the same thing happens every year, and as I have given the most protected quarters I could to these plants, may I not justly include the cause of injury as one of the opposing conditions to general success with this plant as an open garden subject? Of course I am aware what can and should be done for the plant considered as a specialty, but it had been suggested that it needed only ordinary care or skill. I beg to repeat that, owing to the nature and form of the plant, in a wild state it is favoured and saved from being blown over by the herbage, &c., that naturally surrounds it, such as Grasses, Ferns, Polygonatums, &c., and it might not be amiss did we afford it in our gardens some such helpful neighbours. Nobody can deny that a full foliage plant like this if prematurely broken when the leaves are quite green must be robbed of much

creases in a wonderful manner. In addition to this it is a source of considerable profit, for the blooms are daily cut and marketed in London and Brighton, whilst not a few go as far as Scotland. The striking beauty and wonderful effect of a garden of one Lily no words can describe, but in this respect I saw it to advantage, for usually the flowers are all cut daily as fast as they expand, but in this unusual year a display generally of six weeks' duration will only last in full beauty about a fortnight. And yet with all the great display I saw, no less than 200 dozen flowers had that morning been cut and sent away. More than double this number has been cut in one day, and the quantity sent away in a week is enormous.

The Lilies are everywhere; the whole garden is full of them; and by far the greater part is shaded and overhung by large old spreading Apple trees. The Lilies are in long narrow beds 3 feet to 4 feet wide, four rows in each bed, with a very narrow alley between the beds. They are planted quite up to the stems of the Apple trees, and apparently not an inch of space is wasted. Apart from their

of its vigour for the following year, and I question whether we may not find other reasons for mingling with its roots other suitable plants. It is self-evident that in a position where the plant is liable to be broken down prematurely, it is equally liable to have its leaves prematurely browned, and this might be prevented by a growth of some such plants as Ferns of its own stature, *Linnaea borealis* or bog-loving Irises.

Primula Rusbyi.—According to my experience, this is one of the rarer Primulas, hard to kill and even more difficult to grow successfully. I am induced to pen this note from the rapid improvement of a specimen since I introduced it to full sunshine and a deep porous soil whose chief component is burnt clay. Under these conditions of soil, where the plant has never lacked moisture it has withstood the most powerful sunshine, and indeed, from the stoutness and glossy character of the foliage, must have revelled in it.

Trifolium alpinum.—When cleanly grown this is a lovely alpine plant, fit for the company of the choicest. One rarely sees it, however, on rockeries and more seldom still in perfect condition. It is a beloved morsel of slugs, and I think they form the chief enemy of the plant, because it is naturally vigorous and in no way fickle as to conditions of culture, but it is hard to keep slugs from it where they exist. A constant scratching of the soil about the plant with alternate sprinklings of silver sand has helped to save the plant.

Plumbago Larpentæ.—This is decidedly a shy bloomer, and I think the general cause is not far to seek. It is that our summers are not long or sunny enough. The present summer serves to help to such conclusion, and, besides, we have long known that in such places as Torquay and Bournemouth it does better than in colder districts with more rainfall and a lower register of sunshine. A very old plant here, that has sometimes shown clusters of buds in late summer that never opened, and that more often has never had any buds at all, is now likely to open its richly-coloured flowers in time to escape early frosts. In all cases it should have a warm position, dry as may be in winter, but not lacking plenty of moisture when growth has fairly begun.

Stobæa (Berkheya) purpurea.—Long as this curious and somewhat scarce herbaceous plant has flourished here, I had never until this morning noticed that its flowers were so agreeably perfumed. The smell, at least when several heads are fully out during sunshine, resembles new hay.

Veronica crispifolia, if it does not dazzle, at least interests many whose notice it attracts before scores of other more showy things. It is a decidedly distinct species, and, I think, a really rare plant. Some people might not care for it, but then there are but few plants that everybody falls in love with. If grown well it is beautiful and quaint. I have long guarded it in the hope that I shall some day have a damper or better watered garden in which to do it justice.

Campanula Zoysi.—This is another alpine gem that has responded to the present exceptional summer weather in a way highly satisfactory to the gardener. It is setting bulky capsules of seed for the first time to my knowledge for twelve years. We can do very well with the aid of seed to help us with the propagation of a plant that is not always a safe one to divide, and even then it is slow if all goes well. It has also flowered very freely this summer, some of the larger plants three times, making complete cauline growth from the radical leaves in each interval, so that this little plant had lived "fast" in the full measure of 1893 sunshine. J. Wood.

Woodville, Kirkstall.

Clematis Jackmanni in a mass.—In the garden here a round bed 14 feet across is planted with this Clematis. Every winter, when the plants die down, they receive a good dressing of manure. In spring, when growth begins, we place some

strong stakes in the centre of the bed, sloping them off gradually to the outside, keeping them the same shape as the bed, allowing them to be about 3 feet high in the centre and 6 inches in the front. Over these the shoots are trained as they grow, so that they do not get matted together. They quickly cover the whole, and for three months during the summer this bed is a glorious sight, contrasting finely with the Dahlias, &c., in the other beds.—J. Crook, *Forde Abbey*.

Tufted Pansy Bluebell.—I am pleased to agree with "A.'s" high estimate of the value of this fine old sort. There are few Pansies or other plants more effective in contrast with variegated Pelargoniums, variegated Grass, variegated Mesembryanthemum, or variegated Alyssum. Few tufted Pansies are more generally used than the Bluebell unless it be the mauve-coloured Mrs. Turner. Bluestone is another that was much used at one time and thought by not a few to be superior to Bluebell.—F.

Violets and the hot weather.—The present is not a very favourable time for Violets where growing in the open ground. Here we have them growing in the open quarter and have them mulched with rotten leaves and manure, damping them over every night, but yet they are affected with spider. Last year they had the same thing happen to them and at one time looked badly. At the end of August we commenced watering and damping them with weak manure water with the best results. As the autumn came on they made splendid growth, which induced me to leave them ten days or a fortnight longer in the open ground. When they were put under glass, they quickly lost the spider. Recently when looking over a garden at Freshford, near Bath, I saw a grand lot of de Parme growing in pots. These were stood in some long grass, which gave them natural shade and kept them cool.—J. C., *Forde Abbey*.

EAST LOTHIAN STOCKS.

I NOTICE "R. D.'s" seasonable and useful note on these (p. 153). It is impossible to over-estimate the value, the beauty, and fragrance of this fine strain of Stocks. For a good many years I have scarcely cared to grow any other. Brompton, Intermediate and Ten-week Stocks are poor and uncertain contrasted with good strains of the East Lothian. By sowing the East Lothian at different times it is possible to fill the season with Stocks through its use alone as well or better than by growing all the known sorts. For example, if anyone wants Stocks in plenty in the early spring he has only to make a sowing of the East Lothian in August. Prick out or pot up so soon as fit to handle, and remove under glass early in October. Place the plants in a temperature of 45° to 50° through the winter, and if fully exposed to the light, they will flower all through the spring. Before these spring-flowering batches are over, the earlier batches of East Lothian Stocks will begin to bloom under glass or in the open. It is also good practice to make three sowings of these Stocks in the spring—one in February, another in March, and a final one about the end of April in the open air. The two first should be pricked out into cold frames to be bedded out early in May. If the plants are sturdy and strong they will begin to bloom in July, and continue to do so in good soil and under liberal treatment until the frost cuts them down in December. Before this happens it is easy to pot up some of these Stocks. Kept moist and close for a few weeks and placed in a temperature of 50° or so, they will continue to bloom through the winter and prove invaluable for cutting. But a better plan to ensure a liberal supply of Stocks through the winter and very early spring is to grow the later sown plants specially for potting up about the end of September. Planted out in an open space at a distance of about a foot apart, kept clear of weeds, and rogued of all single varieties, unless, indeed, the single white is valued for bouquet work, which it mostly is, these plants will be

strong and bloom freely. Carefully potted and shaded for a few days, they will hardly look behind, and prove alike invaluable for cutting and furnishing. It may be prejudice, but I have never cared for the purple, and with such decided colours as crimson, scarlet, and white we hardly want it. There are very few plants that will yield such a rich harvest of beauty and fragrance out of doors or under glass as East Lothian Stocks. They enjoy a good deep soil, but in dripping seasons any excess of rich manure is apt to foster growth at the expense of bloom. Finally, it is wise to have a good stock of surplus plants in reserve until beds, groups or border of Stocks show flower. Where uniformity is desired, rogue out all the singles and replace with doubles so soon as they can be seen, and plant out the singles by themselves or pot them up for seeding under glass, the latter being the surest mode of maintaining and even heightening the high qualities of East Lothian Stocks. D. T. F.

FLOWERS AT THE ZOO.

ONE of the best places in London to see good summer flower gardening is at the Zoo, where Mr. Young, the head gardener, has produced many fine effects in colour without excessive use of carpet plants. Every arrangement is in a sense graceful, and both hardy and tender things are used. Opposite the saloon excellent contrasts are obtained with the Celosias, now so popular for bedding, and if not overdone they are remarkably striking, the feathery character of the inflorescence relieving otherwise flat surfaces. Early Chrysanthemums, such as Mme. Desgrange and its varieties, are planted freely, and this year they are blooming very early, due to the severe dryness of the summer. A Pelargonium which we noticed here is called Coustance; it is a pink coloured variety and very pleasing. One bed was composed of Pelargonium Fire King as a groundwork, relieved with Lobelia cardinalis and the variegated Abutilon Thomsoni. Here the herbaceous Lobelia is largely used, and the effect of its rich crimson-coloured flowers is remarkably brilliant. This year the plants are neither so tall nor so robust as usual, owing to the drought. A very fine bed is composed chiefly of Ageratum The Zoo, which was raised here, whilst the Sweet-scented Tobacco (*Nicotiana affinis*) is well used. Few plants are more charming than this which is in great beauty on cool, dull days and towards evening is at its best, the ivory-white flowers spreading their fragrance over a large area. The plants at the Zoo are not of the stereotyped order. There is variety, and things used which one does not often see in such places. A bed of Chinese Pinks was of more than ordinary interest, the strain representing flowers of varied colours, from pure white to bright crimson, and beautifully blotched at the base of the petals. It would add to the interest of gardens if such a fine assortment of hybrids as are in flower here were to be planted. One wants variety, not a repetition of common things. We are pleased to see that the herbaceous Phlox is planted in quantity and only the best varieties for colour. We have of late made notes of the best Phloxes, and they are of great service when a good selection is made, rejecting all magenta and washy shades, which quickly fade.

Another flower which we see to perfection is the Zinnia, which is very handsome when a good strain is obtained. The colours are striking and varied, and a well-planted bed is remarkably effective. The visitor to these gardens will see various schemes of colour, but the most striking is that facing the monkey house, where the beds are in splendid condition even at this late season and after a period of excessive drought. One bed is composed of Pelargonium Henry Jacoby, outside which is a line of Iresine Lindenii, then Lobelia Snowball, one of the best of all Lobelias, the flowers white and the plants remarkably compact. One seedling Lobelia raised here is very fine, the flowers being of the deepest possible blue and very striking against the

turf. A delightful edging was one composed of blue Lobelia and the variegated Dactylis. We do not remember to have seen the two plants associated together before, but the contrast of colour is certainly charming. A plant used to advantage and it might be more seen in other places, is Veronica Andersoni variegata, which has very brightly variegated leafage, and should be more often planted than at present. The centre of the bed is filled with Pelargonium Mrs. Holden, and the India-rubber Plant is used to break the surface, whilst in the same arrangement are the silvery Centaurea, the edging composed of Blue Stone Lobelia and the golden-leaved Fuchsia. A semi-double flowered Pelargonium of merit is Archduke Rudolph, which has carmine coloured flowers. As a rule double and semi-double varieties are a failure in the open, being more satisfactory under glass. Such well-known Ivy-leaved varieties as Mme. Crousse and Abel Carrière are well planted, but not to excess. A very beautiful bed is composed of principally that fine Begonia named Worthiana, which has scarlet flowers and of a rather drooping aspect, therefore throwing off rains better than the ordinary tuberous kinds. Begonias are very fine here, and some charming associations of colour are made with them, but the season has been somewhat unsatisfactory for this class, except B. Worthiana. Used with it in the present instance are the graceful Zea gracilis, its leafage beautifully variegated, and Acacia lophantha. Near the main entrance the narrow borders skirting the walk are filled respectively with tuberous Begonias and double white and crimson Stocks. It is such charming flowers as these that give pleasure.

WATER BOUQUETS.

I OBSERVED a note of inquiry respecting these curious and pretty objects recently. I think so far I alone have drawn attention to them, and they have been seen by me only at Basingstoke, where a former resident, Mr. H. Loe, showed the first example, and now several are constantly exhibited for prizes at the annual exhibition. Whilst all are set up under glass globes and on glass dishes, they vary more or less according to variety of flowers and foliage employed. A few varieties or colours and light single flowers seem to be best, although one recent bouquet had some pretty Tea Rose buds, with foliage and a few single yellow Marguerites intermixed. I should think small Japanese Chrysanthemums, especially singles intermixed with foliage, and a little Fern would do admirably. A glass shade for retaining the water should be at least 9 inches in diameter, and if 12 inches so much the better, as the bouquets can then be larger. The flowers should in no case be crowded, and must be kept well within the dimensions of the glass covering, or otherwise they will be distorted by contact with the glass. The shade should be stout and have a very even base. A glass dish of the same width in the centre with a raised margin is the best receptacle, although silver or china may be used, but it should be very flat and even, so that the base of the shade fits exactly. The flowers should have short stems, and of course be tied tightly, then be secured to some dead weight, such as a piece of lead or other metal covered with black cloth, so as to hide it from view. A large pan or tub is useful in which to stand the dish first, then on to that the bouquet, kept in position by the piece of metal, should be placed in the centre of the dish, and held by the hand whilst water is poured into the pan. As the water rises the bouquet will come erect and the pan may be filled up. The shade to be employed as the cover should be thoroughly cleaned, then be laid on its side in the water to fill, and then be gently brought over the bouquet, but so carefully that the body of water in it is retained. When erect and fitting close to the edge of the dish, the entire exhibit may be lifted out and allowed to dry on the outside. It is then ready for exhibition or for any room decoration. I do not know how long such a bouquet will keep fresh and sweet; that depends

materially presumably on the freshness of the water. The bouquets which I saw recently at Basingstoke had been carried in cabs nearly two miles, so that it is evident with ordinary care there is no difficulty in having them transmitted from home to shows. Of course they are heavy, and it may be for that reason perhaps that those of only moderate dimensions are shown. In one case the flowers were too loosely displayed, so that some touched the glass shade. In another they were far too hard-bunched. A. D.

FLOWER GARDEN NOTES.

THE chance that roots of Nicotiana affinis would have of coming safely through the winter (p. 217) would depend first of all on the severity of the weather, and still more on the particular position of the plants, rather than on any artificial protection in the way of mulching, unless this was put on very heavily. We had here a spell of exceptional cold for a short time, the thermometer for three successive nights dropping to within a few degrees of zero; the frost penetrated the ground to a great depth, and both the Sweet Tobacco and Galtonia candicans, although mulched with a 2-inch thickness of leaf soil, have failed to come through this year. On the other hand, what are known as hardy Fuchsias, such as gracilis, coccinea, globosa and Riccartoni, never receive protection in any shape or form and always come safely through the winter. Does Mr. Crook allude to these or to so-called bedding varieties? Hardy Fuchsias, especially coccinea and gracilis, although not at their best this year, hold their own in connection with other things as among the best groups to be found on large herbaceous borders. A very pleasing combination can be formed with either of the above named, flanked on either side with the white Japanese Anemone and faced with Aster acris or A. bessarabicus. If each of the three subjects forming the group be planted in sufficient quantity to furnish a bold display of flower, the effect will be very pleasing. Several of the early-flowering Starworts blend well with these hardy Fuchsias, and such an association is, I think, preferable to grouping them with the summer Chrysanthemums, as although a fine bank of flower is thereby obtained, the general effect is rather flat and table-like. If there is facility for a good preparation of the soil, a few plants of Constance, Henry Patrick, or A. W. Tait Dahlias may be worked slightly in the background between the clumps of Fuchsia. Whilst on the subject of Dahlias I may note that some of them will be found exceedingly effective in large beds that are partially devoted to small conifers. Thus one of our best beds at the present time consists of seven plants of Retinospora plumosa filled in with Guiding Star and Martial pompon Dahlias in alternate plants. The flowers of the Dahlias thrown well above their own foliage show to great advantage against the rich green of the Retinospora.

The practice of heading back Pyrethrum uliginosum and some of the Phloxes to curtail the height of the one, and to extend the flowering season of the other, was not adopted this year, and present circumstances show it would have been of little use. The natural height of the Pyrethrum is not much over 3 feet, whilst the back or later growth of the Phloxes that in favourable seasons gives a nice bit of flower was prematurely withered. Chrysanthemum maximum and Rudbeckia Newmanii are flowering at the height of 1 foot. The flower-stalks of the former were earlier in the season a mass of black aphid, necessitating a free use of insecticide. Pyrethrum, as may be supposed, have utterly failed to furnish a second supply of flowers. They may generally be relied on to give quite a nice display at this season, and were duly headed back for that purpose after the first flowering, but the desired effect was not produced. We have plenty of flowers from the double white Yarrow, also Achillea rosea, showing that these are good any-weather plants.

This has been emphatically a Carnation week, the general planting of layers of border varieties

being carried on with vigour and despatch, although had I known the promise of rain would have come to nothing, and instead thereof the dry time with a powerful sun would have continued, the operation would have been postponed until later in the month. All newly-planted stuff must necessarily suffer from the influence of a powerful sun, and although well rooted layers will hold their own, those that are not over-well provided in that way will have to be mulched and watered. Why there should be such a marked difference in varieties as to the length of time necessary to produce a thoroughly well rooted layer is a mystery, but I think it must be attributed to the constitution of the grass, a somewhat tough, wiry shoot being longer doing its work, and *vice versa*. That the difference does exist in a marked manner is an undoubted fact. This season, for instance, anxious to secure good stuff of Countess of Paris at an early date, I started the layering with this variety, but they are nothing like such good plants at the present date (September 8) as others, notably Raby, Murillo, and Mrs. R. Hole, that were not put down until more than a fortnight later. One is always sure of the Clove section; the grass is fleshy and succulent, and roots are emitted quickly and with great freedom. The value of Stocks as dry-weather plants was the subject of comment in a recent note, and I saw the other day ample corroboration of the same in the shape of a splendid batch of the East Lothian. They were in about as dry a position as could well be imagined, and had not made very robust growth, but were flowering with great freedom, and had evidently been a long time in bloom. The strain was an exceptionally good one, the trusses, considering the season, being of large size, of a clear pure white, and the percentage of singles very small. Although somewhat late for sowing, I lost no time in securing a good pinch of seed with the view of utilising the variety rather largely in the season of 1894. Complaints are rife as to great losses among Polyanthus; indeed, where they are quite out in the open, fully exposed to the sun, many are literally scorched up; these quarters will have to be made up by-and-by with seedlings from a north border. The different members of this make such a brave show, and are withal so valuable for cutting, that no garden is complete without at least a few representatives from each section. E. BURRELL.

Claremont.

Tuberous Begonias in the open.—The tuberous Begonia is not so fine this year as last, and the reason is that the protracted drought has proved too much for it. A cool and moist season suits the plants best; then they are superb and give colour to the garden until frosts occur. The greatest failure has been with the double kinds, which are never so satisfactory as the singles; at least, we mean the big-flowered doubles, which seem to lose character after the first blooms have perished. There is, however, a very distinct class of doubles that are well worth planting freely, and more of a semi-double character, the flowers much smaller than those of the purely florists' type. As yet these kinds are somewhat expensive, but will get cheaper. One named Mme. Courtois is delightful. Like the others in this group, the plant is neat in growth, dwarf, and the flowers pale yellow, whilst a free display is made throughout the season. The colours are extensive in this group, ranging from crimson to white.

A note on the London parks.—The London parks look extremely gay even at this late season and after the long drought. We are pleased to see that the rigid style of bedding is fast departing, and a greater variety of things used than was the case a few years ago. In Battersea Park several large beds heretofore filled with zonal Pelargoniums are now planted with tufted Pansies and Antirrhinums mixed and in distinct colours. This is a welcome change, as both these flowers last in beauty throughout the summer, and a few days ago seemed likely to keep up a display until the time of frosts. Fuchsias are very beautiful in the majority of the parks, particularly in Hyde

Park, where they are used freely in the beds and also grouped on the turf. Many fine things are to be seen here, splendid specimens of *Eucalyptus globulus*, the *Plumbago*, *Heliotropes* and *Coral Tree*. In Ravenscourt Park, on the boundary of Hammersmith, much has been done with hardy and alpine flowers. *Campanulas* of many kinds and other things are grouped naturally, and the rockery is not a burlesque of its name. The herbaceous *Lobelias*, although comparatively poor this year, are very showy. For bedding few plants are more useful in late summer.

Cactus Dahlias.—There is a material development in the right direction so far as the Cactus section is concerned, and indeed we have of these some now so charming, that to surpass them seems difficult. But whilst all remember the beautiful scarlet *Juarez* as the first and best type of Cactus Dahlias, we have in some of the newer varieties retained that form and in others so far departed from it, that whilst the petals are pointed, some are fluted, some are incurved, and in various ways presenting divergences from the early form, yet retaining the true Cactus style in the most pleasing way. It seems hardly probable after the present year that any grower setting up a dozen bunches of these Dahlias will henceforth include any of the coarse flat-petalled varieties, but will only exhibit true Cactus varieties. A distinct addition to this section is *Keynes*, *Williams and Co.*'s beautiful straw-yellow *Lady Penzance*. The lovely mauve and white *Delicata* has been shown in remarkably fine form this season, so also has *Countess of Gosford*, reddish salmon, yellow centre, *Countess of Radnor*, *Sir Roger*, bright salmon-carmine; *Robert Cannell*, one of the very best; *Ernest Cannell*, *Bertha Mawley*, vermilion, shaded violet; *Duchess of York*, rich orange-red; *Chancellor*, new, deep magenta, shaded violet; *Beauty of Arundel*, and the old *Juarez*, form a dozen of the very best. What two or three years may bring forth has to be shown, but there can be no doubt that very soon we shall see these Cactus Dahlias so varied and beautiful, that everybody will grow them.—A. D.

STOVE AND GREENHOUSE.

SWEET-SCENTED PELARGONIUMS.

A LARGE group of these plants is rarely seen now. Mr. Hudson, of *Gunnorsbury House*, at the late show at *Earl's Court* staged a dozen of these Cape Pelargoniums in very fine condition and of large size, the plant of *P. radula majus* being a perfect specimen, though there were others equally good. I name this as I have never seen it finer. The variety named above is most useful for cutting, as it is a free grower. *Capitatum* is also good; this is rose-scented, and was a picture of health and nearly 6 feet through. *Fragrans*, a nutmeg-scented variety, is also a free grower and good for cutting. This is also attractive on account of its mass of white blooms, the flowers having red lines on the upper petals. There are others equally useful for cutting, such as *Fair Ellen* and *Prince of Orange*. A very fine plant of *quercifolium* was staged; this has purple flowers, and is much esteemed for its strongly-scented leaves, the centre of which is black, the margins wavy and of a beautiful green. *Quercifolium minus*, a variety much resembling the last-named, but with finer cut foliage, was also staged in fine condition. *Lady Heytesbury*, with reddish-coloured blooms, *Pretty Polly*, a dwarf, bushy, almond-scented form with large leaves, and *Rollissor's Unique*, a free-growing variety, were also shown correspondingly large. *Denticulatum*, with lilac or rose-purple flowers, was very beautiful and of large size; this is a small-leaved, deeply-cut variety. *Lady Plymouth*, a variegated sweet-scented form, was also beautiful, and though not so free a grower as some, it should be in all collections. A variety called *Pheasant's-foot* was very fine

this is a most desirable variety, having beautifully cut foliage and most fragrant. It is one of the best for bouquet work, and sometimes is grown under the name of *denticulatum*. One of the finest plants staged was *P. filicifolium odoratissimum*—a grand specimen. This variety possesses a peculiar scent and has very finely-cut foliage. At times its fragrance is overpowering, and the foliage being of a gummy nature it soon gets dirty if not well grown. Mr. Hudson also grows other varieties than the above. Of course, such large plants are of a good age, as it is impossible to get size if hard cutting is resorted to. Many of the plants staged had done good service as decorative plants during the season in town, thus pointing out their utility not only for cutting, but for decorative effect. It would be of great benefit to the readers of THE GARDEN if Mr. Hudson would give a few notes as to culture of some of what I term miffy kinds, as all thrive equally well under his treatment. Now is a good time to start with these plants, as cuttings struck now will lay the foundation for the next season. I would point out the importance of careful watering and not over-potting, as these Cape plants soon get a bad colour if over-watered or over-potted. I cannot conclude this note without referring to Mr. Hudson's fan-trained plants. He had specimens of *radula* and others trained on a flat trellis 5 feet to 6 feet high and quite 8 feet at base, thus showing what can be done with these plants. When trained in this way they form a screen and are admirable for rooms and other purposes. Of course, the freer-growing kinds must be selected for this purpose, and in this case they are not in extra large pots. In addition to the group mentioned above, two groups were staged at the R.H.S. Islington show, including the fan-trained plants, and I question if any group in the Agricultural Hall attracted so much attention.—G. WYTHES.

— Two or three times last season Mr. Hudson, of *Gunnorsbury*, exhibited a number of specimen plants of different scented-leaved Pelargoniums that, from the fact that they are now-a-days so seldom seen, attracted a considerable amount of attention. That the interest in them has by no means passed away was shown at the Agricultural Hall, where Mr. Hudson exhibited a collection of twenty varieties, as well as some large trained specimens. Considering that there was no display of showy blossoms to attract notice to these old-fashioned subjects, they found many admirers, some of whom, at all events, were surprised to see so many forms. The twenty plants were grown as bushes, some larger than others, but all well furnished with healthy foliage. The different forms composing the groups were as follows: *capitatum*, *radula*, *quercifolium*, *denticulatum*, *Pheasant's-foot*, *Scarlet Unique*, *Purple Unique*, *denticulatum majus*, *fragrans*, *quercifolium minus*, *Pretty Polly*, *Shottesham Pet*, *Lady Heytesbury*, *Little Gem*, *Fair Helen*, *tomentosum*, *Major Clarke*, *crispum*, *Prince of Orange*, and *Lady Plymouth*—this last a variegated-leaved variety, which when first sent out, now many years ago, was thought very highly of and for a time was in great demand.—H. P.

Ixora macrothyrsa.—This splendid type was recently in bloom in the *Victoria Regia* house at *Kew*. It is remarkably showy, and produces large heads of brilliant orange-scarlet flowers. Unfortunately, the present craze for *Orchids* has overshadowed many beautiful stove plants.

Lotus Jacobæus.—This at all events possesses the merit of distinctness, for there is nothing else with which it can be confounded in our gardens. It forms a much-branched, but slender-growing plant, with hoary foliage and a profusion of Pea-shaped blossoms of a deep purple colour, almost black. If seeds are sown in the spring they will yield plants that flower well in the summer and early autumn months, either planted out in a warm border or grown in pots for the greenhouse. When plants are raised from seed the progeny shows a certain amount of variation, some being a good deal superior to others. In the best forms the

blooms are of a rich velvety hue, but in some seedlings the flowers are tinged with green, and are not nearly so effective. Cuttings strike root readily, and this is the best way of increasing the deep-coloured forms. The cuttings should be taken in the spring, as treated in this way they flower well the same season. The *Lotus* in question is a native of the *Cape de Verd Islands*, and has been long grown in this country.—H. P.

Griffinia hyacinthina is one of those fine stove plants so little seen in gardens. A very beautiful form of it is in bloom in the stove at *Kew*, one of the richest in colour that we have seen, the flowers very deep purple-blue and borne in a large head. It is strange that such a charming species should be neglected when its flowers are not only large, but produced with freedom and of a delightful colour. It was introduced as long ago as 1815 from South America, and belongs to the *Amaryllis* family, requiring similar treatment. A coloured plate of this was given in THE GARDEN of October 26, 1889.

Lagerstroemia indica.—A specimen of this charming greenhouse shrub just received reminds one what beautiful subjects there are once popular that are now scarcely ever seen. Among such must be included this *Lagerstroemia*, or *Crape Myrtle*, as it is sometimes called, which is just now, where it has been at all favourably treated, flowering with great freedom. It forms a freely-branched shrub that reaches a height of 6 feet to 10 feet, and is clothed with ovate leaves of a deep shining green, which are in general appearance a good deal like those of a *Myrtle*. The flowers, which are borne in large terminal panicles, are of a rich bright pink, with the petals crimped in a very pleasing manner. As a great many flowers are open on a panicle at the same time and are disposed in a somewhat irregular fashion, each cluster of blossoms presents the appearance of a mass of beautifully crisped petals, quite unlike anything else we have in our gardens. The flowers, however, quickly drop. Despite its name, *L. indica* is said to be a native of China, from whence it was introduced in 1816. It will do well planted out in a warm, sunny part of the conservatory, or it may be kept in large pots or tubs, as is often done in the case of *Camellias*. The cultural requirements of the *Crape Myrtle* are by no means exacting, the principal point being to guard against over-watering during the winter, as the object is to ripen the wood as thoroughly as possible in order to ensure the following season's display of bloom. Propagation is easily effected by means of cuttings, which if not too vigorous strike root readily if taken during the summer months.—H. P.

Zonal Pelargonium Mrs. Wright. which we noticed recently in bloom in the nursery of Mr. H. J. Jones, *Hither Green*, *Lewisham*, represents a very distinct break in colour. It approaches more closely a bluish shade than any variety known to us, but this is no special recommendation, although the colour is remarkably bright. It is strictly a magenta shade, and may please those who require a new, distinct and very striking flower. As regards other points, the plants are strong in growth, free, and bear large trusses, the individual blooms of good size and shape. We hope that, because this magenta-coloured variety is in a sense pleasing, we shall not be inundated with varieties of a dull and objectionable magenta tone.

Anthurium Dechardi (H. Buxton).—This is the name of the plant you send me a spathe of. I am not surprised that you have not seen it flower for these two years. In the first place, your plant may not have been strong enough to bloom, and then again, although it makes a fine specimen, it is not so very free-flowering as some of the species. The spathes are white in front, tinged with green behind. There are several white spathed *Anthuriums* which are well deserving attention, *A. ornatum* and *A. Laingi* being amongst the best.—W. H. G.

An improved Rose of Castile Fuchsia.—“D.” says the flowers of this are larger, growth more robust, and wonderfully free to flower. The first

large flowers may or may not be an advantage, but as to the other two, as I have grown the Rose of Castile from 6 feet to 9 feet high, its growing powers are ample for most; and as far more free flowering plants have been shown again and again on which the leaves were mostly hidden by the blooms, it is difficult to see how the improved Rose of Castile can be more free-flowering than the old one.—D. T. F.

Hoya carnosa.—A short note recently in THE GARDEN on the value of this plant as grown in a pot prompts me to say that for covering the back wall of a late viney where but little else will grow this Hoya is a capital subject. Plenty of drainage and a compost consisting mainly of rough peat with abundance of water, both at the roots and overhead during the growing season in spring, will induce the production of shoots 3 feet to 6 feet long in one year, to be followed by numerous trusses of the sweetly perfumed blossoms.—E. M.

SHORT NOTES.—STOVE AND GREENHOUSE.

Stigmaphyllon ciliatum (*G. Maxwell*).—The flowers of this plant resemble those of an Orchid very much. It is a very fine stove climber and also a very free bloomer, the flowers being of a rich orange-yellow. It should be potted or planted out in a mixture of loam, peat and leaf-mould made sandy.—W. H. G.

Campanula pyramidalis.—At Laxenburg we used to plant out the *Campanula pyramidalis* the second year and put them in their flowering pots in autumn in order to get strong plants to flower the third year. In mountainous parts of Austria I found this *Campanula* in places where hardly any other plant could exist. No soil was to be seen—only small pieces of stones.—L. KROPATSCH, Vienna.

Curious growth of a Gloxinia.—I send you a photograph of a *Gloxinia* which seems to me peculiar in its mode of flowering, four flowers being borne on a whorl instead of each stalk bearing one or two flowers, as is generally the case. It is the only plant flowering in this way out of a large packet of seed sown at Coombe House, Copplestone, the residence of Mr. J. Macpherson.—Mrs. A. M. BARTON.

TREES AND SHRUBS.

THE PINK BROOM OF NEW ZEALAND.

(*NOTOSPARTIUM CARMICHAELIÆ*.)

THERE are a few shrubs natives of New Zealand that may be considered hardy in this country, at all events in the southern portion, among them being some of the *Veronicas*, *Olearia Ilaesti*, and the pretty and distinct subject here illustrated, *Notospartium Carmichaeliæ*, known as the pink Broom. As indicated by the popular name, this is a good deal like some of the Brooms, having green, leafless branches disposed in a very graceful manner, and, as a rule, about the end of June the flowers are produced. They are Pea-shaped, small, of a bright rosy pink colour, and borne in dense crowded clusters towards the points of the shoots. Though it cannot even when in flower be regarded as a showy shrub, yet it is both pretty and interesting, and the graceful manner in which the branches are disposed renders it at all seasons a very attractive object. As a shrub for the bolder arrangement of rock-work it has been before now recommended in THE GARDEN, and in such a position its graceful habit will be seen to great advantage. It is said to be one of the most beautiful plants of New Zealand, and to sometimes attain there the height of 20 feet, but it is herein spoken of as a shrub, for such it must be regarded in this country, and one that when but a few feet high

will flower with the greatest profusion. The *Notospartium* is one of the few New Zealand Leguminosæ, for, singularly enough, though this order is largely represented among Australian trees and shrubs, the New Zealand members of it are very limited. This last is one of the many features of resemblance between the flora of the temperate portion of South America and that of the New Zealand Islands. *Notospartium Carmichaeliæ* was introduced by Messrs. Veitch, and a first-class certificate was awarded it by the Royal Horticultural Society in July, 1883. It is now pretty well known to lovers of out-of-the-way plants, but is not in general cultivation, certainly not so much as it might be, for, apart from its grace and beauty, it is by no means an expensive plant. This shrub has proved to be hardy with Messrs. Veitch on the exposed slopes of Coombe Wood,

Notospartium Carmichaeliæ. Engraved for THE GARDEN from a photograph of a plant in Messrs. Veitch's nursery at Exeter.

and the plant, part of which is here illustrated, flowered freely in the rock garden of the Messrs. Veitch at Exeter. T.

The double Deutzia.—In the valuable article in THE GARDEN upon *Deutzias* (p. 181) it is stated there are two varieties of this *Deutzia*, one in which the flowers are pure white, and the other with the outside of the blossoms tinged with pink. This may be so, and most of us have seen or grown the improved double white *D. candidissima* or *Pride of Rochester*; but I, and possibly other growers, have had pure white and purple-tinged flowers from the same plant. My first stock of this most useful late, good staying *Deutzia* was planted in very sunny quarters, and as they were grown to add to the supply of white flowers, it was a great disappointment to find the blooms so largely suffused with pink, with a suspicion towards purple. Part of the stock was moved on to a shady border, and they, as well as the cuttings struck alike from those in the shade and in the

sun and grown in the shade, all bloomed as white as *D. candidissima* ever afterwards. This remedy was suggested years before by the different conduct of the white *Spiræa acerifolia* in sunshine and shade. In the former it is dirty white, which renders its extremely graceful bloom almost useless for decoration. Grown in the shade it is as white as driven snow and has no rival for decoration. *D. parviflora* promises to prove a welcome addition to the genus and to form a charming contrast to *D. gracilis*.—D. T. F.

Leycesteria formosa.—I recently came across a bush of this *Leycesteria* on an exposed part of the Surrey hills, and very beautiful it was, being profusely laden with blossoms; while more particularly noticeable was the fact that the large reddish purple bracts, which really form the showiest part of the inflorescence, were a good deal brighter coloured than usual, thus more nearly approaching the descriptions given by travellers who have made the acquaintance of this distinct shrub in its Himalayan home. It is certainly a very ornamental shrub, which deserves better treatment than is usually bestowed upon it, for this *Leycesteria* is generally seen crammed into some shrubby border, where it has one continual struggle for existence. Given a position clear of stronger-growing subjects, a good open soil that is not parched up at any time, and exposure to full sunshine, it will form a specimen whose merits must on no account be passed over.—T.

Cut-leaved Bramble.—Many members of the genus *Rubus* are very ornamental, and at the same time widely dissimilar from each other; for instance, we have the Rocky Mountain *R. deliciosus*, an unnamed shrub, different members of the Raspberry section, such as *R. spectabilis*, *R. odoratus*, and *R. nutkanus*, while of the Bramble proper one of the most ornamental is the cut-leaved form known as *R. laciniatus*. This is a vigorous growing plant that should be limited to the wild garden, or at all events so situated that it cannot encroach on weaker neighbours. When allowed to grow at will it forms a dense tangled mass, clothed with very ornamental foliage, which is cut in a pleasing manner. The fruits, too, are large and of good flavour, and in this country at least they are pretty generally considered superior to the American varieties. While on the subject of Brambles a word may well be spared at this season for the double pink-flowered form, which is very ornamental when in bloom, that happening at a time when very few outdoor shrubs are in flower, while it will yield satisfactory results even where the soil is hot and dry.—T.

THE SECOND BLOOMING OF WISTARIA SINENSIS.

"W. S. H." refers to his fine old plant of this about seventy years of age as blooming profusely the second time if the first bloom is poor, and *vice versa*. "If it fails to flower freely in May I get a heavy bloom in July from the young wood" (p. 182). No doubt this is so, especially with old plants. Few plants are more free-flowering than this hardiest and most showy of our hardy climbers. Hence old plants especially smothered with bloom in May may have little life and strength left to grow or bloom much again through July or August. On the contrary, when the frost kills the raceme of blooms in embryo in April, plants thus lightened of their legitimate burdens make up for this relief by flowering more freely on the young wood later on.

But all this fails to do justice to the double flowering qualities of the *Wistaria*. This, in fact, is natural to it in our climate under liberal culture and free-and-easy training. I have grown and rooted many fine *Wistarias* old and young, and have seldom seen them fail to bloom twice. Under ordinary conditions the

first bloom is by far the most plentiful, though, failing that, the second may prove the more numerous, as noted by "W. S. H." In nearly all cases, however, the second blooms are in longer racemes, and are more graceful in their vernal setting of leaves and branchlets. In order to develop the second blooming to the uttermost it is of the utmost importance to leave all the summer growths severely alone. Every strong growing shoot cut off the *Wistaria* in summer also means the removal of possible blossoms in embryo. Any pruning necessary to limit the area of this free growing plant should be given in winter or early spring. Two things strike observers as singular in reference to *Wistarias*. The first is that none of the species or varieties, notably the double, the white, and the form with bright silvery variegated leaves, has made much headway in gardens. The next is that, hardy and free flowering as *Wistarias* are, they are seldom used as standards or for the clothing of arches or arbours, though they are admirably adapted for either purpose in warm situations. One thing more should be noted: the older the plants the more free flowering. In this respect they somewhat resemble some of our best Figs. Close to where I write there are two Brown Turkey Figs, of unknown ages, which have ripened two crops a year for over sixty years. And I challenge any reader of THE GARDEN to say if he ever knew a *Wistaria sinensis* too old to flower freely.

D. T. F.

SHRUBS FOR FORCING.

THERE are two very different ways of treating shrubs that are intended for forcing prematurely into bloom; firstly, lifting them from the open ground in the autumn and at once potting them; and secondly, keeping them altogether confined in pots, and forcing them year after year. Where this latter method is practised, it must be borne in mind that after the display of flowers is past the plants need just as much care in their treatment as before, that is, they should after blooming be protected in such a way that the tender foliage will not be injured by cold, cutting winds or spring frosts, and after all danger is over the plants should be plunged out of doors in a spot fully exposed to the sun. They must throughout the summer receive every attention in the matter of water, and an occasional dose of some stimulant will be of service. Where a few shrubs are grown in this way for forcing, and others that may be required are lifted from the open ground and potted, the established plants should be employed for the earliest batches, and those just lifted for the later ones, as in their case much less forcing will be required. As a rule, the blooms on plants that are established in pots retain their beauty for a longer period than those just potted. Hot sunny weather towards the end of the summer and early autumn is very favourable to the ripening of the wood and consequent formation of flower-buds, and such being the case, it is more than probable that forced shrubs will as a rule prove very satisfactory during the forthcoming season. Early potting should as far as possible be followed in the case of plants lifted from the open ground and intended for forcing, as by so doing the roots will take possession to a certain extent of the new soil before they are required to be taken indoors. Thus a good general plan, wherever it can be followed out, is to pot the shrubs intended for forcing as soon as possible after the leaves have fallen. In order to encourage the formation of roots as much as possible

they should be watered when necessary, and if the pots are plunged in a bed of leaf-mould, cocoa-nut refuse, or something in that way, it serves to maintain the soil in an even state of moisture, and also protects from frost. With regard to the different shrubs available for forcing, there are now a great many more kinds than was the case a few years ago. Lilacs, Azaleas, Deutzias, Rhododendrons, Kalmias, Cherries, Plums, Peaches, Almonds, Thorns, *Staphylea colchica* and *Hydrangea paniculata grandiflora* are largely grown for the purpose, but besides these there are the *Laburnum*, some of the *Weigelas*, *Spiraea confusa*, *S. Thunbergi*, the *Guelder Rose*, *Forsythia suspensa*, *F. viridissima*, *Daphne Genkwa*, *Styrax japonica*, *Xanthoceras sorbifolia*, *Chionanthus virginicus*, *C. rectus*, *Berberis stenophylla*, *Choisya ternata*, *Cydonia Maulei*, *Magnolias*, *Zenobia speciosa* and its variety *pulverulenta*, *Cytisus Andreanus*, and others. T.

Weigela Eva Rathke.—If it is as continuous blooming under any conditions as the specimens shown by Mr. Waterer at the Agricultural Hall show would lead one to imagine, this will be a very valuable flowering shrub and must become one of the most popular of the *Weigelas*. The flowers of this variety are of a deep, but bright red, and the specimens shown were as fresh as if it was the end of May rather than that of August. To have *Weigelas* that can be depended upon to bloom at the end of the summer will be a new departure, but at the same time I have observed many of the ordinary forms this season producing a fair secondary crop of blossoms, that is, where the plants have not suffered from the drought. The most continuous blooming of the *Weigelas* that I have observed up to the present is the white *Weigela candida*, a rather erect-growing form, with longer and more Willow-like leaves than any of the others; but, as far as can be determined by a few cut specimens, the newer variety leaves that far behind.—T.

Vitex Agnus-castus.—Unless in especially favoured districts, this is only seen as a wall shrub, and even then it seldom flowers as it is doing this season, for in some cases every shoot is terminated by its spike-like panicle of blossoms. It is in warm light soils rather a free-growing shrub, clothed with digitate leaves, hoary beneath, and imparting to the entire plant a somewhat greyish appearance. The stiff-growing panicles of blossoms are made up of several whorls, the individual blooms being small and of a bluish white tint, so that they are by no means showy; but when borne in such profusion as I have seen them this year, they present a pretty and uncommon appearance. This *Vitex* is a native of a considerable district along the south of Europe and north of Africa, and has, according to Loudon, been known in this country for over 300 years.—T.

Clerodendron trichotomum, recently in bloom in the Coombe Wood nursery of Messrs. J. Veitch and Sons, is an interesting shrub, being in beauty at a season of the year when few kinds are in flower. The growth is very free, and it will succeed well in the open in not too exposed spots where the soil is moderately light. It attains several feet in height and bears a profusion of creamy-white flowers, of which the calyces are purplish red, whilst they are also sweetly scented.

Cratægus coccinea.—There are not many seasons in which the berries of the scarlet fruited Thorn are as brightly coloured as they are this year, nor borne in as great profusion. So numerous are they, that in many individuals the entire tree is quite a scarlet mass, and they then form one of the most conspicuous features in the woodlands, or a single specimen of this Thorn on a lawn will enable its various ornamental features to be seen to the best advantage. The scarlet fruited Thorn forms a vigorous-growing tree that reaches a

height of 20 feet or thereabouts, and is amply furnished with large, bright green, shining foliage. The fact that it does not bloom till the numerous varieties of the common Hawthorn are over is another point in its favour, as by this and a few others, principally North American kinds, the Thorn season is considerably extended. *C. coccinea* flowers about the end of May, and the large flattened corymbs of white blossoms are then very showy, while the autumn display is not limited to the bright coloured fruit, as before the leaves drop they become richly suffused with yellow, with occasionally a flush of scarlet. It is readily increased by seeds, and owing to this circumstance and to its wide distribution there are numerous varieties now in cultivation. Though introduced a couple of centuries ago, its merits are often passed over in favour of greatly inferior subjects.—T.

Clerodendron foetidum.—The hot weather we have experienced during the present season seems to have suited this *Clerodendron*, as it is flowering freely, and I noted some good examples of it in a cut state at the recent exhibition of the Royal Horticultural Society held at the Agricultural Hall. Though one of Fortune's introductions and thoroughly hardy in the warmer parts of the country, it is quite an uncommon plant. Still, when flowering freely it must certainly have a place assigned it as one of the most attractive flowers of the present season. Unlike the commonly cultivated members of the genus, the stems of this are only of annual duration, but of a stout, sturdy nature, and reach a height of 4 feet to 5 feet. The large heart-shaped leaves are very ornamental, while the flowers are borne in large closely packed terminal heads, and make a goodly show. They are of a bright rosy red tint, deeper in the bud state than they are after expansion. This *Clerodendron* succeeds best in a fairly moist spot, and when in a flourishing state will quickly spread underground. The specific name of foetidum is derived from the unpleasant smell given off by the entire plant if roughly handled or bruised in any way. It is also known as *Clerodendron Bungei*, and is a native of Northern China. The only other hardy species, *C. trichotomum*, is altogether a better known plant than the other, and is now generally to be met with in any collection of flowering shrubs. The fact that it does not, as a rule, bloom till the autumn is a point in its favour. This *Clerodendron* will under favourable conditions attain the dimensions of a large bush or small tree, and when in full flower is very ornamental. The flowers of this are white, and protrude from large red calyces after the manner of some of the indoor kinds, while the blooms of *C. foetidum*, both in their appearance and arrangement, are more like those of an *Ixora*.—H. P.

ROSE GARDEN.

POT CULTURE OF THE ROSE.

IT is when the cold, frosty nights of October and November set in that well-developed Roses are esteemed, and even more so in the early spring months. Amateurs and others who make a specialty of Roses always have their plants before them, and whenever there is a press of garden work demanding attention other things may suffer, but the Roses never. My own experience with general gardening has been that gardeners are apt to allow their pot Roses to be neglected during the summer months. Mildew, green-fly, and red spider get upon the leaves, and the time required to keep them clean is not easy to be found. In a season such as we have passed through in the south of England and in gardens where no additional hands have been found to do the work, gardeners have been at their wits' end to keep their plants and flowers in passable condition. Everything has required water,

and water has not been always obtainable, and at such times the plants which have been turned out of doors for the summer are apt to suffer from mere lack of time to give them the attention they daily need. I am tempted to write about pot Roses at this time because I observe our own require to be repotted. I usually do this about the end of August or early in September. We have no room even for the Tea Roses under glass in summer, although I have no doubt that in wet seasons all the Tea-scented group would be more satisfactory if kept under glass in a light, airy greenhouse all the year round. At present we have them out of doors in a sheltered, but sunny place, and the flower-pots stand on a hard bottom of ashes. To do Roses well in pots some care is necessary in repotting them, and the potting material should be of the best quality. They are also impatient of stagnant water at the roots; therefore, free drainage must also be provided for them, and the plants must also be stood in a position out of doors where worms cannot find ingress by the holes in the bottom of the flower-pots. Before commencing to repot, see that the leaves are quite free from insect pests and mildew. They are very liable to be attacked by mildew, and it is very destructive indeed, quite spoiling the leaves and effectually checking their growth. I find the best way to get rid of it is to lay the plants on their sides and thoroughly syringe them with soft soapy water in which has been dissolved about 3 ozs. of sulphur to each gallon of water. This not only destroys the mildew, but also the aphid tribe and red spider. I have only once had to deal with the orange fungus. It appeared on some pot Roses I had in from the nursery, and not having seen this pest before, I was alarmed and felt much inclined to burn the whole lot of plants and stand the loss of them. Second thoughts are often best, and it was so in this instance, for I carefully cut out every bit of disease, and as the plants were not large, I dipped them in the soft soap and sulphur mixture, and, as a positive fact, that was the first and the last I ever had of the orange fungus amongst the Roses. After dipping or syringing the plants, let them lie on their sides for an hour or two to drain off the water, for if it drains down the stems and into the flower-pots, the roots are injured. It will be seen in a day or two whether the leaves and stems are quite free from their insect and parasitical enemies, and if they are, give a thorough syringing with rain water, and when the leaves are dry set about repotting them. I use a mixture of good fibrous yellow loam, to which has been added a fourth part of leaf-mould, as much decayed stable manure and an 8 inch potful of crushed bones to each barrow-load of loam; a little coarse sand may also be added. The old spent soil should be forked out from amongst the roots to a considerable extent with a pointed stick, or, what is better, a pointed iron kept for this purpose. Some tough fibre is always placed over the drainage to prevent the finer particles from mixing with it. The potting material is worked well in amongst the roots and packed in rather firmly with a wooden rammer. See also that the plants are moderately moist at the roots before repotting them, and do not give any water for at least a day after repotting. In dull, drizzly, cold weather water may not be needed, for it is an error to give newly-potted plants much water until the roots have taken well hold of the new potting soil. The Roses may be left out in the open garden until the beginning of October, with the exception of the Tea-scented kinds, which would do better if

they were placed under glass after repotting; moreover, they also prefer lighter potting soil than the Hybrid Perpetual and other hardier Roses. A little light fibrous peat added to the compost as above would greatly improve it for the Teas.

It is pretty well known that the Teas are by far the best for autumn blooming, and plenty of Roses can be gathered from a bed of them out of doors until damp and cold nights prevent the blossoms from opening, and it is after this time that the pot Roses come in useful for autumn and early winter blooming. We have a house, light and airy, constructed for flowering Tree Carnations, zonal Pelargoniums, Bouvardias, &c., and the treatment these require in October, November, and December exactly suits the requirements of the Roses if they have been prepared by resting at the right time after the summer or spring flowering was over. The plants should be allowed to become comparatively dry at the roots and be rested, as they would be in some districts in the south of Europe, where these Tea Roses form a large industry for the production of cut blooms in the winter. In the Riviera scarcely any rain falls from the beginning of May until September. Roses lose their leaves owing to drought and heat, and the long days of summer are their period of rest. In August or early in September they are pruned, and Roses thus treated will flower in the Riviera from late in October until the middle of January. We can imitate very nearly the conditions of the south of Europe with our Tea Roses in pots, for they are far better for our purpose than the Hybrid Perpetuals. Although both are grown in the south of Europe, they are not equally well adapted for greenhouse culture here. The plants should be kept comparatively dry after flowering, and if it rains, keep the rain from them. Prune them in August, and when they have well started they may be placed in the house where they are to flower. This house is heated with 4-inch hot-water pipes in the usual way; and besides this a flow and return 1-inch pipe have been fixed to the roof, one of them about 1 foot from the bottom of the rafters, and the other 9 inches higher up. These small pipes are of much value in drying up condensed water, and also for preventing frost from gathering on the glass at the bottom of the rafters. J. DOUGLAS.

AUTUMN ROSES.

THIS is a very good season for Roses, although in July the flowers were quickly over through the excessive heat. Even when cut for the house they lasted only a short period. But if the weather remains fine, the flowers of several varieties will be in good character through the autumn, a succession being maintained at a time of year when Roses are as welcome as in mid-July. When in the Waltham Cross nursery of Messrs. Wm. Paul and Son a few days ago we made notes of several of the more conspicuous kinds for their autumn-flowering, and it is varieties that are in beauty over a lengthened period that should be freely planted. In spite of the protracted drought the plants appear in vigorous health.

Amongst the Hybrid Perpetual class, that fine Rose Mrs. John Laing was blooming exceptionally well, and whether in the height of summer or mid-autumn this fine variety is satisfactory, whilst the plants are very free from mildew, which has played havoc amongst some kinds. If only half-a-dozen Hybrid Perpetuals were planted, this should certainly be included, its flowers large, finely shaped, very sweetly scented, and rose-pink in colour. There was more competition in the class for twelve blooms of this variety at the Crystal Palace Rose show than of any other, proof of its usefulness.

Another very good autumn-blooming kind is Ella Gordon, which is a vigorous grower, though one does not see it often in gardens. It is a fine autumnal variety, and produces large, full, globular shaped flowers, which may be described as of a clear cherry colour. The clean, broad foliage betokens a robust constitution, and the distinctly coloured flowers are produced with freedom over a long season. La France we saw very good, the rows of it presenting splendid flowers, and the well-known Alfred Colomb was exceptionally free. This still remains one of the best garden Roses, the plants strong growing and the flowers bright red in colour. It is useful both for exhibition and the garden, and is a good autumnal. Pride of Waltham is also a vigorous growing Rose, and bears well into the autumn, the flowers being of a soft flesh colour touched with rose, whilst a note may also be made of the variety Marchioness of Lorne, which from the first time we saw it some years ago in this nursery has maintained its rich promise. The flowers are perhaps a little thin, but large, finely shaped, and exceedingly fragrant, a point upon which one can scarcely lay too much stress when many novelties are practically without this precious attribute. This kind is as fragrant as the old Cabbage Rose, whilst the flowers are of a deep rose colour touched with a carmine shade in the centre. It is evidently a good autumnal, as shown by the plants in this nursery. Charles Lamb has taken a respectable place amongst exhibition varieties, and may be mentioned for its freedom in autumn. The plant is vigorous in growth and the flowers red in colour, a clear shining tint, which is especially pleasing in the long shapely buds. One of the gems of all is the now popular Hybrid Perpetual Augustine Guinoisseau, which at Waltham Cross, as elsewhere, is very beautiful. This is a true garden Rose, scarcely full enough for exhibition, but that is of little moment, as the show should be last considered when estimating the value of a certain variety. We have seen, however, many excellent flowers at the exhibitions, but it is in the garden that its beauty is revealed. The plant is remarkably vigorous and very free, the flowers reminding one of those of La France, hence the name White La France, although "white" is scarcely descriptive, as the flowers are touched with a salmon-rose tint in the centre, whilst they are delicately and powerfully scented. A bed of it would make a delightful feature.

Of the China Roses several are in good condition, but the finest is Mme. Laurette Messimy, which is very free, strong and bright in colour, a rose shade touched with yellow. It is certainly one of the most distinct of its section and blooms well into the autumn.

The beautiful Souvenir de la Malmaison was flowering freely, and two other Bourbon kinds of interest were Queen of Bedders and Queen, the flower of the former of a deep crimson, that of the latter being more of a rosy tone.

That most charming section of all—the Teas and Hybrid Teas—were, of course, in full beauty, and they are unrivalled for long continuance in bloom, in mild seasons giving welcome handfuls of flowers far into the autumn. This class has grown immensely in popularity during recent years, and the large breadths at Waltham Cross are bright with colour. The more recent blooms are less flimsy than those of the earlier part of the season and last longer when cut for the house. One of the best is Marie van Houtte, and this year its colouring is especially characteristic, the flowers touched with yellow and edged with delicate rose. Another favourite, Mme. Lambard, is excellent, and a few other kinds are noteworthy. Grace Darling is remarkably fine, and this Hybrid Tea, one of the late Mr. Henry Bennett's most notable acquisitions, is remarkably free and vigorous when upon its own roots. A good bed of this in the garden is very useful, as flowers appear until quite the season of frosts. They are of cream white colour, suffused with a rosy pink shade, and large and full. Very beautiful also is Viscountess Felkestone, one of the most lovely of all Roses.

It should be grown in quantity, the plants being vigorous in growth and exceptionally free, producing large, delicately fragrant flowers almost cream colour, but sometimes touched with pink, with the centre suffused with a salmon shade. It is a splendid autumnal. The *Bride*, *Mme. Hoste*, *Anna Ollivier*, and *Hon. Edith Gifford* are all blooming freely, but they are too well known to need description. We may point out, however, a few kinds not so familiar which are in excellent condition at present. One is *Sunset*, a sport from *Perle des Jardins*, which has flowers very similar to those of the parent, but differing in colour, this being best described as of an apricot shade. It flowers well. *Coriuna* has been previously described in THE GARDEN, and it is a Rose that we feel sure will become largely grown for its freedom, distinct colour and hardiness. A new Rose that deserves a note is *Christine de Nouë*. It is a satisfactory autumnal, the flowers rich crimson, touched with rose, and the centre shaded salmon. They are large, fragrant, and very charming when cut. *White Lady* is a comparatively recent addition to the Hybrid Teas. The flowers commence to open early in the season, and the plants are now bearing a large quantity, whilst the petals are exceptionally broad, the colour creamy white.

Rose Senateur Vaisse is still one of the finest scarlet Roses we have. This autumn I have had some grand specimens of this old favourite, which, like *La France*, *Baroness Rothschild*, and *M. Niel*, took the Rose world by storm during its first two or three seasons. *Senateur Vaisse* is a good grower, flowers fairly freely, and the blooms are of great size and substance, also exquisitely scented. We do not see this variety exhibited during the summer shows so often as usual, probably because there are many others which produce better summer flowers. It is rather late, but in the autumn few can surpass this and *Mme. Victor Verdier* among dark scarlet Roses.—R.

Standard Roses.—A well-grown standard Rose is certainly very beautiful, especially in a shrubbery and upon a lawn. Far too many purchasers do not sufficiently bear in mind that it is absolutely necessary to choose a variety of vigorous habit. I do not mean that it should be of the climbing section, but that a class represented by *Dupuy Jamain* and *Duke of Edinburgh* among the Hybrid Perpetuals, and *Anna Ollivier*, *Marie Van Houtte*, and others in the Tea-scented class. Unless a Rose is of vigorous habit it is of no value as a standard for more than one or two seasons. To take down the name of a Rose at an exhibition, and order standards of it without making inquiry into its habit of growth is in many cases only courting failure. Purchasers had far better trust the trade grower to send them another variety as nearly as possible approaching the one ordered should the desired kind not be suitable for standard culture. Several Roses have been remarkably well shown this season, many of which are by no means suited for standards. I may mention *Horace Vernet* and *Duchess of Bedford* as striking examples of this.—R.

Rose sports.—Has anyone noticed how the sports from old varieties are increasing? Until the matter is given a little thought, it strikes one as being a most remarkable coincidence that a plant of any given variety should suddenly develop a sportive tendency, and that this should happen simultaneously in different parts of the country. Almost all plants that are usually propagated by any other method than from seed show this characteristic more or less. But to confine myself to Roses. Let us take *Souvenir d'un Ami*. This Rose produced a white sport, both in America and England, almost simultaneously, and they are exactly alike. I allude to *The Queen* and *Souvenir de S. A. Prince*, the former sent out by Messrs. Dingée and Conard, and the latter by Mr. G. Prince, of Oxford, both being distributed during the same year—1890. *Souvenir d'un Ami* also sported with me in 1891, producing exactly the same flower. I have a plant of *Catherine Mermet* which has produced a sport of great promise. It is constant, and seems to

have a little of the following varieties intermingled with a good type of *C. Mermet*. It has a little of the shape and centre of *Souvenir de Paul Neron*, while the outside of the bloom reminds one of *Madame Bravy*; in short it is a combination of the three, and inferior to neither. This week a friend of mine mentioned that he had a similar sport, and when I described mine he said, "It is like mine." Singularly, both were produced two years ago. I have worked three plants from the shoot which sported, and they have been reworked from. All are constant, and the remains of the original shoot continue to throw light coloured flowers. Two of the Hybrid Teas, *La France* and *Lady Mary Fitzwilliam*, have recently produced several sports. Then we have *The Bride*, another sport from *Catherine Mermet*, so that we see some varieties evidently possess a greater sporting tendency than others. Among zonal Pelargoniums we find *Vesuvius* producing a number of distinct sports, while doubtless Mr. Molyneux could point to several instances among *Chrysanthemums*.—RIDGEWOOD.

ROSES ARRANGED FOR EFFECT.

The Royal Horticultural Society deserve the hearty thanks of all rosarians for their persistent efforts not only to record the finest Roses, but to have these shown in the most artistic form. The greatest success yet reached in this very desirable direction was shown in the exhibit of Messrs. Paul and Son, of Cheshunt, at the recent show in the Agricultural Hall, Islington, August 29 and following days. The Roses themselves were good considering the peculiar season, and also that it was a four days' show. It is, therefore, high praise to affirm that the majority of the varieties at the close of such a hot August were nearly up to the average quality, and that a few of them, such as *l'Idéal*, *Marie van Houtte*, *Augustine Guinoisseau* were very fine. In other parts of the show there were also some fine flowers of *Ulrich Brunner*, Mrs. J. Laing, *Star of Waltham*, *Etienne Levet*, *Duchess of Bedford*, and *Duke of Wellington*.

But the great feature in the Rose groups for effect, and especially in the first prize collection shown by Messrs. Paul and Son, Cheshunt, was the massing of particular varieties of Roses into groups or basketfuls, and the placing of the latter at different heights and distributed over large areas on the ground line. Instead of single blooms in threes or in bunches, most of these groups were dozens or more of blooms of the same variety, but always in sufficient mass to form a telling group. In this way it is more obvious that a mass of such Roses as *Alfred Colomb*, *Marie van Houtte*, *Duke of Edinburgh*, *Viscountess Folkestone*, *Boule de Neige*, or *Gloire de Dijon* gives weight to all such groupings. But mere numbers of Roses and masses are apt to lead to a very dreary monotony unless other variations, such as those of height and distance, are introduced. Such variations as well as those of colour and size gave a peculiar finish and charm to this large and telling arrangement of Roses. And then there was another and even more startling innovation in a group of what was generally understood to be cut flowers. Standard and other Roses in pots were used as accessories, if not parts of the Roses arranged for effect. It would have been a thousand pities had the presence of Roses in pots disqualified this strikingly beautiful collection, for it is hardly too much to say that the verdure of the Rose plants, their artistic setting in fact, did very much to win the highest awards for the cut blooms. True, they were good in themselves, skilfully massed and well placed alike as to height and distance, but the verdant leaves and

graceful spray filled and favoured the judges' eyes on their behalf.

Too long rosarians have striven in vain to make Roses look thus after separating those two things which Nature and art alike have mated—flowers and foliage. We have but to join these in due proportion in the future to reap fresh victories in the somewhat new and very charming field of arranging Roses for effect. D. T. F.

GARDEN FLORA.

PLATE 927.

LILIUM DALHANSONI.

(WITH A COLOURED PLATE.*)

THE hybrid Lily now illustrated first flowered at Southborough in July, 1890, and, as its name indicates, was raised from *L. Martagon dalmaticum* fertilised with the pollen of *Hansoni*. It generally blooms in July, but, like everything else in this extraordinary year of heat and drought, it was fully expanded in the third week of June, and being unusually strong and vigorous, I had a photo taken of the group when it was at its best. It is of vigorous growth and constitution, being fully 5 feet high, and in this respect following the habit of the male rather than of the seed-bearing parent. In July, 1891, I sent a spike of it to Mr. Macfarlane, Edinburgh, and in the *Gardener's Chronicle* of August 8 he gave the following description of it:—

HYBRID LILIES.

I received from Mr. Powell, of Southborough Tunbridge Wells, fully a fortnight ago a magnificent flowering shoot of the above hybrid Lily, flowered for the first time by him last year, and noticed by you in the *Gardener's Chronicle* of July, 1890. Its parentage is almost identical with that of the hybrid flowered this season at Haarlem and recently described by Mr. Baker.

Whether it be owing (as it probably is) to the bulbs being young and vigorous, certain it is that the specimens sent over-topped in stature and flower-production either of the parents as grown here, so that the specimen quite recalled Köllreuter's description of some other hybrids which showed "statura ponderosa."

The hybrid has a special interest, as being the progeny of species very nearly related systematically, but widely isolated in geographical range. *L. dalmaticum* is a South European and Himalayan form, while *L. Hansoni* is Californian. In naked eye characters, Mr. Powell considered that the stem showed little of the *Hansoni* parentage; but a comparison both last year and this soon convinced me, in spite of Professor Meehan's remonstrance, that Nature had followed her common laws and that we had a very even fusion of parent peculiarities. The leaf-colour of *L. dalmaticum* is a deep purple-green, of *L. Hansoni* a bright green, while a leaf of the offspring placed between, formed a neat transition in tint.

I have been prevented as yet from making a complete microscopic examination, but from study of the leaf epidermis as to cell shape, number of stomata, &c., I fully expect the hybrid will come very fairly between the parents in its vegetative parts. The flowers, however, Mr. Powell truly remarks, are as exactly intermediate as one could expect. The mingling in diluted degree of the

* Drawn for THE GARDEN in Mr. Powell's garden at Southborough, Tunbridge Wells, by H. G. Moon. Lithographed and printed by Guillaume Severeys.

LILIUM DALHANSONI

deep purple colour of the seed parent with the yellow and spotted condition of the sire is a very nicely balanced one. As stated by Mr. Baker, Lily hybrids have been a rarity, but after microscopic examination of the pollen and ovules of this one, I feel tolerably certain that it may be perpetuated in a pure state or crossed successfully with either parent or another species. The pollen grains seem good to the extent of from 90 to 95 per cent., thus almost equalling the parents. The ovules are well formed, and contain an egg-cell and help-cells of vigorous appearance. It remains for future experiment to prove or disprove the accuracy of this conclusion. On receipt of the specimen in full bloom, it was found that L. Hansoni had finished flowering in the Edinburgh Botanic Garden by a full week, while L. dalmaticum was in bud and only opened on July 29. On inviting an expression of Mr. Powell's experiences, he wrote, "Your observation as to the flowering period of the hybrid being intermediate is correct, for the plants of Hansoni here bloomed before any hybrid expanded, and the other parent (dalmaticum) is now (July 28) in bloom ten days after the others were over."

Mr. Macfarlane's anticipation of its capacity for producing seed has been fully borne out this year and last, and I am going to test its vitality by sowing the seed in the open border this autumn, my experience of hardy bulbous plants being that the seeds will vegetate better this way than in pots. This Lily and L. Hansoni have both done well this year, though my soil is by no means adapted for Lilies generally, being very light and dry. Some very fine imported bulbs of L. Washingtonianum, planted certainly very late (April), only appeared above ground in the last week of August, and must have had a hard struggle to exist, as the drought has killed Rhododendrons established for more than fifteen years. L. eximium did well up to a certain point, and then the buds had not strength to expand; L. tigrinum vars. were not so much affected, as they bloomed well. For all herbaceous plants it has been the most unfavourable year I ever remember. C. B. POWELL.

THE WEEK'S WORK.

ORCHIDS.

ONE of the details of the work that must occasionally crop up is the repainting of the houses. Ours are now being done, and this necessitates a good deal of extra labour, but as the months of August, September, and early in October suit well for painting, so do they also for giving the plants a thorough overhauling. They have all been taken into another house, for the woodwork gets so thoroughly saturated with water, that unless it gets well dried before repainting the work is worse than useless. The houses ought also to be thoroughly well cleaned before repainting them. Sometimes the woodwork has to be well washed, and in places the paint will come off entirely. We are putting three coats of paint on outside and two inside. Allow the paint to be well dried before the plants are returned to the house. The removal of the Orchids and taking them back again will give an excellent opportunity to thoroughly clean, surface-dress, or repot before the winter.

Amongst plants that may be repotted now are the Sobralias. The Odontoglossums may either be repotted now or in the spring. September is a good month to repot them, but I have done so in every month in the year, and the results have not varied much. The Sobralias make numerous thick fleshy roots at this season from the base of the young

growths, and it is a good plan to repot them carefully into larger pots. The specimen plants of S. macrantha soon become pot-bound, and they require good fibrous peat torn up by hand and left in a lumpy state, some Sphagnum Moss, and broken crocks. The flower-pots should be filled to about a third or fourth of their depth with drainage. If the roots are all right leave them as they are, and give a good shift to admit of the compost being packed in all round the ball of roots. We do not raise the surface of the compost above the rims of the pots, as is done with some Orchids, such as Cattleyas, Lælias, &c. It is necessary to see that the roots are well on the moist side before repotting, and the compost should be in the same condition as regards moisture. Do not give the plants any water for about two days after repotting them. Remove any old spent growths to give all those with fresh green leaves ample space and the young ones free scope to develop fully. Water must be applied rather freely to the roots when the plants are growing, but when at rest the soil may be comparatively dry without being quite dried up. Besides the magnificent old S. macrantha, there are now a number of other varieties and species of great merit. The yellow-flowered S. xantholeuca is a superb species, which makes fine strong growth in a well-shaded house, and there is also the charming S. leucoxantha, with pure white flowers and a deep yellow or orange stain in the throat. The best varieties of Epidendrum prismatocarpum are exceedingly well adapted to produce distinct and very handsome flowers in August, and now that such plants have passed out of bloom they may be repotted, and large plants can readily be broken up into smaller ones. Remove all decayed compost, for in time the peat loses its fibre and the decayed Sphagnum Moss unites with it, forming a fine black powder quite useless as a medium for the roots of Orchids. This can easily be shaken from the roots or removed from amongst them with a pointed stick, but it is an error in culture to allow the plants to get into this state at the roots; they should be repotted before so much decay has taken place. They require much the same treatment as Cattleyas, and will thrive in the warmest end of that house. Lælia cinnabarina requires some care to maintain it in a vigorous condition. I have grown it well and flowered it admirably in both pots and baskets suspended near the roof-glass of the Cattleya house for a few years, but the plants have a habit of getting into a weak state, and gradually fail until they are not vigorous enough to produce flowering growths. There must, of course, be a reason for this decline of vigour, and I think it is probably because the plants are over-watered when they ought to be kept dry. They ought to be repotted about this season of the year, and once in two years at least. Do not over-pot them, and use the best peat and Sphagnum in equal portions. The pots ought also to be filled quite half full of drainage, but I believe teak baskets are better adapted to maintain the plants in health than flower-pots. I have tried the shallow pans, but they will not do for very long. The more slender-growing L. harpophylla may be classed with it as regards treatment. I have grown this well for several years in the Cattleya house, using rather small flower-pots.

I see the leaves of the Pleiones have already become quite yellow, and may be removed, but this is not a sign that the plants may have water entirely withheld from them. If this is done the flowers will not come up quite so strongly. The species to flower at mid-winter are P. maculata, the most beautiful of all; P. lagenaria and P. Wallichiana. These grow together and flower very nearly at the same time. P. humilis and P. Hookeri flower in February, and make their growth in the cool house; they will soon complete their growth. There is plenty of work to do at this season, but the most important is repotting, and, subject to having the plants made thoroughly clean, first see that all the repotting that can be done is finished, if possible, by the end of the month. This is certainly the best time to repot Cymbidium Lowianum. The growths are now

pushing away, and soon will appear the points of the flower-spikes, which develop slowly during the winter, and produce their flowers in March and onwards. The best potting soil is good fibrous yellow loam with a little good peat added, some sand and a fourth-part of light, well-decayed stable manure. Good drainage is essential, but do not put in more than enough to prevent sourness in the soil. I use a little coarse sand with the compost. The plants treated as above, well watered and placed in a light position in the Cattleya house, grow with vigour almost beyond belief. Where the spikes push out from amongst the leaves, weak manure water is helpful. The temperature in both the Cattleya house and the warmest house may be allowed to run up at least 15° above the minimum by sun heat, and it is better now not to let the Cattleya house fall below 60°, and the East India house 65° at night. The cool house will be about 50° without artificial heat. J. DOUGLAS.

THE KITCHEN GARDEN.

PLANTING CABBAGE.—There will be no excuse this season for not getting the main plot of spring Cabbage put out early enough to become well established before winter, as the ground will be at liberty and should have been well prepared ere this by digging and manuring. Before planting, however, a good dressing of soot should be applied, this being necessary as a safeguard against the depredations of slugs, as these are apt to appear during the autumn months. Where club has not affected the plants there should be a good supply on hand this season, as I never remember to have seen the plants so clean. In fact growth has been too free, necessitating the pricking out of the forwardest plants a week or two since to check growth. The smaller ones left behind are now just suitable for immediate planting. If the ground has only been very recently dug and appears to be at all loose, it is a good plan to tread it over lightly. There is not much likelihood of such varieties as Ellam's Early Dwarf or Mein's No. 1 running to seed or flower-stem on account of early sowing and planting; consequently these are good varieties to rely upon for the earliest cutting. The former being a small grower the rows need not be more than 18 inches apart, the plants being set out 15 inches apart in the rows. For others of larger growth 2 feet should be allowed, and if the most has to be made of the room, 18 inches in the rows. On light land it is well to plant in lightly drawn drills, but on heavier land plant on the level. If club has attacked the roots all excrescences should be picked off, afterwards dipping the roots in a puddle formed of soil, soot, and lime. As soon as it is seen that the plants have become established, a surface stirring with a hoe will be of benefit in settling the soil well around the stems and making these secure, as if the stems are at all loose, water settles around them, and so lays them open to be either greatly injured or killed by frost if the winter should prove severe. It will be upwards of three weeks or a month before the succession varieties are ready for planting, these being such as Enfield Market, Battersea, and Nonpareil. This last is a capital variety for forming a second crop, and this season it has proved invaluable for the purpose.

FRENCH BEANS IN POTS.—To follow on any later crops which may be growing on south borders to be further protected by lights, a good succession may be afforded by sowing in pots, these in the meantime being placed either in frames or pits until the time comes for housing. If the pots could be placed in a pit where a little warmth could be turned on if the weather should happen to turn out dull and wet, it would be an advantage, as very often the sudden removal from cold frames to heated houses causes the leaves to fall. Osborne's Dwarf Forcing will be found a capital variety for early pot work. Large pots are not needed. This season's seed will produce the best plants, and it may be also necessary to add that the pots should be filled up at once when the seeds

are sown, as half filling and then earthing up are a waste of time. As the seedlings appear keep them well up to the light, and on fine days allow ample ventilation, so as to ensure a sturdy and fruitful growth. Manure water will not be needed until the pots become fairly filled with roots, when a supply about twice a week will suffice.

LIFTING POTATOES.—People who may have taken advantage of the recent fine weather to lift their main-crop Potatoes will have reason to be satisfied, as a wet spell may now occur at any time, and which, besides impeding the operation of digging, also spoils the quality. There is no advantage whatever in allowing the tubers to remain in the ground until the haulm is completely withered. The quality of the Potatoes depends so much upon the storing that care must be taken that this is well carried out. Where the tubers are to be stored in cool sheds, as the cooler these are the better as long as frost is excluded and free from damp, do not place them in large heaps, as they would become heated, when the quality would be lowered considerably. Lay them out in a layer about 18 inches in depth, and if light can be totally excluded, no covering would be needed; but if not, this must be done by lightly covering with clean straw or old mats. Where pitting has to be resorted to on account of the want of shed room or a proper Potato store, the site chosen must be high and dry. The tubers are also better for having the pit formed on the surface, this being about 4 feet in width, building it up sharply. If the pit should be excavated, the tubers do not lie so dry, and, moreover, wet is apt to find its way in.

EARLY SEED POTATOES.—Early seed Potatoes are never in better condition for planting than when their preparation for this purpose is commenced now; therefore, care should be taken that these are not kept too close and warm or placed together in a mass, or premature sprouting will be the result. The tubers should be placed where they can receive the full benefit of light and air and also be kept cool. It is also advisable, if there should be store room, to lay them out thinly; but if not, pack them closely together on end in either shallow boxes or baskets, these being stored so that light can reach them. The first or primary sprout must be preserved. By looking after the seed tubers at this season, the sprout at planting need not be above an inch in length and of a sturdy description. A. YOUNG.

PLANT HOUSES.

GREENHOUSE PLANTS, THE HOUSING OF.—Up to the time of writing these lines there has not been any immediate need for attending to this work, but it will not be safe to defer it much longer. Before another calendar is in print the hitherto remarkably fine weather may have changed, and when that is the case we may reasonably expect a heavy downfall. The summer now drawing to a close has been as favorable as could be possibly desired for the ripening of the growths of all hard-wooded greenhouse plants. For spring-flowering Ericas and New Holland plants it has been a grand time, something after the kind of weather in their native habitats. Such plants, therefore, should be in the best possible condition for another spring. I have already noted that a few rather cold nights, or at least mornings, have been recorded on the thermometer. This is only an indication of what may be expected in a few weeks. It is, therefore, much safer to be prepared by having as many of these plants housed as possible. There is, I am fully aware, a difficulty in many instances as to how the plants are all to be accommodated, but in any case do not let plants of permanent character which have taken years to grow to their present size suffer as compared with others that are grown in a season or less. The Chrysanthemum mania of the present day occupies more attention than formerly, but surely it is not wise to let the Chrysanthemums even, beautiful as they are admitted to be, occupy too much space and all the best positions. If so, add with a large stock of them, it

means later on a blank, or at any rate a house thinly filled with well-grown plants, although skeletons or objects of pity may be plentiful enough.

The greenhouse should have a thorough cleansing before any plants are brought inside. After the hot weather both red spider and thrips will be plentiful enough, and these may transfer their attentions to the fresh occupants if not thoroughly eradicated. Besides using the garden engine or syringe for this purpose with an insecticide at syringing strength, a fumigation or two should be given to make sure work of thrips and aphides. In arranging the plants contrive to have them as near the glass as possible and avoid overcrowding; furthermore, any extra fine plants should stand apart from each other, with smaller ones between them. Swing shelves can be filled with the smallest plants, thus getting the best possible place. Where there are climbers these should as far as practicable have a light thinning, or at any rate be drawn more together so as not to obstruct too much light. In some cases it will not be advisable to thin out other than weakly wood that is of no practical use, such for instance as flowers early in the year upon wood of the previous season's growth; to cut away much of this means a loss of bloom. Whilst the work of cleaning is in process, give an eye to the state of the glass and remove any broken panes whilst the work can be done with ease. There may be a good few of these, especially after the hot weather, being caused by expansion, iron roofs being as a rule the worst in this respect, more especially if the glass happen to have been fitted in too tightly during previous glazings.

When greenhouse plants are first housed, let them have all the ventilation possible; to keep the house close at night at once is an utter mistake, being only the forerunner of mildew and other consequent evils, as adventitious growths, &c. The nearer the atmosphere is like that to which the plants have been accustomed whilst out of doors the better will it be for them. Only in the case of actual frost should the top lights be closed, and then only the last thing at night. Where it is not possible to house all the plants at once by reason of other occupants, then arrange for some means of temporary shelter in the event of frost or heavy rains. The canvas covers now in use can be applied to this purpose over temporary erections. Of course, vineries can be turned to account for some plants, but it should be where the Vines are at least partially pruned. These houses are more often fitted for Chrysanthemums, and should be used for such in preference to the greenhouse proper. Where most of the plants alluded to for housing are not trusted outside at all by reason of the peculiarities of the locality, then a close inspection should be made amongst such as Indian Azaleas for thrips, and other plants possibly for red spider, measures being taken accordingly by fumigation or syringing. In such cases a rearrangement is desirable, so as to make the most of the room. In all cases a point should be made of thorough cleanliness; dirty pots cannot be got at so well after arrangement as during the work. Whilst doing this work look well after the drainage to see that the holes in the pots are not choked by worms. Where any signs of worms are seen in the pots, take the opportunity of watering with a weak solution of lime water to remove them.

JAS. HUDSON.

HARDY FRUITS.

PEARS.—There is a marked slackening in the ripening of Pears on the trees or gathered, and as yet the pips of such naturally late varieties as Glou Morceau, Easter Beurré, Beurré Rance, Josephine de Malines, Beurré Sterckman, Ne Plus Meuris, and Bergamote d'Espere are quite white. All the Pears are above the average in size this season, and it may be the quality will also be equally satisfactory, or in some cases better than usual. Pitmaston Duchess, Beurré Superfin, Louise Bonne de Jersey, Marie Louise, Doyenné Boussoch,

Doyenné du Comice, Beurré Clairgeau, Comte de Lamy, Brown Beurré, Beurré Hardy, and other October and November Pears are already gathered in many early gardens, and most probably are quite fit in later localities. It is many of these that are ripening before they are wanted, and warm rooms will aggravate the evil. The plan of wrapping a portion of the fruit separately in squares of kitchen or other moderately soft paper and then packing them closely in boxes or drawers, storing these in quite cool rooms or sheds, ought to be given a trial this season. It must inevitably retard ripening considerably. Too much must not be expected from it, however, or much fruit may have ripened and commenced to decay before being noticed.

TRANSPLANTING PEACH AND NECTARINE TREES.—Where the trees have ceased growing for some time past, the young wood being well matured and the buds plumped up, transplanting may now safely be resorted to. Being properly carried out before the leaves fall, there is every likelihood of fresh root fibres being formed before the resting period arrives, the check of removal being partially recovered from accordingly. Transplanting fairly large trees need not interfere with their ability to crop well next season, and in some instances an improvement in the quality of the fruit will be noticeable the first summer after, the improvement being still more marked the following year. Many young or comparatively young trees are, however, still in a very green, growing state, and wholly lifting and transplanting these would most probably end badly, shrivelling of the leaves and young wood resulting. Transplanting is principally recommended where the wall trees need rearranging, partial lifting and root-pruning being the safer and better course when the trees are in their right places. Old trees that are moved should have their fresh site extra well prepared for them, good fresh compost promoting a strong root-action, the top-growth being improved accordingly. Let them have the benefit of as much fresh turfy loam as can be spared, mixing with it, if the bulk is insufficient, some of the best of the garden soil not previously occupied by the roots of fruit trees, adding at the same time a little well-decayed farmyard manure, ashes and burnt earth from a garden smother and a sprinkling of bone meal. In lifting, first open a deep, wide trench at a good distance, or say 5 feet from the stem of the tree, and gradually undermine, saving as many of the best roots as possible and a flat moderately large ball of soil about the stem. See that this is properly undermined, all deep-running roots being cut, before sliding the ball and roots on to a short stout plank or short-handled stone barrow necessary for the purpose of carrying the tree to its fresh site—the latter to be made quite firm, enough fresh soil being placed in the hole to raise the collar of the tree slightly above the level of the border. Slide the ball on to this, spread out the roots, prune the ends of these, also cutting away any that are badly bruised, and distribute them thinly and evenly through the fine fresh soil that is prepared for their reception. Avoid burying the roots deeply, the topmost of them being covered by about 2 inches of soil. Give a good watering if either the old or fresh soil is at all dry, and frequently syringe the trees. The latter detail is especially to be recommended during bright days, mats being also hung over the trees if they are inclined to flag badly. The trees should be only lightly secured to the walls for several weeks, as they are certain to sink somewhat.

ROOT-LIFTING AND PRUNING.—Deep root-action is responsible for many failures or partial failures with Peach and Nectarine trees, those with plenty of root-fibres near to the surface giving by far the best returns. Root-lifting and pruning are the remedies for a too deep root-action, and owing to the crops being cleared off so early, this important work may well be commenced earlier than usual. Root-pruning is also very necessary where the trees are growing too rankly to be productive. Quite young trees may be completely done in one season, but large trees that are in less robust health should only be half-lifted this autumn and finished off

next year. Treated in this manner, there will be no very severe check given or the risk run of the loss of a crop. Proceed with young trees much as advised in the case of preparing trees for transplanting, working up to the stem sufficiently near and undermining so as to be able to cut through any deep running roots there may be immediately under the stems. Very little or no fresh soil would be required by these, the roots, duly pruned so as to leave no broken or jagged ends, being brought up a little nearer the surface. Make the soil very firm under the trees, or the latter may sink to an injurious extent. In the case of old trees, the roots on the side lifted should be relaid in quite fresh compost or such as advised for those transplanted, and this, as well as bringing them up to where they will get the benefit of more food, warmth, and air, will stimulate them into greater activity, and a marked improvement in the health of the tree be soon apparent.

W. IGGULDEN.

KITCHEN GARDEN.

HOW TO AVOID SPOILING CELERY.

THERE is no gainsaying the fact that much Celery is annually spoilt by either neglect or mismanagement. This season there is every likelihood of a repetition of former blunders being made, and a word of warning will not, therefore, be out of place. There are several ways of spoiling Celery open to cultivators, but none is so largely responsible for so many failures or partial failures as that of neglecting to supply the requisite amount of moisture to the roots. After a few inches of soil have been returned to the trenches, this being the first step towards moulding up the stems, it seems to be taken for granted that no more watering will be needed, yet no greater mistake could well be made during nine seasons out of ten. Placing some fine soil in the trench does certainly check the loss of moisture by evaporation from about the roots, but not from the foliage, the hungry roots soon absorbing and getting rid of what is within reach, the soil as a consequence soon becoming dust-dry. The fresh soil added to the trench may, owing to rainfall or make-believe watering, be in a moist state, while that underneath, and which is to principally support the plants, is most injuriously dry. Very often premature bolting or running to seed is attributed to a check the plants have experienced in a young state, and they may certainly be spoilt by being raised too early or subjected to too much heat, extreme dryness at the roots also doing harm, but more often than not the mischief is done after they have been planted out and are well established. This summer, owing to the great amount of sunshine, frequently accompanied by parching easterly winds experienced, abundance of water has been needed by Celery. In my case no moulding up is done in either the first or second stage until after the soil about the roots has had enough water given to thoroughly moisten it. It is an easy matter to test the state of the soil where the roots are, by means of a stout, pointed stick, and this season the final addition of soil to the early rows should not be made before enough water has been given to well moisten it if necessary. In the case of later rows, water should be given freely both before and after the first addition of soil has been made, and it may even be found necessary to water still longer. It must be a very heavy and continuous fall of rain that will reach the roots of Celery, but unless sufficient moisture is provided, not only will bolting be

the order of the day, but the growth generally will not be so strong as desirable, nor the quality of any that may reach the dining table satisfactory. It need hardly be added that liquid manure is never thrown away upon Celery, but it should not be very strong, abundance of water being what is most needed. Above all things avoid applying dribbles. If two rows cannot be given a thorough soaking at one time, then be content to water one.

Celery can be spoilt by moulding up too soon, and also by this operation being delayed too long. If soil is heavily banked up to comparatively weakly plants, it presses so heavily against them, as to quite check the development of the heart, bulging and splitting at the base being the consequence. On the other hand, when the plants are allowed to assume their natural position, the outer leaves quite touching the ground, and the rest opening out nearly as badly, the stalks cannot often be got back to an upright state without splitting many of them. Without good sound outer stalks or leaves to protect them, the hearts stand but a poor chance of attaining a good size, protection also being needed against slugs and such like. Lately it has been my duty to pass through and award points to a large number of allotments, as well as cottage gardens. In very many of them a row of Celery was to be seen, but scarcely one in a dozen promised to be good for much, owing to the plants not having been prevented from opening out badly. Very many amateurs' rows of Celery are in much the same plight. Before the plants assume the horizontal position, enough soil ought to be chopped down from the sides of the trench, and levelled about the Celery, to just keep the outer stalks nearly upright. When the heart begins to rise, the plants having by that time strengthened considerably, more soil should be added, though not to the extent of badly confining the hearts. In some, or most instances, in fact, yet another moulding up is ample, though extra strong Celery may have a fourth addition with advantage, not more than a half of the leaves of early and second early rows protruding at the final moulding, and rather less in the case of the latest rows.

Slugs spoil very much of what otherwise would be good Celery. Once they get past the outer stalks very short work is made of the hearts, and slug-eaten hearts mean so much labour and space wasted. It is the heavier soils that are most frequented by slugs, and they particularly delight in a depth of lumpy ground. More than ordinary pains should be taken in breaking down the soil used for banking up around Celery, and soot and lime ought also to be very freely incorporated with it, dusting it well against the stems being advisable in extreme cases. The soot may disfigure the Celery somewhat, but if proper pains be taken, every particle of it may be washed away from the hearts, and better this little trouble be necessary than have much slug-eaten Celery. In any case the stalks should be gathered well up together, and kept so, either by being held or tied, while the soil is distributed lightly and evenly against them. If ties are used, then must these be undone after the soiling is completed, or they will unduly confine the growth of the heart. Where the most care is needed is when two or more rows are planted in each trench, the plants when at all crowded not growing so strongly as desirable, the hearts suffering from being unduly exposed. Supposing there are several rows in a wide trench, the plants being put out squarely, two boards to reach across the trench are needed, setting these tight against two rows, and drawing

out after either soil from the sides or other added fine soil, ashes, or burnt soil has been thrown in. After a layer of soil has thus been evenly distributed over the trench the plants should be loosened, the operation including the tying up, earthing being repeated in about three weeks after the previous addition. Celery is sometimes wholly surrounded by either ashes or burnt soil, though in but few cases is this absolutely necessary either to preserve it from slugs or to ensure long keeping. A very large quantity of either is not required if boards are first placed against the plants, and, after the ordinary soil has been banked up against this and the ashes or burnt soil placed inside, they may be drawn out and similarly used further along.

GROWER.

WINTER GREENS.

WHILST but a few weeks ago there seemed to be a promise of great abundance amongst all descriptions of winter Greens, that promise has been very much discounted by the later and prolonged spell of drought, though not of great heat; growth has been checked, and the robust appearance of the leafage has changed very much to blue or else to a blighted aspect. That heavy rains and cooler weather may do very much to bring about an improvement there can be no doubt, but September is the chief growing month for all descriptions of Brassicæ. I am referring chiefly to market crops in fields, and in many districts the present promise is poor enough. Where there were liberal July rains and stuff was got out at once, things are better, especially in the Brussels Sprout, autumn Cauliflower and Scotch Kale sections. In some cases Brussels Sprouts are wonderfully good, but that is due to early planting. Apart from general suffering from drought and aphid, club is also very troublesome, a disease partly due to grub or maggot in some forms, to fungus in others, but this season it seems to be chiefly due to the long-continued dryness of the ground and great sun heat. A grower told me the other day that where plants had been put out whilst the whole soil was moist after a fairly good rain, they had done well, but where watered in two or three times during drought, they had either clubbed badly, or were very much dried up now. A few waterings, with all the surrounding soil so hard and dry, had simply sufficed to create a baked condition of ground about the roots, which had rather helped to strangle or starve them than to promote growth, although doubtless efficacious so long as the moisture endured. The worst results seem to have followed when the holes made to hold the plants were first filled with water, a plan much in favour with some, but this season it seems to have created a puddle into which the roots were placed, and then the ground was baked almost as hard as a brick. Of course, watering has been done liberally enough in previous years, and plants have done very well after, but then never before under such conditions as those which have prevailed this season, for in spite of some excellent rains in July and a few here and there in August, the summer has been almost unparalleled for dryness and length of sunshine and drought. The Autumn Giant Cauliflowers are this season getting over very early, whilst the later plantings that might have given heads in November seem to be so weakened, that what heads may come will be very poor indeed. The best of all the Cabbage tribe is the Brussels Sprouts, but even these are in many places very much blighted. Kales seem as well able to endure heat as cold and moisture, and where got out early are very good. Still, in the market fields these constitute but a very moderate portion of the winter green crop. We could now do with some heavy rainfall on all of our garden and field crops; the earlier it comes the better, so that some fresh clean growth may be made before the winter frosts stop further development.

A. D.

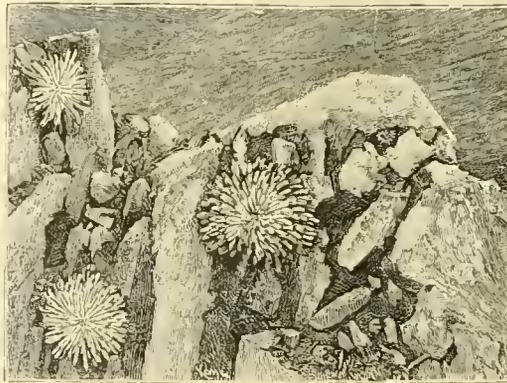

CHRYSANTHEMUMS.

SEASONABLE NOTES ON CHRYSAN-
THEMUMS.

SECURING the buds should now be attended to. It is a pity to have them destroyed for the sake of a little attention after so much time has been bestowed upon the plants. Growers of Chrysanthemums for large blooms living in a district much exposed to south-west winds know quite well the risk they run if the buds are not rendered secure when they experience an equinoctial gale from that quarter. As a rule we in the south of England experience such a storm some time after the 1st of September and before the 15th of that month. I have had many bloom buds entirely spoilt by such a gale of wind. It is not that the buds are actually blown off, but they are so "whipped," as I term it, that they are bruised and rendered useless. When once the bark tissues of a bud are damaged, it is impossible for that bud to swell uniformly, the consequence being a one-sided bloom, which is useless. It is not only the buds that are injured by these wind storms, but the succulent foliage at the apex of the plants is also damaged and much of it blown off. The leaves upon the unsecured shoots have so much more play, that the edges are often torn in pieces, the leaf-stalks also being damaged. All such checks as these cannot be otherwise than injurious to the plants. The Princess of Wales family is perhaps the most susceptible to injury from this cause owing to the flower-bud peduncle being so weak in comparison to that of many others, notably the Japanese section. Were they all like Avalanche, for instance, in this respect, they might defy the fiercest wind unsecured, but as they are not, means must be taken to afford that necessary protection. Some cultivators still adhere to the practice of allowing the points of the shoots to hang loosely for at least 1 foot and sometimes 2 feet from the point. They think they are more secure from wind in this way than when they are tied to the stakes their full length. I have heard such persons complain of the loss of as many as fifty points after a single gale of wind; whereas in my case with the shoots and buds made secure the losses have been very few.

In cases where the ordinary stakes are not long enough to secure the buds properly by tying the peduncle firmly, I advise the use of builder's laths split into widths of about a quarter of an inch. These cut from 6 inches to 1 foot long according to the length of the peduncle answer even better than round stakes, as the flat laths fit neatly to the stem of the Chrysanthemum plant and the peduncle, thus rendering all secure. Not only are these supports of great service now, but when the blooms are developing they save many a flower from otherwise coming to grief. Where they are not supported at all and have escaped the wind the buds stand erect and are apparently quite safe, but when the blooms are half or three-parts expanded they are liable to snap off just half-way down the peduncle. It is very annoying to find several of the finest blooms in this state, whereas a few minutes' attention would have avoided such a casualty. Some persons may be apt to think I am too minute in such details, but having experienced the loss of fine blooms through no other cause, I do not consider any detail is too small to pay attention to—certainly now-a-days, when the competition is so keen, and every little point tells for or against, as the case may be.

Late-flowered varieties like Leon Frache, M. E. A. Carrière and Etoile de Lyon cultivated to give quantity of flowers rather than for their individual quality are now making most satisfactory progress. My method of cultivating this section is to strike the cuttings rather later than for the large bloomed class, top them at 4 inches high, and induce them to grow freely so that at the present time each plant in 8-inch and 9-inch pots has about ten branches, which in time will throw out other side shoots and give abundance of bloom during December and the early part of January, when flowers are not over-plentiful. Some are grown two in one pot for the sake of convenience, taking from these a rather less number of branches. For decoration, either as plants or for cutting, I find the system answers really well and economises space. Most of the branches are now forming a central bud, with numerous short side growths pushing from just below this bud; these shoots will produce several blooms each, small, of course, but as they will be available in numbers and on shoots from 1 foot to 2 feet long, they will prove very serviceable for tall vases. Each plant has one stout stake affixed near to the stem; to this the branches are loosely tied, so that they are

No. 2.—Mode of planting abruptly sloping or vertical fissures.

secure from strong winds and do not occupy as much space as those plants with more shoots, obtained by constant topping of the young growth in the spring. Special attention should be paid to these plants in the matter of watering them regularly and supplying them with stimulants as required; the small pots quickly become filled with roots, and as the plants are well furnished with branches, they absorb a quantity of moisture and exhaust the soil very quickly.

The plants growing at the base of walls have made wonderful progress of late where the roots have been constantly supplied with moisture and the foliage kept free from insect pests and mildew. Such varieties as Etoile de Lyon are now showing the crown-bud, and if a few large blooms are required from these wall plants, the shoots clustering about the bud should be removed to give strength to the central bud. Continue to fasten the leading shoots to the wall; those growing from the front may be neatly tied to the main branches.

E. MOLYNEUX.

October-flowering Chrysanthemums.—This should prove a good season for what I may term the October section of Chrysanthemums. Dealers' descriptions are all very well in their

way, but the best test is to be had from the larger body of cultivators. It would prove of great assistance if those people who are in the position to do so would state, as the different varieties come into flower, what they really find to be the best. I do not mean those grown solely for the production of large flowers, but rather those which succeed well as freely-grown bushes for conservatory decoration. I have several varieties under trial, and will give results in due season if any should prove worthy. I note that "H. S." (p. 126) gives a list of the better-known varieties and also mentions a few of last year's introductions. It would prove of value if, as these come into flower again this season, he would state whether they bear out previous opinions. We do not want long lists, as these are bewildering, but rather a few kinds of distinct shades of colour and with a good habit. Those which will do well in 7-inch pots are the most useful.—A. YOUNG.

THE ROCK GARDEN.

GENERAL HINTS ON PLANTING.—II.

(2) PLANTING CHOICE ALPINES ON SLOPING
GROUND.

A SLOPING position of the ground is most beneficial to all plants enjoying a comparatively dry situation, especially during the winter months.

Many varieties of Androsace, the choicest kinds of Saxifrages, Draba, Silene, &c., prefer this position to any other, as there is no danger of their leaves suffering from the consequences of continuous winter rains. There is, however, a danger of the soil around the plants being washed away during heavy rain or watering with a hose unless due precautions are taken to prevent this, and there is also a danger of too much drought in summer. I find the best way of preventing both is to place on the lower side of the plants a few stones which would arrest the progress of water flowing over the slope, and not only prevent a wash, but enable the water to penetrate to the roots of the plants instead of simply flowing over the surface. If the soil above the plants is of a loose nature, stones slightly projecting might be placed on the higher side of the plants, as other-

wise there would be a danger of some of the tiny gems being completely buried by loose soil and grit washed down from a higher level. These protecting stones should be larger than the stones generally used for covering the surface of the soil, and they should be let firmly into the ground so as not to be easily displaced. In other respects the planting of alpinas on such sloping positions, and the crevices prepared underground, would have to be after the same method as that described in my last essay when speaking of the planting of alpinas on elevated level ground. I need only add that the small stones used for covering the surface of the soil should be more firmly driven into the ground than those covering more level spots, as otherwise they might roll down the slope and leave the roots of the plants unprotected. When watering such sloping spots care must be taken to water as much as possible the highest parts, as the water would naturally drain off to the lowest level.

(3) PLANTING ABRUPTLY SLOPING OR VERTICAL
FISSURES.

In every rock garden, no matter whether it be large or small, or even whether it be well constructed or otherwise, there must of necessity occur an enormous number of abruptly sloping or even upright fissures where the stones join or nearly join each other, and in my opinion

these fissures, as a general rule, offer advantages which are not nearly enough appreciated. In most cases we see them either empty, forming a hiding-place for snails and other pests, and at the same time allowing the rain water to escape before it can penetrate to the roots of the plants, or in other cases we see them stopped up with cement or mortar. On the other hand, there are hundreds of varieties of charming plants for which such crevices would be just the very thing. Even if they should occur on the shady side of rocks we have such gems as *Ramondia pyrenaica*, *Linnaea borealis*, *Saxifraga juniperina*, an endless

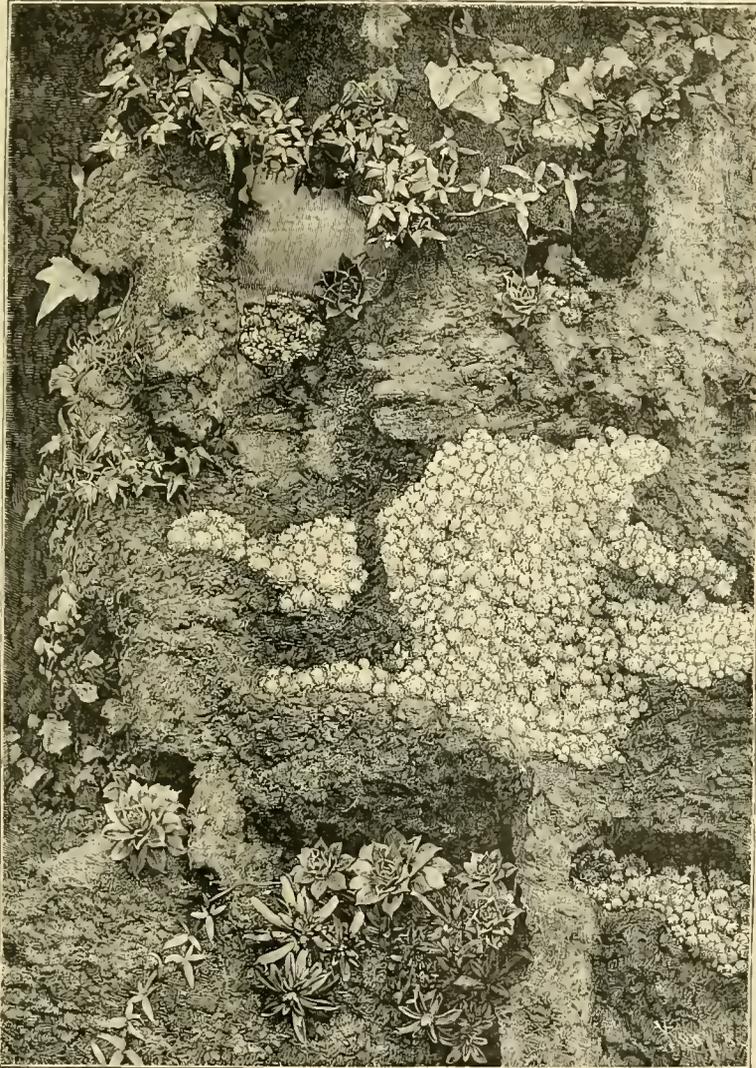

ance of others which would prefer such a position to any other. In slanting fissures on the east or west side, too, we may grow the choicest kinds of *Androsaces*, *Silene acutis*, *Phyteuma comosum*, *Aretia Vitaliana*, *Saxifraga Bursariana* and hundreds of other gems.

Yet it is surprising how many people make scarcely any use whatever of crevices of this kind. I would, of course, not for one moment advocate that all such fissures without exception should be planted, and in an earlier essay on the construction of rocks with regard to effect I have pointed out what fissures should be stopped up; but, generally speaking, I think

difficult to approach after completion of the work and can be planted with greater facility during the progress of the work, as, for instance, the underpart of an overhanging boulder or a deep cavernous recess, whose sides after completion of the foreground would be almost unapproachable. When commencing the general work of planting (after the rocks have been at least roughly completed), the upright fissures or abruptly sloping narrow spaces visible between the stones must at all times be the very first to be dealt with, as the small stones used for filling up the exterior of such a crevice both below and above the plants inserted would form a substantial support to the little plateau thus formed on a higher level, and which could not be planted until after the crevices on a lower level had been properly secured, so as to prevent any possible chance of the soil being washed away when the plants are watered.

As a practical illustration how to proceed with the planting and filling-up of an upright crevice, I cannot, perhaps, do better than describe my own method of procedure. Supposing, then, that the crevice in question is about 2 inches or 3 inches wide and 2½ feet or 3 feet long, I should in this case begin at the bottom by driving a wedge-shaped stone firmly into the ground so as not to project beyond the larger stones on either side. The space behind this wedge-shaped stone is then filled in with the proper mixture of stony soil, which is firmly rammed with a stick. The front part of the crevice is then built up with small stones resting firmly on the stone just referred to and held together by a tough mixture made by wetting ordinary clay, common Moss, and a little soil, and mixing them to the consistency of mortar. As the crevice is thus built up in front, so must the soil and stones intended for the roots of the plants be again filled in behind and firmly rammed. The height to which the crevice should be filled in this manner before the plant is inserted must, of course, depend on the nature of the plant to be used and the room it would require to develop its full beauty. Let it be supposed then that, in this case the plant selected is *Androsace sarmentosa*, and that the crevice has been built up to the height of at least 15 inches above the ground before the plant is inserted sideways. Small stones are then wedged in on each side of the rosette of leaves, but so that, though the plant is firmly held in front, there would be plenty of room behind for the roots to descend. When the plant is thus secured the remaining part of the crevice above the plant is built up in precisely the same manner, but care must be taken to use small stones only, which would rest on the stones at each side of the plant and not on the plant itself, and which would leave between them miniature channels through which the water could percolate to the roots of the plant below, but which would not be wide enough to allow the soil to escape. When in this manner another foot or so above the first plant has been filled up, a second plant of the same or another kind may be inserted sideways in the same manner and the crevice again filled up above this, so that the water can readily percolate.

The second illustration (No. 2) shows *Saxifraga longifolia* planted sideways on this principle. It will readily be seen that if the stones filling the crevice above the plant were not placed longitudinally (*i.e.*, in the same direction as the crevice), rain water could not penetrate these fissures so readily, and death from drought would probably be the fate of the plant. When the filling up and planting of a vertical or abruptly slanting fissure have been completed,

No. 1 — Houseleeks and other plants growing sideways in upright fissures.

number of *Primulas*, and scores of other varieties, to say nothing of choice *Ferns*, for all of which no better place could possibly be found. But if these abruptly sloping fissures occur on the sunny side, we may choose from a legion of varieties which would be suitable to fill them to advantage, especially plants having their leaves arranged in the shape of a rosette. We have neat kinds of *Sedums*, *Saxifrages* and *Sempervivums* by the hundred, and the illustration (No. 1) shows *Houseleeks* and other plants luxuriating in such a position; we have *Androsace sarmentosa*, *Umbilicus chrysanthus* and *U. spinosus*, the lovely varieties of *Edraianthus*, many dwarf *Dianthus*es and an abund-

it would be a step in the right direction to embellish such fissures with suitable plants far more extensively than has hitherto been the case. Care must, of course, be taken, especially in the select part of the rock garden, to choose only such varieties as are not likely to become too crowded, but which will flourish in the same position for years without injury to each other.

When constructing a rock garden, I make it a practice to leave all upright or abruptly sloping crevices open till the time of planting, when the filling-up might be done in a way suited to the special requirements of the plants used. An exception is made with places which would be

all projecting small stones should be driven in with a hammer until they are flush with the larger stones and the whole appears like a mass of solid rock.

That after planting a good watering should be given, and that this must not be performed during bright sunshine are rules of such an elementary character that not even the most inexperienced amateur is likely to make a mistake in that direction. F. W. MEYER.

Exeter.

(To be continued.)

ORCHIDS.

ONCIDIUM LOXENSE.

THIS has only been introduced once in a living state, and that was by Mr. Sander, who received some plants from Edward Klaboch about ten years since. I do not think it has ever before or since been imported alive, so that "H. E." may take it for granted it is by no means a common plant. It is said to make a branching panicle of flowers upwards of 12 feet in length, although I do not think it has produced one in this country more than 7 feet long. The plant was first named by Lindley many years ago, and he includes it in the section *microchilum*, or small-lipped species. This plant, although it agrees with the small-lipped section in its habit of growth, by no means depends for its beauty upon its sepals and petals, for it has a large and handsome lip. I have seen but three plants of this species in bloom, but all three have been different varieties, differing principally in the intensity of colour in the lip. A flower from the late Mr. Wyatt's collection before it was dispersed was by far the richest and best I have seen, the sepals having a greenish-yellow ground, barred transversely with brown; the petals rich chocolate, saving the extreme tips, which were of a fine rich yellow; the lip large, thick, and fleshy in texture, and rich deep golden yellow, dotted with red at its base. The other plants had paler coloured lips and less bright sepals and petals, so that though the plant appears to be somewhat restricted in its distribution, there does not appear to be any want of variety. It comes from the neighbourhood of Loxa, in Ecuador, and grows at from 6000 feet to 9000 feet altitude in the mountains, so that it will thrive well in the *Odontoglossum* house. It does not require any rest by drying, although much less water is necessary in the winter season, but at all times the water should be kept from the young growths.

WM. HUGH GOWER.

Calanthe colorans.—"J. P." sends this for a name. It is one of the evergreen section, and appears to be very nearly allied to *C. veratrifolia*, from which species I at once distinguish it by the yellow crests of the lip and by the blade of the lip, which changes to an ochrous colour with age, characters which *C. veratrifolia* is quite devoid of. Like *C. veratrifolia*, it is suitable for growing in a mixed stove with other ornamental-leaved plants. *C. colorans* likes shade, and to be potted in a mixture of loam and peat with plenty of root room. At this season of the year its pure white flowers are very telling. I think this is still a rare plant in collections.—G.

Aerides Lawrenceæ.—I have just received a very fine spike of this, which was named in honour of Lady Lawrence, of Burford Lodge. The plant from which the flowers sent were cut is carrying four other spikes, and in this state it must present

quite a gorgeous appearance with its enormous wax-like fragrant flowers of a pure white, tipped with rich amethyst-purple, having the spur tinged with green at the tip. It is just ten years ago since this plant was introduced from the Philippine Islands by Mr. Sander, and we are told that *Phalæopsis Sanderiana* and *Vanda Sanderiana* are found on the same tree as the plant here referred to.—W.

Catasetum Bungeorothi Pottsonianum.—A flower of this beautiful variety of this fine species comes to hand from M. Linden, of Brussels. The sepals are white, faintly dotted with rose, the broader petals being suffused for about a third of their length from the tips with clear rose and profusely dotted with the same colour over their entire surface. The large ivory-white lip is stained with orange at the mouth of the cavity of the spur, and dotted with rose colour in the centre. It is a remarkably handsome and a rare variety, well deserving the attention of growers of these plants.—G.

Cattleya O'Brieniana.—This is a beautiful flower. Having a flower before me sent by Mr. Sander, of St. Albans, who first imported the plant, I am enabled to see its beauties under more favourable circumstances. At first sight the bloom resembles a good variety of *Cattleya Lodigesi*. It measures upwards of 4 inches across, the sepals and petals being of a beautiful soft satiny rose; lip three-lobed, the side lobes white, tinged with satiny rose at the rounded tips, front lobe white, marked near the end with the same soft colour as the petals, and veined with bright rosy purple.—G.

Oncidium Jonesianum.—A fine spike of this very attractive species comes from Mr. Sander, of St. Albans, who says, "We have a fine lot of this species flowering now." It is one of the most beautiful and showiest species in the genus, forming long racemes of flowers, which are individually upwards of 2 inches across, the sepals and petals large and broad, creamy white, profusely spotted with bright chestnut; lip three-lobed, the side lobes having an auricle of golden yellow on each side of the upper part, the lower rounded portion being white, dotted with chestnut; the broadly oblong blade is pure white, with a few scattered dots of chestnut.—W.

Stanhopea platyceras.—I am in receipt of a letter from Mr. Lidderdale, of Berkhamsted, telling me that seeing I had stated in an article in THE GARDEN recently that I knew of but one plant of this species in the country, he had two coming into flower in his collection and inviting me down to see them. On account of my absence from home I could not avail myself of the opportunity to renew my acquaintance with this fine broad-horned species, which was introduced from New Grenada by the Messrs. Low, of Clapton, nearly thirty years ago. I am glad to find this genus increasing in popularity with the various growers of Orchids in this country.—W.

Catasetum macrocarpum.—"H. C. T." sends a remarkably handsome form of this Orchid for a name. This plant has several names, amongst them being *C. Claveringi* and *tridentatum*. Whether these have been given to various forms or not I cannot say, but they are accepted as synonyms of *C. macrocarpum*, and so I give them here. The flower is large, the sepals and petals large, having a ground colour of greenish yellow, almost entirely covered with bright chocolate-brown; lip large, bright golden yellow on the outside, the inside spotted with reddish crimson; the point of the spur of the lip on the outside tipped with green. No wonder these plants are again coming into favour, for "H. C. T." says he has seventeen of these gay flowers open or opening.—H.

Dendrobium Phalæopsis.—"R. F." sends me some flowers which he says are from a plant imported before the name *Schroederianum* was ever thought of for this species, asking what I think of them. The sepals and petals are of a warm purple, and the lip of a deep rosy purple veined with deep crimson. It is a very beautiful form of the species, but for size of bloom, as I have seen the

variety called *Schroederianum* growing with Mr. Sander, the flowers now before me will bear no comparison. Mr. Cypher, of Cheltenham, also told me some time ago that he had the plant with growths much finer than it makes in its native country, so that we may expect something good later on.—G.

SHORT NOTES.—ORCHIDS.

Habenaria carnea, which reminds one in general expression of *H. militaris*, is in flower in Messrs. Sander's nursery at St. Albans. The flowers are much larger, however, than those of the brilliant scarlet *H. militaris* and of a very delicate flesh colour.

Catasetum cernuum.—"R. C. F." sends me a flower of this species, saying it resembles that of *C. Christyanum*, which has the sepals and petals deep chocolate-brown and a purple fringe to the lip. In *C. cernuum* the flowers are green, spotted with purple. I have had this species with as many as twelve flowers on a spike, and I have no doubt my friend's plant is very interesting with three spikes of bloom, although it is not one of the showiest kinds.—G.

Odontoglossum grande.—F. Wilkinson, of The Gardens, Highlands, Minchinhampton, sends me a grand spike of this plant having eight of its large flowers upon the scape. I think I have seen the same number upon one or two occasions before, but it is not usual by any means. I have had it with five and six blooms on a scape, but if we could perpetuate such a grand free-flowering variety as that which Mr. Wilkinson has, it would be a decided acquisition.—W. H. G.

Masdevallia Harryana armeniaca.—From Mr. Seeger, of the Orchid Nurseries, Dulwich, come several varieties of this fine plant, but the form here noted strikes me as being the most noteworthy amongst the whole lot. The flower is of good size and shape, having the points of the lower petals turned inwards, the colour being a beautiful shade of deep rich apricot with streaks of fiery red, the throat being bright light yellow. What a pity the flowers of these plants do not last longer in water when they are cut.—W. H. G.

THE FRUIT CROPS.

NORTHERN.

Newton Hall, near Chester.—The fruit crop in this neighbourhood is very satisfactory so far. Strawberries were very good, but very soon over. Raspberries and Red Currants very good. Gooseberries were abundant; not quite so large this year, but very good. Apples Keswick Codlin and Lord Suffield are doing well. Some trees of the late sorts are better than others. *Mère de Ménage*, Potts' and Dumelow's Seedling are carrying good crops. I have just seen two trees of the *Jargonelle* very heavily laden with fine fruit. Other sorts are very good here, especially *Marie Louise*. Damsons are not so heavy this year as I have seen them; the trees bloomed well and set their fruit, but most of it dropped off. Plums were blighted a little in places, but the *Victoria* seems to be the heaviest cropper. I have not noticed so many green and black fly or caterpillars about this year. Roses here have been very clean.

Vegetables have done well with the exception of Onions and Cauliflowers. Onions were troubled very much with the maggot. My ground is very heavy, but it is trenched and liberally manured, and the season has suited it well. Some of the Onions measure 10 inches in circumference, and altogether the best crop I have had. Peas were very good, not quite so tall, and coming in very quick. Scarlet Runners are doing well with a little attention as regards water and mulching. Carrots are doing well. Potatoes are looking well. The early sorts were very clean and bright skinned

and of good flavour. No sign of disease.—R. WAKEFIELD.

Wythenshawe, Northenden.—Apple trees flowered most profusely, and the weather being favourable, there was an abundant set of fruit. A large proportion of it has prematurely fallen, which is no doubt attributable to a deficiency of moisture at the roots. There is, however, sufficient left on the trees to form a good crop. Lord Suffield, Cellini, Keswick Codlin, Wareham Russet, Alfriston, Lewis's Incomparable, Old Hawthornden, Dame-low's Seedling, Stirling Castle, Lord Grosvenor, Grenadier, Lane's Prince Albert and Greenup's Pippin are bearing the heaviest crops of the culinary sorts. Summer Thorle, Ribston Pippin, Irish Peach, King of the Pippins, Cox's Orange Pippin and Sturmer Pippin are the best of the dessert kinds. There was a great deficiency of Pear bloom both here and in this district generally. This applies to both wall trained trees and standards. Some sorts, such as Beurré d'Amanlis, Citron des Carnes, Williams' Bon Chrétien, Louise Bonne of Jersey, Green Chisel, Beurré Superfin, Autumn Nelis and Autumn Bergamot flowered freely and are now bearing a fair crop; there is, however, a scarcity of the later and most valuable sorts. Casting of the fruit has not been so prevalent amongst Pears as Apples, except in the early stages of growth. Cherries, both dessert and cooking kinds, have been abundant. I have never seen better crops nor finer fruit on standard Morellos than this year. Plums and Damsons were one sheet of bloom and the fruit set very freely, but owing to the scarcity of rain to wash the foliage and moisten the soil, the trees were attacked by aphid, which has seriously crippled the young growth and caused a good deal of the fruit to drop off. Gooseberries were a very heavy crop. Owing to that fact and the dryness of the soil, they have been smaller than usual. They were badly attacked by aphid, and in some instances by caterpillars, which have given some trouble to eradicate. Currants, both Black and Red, have been very plentiful, and in moist heavy land the individual fruits have been of large size. Raspberries are a very good crop, but generally of small size, except the earliest fruits. Strawberries did not flower so freely as they sometimes do, but there was sufficient to have produced a good crop had the season been favourable to their growth. On heavy retentive land the first fruits swelled to an average size, but the later ones were much smaller than usual. On light sandy soils, which quickly gave off the moisture, not only the fruit, but also the leaves were very much shrivelled. To anyone who might be in doubt as to which was the most suitable kind of land for Strawberry culture, he would have an object lesson this season that would be most convincing. All small fruits, except such as were grown in specially favourable situations, have been below the average size, but none of them have suffered so much in this respect as Strawberries. There have, however, been two gratifying circumstances, namely, that the fruit was excellent in flavour and that there has been comparatively little loss from damping off, facts which, in my estimation, more than counterbalance any deficiency in quantity.

The vegetable crops, considering the dry weather, are looking remarkably well. A good many Cauliflower plants have been destroyed by maggots attacking the roots, and Celery is not so large as it usually is at this time of year. Potatoes never looked better, and the earlier sorts are yielding most satisfactory crops of well-flavoured tubers. Our total rainfall for the first six months of the year was 8.44 inches; the average for the same period of the last twelve years 12.95 inches.—W. NEILD.

Aldin Grange, Durham.—Here in the north the drought did not affect us as it did in the south. The wonderfully fine spring gave us an abundant set of almost all kinds of fruit indoors and out. Strawberries were a good crop. Raspberries unusually abundant; also Gooseberries and Currants. Apples and Pears are quite above the average, and in most cases a heavy crop. Jargonelle Pears are as large now as I have some-

times seen them in September. Altogether it is one of the best seasons we have had for many years, a light hay crop being about the only thing we have to complain of.—W. A. JENKINS.

Seaham Hall, Co. Durham.—The rainfall has been over 7 inches this year. Bush fruit is about the average. Strawberries suffered the most, and part of the Apple crop dropped owing to the dry weather. The Codlin sorts have a fair crop, but others are poor. Pears, especially the Jargonelle, have a good crop. Cherries suffered. Peaches are not grown here, as they do not ripen.

Potatoes look very promising, but lately I found several diseased. The vegetables look well, especially the Peas, but Carrots have the grub. Field Potatoes promising.—R. DRAPER.

Underley, Kirkby Lonsdale.—Bearing in mind the wet sunless year of 1892 and severe winter with us, we entered the present year with rather a gloomy forecast. February was a very wet month; then March brought glorious weather, spring coming in with leaps and bounds, giving every promise of an early season. There was a remarkable absence of frost. Strawberries began flowering in April. Some varieties did not set well, but on the whole we had a grand crop, which I account for by the common sense system of management of keeping the spade from among the roots and mulching early. We commenced the season out doors the first week in June with that excellent early variety John Ruskin, then came Sir Harry, Dr. Hogg (a grand old sort), Sir J. Paxton, and lastly Oxonian. Noble is a failure with us. Apples are a splendid crop, some varieties bearing that have not had any on for years. Amongst the constant bearers I must mention Keswick Codlin, Northern Greening, also New Northern Greening, an improvement, Annie Elizabeth, King of the Pippins, Lord Suffield, Stirling Castle and Fearn's Pippin. This year Golden Noble, Grenadier, Ecklinville and Hawthornden are bearing well. The fruits are larger now than they were last year in autumn. Pears on walls are a light crop; they were much infested with caterpillar, which caused a lot of hand-picking. Marie Louise does well. Plums Victoria and Kirke's Green Gage on walls an average crop. Standards are a failure owing to bullfinches taking the buds. Peaches under a case are a good crop, particularly Early York, Hale's Early, and Princess Dagmar, while Lord Napier Nectarine is also good. Cherries a good crop. Bush fruits good and clean. Gooseberries a heavy crop, especially Whinham's Industry and Warrington. The caterpillar was a pest, but got rid of with persistent pickings and dustings of lime.

Vegetables generally have done well. Cauliflowers are our biggest failure, so many blind ones. Onions transplanted early in March are a fine crop. Peas have done well; William I. sown in February was ready the last week in May, quickly followed by Jubilee. Early Potatoes did well, and late ones look healthy. Everything is a month earlier than usual; the much-needed rain came at the end of June, and crops have improved amazingly. Ours is a light gravelly soil.—W. A. MILLER.

Abney Hall, Cheadle.—As regards Apples and Pears, they are first-rate. As to Apples, for a week or two they have been at this early season for the district fit to use for tarts, and it is a great relief to the trees to have the fruit thinned, as those left are swelling up finely after the rains. Judging from memory, it used to be about the first or second week in August before we began thinning the Apples, so we are about a month earlier this year. As regards Plums, the crop is not so heavy, and the dry, hot weather has favoured the attack of aphid. The Czar on the wall, however, is now almost ripe. Small fruits upon the whole have been good. Gooseberries are the heaviest crop I have yet seen in this place, but, owing to the dry weather, the red spider has been very hard on some of the bushes. Where the ground was poor the spider was worst, and where the bushes had a good top-dressing of manure the spider has had least power and the fruit has been

best. Of Strawberries we have had fine fruit, and we still grow President for a main-crop. There is nothing, I find, like young runners for producing fine fruit.

In reference to vegetable crops I am able to report favourably. To begin with, and it is a good item, we never had better Peas, nor so early. The earliest sorts were William I. and American Wonder. The former is the best; still, under certain circumstances, the latter has some good points in its favour. For instance, early in the year when sparrows devour the "Pea green" whenever they can get at it, American Wonder could be started, as we did it, under glass. I planted it out, staked it with small sticks, and then threw a net over the bed, which kept the birds off till the pods were ready to gather. Our best main-crop Pea is Ne Plus Ultra, and no Peas needed to have done better than ours. On the main stems I have counted as many as twenty to twenty-four pods, not counting the laterals, which had on them as many again. On good ground with tall sticks and rows 6 feet apart they crop splendidly, and when on the table they are first-rate. Cauliflowers have not done quite so well. The dry, hot weather has favoured grub at the root, and the heads have not been so good. Potatoes have been early and good. We got Early Puritan on May 29 from the open ground, which is about a fortnight earlier than usual here for the first dish.—ROBERT MACKELLAR.

Caldy Manor, West Kirby, Cheshire.—The sub-soil of this district consists chiefly of the red sandstone, very porous, hence the soil is very light, consequently the exceptionally dry spring and summer have been very much against the cultivator in this neighbourhood, especially so with regard to small fruits. Apples and Cherries are the only crops that are above the average. Trees are making good healthy growth. Plums a light crop. Trees on walls, having been well seen to with pump and hose, are clean and making good growths, but in orchards, where time cannot be given to them, the trees present a miserable appearance, all growth being checked by green-fly. Pears light crop, but good in quality; trees vigorous and commenced to grow very early in the season; equally so in orchard and on walls. Figs average crop; trees very healthy. Peaches consist of young trees only nine months planted, consequently not in bearing yet out of doors. Raspberries average crop, good in quality, plants vigorous, making unusually long growths. Gooseberries not an average crop and fruit small; trees attacked with red spider and green-fly; caterpillars appeared very early and required strict attention to keep them under. Black Currants a complete failure. Trees and crops looked remarkably well in spring, fruit setting and swelling to the size of small Peas, then dropping off, with many of the leaves also. Red Currants light crop, poor in quality; trees attacked with fly. Strawberries: Noble exceptionally heavy crop, large in size and of good flavour, which this variety generally lacks. President and Vicomtesse Héricart de Thury fair crop, the latter small in size. Sir Charles Napier and Sir Joseph Paxton almost failures, all treated the same, mulched and well supplied with water from hose pipe. The first dish gathered from open break on May 25, variety Noble, being one month earlier than in 1892.

The season of 1893 will be long remembered here for the early dates on which the first dish of each kind of vegetable was gathered for the table, and for the short time many of them remained in good condition for use. Peas were excellent the early part of the season, especially so Exonian, Duke of Albany, and Telephone, and gave good returns up to the end of June. All, about 2 feet shorter than they usually are, came into bearing much sooner, and did not give the quantity nor last so long as they do in ordinary seasons. The very hot sun of July brought thrips in its train, and Peas in bearing at present are infested with them. The only one variety that is free of them and in a healthy condition is Autocrat, which promises to be an excellent dry-weather Pea. I may state that the seed was sown in prepared

trenches (much in the same way as for Celery), mulched, but not watered. Beans, kidney, are doing remarkably well, bearing enormous crops, especially Smythe's Hybrid, beyond anything I have seen. Runners are also promising well, just coming into bearing. Early Broad Beans did well, but are now attacked with thrips and present a miserable appearance. Early Potatoes were of excellent quality, but the crop was light and many small tubers; second earlies are also small and good, but the late crop promises well since the rain on the 8th and 9th ult., and we look forward to good crops free from disease, which has not appeared so far. Marrows, Tomatoes, and ridge Cucumbers growing and fruiting well. Turnips, Spinach, and Radishes are very unsatisfactory crops in our light soil this season; Onions also disappointing, being attacked by the Onion fly. Cabbage an excellent early crop, much appreciated because of its being so early. Cauliflowers not satisfactory, many of the plants dying from the attacks of the fungus that is so often troublesome in light soils. Broccoli, Brussels Sprouts, and other winter crops are looking well since the rain. Carrots, Beetroot, Parsnips, &c., looking well. Asparagus was early, but it is a crop that does not grow well here from the effects of the very high winds we get off the Irish sea.—WM. NEISH.

Appleby Castle Gardens, Appleby.—Apples are a very good crop, and of large size for the time of year. Pears very poor. Plums good crops (on the walls some trees suffered when in full bloom with the 12° of frost we had one night); upon the whole they are good. Apricots and Peaches poor on the open wall. Currants, Gooseberries and Raspberries very heavy crops. I have not seen such crops for many years. Strawberries very poor, almost burned up with the dry weather we had.

Early Cauliflowers suffered very much from the exceptional season through which we have passed. The later crops are good; all other vegetables are looking very well. Peas and Potatoes are especially good.—DAVID LESLIE.

Warter Priory, East Yorkshire.—Considering the long drought we have had here, the fruit crops are fairly good, and quite a month earlier than last year. Apples, cooking kinds especially, are a good average crop; dessert kinds rather below average, but fruit very fine. Pears fairly good average, Burrell Giffard and Jargonelle being the best; these two kinds are remarkably good. Apricots and Plums are very good indeed, and required a good deal of thinning. All kinds of bush fruits a good average crop and very fine, especially Black Currants. Strawberries average crop, but soon over. Morello Cherries good average; no dessert kinds grown outdoors.

Vegetables have been almost a failure here, with the exception of Potatoes, which are better than usual and free from disease at present. Cauliflowers and Carrots a total failure. Onions are growing now since the rain, but at one time they looked very bad. Shallots very bad, full of grub. Peas, early kinds very good, but had it not been for one good row of Sharp's Queen our main crop might have been counted a failure, the other kinds being very poor. Has any reader of THE GARDEN found this variety do better than others this dry season?—A. F. PIKE.

Donisthorpe House, Moortown, Leeds.—Strawberries, Raspberries, and Gooseberries heavy crops. Plums, Apples, and Pears light crops.

Vegetables of all kinds extremely good. We have not suffered from the extreme drought as other parts of the country have done. In this garden we suffered very little, from the fact that we manure the land heavily with horse manure, no cow manure, except as top-dressing to Strawberries and Raspberries, being given, and we take care it is in a moist condition when used.—S. WHITE.

Crofton Hall, Wakefield.—We have a heavy crop of Apples, Keswick Codlin, Lord Suffield, Old Cockpit, and Emperor Alexander being very heavily laden; other sorts good crops. Pears a fair crop. Plums are an excellent crop, especially on walls. Gooseberries have been an enormous

crop, and other bush fruits have done well. Strawberries were a poor crop owing to the drought. I think this the best fruit year in this district since 1887.—CHARLES WATTS.

Cusworth Park, Doncaster.—Considering the dry spring (we had three months without any rain), our garden looks well. Apricots a good crop. Peaches and Nectarines a good crop. I gathered first dish of Peaches from open wall on July 7. Plums and Pears very heavy crops on both walls and standards. Apples very heavy crop. Cherries moderate. Small fruits good crops, except Black Currants, which were only light. Strawberries a good crop. Walnuts very heavy crop; Filberts and Cobs good.

Vegetables of every description are good. We had to water both trees and crops every day in the spring, or we should have had quite a failure.—G. A. KEYWOOD.

Aldenharn Park, Bridgnorth, Salop.—The fruit crop in this district taken on the whole is the best that I have seen for the last sixteen years. Here all fruits are as near as possible a month earlier than in any previous year. Apricots were very plentiful, and were all gathered by the end of July. This season, strange to say, I have not lost one branch, not even from the Moorpark. Peaches, Plums, and Nectarines are good and ripening well. Strawberries were much better than usual, especially Noble. Gooseberries and Currants bore heavy crops, but towards the end of the season the bushes were badly attacked by caterpillar and red spider, which I fear will be against their well-doing for another season. Apples and Pears when in bloom looked more promising, but as the fruit was setting, dry frosts and cold winds at night caused many of the young fruit to drop off, and most of the trees (especially where exposed) looked brown and sickly. The down-pour of rain which fell on June 14, though only falling for seventy-five minutes, added 2.08 inches to the rainfall of that month. This seemed to thoroughly cleanse the trees, and they are now looking healthy, and bearing in most cases good average crops. Morello Cherries are finer than I ever remember, but the wasps have taken full possession, and I fear will soon shorten the supply. The Morello, when it can remain on the tree till it becomes almost black, makes a very handsome dish for dessert, and is much liked.

Vegetables in general are good with the exception of late Peas, which are badly affected with mildew. Potatoes in many places are showing signs of disease.—F. CANNING.

Chetwynd Park, Newport, Salop.—The fruit crop generally is under average. The soil is very light and sandy in this district; consequently this most exceptionally dry season has been very trying. Small fruits generally have been very good. Strawberries suffered most, early ones burnt up, later ones good. Gooseberries lost a good deal of foliage from spider, but Currants a heavy crop and bushes healthy. Apples and Pears much under average, after a most promising blossom. The trees are all looking healthy and clean now, but were much infested with caterpillar early in the season. Plums only moderate; Victoria, Early Orleans, and Gages are the best. Apricots a good average crop. Everything has been quite a month earlier.

Kitchen garden crops are looking well now, but I have had great losses among spring-sown Cauliflowers, and Peas have not filled well.—N. SILVERWOOD.

Teddesley Park, Penkridge, Staffs.—The Apple crop in this part of the country is very variable, some kinds only half a crop, while others are a failure. Keswick Codlin, Lord Suffield, Cellini and King of the Pippins are heavily laden. All trees bloomed splendidly, but cold, dry easterly winds greatly reduced the fruit prospects. Pears are a light crop. Plums are a heavy crop, so much so that they require thinning. Peaches and Nectarines a poor crop. Early Beatrice has been the best. Apricots good. Strawberries a good crop and of fair quality. Raspberries good, but small, owing to want of rain. Gooseberries and

Red Currants a heavy crop, though somewhat small. Black Currants fair—a very short season for small fruits. Morello Cherries fair crop, but they dropped badly when stoning. Damsons under average. Walnuts a poor crop.

All vegetables have suffered more or less from the dry season. Cauliflowers especially have been very poor. Peas have stood fairly well here, having been grown in a cooler part of the garden. Runner Beans have dropped a great many of the first blooms. Early Potatoes are turning out better than was expected. Late Potatoes are looking remarkably well with no sign of disease.—F. CLARK.

Kirklevington Hall, Yarm, Yorks.—The fruit crops in this neighbourhood are very good with the exception of Strawberries, which suffered from the drought. Apples and Pears are a very good crop. Plums very heavy. Cherries above average. Gooseberries, Black and White Currants and Raspberries are very fine and heavy crops. Apricots are thin, but good in quality.

All vegetable crops are as good as I could wish, and three weeks earlier than usual.—ALEXANDER CUNNINGHAM.

Combermere Abbey, Whitchurch, Salop.—Small bush fruit, such as Currants (Black and Red), Gooseberries, and Raspberries, in this garden have been very heavy crops and of good size. Apples, on the whole, very good; Lord Suffield, Ecklinville Seedling, New Hawthornden, Stirling Castle, Ribston Pippin, Cox's Orange Pippin, and several others very heavy and finer than usual at this time. Apricots on walls, Morello Cherries, and Plums tremendous crops. Pears good on walls, but rather smaller than usual in the borders through a long spell of dry weather. Damsons here are very scarce, but I believe the crop in the neighbourhood is fair, but not up to the average. Apples in orchards I hear are small, especially on old trees.

Vegetables have been scarce and of poor quality in this neighbourhood.—N. E. OWEN.

Greystoke Castle, Penrith.—Apples, Plums, Cherries, Gooseberries, and Raspberries very good crops. Strawberries and Pears medium crop. Inside fruit, such as Grapes, Peaches, and Nectarines, extra good. Figs medium crop.

Vegetables are remarkably good in this district with the exception of Onions, which seem to be quite a failure.—CHAS. MILNE.

Burton Constable, Hull.—Apples average, good. Pears under. Plums good and plentiful. Cherries over. Peaches and Apricots over average and good. Strawberries heavy crop, but the dry weather made a very short season. Small fruits average. Nuts average. The long-continued drought very seriously affected all small fruits except Gooseberries. The promise was very good for Raspberries, but only about one-tenth ripened. Apples have not looked so good for years, or the trees so clean and healthy.

Potatoes are splendid, both early and late, with no appearance of disease.—THOS. LAMBERT.

Waterdale, St. Helens.—Fruit and vegetables around this district are looking exceedingly well after such an exceptional season. No doubt we have benefited by our deep clay sub-soil. Peaches, Nectarines, and Apricots are not grown outside. Of Apples and Pears only a few suitable varieties are grown which are very satisfactory. Cherries cropped well, but small; Morellos very good. Plums and Damsons average crop. Strawberries with a good supply of water have been grand both in quantity and quality; the most suitable varieties are Vicomtesse Hélicart de Thury, President, and Sir Joseph Paxton. Red, White, and Black Currants had plenty of fruit on, but poor in quality, being overrun with spider and fly. Gooseberries the same. Raspberries plentiful and good where a supply of water was at hand, but otherwise poor.

Vegetables all round are very satisfactory, particularly so where the system of deep cultivation is carried out. Potatoes are very largely grown, the early sorts being good both in quantity and quality, but small and free from disease. The rain

just came in time for the main crops, and they have every appearance of producing satisfactory results.—JAMES SMITH.

NOTES OF THE WEEK.

Cuphea platycentra appears to have been overshadowed by showier things for summer bedding, but it is a very charming plant, especially when used as a groundwork, the bed relieved with taller things. The *Cuphea* is in full beauty now, each little bushy plant smothered with small vermilion coloured tubular flowers. Cuttings strike readily in autumn or spring, and the plants may be easily raised in the latter season. Against many plants used in summer bedding it is quiet, but when disposed as mentioned it has a very pleasing effect.

Rose Comtesse Riza du Parc.—A large bed of this variety is very beautiful at Kew. It is one of the finest of the Tea Roses, the flowers being produced in a large head, rose-salmon in colour, touched with white, whilst when expanded they are white, with rosy margins, so to speak, to the petals. The leafage is robust, abundant, and the plant of vigorous constitution. Even at this comparatively late date for Roses, the plants are in full bloom, and likely to continue so whilst the weather remains open.

Arctotis reptans is a very old garden plant, but one does not see much of it. It is in bloom in the herbaceous ground at Kew, and is sufficiently attractive at this season to justify a note. The plant was introduced from the Cape in 1795, and bears very large flowers, orange in colour, and like those of a magnified Marigold, the shoots creeping or trailing on the surface of the soil, whilst the leafage is of a glaucous shade. Its bright aspect in mid-September suggested the thought that such a plant might be used for edging large beds and as a groundwork to beds filled with other things. The drought seems to have had little effect upon it—just the kind of plant one requires in London parks.

Plumeria lutea is in bloom in the Palm house at Kew. It is a noble plant, but unfortunately not very free-flowering, although when in full beauty it repays for careful culture. The specimen at Kew is several feet in height, the leaves large, very handsome, and rich green, set off with lighter coloured veins. The flowers are borne in a close head and a little over 2½ inches across, of flattish form and tender colour, the segments white, touched at the margin with rose, and the centre is rich yellow. It will scent a large house, the fragrance not unlike that of the Cowslip, but more overpowering. *P. lutea* is quite one of the best of the genus, and was introduced from Peru in 1815. Even when not in flower its leafage is sufficiently handsome to retain the plant in the stove.

Notes from Almondsbury.—Autumnal days after a hot summer are very delightful. Quaint heads emerge from the bare ground, and you discover the *Belladonna* is about to bloom after four years' waiting. *Zephyranthes candida* has a fair number of blooms; the bed is two years old. *Pan-cratium fragrans* is pushing up a huge scape, the second in two years. Other bulbs are in a very forward state—*Freesias* and *Cyclamens*, for instance, while *Chrysanthemums*, owing to the heat, are very backward with me. I cut down all my *Delphiniums* this year very early, and the amount of bloom now showing is very large. The large-flowered *Anomatheca cruenta* is doing very well. *Crocasmia aurea imperialis* I can do nothing with, whether in a pot or in the border, but nothing gives so great pleasure as *Funkia grandiflora sub-cordata* in my 9-inch pots. I think I shall have about 1400 blooms, as there are from six to eight spikes in each pot, and the fragrance is very delightful. Hardy plants of this race ought to be introduced into our villages, where a good thing is always appreciated. I can assure you we have got

beyond the stage of gigantic Dahlias and Sun-flowers, and a novelty is much sought after.—C. O. MILLS, *Almondsbury*.

Water Lilies and water rats.—"A. II." (p. 215), in writing of the enemies of Water Lilies, does not credit the voles or water rats with all the mischief of which they are capable. Growers of the new and fine hardy hybrid kinds will do well not to trust the rats too much in the neighbourhood of their plants, or they will assuredly attack the leaves as well as the flowers and soon do great damage. Here, where the common *Nymphaea alba* and the *Nuphar lutea* are plentiful enough to allow one to be amused by watching the work of these destructive little animals without fear of the plants being much affected by their attacks, I have seen them swim out to and pluck the leaves from the *Nymphaeas*, carrying them at once to the bank-side. The stem is bitten through about 6 inches from the leaf and is then held in the mouth in a position that keeps the leaf sheer out of the water. The rat then makes full speed to its destination, and as the animal swims deeply enough to be almost hidden, it is rather startling at first sight to see the leaf—sail-like—travelling swiftly over the surface of the water without any apparent means of locomotion. Amusement at the sight would, however, soon be turned to chagrin if this happened to some of the rare and expensive Lilies, so the rats had better be kept under as much as possible.—J. C. TALLACK.

Belladonna and Plantain Lilies.—Two of the successes of a year which has been none too prodigal of its favours are the *Belladonna Lily* and *Funkia grandiflora*, both of which plants are flowering with much greater freedom than I have ever before had them. The former especially is fine, many of the scapes carrying ten, and in one instance at least eleven flowers, and glorious flowers they are, showing that, in common with its near relative, the *Jacobean Lily* (*Amaryllis formosissima*), it thoroughly enjoys a good baking during the period that passes between the going of the leaves and the coming of the flowers. The flowers, too, are much earlier this year than they are usually. Last year they got spoilt by the 13° of frost registered on the morning of October 26. Very few hardy plants pay better than this for care taken in the selection of a suitable spot in which to plant. Close up to a south wall and with the soil raised slightly above the surrounding level, a full amount of sunshine and perfect freedom from drip, seem to be the conditions which suit it best; in fact, north of London it is useless to plant the bulbs under less favourable conditions than these. The *Funkia* succeeds with similar treatment and is well liked for the delicious scent of its flowers and its handsome foliage, which, however, is very liable to become disfigured by the attacks of slugs and especially of caterpillars, which are only found with difficulty, and probably not till they have done a lot of mischief.—J. C. TALLACK *Livermere Park, Bury St. Edmunds*.

SOCIETIES AND EXHIBITIONS.

ROYAL HORTICULTURAL SOCIETY.

SEPTEMBER 12.

AFTER the larger display, into which more energy was thrown, at the Agricultural Hall a fortnight back, it could hardly be expected that there would be a large exhibition on this occasion. What was lacking in quantity was, however, fully made up in quality. Orchids were decidedly better, being also shown in larger numbers than a fortnight ago. A show that lasts four days is too long for Orchids, hence the difference. *Cypripediums* in new hybrid varieties were numerous, and amongst these there were several choice and distinct acquisitions. In the floral section there was a beautiful display of autumnal Roses in great variety, constituting in the eyes of many much more interesting and instructive exhibits than when the monster flowers

are *en evidence* at the end of June and early in July. Other features here were the cut specimens of hardy flowers, including cut *Canas* from Chiswick, *Phloxes* from Cheshunt, and Dahlias from Swanley and elsewhere, all contributing to make a good display. Choice varieties of cut examples of the grand hybrid forms of the javanico-jasminiflorum group of *Rhododendrons* and *Streptocarpi* were also exhibited from Chelsea. There was also a very fine exhibit of tufted *Pansies*, marvellously fresh, from Rothesay; also a new race of single *Cactus Dahlias*. Fruit was shown in good quantity, and in every way excellent. Several individual dishes of Apples were all that one could desire. To all it was one of the heaviest day's work the fruit committee have had for a long time, in most cases a close scrutiny being absolutely necessary. Amongst vegetables, Onions and a few promising new Potatoes were the chief features. The lecture upon the *Pentstemon* and *Phlox* was well received, the remarks therein being practical and to the point. The small company present, however, points to the fact that many supporters are out of town.

Orchid Committee.

A first-class certificate was awarded to—

CYPRIPEDIUM APHRODITE (*C. Lawrenceanum* × *C. niveum*).—This is a remarkably fine hybrid, and must rank among the very best kinds yet raised, being so distinct. The flowers have the form of *C. niveum*, but the other parent has imparted so much additional vigour to the plant, the flowers being more of the size of *C. Lawrenceanum* with broad petals, the dorsal sepal also extra fine. The ground colour is that of *C. niveum* with faint spots and veinings of pale bronzy-purple and the plant bore a twin-flowered spike. From Messrs. Jas. Veitch and Sons.

Awards of merit were voted to—

LÆLIO-CATTLEYA EPICASTA (*C. Warscewiczii* × *L. pumila*).—A decided cross with flowers of the form of those of *L. pumila*, but larger and with the colour to a large extent of *C. Warscewiczii*, the lip being well marked and of a purplish crimson shade, the throat golden yellow on the inner part. From Messrs. Jas. Veitch and Sons.

LÆLIO-CATTLEYA NYSA (*C. Warscewiczii* × *L. crispa*).—This is an exceedingly choice hybrid, very distinct and unusually rich in its colouring; the flowers are large, the sepals being of a pale blush, suffused with lilac; the lip is, however, the distinguishing feature, being of a deep, velvety magenta colour and of large proportions, with the fringe of *L. crispa*. From Messrs. J. Veitch and Sons.

CYPRIPEDIUM LEONE (*C. insigne* Chantini × *C. callosum*).—A grand hybrid, bearing twin flowers on the spike and of fine proportions; the dorsal sepal is unusually long, at least 2½ inches, with a broad white margin, the other colouring being more after that of the last-named parent, brown and green shades predominating; growth very vigorous. From Mr. H. S. Leon, Bletchley Park.

CYPRIPEDIUM CENOSUPERBIENS (*C. cœnanthum* × *C. superbiens*).—With extraordinary large flowers, much larger than in *C. superbiens*, but with its outline, the colour, on the whole, partaking more of that of *C. cœnanthum*, the petals being dark, with darker spots; the pouch also large, likewise the dorsal sepal, this latter being striped and spotted in a distinct manner; one of the noblest of all the hybrids. From Sir Trevor Lawrence.

CYPRIPEDIUM CLOTHILDE MOENS.—This hybrid takes after *C. Leeanum* in form, being a cross between it and *C. Haynaldianum*. The foliage is somewhat erect; the petals spotted with lilac-purple. The spike bore three flowers; a distinct-looking variety. From Mons. Linden, L'Horticulture Internationale.

A silver Flora medal was awarded to Messrs. Sander and Co., St. Albans, for a group of choice kinds. This group included a grand example of *Aerides Lawrenceæ* with three extra fine spikes, long, and bearing large individual flowers. This is one of the finest, if not the finest of all the genus

Oncidium Jonesianum was represented by good examples of culture, freely flowered. Other good things were *Angrecom articulatum*, with medium-sized waxy white flowers, eighteen or more to the spike; *Miltonia Moreliana* with flowers of deep vinous purple; *Habenaria carnea*, certificated at the Agricultural Hall, *H. militaris*, and *Cattleya Gaskelliana alba*, a pure form with fine flowers. *Oncidium incurvum album*, *Lycaste Skinneri pulcherrima* and a few good *Cypripediums* were also included.

A silver Banksian medal was awarded to Messrs. Hugh Low and Co. for a prettily arranged group which included several plants of *Stanhopea Amesiana*, with large waxy white flowers (this might be termed a white form of *S. tigrina*). *Miltonia Roelziana* and the white variety were shown here, also *Cypripedium tonsum*, a pale yellowish green variety, delicate and beautiful. A singular plant was *Cypripedium Victoria Mariæ*, bearing small flowers on an extra stout spike, more curious than beautiful. *Cypripedium Schröderæ* and *Saccolabium Blumei* were also shown.

A bronze Banksian medal was awarded to Mr. R. J. Measures, Cambridge Lodge, Camberwell, for a collection of hybrid *Cypripediums* that included several distinct and novel forms—*C. Hebe*, after *C. Lawrenceanum*, with darker flowers and even more robust growth; *C. radiosum*, after *C. Spicerianum*; *C. Diana* and *C. picturatum*, each exhibiting signs of the same parentage; *C. Ganesa*, pale yellowish green with very glossy flowers; and *C. Schomburgkianum* (a species).

Other exhibits embraced several cut examples from Mr. Statter, Stand Hall, Manchester, of *Cattleyas*—*C. guttata Leopoldi* (Stand Hall var.), a dense spike of thirteen flowers, the colour unusually dark and freely spotted; *C. Statteriana*, a choice hybrid (cert. in 1892), after *C. aurea*, richly coloured; *C. Parthenia*, a light coloured hybrid with rosy lilac lip; *C. minuca*, another seedling, related to *C. Loddigesi*, but larger; *Lælia elegans* (Blenheim var.), a fine form; and *Cattleya Victoria Regina*, not remarkable for its beauty or size or habit of spike, or, in fact, for its colour; such a name should have been given to something better. Sir Trevor Lawrence, as usual, showed some choice things, *Cypripediums* being this time prominent. *C. conco-lawre*, paler than *C. Lawrenceanum*, with the form of *C. concolor*; *C. præstans glanduliferum*, a remarkably distinct variety with narrow petals, greenish yellow in colour, with bead-like spots of a dark shade, the dorsal sepal being striped with almost black lines on a whitish ground. Mr. S. J. Lutwyche, Beckenham, showed *Lycaste Skinneri* in bloom, one spike bearing two flowers—a vigorous example. Mr. Ingram, Elstead, Godalming, showed *Cypripedium L'Unique*, with small, but pretty flowers of novel form and colour; also *Cattleya Alexandra*, which is a form of *C. guttata*, or nearly allied to it. From the same source came *Cypripedium Adonis*, a hybrid between *C. hirsutissimum* and *C. Curtisi*, distinct in colour. Mr. Elliott, Christchurch, Hants, showed cut blooms of a fine form of *Cattleya Gaskelliana*, and the Hon. Mrs. Foley, Fordingbridge, a finely flowered plant of a *Cattleya* nearly related to *C. Trianae*, if not identical with it, the two spikes each having four flowers. Mr. N. C. Cookson, Oakwood, Wylam-on-Tyne, showed *Lælia Clive*, the seed parent of which was *C. Dowiana* crossed with the pollen of *L. præstans*; the flowers take after the latter in size and form, so also does the growth, the only exception being in the lip, which is large in proportion and resembles that of *C. Dowiana*. It is the result of the same cross as another hybrid named *Lælio-Cattleya Ingrami*, which, raised by Mr. Ingram, received a first-class certificate at the late Temple show.

Floral Committee.

No plant or flower received a first-class certificate on this occasion, but awards of merit were voted as follows to—

DAHLIA CANNELL'S GEM.—A new variety, with remarkably pretty flowers of medium size, and of a dark terra-cotta shade. From Messrs. Cannell and Sons.

SINGLE DAHLIAS.—*Phyllis*.—A light ground colour, suffused with lilac and marked with dark crimson blotches and stripes, very showy. *Demon*.—An intensely dark velvety maroon self, distinct and rich in colour. *M.C.C.*—A large flower, golden ground colour, striped and blotched with dark orange, a fine variety. *Golden Locks*.—A pale lemon-yellow self. All coming from Mr. T. W. Girdlestone, Sunningdale.

ROSE ADELINA MOREL (Noisette).—A lovely miniature Rose, quite a gem in its class, apparently profuse in flower, the colour a rich shade of apricot with lighter markings, beautiful for button-holes. From Messrs. Paul and Son.

PHLOX MOLIERE.—A pale rosy pink with lighter shading towards the centre and a dark eye; flowers large, distinct, and good. From Messrs. Paul and Son.

CANNA QUASIMODO.—A formidable rival to *Mme. Crozy*, of the same character, but of a lighter shade, the truss fine, the flowers large. From Messrs. Vilmorin, Paris.

A silver Flora medal was awarded to Messrs Paul and Son for a splendid display of hardy flowers, in which the cut Roses in bunches and the single trusses were unusually good for the autumn. The style of showing the decorative Roses in bunches by this firm is most commendable. A lovely plant included in this exhibit was the herbaceous *Clematis Davidiana*, with small pale porcelain-blue flowers; not unlike and of the size of *Hyacinth* blooms, and produced in small clusters close down to the axils of the leaves; the foliage is that of a true *Clematis*, but of more substance. Some good *Phloxes* were included here, as *Granville*, a large blush-white; *Michael Cervantes*, a light form with dark eye; *Henry Marger*, similar, but larger; *Auguste Riviere*, a dark salmon; and *Perle*, a pure white of good quality. Hardy border flowers were represented by *Montbretia crocosmiflora* and *M. Golden Sheaf* (a pale golden colour). *Senecio pulcher* in fine form, *Coreopsis lanceolata*, *Funkia subcordata grandiflora* (too long a name), a beautiful white variety; *Cyclamen hederifolium*, pale rosy mauve; and *C. h. album*, a white form, both lovely autumn flowers. *Crocus speciosus*, a pale lavender-blue variety; *Helianthus Maximilianus*, *Rudbeckia purpurea*, *Gaillardias*, *Asters*, and other *Helianthus* in variety were also included.

A silver Flora medal was awarded to Messrs. W. Paul and Son for a splendid display of autumnal Roses, an exhibit of a most instructive character; the flowers of all the popular kinds were of excellent quality and good colour, the best known sorts being drawn attention to by additional bunches stood between the boxes, a large number of which were staged. Would that such exhibits as those from Waltham and Cheshunt were more frequently seen. A silver Banksian medal was awarded to Messrs. Dobbie and Co., Rothesay, for a splendid exhibit of tufted Pansies put up in their characteristic style. The best of these were *Blue Cloud*, *Colleen Bawn*, *Duchess of Sutherland*, *Countess of Kintore*, *Hyacinth*, *Duchess of Fife*, *Goldfinch*, *Edina*, *Favourite*, *Archibald Grant*, *Dawn of Day*, *Bullion*, *Lemon Queen* and *White Duchess*. A fine strain of French Marigold was also shown in fine colour. A novelty in this exhibit was the break in single Dahlias, these being of true Cactus type, quite distinct from the ordinary form of singles. A silver Banksian medal was also awarded to Messrs. Cannell and Sons for an excellent exhibit of Cactus Dahlias, composed mostly of varieties raised by the firm; the best of these were *Emily Girdlestone*, *Miss Violet Morgan* (terra-cotta and yellow), *Mrs. Douglas*, *Duke of Clarence*, *Maid of Kent*, *Amphion*, *Ernest Cannell*, *Mrs. Keith*, *Bertha Mawley*, *Robert Cannell*, *Oban* (a dark Mrs. Douglas), *Lilacina*, a decorative variety, with lilac coloured flowers suffused with purple, and *Countess of Radnor*. A bronze Banksian medal was voted to Messrs. J. H. Crasp and Co., Clyne Valley Nurseries, near Swansea, for *Asters*, *Vallota purpurea* and *Celosias*.

Other exhibits comprised a splendid boxful of cut javanico-jasminiflorum *Rhododendrons*, hybrids raised at the Chelsea establishment of Messrs. Jas. Veitch and Sons, who never exhibited them in

finer condition than on this occasion, the trusses being of grand size, the flowers of rich and varied colours. Along with these was a boxful of newly-raised hybrid *Streptocarpus* (from seed sown in January last). These were in the colours most decided advances both in the light and dark kinds; the white grounds are perfectly pure, with well defined markings in the throat of each flower; the dark grounds show also the same distinctiveness and purity of colours. From the R.H.S. gardens at Chiswick, Mr. Barron brought up some of the best varieties of the new dwarf race of *Cannas* that are forming important features in the garden this season; the best of these were *Quasimodo* (certificated by the floral committee) *President Carnot*, *Jeanne Chartan*, and *Guillaume II*.

Fruit Committee.

There was a considerable quantity of fruit staged, several varieties of seedling Apples, Peaches, and a good collection of Onions from Chiswick Gardens.

First-class certificates were awarded to—

PLUM RIVERS' GOLDEN TRANSPARENT GAGE.—This is a roundish golden-yellow fruit, and a valuable addition to our late dessert Plums. The flesh is firm, juicy, and of splendid flavour. From Messrs. Rivers and Son, Sawbridgeworth.

ONION A 1.—This variety recently received three marks at Chiswick for its size and free cropping qualities, and six large bulbs were now sent to enable the committee to grant the award obtained at Chiswick. It is a large bulb, firm, of good shape, and more globular than other varieties. Sutton and Sons.

POTATO TRIUMPH.—This, a seedling from *Magnum Bonum*, is a splendid variety and heavy cropper, tubers large, white, somewhat oval in shape, and with rough skin, an excellent keeper. It received three marks at Chiswick both for cropping and good cooking qualities. Sutton and Sons.

POTATO WINDSOR CASTLE.—This variety also received a similar award at Chiswick. It has been largely grown, and may be termed a dwarf *Magnum Bonum*. The tubers are pebble-shaped, rather long, flesh white. It is a heavy cropper of splendid flavour. Sutton and Sons.

Awards of merit were given to—

GRAPE CAPE MUSCAT.—A variety of great merit, and though not shown in the best condition, some of the berries being decayed, it possesses considerable value. The berries are large, black, oval in shape, with a decided Muscat flavour. This should make a useful late variety when well grown. It was raised from Grapes received from the Cape. Mr. Weir, Acton Park Gardens, Wrexham.

PEACH DUCHESS OF YORK.—A large pale skinned freestone variety slightly tinged with red on the sunny side. It is a seedling between *Byron Nectarine* and *Lord Palmerston Peach*, but said to be earlier than the latter and to be a heavy cropper. The fruit staged was gathered from trees in a cool house. A dish of *Lord Palmerston* was also sent for comparison. From Mr. Divers, Ketton Hall.

APPLE BARTLETT'S GLORY.—A variety of great merit, somewhat like *Beauty of Bath* in shape and colour, but with rich flavour, firm flesh, and of nice appearance, stated to be in season from December to January. The fruits staged were in excellent condition for dessert, perhaps owing to the unusual season. From Messrs. Brown, nurserymen, Wells.

A very fine collection of Peas, Peaches, Plums, and Apples was staged by Messrs. Rivers. A few very fine varieties of unnamed seedling Peaches and Pears were sent. Some very fine *Lord Palmerston Peaches*, *Grand Duke Plums*, *Comte de Chambord*, *Lebrun*, *Fertility*, *Princess*, *Conference*, *Louise Bonne of Jersey*, and *Beurré Superfin Peas*, *Peasgood's Nonsuch*, *Flower of Herts*, *Cox's Orange*, and *Washington Apples* were also included (silver Knightian medal). Messrs. Laing and Sons, Forest Hill, staged a representative collection of hardy fruits, nearly 100 dishes. The best Apples were *New Hawthornden*, *Blenheim*, *Beauty of*

Kent, Gravenstein, Cellini, Emperor Alexander, Yorkshire Beauty, Peasgood's Nonsuch, and Fearn's Pippin. General Todtleben, Pitmaston, Brockworth Park, Beurré de l'Asomption, and St. Michael Pears were also good (silver Knightian medal). Mr. Payne, gardener to the Bishop of Bath and Wells, staged a grand dish of Peasgood's Nonsuch Apples grown on a south east wall. The tree was planted seven years ago, and the fruit was thinned to sixty-two. This was a remarkable exhibit, each fruit being very fine. It was stated none of the sixty-two fruit was under 1 lb. weight, those sent being nearer 2 lbs. (bronze Bonisian medal). A seedling Peach named Late Devonian was sent by Messrs. Veitch, Exeter, but too ripe. A couple of dishes of Barrington Peaches of excellent quality came from Mr. W. Miller, Ruxley Lodge Gardens, Esber. A box of Black Prince and Vicomtesse Héricart de Thury Strawberries (second crop) was sent by Mr. Slowgrove, Gutton Gardens, Reigate, also seven dishes of very good Pears, the best being Doyenné du Comice, B urré Diel and Doyenné Boussoch. Twelve dishes of Pears were sent by Mr. Bannister, Cote House Gardens, Westbury-on-Trym, the best being Durondeau, Pitmaston and Duchesse d'Angoulême. Three varieties of Melons grown in the open air (planted end of July) came from Dr. Emerson, Claringbold, Broadstairs; the fruits, though small, were of good flavour, showing the favourable season for experimenting with this fruit in the open. A very fine dish of Lane's Prince Albert Apple grown on a pyramid was sent by the Rev. J. H. Brown, Bedstone Rectory, Salop. Seedling Apples came from Miss Winckworth, Rochester, also from Miss Lever, Petersfield. Mr. A. Dean, Kingston, sent Shepperd's Seedling Apple. Apples named Monstrous Pippin came from Messrs. Brown, Wells; these were good specimens of Warner's King. Many of the Apples submitted to the committee were local kinds. Tomatoes were sent by Mr. Pitcher, Albury House, Surbiton. From the society's gardens were staged forty-six varieties of Onions grown in the open. Several of these received three marks recently at a meeting at Chiswick, the Southport Red Globe and Yellow Globe being specially noticed as good stocks. The White Southport Globe is useful for immediate use, and the Madeira Globe from Mons. Vilmorin is very fine. Prizetaker, a very fine variety from Messrs. Henderson, New York, is also a grand bulb and with good keeping qualities. Several varieties of Messrs. Deverill's noted types were staged, Cocoa-nut being very good. Messrs. Veitch, Chelsea, have a fine type in their Yellow Globe; this much resembles the Southport variety. Messrs. Carter's Hulborn Onion is of fine growth and very prolific. Messrs. Laxton, Bedford, have several varieties possessing great merits both in size and keeping properties.

The lecture on Pentstemons and Phloxes by Mr. J. Douglas was read by the assistant-secretary, the lecturer being unable to attend. He stated that the Pentstemons were most useful for the flower garden. Pentstemons are readily increased by cuttings, and this last mode of propagation is admirably adapted to obtain large blooms. They like a good deep soil, plenty of food in the way of decayed manure, and moisture during growth. The plants seed freely, and the seed-pods should be removed if not wanted, as they soon exhaust the plants if allowed to remain. The flowers are so readily fertilised by insect agency, that various colours are rapidly produced. But to get good flowers of perfect colour, size and substance combined, the florist does not trust to natural fertilisation, but selects those plants likely to give the best results. Plants are readily raised from seed by sowing in heat in February, pricking out the seedlings as soon as fit to handle into a warm bed, and gradually as growth increases hardening off and planting out in the open the first week in May. They will flower freely in the autumn if planted in rich soil and carefully tended. For herbaceous borders Pentstemons are specially adapted. He advised giving one stake to the centre growth, as this induced the side growths to make more progress and furnish a succession of strong blooming shoots.

The Pentstemon was of great value for cutting, and when used for large vases was most effective.

The Phlox is different from the Pentstemon on account of its hardiness, as it stands our winters uninjured. The lecturer referred to the various forms, their habit, and the great success obtained by selection. With so much crossing the varieties have become much mixed and not vigorous in all cases. With the older forms there are several drawbacks, such as smallness of bloom and want of vigour. Propagation is readily effected. Those who cannot get their stock from cuttings will find it best to divide in early spring, chopping the old stools into pieces and replanting in good soil. By this means varieties are secured that would be lost if raised from seed. Cuttings struck in a hot bed as advised for Pentstemons is the best mode of culture, as by this method specially good flowers are secured the following season. Cuttings struck in spring on a hotbed, choosing young shoots and planting out when hardened off, make good flowering plants by autumn. These also make specially fine pot plants for house decoration, and may be planted out afterwards. Phloxes are also secured from seed, and in such seasons as we have had this year seed is produced freely. This should be sown in February on a hotbed, planting out the seedlings in May 1 foot apart.

Mr. Wilks said that Pentstemons with him were hardy, but needed frequent propagation.

GARDENING AND FORESTRY EXHIBITION, EARL'S COURT.

SEPTEMBER 13 AND 14.

ONE of the best shows held at Earl's Court this season was that of Wednesday and Thursday last, when the chief exhibits were Dahlias, perennial Sunflowers, and fruit.

Dahlias.

The flowers were extremely fine, better even than at the Crystal Palace, and the colours remarkably pure. The largest class was for sixty show and fancy kinds, distinct, and the first prize was well won by Mr. Chas. Turner, who had exceptionally fine blooms, large, clear in colour, and even. We may point out that the best were Mrs. Gladstone, Glowworm, Mand Fellowes, Flag of Truce, Comedian, R. Dean, and Purple King. The blooms of Messrs. Keynes, Williams and Co., Salisbury, who were second, were smaller, but highly finished; whilst Mr. S. Mortimer, Swiss Nursery, Farnham, was a good third. Several competed, and the display was one of the best we have seen this season. The other class for show blooms open to nurserymen was that for twenty-four, distinct, in which the premier award was gained by Messrs. Saltmarsh and Son, Chelmsford, who had very creditable examples of well-known kinds, such as Harry Keith, T. J. Saltmarsh, Rev. J. Godday, Ethel Britton, R. T. Rawlings, and Prince of Denmark. The second place was secured by Mr. Arthur Rawlings, Old Church, Romford, Essex.

In the show section amateurs exhibited splendid flowers, and Mr. J. T. West, gardener to Mr. W. Keith, Cornwalls, Brentwood, was highly successful throughout the various classes. He was first for twenty-four show blooms, having smooth, remarkably well coloured flowers. We especially noticed as of merit Arthur Rawlings, R. T. Rawlings, Mr. Glasscock, Sunbeam, Lustrous, George Rawlings, Duchess of Albany, and Prince Bismarck. A very good second was Mr. T. Hobbs, Easton, Bristol; but in the other classes the flowers were conspicuously small. The best twelve came from Mr. J. G. Fowler, Glebelands, South Woodford, who had especially fine the lighter coloured flowers, as Mrs. Gladstone and Ethel Britton, whilst those from Mr. W. Hopkins, Bristol, were, if small, very neat and smooth.

One of the principal features of the show was the class for a collection of Dahlias, any types and arranged for effect. The finest arrangement came from Messrs. J. Cheal and Sons, Crawley, who had

a beautiful display, comprising all the leading kinds and many recent novelties. One wants, however, to see such a group at a distance to get the true effect of the various colours. A highly praiseworthy group was that from Messrs. Keynes, Williams and Co., who were second. The leading feature was an arrangement of cork bark, relieved with scarlet decorative Dahlias. Messrs. Paul and Son, Cheshunt, were a good third, but the flowers were small. The most interesting feature consisted of the Cactus Dahlias, and several superb collections were shown. The finest eighteen bunches were from Messrs. Keynes, Williams and Co., and such a lot it would be difficult to beat. Lists of varieties are of little practical value, but we mention the following true Cactus kinds, as they are worth cultivation: Gloriosa, brilliant crimson; Countess of Radnor, Bertha Mawley, Countess of Gosford, Sir Roger, a fine orange-scarlet kind; Apollo, scarlet; Lady Penzance, clear shiniog yellow; Delicata and Vulcan, deep crimson. This type looks remarkably handsome in bold bunches. Messrs. J. Cheal and Sons were placed second, and Messrs. J. Burrell and Co., Cambridge, third. In the amateurs' section the best nine bunches were from Mr. E. Brown, gardener to Mr. W. Morris, Oak Lodge, Horley, who had especially fine the variety Delicata, the true ideal of a Cactus Dahlia, being beautiful in shape and exquisite in colour, shining salmon-rose. The pompon section occupied much space. The chief class was for twenty-four bunches, and the first prize was awarded to Mr. C. Turner, who had very fine flowers, and we are pleased to see that this charming section is not getting spoilt by a desire, at one time prevalent, of getting the blooms as large as possible. Mr. Turner's collection included four novelties of merit—Irene is excellent, the flower white edged with crimson; Clarence, deep maroon; Captain Boyton, of a still darker shade; and Evelyn, scarlet. Messrs. J. Cheal and Sons were second. The beautifully fresh and clean coloured flowers from Mr. J. T. West won him the first prize in the amateurs' division for twelve bunches; the more important kind was Little Julia, a brilliant scarlet flower of great merit. Only one class was provided for single Dahlias, namely, for twelve bunches, and the first prize was won by Mr. T. W. Girdlestone, who had splendid flowers. Very fine were Yellow Satin, rich yellow; Pysche, buff, touched with red; Yellow Dwarf, Ruth, crimson; Demon, a superb variety, the colour intense maroon, set off with bright yellow stamens in the centre; and M.C.C., a large flower, orange with stripes of scarlet. We do not care greatly, however, for the striped flowers

Stove and greenhouse flowers were quite a leading feature. The collection of cut blooms, not less than ten varieties, from Mr. G. Wythes, gardener to the Duke of Northumberland, Syon House, was superb. We never remember to have seen a finer collection. The leading things were Hymenocallis macrostephana, Allamanda Hendersoni, A. grandiflora, Nerine Fothergilli major, Ixora Fraseri, Dipladenia Lady Louisa Egerton, white, flushed with rose, and several varieties of Bonvardias. Mr. J. Prewett, Swiss Nursery, Hammersmith, was second, but his exhibit was far inferior. The other chief classes were for Chrysanthemums, Sunflowers, and Michaelmas Daisies. As regards Chrysanthemums, we may mention that twelve very fine bunches came from Mr. E. F. Such, Maidenhead, who had the following varieties in excellent character: Mr. Selby, rose; Filberta, yellow; Golden Fleece, rich yellow; Mrs. J. R. Pitcher and Alice Butcher. For twenty-four Asters, Messrs. Saltmarsh and Sons, Chelmsford, were first, and the flowers were exhibited in bunches, a far better way than having only single blooms stuck on cards; this is most objectionable. Mr. John Walker, Thame, Oxon, was second. The Sunflowers made a great show of colour, the first prize going to Messrs. J. Burrell and Co. for a collection, in which all the leading perennial kinds were well represented, whilst Messrs. Paul and Son were second. Messrs. Paul and Son were first for Michaelmas Daisies, which comprised a most interesting lot of varieties.

Miscellaneous contributions were more numerous than at any show we have attended at Earl's Court. A gold medal was awarded to Mr. T. S. Ware, Hale Farm Nurseries, Tottenham, for a splendid collection of Dahlias relieved with *Eulalia gracillima*. Every type of Dahlia was represented, and a most interesting display was the result. A gold medal was also given to Messrs. J. Laing and Sons, Forest Hill, for a large group of tuberous Begonias, principally the double varieties, arranged in distinct masses according to colour. It was well worthy of this prize. A silver-gilt medal went to Mr. John Walker, Thame, Oxon, for a very fine display of flowers, comprising a large collection of show Dahlias and Walker's quilled China Asters, set up in bunches. Mr. Chas. Turner had a large assortment of show and fancy Dahlias (silver medal). Mr. Mortimer, Farnham, also had a similar exhibit and received a like award. Messrs. H. Cannell and Sons, Swanley, Kent, showed a large collection of Cannas, of which the principal varieties were Souvenir de Jeanne Charreton, crimson; Mme. Crozy, scarlet; and Souvenir de Mme. Liabaud, crimson (silver medal). A similar award was made to Mr. G. Humphries, The Nurseries, Kingston Langley, Chippenham, for Dahlias in various classes, and to Mr. E. F. Such, also for Dahlias. Miss C. B. Cole, The Vineyard Nursery, Feltham, was awarded a silver medal for three vases filled with autumn foliage and berries, a very pleasing association of quiet colours. We may mention also that Mr. W. Salmon, Ivy Cottage, West Norwood, had a miscellaneous collection of China Asters, Dahlias, &c., which gained a silver medal. Bronze medals were awarded to Mr. J. R. Tranter, Hart Street, Henley-on-Thames, for autumn flowers, to Messrs. Saltmarsh and Son for Dahlias, and to Mr. A. W. Young, South Norwood, S.E., for flowers of tuberous Begonias and Gloxinias.

New Dahlias were shown in plenty, but they have for the most part been described in THE GARDEN as having had certificates at other places. This does not pretend to be a complete list, but we may briefly refer to a few of those likely to become popular. The Cactus variety Matchless from Messrs. Perkins and Son, Coventry, is a good addition, the flowers rich maroon. The show variety Mrs. Vagg, from Mr. Arthur Rawlings, Romford, is of note for its smoothness and fine crimson-purple colour. In the same section is the variety Duchess of York from Messrs. Keynes, Williams and Co., the flowers suffused with reddish rose on a yellow ground. The Cactus variety Lady Penzance, from the same firm, has been already noted. Pompon variety Pomponet, rose-yellow in the centre, and a shapely flower, from Messrs. Cheal and Sons, is worthy of mention. Several of the flowers, however, were far too small, not naturally so, but shown out of condition. Mr. J. T. West had the Cactus variety Mary Hillier, a very beautiful orange-buff colour, one of the true shape; but the kind named Florence Keith is a little too broad in the petals for a true type. Many sterling novelties are described in the report, as in Mr. Girdlestone's collection of singles.

Fruit.

Some very fine hardy fruit was shown, Peaches being specially good; also Pears and Apples. There was a great number of miscellaneous collections staged, these being placed in the main building. Mr. G. Woodward, The Gardens, Barham Court, Maidstone, was easily first for three dishes of Peaches, showing Princess of Wales, Nectarine and Sea Eagle; second, Mr. W. Carr, Croydon Lodge, Croydon, who had very good Grosse Mignonne, Salway, and Princess of Wales. Mr. Edwards, Sevenoaks, was the only exhibitor for a single dish, being awarded second prize. For the single dish of Peaches, Mr. J. Sanders, Poulton Gardens, Ramsey, was first with very fine Sea Eagle. For dessert Apples, first, Mr. Woodward, with very fine dishes of Cox's Orange, Ribston, and Washington; second, Mr. P. Cavanagh, the Convent Gardens, Roehampton, who had good Jefferson, Cox's Orange, and Ribston. In the class for cooking Apples, Mr. Woodward was again to the front with very fine

dishes of Stone's, Warner's King, and Peasgood's Nonsuch. The Pear class was very fine indeed, Mr. Woodward showing a grand dish of Pitmaston, the finest Pears in the show; also very fine Marguerite and Souvenir de Congrès. There was no competition in the class for collections of dessert Plums, and only two collections in the culinary class, Mr. McIndoe being first with twenty-five dishes; second, Mr. Potter, with a smaller collection. In the class for three varieties of dessert Plums, Mr. McIndoe was a good first, having very fine dishes of Transparent Gage, Jefferson and Grand Duke, Mr. T. Hester, Plumstead Common, being second. For cooking Plums, Mr. McIndoe was first with fine Magnum Bonum, Goliath and Pond's Seedling.

Mr. Payne, gardener to the Bishop of Bath and Wells, was awarded a silver medal for a dish of very fine Peasgood's Nonsuch, the same fruit as exhibited at the meeting of the R.H.S. Mr. Poupart, Twickenham, was awarded a silver-gilt medal for ninety dishes of Apples, forty dishes of Pears and a few Plums, the best Apples being Nelson's Glory, Warner's King, Cox's Pomona, Ribston Pippin, Lord Derby, Cellini, Peasgood's Nonsuch and Lady Henniker. The best Pears were Doyenné du Comice, Beurré Bosc, Beurré Clairgeau and Uvedale's St. Germain. Messrs. Spooner, Hounslow, were awarded a silver-gilt medal for a good collection of Apples, the best being Manks, Lord Suffield, Cellini, Duchess Favourite, Pott's Seedling, Councilor, Blenheim Orange, New Hawthornden and Hoary Morning; Beurré Diel, Pitmaston Duchess and Calebasse Pears also being good. Mr. W. A. Hester had a nice collection of fruit and ornamental Gourds. There were very good Beurré Clairgeau, Duchesse d'Angoulême, General Todleben, Pitmaston Duchess and Doyenné Boussoch Pears; also dishes of Grapes and Plums. Mr. W. A. Trotter, Ledbury, again staged his collection of dried fruits. Mr. Wilkins, Inwood House, Dorset, staged a very fine collection of Onions, and was awarded a silver medal. Messrs. Paul and Son, Cheshunt, staged a nice collection of Apples and Pears. Mr. R. Maher for a collection of Pyrus fruits had a bronze medal. Mr. A. H. Richmond had good Lord Palmerston Peaches (bronze medal). Mr. W. Smith, Harrow, staged good vegetables, having Beet, Gourds, Beans and Tomatoes (bronze medal). Mr. Cavanagh, Roehampton, staged Apples, and Mr. Potter, very fine Calebasse Pears.

A full prize list will be found in our advertisement columns.

The weather in West Herts.—On Wednesday in last week the shade temperature rose to 80°, which, with one exception, is the highest reading that I have as yet recorded here in September. Thursday was also unseasonably warm, but since then most of the day temperatures have been about average. Several nights, however, proved cold, and on Tuesday night the exposed thermometer indicated 2° of frost. About a week ago the temperature of the soil at 1 foot deep had risen to 65°, and at 2 feet deep to 63°, but now stands at 59° and 60°. Rain has as yet fallen on but three days this month, and to the total depth of only about a quarter of an inch. No measurable quantity of rain water has come through either percolation gauge for nearly three weeks. On Tuesday over ten hours of clear sunshine was recorded. It may interest your correspondent, A. White, to know that on the 4th inst. the temperature of the ground here at 1 foot deep was, as with him, 64°. The soil will be found to be, as a rule, at this depth coldest about 9 a.m. and warmest about 9 p.m. The readings I quote in these notes are taken at 3 p.m., or midway between these two extremes.—E. M., *Berkhamsted*.

Two of the finest Cactus Dahlias are Delicata and Lady Penzance. They have been exhibited on several occasions this autumn, and always won admiration. The flowers are of the true Cactus shape, and if smaller than those of the coarse so-called decorative kinds, are refined,

and with the characteristic pointed petals. Delicata is of lovely colour, very difficult to describe adequately, but a kind of salmon-rose, quite a satiny lustre pervading the bloom, and the centre is touched with yellow. Lady Penzance is of a peculiarly soft yellow, almost lemon shade, certainly one of the most beautiful acquisitions to this class this year, and shown on several occasions in splendid condition by Messrs. Keynes, Williams and Co., of Salisbury. In both cases the plants are very free and the flowers produced well above the leafage, unlike the older kinds of this section.

The Flora of Mount Kina Balu, North-West Borneo.—It will doubtless interest some of our rare plant-loving readers to know that Dr. O. Stapf (assistant for India in the Herbarium, Kew) has prepared a very elaborate paper on the peculiar botany of this gigantic mountain. A total of about 400 species of plants is known from this habitat, and of these a very large proportion is new species. The specimens are mostly in the herbarium at Kew, and comprise the collections of Low, St. John, Burbidge, and P. C. M. Veitch, Burbidge on his second journey, and those of the Drs. Hailand. When we point out that this great mountain is the only known habitat for the finest of all the species of *Nepenthes*, some idea may be formed of its botanical riches. Here between 5000 feet and 10,000 feet altitude, in a zone of continual cloud grow *Nepenthes Rajah*, *N. Edwardsiana*, *N. Lowi*, *N. villosa* (not *N. lanata* = *N. Veitchi*), *N. Harryana*, *N. Burbidgeae*, and several other fine species as yet unnamed. There are also splendid *Rhododendrons*, *Orchids*, and *Ferns* as yet unknown in our gardens. Dr. Stapf's paper is to be published in the Transactions of the Linnean Society, and will be looked for with much interest.

Names of plants.—*T. Abbot*.—*Tetragalobus purpureus*.—*H. Jessop*.—1, *Limncharis Humboldtii*; 2, *Phyllotanium Lindenii*; 3, *Arabia Guiltylei*; 4, *Cissus discolor*.—*H. J. B.*—1, *Lythrum hysopifolium*; 2, *Solanum Dulcamara*; 3, *Galeopsis Tetrahit*; 4, *Polygonum minus*; 5, *Lychuis vespertina*.—*J. Bacup*.—1, *Odontoglossum Schlieperianum*; 2, *Oncidium Jonesianum*; 3, *Miltonia Schroederiana*; 4, *Maxillaria luteo-alba*; 5, *Philodota imbricata*; 6, *Ornithocephalus grandiflorus*.—*M. M.*—1, *Clematis coccinea*; 2, *Cuphea jorullensis*.—*J. Campbell*.—Cannot name garden varieties of *Dracæna* and *Crotons*; send them to a grower.—*B.*—1, *Lælia elegans prasiaca*; 2, *Cattleya granulosa*; 3, *Lælia Dayana*.—*N. Macartney*.—1, *Oncidium longipes*; 2, *Epidendrum nemorale*; 3, *Epidendrum Stamfordianum*.—*C. M.*—*Scelopendrium vulgare reniforme*.—*W. M.*—1 (with berries), *Solanum nigrum* (Black Nightshade); 2, *Verbena officinalis* (Vervain); both British plants.—*E. Semper*.—1, *Helianthus multiflorus maximus*; 2, *H. decapetalus*; 3, *Heliopsis laevis*, poor form.—*A. Dickson and Sons*.—*Polygonum cuspidatum*.

"The Garden" Monthly Parts.—This journal is published in neatly bound Monthly Parts. In this form the coloured plates are best preserved, and it is most suitable for reference previous to the issue of the half-yearly volumes. Price 1s. 6d.; post free, 1s. 9d. Complete set of volumes of THE GARDEN from its commencement to end of 1892, forty-two vols., price, cloth, £30 12s.

"Gardening Illustrated" Monthly Parts.—This journal is published in neatly bound Monthly Parts, in which form it is most suitable for reference previous to the issue of the yearly volumes. Price 5d.; post free, 8d.

"Farm and Home" Monthly Parts.—This journal is published in neatly bound Monthly Parts, in which form it is most suitable for reference previous to the issue of the yearly volumes. Price 5d.; post free, 8d.

"Hardy Flowers."—Giving descriptions of upwards of thirteen hundred of the most ornamental species, with directions for their arrangement, culture, &c. Fifth and Popular Edition, 1s.; post free, 1s. 3d.

"The Garden Annual" for 1893.—Contains Alphabetical Lists of all Branches of the Horticultural Trade. The Lists of Gardens and Country Seats (containing over 9000) have been very carefully and extensively revised, and are admitted to be the most complete ever published. Price 1s.; by post, 1s. 3d.

All of our readers who are interested in the improvement of cottage homes are invited to help us to make **Cottage Gardening** known. It is published at the very lowest price to meet the wants of those for whom it is intended, and copies will be sent for distribution, free, by the publishers, Messrs. Cassell and Company, La Belle Sauvage, Ludgate Hill, E.C.

No. 1140. SATURDAY, September 23, 1893. Vol. XLIV.

"This is an Art
Which does mend Nature: change it rather; but
THE ART ITSELF IS NATURE."—Shakespeare.

ORCHARD AND FRUIT GARDEN.

VARIETY DESIRABLE.

Good as may be the advice not to plant too many varieties of any kind of fruit, it is yet possible to err in the opposite direction and not grow enough. This applies not merely to private gardeners, but also to market growers, amateurs, and cottagers. That unlimited collections are a mistake and a great nuisance in some cases there is no disputing. They are right enough where the owner is an enthusiast, and likes to be thoroughly acquainted with the merits or demerits of as many varieties of one or more particular kinds of fruit as possible, but are far from being profitable. When, however, the other extreme is touched and the collections are of very limited extent, then the chances are a good succession of fruit will not be had five years out of six. Certain seasons suit certain varieties. Take Apples for instance. If asked to name a dozen varieties that have done really well in the garden under my charge I could not do it. By doing "really well," I mean this to include other qualities in addition to free bearing. Some, owing to the drought, are much too small; others from causes which date back to the flowering period are malformed, while not a few have ripened far too soon and have kept very badly indeed. With me Cox's Orange Pippin stands out pre-eminent, being in fact the Apple of the year. The crops are heavy, the fruit of good size, well coloured, and apparently not very much earlier than usual. Yet this excellent variety was nearly a failure last year, and did not crop so well as desirable in 1891. Last year King of the Pippins was particularly good; this season not more than a fifth of the fruit on the trees is worth the trouble of gathering or storing. Last year neither Margil nor Adams' Pearmain was satisfactory in any way, but they are very good this year. Last year Court Pendu Plat was very much better than it is this season, and it is very few Ribstons or Blenheim Pippins we now have for storing. Early dessert Apples have been particularly disappointing, all of them keeping very badly indeed. Much the same remarks apply to the cooking varieties. Codlins that sometimes keep till November are already over, other soft second early sorts behaving very similarly. Luckily, we have Tower of Glamis, Lady Henniker, Flower of Kent, Reinette du Canada, and such like firmer varieties to fall back upon, though of very late sorts there are none that have produced heavy crops.

It is much the same with Pears as with Apples. I could point to long rows of trees against walls and in the open, all presumably of most reliable varieties, yet not more than half of them have borne satisfactorily this season. For the first time for several years past Beurré Diel has nearly failed, and other well-known productive varieties, including Pitmaston Duchess, Vicar of Winkfield, Easter Beurré, Beurré Hardy, Passe Colmar, Josephine de Malines, and Chaumontel are cropping very lightly on some walls, although more satis-

factory on others. With me and hereabouts Glou Morceau is the Pear of the year. Never before have I seen such heavy crops of fine clean fruit of this variety, this applying to pyramids as well as wall trees generally. So valuable will these fruits prove, the quality of this variety when in good condition being as near perfection as a Pear can well be, the season also being comparatively late, that if we do not get a similarly good crop during the next three or more years, I am of opinion the trees will yet have paid their way. Yet if very limited collections were closely adhered to, Glou Morceau, owing to its propensity to disease, in the shape of fungus spots and cracking, would be left out in the cold. Ne Plus Meuris has this season attained something like its full size, and will, therefore, be of good quality when most other varieties are over. This variety is included in but few limited collections. To all appearance, Easter Beurré is in better condition, being freer from spot than often seen, and should the fruit keep and ripen well, the summer of 1893 will have done much to bring it back into favour. Plums have not been so variable this season, all alike on walls doing well with me. This applies more especially to their productiveness as I need hardly say that the quality as well as the period of ripening differed considerably. It sometimes, very often in fact, happens that varieties succeed well in one year and fail badly in others, a very great difference being observable in a row of trees, all different varieties; and to be nearly or quite certain of a supply of good Plums every season, the selection of sorts must not be very limited in extent. It is very much the same with Apricots, though this year all alike were remarkably productive. As far as Peaches and Nectarines are concerned, there is not much difference to be noted as far as their productiveness is concerned, but they differ greatly both as regards quality and period of ripening, and a moderately large number of varieties should be grown wherever there is good room for them. Without a fairly good number of varieties there is a chance of the supplies of good fruit being scarce in some seasons, and, it may be, too plentiful in others.

That brief lists of both reliable and good varieties of most kinds of fruit can be given I do not dispute, but they are only reliable to a certain extent. They may all be of a very free habit of growth and do their best to produce good crops annually, but yet fail, owing to being either in flower, or the fruit at a critical period of swelling just when very unfavourable weather is experienced. A difference of not more than three days in the flowering period of two varieties may lead to one having all its flowers or embryo fruit crippled by frosts and those of the other escape injury. Sometimes those that flower early escape, the late-flowering varieties being caught by frosts. At others it is the early-flowering sorts only that come to grief, the rest not being subjected to trying weather. Occasionally the flowers escape damage by frosts and the fruit sets well, only to be caught by frosts before there is either enough foliage or the fruit sufficiently forward to be hardy. Another good reason why a fair number of varieties should be grown has already been given, viz., the fact of some one or more of each kind developing extraordinarily good qualities in certain seasons and under certain conditions. In addition to the productive habit of varieties being taken into consideration, the quality of the varieties ought also to be studied. Soils and subsoils vary so surprisingly in their constitution, that it need

be no matter for surprise that varieties of fruit vary greatly in quality even in a single locality. All growers cannot test the best of the varieties that may be recommended for their particular soil or locality, but they should try as many of them as they have good room for, and retain those only that do give satisfaction.

Where the mistake is often made is the retention of so many varieties that have repeatedly failed to come up to expectations. Worthless variety is not desirable, but when the selection is good, then it ought not to be limited in extent. Either gradually root out or regraft the trees of sorts that have hitherto done badly or are of poor quality, their places being taken by others bearing a good reputation, and which, therefore, are worthy of being given a trial. This is not the time of year for regrafting trees, but it is well not to be very late in the autumn before bespeaking the requisite number of grafts, or the best of them may have gone the way of very many more prunings. Now, however, is the best time to place orders for fruit trees. If delayed till midwinter or later, the chances are the stock of trees of many of the best varieties will be exhausted. W. I.

Apple Peasgood's Nonsuch.—This Apple is generally known on account of its large size and handsome appearance. But it is not so generally known what an admirable tree it forms as a standard, it being more often grown as a bush. As a standard it makes a very handsome head and bears most freely. The fruits individually are, of course, not so large as those produced by the more highly cropped bush trees, but they are large enough for any purpose.—A. YOUNG.

Apple Pott's Seedling.—This fine cooking Apple is a very desirable variety to plant where Lord Suffield will not succeed, as whatever merits this latter variety may have, it will not succeed on soils which are cold and heavy. Pott's Seedling will do this, it being a strong grower as a standard. It is a remarkably free bearer, the fruits being clean, of good form, and excellent quality when cooked. Altogether I consider it a very desirable variety for orchard culture. Although it is recommended for planting in place of Lord Suffield, it remains in condition quite a month later than that variety, and does not need to be gathered quite so early.—A. Y.

Peach Sea Eagle.—This appears to be becoming a very popular Peach, and although its quality is not so satisfactory every year as it is this, yet it is a most valuable variety for open walls. It is of very large size, handsome shape, and, where well exposed to the sun, of a most brilliant colour. It is one of the most regular bearing sorts that I know. It also has a fine constitution, the tree maintaining a healthy appearance season after season. To ensure good quality I find that it is best to allow the fruits to remain on the tree as long as possible, and then if kept in a cool fruit room for a couple of days the quality is first rate.—A. H. S.

Pear Pitmaston Duchess as a standard.—Anyone might think that, owing to the large size this Pear generally attains when produced on trees against walls, or even on bush or pyramid trees, the variety would not be suitable for growing as a standard. This is not so, however, as on account of the better exposure and the greater quantity of fruit the trees carry, the fruits, although of course large as compared with those of most other varieties, are not too large to be appreciated for dessert. Pitmaston Duchess really forms a fine standard, and this season I should not be at all surprised if the quality of the fruit exceeded that from wall trees or bushes.—A.

Apricots in heavy soils.—On warm soils fairly good crops of Apricots, and these of good quality, are obtained year after year, but on heavy

soils and in cooler districts it is different. Success with Apricots does not merely depend upon the setting of the fruit alone, as, if so, I should have little to complain of during each successive season. This year the ripening has been quite satisfactory and the trees very clean and healthy. Our Apricot wall has a western aspect; consequently the fruits ripened more gradually than on full southern exposures, the regular and high temperatures being the cause of this.—Y. A. H.

NOTES FROM WARWICKSHIRE.

DISASTROUS as the long-continued drought has been for many garden crops, it has by no means had a like effect upon fruit crops, and when the present year has passed, I anticipate that it will long be remembered. In the neighbourhood of Warwick, heavy crops of Apples are the rule, notwithstanding that much of the fruit dropped in a young state when the trees were suffering from lack of moisture at the roots. This was especially noticeable on the light soils resting on sandstone or gravel, which abound in the district, but where the trees are growing in the deep and rather stiff loams to be met with in some parts, very little fruit has fallen and the trees are loaded. The early varieties, such as Lord Suffield, Keswick Codlin, Irish Peach, and Worcester Pearmain, were ready for gathering on July 21, this being fully three weeks earlier than last year. The majority of early kinds are somewhat small, but since the recent rains midseason and late kinds are swelling up their fruits splendidly, and promise to be not only abundant, but really good. The trees generally are in a clean, healthy condition, and having made short-jointed sturdy growth, look extremely promising for another season. Among a number of varieties growing in this neighbourhood, Manks Codlin, Stirling Castle, Ecklinville, Keswick Codlin, Lord Suffield, Golden Spire, Summer Golden Pippin, and Sturmer Pippin are carrying the heaviest crops. The branches of these are wreathed with fruit. Cox's Orange Pippin, King of the Pippins, Worcester Pearmain, Kerry Pippin, and Warner's King have good average crops; Hambledon Deux Ans, a variety not much grown, is also cropping well. The whole of the above are growing on large pyramids, the branches being unshortened, but thinly disposed. On standards in orchards we have good crops of Keswick Codlin, Hawthornden, Hanwell Souring, Wyken Pippin, Cox's Orange Pippin, Domino, and Worcester Pearmain. Peasgood's Nonsuch is, I fear, a poor cropper except when grown on the French Paradise stock, for even this year we have few fruits of it. Pears are a very heavy crop. It is quite an unusual sight in this neighbourhood to see large pyramid trees so richly studded with fruit as this year. Trees of Jargonelle and Green Chisel are perhaps the most prolific of all; Williams' Bon Chrétien and Louise Bonne of Jersey are also good both on walls and as standards in orchards. Gansel's Bergamot and Marie Louise, which seldom bear well except when given wall protection, are this year carrying good crops in the few instances in which standard trees of them have come under my notice. Standards of Citron des Carmes and Clapp's Favourite have also good crops. Ne Plus Meuris, Baurré Diel and Doyenné du Comice are particularly good among trees trained to walls. Very heavy crops of Plums and Damsons are the rule throughout the district. Many of the trees, however, have suffered considerably from the attacks of white aphid. Where this has been the case the fruit is rather small. Bush fruits have been only an average crop, although at one time there was every appearance of a heavy one. The drought and caterpillar, however, did much damage among them and prevented the fruit from swelling satisfactorily. Early Strawberries were abundant and good, but insufficient moisture at the roots prevented later ones from swelling to their usual size; this rendered the crop a rather light one. Apricot trees are, as a rule, loaded with fruit, the variety grown here being mostly Shipley's, a few young trees of Moorpark having only a light

crop. Peaches are rather partial, Dymond, Royal George, Sea Eagle, Hale's Early, and Bellegarde being the heaviest crops. Figs are early and abundant. But few Cherries are grown in the neighbourhood with the exception of the Morello. These are a good average crop on walls, but I noticed recently a few standard trees in an amateur's garden carrying wonderful crops.

Turning to vegetables, a far different state of affairs must be chronicled, and I trust it will be many years before we again encounter a season so trying for them. Cauliflowers and Peas seem to be the greatest sufferers. The effect of the drought began to be felt shortly after the second early batches of the former were set out, and where they could not be continually watered up to the time of cutting a large percentage were button-hearted, and the best exceptionally small or loose. I do not remember a season during which so few good Cauliflowers were to be met with. Where the wise precaution of heavily mulching Peas at an early stage of their growth was taken, an occasional supply of water afterwards being given, the results have been fairly satisfactory. Under less favourable conditions the crop has been almost a failure, varieties which should attain 6 feet beginning to flower when about one-third of that height. Carrots and Beetroot have done well, though the roots are somewhat smaller than usual. The tops appear perfectly healthy, and the beds are as even as it is possible to have them. Onions generally are rather small, and the beds patchy on account of the ravages made by maggot. Where special attention has been given them in the matter of watering, splendid bulbs are the result. Early Potatoes, though small, have been clean, of good quality, and altogether free from disease. Late varieties have made much less top-growth than usual, but look most promising. W.

LATE GRAPES.

It will be interesting to observe how Grapes keep during the forthcoming winter. Most growers are of opinion that unless the Vines are subjected to a somewhat high temperature during the ripening period the berries are apt to shrivel if they remain on the Vines after the turn of the year. The late kinds began to colour this season a month earlier than usual, and have had the benefit of an abnormally high temperature. The temperature at night too has been much over the average, so that very little fire-heat has been needful. I much doubt indeed if artificial warmth is beneficial when the thermometer runs up daily to over 100°, and does not drop below 70° in the evening. During the month of August the thermometer seldom registered less than 50° at any time during the night, and at 8 o'clock in the morning it was up to 90° in a east-to-house fronting south on at least five days out of the seven. Under any circumstances I do not consider high temperatures advisable, and when the natural warmth is so great throughout the day, I think the Vines need as much rest as they can have during the night. Everyone knows how refreshing the cool, moist night air is, and how much better plants in the open pass through periods of hot weather when the leafage is nightly covered with dew than when the atmosphere remains in a parched condition throughout the twenty-four hours. It must surely be the same with Vines under glass, and artificially drying the atmosphere by fire-heat can scarcely be the right thing to do when the air is so parched during the daytime.

If the pipes are moderately heated at night, the house should never be quite closed. The more or less free admission of air will in a great measure counteract the aridity engendered by the hot pipes and will assist in keeping off attacks of red spider and mildew. Even when the berries are beginning to swell and the house is closed early and well damped down towards evening, the ventilators should be opened at the top of the house again a couple of inches or more. When the nights are of the still sultry nature, which in a general way has been their characteristic feature during the past

season, I consider it helps the swelling of the berries and strengthens the foliage to open the front ventilators at night, allowing a free passage of the moist refreshing night air through the Vines. I have been in vineries which were tightly closed all through the night in the months of July and August, the pipes at the same time being heated. This is a practice which common sense must condemn. In the case of late Grapes especially, the exclusion of night air when the berries are swelling and beginning to colour must be wrong. A very confined atmosphere during the night induces softness, and although the foliage may have a very green healthy appearance and the berries will swell up well, they will, to a certain extent, be deficient in solidity. In the case of Grapes that are intended for use during the late winter months, the berries cannot be too firm. If when making their growth they are subjected to a very moist confined atmosphere for many hours at a time, the skin is wanting in the toughness that enables them to remain in good condition in mid-winter. J. C. B.

OLD APPLE TREES.

THE present season has brought into special prominence the great value of old Apple trees; indeed, there can be no doubt whatever but that the old standards have proved to be not only too strong to be affected by the drought, but they have carried wonderful crops of fruit. It is one of the marked characteristics of the season that whilst the roots have been suffering from want of moisture, the exceeding abundance of warmth and sunshine has acted as an opposing agency, and now we see the finest fruits on these old standards that the trees have borne for many years. When we hear henceforth silly talk about planting for one's heirs, we may well remember the experience of the present year, for to old trees do we owe chiefly the abundant crop of Apples that we now have. It must not, however, be supposed that old trees do not frequently bear. Probably no trees are more regular than are the patriarchs of our orchards, but we do not always note their value, and much less often do them justice. When trees bear a few fruits one year and a good crop the next, and so continue in that way almost for generations, we may well ask whether it would be possible under any other conditions to obtain from the same area of soil so much of value as many of these old trees give. Of course, it is said that many produce only small inferior samples. That is to some extent true, but when we meet with others that are of fine varieties and carry splendid crops, we see ample evidence that the fault lies not in the form of trees or in age, but rather in the ignorance shown by our fathers in planting sorts that are now found to be comparatively worthless when others of greater value could be had. Then the existence of these old trees has a moral, which we should be quick to utilise. It is that where they do so well and are so fruitful, there are the soil and situation on which to plant other trees for the keeping up of our Apple supply. Of course, I do not mean in the same orchards; I rather mean in the same localities. Still further should we plant only varieties that are proved to be fine and good in those localities, or have a good reputation for health, size of fruit, and endurance elsewhere. I have seen many very fine trees this season that may be 100 years old, and yet look as if under good conditions they would endure for yet another half century. It seems not at all improbable that amongst these old varieties are many that have merit worthy of perpetuation. It was fondly imagined that the great Chiswick Apple

congress brought together all the best old Apples in the country, but that was far from being the case. A few districts were well represented, but myriads of varieties in orchards and gardens were not shown. Some of these may be found in commerce, some not. Most of them have local appellations, and it is very probable that many of the ancient trees are seedlings; indeed, that fact may to some extent account for their great age. Still, many wonderfully fine trees of such a variety as the Hambledon Deux Ans that must have been worked are to be found in Hampshire, and in other counties varieties of similar old reputation are to be found. The Deux Ans is far from being classed as of the best merit, and yet it is a most valuable Apple for use from March to June, one of the heaviest croppers and best keepers. There are not so very many Apples that are really good for cooking after March sets in. That it is possible in many cases to materially improve the condition of some of these old trees by harder thinning of the heads there can be no doubt. It is not easy to mount aloft so high and into such huge heads and thin out the branches so much as is desirable, but work of this description needs to be done in such cases only about every three years. It is quite remarkable to note how many of these giants may be seen literally without a dead shoot, whilst we may see others only fit for the woodstack. These latter are sorts that may have done very well for a few years, but did not possess the stamina essential to old age and long bearing. They soon exhausted the fertile properties of the soil, and then began to decay. These are sorts to be avoided when trees are being planted for endurance. Nearly all the finest of these growers are good keepers, a special point in their favour, and such sorts as Blenheim Pippin, Deux Ans, Shepherd's Seedling, very fine in Surrey, Warner's King, Annie Elizabeth, Waltham Abbey Seedling, &c., are typical of the old trees that are yet to be found in plenty, and which whilst we strive to sustain we should also strive to continue to future generations by planting them as freely as our forefathers planted for us. A. D.

AUTUMN PRUNING OF FRUIT TREES.

THIS season should afford an excellent opportunity of giving fruit trees growing in the open a general overhauling in the matter of cutting out any superfluous branches or growths not required for the extension of the tree. Fruit generally will have been gathered earlier, so there will be quite a long time for trees to recuperate their energies before the leaves fall, as I suspect the earlier ripening of fruit will not affect in the least the maturation of the foliage. By cutting out branches whilst the leaves are still on them, a better idea is gained than if this operation were left over until the dormant season, of the amount of pruning necessary for the well-being of the tree. At this time one can see at a glance whether the branches are crowded or not. At this time the wounds quickly heal over and the fruit-buds are decidedly strengthened through this operation, at least those which were over-shadowed on account of the shaded state of the trees or branches. With tall standards a limit must be allowed, as on account of their form these are not so easily manipulated as in the dormant season, but with pyramids and bushes the case is different.

All pyramid trees should have the branches far enough apart to allow direct light to reach right up to the main trunk, and not merely at the outer edge. When this latter is the case the trees only produce a mere tithe of the fruit they will do with more rational treatment. This will also be found to be the most suitable time for thinning out crowded branches of Plums and Cherries, more

particularly in the case of the latter, which are so liable to gumming when the thinning out is left to the dormant season. I am also very much of the opinion that much of the gumming which affects Morellos when growing against walls may be traced to hard winter pruning. This will be found to be the most suitable time for both pruning and nailing in the growths of the Morello. It is work which I always attend to at this season, not only for the benefit of the trees, but because the work is more quickly performed than in the winter. Apricots also are the better for having any of the spur-like growths pruned in now, and it is the same with Plums growing against walls. Pears either growing against walls or as espaliers are often crowded up with spurs, and instead of thinning these out at the winter season, they may well be shortened in now to the sure benefit of those remaining. It is just the same with these as with trees growing in the open, for whilst the foliage is still fresh it is a gauge to go by as to the extent of pruning necessary. Y. A. H.

Peaches and sunshine.—In a discussion which took place in THE GARDEN some months ago on the comparative merits of home-grown and imported Peaches, a writer stated that hot sunshine exercised a deteriorating effect on flavour, and that was one reason why we could never expect to get Peaches from abroad so good in quality as those produced in this country. This was quite contrary to what the nature of the Peach would lead one to expect. I always thought that the warmer the summer the better the quality of the fruit, and for this reason one might reasonably expect to get really good-flavoured Peaches from abroad, where the sun is more constant and has so much more power than is the case in ordinary seasons with us. I find that I was not mistaken as regards the influence of sunshine on quality, for Mr. Young, in a note on hardy fruits in a recent number of THE GARDEN, says that with him Peaches have this year been unusually fine and good. This has been one of the hottest summers the present generation of Peach growers has ever experienced, the temperature probably ranging as high as in California. If the fruit has under its influence come good in flavour, it is evident that Peaches of fine quality can be grown both in California and at the Cape. —J. C. B.

Lord Suffield Apple.—It may add a little further interest to Mr. Beaven's article on Lord Suffield Apple on p. 241 if I state that it was raised by a Thomas Thorp, who had a garden at the top of Boardman Lane, at Rhodes, near to Middleton, Lancashire, and who brought out several varieties of fruit, but none so good as the Apple Lord Suffield. It is supposed to be something like sixty years since the variety first fruited. It was not long since stated in one of the Manchester papers that the original tree still stood in the garden at Rhodes, but Mr. James Percival, of Rochdale, informs me it is not now in existence. He states, "Some sixteen or seventeen years ago I was in the garden where the Apple was raised, and what remained of the tree was then lying on the garden walk, it having then been dead about twelve months; the bole was about 7 inches in diameter, and the trunk was devoid of branches, which had probably been used for fire-wood." Mr. Percival further states that one of the earliest propagated trees was brought to his grandfather's garden at Prestwich some fifty years ago, the tree about 2 feet in height; it missed fruiting the first year, but the second year it bore two fruits, one of them weighing 8 ozs., and the tree produced fruit each year afterwards. It was named Lord Suffield after the nobleman who was at that time lord of the manor of Middleton, and who took a great interest in fruit growing.—R. DEAN, *Ealing, W.*

Late Pesches.—This has been a splendid season for late Peaches, and will help to redeem their character in the estimation of many cultivators. Every kind of fruit in this garden is about a month earlier than usual, and this in cold fruit houses as well as outside. The late Peaches which

ripen early in October are now ripening. I find late kinds very useful to help make up the number of dishes of fruit for shooting parties, &c., and although they are very poor in flavour in a general way, they are nevertheless useful, especially for cooking. I grow all the Peaches in a cold house, and this year the late kinds are infinitely better in flavour. Walburton Admirable I think the best flavoured large late Peach. This I grow on a back wall and get grand fruit. Sea Eagle is doing well. The latest kinds are Gladstone and Late Admirable. With me both of these kinds are given to stone-splitting, and a goodly portion drop off before they are ripe. Gladstone is a fine locking kind and bears freely. I had last year fruit of it from a cold house in the middle of October, and this season it has coloured up grandly. I found a tree of Royal Vineyard here. It is a fine grower and bears a heavy crop, but the flavour is very poor. The old Noblesse gives fruit till the end of September from trees growing on a front trellis, and the flavour is very fine.—J. CROOK, *Forde Abbey.*

An Apple from Ireland.—Can it be that Mr. W. B. Hartland's Gibbon's Russet or Cherry Brandy Apple (see p. 228) is the Brandy Apple once fairly popular in England? Only Mr. Hartland's experience of getting a whiff of exquisite perfume from his Apple the third day after being placed in a drawer would hardly apply, as the Brandy Apple was a good keeper. By the way, we are sadly in need of more Russets, for they are all good in their season—at least I have never known a bad one. Has any reader of THE GARDEN? I note that Gibbon's Russet is a mid-winter sort, as was the old Brandy Apple, at one time the most orthodox of all Apples for mincemeat.—D. T. F.

NECTARINES.

THE hot weather has suited Nectarines, as the trees have borne excellent crops, the fruit being of a splendid colour and of better flavour than usual. Though the soil in this district is very light, yet by mulching and plentiful supplies of water there are generally excellent crops. Wasps and red spider have been most troublesome, also earwigs, but I never saw the trees more promising than they are now, the buds and new wood much resembling those of indoor trees, thus showing the effects of a warm season. Many complain of Nectarines cracking, and this is one great failing, as the smooth skin is soon injured. In my case Elruge is the worst offender. Lord Napier is the best doer on open walls, and though in light gravelly soil I cannot get the fruit so large as from trees grown in good sound loam, yet this variety can always be relied upon. I have not yet seen the new seedling recently sent out by Messrs. Rivers tested in the open, but should it succeed like Lord Napier, which it much resembles, it will be a great gain if it can be obtained much earlier. The impression often prevails that cold injures the bloom; whereas, this season during the setting period we had from 18° to 20° of frost and no injury followed. Coddling by thick covering is worse than cold. Shelter from east winds and a good coping are better than a thick protecting material. Nectarines should always occupy the best position, that is the warmest wall, and be given plenty of moisture at the roots, and if the trees could be regularly damped down every day as the sun declines, there would be few complaints as to spider.

To prove how injurious a hot dry wall is to these fruits, I saw some new walls cemented all over. Very large trees were planted in the best way possible as regards soil and position, but they were burnt up, the cement being too dry and not retaining the moisture. I also object to fixed wide glass copings, as the trees do not get the rain and dew so beneficial to them. Lifting, so often overlooked, is often required, as once the trees go down into poor soil there is never fine fruit. When the roots are kept near the surface, well mulched twice a year, and the border given plenty of moisture, there are good results. Thinning the growths in summer

will do much to prevent bad or cracked fruit, as it allows the wood to get hard and the buds to plump up. This season our Pitmaston and Pine-apple Nectarines have been equal to indoor fruit; indeed I never saw them do better in the open even on east walls; the fruits have been good and from two to three weeks earlier than usual. There need be little fear of failure if trees not doing well are lifted early and new material given them, adding lime rubble to soils requiring it, and good stiff loam to light soils.

S. H. B.

TREES AND SHRUBS.

THE JAPANESE HORNBEAMS.

OF the Oak family, it is in *Carpinus* only that the forests of Eastern Asia are superior to those of America, where we have a single species of Hornbeam, a small tree confined to the eastern side of the continent. Europe possesses also a single species which extends to the Orient, where a second species is found. The forests which cover the Himalayas contain two species; at least two or three others are found in the Chinese empire; and to the flora of Japan six species are credited. One of the Japanese species, however, *Carpinus erosa* of Blume, is a doubtful plant; another, the *Carpinus Tschonoskii* of Maximowicz, from the Hakone Mountains and the region of Fugi-san, I have never seen; and a third, *Carpinus yedoensis*, a small tree cultivated in gardens in the neighbourhood of Tokio, is, perhaps, like many of the plants cultivated by the Japanese, a native of Central Asia. Three species are certainly indigenous to the Japanese soil.

CARPINUS LAXIFLORA resembles, in the character of the bark, the size and shape of the leaves, and in the structure of the flowers, the European and American Hornbeams. It is a graceful tree, occasionally 50 feet in height, with a trunk 18 inches to 20 inches in diameter, covered with smooth pale, sometimes almost white bark and slender branches. The leaves are dark green above, pale yellow-green below, 3 inches to 4 inches long, 1 inch to 1½ inches broad, prominently many-veined, and in the autumn turn yellow or red and yellow. The fruit is produced in lax hairy catkins 4 inches or 5 inches long. This fine tree is common in all the mountain forests of Hondo, where it is most abundant at elevations between 2000 feet and 3000 feet above the sea; in Yezo it reaches the southern shores of Volcano Bay, where, near the town of Mori, it is common in the Oak forests, and grows to its largest size.

The other Japanese species of *Carpinus* differ from *Carpinus laxiflora* and from the American and European species in their furrowed scaly bark, in the stalked bract of the male flower, in the closely imbricated bracts of the fruiting catkins, which look like the fruit of the Hop-vine, and in the form of these bracts, which are furnished at the base with a lobe which covers the fruit and is more or less enclosed by the enfolding of the opposite side of the bract. On account of these differences these two trees are often referred to the genus *Distigocarpus*, founded by Siebold and Zuccarini to receive their *Distigocarpus Carpinus*. Botanists now pretty generally agree that the characters upon which *Distigocarpus* was founded are not of sufficient importance to justify its separation from *Carpinus*; and *Distigocarpus Carpinus*, if the oldest specific name is used, becomes

CARPINUS CARPINUS. By Blume, who first united *Distigocarpus* with *Carpinus*, it was called *Carpinus japonica*, the name under which it has appeared in all recent works on the Japanese flora. It is a tree 40 feet to 50 feet in height, with a trunk often 12 inches to 18 inches in diameter, and wide-spreading branches which form a broad handsome head. The branches are slender, coated

at first with long pale hairs, and later covered with dark red-brown bark often marked with oblong pale lenticels. The winter buds are half an inch long, and covered with many imbricated thin, light brown, papery scales, and at maturity are nearly an inch long and hairy on the margins. The leaves are thick and firm, dark green on the upper surface, paler on the lower, 3 inches or 4 inches long and about 1½ inches wide, with stout midribs and many straight prominent veins slightly hairy below and deeply impressed above. The nutlet is slightly flattened, with about ten straight prominent ridges extending from one end to the other. *Carpinus Carpinus* is common in the Hakone and Nikko Mountains, between 2000 feet and 3000 feet elevation above the sea; it apparently does not range very far north in Hondo or reach the island of Yezo. This interesting and beautiful tree, which is remarkable among Hornbeams in the character of the bark and in the female inflorescence, appears to be perfectly hardy in New England. For a number of years it has been grown in the Aroold Arboretum, and during the last two seasons has produced flowers and fruit here. In its young state it makes a handsome, compact, pyramidal, bushy, and very distinct-looking tree. The most beautiful of the Hornbeams of Japan, as it appears in the forests of Yezo, is

CARPINUS CORDATA, which often attains the height of 40 feet, with a stout trunk sometimes 18 inches in diameter, covered with dark, deeply furrowed scaly bark. The stout branchlets are of an orange colour, or, when they are three or four years old, light brown. This species is remarkable for the size of its winter buds, which are fully grown by midsummer, and sometimes nearly an inch long. The leaves are thin, 6 inches or 7 inches long and 3 inches or 4 inches broad; they are light green on both surfaces, although rather lighter coloured on the lower, with conspicuous yellow midribs and veins slightly hairy below and impressed above. The catkins of fruit are often 5 inches or 6 inches long and 1½ inches wide. This is the only species of Central Yezo, where it is one of the common forest trees, growing with Oaks, Magnolias, Ashes, Walnuts, *Acanthopanax*, Birches, &c.; it is also grown in Hondo at high elevations, although it is here much less common than farther north. This fine tree is apparently still unknown in American and European gardens; it is one of the largest of the Hornbeams, and certainly one of the most distinct and beautiful of them all. As it grows in its native forests with a number of trees which flourish here in New England, it may be expected to grace our plantations with its stately habit, large leaves and long clusters of fruit. An abundant supply of the seeds, with those of *Betula Maximowicziana*, was the best harvest we secured in Yezo.—*Garden and Forest*.

Hydrangea quercifolia (H. P. W.).—This is the plant of which you send me a specimen, and it is a plant but seldom met with. It is a hardy species with white flowers, and presents quite a beautiful appearance; the leaves are about 6 inches long, obtusely lobed, and the terminal trusses of bloom are not arranged in a dense tuft.—W. H. G.

Halesia diptera.—A correspondent in *Meehan's Monthly* calls attention to the fact of a difference between *Halesia diptera* and *Halesia tetraptera* that has not before been noted—namely, that *H. diptera* does not commence to flower until a considerable time after *Halesia tetraptera* has gone out of bloom, this rendering any chance of hybridisation between them, as has been sometimes suggested, still more doubtful than some have supposed.

Dwarf Pomegranate in flower.—For some years a plant of this has with us on a south wall in the immediate neighbourhood of London been a very attractive object during the autumn months, by reason of its richly coloured blossoms, but this season it has surpassed itself in consequence of the profusion in which they are borne, for though the plant itself is little more than a yard high and about the same in diameter, it is thickly studded with expanded blossoms and unopened buds.

These last are of a bright sealing-wax-like tint, but when fully expanded they are more of an orange-red and wonderfully showy. The intense heat of the past summer is no doubt the cause of such an unusual display of bloom. For a low wall in front of a hothouse I know of nothing during the autumn prettier than this Pomegranate, while before it flowers the neat growth and bright shining foliage form a pleasing feature. There yet remains another item to note concerning this Pomegranate, and that is, on a sunny wall the leaves usually change to a bright golden tint before they drop. This dwarf form of the Pomegranate is said to have been introduced into this country as long ago as 1723. For higher walls the other varieties are equally as valuable as this is for low ones.—H. P.

Erica multiflora.—This is a near ally of the Cornish Moor Heath (*Erica* or *Gypsocallis vagans*), from which it differs among other features in being later flowering, for it is generally in full bloom at the time the other is almost if not quite over. The flowers, which are crowded together towards the points of the shoots, are of a rosy red colour, and as a rule a succession is kept up for some time. It is especially valuable from the fact that, with the exception of *Erica stricta*, this is usually the latest of our hardy Heaths to flower, for it will often continue the Heath season till November, while the pretty little *Erica carnea*, which commences the season, will in some winters produce its earliest blossoms soon after Christmas, but its flowering period extends well on into the spring, and after that other forms keep up a succession till autumn is well advanced. The different varieties of the Grey Heath (*Erica cinerea*) and of the Ling or Heather (*Erica* or *Calluna vulgaris*) would alone form a very interesting collection, as they vary greatly from each other and from the type.—T.

Pancreatium speciosum is an old plant, but, nevertheless, very beautiful, and not always in such splendid condition as a specimen in the Palm house at Kew. This is one of the finest examples we have seen, and is bearing upwards of half a dozen large heads of bloom, which present a mass of purest white, relieved only by the yellow stamens. It is interesting to note that this is the second time of blooming, as the plant was in full beauty about the month of June. This fine species came to us from the West Indies in 1759, and it would be well if a little of the attention given to Orchids were paid to the many beautiful stove plants which have been long neglected. Nothing in its way is more beautiful than a large specimen in full bloom of *P. speciosum*.

Plumbago capensis and var. alba.—Both the blue and white-flowered varieties of this old Cape of Good Hope plant are used with good effect in the large temperate house at Kew. The blue one, now beautifully in flower, is trained up one of the double pillars of the house, which it covers from top to bottom, and is consequently some 30 feet high. The effect produced by the abundance of clear pale blue flowers amongst the surrounding greenery is very pleasing, and suggests that it might well be used more frequently in this way in cool houses. The flowers are gracefully borne in large trusses at the end of long slender shoots. The white-flowered form is also in bloom, but, although well worth growing for the sake of variety, is apparently neither so robust nor so free-flowering as the older blue form. Grown in the cool house these plants only bloom once during the year—in autumn; but in intermediate or stove temperatures flowers are produced in early summer, and thence more or less continuously up to autumn. The plants require to be pruned back almost to the old wood each winter, and this amount of pruning suffices for cool-grown plants. In the warmer houses it is necessary to prune during the summer, although this often means little more than removing the old flower-heads. As pot plants the *Plumbagos* are useful, but it is only when planted out in rich soil and given abundance of water that their full value can be seen.

ROSE GARDEN.

ROSE GLOIRE LYONNAISE.

WHEN first introduced this was spoken of as a yellow Hybrid Perpetual, but pale lemon-white is a truer description; nor does it belong to the Hybrid Perpetual section, being one of the so-called Hybrid Teas. Gloire Lyonnaise, raised by Guillot et fils in 1884, was the result of crossing H.P. Baroness Rothschild with Tea Mme. Falcot. The issue of this was crossed with the latter again, and the result crossed a third time, so that we see there is very little of the Hybrid Perpetual blood left in it. The shape and size of the bloom are exactly what might be expected from a cross

would have produced such a tall and vigorous seedling. The Brier, Manetti or De la Grefferaie suits Gloire Lyonnaise equally well, and by far the best way of growing it is to cut away the shoots after flowering, thus allowing the whole strength of the plant to go to the production of more wood for the following season. As a button-hole Rose it is grand, keeping its long, pointed shape well when cut in a young state. It is singularly free from mildew and red rust. Most of the Hybrid Teas are quite as badly affected by the latter disease as the Hybrid Perpetuals, but this variety seems exempt. The true Teas and Noisettes are also free from it, and probably being crossed three times with a Tea Rose is the reason Gloire Lyonnaise is more proof against red rust than the remainder of its class. This would seem confirmed by the following Hybrid Teas being equally free, viz.,

Rose Gloire Lyonnaise. Engraved for THE GARDEN from a photograph sent by Mr. C. J. Grahame, Croydon.

between these two varieties, while in substance it is also midway between the two. Its colour I have already described, but when we come to its growth and foliage, one fails to find the least trace of either parent. At first it did not bloom freely, but when it came to be better understood and was cultivated upon the pegged-down system, we got a really splendid show of flowers.

The strongest plants of Gloire Lyonnaise that I have ever seen were in a Sussex garden. Here they annually produced shoots of 6 feet to 12 feet long and of proportionate substance. Pegged down in the spring, these shoots produce large quantities of bloom during early summer. This Rose is not perpetual in the same sense as General Jacqueminot and other Hybrid Perpetuals. Among pedigree Roses one often finds some startling developments of growth. Taking this variety as an example, who could have expected that its parents, both short growers,

Cheshunt Hybrid, Gustave Regis, and Reine M. Henriette.—RIDGEWOOD.

— It is interesting to note how some Roses which at first show no inclination towards autumnal blooming afterwards develop that character, although, of course, never to the profuse extent which characterises the true Teas. Gloire Lyonnaise has been giving some splendid flowers of late, solitary, but very fine at the end of its 6-foot wands. When pegged down this is a wonderful Rose, all the shoots for pegging down next year standing up erect and straight, most of them averaging 6 feet in height. Whatever may be necessary for the production of exhibition blooms, our group of this Rose proves that a quantity of manure and high feeding are unnecessary. To enjoy Roses in the garden only, they need no extra encouragement, otherwise we should not get such shoots six years in succession without a particle of manure during that period.—A. H.

— Mr. C. J. Grahame, who kindly sent the photo from which the engraving was prepared, says:—

Gloire Lyonnaise, although not very generally known or much grown, should be in all good collections. It was raised in 1884 by the great French house of Guillot et fils, of Lyons, and this is certainly in its favour, as most of this firm's productions are desirable. The Rose is a Hybrid Tea, and, like others of that class, is not so suitable for exhibition as Roses of the true Tea race. This fact may have acted as a deterrent to its more general cultivation, but it has other and good qualities which should be considered.

The colour is correctly described by the raisers as "coloris blanc, chrome au centre, passant au blanc pur," and they also call special attention to its habit. I think that Gloire Lyonnaise is well worth growing. It is very free flowering, and if the buds be cut when about half open, they will develop in water into Roses of good size. It has hardly sufficient substance to be quite depended on for exhibition, although I have staged it two or three times this season, knowing it to be most effective. The petals of the Rose being large and their form attractive, the light lemon tint is of decided advantage in contrast with other Roses of darker colour. It makes a good standard.

Rose W. F. Bennett.—In THE GARDEN for August 26 (p. 178) Mr. Fish writes as if he were disappointed with the reception that the above-named Rose has met with at the hands of the public. I, however, do not see why he should be, seeing that, in my opinion at least, it has only its fragrance to recommend it. As to its colour, we do not want any red Teas unless they possess more characteristic features of the class than does W. F. Bennett. Indeed, I do not think we want that colour at all in the Teas. Raisers of new varieties may let us have the fragrance of the Rose under notice, but to be acceptable it must be associated with some other colour but red. I should like W. F. Bennett better if the flowers had more staying power. If grown under glass half an hour's sunshine in the month of March is sufficient to spoil the most promising flowers, so quickly do they open and show an objectionable eye. There is another so-called red Tea Rose, Reine Maria Pia, that has no other merit but a vigorous constitution to recommend it, and I am surprised that nurserymen should give its name room in their catalogues. Mme. Etienne Levet approaches the Teas in habit and constitutional tendencies perhaps more than any others in the same line of colour.—J. C. CLARKE, Taunton.

Tea Rose Souvenir de Therese Levet.—What a remarkable contrast this deep-coloured Rose affords in a box of blooms of Teas. It was particularly noticeable in stands of twelve Teas shown both by Mr. A. H. Gray and Dr. Budd. It has been described as a "crimson Niphotos," but the blooms at Bath, and especially Mr. Gray's, were something more than crimson, for the petal edges were shaded with a darker tint. In both flowers there were great strength of petal and substance, and indeed the brilliant appearance of the flower suggested that a bright Hybrid Perpetual had become mixed up with the Teas in error. Messrs. Geo. Cooling and Son, of Bath, describe it as of a "deep rosy crimson colour," which, I think, is a correct one. The rich shading seen in Mr. Gray's bloom was probably the result of high cultivation.—R. D.

Autumn blooming of Roses.—The season of 1893 will long be remembered by all lovers of Roses in the south and west for the absence of any really good Rose blooms in the summer. In this garden I hardly saw a good Rose from the first flowering, as before the blooms were expanded they were injured by insects and burnt by the sun. During the month of June I looked over Messrs. Cooling's Rose grounds, and although a portion of the Roses is in low-lying ground, I could hardly find a really good bloom. Not so with the

autumn blooming; with me this is most satisfactory. After the rain the plants started into fresh growth, making fine strong shoots and leafage. Many of the shoots on the Hybrid Perpetuals are from 5 feet to 6 feet high. On these sturdy growths there have been some very fine blooms. In some varieties these shoots are crowned with from three to five blooms in a cluster, and many of them come very fine. All the smaller growths are bearing one or two blooms, and these are very beautiful, being shaded somewhat. Most of our kinds have bloomed more or less, but the following I have noted as extra good: Magna Charta, Mme. Victor Verdier, Jules Margottin, Cheshunt Hybrid, John Hopper, Fisher Holmes, Celine Forestier, La France, Marie Baumann, Peach Blossom, Senateur Vaisse, Alfred Colomb, Souvenir de la Malmaison, Duke of Edinburgh and that good old variety Gloire de Dijon. According to present prospects we shall have a good supply for some time to come.—DORSET.

STOCKS FOR ROSES.

THERE are few, if any, points in the culture of Roses that have caused more discussion, or upon which some few rosarians have expressed more emphatic opinions than the selection of stocks. While agreeing that it is right for everyone to speak as he finds, I cannot help remarking that, in my opinion, many writers have unduly tried to force a certain stock upon the public, simply because it thrived well with them. When writing upon manures for Roses I endeavoured to point out the great importance of applying manure most suitable for the soil. The question of stocks and Roses is very similar, although not quite so clearly defined as in the former case. Both the variety and soil must be borne in mind when deciding what stock to cultivate upon.

THE DE LA GREFFERAIE

is a grand stock for almost all soils when extra strong growers are cultivated. Before going further, I may state that when a Rose is worked upon any given stock, the strength and root power of the latter are considerably affected by the former. For example, if we work a strong grower upon a strong-growing stock, we shall get extra vigorous growth; but if we place a weak-habited kind upon the same stock, the latter will not grow and root so freely, because there is no outlet for its natural energies. Similarly, if we work a strong grower upon a weak stock, the latter is forced to make root more freely than usual in order to meet the demands of the vigorous-growing Rose. It is simply a question of supply and demand, and what we should aim at is to fit these two as nearly as we can. The De la Grefferaie making very strong root-growth and supplying an abundance of sap is an excellent stock for the extra vigorous growers, especially upon heavy soil. I also fancy that it puts more colour into the blooms than the Manetti, while I am certain it is an excellent stock for many Roses which are liable to break out from the latter. Hybrid Perpetuals, as Marie Verdier, Louis van Houtte and Sultan of Zanzibar, also Teas, like Bouquet d'Or and a few more, do not form a strong union with the Manetti, although other Hybrid Perpetuals and Teas like Gloire de Dijon, Kaiserin Friedrich and others do. All of these varieties, with Captain Christy and Reine Marie Henriette among the Hybrid Teas, do well upon the De la Grefferaie.

BRIERS,

both cutting and seedling, are great favourites, and deservedly so. I do not know of any Rose that will not thrive upon them, according to

the strength of the variety; but with me, Maréchal Niel, William Allen Richardson, and Bouquet d'Or make an even better union upon the De la Grefferaie. Cutting Briars are rather more suitable for shallow soils than the seedlings. The latter make deep roots, while the former are inclined to root much nearer the surface. In the case of a light and naturally dry soil, provided it is of a fair depth, I would prefer the seedling Brier, as it would be better able to stand against a dry season like the past has been. Respecting the varieties, their strength, &c., there seems to be no choice between the cutting or seedling form. When a seedling is planted out while very young, it is apt to make one, or at most two strong tap roots. In the case of its remaining in the same position after being worked, it is difficult to secure any surface roots that might benefit from future mulchings. For this reason I would strongly advise that all plants worked upon the seedling Brier be transplanted in their maiden stage. We do not want the extreme of deep rooting, and this is avoided by transplanting, as when the tap roots are cut, they will only be slightly more given to deep rooting than are the cutting Briars.

THE MANETTI

has suffered a great deal of abuse during the past six or seven years, often wrongfully. True, it is not suitable for all Roses, but then it is eminently so for many. More easily and cheaply propagated than any other, besides being more certain to live when transplanted for working upon, and also when removed to its permanent quarters, this stock has undoubtedly brought the Rose into far greater popularity, owing to the small cost at which a good plant can now be produced. I am not going to prefer it to the Brier, as if I had to make choice of one stock only, it would be the latter. But I do honestly think the Manetti is a much better stock when properly handled than many amateurs would have us believe. It is grand for pot Roses, also for the majority of Hybrid Perpetuals and Bourbons out of doors. Some complain that plants worked upon this stock are short-lived. I do not find such the case; in fact, not more so than the same variety upon any other stock, provided they are suitable to one another. Many Teas and Noisettes will do well upon it. Recently I saw a Maréchal Niel that was worked upon this stock ten years ago, and which was in grand form. All Teas, Hybrid Perpetuals, Bourbons, &c., will thrive upon it when grafted and cultivated in pots better, in my estimation, than they do on the Brier stock. Still, I am not recommending it for Teas and Noisettes out of doors. In this case I prefer the Brier. I would not have written so much in favour of the Manetti did I not feel that it has been unjustly abused by many, and I would like to point out what I fancy is one reason for this. It is only since the cultivation of Roses has been better understood, and reached a higher standard, that the newer stocks have come into more universal use. Previous to this, Manetti stocks were made carelessly. No eyes were removed from their base, or, at any rate, the importance of doing this thoroughly was not so clearly recognised as at present. The cuttings were also made longer and budded without being transplanted. Consequently the Rose bud was not inserted upon the base of the roots, and an enormous lot of suckers frequently resulted. The other dwarf stocks came into use just as the great importance of this was fully realised, and hence to a great extent the disrepute of the Manetti. Made as the cuttings are now—or at any rate should be—and transplanted, this stock is no more prone

to suckers than any other. It is considerably earlier than the Brier, and for longevity I can show plants that have thrived upon it for the last twenty years or more.

For many Teas, especially those with a drooping tendency, such as Souvenir d'un Ami, &c., I would strongly recommend the short hedge Brier. It keeps the flowers off the ground and prevents much of the splashing from thunderstorms. Nor do we get such succulent growth as many dwarfs produce, and I am certain that the majority of the blooms are better finished when cultivated upon this stock. A stock may be made from any strong growers of the Polyantha section, or from such as Aimée Vibert, Miss Glegg, and others among the Noisettes. Gloire de Bordeaux, too, makes an excellent stock, so do Dundee Rambler and others of similar character. RIDGEWOOD.

Rose Celine Forestier.—A short time ago there were some notes in THE GARDEN in favour of this Rose. I, too, have much to say in its praise. I have a small plant growing against a north wall in the kitchen garden, and during the latter half of July and the month of August this gave a second bloom, which came in useful. This Rose is considered by many to be tender. It is true it is not as hardy as Gloire de Dijon, &c. Nevertheless, it cannot be considered tender compared with many kinds. The plant above mentioned stood the severity of the two last winters unprotected. I well remember this Rose many years ago when living at Ven Hall, Dorset, making a fine show. In this garden the plants never received any protection and they made large bushes. I believe the secret in getting many tender Roses to succeed is to use every effort to ripen their wood.—DORSET.

Strong & weak plants.—What many amateurs consider a strong plant is really only a coarse and over-fed specimen. Different varieties have distinct habits of growth; therefore we must not expect to get a plant of Louis van Houtte, La France, or Comtesse de Nadaillac equally as strong as one of Mrs. John Laing, Duke of Edinburgh or Gloire de Dijon. No wood that has grown succulent and pithy is of much service, nor will it pass through any but the mildest of winters without being seriously affected, if not quite killed. Fortunately, the present season is not likely to produce much growth of this description; indeed, I fancy that many amateurs will complain about the smallness of their plants when received from a nursery. Now, provided the wood is healthy and ripe, a small plant is preferable to one having strong growth. In the first case, all of the wood will survive the winter and transplanting; whereas, in the second case you will probably lose a good bit, nor will the coarser plant produce such satisfactory results later on. What most amateurs look upon as being strong plants have generally been grown in very rich soil, either with the object of getting a large and showy plant, or else in the endeavour to secure a few extra-sized blooms for exhibition. In justice to the nurseryman, I may remark here that the majority of good show blooms do not come from coarse, over-fed maiden plants, but from a generously treated subject of fair strength. What maiden plants I have seen this year are looking wonderfully well, beautifully firm in growth and in many cases already possessing wood that is hard and serviceable and which is likely to pass through the winter well. A strong and coarse specimen not only fails to do this, but much of the young growth in the spring is also unsatisfactory.—R.

SHORT NOTES.—ROSES.

Rose Mme. Elie Lambert.—Among recent new Teas this looks decidedly promising, and it is certainly distinct. Its flowers are full, fine and erect, very pale, almost white externally, but deepening from

flesh into rosy pink toward the centre. It was raised by Elie Laubert, a name quite unfamiliar among Rose growers.—A. H.

Rose Paul Neyron.—This is a fine Rose when seen at its best. With me it has produced some very fine blooms this autumn. I never had it do so well before. It is very sweet scented, which is more than can be said of many large Roses.—J. C. F.

Rose Mme. Welch.—This fine Tea Rose is in danger of being overlooked. It is very constant in flower, free, and striking, with an erect habit which displays its rich colouring to advantage. Pale externally it has many tints within, and glows with peculiar brightness.

Rose Archiduchesse Marie Immaculata.—This appears to be a promising kind. It was sent out in 1887. A group planted last winter, however, has thrown some striking flowers lately. The colour is almost indescribable, being an admixture of coppery and metallic-red hues, such as are found in *Ideal*, only the flower is larger, fuller, and has a bold appearance. Its name will hardly commend it to general notice.—A. H.

Rose Duchess of Albany.—This is the deep tinted form of *La France*, and own-root plants have lately been giving splendid flowers of rich colour and full fine form. It is said to be sometimes dull in colour, but we were recently looking at some fine flowers with the setting sun shining on them, and they were very beautiful.

Rose Augustine Guinoisseau.—This was noted quite early in the season as giving great promise. There has been no more constant Rose throughout the year, and it is as fine in autumn as it was in early summer. It is a sterling addition and a noble Rose. The heat is supposed to favour light Roses, and this has certainly been matchless in form, tender in colour, and exceedingly free. It is described as a white *La France*, but this is misleading. It has affinities to *La France*, but, far from being white, it is refined and delicate in colour, and of a clear flesh tint, more beautiful by far than if it were pure white.

FLOWER GARDEN.

NOTES ON TIGRIDIAS.

THE two new varieties of *Tigridia* which a few of our dealers are offering, *T. grandiflora rosea* and *T. grandiflora liliacea*, are both very handsome, with large showy flowers. They have not borne as many flowers as *T. pavonia* or the variety *alba*. I believe they are natural crosses between the other older varieties, because I have found both of these among plants of *T. conchiflora*, and not only good types of them, but flowers of various shades of red and yellow, so that occasionally it was hard to tell whether certain plants should be classed as *T. conchiflora* or *T. pavonia*. There were some that seemed to be intermediate between the yellow and white, having a creamy shade, so that it would seem as if they might as well be placed with *T. pavonia alba* as with *T. conchiflora*. But this variation seems to be nearly all in *T. conchiflora*, with very little in *T. pavonia*. *T. pavonia alba* shows no varieties of shades. Occasionally a plant of *T. pavonia* or *T. conchiflora* is seen among the plants of the variety *alba*, but each plant of the variety *alba* is like all the rest, seeming not to have become mixed by the insects as the others have. The bumble bees are the most numerous visitors of the Tiger Flower here, and I believe are aids to their fertilisation. Occasionally honey bees are seen among them, but only a few. In the new

T. GRANDIFLORA ROSEA the outer portion of the flower has a rosy tinge and the inner lighter variegations are yellow, while in the variety *liliacea* the outer portion of the flower is reddish purple and the inner variegation is light or nearly white. In all

of the flowers that I have noticed, rose and yellow go together, and white and reddish purple. I could not find a flower in which the inner variegation was white and the outer one rose. I believe that the variety *rosea* is a cross between *T. pavonia* and *T. conchiflora*, and the variety called *liliacea* is between *T. pavonia* and the variety *alba*. Last summer in an old Mexican garden, Mr. Pringle found a rose-flowered variety of *T. pavonia*, which was so distinct from any other form of *T. pavonia* which he had seen, that he secured a hundred or more bulbs. The flowers of this variety are not so variegated in their inner portion as in the variety *rosea* above mentioned, but in what variegation there is, the yellow predominates.

TIGRIDIA VAN HOUTTEI was first discovered by M. B. Roezl, about twenty years ago, in Mexico. A few seeds were sent to Belgium from which flowering plants were raised, and these were illustrated by a coloured drawing in the *Flore des Serres* of August 20, 1875. Last year Mr. Pringle secured an ample supply of these bulbs from the original locality where Roezl found this *Tigridia*, and I believe these are about the only plants of this species now in cultivation. The plant grows about 10 feet high and bears in long succession fifteen to forty and perhaps not rarely sixty flowers; they are erect, bell-shaped, lilac and purple, and each $1\frac{1}{2}$ inches wide. The flowers are not striking. The red, yellow and white, which so quickly catch the eye in the varieties of *T. pavonia*, are almost entirely lacking in this, and one might pass it in full flower without notice. Yet, upon examination, the flower is beautiful; its delicate markings of lilac and purple of various shades are so unlike those of all the other *Tigridias* that it is the more interesting, and who can tell how useful it may be in crossing with other species and in increasing the number of new varieties? Its flowers are more durable than those of most species and remain open late in the day when others are all closed. After what has been said in favour of the other species of *Tigridia*, the little

T. BUCCIFERA, which I believe is the only species yet found in the United States, is, in my estimation, second to none. It is certainly a most charming little plant, and if it could be had at a reasonable price it would be largely grown. It is very scarce.

T. PULCHELLA is also very distinct from the others. It is a shy bloomer than most species, and bears from one to four or five flowers. The inner portion of its flower is in the shape of a cup, white, with purple spots, while the three outer segments are very dark purple, or almost black. The flowers vary in size from half an inch to $1\frac{1}{4}$ inches or more across in the strongest plants.—F. H. HORSFORD, in *Garden and Forest*.

Pink Ernest Ladhams, which was shown at the recent exhibition in the Agricultural Hall, is an interesting variety, as it throws up a succession of the large, fragrant, delicately coloured flowers pale lilac in colour, with a dark coloured blotch at the base of the petals. Its perpetual blooming character adds greatly to its value.

Heuchera sanguinea flowers freely with me in a rather heavy clay loam, no peat or leaf-mould being used. The situation is in the front of a flat border with full exposure to the sun. After blooming last summer, I divided some of the plants, and this spring replanted them in their old position next to their old neighbours. Both the old plants and those divided bloomed freely this season.—H. C. EGAN, *Egandale, Highland Park, Illinois*.

Crocsmia imperialis.—This is, as stated on p. 218, vastly superior to the ordinary form, and that this superiority is generally recognised is shown by the fact that the price is well maintained; indeed, it will probably be some years before it can be regarded as cheap, for this variety cannot be increased to anything like the same extent as the ordinary form, which will take possession of a piece of ground and fill it with a mass of roots, as from each corm numerous creeping shoots are pushed forth; whereas, on the other hand, *C.*

imperialis will seldom produce more than one. As far as a limited experience of it in a warm border in front of the greenhouse will allow me to speak, it does not appear to be so hardy as the common kind, but that might possibly be accounted for on the ground that the newer form was grown for a time under glass. A few seeds will often ripen from which young plants can be raised. The groups of this in the succulent house at Kew have been really splendid.—H. P.

The dwarf Antirrhinum.—This type of *Antirrhinum* is referred to in *THE GARDEN* (p. 215) by "D. T. F.," but if the Tom Thumb *Antirrhinum* race is the dwarf *Antirrhinum* of this note, then I hope no one will have such plants in the garden. They are very dwarf, only a few inches in height, the flowers resting closely upon the dense leafage. All the natural grace, freedom, and beauty of the plant as we know it in most gardens are gone. I have seen many flowers spoilt, either by making them of abnormal size or erratic colours, but nothing quite so ludicrous as this new race of *Antirrhinums*. They are useful, perhaps, for edgings, but many other better things can be selected for the purpose, and a bed of the ordinary white and crimson varieties is far more beautiful.—F. P.

NOTES FROM CLITHEROE.

IN spending a few hours at Holden Clough, near Clitheroe, or, more strictly, in Bolton-by-Bowland, the residence of Mr. R. Milne-Redhead, I was struck with many things growing and flourishing in the beautiful gardens in nearly every aspect, and in such a manner as to make one wonder why common and uncommon things could grow so differently in one place to what they do in another, where the climate is practically the same. Of course all the conditions of plant life where we see such facts are not really the same, and it is precisely at this point where, when we read and learn aright, we may draw some useful conclusions for every-day practical gardening. Holden Clough is close on the boundary dividing Lancashire and Yorkshire, the great valley of the district being drained by the river Ribble, a pretty tributary of which passes through the Holden Clough grounds, where, owing to its swiftness and force, it has cut for itself gorge-like features, and liberally furnished its bed with massive or exposed boulders. Not only is the bed of this small river deep, but the Clough has long steep slopes at each side. At the entrance to the Clough the ravine is narrow, the carriage drive in one part being on a shelf above the river. Soon the view widens, continuing to do so until the residence is reached, when a little beyond it narrows again to a sort of ravine higher up. It is in this charming natural enclosure that horticulture and arboriculture are indulged in with rare taste by the proprietor personally. The general aspect is to a degree one of natural quiet and rest. Ferns from almost all parts of the world were flourishing on the wood and river banks between shrubs and big stones, and by little rills falling into the river from the hill sides.

I made a guess that the Clough would enjoy some 6° or 8° of higher temperature in winter, and I suppose it is so. Certainly I saw many things that I could only attempt in my part of Yorkshire in a cool greenhouse, and many things were growing fully exposed that we generally consider to require shade from mid-day sun as well as sheltered aspects from winter cold. Conifers were charmingly clean, and showed their foliar bloom or tints as rarely seen. Conifers are a feature of the place, though the gardens are comparatively young. Rare climbers festoon the house, and nearly every one for that position has been selected for its double use of beauty and perfume. Everywhere is the ground clothed, excepting the hard walks and drives, and a garden promenade may be undertaken almost without leaving the sod. Daffodils and other hardy bulbs are grown in vast quantities. In the gardens at Holden Clough, *Cistus ladaniferus* is quite at home as a tall climber on one of the house gables. *Roses*

open their buds here as they only do in few places. I saw growing in full sun plants of *Ramondia pyrenaica* that would have been burnt up if grown in a similar aspect in more exposed gardens or an atmosphere less tempered with moisture.

Primula scotica grew with such robustness as to more nearly resemble *farinosa*, and *farinosa* had more the appearance of young Cos Lettuce than aught else. Even the Killarney Fern was thriving in exposed places, so far as plant positions could be termed exposed in this sheltered garden. *Adiantum pedatum* was nearly 2 feet high. The Holly Fern had fronds nearly a foot long of an olive-green and leathery texture. Within the limits of the Clough every form of gardening almost is attempted, at least short of glass structures for tropical plants, and all seem to be successful. The orchard houses were especially attractive in the centre of the kitchen gardens; large quantities of fruit had been picked, and still there remained great profusion on the small trees—mostly in pots.

The rockeries, which are artificial, are delightfully covered with hundreds of the choicest alpine, many of which have been collected by the lady of the house. New rockeries have just been constructed, and though of but very recent date, they have a natural and quiet effect already. There are a few beds on the main lawn, but no bedding, in the gardener's acceptance of the term. Natural flowers, herbage and shrubs have not been trimmed away with a too ruthless hand, and I noticed that in many instances such natural vegetation afforded the most delightful shield for setting off a good tree, a group of conifers, or a batch of flowers. Even the common Burdock on the upper banks of the river gorge and fringing the dressed lawn could not have been improved upon by many things we grow as rarities.

The Gunneras were there and *Saxifraga peltata*, but I could not see that they gave a better effect than many of the wild things that existed in profusion, and which, as I noticed, were singularly free from the ravages of grubs and insects. Having mentioned a few things and the way in which they grow under the conditions described, may we not draw a lesson of a useful character therefrom. It has long been clear to my mind that if we can get the protection of tall trees sufficiently far away, and if we can grow companion shrubs so as to increase surfaces for radiating heat and evaporating moisture, we shall begin to find that our plants are helping each other to flourish rather than, as we often see, fighting to kill their neighbours.

J. WOOD.

HARDY WATER LILIES.

JUST a line to say that I have growing here not only the Water Lilies not mentioned by me in my former article, as alluded to by "A. H." at p. 215, but several others obtained from other raisers. My idea was to mention only the very best of M. Marliac's seedlings, but he is by no means the only raiser of choice hybrid Water Lilies on the Continent, and in America these flowers are appreciated even more highly than so far with us in Britain. In addition we have a good many seedlings of our own, and it was this fore knowledge of potentialities far beyond our present actual attainments which led me to see that the water garden of the future was as yet merely in its infancy.

I believe that there are varieties of *M. Laydekeri rosea*, but at all events ours is so far simply a rosy carmine phase of *N. pygmaea* just as *N. pygmaea Helvola* is a yellow phase of that plant with reddish instead of green leaves. All who have so far seen our pond Lilies are simply astounded that such beauty of form, size, colour and perfume are possibly obtainable except from under a glass roof. No one had seen such Water Lily beauty in the open air and in a common cold water pond. Of course I know wherever a tank or pond is heated by exhausted steam, &c., even subtropical Water Lilies may then be grown, and

have been, and still are, beautifully grown in the open air.

As no one replied to my inquiry as to the origin of *N. candidissima*, perhaps the finest of all wild white Water Lilies, or *Nymphæas*, I may say that in referring to Boissier's "Flora Orientalis," vol. i, p. 104, under *N. alba*, he says that it varies much in foliage and flower, and adds further that a gigantic form two to three times larger than the type exists in Lake Siavo, in Macedonia.

Just as I write, Mr. Ed. Whittall, of Smyrna, tells me that his collectors have found a most exquisite rosy Water Lily high up in the mountains, where the climate is not unlike our own. This is good news for all Water Lily growers, and very encouraging to botanists as well. Of course, it may be only an upland form of *N. stellata*, but even so if it prove to be hardy here with us we shall not complain. All who travel where *Nymphæas* grow or are wild in Europe or in America, cannot be too careful in their observations of these lovely flowers, which are far more variable than even the most sanguine of us had supposed to be the case.

F. W. BURBIDGE.

The Japanese Anemone.—About Philadelphia, and possibly elsewhere, says *Meehan's Monthly*, it is nearly impossible to keep it, as the Spanish beetles devour the foliage. Clematis, Ranunculus, and all plants to which the Anemone is allied suffer likewise. They can be destroyed by sprinkling the plants with Paris green, though this is not a nice article in a flower garden.

The Belladonna Lily in the open.—Your description of this in last week's GARDEN reminds me of a border of it in East Anglia many years ago. The border in front of a conservatory was formed of about equal parts of peat, loam and sand and about 30 inches deep with a sharp pitch to the south. The only protection ever given was a few handfuls of common Bracken during the severest portion of the winter, and this border became a perfect thicket of bulbs that used to bloom superbly every season.—D. T. F.

Nemesia floribunda.—This is sufficiently attractive to merit a note, and is pretty in a mass. It is of a neat, dwarf, but spreading habit, blooms profusely and for a long time. It grows about 1 foot in height and branches out freely, each shoot flowering as it grows. The flowers look so much like those of the annual *Linarias* that they might be mistaken for them, having the same form and characteristic spur. The flower is chiefly white, but has a rich boss of lemon-yellow near the mouth of the flower. It is also sweetly scented.—A. H.

Double dwarf bedding Begonias.—When at the Taunton flower show in August I was much interested in a group of dwarf Begonias, double flowered, for bedding, shown by Mr. B. R. Davis, nurseryman, Yeovil. Seeing that the tuberous-rooted Begonia is destined to be largely employed as a bedding plant, Mr. Davis turned his attention to obtaining double varieties of dwarf and compact growth, small flowered and free blooming, and he has succeeded to a remarkable extent. Mr. Davis holds the opinion that these small-flowered free-blooming Begonias, being more persistent in holding their flowers than the single varieties, stand rough weather better and are more durable in consequence. A few attractive varieties were to be seen in Mrs. Hope, scarlet; Lafayette, deep scarlet, very fine; Robin Adair, crimson; Colonel Lausedot, deep yellow; Louis d'Or, pale yellow, and *Gardeniflora*, white.—R. D.

Cockscombs in Hyde Park.—This was one of the surprises of my visit to the park at the end of August. Nice Cockscombs of a good dwarf strain were being planted out of 8-inch pots almost thick enough to touch each other, and gave the beds a rich, if rather a formal appearance. On the spot I longed to mix them with *Celosias*, as I notice from THE GARDEN has been done in Regent's Park. These or the older fashioned *Lovelies-bleeding* would go well with such formal stiff

plants as the old Cockscomb. Of course, the latter are costly bedders, and unless in small quantities or with national resources behind them, may hardly be worth the candle. But it is worth noting as an illustration of our national enterprise in decorative gardening, that Cockscombs almost full grown were being planted out in quantity in the last week of August. Most of the gardening between Hyde Park Corner and the Marble Arch, and especially the more picturesque style at the park end of the Serpentine, furnishes a useful school for the nation, as well as a fair illustration of our style and resources in decorative gardening.—D. T. F.

The autumn Crocuses.—One of the most striking plants or groups in Mr. Barr's fine collection of hardy plants at the Agricultural Hall, Islington, the other day was that of the *Colchicum variegatum*. Its vigour and the richness of the marking in the flowers suggested the question so often recurring, Why are these lovely Crocuses not more generally grown? Unless in botanic gardens, or with commercial growers and collectors, one seldom meets them in quantity. Occasionally, too, but rarely, one lights on them wild or semi-wild in mead, lawn or home woods; but we really need them in infinitely greater variety and in tens of thousands instead of units.—D. T. F.

The Hollyhock has bloomed in many places extremely well this season, and we have seen little of the disease which for years practically banished this favourite from our gardens. Recently we saw a row of a primrose-coloured variety, at least the outer segments were of this refined shade, whilst the centre was of rich yellow. The plants were against an outer fence, and made a charming autumn picture. Hollyhocks require a thoroughly deep and rich soil, and during dry weather plenty of water at the roots, and if a mulch of manure can be given, the results will be more satisfactory. Many beautiful shades of colour occur amongst a good strain of Hollyhocks, but the most delicate tones, such as creamy white and primrose, are the more pleasing. At exhibitions this fine flower cuts a sorry figure. We recently noticed several stands in which not a particle of foliage was to be seen; the flowers were simply stuck on the boards like *Chrysanthemums* or florists' Carnations. Unfortunately, the Hollyhock is so formal, that it has a more grotesque aspect thus seen even than the other flowers mentioned.

MICHAELMAS DAISIES AT CHISWICK.

THOSE interested in the perennial Starworts will find a very large and interesting collection in the Chiswick gardens of the Royal Horticultural Society, where an entire border running the whole length of the large vinery is devoted to them. This year, owing to the drought, the plants are blooming much earlier than usual, and the brilliant sunshine of the past few days has told upon the masses of flowers. A large number of the finest kinds were recently in perfection, and a few notes upon them may prove interesting. This collection is extensive, and comprises a number of rare and charming varieties not easy to get in nurseries. It is such types as these that one wishes to see in gardens to take the place of the many weedy kinds often grown.

Two of the more important are *A. acris* and *A. Amellus*, both dwarf kinds, which make a gay mass of colour. The former seems to vary greatly, and some of the forms are poor, but the true variety is about 2½ feet in length, bushy, dense growing, and smothered with lilac-purple flowers. *A. Amellus* varies little. The varieties *bessarabicus* and *major* seem practically the same, the latter perhaps the taller, all having large, rich violet-purple flowers. The principal varieties in bloom are those of *A. Novi-Belgii*. We made careful notes of the finest, and all those mentioned deserve a place in our gardens. Purity is in the way of the variety Harpur Crewe, and both are not required in the same garden; the former is the better of the two, of pyramidal habit, the flowers white. This is

of course not a good year to judge of the height of the plants, as many, naturally tall, are of medium height by reason of the dry season. The very tall kind named Robert Parker is a case in point, and this variety is blooming freely. It is a very fine kind, graceful, yet compact, and the flowers are of a light lilac-purple colour, quite distinct from those of other Michaelmas Daisies. Janus is very free-blooming, the flowers white, starry, but very pleasing against the narrow leafage. One of the more distinct is Ravenna, the flowers rich lilac, yellow in the centre, and showy. Arcturus is charming; the flowers deep violet-blue, and the leaves of an intense deep green. A good group of this in the garden would create a fine feature. A. Shorti, a beautiful Aster now well known, also A. ericoides, must be mentioned. A bright bit of colour is contributed by A. Linosyris, synonymous with A. linarioides; its flowers are yellow, hence the popular name of Goldilocks. We shall note others as they bloom.

THE WAND FLOWER.

(DIERAMA (SPARAXIS) PULCHERRIMA.)

THE plant now illustrated is perhaps the most graceful of all the Cape Irids; indeed, it is so distinct and effective as seen at its best, in borders or rock gardens, that the wonder is it is so rare. One reason may be the fact that it is not perfectly hardy in all soils and positions. It is like Romneya, Fremontia, Mutisia, Berberidopsis, or Embotrium, and requires not only a specially suitable position in deep sandy soil, but careful and special culture as well. It is easily raised from fresh seeds sown two or three together as soon as they ripen, and placed in a cold frame or on a shelf in the greenhouse. As a rule they germinate not later than the following spring, and the seedlings may be planted out in May in positions where they are to flower. A deep, rich, sandy border in full sunshine or a nook on the rockery suits it best, and it is next to impossible to plant too deeply. On the approach of winter cover the clumps with peat earth or dry coal ashes so as to keep out frost, and when growth commences, a plentiful supply of water may be given with advantage. I have seen this species and its ally, *D. pendula*, with spikes 8 feet to 10 feet in length, hung with their bell-shaped flowers in the most elegant manner on hair-like pedicels. The movement of its flowery wands swaying to and fro in the slightest breeze is very beautiful, and a good group of these plants always forms a focus spot for visitors to admire in the garden. They are plants that all Iris lovers should grow, and their beauty and grace are worthy of any little extra trouble and cultural attention.

D. pendula is the hardier kind of the two, with paler rosy flowers, those of *D. pulcherrima* varying from lilac to rosy crimson.

F. W. B.

Dahlia Flambeau may be described as a decorative variety, although, fortunately, not coarse. A mass of it we made note of recently was very showy, the scarlet flowers, held well up above the foliage, having a bright effect. It does not follow that all the beautiful kinds one sees at exhibitions are of value in the garden.

Sphenogyne speciosa.—This is a really beautiful annual, and is most generally known under the above name, although it is called *Ursinia*, under which name a pretty cut appeared on p. 217, which shows the graceful form of the blossom, but does not convey any idea of the free, graceful spreading growth of the plant. Like all the best annuals, it must have abundant room to grow, and cannot possibly reveal its beauty when a dozen plants are languishing where there is only room

for one. It makes a dense cushion of rich growth, each plant capable of covering nearly 2 square feet of ground. When the plants have such freedom they go on blooming for about three months. The starry flowers, borne on slender stems, are especially brilliant in sunshine, but they close at night and remain closed on wet days. From seed it gives a little pleasing variation in colour from pale lemon-yellow to deep orange, some of the flowers having a broad black band around the disc, and others little or none at all. It lasts quite long enough to be used with good effect in summer flower gardens with other annual or tender things.—A. H.

Venus's Looking-glass (*Specularia*).—This is one of the pretty old annuals which was frequently met with in gardens at one time, but is now rarely seen. There are several species and varieties. They resemble the annual Bell-flowers very much, but long known under a popular name, they are still kept distinct by those who

The Wand Flower (*Sparaxis pulcherrima*).

care for them. The typical kind has flowers of a deep violet hue, and is a good annual in every way, whilst there is a white-flowered form of it. Another species flowering abundantly at the present time is *S. pentagonia*. It is lasting and showy, and has the largest flowers of any. Its colour is violet, shading to blue and white at the base of the flower. It opens wider and is deeper in the throat than the commoner species. Its habit is dwarf, but it branches freely and flowers profusely.—A. H.

Daffodils for naturalisation.—From a purely decorative point of view a few of the Daffodils stand out well above their fellows as being always good and effective. For growing amongst Grass, *N. princeps* is perhaps the best, as the flowers lose none of their size and are borne in the greatest profusion year after year. A large group planted in the orchard here six years ago flowers splendidly and increases rapidly. Some of the kinds tried have not done nearly so well. *N. pseudo-Narcissus* comes dwarfier every year, and the flowers of such as *Horsfieldi* and the double Orange and Sulphur Phoenix get fewer. *N. obvallaris* (Tenby Daffodil) and *N. Telamnius plenus*, however, with *N. prin-*

ceps are all that I could wish. I planted large groups of various kinds before Grass was sown between the orchard trees. The ground had previously been cultivated for some years, but this was discontinued, as the trees were covering most of their allotted space. Groups of Crocus were also planted, and others have since been added; these, too, are doing well. The present being a good time for planting Daffodils, all who have the opportunity should plant bold groups of these fine and fairly cheap kinds; the effect in April will be glorious and the flowers will form a fine addition to the cut-flower basket when needed. No manure should be used when planting unless the ground be very poor, as this often gives rise to disease and decay.—J. C. TALLACK.

NOTES ON HARDY PLANTS.

Clematis Davidiana.—Whether this is likely to prove a good and useful plant in the common acceptance of the word, I should not like to say, but it has obtained good credentials from high places. What the flowers lack in size is made up in numbers, and when the bulky clusters are seen in profusion, the colour is by no means wanting in effect. The flowers show up in round, compact masses of lively heliotropemauve colour. The scent is another good feature for a Clematis; this is in the way of Mace and Lavender. The habit is also distinct. A specimen here has been in flower a month, and there are yet buds enough for several weeks' succession.

Philesia buxifolia.—Doubtless this can be grown out of doors, as I have so cultivated it for several years, but—and this word is full of meaning here—it rarely flowers in the open. When we recall the charming little bell-shaped flowers, in the way of those of *Lapageria*, the disappointment is all the more keen that the flowers do not appear. I take it that the muggy winter season harms the evergreen foliage and so hinders flowering. Anyhow, the plants thrive in summer, making both twig and sucker growth, and they are propagated entirely in open air conditions, so whatever may be the reason why the flowers are so few, the plant is of proved hardiness. It flowers much better, I know, in a cool greenhouse. It loves moisture in the growing season and peaty soil.

Orchis foliosa.—This is the very best time to plant this the noblest of hardy Orchids suited for the ordinary border. If planted this month the roots push with remarkable promptness and vigour compared with later plantings; whilst roots left till spring, if not growing in pots, will have both deteriorated and be liable to die off, as well, if they live, as have little chance of forming good new tubers. I think it is advisable to plant the tubers at least 6 inches deep, measured from the apex, for I have known some to be killed by very severe frosts in damp soil, especially where not protected by shrubs or old leafage of neighbouring plants. We cannot wonder very much at this with a Madeira species; the surprise is rather the other way—that the plant so rarely suffers, though so early in its growth as to get all the most trying late frosts on its new foliage.

Micromeria montana is a soft-wooded minute shrub, flowering when most things are past; the upper halves of its branches are changed into spikes of small blossom of a rosy soft blue or purple. Though not showy, it is charming, and, of course, the perfume of both leaves and flowers, and especially when both are combined, is one of the sweetest and most spicy I know. It enjoys plenty of sunshine, and you get a better, dwarfer habit by growing it in stony soil. Under these circumstances you may depend on it as a fairly good evergreen. Height 6 inches to 10 inches.

Stachya corsica.—It would be hard to describe the loveliness of this as seen in a good-sized patch of, say, 9 inches or a foot across. On a pale green cushion of small leaved herbage the Orchid-

like white flowers have a pretty and uncommon effect. It flowers nearly all summer, and it has the merit of divesting itself of its dead flowers in such a way that the plant and flowers always look fresh; this is no mean feature with any plant, and in the present case of white flowers produced in long succession, it makes all the difference between neatness and shabbiness.

Bellium bellidioides.—Though but a small Daisy, when plants are propagated after the first summer crop of flowers, they not only form vigorous verdant tufts, but come into flower again in the autumn, and at no time could this simplest form of flower be more acceptable than when the wild kind is all but invisible. Besides, it is well marked in its dissimilarities, and its long stems of thread-like thinness allow the dainty flowers to pose in a fashion quite their own. It may be made a good showy thing in the autumn by simply midsummer root-division.

Cornus canadensis.—Many people say they cannot grow this. I do not pretend to say what the reason is, but I will give a few facts. In black soil—nearly all decayed leaves and peat—and in a position where, though the soil is light, it cannot get dry, a dish or depression being formed in the midst, the plant grows rampantly; aspect south-east. I find also that it does quite as well in pots in turfy loam and peat always kept cool and moist, plunged in sand. I have seen it planted in other gardens where it has been said it would never grow before, and under similar conditions as I have described it has begun to flourish the same as with me. I think, therefore, that the soil and moisture are the main points to look to. Just now the plant is lovely in its autumnal tints, and all summer the showy white bracts with their crimson tips gave the plants quite another character. No plant is more fascinating and at the same time more unlike all other rock garden species. True, it rambles at the root, and let it ramble on, for nothing can be more delightful.

Arctostaphylos (Arbutus) alpina.—This is just beginning to put on its glorious autumn glow. Though the fruits of this Bear-berry are of a duller colour than those of the more common *A. Uva-ursi*, it gains by comparison by its rich fiery red foliage. It is a mountain plant, as implied by its name, but no evergreen creeper is more easily accommodated in gardens of a low elevation. Indeed, I used to see it grown splendidly by the late Mr. Niven in the Hull Botanic Gardens. I have not tried it in chalk, and possibly it might not do in that, but in all other sorts of soil it seems to do, and better with a mixture of peat. It is also invigorated by liberal and frequent top-dressings over its long trails during summer. Indeed, by this process you get it to spread quickly and thickly, and when other patches are desired they may be soon made by taking a few rooted layers from the older plants that have been so treated. The one essential thing for this deep, glistening, green creeper is plenty of sunshine, and with that its stems and leaves become beautifully coloured in the autumn. I may mention that it is one of those plants, of which we have all too few, that may be used as a foil for bulbous plants, through which they may grow in winter and spring, and so sustain their flowers erect and save them from splashes, and then all the rest of the year look no worse for the service rendered to the bulbous flowers. Its habit is perfectly flat and neat in the extreme. It is also a fitting subject for stony ledges, over which its trails may extend. It is a decidedly better plant than *A. Uva-ursi*, though both are worth growing where there is plenty of space.

Eupatorium purpureum.—Tall coarse grower as this is, it doubtless deserves a word of praise as a good hot-weather plant. Specimens here have been in flower for six weeks, and are yet showy. The plants are 5 feet high, and the colour of the flowers a red-purple; still there is something in the shade which would warrant one in describing it as a rich colour, though sombre. The fact that many people have admired it may somewhat indicate its value. There is, however, another point

that should be noted: it is a variable species, and a group in another part of the garden, the original plant of which came from another source, is not so rich in colour, being paler. I fear, therefore, intending planters would have to take their chance as to getting hold of the more desirable variety.

Androsaces.—These often go off in an unaccountable way about this season. The death of these plants is often caused by worms, which in a dryish season work hard on the surface during the dewy night, drawing vegetable refuse and green stuff into their holes and forming small hillocks of little stones over the opening. It is by a loop action that they take hold of these plants, which are of convenient form to enable them to break away pieces. Especially such kinds as have stolons—*sarmentosa*, *villosa*, *Chamejasme*, and even the long-stemmed *carnea*—are easily broken by the larger worms, as they offer button-like tufts of foliage to pull by, and it is because these tufts are too large and firm to permit of their being taken into the holes, or even securely covered by small stones, that we see them and grieve about them, otherwise many of us would wonder how in a few nights our plants become so much less. This is no mere theory. I have watched the whole thing, as others may do, and I venture to submit that more of our alpine "go less" in this way than we are apt to believe. Of course, this business cannot go on if there are no resident big worms within, say, a foot of the plants, because they do not altogether leave their holes when they do it, but hold by their natural rough skin, anchor-like. It is not an uncommon thing to see these plants in detached pieces, and others (including *Gentiana verna*, almost more than any other) mixed with bits of stone and rough soil, as if done by means of a small rake. The only remedy is to get rid of the worms by one or other of the well-known methods.

Helenium Hoopesi is really most distinct, and in fact the true thing is scarce. It may be known just at present by its big strap-shaped radical leaves, so much resembling those of *Helenium bullata* or the better-known *Lilium candidum*. They are fleshy and glabrous, with a distinctly pale midrib. It flowers early and has large heads of a glorious deep yellow on silvery or lanate stalks. It is by far the best *Helenium* I know.

Trillium grandiflorum.—Could planters of this favourite now see the amount of root action going on, they would no longer hesitate as to the best time to plant it. The roots from the base of the crown, as well as from the lower parts of the tuber, are pushing rapidly, and fortunate are those who have got their plants into their permanent places, so that such rooting can all go to the credit of the future well-being and establishment of the plants.

Aster pyrenæus is one of the earlier bloomers and now out somewhat sooner than usual. The true plant is vastly superior to any of the Michaelmas Daisies that have done duty for it in commerce, for hardly any species has been more misrepresented. The heads are large, and if the colour is a pale purple, it is bright and effective. The plant, too, is dwarf.

Rhexia virginica.—I have not had much to do with this. I am shy of Virginian species, especially those requiring moist places, because if you have, to begin with, a plant of doubtful hardiness, it is hard to winter such as must have damp soil unless you take them up in winter and store the roots, and this, to my mind, is all too artificial as hardy gardening. Still, some things are worthy of any care if it will bring about successful results, and perhaps this is one of them. I think the very warm summer has suited the plants, as some weaklings here have quite renewed their vigour and will shortly flower.

Primula Sieboldi and all the *cortusoides* group would have been much better if divided and transplanted in June whilst in a leafy state compared with similar treatment at this time. The difference would have been that the June batch would now have been well established, their newly-formed roots would have been made in the new soil, and

frost could not have lifted them. As the old plants are now, they cannot have much more root to make this year, and what they have will be more or less broken during removal; still, being a very hardy and vigorous class, the transplanting may yet be done safely, but the results cannot be so good.

J. WOOD.

Woodville, Kirkstall.

FLOWER GARDEN NOTES.

A REVIEW of the flower garden at the present time and a retrospect of the same during the last four months (always an essential feature at the close of summer) emphasise the fact that many bits of the garden have shone prominently during the present season a long way in advance of other beds and borders. One of the best things at the present time is a long north border, which, having been cleared of old shrubs, was planted in the autumn of 1891 with *Polyantha* Roses, *Paquerette* and *Anna Maria de Montravel* predominating. The space between the Roses was sown last April with *Mignonette*, which has stood its ground better in this cool spot than anywhere else in the garden, and is still flowering freely in conjunction with goodly clusters of *Roses*. This race of *Polyantha* *Roses* might with advantage be more extensively planted; they make a brave show in large beds, closely planted to monopolise the whole space or thinly, as above mentioned, with a carpet of *Mignonette*. There is not a large number of varieties, but a nice bed can be made with, in addition to those already named, *Gloire des Polyantha*, *Golden Fairy*, *Little Dot*, and *Perle d'Or*. If facilities for watering were not to hand, the best beds have been those planted with old-established stuff that was able to hold its own against the drought. Two specially bright beds consist of alternate plants of *R. V. Raspaill*, *Pelargonium* and *Centaurea ragusina*, the *Pelargoniums* being old winter-flowered stuff turned out of 6-inch pots, and the *Centaureas*, early sown seedlings that had been potted on into 4-inch pots. This is a very bright combination, the contrast between the white and the glowing scarlet being good. Quieter, but none the less pleasing, beds are formed by planting *Lady Molesworth*, *Heliotrope* thinly and filling in with *Centaureas*. To break the flatness of such beds, it is well, unless they make very strong growth, to put a stake occasionally to *Pelargoniums* and *Heliotropes* and lightly tie two or three shoots to the same. If these are encouraged to mount the stakes as quickly as possible and then left to their own devices, there will be nice elevated bits of colour here and there in the beds without any apparent stiffness. Double *Zinnias* with a little help at planting time have done remarkably well, and must rank among the best of the summer bedding annuals. An excellent strain and assortment of colour are obtainable from a half-crown packet of seed. They make very handsome beds associated with tuberous *Begonias*, always provided the colours are nicely blended and the plants are not crowded. They may each be set at intervals of 4 feet, that is, 2 feet clear throughout, the bed being finished and carpeted with *Mesembryanthemum*, *Koniga* variegata or *Cannell's dwarf Ageratum*, as may be thought best. Foliage as opposed to flower bedding has come well through the dry season, *Coleus*, *Iresine*, *Beet*, and the white-foliaged plants, as represented by *Centaureas*, *Cineraria maritima*, *Gnaphalium*, and the variegated *Grass* (*Dactylis glomerata*) having all done well. I cannot say so much for the *Alternantheras*; the amount of water given essential to secure growth seems to have developed luxuriant growth at the expense of bright, well-defined colour, and it is very doubtful if they will be seen at their best this season, as the nights are getting cold, and this morning (September 12) the outdoor glass dropped to 31° at 2 feet from the ground. I should say there would be a ground frost of quite 3°. *Marguerites* have done well, especially the small-leaved variety, not so strong in growth as usual, but very full of flower. *Marguerites* make bright beds, associated with alter

nate plants of Dahlia Fire King, or thinly with Annette Fuchsia on a carpet of dwarf purple Petunias.

Reference has already been made to the occasional use of flowers in connection with ornamental shrubs and trees of small size, the mixture of Dahlias and Hollyhocks with small Cupressus and Retinospora, the backing of groups of Delphiniums with the double-flowered *Deutzia scabra*, &c., and as the planting season is fast approaching, it may be well to note any additional work that may be done in this direction. Thus, if on small lawns where few flower beds are to be found, occasional groups of plants are placed to give a bit of bright colour through the summer months, a background can be formed with a plant or two of *Ailanthus glandulosa*, of the large-leaved *Magnolia tripetala*, or *Prunus pissardi* if that colour is required. A very pretty group that came under my notice this summer had *Ailanthus* in the background, with excellent spikes of *Campanula pyramidalis* rising through its foliage, the front of nicely-grown plants of *Rose of Castile* and *Covent Garden White Fuchsias* and *Raspail Pelargonium*, interspersed with *Francea ramosa* and *Areca lutescens*, plants used as an edging being double seedling *Begonias* (a nice strain), dwarf *Campanulas* and *Onychium japonicum* Fern. Now groups of this description might with advantage be employed on many lawns, and, given a background of certain height and colour, an effective display could be made. Nice plants of *Ricinus Gibsoni* would, for instance, contrast well with any bright variegation, and white-flowered *Campanulas* associate well with the Castor-oil plants, also *Galetia candicans* and some well-grown summer *Chrysanthemums*. These are merely a few examples of what may be done with pot plants. A happier arrangement is the effective association of herbaceous plants in their many classes with ornamental trees and shrubs, and to provide for and carry this out satisfactorily should be the aim of all true flower gardening.

Claremont.

KITCHEN GARDEN.

THE MUSHROOM SEASON.

THE Mushroom season has now fairly commenced, and failures there will no doubt be in abundance, as I daresay there is no other crop which has to be produced by the gardener that has caused so much anxiety as the Mushroom. Why there should be so many failures it is difficult to say. It is not my intention to enter upon imaginary causes of failure, but rather to point out some of the shoals to steer clear of, so that success may be assured. The best of cultivators are apt to have a failure with a bed occasionally through some unforeseen circumstances, but I do not see any reason why failure should follow after failure, that is where there is suitable material to work upon. In the majority of gardens where Mushroom growing has to be carried out there is generally the right kind of material at command, even if only in limited quantities. Those who can collect sufficient for a good-sized bed in the course of a week have a decided advantage over those where this process extends to three or four. With these small quantities there is danger of the manure becoming too dry for the perfect growth of Mushrooms either by having much of the manurial elements dried out or burnt out, both being of very frequent occurrence. Whenever I have had a small quantity to deal with, it has been laid out in a layer of about a foot in thickness as it is being collected. There is a mistaken impression that the droppings only are the best for forming into beds, but a bed which is formed of quite one-half of the bulk of

short litter is much to be preferred. The temperature of the bulk is steadier, and it is maintained longer than when only the droppings are used. Another advantage is that it can be prepared more quickly. Even where there is ample material this is very often spoiled in the preparation by being allowed to become overheated before it is turned again. Manure which is allowed to become white before being turned is in danger of this, as when such occurs, much of the manurial properties is lost, and the moisture necessary to maintain a steady heat when the bed is made up is burnt out. By being turned daily after being thrown in a heap, the moisture and the violent heat are gradually disseminated and the whole mass becomes well divided. In the course of a week or so the most violent heat will have been dispersed, when turning will not be needed quite so often, but very likely on alternate days for a few times. A good guide is to have a stout stick thrust into the centre, when the heat of the bulk could be gauged by feeling this. When ready for making up, the material should just feel warm. If made up into the bed before this stage is reached, the temperature is apt to rise very high and then to drop too low. When a bed acts in this manner, it is quite evident that a crop of Mushrooms will not be secured. What is needed after the bed is made up is a steady and regular heat. It will also be noticed that a bed which has been made up before the material was ready for the purpose will, if it is examined, be found to be quite dry on account of the violent heat.

With a supply of good material, it matters little where the bed is made as long as the atmosphere is sufficiently confined and an equable temperature maintained. The worst positions are those which are naturally dry and arid. There are, no doubt, many Mushroom houses of this description, and which are the cause of many failures. The young Mushrooms may appear all right, but they do not grow so vigorously as they ought. This is the reason why Mushrooms generally grow so well in underground cellars. It is no criterion to go by that because a Mushroom house is elaborately fitted up, it is suitable for the growth of Mushrooms. I have a vivid recollection of the fine crops which were produced annually from a low underground shed. The bed cannot be made too firm; in fact, the firmer in reason the longer is the heat maintained.

The spawning of the bed is the next consideration. It is highly important that the very best spawn be obtained, as even in these days of supposed advancement in the making of Mushroom spawn there is much that is inferior. I like fresh spawn, although some growers maintain that old spawn is equally good if it has been kept in a cool and dry place, but of this latter I am not so certain, as the most of my failures have been brought about through using old spawn. After the bed is formed and there is every likelihood of its being ready for spawning in the course of a few days, the spawn is the better for being started. This is best managed by laying the bricks on the surface of the bed. If it is good the spawn will be seen to have commenced working. As regards the most suitable temperature for spawning the bed, I have the best results when this is at about 80° or 85°. This is not by any means a high temperature, but I take the gauge from the centre of the bed, so that the heat of the place where the spawn is placed would be a few degrees lower. As regards soiling over the bed, as long as it is known that the spawn is good, there is no benefit whatever in deferring this. If the soil be placed on whilst in a

fairly moist state it will bind quite sufficiently. The practice of adding water, and also of smearing the bed over afterwards with water and the back of a spade, is not at all a good plan. As the temperature declines in the bed, an old mat or two thrown loosely over the surface will assist in maintaining an equable temperature and also prevent the bed from becoming too dry. In a close Mushroom house or shed a light covering of old mats is much to be preferred to either hay or straw. It is a great mistake to use artificial heat too freely. If the structure could be maintained at a temperature of 55°, artificial heat should not be used, and when it is found necessary to use it, do not allow the temperature to rise above this. I have also found it a good plan after the young Mushrooms commence to appear to remove the loose older mats from the surface, and in their place to lay a clean mat over the whole bed, keeping it from resting on the surface by strips of wood laid on bricks. This maintains a genial warmth about the surface of the bed, and is a good system to adopt in close and darkened structures. In more exposed sheds, dry hay or even long litter from the stables forms the best covering.

A. YOUNG.

POTATOES AND THE DROUGHT.

As far as early and in some instances second early varieties are concerned, the great heat and drought of the summer we are just leaving behind only had the effect of forcing maturation and lightening the crops. It is only of the latter consequence that we have any reason to complain, for it is very certain Potatoes freer from disease and of better quality were never lifted. All things considered, we have every reason to be satisfied with the effect of the heat and drought on early and second early Potatoes, for not only were the crops moderately heavy and the quality excellent, but early maturation gave good opportunities for getting in successional crops that many have taken full advantage of. It is not often that so many and such good breadths of winter stuff, including Brussels Sprouts, Broccoli, Savoys, Borecole, and such like, are seen in all directions as they are this season, nor do I remember having previously seen such promising crops of winter Turnips as are generally observable at the present time.

When, however, we come to look into the effects of heat and drought on the later varieties of Potatoes there is less reason for congratulation. Tuber growth of these ceased at much the same time as in the case of second early varieties, the crop being both light or much under the average and the tubers small. Before maturation was complete, that is to say, before the growth of haulm had wholly ceased and the skins of the tubers had fairly set, the rains came and restarted them into active growth. Instead, however, of the tubers growing afresh in the usual manner, that is to say, by forming a series of small Potatoes, the protuberation quite unexpectedly took the form of a considerable lengthening out. To such an extent has this taken place, that there are actually very few really round Potatoes to be seen in this part of the country, all more or less partaking of the kidney shape. For instance, Holborn Prolific, which with me has hitherto given a good crop of roundish oval tubers, is this season quite altered in outline. The first growth was right enough, but to this was added another length, so that many of the tubers are 9 inches long, and in shape resemble what remains of an old wooden doll after

the legs and arms have been broken off. Laxton's General growing alongside has behaved very similarly, and very few round tubers are to be found on lifting Reward, Abundance, or other varieties that should be round. The Gentleman, a long thin kidney variety, has added another length, and so also have Magnum Bonum and Bruce, a form scarcely distinct from Magnum Bonum. On the whole, the crops are heavy, or more than double in weight to what they would have been had the rain not fallen when it did.

The question is, therefore, what effect will this second growth have on the quality of the tubers? Opinions vary somewhat at present, some that have cooked a few or many of these dual tubers reporting that they are wretchedly bad, tasting much the same as frosted Potatoes; others saying that they are very good indeed. On examination it is found that the two growths can readily be separated, the skin on that portion of tuber first formed being set hard, while the later growth is still very tender, and can be scraped much as early Potatoes are prepared for cooking. All or most of them have a "waist," that is to say, a contraction between the two growths, so that if need be it is an easy matter to separate the new parts from the old, and to cook them separately. Thus treated, the older portion is dry, mealy, and full flavoured, no great absence or loss of starch being apparent, while the newer portion requires rather less boiling and meets the taste of those who like a rather close or firm Potato. One way out of the difficulty that has been found to answer well in the case of tubers that cook very badly nearly or quite entire is to cut them up into 2-inch lengths, put them on in cold water, and boil slowly till all are well boiled through. Thus treated—salt being added when the drying or steaming commences, they are "good enough for anything." It may be that as the newer portion of the tubers becomes more matured there will be little or no difference in the quality generally, all being cooked together in the usual manner. Should this, unfortunately, not prove to be the case, it will be next to impossible to separate the two ages, and the other alternative, viz., that of slicing up the tubers, ought to be given a fair trial.

Somerset.

W. IGGULDEN.

Onions.—"A. D.'s" statement on p. 226 that large bulbs of Onions will not keep needs to be accepted with some reservation. It is generally admitted that the season of 1892 was prejudicial to the proper maturation of some vegetables that have to be kept through the winter for cooking. In November last I had four large exhibition Onions given me, and for some four months I carried them about with me, as I employed them as illustrations of high culture, symmetrical appearance and solid weight of flesh, using them more as showing what can be done with this esculent when grown for a definite purpose. In March they were stood on a bed of soil in a cool greenhouse and in April planted in the open, for the simple purpose of testing the produce in the form of seed. Each bulb produced seven and eight seed stems and a remarkably good crop of seed of excellent quality. This case appears to me to afford substantial proof that large Onions do keep, and from what I have seen during several winters, I am convinced that if the bulbs be properly matured and carefully preserved, they will remain firm and solid for a considerable time. Why, then, should there be so much condemnation of large Onions, provided they are solid and symmetrical, I cannot conceive. In relation to fruit exhibiting, large bunches of Grapes, Apples, Pears, Currants, &c., always find favour, provided they are sound, handsome, and of good quality. Why it should be neces-

sary to demand of competitors that all Onions exhibited should be raised from seed sown in the open ground, I cannot understand. If an Onion grower chooses to sow his seed in boxes in a vinery or other warm house in order to get a good start, I fail to see why he should not do so; besides, upon whom is the burden of proof of having been sown in the open air to rest? I know gardeners who say they get the best produce from a bed of Onions the plants forming which had been transplanted, and Mr. A. Young states distinctly in his capital article on the "Onion Fly" on p. 225 that transplanted Onions are seldom, if ever, affected by the fly. Let the gardener have a free hand, and if he finds the production of what are termed "monstrosities" is a mistake and leads to loss, the matter will soon right itself. Freedom in such matters is far better than restriction.—**ALLIUM.**

TREATMENT OF SEED POTATOES.

THIS season early and second early Potatoes matured exceptionally quickly, and in most cases were lifted and that portion of the crop available stored fully a month sooner than has happened for many years past. The weather since these tubers were dug has been very hot and close, the warmth reaching all places where Potatoes are ever placed, whether above or below ground. One effect of this has been to cause an early sprouting of all not kept in a cool, airy place, those in particular that were placed in cellars and other dark places being remarkably forward. Unless, therefore, steps are immediately taken to check rapid sprouting this will have a most injurious effect on next season's prospects. When the first strong sprout is grown to waste, that is to say, owing to its earliness and great length, it has to be pulled off, those that follow rarely, if ever, equal that first formed. Especially is this the case with Ashleaves and the choicer kidneys of the Lapstone type. Now, unless there is a strong sprout from a seed tuber either on it when planted or forming soon after, a full or heavy crop cannot be had by any chance. The aim of all good growers, whether professional gardeners, amateurs, or cottagers, ought then to be the careful preservation of the seed-tubers, now being stored, in as dormant a state as possible. Nothing in the shape of a heap of them should be formed. At lifting time let them be separated from the ware and quite the smallest Potatoes—good medium-sized uncut tubers being the best for planting—and kept stored thinly till next spring. Greening Potatoes by exposure to the light and air is so far advisable, inasmuch as it slightly retards sprouting, but this ought not to be brought about by leaving them for several days or weeks lying on the ground or on paths, boards, or mats in the open. Years ago when I tried this old notion, it became evident before planting time arrived that not a few of the tubers had taken disease between the lifting and storing times, this being effectually hid by the coat of green. Tubers thus diseased do not decay rapidly, and perhaps the first indication of its presence is in many cases the weakly growth of the sprouts. It need hardly be added that diseased sets cannot support a strong growth of haulm till it has time to become self-supporting, and ought never to be planted. Disease germs are far more plentiful in the air than most of us are aware of, but if they cannot reach the tubers before their skins are dry and well set they will not affect them afterwards, always provided the Potatoes have been properly stored. So certain am I that it is possible for the tubers generally to be lifted in a sound state and yet become diseased in the interval between lifting and storing, that it is always my endeavour to do all the digging of crops that are to be stored in dry weather, and while also the ground is in a semi-dry state. This admits of the tubers being placed under cover or in heaps and lightly covered up almost as fast as they are dug, and in any case I greatly object to leaving a lot of newly-dug Potatoes on the ground to dry all night long. It is a bad practice frequently resorted to, especially by cottagers.

Premature sprouting is detrimental to ware or cooking Potatoes, though not to any appreciable extent if the shoots are rubbed off before they are more than 1 inch in length. Nor can it well be prevented, as they must be stored in heaps, either under cover or in the open, and also be kept quite in the dark. As already intimated, seed Potatoes are very different, and sprouting must be prevented as much as possible by storing thinly as well as exposing the tubers to light and air. Keeping them in single layers, resting in the case of Ashleaves on the smaller end or that previously attached to the plant, cool and fairly light, are the best preventives of premature sprouting and also the surest way of having the sprouts stout and strong when the proper time arrives for growth to be made. Shallow trays with the corner blocks 2 inches higher than the sides are very handy for storing seed tubers in, as these can be packed one above another and yet not unduly shade each other. Any kind of flat box or shallow basket blocked up well one above the other is preferable to storing in deep boxes, hampers and such like. The tubers should at planting time be quite firm and the sprouts short, yet how often do we see cottagers turn them out from a spare room or elsewhere all matted together and shrivelling. Protection must certainly be afforded during the prevalence of severe frosts, and if the room or outbuilding when closed cannot be depended on to protect sufficiently, then ought mats, blinds, straw litter, or even several coverings of paper to be used as well. M. H.

GARDEN FLORA.

PLATE 928.

WHITE VARIETIES OF LÆLIA ANCEPS.

(WITH A COLOURED PLATE OF (1) L. A. SCHREDERIANA, (2) L. A. SANDERIANA.*)

THE beautiful plants represented in this week's coloured plate are varieties of the well-known species *L. anceps*, which was introduced from Mexico nearly sixty years ago by the Messrs. Loddiges, of Hackney. This species has always been a great favourite with Orchid growers, as its blooms open in mid-winter and produce a charming bit of colour at the very dullest season of the year. The flowers last in perfection a very long time. White Orchid blooms have always been highly appreciated by growers at home, and their value is also being found out by the natives that bring in flowers to those who are collecting plants. The first of these white-flowered forms of *Lælia anceps* was sent home by Tucker, then collecting for the Messrs. Low, of Clapton. This plant passed into the hands of Mr. Anderson, then gardener to the late Mr. Dawson, who had a far-famed collection at Meadow Bank, Uddingstone, near Glasgow, and with whom it flowered in the autumn of 1869. It was dedicated to Mr. Dawson by Professor Reichenbach. This variety has never again been found. Mr. Sander, of St. Albans, has given us the albino forms of *Lælia anceps* which now adorn our plant houses, and he tells us that most of the white-flowered species that he has imported have been sent by his collectors from the side of the country bordering on the Pacific, and not from the Atlantic side, where the typical plant abounds, and where *L. anceps Dawsoni* is stated to have been found, as well as *Percivaliana*, *Hilliana*, and others. These plants, which come from the Pacific side

* Drawn for THE GARDEN by H. G. Moon, in the St. Albans Nursery, February 25, 1893. Lithographed and printed by Ben George, Hatton Garden, London.

1

1 LAELIA ANCEPS SCHROEDERIANA .2 L A SANDERIANA

of the country, with which communication is more difficult, are necessarily much longer on the way, and when unpacked are found to be much shrivelled and exhausted. Then again, as these plants come from a warmer part of the country, they will not grow with their native vigour in so low a temperature as the species and varieties which come from a cooler latitude. The most of our growers quite ignore this fact, and suspend them side by side. Here they make fair-sized growths, but they cannot be ripened sufficiently to form flower-spikes; consequently they have obtained the character of shy-bloomers. This, I think, can be obviated readily by different treatment. Mr. White, who has the care of Sir Trevor Lawrence's collection at Burford Lodge, has the plants growing most vigorously in a bright and hot house, and sending up many spikes which will yield a fine display of bloom during the coming season. These plants should be grown in well-drained baskets, and they should be kept near the glass exposed to the full sun and light. During the growing season they require an abundance of water and a very moist atmosphere, but after growth is finished and the flower-spikes made up, much less will be necessary. The plants should not be allowed to get too dry. In potting use good peat fibre, from which all the fine soil has been shaken, mixing with it a little clean chopped Sphagnum Moss and pressing the whole down firmly.

L. ANCEPS SCHROEDERIANA.—This variety appears to be the giant of its race, for not only does it make very strong growth, but its flowers are exceptionally large, stout, and of good shape and substance. The sepals and petals and the front lobe of lip as well as the exterior of the side lobes are of the purest satiny white, and it is only in the throat where any colour occurs; here it is streaked with numerous broad lines of purplish crimson. Of this variety Mr. Sander observes in his "Reichenbachia": "It is very curious and peculiar that these forms are not to be found growing wild in the forests. Every plant we have sold had been cultivated and grown on trees in front or near the huts of the Mexican Indians, and had to be purchased separately. In these trees the plants had been growing for centuries." It appears to be as rare as it is beautiful.

L. ANCEPS SANDERIANA.—This is another charming form with pure white flowers, saving the lip, which is coloured very much in the way of the variety Dawsoni, but the flowers are smaller. It is an exquisite variety.

L. ANCEPS WILLIAMSII.—This is another white variety introduced by Mr. Sander. It has larger flowers than the typical plant, and these are of the purest white, saving the orange-yellow in the throat, where it is also marked with broad radiating lines of rich crimson. The variety called Stella comes very near to this plant, but the radiating lines within the throat are of a deep rich purplish crimson.

L. ANCEPS VIRGINALIS.—A variety with somewhat smaller flowers than the usual form. The flowers are of the purest white, saving a tinge of yellow in the throat, where it is quite destitute of any coloured lines. It is very often called variety alba.

L. ANCEPS DAWSONI was the first white-flowered variety brought home to our gardens in a living state. It is a very chaste and beautiful form, the flowers large, measuring nearly 5 inches across, sepals and petals pure white, the side lobes of the lip stained with rosy purple on the outside. The throat is marked with numerous forked lines of rich purple, the crests on the disc yellow, the front portion of the anterior lobe of a rich deep magenta-purple, white at the base. Although the oldest of the albino varieties, it still retains its position as one of the handsomest forms known.

L. ANCEPS PERCIVALIANA.—In this variety we have one of the smaller-flowered kinds, but it is one of the freest that I know; the sepals and petals

are white, flushed with a tinge of blush-pink; lip three-lobed, the lateral lobes deep purple at the tips, below which are some purple dots, the throat streaked within with purplish crimson on a deep yellow ground, which passes into a creamy yellow on the base of the front lobe, broadly tipped with purplish magenta. It is one of the most beautiful of the white forms of the old *Laelia anceps*. It appears to be a much freer deer than the forms from the warmer parts of the country.

L. ANCEPS HILLIANA.—A very beautiful kind, which comes from the same district as the two last-named varieties. It is a very free grower. The sepals and petals are pure white, the lip three-lobed, side lobes somewhat pointed, and having the tips blush-pink. The inside of the throat is yellow streaked with purple, the front lobe of a delicate blush-pink.

L. ANCEPS VEITCHIANA is a charming variety, with large flowers of good substance; the sepals and petals are white, slightly tinged with pale lilac, the side lobes of the lip streaked with lines of pale rose within, the front lobe rosy purple. It is a very charming and distinct form.

L. ANCEPS VESTALIS.—A large-flowered beautiful variety, with broad, pure white sepals and petals. The lip also is white, with a soft yellow ground, some purple stains on the side lobes, and a few darker purple veins.

The above are the principal white forms of this fine old species. There are many other kinds, but these differ only in some slight degree. I hope to see as grand a display made by these white forms as I have seen made by the many-hued varieties of the normal plant.

WM. HUGH GOWER.

THE WEEK'S WORK.

THE KITCHEN GARDEN.

PROTECTING VEGETABLES FROM FROST.—The temperature has fallen dangerously low of late, and as frost may be expected now at any time, any vegetables which will assist in prolonging the supply should be protected, as very often a slight covering only will be sufficient to ward off a moderate amount of frost. At this season an early frost may occur, and be sufficiently severe to injure tender crops. It may be several days before another visitation, and the weather in the meantime be sufficiently favourable to keep the uninjured crops in good order for a few weeks longer. This shows the necessity of covering such crops as French and runner Beans, Vegetable Marrows, Globe Artichokes, and exposed heads of Cauliflowers. French Beans which have been prepared for late crops, to be eventually covered with frames, should have these placed over at once. Others may be quickly protected with mats, waterproof canvas, or even tiffany, with supports for keeping the coverings off the tops. Light tiffany will form the best covering for runner Beans, this being lightly thrown over the top. A frame may be placed over a portion of the Vegetable Marrows. In the case of Globe Artichokes, any good heads and also later ones from this season's planted suckers will be sure to prove acceptable as long as they can be secured, and any form of light protection should be devised. Cauliflowers, of course, can be saved by bending the leaves over the heads.

LEEKS.—Leeks where growing on well-manured soil or where planted in prepared trenches are growing very well this season, and if it is desired to further increase the size, a soaking of liquid manure may be given with advantage, at least to those growing in trenches, pouring it along each side in sufficient quantity to reach the roots. The amount of soil to be added to ensure blanching will depend upon the depth they were planted. If they were planted with the roots near the surface, very little blanched stem will be secured unless they are well moulded up. When they are to be

blanched each plant should be drawn up carefully together and the soil added lightly, care also being taken that the hearts are not smothered up. In the case of the very large Leeks the practice is sometimes adopted of placing folds of brown paper around previous to adding the soil, so as to ensure the shanks being quite clean when required for special purposes, but for all ordinary use the soil is sufficient. If the plants are of a good size earthing may take place at once. If previous instructions have been carried out as regards planting in deep holes formed with the dibber, a shank long enough for all ordinary use will be secured, but to further increase the length the rows may be moulded up, drawing the soil for the purpose from between the rows with a hoe.

WINTER SPINACH.—Up to the present time the plants have done well, the seed having germinated freely, but unless the rows are unduly crowded on account of thick sowing, thinning should not be carried out too early. Not but that early thinning is beneficial to the plants, but on account of the often sudden appearance of grubs it is best not to be in too great a hurry, but to carry out the process gradually until the plants are eventually about 6 inches apart. The surface should now be occasionally stirred with a Dutch hoe, both to disturb any grubs that may be present as well as to destroy weeds. It is best to defer gathering until the winter season really arrives. A sowing may also well take place at once, so as to form a succession to the above next spring. This latter will come into use just as the former has run to seed, and will prove useful at a time when there is often a dearth of other vegetables.

PROTECTING OPEN-AIR TOMATOES.—With a continuance of fine weather, quantities of fruit should be secured, as rarely have plants in the open air carried such fine crops as this season. But as the nights are now colder, it is not safe to leave them unprotected, and as the fruit is of much better flavour when ripened on the plant, ripening may be hastened by placing spare lights in front of the plants. Of course, there are quantities which will not ripen on the plants, and these should be cut with a fairly long length of stem and hung up in a dry and warm plant house or even in a warm kitchen. The smaller green fruits may be used up for pickling, &c., as so fully detailed by "W. I." in a recent number of THE GARDEN, as there are now several useful recipes for using up green Tomatoes for winter use.

A. YOUNG.

ORCHIDS.

It is very seldom indeed that Orchids in the British Isles have the advantage of such a long-continued spell of sunshine as they have enjoyed this autumn, and as this was preceded by an exceptionally brilliant summer, it will be interesting to note the effect of it upon Orchid collections. We have now gone through the period of bright sunshine, and colder nights, with much shorter days, warn us that we are within a short period of the winter season again. Week by week there is a shorter period of light, and it behoves us to note this and alter our treatment accordingly. It is easy to make a mistake in respect to overdoing the plants both with water in the atmosphere and at the roots. During the hot, dry summer weather the paths and stages might be deluged with water, and but little harm would be done to the plants even if a few dull days should occasionally intervene in a period of sunshine; but it is different now, for the nights are cold, and even by day moisture does not evaporate very fast. It is very desirable that the moisture should be allowed to evaporate to the extent of the floors and stages being dry for a few hours in the day. We may expect heavy rainfall soon, and this will cause the outside air to be thoroughly moist at all times, so that heated dry air cannot pass into the house from outside. Some houses require much more damping down than others. Span-roofed houses, which have a great surface of glass exposed, require more moisture than a half span, and the lean-to house needs less than either. From the

end of this month until cold weather sets in, when a good deal of artificial heat has to be applied to keep up the temperature, the Cattleya house need only be damped down in the morning and again in the afternoon. The East India house may be damped more frequently, and for the cool house, where no artificial heat is really needed at present, once on dull days will be enough; but after a day of bright sunshine the house should be damped down both morning and evening. Many Orchid growers have an idea that the atmosphere should be kept at saturation point. If it is intended to promote and encourage disease, especially "spot," in the warmest house, I would say keep up a constantly moist atmosphere and shut up the house entirely, except a little ventilation in the daytime. To keep such choice Orchids as Phalenopsis and Saccobulbiums clean and healthy, let the house become dry at mid-day, damping down moderately in the morning and about 3 or 4 p.m. The temperature may rise to 85° or 90° by sun-heat, but be careful not to allow the sun at the hottest part of the day to shine upon the plants. The house should be shut up in the afternoon with this temperature, and be damped down at the same time. In a few minutes the glass becomes slightly obscured by condensed moisture, and the sun does not cause any injury through the glass when in this condition. The Cattleya house may be freely exposed to sunlight—in fact, after this, shading the division where the Lælias and Cattleyas are growing may be considered a necessary evil, and the blinds should only be let down if it is seen that the leaves are likely to be scorched. The temperature of this division at shutting up time may be from 75° to 80°, and when the temperature of the warmest house falls to 70° and the Cattleya house to 60°, it must be maintained about these figures by artificial heat. A little heat should be kept in the cool house; it is not necessary to keep up the temperature if the ventilators are closed, but heat should be used with a little ventilation to keep the flowers in good condition. They are apt to spot if no artificial heat is used, and very soon decay at this season. The temperature should be about 50° as a minimum, and rise about 10° by day.

Continue to clean and repot any plants that need it. A good time to repot *Odontoglossums* is when they are starting into growth, and any very choice varieties should have their wants studied in this respect. They do best when fairly well rooted before repotting, and the roots should not be disturbed more than is necessary. Any plants that have gone wrong at the roots should have the bad soil removed with all traces of decay on the roots of the plants themselves, and be repotted in a much smaller size. *Maxillaria grandiflora* has now passed out of bloom after giving a profusion of its beautiful white flowers for two months. I am now about repotting it, and it seems to thrive best with a portion of fibrous loam amongst the peat. It is a vigorous growing plant, and should have a good shift, and soon fills the new potting material with the fibrous roots. Get all the repotting in this house done if possible by the middle of October. Most of the *Dendrobiums* have been removed from the warm house wherein they made their growth to a warm greenhouse temperature with moderate ventilation at first. If no other convenience can be had for them, they may be placed in ainery from which the Grapes have been removed, or at least where they are ripe. The dry atmosphere seems to suit them, but it is not well to allow a draught of cool air to blow directly upon them. I find they do well on a stage against the back wall of theinery, but it is much better to keep them in a house that can be specially adapted for them. A few late plants of *Dendrobium nobile* have not quite finished their growth, but they were June flowering specimens, and will be reserved for late blooming next year. *D. Dalhousianum* and *D. Brymerianum* will not finish up their growths for a few weeks yet, but they are earlier than they were last year. All the *D. Farmeri*, *D. thyrsiflorum*, and *D. Paxtoni* types have made their growth and are now placed at the coolest and also the lightest end

of the Cattleya house. On the shady side of the Cattleya house we have our plants of *Aerides Fieldingi* and the *A. crispum* type. They are now making their growth and require to be kept moderately moist at the roots, in order to keep the Sphagnum Moss growing freely. They do not like a close, stuffy atmosphere, and seem to enjoy their position in this house. *Cypripedium caudatum* also does well in the same position, and *Cœlogyne cristata* has done much better since we used a little loam in the compost and placed the plants in a shady part of the house. They also being in full growth require plenty of water. *Cymbidium eburneum* and *C. Mastersi* are also grown in this position; it is well known that they succeed best in good yellow loam. Most of the Cattleyas have finished up their growths, but a few have not yet done so, and where this is the case, be careful not to allow water to lodge between the peryony coating of the pseudo-bulb and the bulb itself. The outer coating in bulbs that have not finished their growth is soft, and contains much moisture. As the bulbs ripen the covering gradually dries up, but in this process much moisture is given off, and in the rather confined air of the house it lodges between the sheath and the bulb, and I have known this natural moisture itself cause decay. If much moisture is present lay the plant on its side, firmly grasp the base of the bulb in the hand, and draw it up the sheath; in this way the moisture may be pressed out at the top. Watch such plants until it is seen they have passed through the critical period. We have not yet finished repotting all the plants of *Lælia purpurata* that really need it, but they will all be finished in the course of next week.

J. DOUGLAS.

FRUIT HOUSES.

PEACHES FLOWERING PREMATURELY.—Trees of early American varieties that were rather hard forced and some time since lost their leaves, either in due course or from red spider attacks, are showing a tendency to flower again. This is what has happened, or is happening, with other fruit trees in the open, and no one need be surprised if Peach trees under glass behave similarly. All the same, the occurrence is much to be regretted. If it is the whole of the young wood that is flowering thus prematurely, then the best thing to be done is to attend to the pruning, cleaning, and re-tying at once, and if crops set, leafy growth also commencing, do all that can safely be done to sustain this activity. By the time more heat is required, it may perhaps be safely accorded to the rest of the trees, an extra early and, it may be, very valuable supply of fruit being the outcome. If only a few of the short spurs show signs of flowering, then probably the right course to pursue would be to remove these unnaturally early flowers, and to retard the rest of the tree as much as possible. To all appearance very little excitement would also start the buds of all early forced trees, and the aim of the cultivator should be, therefore, to keep the houses as cool and airy as possible. *Chrysanthemums* are largely stored in high lean-to Peach houses, but they must not be unduly favoured this season, or some of the trees, notably those that are most shaded by the tall plants, will be in flower before they are got ready for next season. Much of the liquid manure given to *Chrysanthemums* finds its way into the Peach borders, and if the latter are not new and somewhat rich, it will do good. Give abundance of air, leaving a chink on even in frosty weather, and fire-heat will not under these circumstances greatly affect the trees. Shade the blooms from bright sunshine, and there will then be little or no damping off to complain of.

EARLY VINES.—These seem disposed to hold their leaves longer than desirable, especially where the pruning is usually done late in this month. All that can be done at present is to half prune the laterals, cutting them back, say, to the third, or, at the most, fourth joint, and to keep the house as cool and dry as possible. Pot Vines are also fresh in appearance. These should still be kept

against sunny open walls and prevented from becoming very dry at the roots, the pots being eventually covered over with enough straw litter to ward off both heavy rains and severe frosts. If the short laterals on these young canes have not already been cut out, do it while yet the leaves retain their freshness, as winter pruning is apt to be attended by bleeding when the Vines are started.

SUCCESSIONAL VINES.—Many of these will have been nearly or quite cleared of their crops, this admitting of a heavy syringing with clear water being given occasionally with a view to getting rid of red spider and other insect pests. First remove all sub-lateral growth, and then, if a garden engine is available, use this in preference to a syringe. While yet the leaves are green is the best time to renovate the borders, this taking the form of either a fairly rich top-dressing or the substitution of fresh compost for some of the old exhausted soil at the front of the borders. If a top-dressing only is applied, this being sufficient if the border has not been long made, let it consist principally of turfy loam, adding some good flaky manure, burn-bake, a sprinkling of wood ashes and bone-meal. Before applying this, loosen the surface of the border, give a good soaking of water, next day carefully remove the soil down to the roots, and then give a liberal top-dressing with the compost. Where the crops have been heavy and the borders are naturally much exhausted, a good soaking of fairly strong liquid manure might be given with advantage, nothing answering better than either sewage water or diluted drainings from a mixed farmyard. Fresh soil is what Vines like, and, in addition to top-dressing as just advised, it pays well to renovate the fronts of either inside or outside borders. Supposing the Vines are in good health, no ill results from an injuriously deep root-action having been apparent while the crops were ripening; then all that is necessary is to remove a width of about 3 feet of soil from the front of the border to be renovated, saving the best of the young roots found as the soil is forked away, the older or naked roots being freely pruned. All, after bruised or broken ends have been cleanly cut off, should be relaid in fresh compost, consisting largely of roughly chopped up fibrous loam to which a little good decayed manure and the other ingredients recommended for the top-dressing have been added. This should be very firmly packed up against the old soil, or otherwise when it settles there will be a bad division and the breakage of roots to deplore. Many fresh roots will be formed in this fresh soil before root-action ceases this autumn, and next season it will afford good support to the hard-worked Vines.

PARTIALLY LIFTING VINES.—When the crops fail to ripen satisfactorily, shanking being very prevalent, and when also the wood ripens badly in spite of a free application of fire-heat, then it may safely be assumed that the root-action is much too deep and altogether faulty. Market growers who are not bound to have a full crop of Grapes every season in each house can afford to root out exhausted Vines and to form fresh borders in their own rough and ready fashion for a fresh stock of young Vines. Private gardeners are differently situated, these finding it imperative to restore their old Vines to good health and a productive state without the loss of a season. As it happens, it is possible to do this effectively, the restored Vines sometimes fairly eclipsing much younger ones in wholly new borders. It is useless attempting these restorative measures without a good supply of fresh soil, not necessarily all turfy loam, though this is what most growers prefer. Failing a good heap of fresh loam, roughly chopped up, procure as much of this as possible and supplement it with the requisite quantity, or say to the extent of one-half of the bulk, of strong garden soil. In either case add very little decayed manure, and "burn-bake" (the residue from a garden smother), wood ashes and half-inch bones freely. When this heap is ready, or at the same time as it is being prepared, commence searching out the roots of the Vines to be operated upon. Commence at the front of the

border and gradually undermine till about two-thirds of the border has been forked over and wheeled away, and by that time most of the deep running roots should have been found, cut through and the reserved parts taken care of. If this work is done in either bright weather or during the prevalence of cold drying winds, syringe the bared roots occasionally and keep them matted over as much as possible. All should be duly lightly pruned, the older ones, if very woody and bare of fibres, being also cut rather freely. Whether the same space as before shall be occupied with fresh soil should depend upon circumstances. The roots not being very long or worth preserving to a great length, then it may be possible to remake the border piecemeal. In any case renew the drainage if much clogged and bring the roots up to nearer the surface, distributing them thinly throughout the fresh soil. They will form fresh fibres more quickly, and most probably this autumn if surrounded by a little of the best compost in a fine state, the burn-bake in particular coming into contact with them. The advice to make the new part of the border firm, especially adjoining the older part, must be repeated, as it is of vital importance. If the fresh compost is somewhat dry, give water in the course of three or four days, while in the case of outside borders precautions will have to be taken against their becoming badly saturated later on. When Vines have been very roughly handled at the roots they are apt to flag badly when the sun shines. In extreme cases this should be prevented by shading them, but, as a rule, keeping the house rather close for a few days and syringing the foliage very frequently are all that is necessary. It is important that the old leaves be kept fresh as long as possible, root action being briskest in the autumn and while they last.

PRACTICAL.

PLANT HOUSES.

PLANTS FOR FORCING OF SHRUBBY HABIT.—No time should now be lost in turning attention to any additional stock of this description. It is a mistake to defer potting-up till the winter is upon us; far better get it done early, so that the plants by fresh root-action can overcome in some measure the check they have received in its performance. The potting of this class of plants is oftentimes done in too much of a hurry, or only in a superficial manner. It pays, on the other hand, to give it good attention, more particularly if the stock of any kind is to remain under pot culture for a few years to come, as may be done in the case of Azalea mollis and the Ghent varieties, the Dentzias, the shrubby *Spiræa confusa*, the early-flowering *Rhododendrons* and the Guelder Roses. When the potting is done well the plants receive more benefit from the start, standing much better when in flower and giving less trouble with respect to watering. Let soil suitable to each kind be chosen and as nearly in accordance with that in which the previous successful growth has been made. In most cases this will consist of loam, either heavy or light, with some peat for Azaleas and *Rhododendrons*. In every case pot firmly, not giving too large pots, but sufficiently so to make provision for a proper supply of water. After potting has been done and a thorough good soaking of water has been given, plunge the pots over the rims in coal ashes if sufficient are to hand; if not, use leaves instead. This plugging will keep the roots in a congenial state as regards moisture without needless waterings, and when frost comes, the work of protection is already done. The evergreen kinds may have a few syringings if they exhibit any distress in the foliage. A position for these plants should be chosen where they do not get much sunshine, a little being beneficial, either of the other extremes being prejudicial. The best plants for the foregoing purposes are *Andromeda floribunda*, Azaleas (both mollis and Ghent varieties), *Dentzia gracilis* and *D. crenata flore-pleno*, *Hydrangea paniculata grandiflora*, *Kalmia latifolia*, Lilac Charles X., and the beautiful white variety *Mme. Legraye*, *Prunus sinensis fl.-pl.*, *Rhododendron Early Gem*,

R. Nobleanum in several shades of colour, *R. caucasicum album* (Cunningham's dwarf white) and other early-flowering hybrids, *Staphylea colchica*, *Viburnum Opulus* (Guelder Rose), *Spiræa confusa*, &c.

PLANTS FOR FORCING OF HERBACEOUS HABIT.—As in the case of the foregoing, these also should be potted up early whether they be forced early or not, and generally the same remarks apply save that a somewhat richer soil with manure in it will be an assistance to them. In the case of these plants the utmost has to be got out of them the first season, the second year being more of a resting one; hence they will take a considerable amount of feeding. Large pots are not in any case desirable. *Spiræa japonica*, for instance, is oftentimes over-potted. As soon as all of these plants are potted they should be stood fairly close together, being plunged and well watered as in the case of shrubby plants, but the positions should be different, a more sunny spot being the better for them. These have not any shrubby or leafy growth to maintain, the ripening process being facilitated rather than otherwise by exposure. Do not let *Helleborus niger* (Christmas Rose) escape notice; this is very useful in pots, being more of an Evergreen, or at any rate retaining its foliage much longer. This plant should be kept fairly shaded after potting. Besides such every-day plants as *Spiræa japonica* and Lilies of the Valley, note should be made of *Spiræa japonica compacta multiflora*, *Spiræa astilboides*, Solomon's Seal, and *Dielytra spectabilis*, the last named always requiring potting carefully. Another plant, but one of a more shrubby habit, is *Clethra alnifolia*, profuse flowering, and strongly recommended as a distinct thing for pot culture. Do not let any stock of the foregoing lie about after being received or lifted if of home growth, but get the potting done at once. If the plants of home growth are large, such as large bushes of Lilacs and *Rhododendrons*, then boxes and baskets even can be turned to good account in place of pots if more convenient.

OTHER AUTUMN POTTING.—*Campanula pyramidalis*, where grown to any extent in pots and of large size, may possibly require another shift. I have some now in this condition, the plants, having got far too large to be left as they are for the winter, being much pot-bound. These will now have a shift, using good loamy soil and potting firmly; it would have been all the better if attended to a little sooner, but there are at least six weeks left for them to re-establish themselves before being put into winter quarters. Most of these plants will take 10-inch pots, thus making large stuff to flower next summer. Where it is seen that no potting is really needed, none will be given, a selection of the most vigorous plants being made.

MARGUERITES.—Any stock of these, whether white or yellow, and which may be starved in their present pots, will be all the better for a shift, otherwise they will not improve as time goes on. If potted and a fresh growth now obtained, they will prove useful again after Christmas. Young plants also will take a shift if they are wanted of larger size. Cuttings, too, may now be struck readily enough in cold frames for a successional stock. It is never advisable to keep leggy or scrubby plants of either colour when young ones can be worked up so easily.

PRIMULAS AND CINERARIAS.—Where it is seen that a further shift will be of real benefit to the plants it should be attended to at once. This will be mostly the case where young stock has come on rapidly, and not so much so where already in pots of 6 inches or so in diameter. In both cases it should be borne in mind that large pots are an evil rather than otherwise. All the exposure possible to light and air should now be given these plants; the only thing to guard against in doing this is a slight frost. The Cinerarias in particular must be kept quite cool, otherwise green-fly will be troublesome. The Primulas ought not to be allowed to suffer in the slightest from excess of moisture.

JAMES HUDSON.

Autumnal Croci.—These are now quite gay, and are thrusting up their diaphanous cups along

with the Zephyr Flowers and the Meadow Saffrons or *Colchicums*. *Crocus speciosus* and *C. zonatus* are so far the prettiest, the former being blue with delicate lines on its perianth segments, and the latter is delicate rose-lilac with a yellow throat. *C. nudiflorus* is also in flower along with others less showy.—F. W. B.

ORCHIDS.

LÆLIA PUMILA AND LÆLIA DAYANA.

I AM in receipt of flowers of both these plants from the neighbourhood of Derby, asking me to tell the sender which is *Lælia præstans* from amongst them. I cannot do this from the flowers sent, for Nos. 1, 3 and 5 are forms of *Lælia pumila*; whilst 2 and 4 are varieties of *L. Dayana*, which by some authors is considered but a variety of the first-named species. The true *L. præstans* is a very unusual plant to find in collections. *Lælia pumila* was first named by Hooker *Cattleya pumila*, and it was thought to be a native of the hot parts of British Guiana; but some few years afterwards it was found to be a native of Southern Brazil in a far cooler latitude, and about fifty years ago it arrived in Europe in some quantities under the name of *Cattleya marginata*. This name well described the flower, for the lip has a well-defined white marginal border. The plant had already been figured under the name of *C. pumila*, and although the generic name could be altered, by the rules of botanical law its specific name must remain. It is a lovely little plant, which grows and flowers freely annually under much cooler treatment than was formerly considered requisite for it. I do not like the block system of culture for it, because it is so very apt to suffer from neglect through the resting season, this neglect causing the pseudo-bulbs to shrivel, and bringing about weak growths the next season, which could not flower. It appears to grow naturally at a moderate elevation, and in the summer season does well at the cool end of the *Cattleya* house with a slight protection from the sun's rays. In the winter it should be stood in a temperature varying from about 50° to 55° and be kept slightly moist, just enough water being given to prevent the bulbs and leaves from shrivelling. It does best in small hanging earthenware baskets, which, well drained, do not allow of a great quantity of soil being put on to the roots. *L. pumila* is a very dwarf grower, seldom exceeding 6 inches in height. The flowers, usually solitary, are very large for the size of the plant, each measuring between 3 inches and 4 inches across, the sepals and petals varying from purplish lilac to rosy purple or mauve, the lip being of a rich deep crimson, front lobe bordered with white and usually having a light triangular patch in the centre; the side lobes mostly white.

LÆLIA DAYANA is one of the Brazilian discoveries of Boxall about eighteen years ago whilst collecting for Messrs. Low, of Clapton. This plant will grow and flower freely in the same house and under the same conditions as the *Odontoglossums*, and as it and *L. pumila* are found growing in company, the same treatment under cultivation answers for both. *L. Dayana* is of about the same height, but is slightly more robust in habit, I think, and it should be potted in precisely the same manner. The flowers, produced singly, each measure 4 inches across, the sepals and petals being of a rosy mauve or rosy purple, lip large, the large undulated front lobe of a very deep purplish magenta, which extends right round. It has seven raised keels on the lip and a white throat.

L. PRESTANS more nearly resembles *L. pumila* than *L. Dayana*. The true kind is very distinct and beautiful; the flowers are very thick and fleshy in texture, the front lobe of the lip having usually a light triangular patch in front, and the remaining portion deep rich purple, the throat orange-yellow. This is the true plant; it is very rare in collections, and I have frequently seen the ordinary form of *L. pumila* made to stand for it.

WM. HUGH GOWER.

Cattleya labiata *Eldorado*.—The value of this *Cattleya* lies in its naturally blooming during the later summer months when Orchid flowers are generally scarce. Unlike the majority of other *Cattleyas*, it requires to be grown somewhat warmer. In fact, I find the best position for it is in the warmest house, as the increased heat and moisture throughout the summer months are just what are needed to cause a healthy growth, the flowers also appearing at the same time. As the resting season is throughout the winter months, it requires to be kept well on the dry side and also freely exposed to light. The temperature of the structure in which I keep it throughout the winter months ranges from 60° to 65°, this appearing to suit it admirably.—A. Y.

Vanda Sanderiana comes from three readers. One from "G. B." is with a note complaining that it is a bad variety. I am under the impression that there is not a tad variety of this plant known. At the same time I am quite willing to admit that some forms are far better than others, but it is such a wonderful species that I cannot say I have ever seen a bad one, the flowers being upwards of 4 inches across, and borne in a raceme of twelve or more together. Thos. Ross also sends a very nice form, but from Mr. Denny comes the most highly coloured and best variety, although not the largest known, for in point of size that from "G. B." is the largest, but the petals are narrow and the lower sepals are not well developed, so that the flower appears starchy, besides which the colours are very pale. Perhaps these are the first flowers from a newly imported plant which has been treated to much shade, whilst naturally it gets plenty of sun. It may improve. Those from Mr. Ross appear to be quite of the normal character. Mr. Denny's flower is very good; the dorsal sepal and the petals are of a deep bright rose, the petals tinged with buff and freely spotted; the lateral sepals large, having a ground colour of pale nankeen, suffused and netted with purplish crimson, but the ground colour is more visible towards the margin; lip small and spurless, side lobes erect, nankeen-yellow, front lobe somewhat heart-shaped, reddish purple, with four or five ridges or keels in the centre. It is a wonderful flower.—H.

Phalænopsis grandiflora.—In the size and purity of its flowers this species is unsurpassed by any of the *Phalænopsids*, beautiful and chaste as nearly all of them are. Properly speaking, it should now be called *P. amabilis*, whilst what is known as *P. amabilis* in gardens is *P. Aphrodite*. It is difficult, however, after half a century's use to alter the names without creating confusion. *P. grandiflora* was the first *Phalænopsis* known to European botanists, having been discovered on the island of Amboyna by Rumphius in 1750. It was not the first in cultivation, however, the species known generally as *P. amabilis* (properly *P. Aphrodite*) having been introduced from Manila by Cuming in 1836, whilst *P. grandiflora* was sent to Messrs. Veitch in 1847, or within three years of a century after its first discovery. Like most of the *Phalænopsids*, it possesses very handsome foliage, the leaves being large, bright green, and very thick and leathery. Its huge blossoms, sometimes between 1 inch and 5 inches in diameter, have the petals very broad and rounded, and much larger than the more pointed sepals, the two lower ones of which the petals overlap. Both sepals and petals are pure white. The lip is three-lobed, with the middle lobe again divided at the apex into two thin curling horns; it is also white, except that the margin of the side lobes and the

horns on the middle one are yellow. Where a number of plants are grown this species will be in flower for half the year, from April to October.

Lælia pumila var. *Dayana*.—In several respects *Lælia pumila* deserves to be included amongst the most noteworthy of autumn-flowering Orchids. It is easily grown, never fails to bloom, and its flowers remain long in good condition. There are some three or four forms of it under cultivation, all of which possess first-class merit. The variety *Dayana* is now in flower. In habit it is the same as the typical *L. pumila*, a dwarf plant with leaf and pseudo-bulb, together only 4 inches or 5 inches high. The flowers are remarkably large in proportion to the size of the plants, occasionally measuring nearly 4 inches in diameter. The sepals and petals are bright rose-purple, the petals, which are much the larger and broader, being of a deeper shade. The lip is very beautiful—it is funnel-shaped—the throat and disc white, marked with several parallel purple lines, whilst the outwardly spreading margin is of a rich glowing purple-magenta. In the typical *L. pumila* the lines on the centre are yellow. The original form first flowered in this country in 1838; it is a native of Southern Brazil. The variety *Dayana* was described as a species by Reichenbach in 1876. It had been introduced from Brazil by Messrs. Low, and had flowered in the autumn of that year with Mr. John Day, whose collection at Tottenham was at that time one of the oldest and most valuable in the country.

Spathoglottis Fortunei.—This is a pretty little Orchid not very frequently met with now in gardens. It is a native of the granite mountains of Hong Kong, from whence it was introduced in 1845. It is well worth growing for the sake of the numerous brightly coloured flowers it produces at this season, as may be judged by several panfuls flowering now at Kew. Its one defect, which pertains also to some other species of *Spathoglottis*, is the meagreness of its foliage. The flat, tuber-like pseudo-bulb bears only two or three leaves, which are each a foot long and plaited, but thin and narrow. The flower-scapes are as long as the leaves and carry from four to eight flowers, which are each 1½ inches in diameter. The sepals and petals are ovate and bright yellow, as is also the conspicuously three-lobed lip with the exception of a chocolate-coloured patch on the tips of the side lobes. This *Spathoglottis*, like all the other species of the genus, is terrestrial, and should, therefore, be potted in a mixture of turfy loam, sand, and leaf soil. The plants like to be kept moderately moist when growing, but after flowering, and as the leaves die off, the supply of water should be gradually reduced until finally it is stopped altogether. In spring when signs of growth become evident, the pseudo-bulbs should be repotted and started in a little heat. At all other seasons the temperature of the cool house suffices.

Stenoglottis longifolia.—When South African Orchids become better known in English gardens there is every likelihood that this species, if it can be found in sufficient quantity, will become one of the most popular. Several plants growing in a broad shallow pan in the cool Orchid house at Kew are flowering very prettily now. The dark green leaves, which are long and narrow, spread in rosette-like fashion near the surface of the soil, and from the centre rises the tall slender flower-spike. This is quite 18 inches high, and bears on the upper half numerous rose-purple flowers. The flowers are small, but are produced so freely as to produce quite a gay effect. This little Orchid is in fact as charming as it is unconventional. It has been grown at Kew for six years, and, judging by its appearance, is perfectly at home under cultivation; the plants have indeed got stronger each year. The species is terrestrial, and is found in Natal, generally in moist places, and sometimes on stones on which a layer of vegetable humus has accumulated. It may be grown in loamy soil lightened by the addition of silver sand and leaf soil. It should be given the coolest place in the *Cattleya* house dur-

ing the early part of its growth; afterwards the cool house is better. It continues in bloom for two or three months. A figure of it was published in the *Botanical Magazine*, t. 7186.

SHORT NOTES.—ORCHIDS.

Cattleya Harrisonæ *maculata*.—I have flowers of this variety from Mr. Denny, the sepals being of a soft rose freely dotted with purplish crimson. It is a very striking form of this old favourite, well deserving attention.—W.

Cattleya bicolor.—Three very handsome flowers of this species come from Mr. G. Draper, asking if any one is worthy of a name. They are very fine, yet I should not give them distinctive names. The most distinct appears to be very like the form called *Measuresiana*; hence one requires to be careful in giving additional names.—W. H. G.

Cattleya Dowiana.—Mr. Denny, of the Gardens, Down House, Blandford, the residence of Sir W. Marriott, Bart., sends me a nice flower of this species, the petals having a streak of crimson at the tips, the lip beautifully netted with golden veins and bordered with the deepest crimson-purple. Most people appear to have discarded the typical plant in favour of the variety.—W.

Dendrobium Phalænopsis Schroederianum.—Quite a batch of these flowers comes to hand from Mr. Cypher, Queen's Road Nursery, Cheltenham. Mr. Cypher says the plants have made remarkably fine growths. Many of the plants have three spikes of bloom, some racemes bearing as many as twenty flowers. Those sent comprise many varieties, some being deeply coloured, whilst others are almost white in the sepals and petals. Mr. Cypher tells me he has about 100 flowers open, with more to follow.—G.

Odontoglossum Insleayi splendens.—The first flower which has come under my notice this season came to hand on the morning of the 14th inst. from Mr. B. Whitworth. It is a superb flower, measuring upwards of 4 inches across and beautifully coloured. The sepals and petals are of a rich shining brown, with a few transverse lines of deep yellow; lip large, clawed, the claw deep red, banded with bright yellow, the blade bright yellow in the centre, with a broad marginal band of rich spots and blotches. The flowers of this plant, although open quite a month before the usual time, do not appear to have suffered either in substance or colour.—W. H. G.

Cattleya Hardyana.—From R. Elphinstone, gardener to Mr. J. C. Parr, of Grappenhall, comes a very fine form of this plant, with deep rosy purple sepals and petals. The lip is large and broad, and it has unusually large bright golden yellow eye-like spots at the opening of the throat, the front portion of the anterior lobe being of a very rich magenta-purple, the same colour being carried up through the golden yellow in a broad band connecting the side lobes, which are heavily marked with lines of the same colour. The lip, too, is prettily frilled. Grand as this flower is, it is not equal to that of the original plant in the possession of Mr. Hardy, Timperley, which has a lip three times as large and heavily frilled and undulated.—G.

Asters at Kew.—The rich collection of Asters, or perennial Starworts, in the Royal Gardens, Kew, is full of interest now, and they will be found at the lower end of the herbaceous ground. We hope that the Starworts will also be planted in other portions of the gardens, amongst shrubs and so forth, as they are very beautiful thus used. Several lovely varieties were in bloom a few days ago besides *A. acris* and *A. Amellus*, which have been already noted. The following forms of *A. Novi-Belgii* are well worthy of mention: *Niveus* is remarkably free, the shoots laden with huge white flowers, the centre yellow. *Densus* is, as its name suggests, of dense, compact growth, the flowers

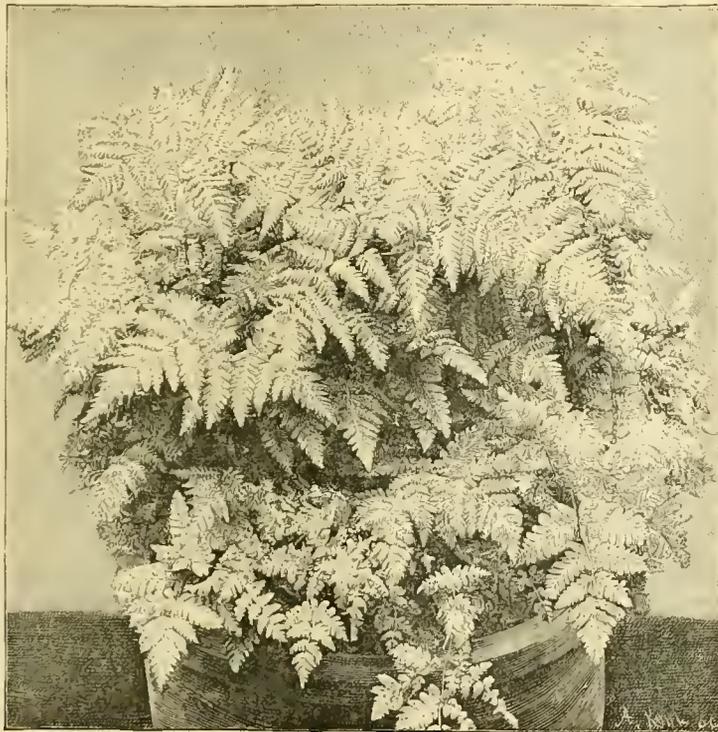

ric's lilac purple; whilst another good kind is *laevigatus*, better known as *longifolius formosus*, which is also dwarf, the flowers of a rose-pink colour. *Janus* is tall, fully 5½ feet in height, the flowers pure white, tinged with purple-rose; and *Arcturus* is of note for its deep green leaves and intense violet-purple flowers. *A. puniceus lucidulus* is one of the tall-growing kinds, rising nearly 6 feet in height, the flowers of a pale lilac colour and produced in profusion. *A. patulus* is a mass of light purple bloom, the shoots bending beneath its weight. *A. cordifolius*, a picture of small lavender flowers, and *A. Lindleyanus*, light purple-blue, the growth dwarf and spreading, are also noteworthy. One of the most beautiful of all is *A. Shortii*, which is well known, and a cloud, so to say, of light purple flowers.

FERNS.

THE OAK FERN.

(POLYPODIUM DRYOPTERIS.)

OF the four native species of Polypodies with deciduous foliage, the *Polypodium Dryopteris*, or, as it is popularly called, the Oak Fern, for

The Oak Fern (*Polypodium Dryopteris*).

which appellation there is no reason, unless it be that it is so named from being sometimes found among the Moss about the roots of Oak trees, is undoubtedly the one most generally known, as it also is the one growing most abundantly in a less restricted habitat. On account of the peculiarly bright pea-green colour of its short triangular fronds, which seldom exceed 10 inches in height, and also of its compact and close habit, it is much admired and generally used for forming in the hardy fernery edgings which all the summer possess a freshness looked for in vain among any other Ferns of dwarf habit. These fronds have, when only partially developed, a very peculiar aspect, as the pinnae on each branch are rolled up, resembling so many small Green Peas; they are, like the fronds of all the other Polypodies, produced on slender, creeping rhizomes, which, contrary

to those of the evergreen species and varieties, are strictly underground. The Oak Fern is always found in perfectly cool, sheltered, moist places where the temperature is subjected to very little variation during the summer. In planting the Oak Fern, a spot where moisture and shade can always be depended upon should, if possible, be selected, and a shallow bed made of a compost of two parts of fibrous peat, one part of leaf mould, and a free admixture of silver sand, or, better still, of broken sandstone. If grown in pots for a cool frame or the greenhouse, where it makes a most pleasing object, as in the illustration herewith, the above mixture will be found equally suitable; but in either case avoid putting in too much soil; a depth of from 3 inches to 4 inches is quite sufficient. It is also indispensable that thorough good drainage should be secured, for, although the growing plant delights in an abundant supply of water, yet water remaining about its roots is very injurious to it. In planting, great care must also be taken to prevent the rhizomes being buried too deeply, in which case they seldom grow; they must be only just below the surface of the soil, which

should only cover them lightly, and through which it is advisable to let the tips protrude. After the planting, which should take place about April, is done, a moderate watering must follow, after which the soil requires to be kept constantly moist until the new fronds begin to unfold, when, as they increase in size, a free supply of water will be necessary to keep the atmosphere always moist about the plants. This Polypody is readily increased by division. Although totally deprived of foliage during four or five months of the year, the Oak Fern should never be allowed to get dry at any time, for the rhizomes soon shrivel up and the spring growth then only produces small or deformed fronds, and the plants are very much weakened. It is also advisable to give plants grown in pots a slight covering during the winter, though not requiring the same attention when planted out.

This species does not appear to have produced any constant variations. Several multifid and other curious forms of it have from time to time been noticed, but none of these remained constant under cultivation.

Variegated Ferns.—Mr. Hemsley's timely and able article on variegated Ferns will be of great service to cultivators and decorators. *P. tricolor* was thirty years ago, as now, the most beautiful as well as the most miffy of this class of plants. For one plant of it grown now there were probably a hundred at that time. Though comparatively few growers succeeded, fewer still were content unless they tried to grow the variegated Fern, *Pteris tricolor*. There is little to add to Mr. Hemsley's cultural instructions. A temperature of 50°, with the tops near the glass, and never syringed nor watered overhead, yielded the best results in growth and colour. In watering, great care was also taken not to wet the plants. In fact, water was not allowed to touch the fronds, only as invisible vapour. *Pteris argyrea* is quite a different plant, and is easily grown either in a warm greenhouse or the stove. Plants may be pushed on rapidly under similar treatment to that given to *P. tricolor*. But it can also be grown in cool houses or pits, as described by Mr. Hemsley. *Pteris argyrea* comes freely from spores. It thrives best wintered in a cool stove or warm greenhouse, though it will bear room or greenhouse treatment admirably in the spring. Considering the hardiness, rapid growth, and extreme elegance and beauty of this Fern, it is surprising that it is not grown more largely than it is.—D. T. F.

SMALL SCALE FERNS.

(MICROLEPIAS)

THIS is a somewhat numerous family of plants, widely spread both throughout the Old and the New World. They are associated by most authors with the *Davallias*, but to my mind they are quite distinct. The genus contains some rapid growing plants, whilst from the fact of their being found in many parts of the globe, they will thrive under various conditions, so that excellent specimens can be selected either for the cool house or stove, and they may be grown in pots or in hanging baskets according to the taste or the wishes of the proprietor. *Microlepias* grow very freely and rapidly, and they do not require very great heat or moisture in the atmosphere. I have, however, observed that a sudden change will quickly cause the fronds to turn yellow and decay. For soil use peat and loam roughly chopped, mixed with some sharp sand. Drain the pots or baskets well, and let the plants have a liberal allowance of water during the summer season; less will suffice, of course, during the winter, but the plants must not be allowed to get dry at any season, or they will become greatly crippled by the loss of fronds. The following are a few of the best kinds:—

M. PLATYPHYLLA.—This plant, also known by the name of *M. lonchitidea* and *Davallia lonchitidea*, is a noble growing and very handsome Fern, having fine spreading fronds some 4 feet or 5 feet long or more, and upwards of a foot wide. This makes one of the most beautiful specimens it is possible to conceive. It is well adapted for pot culture, making a splendid ornament in the stove or upon the table at a public exhibition. It comes from the East Indies and requires a stove.

M. TRICHOSTICHA is another strong-growing handsome kind, a native of Java and other islands in the Indian Ocean. It makes fronds some 3 feet or more long, much divided, and pale green. It is equally good for decoration as the preceding, and, like it, requires stove treatment and a liberal supply of water.

M. SCABRA.—Although this plant is a native of Japan, it will thrive well and make a distinct and handsome specimen in the cool house fernery. The fronds vary from 9 inches to 2 feet in length, and the colour is rich deep green.

M. CRISTATA.—A very elegant plant, somewhat more rare in cultivation. It comes from India and many of the Indian islands, requires stove treatment, and makes fronds some 3 feet long and a foot or more broad.

M. NOVE-ZELANDIÆ.—This plant used to be common in our gardens, where it was known familiarly by the name of Davallia. It serves to make a good front edging to a greenhouse fernery either on the ground or upon the stage, but I have seen it used with fine effect in the Wardian case, for which it is admirably adapted. Its fronds are usually about 6 inches in length, but occasionally some will be seen nearly double this length. They are very finely divided and bright glossy green.

M. STRIGOSA.—In this we have a very fine and handsome plant, a native of Japan. It makes a grand specimen when grown in the greenhouse. The fronds are some 3 feet or more long by about a foot in breadth.

The whole of the above kinds can be grown in the same collection without the slightest fear of sameness, and all will make elegant specimens.

W. HUGH GOWER.

SHORT NOTES.—FERNS.

Selaginella lævigata.—"Globe Trotter" sends me what I take to be this species. Perhaps, if these specimens were actually gathered by "G. T.," he will remember if the frondule had a deep shade of metallic blue. It used to be grown under the name of *S. caesia arborea*, but I have not seen it for years.

—W. H. G.

Tænitis blechnoides (*Globe Trotter*).—This is another nice Fern. It is widely spread in various parts of India. The fronds are pinnate, the pinnae lanceolate, dark green, having a continuous line of sori about midway between the midrib and the margin. The plant has been in cultivation in this country, but I do not know if it is at present.

—W. H. G.

Psomiocarpa apiifolia (*Globe Trotter*).—You appear to have found two or three rare Ferns in the Philippines, and this is one of them. I was some time before I could define it. I took it for an *Anemia*, but there is no doubt the above is the name of your plant. It is very rare, and I do not think it is in cultivation at the present time. I have not seen it growing for thirty years.

—W. H. G.

Ophioglossum pendulum (*Globe Trotter*).—This is the name of the long ribbon-like fronds, but you do not appear to have a specimen with a perfect frond. It belongs to the same family as our common Adder's-tongue Fern, which is to be found plentifully in damp places. This species is frequently to be found growing out from the base of *Platynerium*s, *Drynariæ*s and such-like plants which grow upon the branches of the forest trees.

—W. H. G.

THE FRUIT CROPS.

NORTHERN.

The Gardens, Edmondthorpe Hall, Oakham.—Apples are a very heavy crop, and fine in size for the time of year. Pears under average; the frost caught the trees in bloom. Plums and Damsons a good crop. Peaches and Nectarines a good crop and early. Strawberries under average; our best were Forman's Excelsior and President; Keens' Seedling, James Veitch, Vicomtesse Hélicart de Thury, and Sir Joseph Paxton were a failure owing to the dryness of the season and the late frost. Raspberries a good crop; we had them mulched with stable manure at the beginning of

April, which no doubt benefited them and kept them from getting very dry, and they are making good canes for next season. Apricots good crop. Gooseberries good crop. Red, White, and Black Currants all good.

Early Potatoes turned out well. Peas were grand and very early; we picked at the beginning of June the first dish of Exonian, which I consider a grand early Pea. Runner Beans are good and very early.

Childwall Hall, Liverpool.—Apples here are a full average crop, the fruit giving every promise of being quite up to the average in point of size, and above average in point of colour. Pears on walls are about an average crop, but trees in the open are carrying but few fruits. Plums are better than they have been for several seasons, Green Gages, purple Gages and Victoria being exceptionally good for this locality. Damsons are seldom remunerative; this year, however, they are carrying a full average crop. Sweet Cherries may be said to be scantily cropped, but the Morellos are very good; the size is hardly up to the desired standard, which may easily be accounted for by the long-prevailing drought. Raspberries were plentiful while they lasted, but their bearing season was very short this year. Gooseberries are an abundant crop, the trees healthy and comparatively free from caterpillars. Strawberries suffered considerably from the drought, the variety showing the greatest distress being Waterloo. This was practically good for nothing, what fruit there were being black and tasteless. In our collection President behaved as well as any. Currants of all sorts were poor, and where not netted betimes became a speedy prey to the birds, which were simply voracious during the hot dry weather. Our soil is fairly deep, so that we suffered less than some of our neighbours, but most fruits and vegetables, too, are this year about three weeks earlier than usual.

Naworth Castle, Carlisle.—Speaking generally, the fruit crops in this district are good. Apples are above the average. Plums are good, especially Victoria, Magnum Bonum, Golden Drop and Green Gage. Apricots and Pears are an average crop. Cherries have been good. Gooseberries, Black and Red Currants have been very heavy. Raspberries were a very heavy crop, but the flavour bad. Strawberries have been a very heavy crop and the fruit of good flavour.

Vegetables have been good. Early Peas have done well, and late crops I have never seen better. Beans of all kinds are a heavy crop. The grub has been very troublesome amongst Carrots and Onions. Early Potatoes were an average crop; late Potatoes in the fields are looking remarkably well.

Alnwick Castle.—Fruit and vegetables are about three weeks earlier than usual. There are some full crops of Pears, but generally scarce. Peaches half a crop, trees healthy. Of Apples, Keswick Codlin, Lord Suffield, Lord Grosvenor, Ecklinville, Lane's Prince Albert, Tower of Glamis, and others are very fine. Trees which yielded heavy crops last year have little fruit this season. Plums on walls very fine, Victoria, Jefferson, Kirke's, Lawson's Golden Gage, and Rivers' Early Prolific being good. Trees in the open of Victoria are good this year. Apricots do well here. Strawberries in late situations have been good. Macmahon is undoubtedly the most valuable, followed by Sir J. Paxton. Bush fruit generally splendid.

Early Potatoes are a light crop and small. The late kinds are looking remarkably well.

Alton Towers, Cheadle.—This season has been most trying in many places, but being on a cool red sandstone we have suffered very little; indeed I may say we have had a most splendid spring and summer so far, and all our crops are excellent. We have kept up copious watering, and flower gardens are lovely. All vegetable and fruit crops are abundant and really good all round, quite six weeks earlier than I ever remember. Potatoes are excellent in every sense of the word, and free from disease. Stone fruit

heavy crop. Apples and Pears never so good before here. Bush fruits and Strawberries very fine, and much above average. Nuts good. Apricots and Peaches excellent.

Peas, Beans, Onions, Carrots, and indeed all vegetables are above average. This has been one of the best seasons so far as I remember during my twenty-five years at Alton Towers.—T. H. RABONE.

Blankinson Hall, Haltwhistle, Northumberland.—Fruit of all descriptions is abundant. In my opinion this is one of the best fruit years, taking it all round, that I have seen, and all fruit is fully a month earlier than last year. Gooseberries and Currants are so plentiful in the district, that growers cannot find a market for them. Apples are good; a few that seem to do best in this district are Cellini, Domino, Lord Suffield, Stirling Castle, Warner's King, Dutch Codlin, Keswick Codlin, Potts' Seedling and Ribston Pippin. Lord Suffield is subject to canker as a standard or a pyramid, but does well against a wall.

Vegetable crops are looking well. Peas and Potatoes have been very good.

Hummersknott Gardens, Darlington.—Apricots above an average crop, fruit ripening up well from three weeks to a month earlier than usual. Early Apples are abundant; late, very thin, large quantities having dropped off during the latter part of June and beginning of July. The Apple blossom was unusually plentiful, but did not set well. This may be accounted for that on the heavy clay here the buds owing to the dull autumn of 1892 were not sufficiently matured. Pears are a fair crop. Plums average crop, not so heavy as in 1892. Early Cherries average, Morellos heavy crop and fine in quality. Strawberries average crop, drought affected early varieties. All varieties of bush fruit very abundant and of excellent quality.

The drought affected to some extent early vegetables, especially Peas, but the rains latterly have helped them; seldom have things looked better than they now do at this season. These remarks will apply generally to the immediate neighbourhood, the soil of which, with the exception of the Tees Valley, is a heavy clay, and consequently has not suffered from the excessive heat so much as the lighter soils.

Allerton Priory, near Liverpool.—Fruit crops, on the whole, here are about an average. Bush fruits have been very good, but unless well mulched and watered the fruits have been small. Black Currants have been especially so on trees shifted last autumn, while on established bushes they have shrivelled very rapidly, making the crop short-lived. Raspberries have been grand. Strawberries good on cool sites, but in drier positions the fruit has been scanty. Apricots an excellent crop. Plums a fair crop, the hot, dry weather seeming to affect them during the setting period. Pears are an average crop. Apples the same; although in the latter case some varieties are very good, others again are scarce.

Vegetables have been good where attended to in the way of watering, &c., but this is not always practicable in large gardens. Cauliflowers have suffered the most, the spring sowings the most so. Beans have been enormous crops, the best I remember to have seen in this district. Where gardens are composed of good soil and depth combined with good cultivation, and where attention can be given to mulching and watering the crops, the results are good, but where the soil is thin and poor and attention cannot be given to these matters in a season like the present, the reverse is the case.

Downton Castle, Ludlow.—The fruit crops in this district are abundant and of good quality. All through the season the heat has been extreme and insects have been numerous, requiring extra attention and labour in applying remedies to keep them under. The Gooseberry caterpillar and red spider have been very troublesome, but by repeated applications of lime water and dusting with soot and sulphur, also vigorously syringing the wall trees, the injury which otherwise would have been

done has been reduced to a minimum. Apples of all kinds are above the average, the fruit being clean and of good size, while the trees have made a good healthy growth. Standard Pears are loaded with fruit, and Marie Louise on walls facing south and west is heavily loaded with fruit of extra size and good quality. Plums on south, west and north walls are over average as to crop, the trees clean and the fruit of good quality. Damsons also are plentiful. Apricots on south and south-west walls, like all other wall fruit, have had to be severely thinned. We commenced picking ripe fruit of Roman on June 27, followed a few days later by New Large Early, fully six weeks earlier here than in previous years. Peaches and Nectarines outside are mostly young trees newly bought and planted last November. They have made excellent growth, but older trees of Dymond and Teton de Venus have a good average crop. Dessert Cherries on west walls have been over average and the fruit good. Morellos on north walls are very plentiful, the fruit large and the trees healthy. I adopt the spur system for Morellos, as well as laying in young wood. Strawberries have been a good average crop; the fruit was ripe five weeks earlier than usual. Raspberries were a good average crop; Semper Fidelis is a valuable late variety. Gooseberries, Black, Red and White Currants have been abundant, the prices for ripe fruit in the market hardly paying people for picking the fruit and sending it to the market. Mulberries are abundant and good. Walnuts and Filberts are greatly above the average in this district. Taking the season and fruit crop altogether, I have nothing to complain of. We have an abundant supply of water both in the kitchen garden and grounds here. I apply early in the spring a heavy mulching of manure to all kinds of fruit trees, whether on the walls or in the open quarters of the garden, giving also during the season repeated applications of clear water and liquid manure, which result in a clean healthy growth. All fruit trees newly planted are mulched with manure as soon as planted, plenty of burnt ashes being mixed with the soil as the planting proceeds. Out of 500 trained bush and maiden trees of all kinds planted last November we have not lost one tree, but all have made growths varying from 2 feet to 3 feet in length.

Here, thanks to deep cultivation with a constant supply of water, our vegetable crops, on the whole, have been satisfactory. We commenced picking Chelsea Gem Pea (sown Feb. 6) on May 12 on a south border, followed by William I., Veitch's Selected, and Exonian a week later. Chelsea Gem has done well here this season, continuing a long time in bearing, as has Exonian. Other Peas with me which withstood the heat well have been Criterion, Gladiator, Prodigy, British Queen, and Ne Plus Ultra; later sown Peas are looking well. Out of a trial of different varieties of French Beans on a south border Ne Plus Ultra has proved the earliest and best. Smythe's Hybrid is a good hot-weather Bean, yielding a succession of good pods and remaining a longer time fit for table than other sorts tried. Extra Early Forcing Cauliflower was ready before Sutton's Queen Broccoli was over, thus continuing the supply. Onions, Carrots, Parsnips, and Beetroot are looking well. Onions in this part with cottagers and amateurs have been a failure on account of the Onion fly. Here by early attention to thinning and repeated dressings of soot with the frequent use of the Dutch hoe between the Onions, we are free from it, and those people who have hitherto failed with their Onions, but who this year have followed out my plan, are rewarded with good beds of Onions. Early Milan Turnip has again proved valuable for early work. Of Lettuces, Golden Gem must be given the first place for earliness, being fit to eat long before Early Paris Market. Perfect Gem Lettuce is a valuable hot-weather Cabbage Lettuce, which does not quickly run to seed. Early Potatoes have been and still are clean and plentiful, and of good quality and size. Myatt's, Mona's Pride, White Beauty of Hebron, Ringleader, and Early Puritan are valuable varieties on this soil. All midseason and late Potatoes look well, with no

sign of disease at present either in the garden or in the field. Abundance, Magnum Bonum, Main-crop, and Schoolmaster are the sorts most relied upon for a general crop.—JOHN CHINNEY.

Calderstones, Allerton, Liverpool.—Apricots are a fair crop, better than we have had for some years. All the early Cherries have yielded an abundant crop. If time would have allowed they would have been thinned. Currants, Red, White and Black, have borne a full crop. Gooseberries have also been a splendid crop; we have been little troubled with caterpillars. Raspberries are a full crop, and the rain coming after the long drought has caused them to continue bearing. Peaches and Nectarines outside are a fine crop and the trees are growing vigorously. We have had little trouble with insects, which I attribute to our having given the trees a good syringing in the autumn, just when the leaves fell, with strong soapsuds diluted with petroleum, at the rate of one and a half wineglassfuls to the gallon of soapsuds. Apples are a good crop, and thinning has had to be resorted to. We had a battle with the caterpillar in the spring. At one time it looked like spoiling the crop, but two sprayings with Paris green routed the enemy, and the fruit, after a portion falling off owing to the drought, is since the rain came swelling away freely, and promises to grow to a good size. The following varieties are doing best with us: Blenheim Pippin, Ribston Pippin, Cox's Orange Pippin, Emperor Alexander, Tower of Glamis, Golden Noble, Dumelow's Seedling, Lord Sniffeld, Keswick Codlin, Lord Grosvenor, New Hawthornden, Ecklinville Seedling, Betty Geeson, Annie Elizabeth, Stirling Castle, Warner's King, Small's Admirable, and Jolly Beggar. Pears are not so good a crop as Apples; Louise Bonne of Jersey, Marie Louise and Jargonelle are as usual the best croppers in this district. Strawberries have been a good crop on deeply dug ground and mulched with good manure in the early spring. Aberdeen Favourite has done well with us. It is a strong grower and of good flavour, rather late, and seems to do well in a dry season.

Peas have been all that could be desired. We depend mainly on three varieties, namely, William I. and Duke of Albany for main crop, with Ne Plus Ultra for late. The Duke is a good dry-season Pea, and as an all-round one I think it is the best we grow. We are growing for the first time one of Laxton's new Peas called Alderman. I think this will take the place of Ne Plus Ultra. It grows from 5 feet to 6 feet high, a splendid cropper, pods well filled, the Peas of a deep green colour, and I think of as good flavour as Ne Plus Ultra. Early Cauliflowers, Brussels Sprouts and all the Brassica family have been troublesome to grow this season, owing to the attack of maggots at the roots. On land that had a slight dressing of gas-lime in the winter and dug in in the spring, the crops seem to do much better. Onions in this neighbourhood are nearly a failure, owing to grub. Nothing seems to stop its ravages; therefore, we shall have to be content with a third of a crop. There has been a marked difference between crops grown on trenched or deeply dug ground and those grown otherwise. The ensuing winter we shall cover all vacant plots with a dressing of gas lime and dig it well in in the spring, as I am convinced that this is objectionable to most garden pests that affect crops at the roots.—W. TUNNINGTON.

Chillingham, Belford, Northumberland.—Strawberries are an average crop, but the season has been short, owing to the heat. Gooseberries average. Black Currants splendid, also Red and White. Raspberries average. Plums are a splendid crop. Cherries, both sweet and Morello kinds, are abundant. Of Apricots there is a fairly good crop on most trees. Peaches very poor out of doors, also Pears. We had 12° of frost on April 12, which did much harm to the blossom. Apples, on the whole, are a splendid crop. Nuts average.

Vegetables are good, except Spinach, which has run very quickly to seed. Nearer to the sea they have splendid crops of all kinds of fruits, but we suffer very much from spring frosts.—RICHARD HENDERSON.

Thorpe Perrow, Bedale.—The fruit crop everywhere in this part of North Yorkshire is a good average. Apples generally are good, especially local varieties. Pears, too, are a good average crop, Marie Louise on south walls being noteworthy, but on other walls not so good. The flowers were imperfect; consequently the trees have been blooming more or less all the summer, and there is no fruit. Bush fruits have been very abundant and good. The same might be said of Strawberries and Cherries. Plums where the soil suits them are extra good, but not here, the soil is too heavy. Apricots on prepared borders are a good crop and very fine. Nuts are bad.

All kinds of vegetables are good, especially early and late Potatoes.—WILLIAM CULVERWELL.

MIDLAND.

Worden Hall, Preston.—Apples are a very good crop. Pears very fair. Of Plums some varieties are good. Damsons plentiful. Strawberries abundant and fine, but their season was short. Cherries very good. Peaches fair. Apricots a failure. Figs moderately good. Gooseberries a capital crop, but the bushes suffered much from red spider, which, no doubt, caused the fruit to be smaller than usual. Red and White Currants, also Raspberries, plentiful. Black Currants a failure. This crop will most likely cause more trouble to gardeners about this district than they are aware of. Nuts are good.

The early part of the year was remarkable for its great heat and drought, which produced curious effects on some kinds of fruit and vegetables, bringing some crops in fully three weeks earlier than usual. However, everything has been plentiful and good, excepting Onions and Carrots; the former are a complete failure through maggot, notwithstanding every means used to prevent it. Carrots nearly as bad. One variety of Pea sown three weeks between each sowing was all ready to gather at once, but has kept up a succession, thus showing the value of growing the branching varieties. Some of the early Potatoes had to be lifted on account of the young tubers starting into growth.—ROBERT FRISBY.

Wrottesley Hall, Wolverhampton.—The fruit crop, I am pleased to say, is, on the whole, very good. Some of the Gooseberries were attacked badly with red spider and brown fly, but the bushes, after being well watered and syringed, finished their crops satisfactorily. Most of the fruit crops are considerably earlier, especially Plums and Apricots, which are quite a month in advance. Other garden crops are quite above the average. We were a long time without rain, but it came in time to give us a very productive season. Strawberries were under the average. Raspberries average. Gooseberries, Currants and Plums were very good and over the average in quantity. Damsons an average crop. Apricots, Peaches, Nectarines, Figs, Apples and Morello Cherries are over the average, and Pears an average crop.—EDWIN SIMPSON.

Quorndon, Loughborough.—The fruit crops, I am sorry to say, are not up to the average. The Apricots are good, but Plums scarce in places, although in gardens where they have been sheltered from the east winds and the situation facing south-west I have seen some good crops. Pears are scarce. Apples of the Codlin kind are plentiful and very cheap in the market, but keeping and late varieties are scarce.

Vegetables have been very scarce this season, lasting but a brief period where the water and labour supply have been deficient. In many places I am afraid the winter supply of vegetables owing to the very dry season will be very poor.—G. COOKE.

Highbury.—Apples are a heavy crop, and Pears moderate, the variety Penrre d'Aremberg being the hardiest and most prolific of any here. Cherries poor, except Morellos, which either as standards or fan-trained are bearing heavily. Gooseberries were a heavy crop, but it would have been otherwise if sparrows had been allowed to

feast on the buds. Raspberries very good, but Currants were poor, our soil being so sandy. Strawberries fine.

Vegetable crops are very light except French Beans, Runner Beans, and Beetroot, which have enjoyed the heat. Broad Beans are a total failure. This climate is nearly as cold, windy, and changeable as in Co. Durham, and good crops of fruit are never expected. Every spring proves disastrous to the blossoms, but the last spring was a great exception, and there is more fruit than for many years. The soil varies very much in the district. Here it is very little better than sand and gravel, and is quite a home for red spider, &c.—W. EARP.

Staunton Harold, Ashby-de-la-Zouch.—Apples on the whole are a very good crop, although a considerable quantity fell from the trees. Pears have withstood the dry weather better, and are an average crop. Peaches, Nectarines and Apricots are carrying heavy crops, but red spider is troublesome. Plums heavy crop, Victoria, Pond's Seedling and Green Gage being the best. Cherries a heavy crop, both of dessert kinds and the Morello. Currants were small owing to the long-continued drought. Strawberries were a poor crop and proved a heavy loss in this district for market growers. Cob Nuts plentiful.—W. HOLDER.

Newnham Paddox, Lutterworth.—The present season will long be remembered for its long-continued drought. I never remember insect pests so numerous as they were this year, and it was only by continual perseverance with insecticides that fruit trees were kept at all healthy. The fruit crops in this locality are on the whole very good. Peaches good, but the trees were badly infested with aphids in spite of repeated applications of insecticides. Apricots plentiful. Cherries, both dessert and Morello, a good crop. Pears a light crop. The trees flowered abundantly, but the blooms were destroyed by the frost on the morning of April 13. The varieties that are carrying anything of a crop are Williams' Bon Chrétien, Louise Bonne of Jersey, Marie Louise d'Uccle, Beurré Bachelier, Josephine de Malines and Bergamote d'Esperen. Plums are under the average. They blossomed most profusely, but suffered from frost and cold east winds when in full bloom. The varieties bearing are Victoria, Jefferson, Claude de Bvay, and Prince Englebert. Apples are a good crop, though the trees were badly infested with caterpillar. Strawberries abundant and fully a month earlier than usual. A great many of the early blooms were destroyed by the sharp frost of April 13. The fruits were large considering the drought, but were over more quickly than I ever remember. Damsons blossomed and set their fruit profusely, but a severe attack of aphids crippled them and caused much of the fruit to drop. Gooseberries and Currants abundant. Raspberries a fair crop; their fruiting season was over quickly and the foliage was badly infested with red spider. Filberts an average crop.

Vegetables in this neighbourhood are good, and look well with the exception of Onions, which are almost a failure. I am glad to say I never had a better crop. The late frosts played sad havoc in some places around here with early Potatoes, and in consequence the crop is poor. Ours have been very good as regards quality and quantity. They escaped the frosts. No disease has yet appeared. Crops in general have improved very much lately with the nice showers of rain we have had. Peas as a rule did not grow to their usual height this year and were soon over.—W. HARMAN.

Colston Bassett, Bingham.—Fruit trees of all kinds bloomed very profusely this season; there was a favourable prospect of a heavy fruit crop, but a long spell of cold winds and dry weather had an unfavourable effect on the flowers, the result being a thinner crop than might have been expected. The fruit is decidedly finer in consequence. Lord Suffield, Keswick Codlin, King of the Pippins, and Worcester Pearmain are a full crop. Pears irregular, few bearing a full crop. Apricots and Plums sufficient for an average, but poor in quality. Peaches not grown outside. Abundance of bush

fruits, but very small. Cherries abundant, especially Morellos. Strawberries soon over owing to the drought, being really not half a crop on the whole. The crops of Walnuts and Filberts are exceptionally light.—W. H. SMITH.

Great Tew Park.—Very few districts have had less rainfall than North Oxfordshire, yet in spite of the great drought and intense heat the fruit crops are good. Apples are above the average, especially Ribston Pippin, Blenheim Orange, and Northern Greening. Most of the Pear trees are bearing a heavy crop, Jargonelle, Williams' Bon Chrétien, Marie Louise, and Duchesse d'Angoulême being particularly good. Apricots are good and abundant; also Cherries, especially Bigarreau Napoleon and Morellos. Plums are an average crop, but some of the trees are badly blighted. Small fruit such as Raspberries, Currants, and Gooseberries are plentiful, but the caterpillars made sad havoc with the foliage both of the Gooseberry and Currant bushes. Strawberries suffered greatly from the drought; they were a poor crop and quickly over, most of the blooms failing to set properly. Cobs and Filberts are above the average, while the Walnut trees are heavily laden.—G. PARKER.

Cholmondeley Castle, near Malpas—The fruit and other crops in these gardens have not suffered from the long drought to any great extent. The fruit trees on walls required careful attention. Apricot, Peach, Cherry, and Pear trees were mulched in March, and during the early summer given three heavy waterings, which have in each case rewarded us with exceptionally good crops, especially in the case of the two first-named. Small fruits are about an average, but Apples very poor.

The vegetables never looked better than this season, owing, I consider, to our situation being low and with a good deep soil resting on a cool subsoil. The garden crops in this neighbourhood on light sandy soils are poor, fruit running small in most cases. Gooseberries plentiful and cheap. Good crops of Apples can be seen here and there, but are the exception rather than the rule.—C. FLACK.

Orton Hall, North Hunts.—Apples are a good crop, particularly Keswick Codlin, Manks Codlin, Lord Suffield, Pot's Seedling, Northern Greening, King of the Pippins, Baldwin, Ribston Pippin, Yellow Ingestre and Striped Beaufin, while many other kinds have only an average crop. Of Pears, the Lammas, Doyenné d'Ete, Beurré Giffard, Louise Bonne, Orange Bergamot, Flemish Beauty and Duchesse d'Angoulême are bearing well, but Williams' Bon Chrétien and many other good kinds are poor. Plums of most kinds are abundant on walls, but in the open rather thin, the want of copious rains causing aphids to spread rapidly. Black and Red Currants have been abundant and of good quality, but Raspberries and Strawberries only fair. Apricots set an abundant crop, but a sharp frost or two when the fruits were the size of marbles thinned them considerably. Peaches and Nectarines are a very fair crop, but red spider is more prevalent than usual. This pest was also destructive to the Gooseberry plantation, particularly old trees on which the crop was thin.—A. HARDING.

Gopsall, Leicestershire.—Fruit crops generally are above the average in spite of the abnormal season, though many trees have suffered from red spider to a greater extent than I ever before remember. Much has been done in the way of mulching and watering, especially stone fruits. Peaches and Nectarines are carrying a full crop. Ripe fruits of Early Beatrice Peach were picked on June 20, the earliest date for a great number of years. Strawberries were also much earlier than usual, and of good quality, but soon over. Apricots above the average. Moorpark a full crop of good quality. Pears and Apples above the average. Several old Pear trees growing on a south wall were badly scalded with the sun on June 25 and 26, when the thermometer registered 118° in the sun. This no doubt will prevent the full development of the fruit. Morello Cherries

good, both in quantity and quality. Gooseberries excellent, also Black and Red Currants. Raspberries light crop. Plums and Damsons average. I append a list of varieties of fruit which have done the best: Of Peaches, Early Beatrice, Hale's Early, Noblesse, Early Rivers, Walburton Admirable; of Nectarines, Lord Napier, Elruge, Violette Hâtive; of Apricots, Moorpark, Hemskirk; whilst of Plums the best were Victoria, Kirke's, Magnum Bonum, Green Gage; the most satisfactory Pears are Jargonelle, Williams' Bon Chrétien, Louise Bonne of Jersey, Marie Louise, Duchesse d'Angoulême, Winter Nelis and Trout; and of Apples, Lord Suffield, Keswick Codlin, Yorkshire Greening, Small's Admirable, Ribston Pippin, Golden Pippin, Claygate Pearmain, Sam Young, Golden Requette; the finest Strawberries were Vicomtesse Héricart de Thury, Noble, Keens' Seedling, President and British Queen.

The vegetable garden has wonderfully improved during the past fortnight since copious showers have fallen. Potatoes are very good, but early varieties rather light. Late varieties look promising, although I have heard several complaining that disease had appeared. Peas have only been second rate owing to the drought, although heavy watering was resorted to.—J. LEE.

Davenham, Malvern.—Apples are under the average, the best kinds being Keswick Codlin, Stirling Castle, Lord Derby, Ecklinville, Golden Noble, Cellini, Margil, Requette du Canada, Sturmer Pippin, Worcester Pearmain, Kedleston Pippin, Cox's Orange Pippin, and Norfolk Beaufin. Pears a fair crop, especially Jargonelle, Thompson's, Williams' Bon Chrétien, Louise Bonne of Jersey, Crassane, Duchesse d'Angoulême, Beurré Diel, Bergamote Esperen, Beurré d'Aremberg, Glou Moreau, and Knight's Monarch. Plums—Early Rivers', Green Gage, Transparent Gage, and Victoria are a fair crop; other varieties very poor. Figs very good outside and likely to finish well. Cherries a good crop, but the fruit is small. Peaches and Nectarines very good; never saw them better. Apricots have never been better, and Moorpark is grand. Of small fruits, Gooseberries, Raspberries, Currants (Red, White and Black) are very good. Strawberries, La Grosse Sucrée and Laxton's Noble, are very good indeed; other varieties failed to swell well owing to the extremely dry air. Nuts very good.—A. BRADSHAW.

Byrkley, Burton-on-Trent.—Apples on pyramids which have never been pruned are so heavily loaded with fruit, that I have had to support the branches with stakes. Orchard trees are a fair average crop, more so where sheltered from east winds. Apricots average crop. Cherries both on walls and in the open are very heavy crops. Currants, Gooseberries, Raspberries, and Strawberries were above the average, the last a month earlier than usual. Peaches are not grown outside. Plums on walls good average crops, but none in the open. Damsons heavy crops, while some trees are bare. Pyramid Pears average crops. Nuts fair.—JAS HAMILTON.

Knowsley.—The year 1893 will be memorable for many things, and especially for the extraordinary heat and drought which have prevailed so far, and the ultimate and full effects of which we shall probably not know for some time to come. The immediate effect is very remarkable and instructive. I have noticed that Potatoes growing upon damp, boggy land look as bright and luxuriant as one could wish, whilst not many hundred yards away upon land of a clayey character the same crop is languishing. I know a few instances where early kidneys have actually turned yellow and died from the heat and dryness. The revivifying effect of the sun upon some old Apple, Plum, and Spanish Chestnut trees which had previously become debilitated by a series of wet and cold seasons is quite remarkable in the colour of the foliage, which is both brighter and some shades darker green; while, on the other hand, there are old fruit trees and bushes that have succumbed to the combined effects of drought, heat, old age, and a heavy crop. Indeed, the crops of fruit are so heavy as to defy thinning by hand, which must

seriously affect the health of the trees as well as the size and quality of the present crop. Gooseberries and Currants are smaller than usual, and in some cases dried up. Strawberries have done well, thanks to heavy watering and a thick mulching of clean straw.—F. HARRISON.

NOTES OF THE WEEK.

Canna lutea splendens is one of the best for the garden in its line of colour. We made note recently of a bold group of it, and were struck with its stately habit and clear colour. The flowers are yellow, marked with a few crimson bars and spots.

Chironia ixifera is in flower in the temperate house at Kew. The flowers are of a rosy colour and produced freely, reminding one of those of *C. peduncularis*, of which a coloured plate was given in THE GARDEN, September 2, 1893 (p. 212).

Odontadenia speciosa.—I send you some flowers of this, known also as *Dipladenia Harrisii* by some—a most beautiful stove climber. It was introduced to cultivation some forty years ago, but is seldom seen now. Our plant has been in bloom row about three months, and a glorious flower it is.—W. B. LATHAM, *Botanic Gardens, Birmingham*.

Pentstemons have proved splendid hot-weather flowers. They have been in full beauty for many weeks, and in the Long Ditton nursery of Messrs. Barr and Son we recently noticed a large collection in full flower. The range of colours is considerable, and cuttings are easily struck in the late summer. One of the richest coloured kinds we noticed at Long Ditton was named *Comediao*, the flowers intense crimson, and produced with great freedom.

Aristolochia gigas var. Sturt-vanti has been a feature of interest in the Palm house at Kew throughout the summer, and those who care for strange flowers should see this splendid specimen before it passes out of bloom. The bloom has by its quaint shape given rise to the popular name of Pelican flower—not an inapt comparison. The colouring is very fine, pale yellow, beautifully mottled with purple, whilst the tail sometimes measures over 3 feet long. It is a native of Guatemala, and one of the strangest of all plants.

Nymphaea odorata caroliniana, said to be the largest and finest of all the *N. odorata* varieties, is supposed to be a cross between *N. odorata rosea* and *N. alba candidissima*, having been raised in the garden of Dr. H. T. Babnson, of North Carolina. It has, we are told, all the vigorous growth of *N. a. candidissima*, with fragrant flowers each 4 inches to 6 inches across, and of a soft and delicate salmon-rose colour, deeper in some specimens than in others.—F. W. B.

Hunnemannia fumarifolia, represented by a coloured plate in THE GARDEN of June 11, 1887, p. 536, is a very bright flowered Poppywort not so often seen in gardens as one might suppose from its long-blooming and showy aspect. It makes a bushy, compact plant. The flowers are clear yellow, not unlike those of the Iceland Poppy, and continue in beauty over a long season. This year the plant has succeeded remarkably well, as it likes a dry soil and warmth, being a Mexican species. It is worth trying, we should think, in hot, dry positions where many other things utterly fail.

A new **Diaa** is blooming in the Orchid house at Kew. It is the result of crossing *D. tripetaloides* with *D. Veitchii*. The plant is of exceptionally robust habit and produces a sturdy stem, bearing flowers not quite so large as those of *D. Veitchii* and self crimson, a deep, rich and striking colour. About the only trace of the former parent consists in a few spots on the lobes of the lip and within the "hood," so to speak. Mr. Watson has

done well to make such crosses as these, and *D. Veitchii* itself, it will be remembered, is one of Mr. Seden's successes. In THE GARDEN, June 10, 1893 (p. 478), we made a note of a cross flowering at Kew between *D. grandiflora* and *D. tripetaloides*. This is named *D. kewensis*, and is a worthy addition to the new Orchids of the present year.

Grapes in the open air in Cheahire.—I send you a small bunch of Black Hamburg Grapes cut from a Vine trained up a brick chimney in the centre of the range of glass houses. There are about twenty bunches round the chimney; all will finish this season. Even last season I cut a few small bunches. The Vine was planted to cover the chimney with foliage; fruiting was never thought about, and now the chimney is entirely hid with strong foliage, and ornamented with small bunches of fruit. Unsightly chimneys in gardens may be covered with Vines, the heat from the chimney ripening the wood and also the fruit.—A. TRAIL, *Falshaw Hall, Wilmslow, Cheshire*.

* * * Fruit of very good flavour and well coloured.—ED.

Impatiens Sultani is not usually thought of as a plant for the open, but, judging from some specimens in bloom in a warm border at Kew, there is no reason why it should not be used for this purpose. The plants are remarkably gay, and will keep in full beauty until frosts occur, each making a bushy growth covered with bloom. At Kew they are planted in a sunny corner formed by the annexe to the Water Lily house, and if this *Impatiens* will behave as well in ordinary years it should certainly be made note of for the garden in the summer months. The flowers of the type are rich crimson, but there are many forms, the salmon tints being very charming, although not so effective in the open as those of a more pronounced shade.

Tufted Pansies at Hillside, N.B.—Dr. Stuart writing to us on September 1 says: The beds of tufted Pansies are in fine state, and when the sun is down the seedling beds from Blue Gown are in their many shades of colour a beautiful sight. Many good things have been raised this season, especially delicate blush and lilac selfs. One new break cannot be seen till next year. The cross seems to be between a blue and a yellow, the centre rather large, golden, and the body colour turquoise-blue. This is a great advance on anything I have yet raised. Hard propagation, in my experience, does not improve the constitution of any flower, and the tufted Pansy is no exception. It sometimes takes two seasons before newly-propagated plants get established into their seedling form. The *Violetta* and *Sylvia* strains should be treated as perennials, cut down in autumn and top-dressed, the roots being allowed to get into the soil as far as possible. The plants are then safe. When plants of the year fall over, they should be taken up, replanted deeply, only the points of the green shoots above the surface, and get a good dressing of river rough drift sand. If well watered they will root from the shoots and make good plants. Had I not treated my seedling beds in this way, I should, with a temperature more than once at 81°, have lost the half of them. Now they are at their best.

PUBLIC GARDENS.

A public park at Ramsgate.—A new public park has just been opened at Ramsgate. The work of laying out the grounds was carried out by Messrs. Cheal and Sons, of the Lowfield Nurseries, Crawley.

A new recreation ground.—The Ecclesiastical Commissioners have offered the Hammersmith Vestry four acres of land in Cobbold Road, Shepherd's Bush, as a site for a public recreation ground. The offer has been referred to a committee to consider the probable cost of laying out the ground.

Peckham Rye extension.—Owing to the prolonged drought, which has seriously hindered the laying out of the grounds, the wooded land at the upper end of Peckham Rye, consisting of over sixty

acres, which the County Council has secured for the public, cannot be thrown open until early in the spring of next year. When laid out the extension will form a very beautiful addition to the fine open space of Peckham Rye.

The Alexandra Palace.—Efforts are again being made for the acquisition of this and the surrounding 431 acres of land as a public place of recreation. A movement is now in progress to induce the various local boards, who voted a total of £75,000 towards the proposal, to allow that amount, or at least a portion of it, to form the nucleus of a fund of £100,000 to carry out the smaller scheme of Mr. H. R. Williams, which is, that the palace, together with the large organ, the statuary, and 100 acres of land, should be purchased. The land included in this proposition is that which Parliament has said must be kept an open space. On the other hand, several Hornsey gentlemen, led by Colonel J. W. Bird, want the £25,000 which the Hornsey Local Board voted towards the Palace scheme devoted to the purchase of Churchyard Bottom Wood, Highgate, which it is believed the Ecclesiastical Commissioners are anxious to sell for building land. A proposal to buy this property eight years ago at the same figure was negatived by the people of Hornsey on a poll by a substantial majority. All efforts to induce the Commissioners to present the wood to the local board have failed.

New recreation ground at Shoreditch.—The Earl of Meath, chairman of the Public Gardens Association, presided on the occasion of the public opening of Goldsmith Square recreation ground, Goldsmith's Row, Hackney Road, E., and its dedication as an open space for ever. Towards the purchasing and laying out of the grounds, the Metropolitan Gardens Association, the Shoreditch Vestry and the London County Council willingly contributed, and further assistance was given by several philanthropists, amongst others by Mr. A. J. Scott, who contributed £300. The extent of the ground was 4½ acres, while the whole extent of the parish was 648 acres. The Earl of Meath, in declaring the ground open, expressed his pleasure at the space having been preserved from the builders. As chairman of the Metropolitan Gardens Association, he was very gratified at the result of their labours, and that the association had been able to help in securing the ground for the people of Shoreditch. It would be a very great improvement to the district and a great benefit to the people. In responding to the vote of thanks, Lord Meath said that in the ten years of its existence the Metropolitan Gardens Association had been instrumental in laying out eighty-six grounds for the use of the public.

LONDON TREES.

THE following interesting letter on London trees from Herbert Maxwell appeared in a recent issue of *The Times*:—

Before parting with the memorable summertime of 1893, it may not be profitless to observe its effect upon trees, so essential to the beauty and health of the metropolis. They afford the one redeeming feature to an otherwise ugly town. Some years ago I brought upon myself a good deal of adverse criticism by quoting Leigh Hunt's saying that it was hard to find a single street in London from some part of which a tree was not visible. I only know of two—viz., Savile Row and a street parallel with Berners Street. London trees have two adverse influences to resist—coal smoke and heat reflected from miles of brick and stonework. The effect of the latter is so clearly marked upon several species at the present moment, that the lesson ought not to be neglected by the Office of Works and by those in charge of squares and gardens, for, although the heat has been very excessive this year, trees in a town are always exposed to greater summer heat than those in the country. The trees which have suffered most are one native species—the Wych Elm and two exotic species—the Horse Chestnut and the Lime. The condition in which these are now and have been for some weeks past ought to convince us of their unsuitability for

town planting. Many of them are entirely leafless; others retain but a mere remnant of summer clothing. The Plane, for which we shall soon have to borrow the title of a humbler green thing and call it "London Pride," has stood the trial fairly well, for although it has shed half its leaves, the other half remain and are still fresh and verdant. By a popular mistake (pointed out some years ago in THE GARDEN newspaper) this tree is called the Western or Occidental Plane. It is not so, but an Eastern European and Asiatic species (*Platanus acerifolia*), and may be distinguished from the American *P. occidentalis* by bearing two or more seed vessels on the fruit stalk instead of one.

Aspens and Poplars have suffered not at all, and should be more largely planted in London. By a peculiar formation of the leaf-stalk, which is flattened midway, they are specially provided with a mechanical means of protection against heat. The leaves hang vertically and possess glands on both surfaces; whereas Oak, Beech, Chestnut, &c., have glands only on the under surface. *Ailantus glandulosa*, the tree of the gods, is in splendid foliage, and, if more care were taken to keep it in shape in its early years, it would soon prove one of the surest ornaments of our streets. But the tree to which I wish to call special attention as invaluable for towns is what is commonly called the Acacia. It is not an Acacia at all, being of the Peaflower tribe; its scientific name is *Robinia Pseudacacia*. Let anyone compare the fine specimen standing at the corner of Lord Sefton's house in Belgrave Square, or a group of young ones in the Green Park, near the Wellington Arch, with trees of other kinds around, and he cannot fail to recognise in this species one which, for beauty of form or freshness of verdure, cannot be excelled for planting in towns.

P.S.—*Ulmus campestris*, called the English Elm because it is not English, has kept its foliage fairly well, but it is dull and discoloured.

ONIONS AND VEGETABLES AT BANBURY.

BANBURY has long been famous for its cakes, its cross and its original displays of Onions, but nothing hitherto seen has been equal to the display of September 14, whether at Banbury or elsewhere. This will be readily understood when it is recorded that such doughty champion growers as Wilkins, Pope, Waite, Lye, Kneller, Doherty, Bowerman and others entered the arena in their well-known strength to fight for the supremacy and the extremely handsome prizes offered by the late Mr. H. Deverill. There are grumblers against these large-sized Onions, but it may not be generally known that large bulbs are milder and of superior flavour to the crowded, small hot ones, and as such make a wholesome appetising dish when served up braised—equal in flavour to best imported Spanish—a point worthy of consideration in these days of waning home industries and agricultural depression. Besides, such displays prove a veritable object lesson, showing the highest system of cultivation, whilst the growers assure me these large bulbs will keep equally well with ordinary grown small ones if care is taken to thoroughly ripen them. Probably a combination of the two systems would be preferable for large consumers. The competition was extremely keen, but Mr. Wilkins, gardener to Lady Theodora Guest, proved invincible in the principal Onion classes, although Mr. Pope beat him in the class for eight distinct kinds of vegetables. A gold medal or timepiece was offered for the largest and handsomest six specimens of either of Mr. Deverill's pedigree kinds, and Mr. Wilkins staged six Lord Keeper, weighing 15 lbs., perfect in shape and well ripened; second, Mr. Lye, Sydmonton Court, with Ailsa Craig, weighing 13½ lbs. For twelve specimens of Ailsa Craig, Mr. Wilkins staged a dozen, weighing 26½ lbs.; second, Mr. Pope, weight 22 lbs.; third, Mr. Kneller. Sixteen competitors, every one good. For twelve specimens of enumerated kinds, Mr. Wilkins was again first with Anglo-Spanish, weighing 20½ lbs.; second, Mr. Waite, 18½ lbs.;

third, Mr. Pope, with Royal Jubilee, weight 18½ lbs., wanted a little more finish. Thirteen competed; a keenly contested class. The next class was for twelve of that best of all keeping Onions, Improved Wroxton. Mr. Kneller was placed first, his dozen weighing 14½ lbs., closely followed by Mr. Wilkins, whose bulbs were slightly heavier, but not so well finished, weight 15 lbs.; third, Mr. Pease. Other classes were provided for cottagers and artisans. For eight distinct kinds of vegetables, Mr. Pope was first with a faultless collection, containing Exhibition Carrots, Lyon Leeks, Glenhurst Favourite Tomato, Middleton Park Beet, Autumn Giant Cauliflower, Aylesbury Prize Celery, Ailsa Craig Onions and Satisfaction Potatoes; second, Mr. Wilkins. W. C.

Lilium Dalhansonii.—By a curious coincidence two Martagon Lilies flowered in my Lily house last June, which I at once referred to the result of a spontaneous cross between *L. Martagon* var. *dalmaticum* and *L. Hansonii*, which flower there in close proximity, the seed being allowed to ripen and come up where it falls. I sent flowers to my friend, Mr. G. F. Wilson, of Weybridge, who agreed with me as to the probable parentage. At that time I had no idea that this cross had been effected before. The portrait in this week's GARDEN closely resembles my plants, which had flowers of exactly the same shape and of nearly the same colour. *L. Hansonii*, which I have grown for a dozen years or more, has never ripened fruit either indoors or out in my garden, but both of the hybrids ripened fruit distinct in form from that of *L. Martagon dalmaticum*, as it is larger in outline and has the ridges formed by the joints of the segments far more prominent. I sowed the seed as soon as ripe. It seemed good, but the offspring, if there is any, will probably approach one of the parents; at least so I find it to be with most of the fertile hybrids of hardy plants which come plentifully in my garden. They may be fertilised with foreign pollen, but not with their own.—C. WOLLEY DOD, *Edge Hall*.

—Kindly permit me to protest against the name of this hybrid Lily, as being not only irregular in application, but also very misleading, if one who was ignorant of its history would venture to attach a meaning to it. Such a one knows, very probably, that *Lilium Hansonii* means Hanson's Lily, *ergo* *Lilium Dalhansonii* must mean Dalhanson's Lily. Then comes the query, "Who was Dalhanson?" Would it not be much better to name this hybrid *Lilium* (hybridum) *Dal-Hanson*, and call it in English the Dal-Hanson Lily?—W. M.

The weather in West Herts.—A warm week. On Thursday and Friday the temperature in shade rose respectively to 77° and 75°, while on Sunday night the exposed thermometer never fell lower than 53°. The temperature of the soil at both 2 feet and 1 foot deep now stands at 60°, or 3° higher than on the same day last year. Rain has fallen on but five days this month, and to the total depth of only about half an inch. The ground remains singularly dry. In fact, no measurable quantity of rain water has come through the 2½ feet of soil in the percolation gauges for over three weeks. Since the beginning of the month the sun has shone on an average for 5½ hours a day, and on ten days the record exceeded seven hours.—E. M., *Berkhamsted*.

Death of Mr. Hugh Low.—We regret to record the death of Mr. Hugh Low, of the well known firm of nurserymen at Clapton, on Sunday, September 17. He was thirty-two years of age, and his death will be regretted by a wide circle of friends; he leaves a widow and two little girls. For some time past Mr. Low had been in indifferently health, but was not taken seriously ill until Saturday, when pneumonia rapidly developed. Mr. Low was in partnership with his two younger brothers, by whom, we understand, the business will be carried on. The funeral took place on Wednesday at Abney Park Cemetery, and was attended by many sympathising friends.

Roses for exposed positions.—Will any reader kindly say what Rose would do best for planting against railings 3 feet high round a piece of water? The position is very exposed. Roses of a free flowering nature and inclined to grow bushy preferred.

Royal Horticultural Society.—The next meeting of the Royal Horticultural Society will take place at the Drill Hall, James Street, Victoria Street, Westminster, on Tuesday, September 26, when prizes are offered for Gladioli. At 3 o'clock Mr. Iggulden, of Marston Gardens, Frome, will deliver a lecture on the "Causes of Failure in *Eucharis* Culture."

BOOKS RECEIVED.

"Hours in my Garden." Alex. H. Japp, LL.D. London: John Hogg, 13, Paternoster Row.

"Orchid Seekers in Borneo." By A. Moore Russan and F. Boyle. Illustrated by Alfred Hartley. London: Chapman and Hall, Limited.

"The Orchards: Fruit Culture for Small Holdings." J. Cranston, F.R.H.S., King's Acre Nurseries, Hereford.

"Cremaion and Cholera." By Sir Spencer Wells, Bart. The Cremaion Society of England, 8, New Cavendish Street, W.

"The Prevention of Preventable Diseases." An address by Sir Spencer Wells, Bart., F.R.C.S., Surgeon to the Queen's Household.

Folgate.—1, *Aponogeton distachyon*; 2, *Ophiopogon Jaburan variegatus*.—H. R. L. N.—*Ecerinocarpus scaber*.—J. H. Lane.—1, *Colchicum Parkinsonii*; 2, *Crocus zonatus*.

Names of fruit.—V. A.—1, Norfolk Beanfin; 2, Siberian Crab. —A. Trail.—1, *Burré Superfin*; 2, *Fondaute d'Automne*.—Henry Parker.—1, Hawthornden; 2, *Keswick Codlin*; 3, *Cellini Danum*.—1, *Marie Louise*; 2, *Burré Bachelier*; 4, *Comte de Lamy*; 5, *Emperor Alexander*; 6, *Cellini*.—Edwin Dodds.—1, *Court of Wick*; 2, too small to identify; 3, *Dutch Mignonne*.—Aun.—1, *Court of Wick*; 2, *Duke of Devonshire*; 4, *Reinette du Canada* most probably; 5, *Beauty of Kent*.

"The Garden" Monthly Parts.—This journal is published in neatly bound Monthly Parts. In this form the coloured plates are best preserved, and it is most suitable for reference previous to the issue of the half-yearly volumes. Price 1s. 6d.; post free, 1s. 9d. Complete set of volumes of THE GARDEN from its commencement to end of 1892, forty-two vols., price, cloth, £30 12s.

"Gardening Illustrated" Monthly Parts.—This journal is published in neatly bound Monthly Parts, in which form it is most suitable for reference previous to the issue of the yearly volumes. Price 5d.; post free, 8d.

"Farm and Home" Monthly Parts.—This journal is published in neatly bound Monthly Parts, in which form it is most suitable for reference previous to the issue of the yearly volumes. Price 5d.; post free, 8d.

"Hardy Flowers."—Giving descriptions of upwards of thirteen hundred of the most ornamental species, with directions for their arrangement, culture, &c. Fifth and Popular Edition, 1s.; post free, 1s. 3d.

"The Garden Annual" for 1893.—Contains Alphabetical Lists of all Branches of the Horticultural Trade. The Lists of Gardens and Country Seats (containing over 9000) have been very carefully and extensively revised, and are admitted to be the most complete ever published. Price 1s.; by post, 1s. 3d.

All of our readers who are interested in the improvement of cottage homes are invited to help us to make Cottage Gardening known. It is published at the very lowest price to meet the wants of those for whom it is intended, and copies will be sent for distribution, free, by the publishers, Messrs. Cassell and Company, La Belle Sauvage, Ludgate Hill E.C.

No. 141. SATURDAY, September 30, 1893. Vol XLIV.

"This is an Art
Which does mend Nature: change it rather; but
THE ART ITSELF IS NATURE."—*Shakespeare.*

CHRYSANTHEMUMS.

CHRYSANTHEMUM PROSPECTS.

FROM the present appearance of Chrysanthemums, one may be able to judge with tolerable accuracy what kind of a flowering season we are likely to have in 1893 as compared with those that have passed. I do not note any signs of diminishing enthusiasm among those who cultivate this flower, whether for exhibition or otherwise, but it is quite clear that the system of growing large specimen blooms holds the field, notwithstanding the annual tirades against it. Raisers of new kinds have somewhat modified the greatest objection we hear of, namely, the extreme height of the plants. Although generally the growth has run up to a greater height than usual, it is possible to make a first-rate selection of varieties none of which shall exceed 4 feet high. My view of the season is that, so far as the exhibitions are concerned, we shall see flowers of great beauty, with, perhaps, a falling off in mere size, this last owing to the buds having been secured by many growers later than usual. The plants of various cultivators vary, of course, as to size and general looks, but all that I have seen are particularly well ripened. The foliage is firm and bronzy and the stems of a very hard character. Plants grew out of the bud-producing propensity which troubled many during early July, and I have seen what is most unusual, flower-buds secured and looking very promising on the third run, as it is known, of such kinds as Princess of Wales, an incurved sort which seldom presents a perfect bloom when the plants are allowed to grow so tall. Blooms of the Lord Alcester type, too, will be plentiful this year from late crown buds. Many of my own plants of this type were topped in July. They produced their flower-buds far too early to please me, but they are dwarf and the growth well finished, without which ripeness, good deep incurved flowers are not to be had. It is pleasing to note several promising novelties among this class. New kinds, and especially fresh colours, are wanted to prevent the incurved Chrysanthemum being overshadowed in popularity, as at present the reflexed, Anemone, and other classes appear to be by the wonderful beauty and richness of the Japanese varieties. One wonders sometimes how far any improvement can take place in respect to this last named division, but with the thousands of seedling Chrysanthemums now growing around London alone, it is easy to anticipate novelties this autumn not less grand than many seen for the first time last year. The best of all last season's gains, Wm. Seward, seems likely to surpass expectations and drive out of cultivation such a dark crimson kind as Jeanne Délaux, which has done duty so long, but does not possess half the vigour of the new-comer. Beauty of Exmouth, John Shrimpton, W. H. Atkinson, Waban, Le Verseau, Miss Dorothy Shea, Primrose League, and many others look well in all collections, and they will play an important part in brightening the stands of blooms this coming show time. One cannot but

notice the decline of the reflexed, Anemone, and pompon Chrysanthemums. It is a pity, for amongst them are exceedingly beautiful flowers. I noticed in the collection of a large grower who, not many years ago, cultivated them well, just a few sorts that he cannot readily part with growing in an out-of-the-way corner of the garden. If we judge from gardens near London and what dealers tell us, single Chrysanthemums are not much favoured.

The strongest plants I have seen are near Reigate, growing in a very open position at the foot of a hill. I can conceive the labour of watering alone during such a summer as we have passed through on such a spot, the plants numbering not far off a thousand. Five or six times a day I was told the grower sometimes looked through the collection, and a plant was not supplied with water because that would be needful an hour later. Each, one could see by the splendid condition of the collection, had had its wants attended to at the proper time. This is a type of an enthusiastic cultivator of the Chrysanthemum who will be rewarded with fine flowers later on. In another garden which I visited the plants were mostly old stools which had been cut down after last year's flowering and remained in the same pots. Those that were newly struck had not been potted beyond 5-inch pots. The whole collection had a miserable, starved appearance, yet I was assured a great amount of pains had been bestowed upon the plants, and the grower expects flowers of great excellence. In this locality there is quite a number of working men cultivators who show their love for the autumn queen by growing the plants under, in some cases, most adverse conditions. All the plants I have seen, more or less exhibit traces of careful culture. Twenty, thirty and up to half a hundred specimens are grown, and mostly for large blooms. Several of these artisans are anxious to compete at the local show, and I hope they will do so with success.

H. SHOESMITH.

SEASONABLE NOTES.

IN many previous articles I have endeavoured to impress upon the notice of cultivators the great advantage derived by those who manage their plants in such a manner as to have them by the early part of October in a thoroughly matured condition. I am now alluding to those plants that are cultivated with the object of producing large blooms. In many gardens where these large Chrysanthemums are grown there does not exist what may be termed a suitable all-the-season-through site where the plants can remain with all the advantages necessary until the time comes for housing them at the end of September, or at the latest by the middle of October. Overhanging trees very often interfere with the plants receiving that amount of light they should do as the days shorten. I strongly advise the removal of the latest grown plants in the incurved section to more suitable quarters, even if it only be for two or three weeks, so that the finishing touch to maturing the wood may be effected. It is only by taking as much pains in attending to all the wants of the plants under such adverse circumstances that success can be achieved. The time is fast approaching when much damage may be done by earwigs to the tender parts of the plants—I allude to the newly-formed flower-buds. Although the present has been a favourable season for all kinds of insect pests, I do not think that earwigs are present in very great numbers. Earwigs do much harm to the

Chrysanthemums in a very short time if allowed to go on unmolested. A nibble or two at a tender bud will cause it to produce a deformed bloom, and this after a whole season's labour is very annoying. I have not found anything superior to Broad Bean stems or Bamboo canes cut into lengths; these thrust in among the leaves harbour the insects during the day. These traps should be daily examined by tapping one end of the tube, the carwigs will run out at the opposite end and can then be destroyed.

Hastening late plants is necessary every season. No matter how early the bulk of the plants may appear to be, there are sure to be some few late in forming their flower-buds, and as uniformity in flowering of the many kinds now necessary to win prizes is essential, means must be taken to push on those plants inclined to be late. It is useless waiting until a few weeks before the blooms are required, and then subjecting the plants to excessive heat to induce them to expand their blooms at the same time as the bulk of the sorts. Even if such a practice were successful, the colour of the florets would be much depreciated, this being a serious matter from an exhibition point of view. If these late plants have not much vigour, hasten them on by the aid of nitrate of soda, say at the rate of half a teaspoonful to one plant growing in a 9-inch pot, given in a liquid state. This should be followed up by two doses a week of sulphate of ammonia at the rate of half an ounce to 1 gallon of weak liquid manure.

Preparations will shortly have to be made for housing the plants; indeed, some require it even at the present moment. Plants that are commencing to unfold their florets should be removed under cover without delay if the beauty of the flower is to be enjoyed, whether it is too early for any particular show or not. Much of the trouble experienced in the damping of the blooms might be traced to the petals getting wet by rain or even night dews through being left outside after the colour of the petals is perceptible. Where a number of plants is cultivated on the large bloom method there are sure to be many too forward. My practice is to house all these early plants together. These early blooms are useful for cutting if developed in a satisfactory manner.

Inexperienced growers of Chrysanthemums do not understand at what date to house their plants so as to have them in bloom at any given period. Without some knowledge as to the length of time particular varieties require to develop their flowers, it is extremely difficult to have the plants in perfection exactly when wanted. The flower-buds of some varieties require a much longer time to develop after they reach a certain stage than those of others. Practical experience alone can render a new grower perfect in this detail, but a few hints on this subject will possibly be of advantage to the inexperienced. Circumstances do not sometimes admit of the plants being housed at exactly the time wished. The locality, too, in which the grower resides has to be considered. If it be a low, damp situation, a grower should remove his plants inside earlier than another person located on a hill, for the reason that in the low-lying district early frosts are more to be feared than where the position is high, and consequently drier. If the tender swelling buds are injured by frost, and they are very susceptible in this respect, the blooms cannot develop evenly and well. It is not wise to leave plants out of doors without protection of some kind in any district after October 8. Housing should commence the last week in September, removing the very early plants

and those with late or backward buds. Take *Boule d'Or* as an example in the Japanese section and any of the Princess Teck family among incurved varieties. These require much longer to expand their blooms fully than any other; therefore, all such should be placed under cover first. Those named will serve as a guide for others. Such as the Queen of England and Prince Alfred families develop very readily, requiring not more than three weeks after the first petals commence to unfold. In some of the Japanese, as *Avalanche*, the petals expand very quickly. Of course, there is all the difference between blossoms expanding freely on plants perfectly healthy and otherwise. Where the roots are not in good condition, many of the base florets commence to decay before those in the centre are nearly fully expanded. Where many plants are grown and facilities exist for arranging them in batches of say three—early, medium and late plants—all the better. So much more command can then be exercised over the development of the blooms. Before the plants are taken indoors, all traces of mildew should be removed. Where the plants are badly infested with this parasite, it is a good plan to lay them on their sides and thoroughly drench every part with the mildew mixture recommended on page 476 of the last volume of *THE GARDEN*.—E. MOLYNEUX.

—The work which should engage our attention now is the necessary preparation for housing the plants, and, where effect is desired, the plans of arrangement thought out. Before the bulk is ready there is sure to be here and there a plant the flowers of which are showing colour. Without a moment's delay place such under cover, for with damaged outside florets the beauty of a bloom may be marred. The mildew pest can be effectually dealt with at this time, and if each plant with any sign of it on the leaves be put on its side, sulphur may be puffed on to the under surface in a thorough manner. In the south, placing the whole collection under cover is generally started the last week of September, it seldom being safe to leave anything outside longer than a fortnight after. I have, however, found backward flower-buds swell better in the open air and I never put a plant under glass to hasten it, but only for safety from frosts. Before the buds show colour they miss the night dews. Unfortunately, many of us are not overdone in the matter of glass structures, so that there is little choice as to positions. A well-ventilated span-roofed house is the one I should select for *Chrysanthemums* to bloom in, and I would so place the incurved sorts that they get less sun than the Japanese varieties. I would divide the latter in this way. There are many, including all those large, heavy, thick-petalled kinds like Mrs. Wheeler, *Etoile de Lyon*, *Beauty of Castlewood*, *W. H. Lincoln*, and so on, that appear to revel in the sun's rays, and need shade only in the morning till the accumulated moisture of the night before has been dried by air. Then there are the thin, many-petalled delicate kinds like *Vivian Morel*, *Sunflower*, *Avalanche*, *Col. W. B. Smith*, as well as very deep coloured varieties, which strong sunshine spoil. Such should be stood in the shadiest part of the house, or otherwise the sun kept from them. Stand the pots as far apart as room will allow. A capital plan with most of the incurved sorts is to take away their sticks and fasten them up the front and sides of ordinary greenhouses, vineries at rest, and the like. In this position the foliage is close to the glass and the flowers become partially shaded, while the blooms, hanging their heads as it were, seem to take on the desired shape more evenly than when tied upright. When all are under cover fumigate each house with good tobacco paper on two or three occasions, whether aphides are seen or not. These are pretty certain to appear when fire heat is employed. There is no danger in tobacco smoke even when the blooms are opening provided air be passed among the plants in early

morning after the operation and that the material is good of its kind. I have heard of plants being spoiled by common tobacco paper; therefore it is well to be careful in this respect. Watering and air-giving are very important matters when *Chrysanthemums* are placed under glass. It is no uncommon thing to see well-grown plants spoiled through improper treatment from this time. I am very cautious at first, and allow the roots to get on the dry side for a few days, as the inside conditions are so different from those in the open air. During this time I throw water among the plants if the weather be at all dry; this seems to put them on good terms with the altered state of things. When well used to being under glass more water at the roots will be required. The collection should be gone through twice a day. Feeding with stimulating manures is still needed, and may be continued till the blooms are well open. I would be very careful, however, about feeding varieties of very high colour like *Wm. Seward*, or delicate growers like *Mrs. Alphens Hardy*. There is little doubt but that overfeeding predisposes to damping in the blooms, so troublesome to many growers. Open doors and ventilators night and day, and gradually lessen the supply of air as the flowers open, so that cold draughts may not play upon them. What I aim at is a nice current of air passing through the houses at all times except when fogs prevail. Growers of *Chrysanthemums* near London know what they mean and how difficult it is to prevent damage being done to opening blooms. At these times keep the ventilators almost closed and the pipes nicely warm.—H. S.

NOTES OF THE WEEK.

United Horticultural Benefit and Provident Society.—We are asked to state that the annual dinner of this institution will take place at the Cannon Street Hotel on Tuesday, October 10, at 5.30 o'clock. Mr. Peter Veitch, of Exeter, has consented to take the chair.

Lilies at Highgate.—Mr. Jenkins sends us photographs of *Lilium speciosum album* Kratzeri and *L. speciosum rubrum cruentum* growing in his garden at Highgate. Two bulbs of the former planted in 1891 produced fifty flowers in 1893, and three bulbs of the latter planted also in 1891, this season bore eighty-four flowers.

Pink Ernest Ladhams.—I herewith send you a few flowers of my new perpetual-flowering Pink, *Ernest Ladhams*, which continues to bloom in great profusion, so much so in fact that, in spite of the flowers that have been cut, the beds now have the appearance of early summer, when Pinks are just at their best.—B. LADHAMS, *Southampton*.

Epilobium angustifolium album.—We noticed this in full bloom recently, and whilst one sees the common kind in gardens, the pure white variety is not so freely planted. It is, however, a fine hardy free-blooming kind, forming a fine mass when allowed to grow without being disturbed. The flowers are pure white, and appear over a long season.

Abutilon Andenken An Bonn is a new variety, which is likely to prove very useful for the garden in the summer months by reason of the large, handsome Vine-shaped leaves, which have a broad cream-coloured margin. We noticed it in the Swanley nursery as a good thing for subtropical bedding. The habit of the plant is sturdy, and betokens a vigorous growth.

Plumeria lutea.—In your issue of September 16 you have a note on *Plumeria lutea* in flower at Kew. I have the same variety in bloom, and also rubra, which, I think, is more difficult to flower, and lasts much longer when in bloom. My plant of rubra has had 150 flowers on one spike, and has been in bloom for over eight weeks.—J. BOYD, *Dunmore Gardens, Larbert, Stirlingshire*.

Sweet Peas from Newry.—Mr. Smith, of Newry, sends us some noble varieties of Sweet

Peas of the most delicate hues and well grown, to show us, as he says, to what a stretch "the abnormal summer has brought us." We cannot see that any summer would bring us anything more fair than these Sweet Peas in colour—azure, cream, purple and chocolate.

A most valuable Carnation for out of doors is *Comtesse de Paris*. It is, I think, about the most persistent bloomer I know. Mine came into flower with the other sorts in July; it has been flowering ever since, and from present appearance is likely to produce its blush coloured blossoms up to the time frosts come.—H. S.

Zauschneria californica was a mass of bloom a few days ago at Swanley, and the past hot weather seems to have well suited such plants as this. It is very bright when in a suitable position, but requires shelter and a warm soil. During a severe winter a little cocoa-nut fibre refuse or coal ashes heaped over the roots will afford needful protection. The drooping flowers are vermilion, produced freely and make a welcome display on the rockery at this season.

Tecoma Smithi was in full bloom a few days ago in the temperate house at Kew. It is, we believe, a hybrid form, and one of its parents is *T. capensis*. Such a form is worthy of note, as it is quite distinct. The flowers are produced in fine heads, whilst individually they are conspicuous, being quite self yellow in the interior of the tube, so to speak, and flushed with reddish brown on the outside. It is very free, vigorous, and in all respects a plant that should become popular.

The scarlet-fruited Thorn.—This is superb this year for its autumn colouring. We saw trees of it the other day which lit up the garden with colour, the foliage yellow, flushed with scarlet—a glorious picture. A group on the outskirts of the lawn or in the park would have a splendid effect. Then one gets the ruddy-coloured berries, produced in profusion this year and more intensely coloured than usual, whilst in late May the flowers appear. Even for its autumn colour it is worth planting. The better kinds of Thorns are not too often seen in gardens.

Collinsia heterophylla.—This came from Mr. Thompson, of Ipswich, who has given us so many new and pretty things among annuals, and flowering as it is beside all the other annual species except *verna*, a good opportunity is afforded of seeing its distinctness. It appears to be a form of bicolor, but quite distinct, being larger alike in leaf and blossom and a little darker in colour. It is quite the best annual species of those now blooming. Others that are pretty and interesting are *grandiflora*, a dwarf kind in shades of blue and lilac, and *bartzefolia*, a pale variety of bicolor.—A. H.

Rudbeckia pulcherrima is one of the most interesting plants in bloom on the Kew rockery. It has been in full beauty for some time, and although not showy, is by no means inconspicuous. The plant makes a compact growth, the leaves narrow, abundant and of a glaucous colour, whilst the flowers are borne on long stems. Individually they are nothing much to look at, but a good specimen of this when in full bloom is certainly attractive. The centre is high, conical in shape, and stands out well, as the petals droop in a distinct way, the colour yellow, set off by a large crimson blotch at the base.

Lobelia Goldelse.—I have not seen any notice in *THE GARDEN* of this yellow-leaved *Lobelia* sent out this year by one of the German seed merchants. With me it has done very well, and is an undoubted acquisition. It has a compact habit, the foliage is of a decidedly yellow colour, and in fine contrast to the dark-leaved *Lobelias* like *Emperor William*. It is, perhaps, not quite so free flowering as the older sorts, though there is nothing to complain of in that respect. It struck me as being more delicate in constitution than its dark-leaved congeners, for my plants were sadly damaged by the cold winds in May, though now they have entirely recovered.—F. R. II. S.

FLOWER GARDEN.

GUNNERA MANICATA.

THIS herbaceous giant is a native of Chili, and may be found growing in many English gardens. Although it is semi-aquatic, it will thrive in almost any soil or situation. It, however, never attains the extraordinary dimensions it is capable of, unless planted in deep rich soil with its toes absolutely in the water by the side of a pond or running stream. The engraving does not give a good idea of its vast size, for the plant is growing in a pit and in a very difficult position for photographing. It covers a space fully 30 feet across, and consists of from twenty-five to thirty leaves, some of them over 9 feet in diameter, upon clear stems 8 feet high. The crowns are as large as a man's body, of a delicate pink colour. Flower-spikes are produced freely, which should be cut as soon as seen, or they will check the growth of the leaves. When they die down in autumn the leaves should be placed loosely over the crowns, with their stems

has benefited by the brilliant sunshine. It grows about 2 feet high, the stems and the large heart-shaped leaves being thickly covered with grey down, whilst its bold, erect, pure white trumpets, which are sweetly scented, stand up from among the leaves. Although rarely seen in gardens it is said to have been in cultivation nearly 300 years.

Flowering of Cape bulbs.—While some classes of bulbous plants, Lilies for instance, have in many places done badly this year, on the other hand the very hot weather has greatly benefited the Cape bulbs, which are this season flowering with unusual freedom. The Belladonna Lilies are quite a mass of bloom, and form one of the most beautiful outdoor features just now. A warm south border in front of a hothouse is undoubtedly the best place for these Belladonna Lilies, for in the open ground in many districts they cannot be depended on to flower well. In planting them thorough drainage should be ensured, and if the soil is a good loam they may remain undisturbed for years and will improve each season. The different Nerines, too, show the effect of such a thorough ripening as they have undergone and are flowering beautifully. They are a charming class of plants that need a thorough roasting during the summer to induce them to flower well. The Watsonias

amongst some other things, from Herr Franz Maly, the collector, of Vienna. These plants bore each one flower of a very pale yellow colour, almost cream colour, on a stalk about 3 inches high. Each flower was about 1½ inches long, and I remarked that the tube appeared to be very thick or swollen, while the divisions of the corolla were of smallish size. Mr. Backhouse told me that these plants did not appear to thrive with him, and he never, during my time, raised any stock from them. The ordinary blue-flowered *C. gelida* of the trade has been retained in his catalogue, very probably for commercial reasons.—W. M.

NEW HARDY WATER LILIES.

M. LATOUR-MARLIAC has sent me a series of six blooms selected from ten or twelve of his new seedlings, and very distinct and beautiful they are as now floating in a big bowl of water as I write.

N. MARLIACEA RUBRA PUNCTATA is a shapely flower 4 inches in diameter, with twenty-two sepals and petals. The four sepals are dark olive-green behind, and pale rosy lilac in front. The petals are of a deep rose-purple and delicately marbled. As looked at through a lens the colour is seen to be formed by deep crimson-purple cells, dotted upon a whitish and crystalline ground colour, but the general effect is that of a rich rose-purple, very dark, indeed approaching carmine in the centre, as contrasted with the orange whorl of stamens.

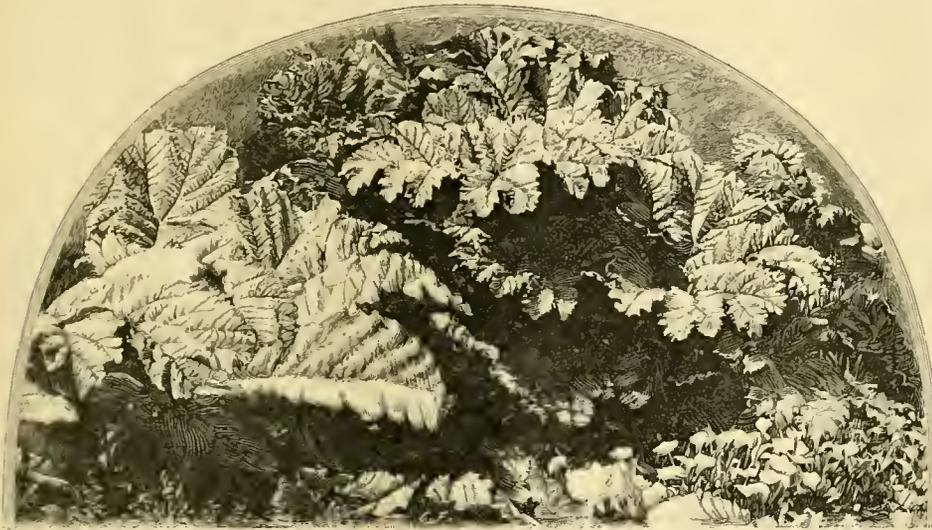

N. MARLIACEA IGNEA.—This is a larger flower and nearly 5 inches in diameter when fully open. The sepals are pale olive-green, edged with rose behind and pale rose, nearly white, in front. There are eighteen shapely petals closely imbricated and forming a beautiful cupped whorl around the vivid orange-red based stamens in the middle of the flower. The petals are of a deep, but bright rosy crimson, and so far this is by far the most brilliant hardy *Nymphæa* that I have yet seen. As seen in the sunlight its petals glint and glow with quite a stained-glass-like effect, not at all easy to describe in words.

N. ROBINSONI.—A smaller flower, barely 4 inches in diameter when fully open. Sepals pale olive-green behind, and of a soft primrose colour, shaded with the palest rose in front. The petals are broad, fifteen in number, and of a soft terra-cotta rose colour, shaded with primrose, and there is a bold tuft of golden stamens in the centre of the flower. This is a most distinct flower, calling to mind the old-fashioned rosy semi-double Hollyhock in form and colouring.

N. LAYDEKERI FULGENS.—Also a small flower, barely 3½ inches in diameter, as fully expanded, having five outer dark green sepals and about fifteen cupped and shapely petals of a dark crimson-magenta colour, glowing like a ruby in the sun. As seen in the shade the crimson petals shade to nearly black in the centre, and of all *Nymphæas* this is the richest and darkest in colour of any I have as yet seen.

No. 5 (not yet named).—Again a small, but shapely star-like flower, barely 3¼ inches across when fully expanded. The sepals are apple green behind and pale primrose shaded with soft green in front. The pointed petals are of a delicate salmon rosy shade, something like *Carolus Duran* Carnation, and there is a boldly radiating group of golden stamens occupying nearly half the width of the flowers. In colouring this variety is absolutely unique amongst Water Lilies. It is a delicate cream-tinted flower shaded with pale rose.

N. LAYDEKERI LILIACEA.—A most dainty flower, even smaller than the last, its blooms being only about 2½ inches in diameter when wide open. The four sepals are dark sap-green behind margined with pale rose. There are fifteen peach-blossom-tinted petals around a small tuft of golden yellow stamens. The rosy petals have quite a silvery lustre in the sunshine, and if examined through a lens this glistening effect is seen to be due to the rosy pigment being dotted or marbled upon a

Gunnera manicata at Trelissick, Truro. Engraved for THE GARDEN from a photograph sent by Mr. W. Sangwin.

on top to prevent them being blown away by the wind. Protected in this way the plants have stood the winter with a thermometer ranging on several occasions below zero. It grows freely from seed, but it can be divided as easily as Rhubarb. The individual flowers are very minute, more curious than beautiful, the chief attraction being in the truly magnificent leaves. W. SANGWIN.

Trelissick, Truro.

Solanum Fontanesianum.—The Solanum family is a very large one, and some of its members are striking in leaf, flower and fruit, but most of them are of questionable value in gardens. The kind under notice is an annual of easy growth, as the seed may be sown in the open air. It has handsome leaves, which are armed with long, very sharp thorns above and below. Its flowers, borne several in a raceme, are each 1 inch or more in diameter, and of a creamy white or pale mauve colour.

Datura Metel.—In an ordinary season little or no success would have been expected with this plant from seed sown in the open air, but at present one of the most striking things among our annuals is a line of this, the seed having been allowed to take its chance. It is a tropical annual, and no doubt

and *Eucomis*, too, have flowered unusually well, while *Vallota purpurea* bloomed very much earlier than I have ever before noticed it. Several plants were exhibited at the Temple show, and in many places it was flowering soon after. This feature was in the case of the *Vallota* certainly not an advantage, as so many other plants were blooming at that time; whereas it usually comes in at a season when many of our summer blooming plants have lost their foliage and before the bulk of autumn flowers are in. The blossoms that expanded during the height of the summer retained their freshness only for a very short time. *Cyrtanthus McKeni* in a warm nook has flowered throughout the summer, while there are still a few blooms on it. The bright coloured *C. angustifolius* and *C. MacOwani* have also bloomed well under similar conditions. The past season has in many places just suited the *Montbretia*, while, on the other hand, in some spots, especially where the soil is light and dry, the foliage was so much attacked by red spider as to cause the leaves to turn yellow and shrivel up.—H. P.

Gentiana gelida.—Mr. Wood is, as usual, quite right in his note on this plant (p. 186). The late Mr. Backhouse had (about the year 1875) on the new private part of his rockery adjoining the dwelling-house two plants which he told me were the true *Gentiana gelida* from the Caucasus, and I think he said that he had received them,

white ground, and not equally floated or diffused through the tissues. This is an exquisite little beauty, resembling *N. Laydekeri rosea* in form, but if anything smaller, and it has a delicate perfume.

Of the above, although all are beautiful and distinct, *N. Marliacea ignea*, *N. Laydekeri fulgens*, and the soft rose and cream-petalled No. 5 are perhaps the best. The intensity of colouring in the two first is quite unprecedented, and the last of the three is quite unique in colour. When I saw these exquisite flowers from M. Marliac, the first flush of satisfaction was succeeded in my mind by a question, Where will all this variety and beauty amongst the *Nymphæas* end? We cannot have too many of them, for they are the most lovely water flowers of all, and as welcome in variety as the Carnation or the Rose.

F. W. BURBIDGE.

NOTES FROM A NEW ZEALAND GARDEN.

We are now nearly a month past the winter solstice, and with lengthening days the flowers and the birds are beginning to stir. To-day (July 20) I noted a good deal of activity among the garden birds. The thrush breaks quite into a burst of song towards late autumn or early winter; why, I cannot tell, unless the bright days of the Indian summer cheat him into a belief that spring has come without winter. The frosts, which here are sometimes hard enough, and the occasional light snows seen undecieve him on this point; but yet during open weather the thrush may be heard more or less throughout the winter. The blackbird, on the other hand, is silent till he has reason to think that spring is close at hand, which I could almost believe he decides by the appearance of the first yellow Crocuses. Apparently Christmas Roses, Japan Quince, Acacia or other winter flowers do not move him to song. To-day I heard his note for the first time; not a decided song, but somewhat diffident, as if he were only trying his voice. The cheery note of the hedge sparrow has been heard in the garden during the last few days. It looks as if this delightful little bird were doomed to disappear before the house sparrow, which bids fair to become an intolerable pest; and, therefore, I am pleased to see a pair of hedge sparrows about to domicile themselves in my hedges. I heard the skylark's song also to-day for the first time. The bird we colonists miss most is probably the cuckoo. No experience possible in this colony quite resembles that of hearing his note in spring for the first time. We have, to be sure, our cuckoos—birds of passage and disowners of their offspring, like their European congener—but without the peculiar note. The nearest approach, in my experience, to the pleasure of the first cuckoo note is that of hearing the earliest spring note of the chaffinch. Another sound of spring, very pleasant to hear, is the long-drawn-out whistle of the starling. To-day, the weather being mild and sunny, the starlings stationed themselves on the ridge of the house and piped in their plaintive

fashion; whether a love-call or a challenge I cannot say. With all this it would be premature to assume that spring is yet here. Winter will no doubt let itself be felt and heard before it goes for good. When I hear the first song of the chaffinch I shall believe that spring has come, but not till then.

Yellow Crocuses are out in sunny places, though in open and shady spots the tips of the grass are hardly visible. This is one of the European bulbs which the New Zealand climate seems particularly to suit. The yellows increase by offsets at a great rate; the other colours sow themselves abundantly every year, but the young seedlings get so disturbed by gardening operations—digging, hoeing, and so on, that not many of them come to anything. I note that the Crocus bulbs that get dug in to a considerable depth seem to grow stronger than these shallow planted, but they do not increase so rapidly, and the same is my experience with most of the Daffodils. The first Snowdrop was cut to-day (July 20) with, I am afraid, not many more to cut. It is curious, seeing spring Crocuses do so well with us, that the Snowdrop should be a difficult subject. I cannot grow Snowdrops, though I have been trying for years. The Crimean and the Smyrna Snowdrops seem to do a little better than the common kinds, single and double. These last somehow dwindle away to a white fungus-like thread, and then vanish. I have little doubt that the trouble lies somewhere in the all-round mildness of the climate, but how this cause operates I should like to know. Why should a bulb that grows and increases so readily in Britain prove such a difficult subject here, where the winter climate is so much less severe? Some light might be thrown upon this point if one knew how Snowdrops fare in the milder European climates, say Italy and the south of France. Will anyone who knows about this report on the subject?

Christmas Roses do fairly well with me. That which I have under the name of *St. Bridg* has a fine large flower, beautifully pure in the white, and very thick and solid in substance; it has pale green leaves that lie close to the ground, but both leaf and flower growth so far has been slow, and the stem is very short. Another variety, with leaves in the style of the typical niger, is much superior to niger, being more vigorous in foliage and a much better bloomer. As a winter ornament to the garden the Hellebores of the niger type are much less effective than another species of which I have several varieties—*H. orientalis*, I believe. These in several shades of greenish white and pink are really very handsome in the borders when most else looks dead enough. The somewhat spiny-fingered foliage radiates all round to a good distance, and the flowers stand boldly up in the centre on upright stems a foot or more in height. Self-sown seedlings are abundant, and though I have taken little care of them, I have had one or two rather good varieties.

The flower that divides the honours of winter with the Hellebores is *Iris stylosa*, and

a most dainty thing it is in shape, colour, and odour. I used to have one plant of this *Iris* from which I could gather a sheaf of bloom at any time during the winter, and, thinking to increase the supply, I made eight plants of it, some of which are now larger than the original plant. But the supply of flowers from the eight plants is smaller than formerly from the one. For two seasons I had none at all. This year, so far, I have had about a dozen blooms, and there may be more to come. I imagine that this lovely *Iris* requires starving to ensure blooms. When the season of bloom is over I shall plant a clump about a yard or so from a macrocarpa Cypress. If in such a neighbourhood it gets more sustenance than is good for it, then it must be hard to starve. Such is the fragility of the blossom of *Iris stylosa*, that it is difficult to get an expanded flower without one or more damaged petals. To have it in perfection it must be cut in the bud stage and allowed to open in water; then I know few things more lovely. There is a white variety which I do not possess. I should be glad if any of your readers who grow it would report as to its merits.

DAFFODILS.

These are on the move, and I expect great things from them this year. So far they have not behaved quite as usual. Usually the first *Narcissus* to show bloom with me is a strong form of *odorus*, which I received a good many years ago under the name of *hiemalis*. As this *Narcissus* usually begins to bloom in winter, the name of *hiemalis* is particularly suitable. But I do not find it in the catalogues, Dutch or English. On looking up Mr. Burbidge's book on the *Narcissus* I find a variety of *odorus* described and figured under the name of *heminalis*. This name is also to be found in the Daffodil conference list, printed at the end of Mr. Barr's little book on the Daffodil, but the plant is noted there as being one of those varieties not identified with any existing form. *Heminalis* has not appeared in Mr. Barr's catalogue, I think, for the last ten years at least, but it will be found in his catalogue for 1880, and I think my *hiemalis* must be an error in transcription (probably mine) for *heminalis*. Can anyone throw any light on the latter name? Did Herbert use it first? and what does it mean? There is no such Latin word so far as I know. Possibly it may be a florist's coinage from *hemina*, but in that case I cannot see the relevancy of the name. The variety I have with label *hiemalis* is an exceedingly valuable kind, vigorous, free-blooming, early and lasting—one of the best of the *Narcissus* tribe, and a great improvement on the typical *odorus*, or what I take to be the typical form. The bulbs of *hiemalis* are very large; the grass is tall and strong; the flowers, borne erect on a long and strong stem, are large and very rich in the yellow. By the way, it is a very curious fact that the name of *odorus* should have been given to that *Narcissus* which has the

least scent of all. Mr. Baker, in his "Review of the Genus *Narcissus*," describes the odour as sweet-scented, and again as possessing a decided fragrance. Such is not my experience of this *Narcissus*; compared with the *Jonquil* and *Tazetta*, it has no scent at all, and its scent is faint even in comparison with that of most trumpet and Peerless *Daffodils*. When *hiemalis* (I use the name for want of a better) blooms, as it ought, about the winter solstice, it is possible to have six months of *Narcissi*, assuming the double poetens to last pretty well through the month of November (your May). This year, *hiemalis*, though early, is not the earliest. About the middle of June I gathered a bloom of the common double Lent Lily (*Narcissus pseudo-Narcissus*). Up to July 22 I have gathered eight blooms, and there are about a couple of dozen nearly ready for cutting, the grass of these clumps being about 10 inches high. Now there are in various parts of the garden two dozen beds or clumps of this variety, which, common as it is, is my favourite of the whole tribe. But these clumps are only just showing the tips of the grass above ground, so that counting from mid-June, when I gathered the first bloom, there is the promise of a very long season of this *Daffodil*. The early blooms this year are the result of an accident, and point to a very simple means of forcing this *Daffodil* so as to increase the length of its season. These early blooms have been sent up by clumps of bulbs that lay almost on the surface on a sheltered border. They were lifted for the purpose of planting them out in the usual way, but the planting was neglected, and they were left covered with, perhaps, less than an inch of soil. The result is a crop of flowers a month in advance of the general bloom. On the other hand, everyone who grows *Daffodils* knows how easy it is to retard the blooming for ten days or a fortnight by simply planting in a shady border, so that, what with hastening and what with retarding, the period of bloom for the *pseudo-Narcissus* may be considerably lengthened. I have not sufficient leisure time to allow of my attempting to seed and hybridise *Narcissi*, though I am sure this might be very successfully done in this climate. The best seed-bearer, so far as my observation goes, is the common *Jonquil*. This produces seed in large quantity and sows itself. This year for the first time self-sown seedlings of this *Narcissus* are showing flower-spathes. I should like to know whether this tendency to seeding is characteristic of the *Jonquil* in British and Irish gardens. On the other hand, I have never observed seed-pods on the late *Narcissus tenuior*, which is nearly as plentiful in my garden as the *Jonquil*. But *Narcissus tenuior* is itself, I suppose, a hybrid between two members of different sections, and is therefore sterile.

Assuming that winter should extend equal distances on each side of the winter solstice (June 21), that is, about six weeks before and after that date, spring may be said to be due about August 1. The most reliable prophet

of spring amongst the birds I find to be the chaffinch. You may trust him not to be premature, and this morning I heard him for the first time this year. After some twenty-four hours of rain, the night had been frosty enough to film thinly over the Water Lily tubs, but the sun rose bright and remained unclouded till sunset. A finer day for spring to open there could not have been, and evidently the birds thought so. In going into town of a morning, I have to walk along a drive a mile or so in length bordered on each side with a luxuriant belt of thick bush, for the most part native trees, such as *Fuchsia*, *Broadleaf*, *Ti-scrub* and so on. This belt is alive with birds, and it may interest lovers of birds in England to know how they thrive here. From end to end of the drive there was this morning a full choir of songsters. The dominant note was the loud, bold, and, as I think, somewhat coarse whistle of the thrush. There seemed to be a thrush on every tree, and their concerted, or rather antiphonic, music made it a little difficult to follow the softer undertones of the smaller birds. But suddenly at one sunny bend of the road I heard the first welcome note of the chaffinch—only one pipe, so that I almost doubted whether I had rightly heard, but there followed his well-known double call chirp, and then I saw him. It was the chaffinch sure enough. A mile further on another broke into song, and repeated his short ditty five times. The date on which I first heard the chaffinch last year was August 2, and then I heard two separate birds, as this year on the 1st. The chaffinch is not, I regret to say, plentiful with us, and his tribe does not increase if it does not diminish. In my experience the chaffinch is for the most part a morning singer; a sunny morning and a sheltered piece of wood are his delight. Other birds were also active. In my walk along the drive in the morning and my return walk in the evening I either saw or heard the following: Two larks, not in song, but fluttering in mid air in an open paddock; blackbirds numerous, but not in song, the chiding chatter, however, that these birds indulge in when disturbed being loud enough, with much strutting and flirting by the roadway; a goldfinch, this bird being very plentiful here; the hedge sparrow in very joyful song and preparing to be busy; the fussy starling, uttering occasionally his long spring whistle; the house sparrow, unfortunately too numerous and noisy. Add to these imported birds three of our own native birds, all interesting. There was the little wax-eye (*Zosterops lateralis*), hunting in flocks for parasites of the aphid tribe, and all the time uttering his shrill monotonous chirp. Next the equally small, but delightful little bird, the grey warbler, called by the natives *riroriro*, and by the learned *Gerygone flaviventris*. You may often see this little bird flitting from bush to bush, the tips of its tail feathers forming a little semi-circle of white. You may also often hear its sweet, but monotonous trill, as I heard it this evening, but you will rarely see it and hear it at the same

time. Often as I have seen and heard it, I have never seen it singing, or, indeed, seen it in repose at all, for it is a little Ariel among birds. The third of the three native birds to which I have referred is the bell-bird, or korimako of the Maoris, *Anthornis melanura* of ornithologists. A few weeks ago it frequented my garden, being attracted by the blossoms of the *Pyrus japonica*, from which it seems to get honey, but of late I have not seen it. Anything richer than the more mellow of its notes it would be hard to conceive, though there are notes in its compass that are not so musical, being more like a husky whisper. So much for the birds on this first morning of spring. I fear I have been tedious on a subject interesting to myself, but which may be considered out of place in a journal devoted to horticulture.

As to flowers on this August 1, the following is a list of plants more or less in bloom in the garden to-day:—

Crocuses in variety, numerous	Violets Allium
<i>Omphalodes verna</i>	<i>Pyrus japonica</i> , red and white
<i>Daphne Mezereum</i>	Rhododendron, fine crimson
<i>Myosotis dissitiflora</i>	Berberis Darwini
<i>Daffodils</i> , double <i>pseudo-Narcissus</i>	Laurustinus
<i>Narcissus odorus</i>	Heaths, three varieties
<i>Hepaticas</i> , several colours	Epacris
<i>Anemones</i> , garden kinds	Bauera
<i>Anemone apennina</i>	Yellow Jasmine
Snowdrops	Cyclamens
Primroses, single and double, various colours	<i>Iris stylosa</i>
<i>Polyanthuses</i> , selfs and laced	Daisies
<i>Arabis</i>	Pansies
<i>Scilla sibirica</i>	Wallflowers
<i>Agathæa cœlestis</i>	Acacias
Honesty	Winter Aconite
<i>Helleborus niger</i> varieties	Flowering Currant
<i>Helleborus orientalis</i> varieties	Spring Snowflake
<i>Helleborus fœtidus</i>	Yellow <i>Corchorus</i>
<i>Vinca minor</i>	Common Broom
	<i>Banksia</i> (species unknown)
	<i>Ionopsisidium</i>

Dunedin.

A. W.

* * * The proper spelling of the *Narciss* you refer to is *heminalis*. The authority for the name is Haworth, and it is figured in "Parkinson," p. 93, fig. 4. It is this year included in Messrs. Barr's catalogue.—Ed.

Tritoma Diana, flowers of which we have received from Mr. Prichard, of Christchurch, Hants, is a very beautiful hybrid raised by Max Leichtlin. It is quite deciduous, not half evergreen, like the varieties of *T. Uvaria*. A light covering of Bracken in winter is sufficient protection in cold districts.

Massing hardy flowers.—This method of disposing hardy plants in borders is well shown at Forde Abbey by Mr. J. Crook, who is an enthusiastic advocate of the plan. It is not merely that by this plan a better effect is obtained, but each kind or variety exhibits its merits far more effectively than is the case where only small or even moderately-sized plants stand singly. A fine cluster of *Rudbeckia Newmanni* was glorious, for it was 6 feet through and a mass of flowers; *Aster Amellus* was the same, so also were big clumps of *Chrysanthemum latifolium* and other things in bloom. *Anemone japonica alba* was a mass of snow white flowers. If this plan could be more fully adopted, it would do far

more than has ever yet been accomplished towards popularising hardy flowers. It is the rule also at Forde Abbey to intermix tender and hardy flowers in the kitchen garden flower borders. In this way double Zinnias are truly beautiful. Seed purchased in colours, sown separately, the seedling plants being put out in this way in blocks from 4 feet to 5 feet long, produced effects that excel immensely all that is got from any mixed bed of Zinnias. The colouring of some of the varieties, too, is so beautiful, that it seems as if nothing at this season could be more attractive. Then large patches of crimson Phlox Drummondii, or white, blue and red Asters are delightful. It is said to be a bad Aster season. Here at least these flowers are as fine and beautiful as Asters well can be. The effort to make outdoor flowers specially effective is at this place remarkably successful, and Mr. Crook practises well what he preaches.—A. D.

FLOWER GARDEN NOTES.

A FAVOURABLE sign of the times in connection with flower garden work is furnished by the ever-increasing display of cut herbaceous flowers to be found at nearly all shows, and the yearly increase in the number of growers, both trade and private, who make a speciality of their cultivation. With the planting season close upon us it may therefore be advisable to devote a few notes to some of the good things that have been prominently to the fore this year, with special reference to those flowers that have proved of great value for cutting. I should like at the outset to make a strong point in the case of the formation of new herbaceous borders in favour of the advisability of planting all things in fair-sized groups, not a dozen different varieties in as many feet, but clumps, a space of 3 square feet given up to each particular flower. To do the border thoroughly well at the outset and to plant in this manner are essential not only for an effective display, but because the majority of herbaceous things do not like the spade and lifting operations going on every year; they will stand for many years with a good annual surface mulching, and in the case of ramblers a little attention to keep them within bounds. I pass by the Iris, Pyrethrum, Phlox, and Pentstemon families that are numbered by hundreds of varieties; new sorts as they appear have always been promptly noted in THE GARDEN, and cultural directions have after appeared. I must, however, say one word in favour of the new dwarf Phloxes, about 18 inches in height, that are likely to prove grand subjects for beds. There is already a great variety in colour, the trusses are very fine, and the individual pips are as a rule beautifully shaped and of immense size. The only objection likely to be made to them for prominent planting is that they are rather short-lived, but it must be remembered that if planted in a mass they would naturally not all be quite at their best at the same time, and if heads were promptly nipped off, they throw up quickly in favourable seasons and furnish a second display. I was very much interested this year in a first experience with *Anomatheca cruenta*, a miniature lily of great beauty. It evidently likes a sunny south border and a rather light, deeply pulverised soil. Given this and a heavy winter mulching of half rotten leaves, there is apparently nothing to be gained by an early autumn lifting and winter storing. Exactly the same remarks are applicable to the *Montbretias* or *Tritonias*, also an exceedingly valuable race for cutting. *T. crocosmiflora* should be largely grown for this purpose; arranged with its own foliage in trumpet vases or white china stands it is very beautiful. Nearly everyone knows the double *Achillea ptarmica*, but the new forms *Snowball* and *The Pearl* are rarer; they are simply dwarf gems, the flowers of a beautiful clear white, nearly as large as those of the double Peach-leaved *Campanula*, and borne on long light flower-stalks. I have noticed many fine displays of the *Sea Lavenders* this summer, *Statice latifolia* and *S. elata*. For large bowls or vases they form an admirable base or carpet with other sprays arranged

to droop gracefully round and over the bowl associated with spikes of taller flowers, of which the *Tritonia* above named or *Spiræa palmata* are examples. The *Sea Lavenders* pay for good cultivation; they like a bastard-trenched fairly good border, and once planted should be left severely alone, as old crowns do not care about removal. Indeed, if when this is really necessary stout pieces of root are firmly inserted in soil similar to that above named, the latter will show considerably more vigour the following season than the old crowns.

A *Funkia* sold as *subcordata grandiflora*, but which, I think, should be simply *grandiflora* or *japonica*, has flowered well this year; the flower-stalk is thrown well above the foliage, and the flowers themselves are very fragrant. This *Funkia* likes a cool spot in the border and a deep, fairly rich soil. Care must be taken in ordering to specify both the habit of this particular variety and the scent of the flower, or the purchaser may possibly be disappointed and get *F. subcordata*, a very different thing. Reference was made earlier in the season to *Gypsophila paniculata*, and (not suffering to any extent from the prolonged drought) it flowered very freely. Like the varieties of *Statice* already alluded to, this *Gypsophila* associates admirably in vases with other flowers with tall or graceful spikes. It is at its best in ordinary seasons on a sunny, rather dry border, and individual plants increasing slowly in bulk should be planted rather closely together. *Helianthus Soleil d'Or* is one of the brightest of garden flowers at the present time, a large bank immediately in front of three or four plants of *Lawson's Cypress* making a very effective group. It has not made quite such vigorous growth as usual, but is a mass of flower. Smaller double flowers are furnished by *Bouquet d'Or*, and fine large singles by *multiflorus maximus*. Two excellent *Starworts* of the present date (September 21) are *Amellus major*, a fine flower considerably larger than the type and of free, robust habit, and *vimineus*, with small flowers and very delicate foliage. Even a short and necessarily imperfect list of good hardy vase flowers would be incomplete without a word on the late summer and October-flowering *Chrysanthemums*. Hardy perhaps in the true sense of the word is a misnomer when applied to this race, but they are so valuable for cutting when other things are getting scarce, that one must include them in a list of useful outdoor flowers. Where the October-flowering sorts are planted either in big clumps on borders or in beds, I should strongly advise a few upright stakes or poles at intervals round about them, and facilities for putting on quickly cross pieces and tiffany or some material of the kind. A late September frost is sometimes of sufficient severity to spoil all bloom if it is quite without shelter. I remember only a few seasons back the blackening of buds of nearly all unsheltered *Azaleas* and winter *Chrysanthemums* where the custodians thereof with an eye to the weather had not turned out late at night, laid all pots on their sides and covered with thick tiffany.

Claremont.

E. BURRELL.

CARNATION PLANTING.

THE Carnation has stood out conspicuously all through the year as well able to resist drought, and if the flowering season has been shorter than usual, it has left us a good legacy in the shape of strong, well-rooted layers. By early planting of these we are carried a long way on the road to success another year. Our own layers leave nothing to be desired so far as strength and abundance of roots are concerned, and I think this must be the general experience, for of many new kinds coming in for trial even from the far north, it is noteworthy that all are strong and well rooted. Apparently the best Carnations of the future will have that all-essential quality—vigour of constitution, as many of the newer kinds are remarkably strong, with rich broad grass. The new *Lady Nina Balfour* is a good example. There is a great scarcity of water in some parts of the country, and one or two cor-

respondents writing to me say they are obliged to defer planting till there are prospects of rain. It is surprising, however, to notice how well the layers have rooted, though scarcely a shower has damped them and the ground has never been wetted thoroughly since they were put down. When planting is pursued during such weather as we have experienced of late, the plants, though they may have good balls of roots, need at least one thorough good watering to start them afresh. The most economical, and certainly the most effectual way of watering them is to leave the soil as a loose cup round the plant and thoroughly soak it, filling up and making firm after. This, well done, usually suffices to start the plants, and new roots are formed in a few days. If plants are put out and made as firm as is essential for them before being watered, overhead watering after, unless very copious, fails to reach the roots. Under the treatment I here suggest, with the additional encouragement of placing a handful of road grit or sea sand and wood ashes in mixture around the roots of the plants, this inducing early rooting, many plants have been put out during the great heat of this September, and apparently they have not suffered in the least.

A. H.

Helianthus multiflorus Soleil d'Or.—This is one of the showiest of all the perennial *Helianthus*, growing about 4 feet in height, compact, and bearing a quantity of large double flowers of an intense yellow colour.

African Marigolds have stood the hot weather remarkably well, at least for many weeks past they have been amongst the gayest flowers in the garden. One scarcely sees sufficient of the best forms of this fine flower, and it is, unfortunately, made to look ridiculous at exhibitions by the absurd way in which it is staged. The orange-coloured kind is rich, and several splendid strains are in the trade; whilst contrast is provided by the kind named *Lemon Queen*, which is rather tall in growth, the large flowers being of a distinct lemon colour.

Nolana atriplicifolia.—The *Nolanas* are very charming annuals of prostrate or trailing habit. They belong to the *Convolvulus* family and are easily grown, doing well when sown where they are to bloom, as they rather resent transplanting. Two or three species are in cultivation, but that named above is about the best, and a very pretty thing when doing well. Creeping on the ground or over stone edgings it flowers profusely, the flowers being about the size of those of the common field *Bindweed*, and of a delightful blue colour with a white throat. With plenty of room, which is generally denied to annuals, it grows and flowers for some time.—A. H.

Gladiolus Childsi.—One of the several races of *Gladioli* that have appeared in recent years is that obtained by Mr. J. L. Childs, of New York, and it contains some striking and very distinct varieties. Mr. Childs kindly sent us a few kinds for trial this spring. *Ben Hur* is splendid, fine in form, with a large open flower of great width and striking beauty. Its colour is a soft salmon shade with darker markings in the throat. *W. Falconer* is very bright in a soft shade of salmon-pink feathered with cerise. *Mrs. Beecher* is most effective, being of a rich deep red; and *Henry Gillman*, also red, has a white throat and a white line down the centre of the petals.

Everlasting Peas.—However unfavourable the intense heat and prolonged drought may have been to many flowers generally, they do not appear to have affected the blooming powers of the pink and white forms of the common *Everlasting Pea*. I have a number of old specimens of both varieties that I grow for cut bloom, and although they came into flower quite a month earlier than usual, they are now in full beauty. I have cut sacks of bloom from them this summer, and evidently only cold weather will stop the production of flowers. I doubt if there is anything finer in the outdoor garden at this time of year than well-established specimens of the white *Everlasting*

Pea; when hundreds of trusses are open at the same time the effect is very fine. We have certainly nothing among hardy climbers that will give for such a lengthened period so large an amount of exquisitely pure white flowers which are invaluable for wreaths and crosses. Every one who has these to make should grow some good specimens of this white Pea, and I have used them freely for this purpose with white Lapagerias—a very pretty combination. The continuous blooming character of Everlasting Peas can, in dry summers at least, only be assured by deep culture. If the roots can run down 3 feet into the ground the plants will continue to bloom even in very parching weather. In shallow soils they are apt to go out of bloom by the middle of August. With a free root-run, picking off all seed-pods that may form, and giving a good soaking about twice in a hot summer, one may gather fine blooms for a period of three months or more from the same plants.—J. C. B.

Hardy Cyclamens make a pleasing show of colour in mid-September, and *C. neapolitanum*, better known under its synonym *C. hederifolium*, is a delightful autumn flower, varying in colour, and with fine marbled leafage. The white form named *album* is very pure, and mixed with the others looks well on the rockery. The hardy Cyclamens are prettier on the rockery than in the open, and in every good rock garden large clumps should be planted to give interest through the winter months. A light vegetable soil suits them best, and little sheltered nooks, so to speak, afford protection to the flowers from the weather.

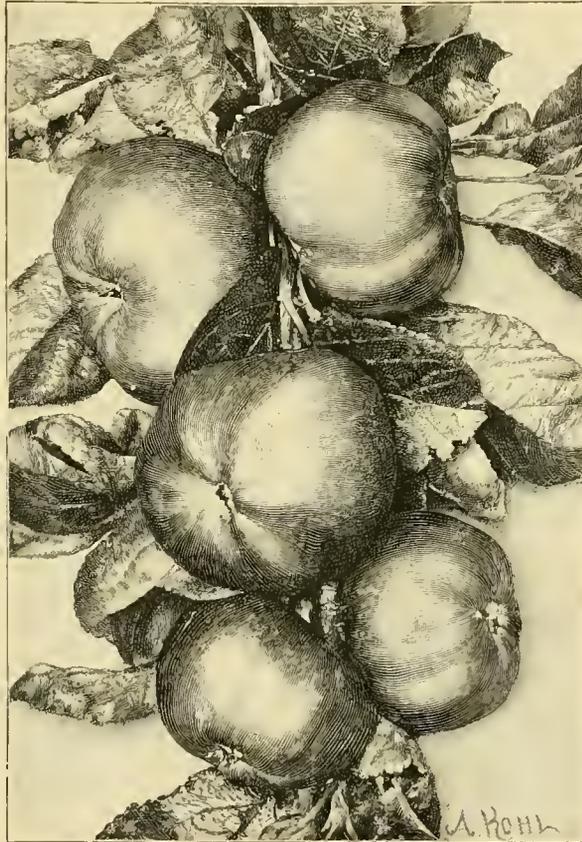

ORCHARD AND FRUIT GARDEN.

APPLE ECKLINVILLE.

ACCORDING to the "Fruit Manual," this excellent Apple was raised early in the present century at Ecklinville, in the neighbourhood of Belfast, by a Scotch gardener of the name of Logan. It has long been extensively grown both in Ireland and Scotland, and to a more limited extent in England. Of late years, however, and more especially since the rage for fruit growing for profit has become more pronounced, Ecklinville has been planted by the thousand, this being one of the few varieties that nurserymen can never grow enough of. Nor is this to be wondered at, seeing that it is included in every selection of cooking Apples, however limited, that is given. This variety possesses the merit of being of very robust habit of growth, and yet is an abundant bearer, quite small trees cropping freely, while large specimens seldom fail to produce fruit by the bushel. It is admirably adapted for growing in a bush form, the branches being erect, very stiff, and not forming a lot of spray. As I have it on the Crab stock and low stem, the trees are about 12 feet through and as much in height, and no trees serve us better than these do—without much trouble, too. It should be added that ours is a heavy clayey soil, and Ecklinville is therefore one of the best for heavy as well as medium soils. Bushes and pyramids on the English Paradise stock also do well, the trees producing freely and looking very healthy, although excessive productiveness greatly checks growth. It forms a fairly large compact head when grown as an orchard tree, and, it need hardly be added, crops heavily in most seasons. Unfortunately, the fruit does not keep well, and this season, instead of its being good throughout October and later, scarcely a sound fruit will be left by the end of September. Ecklinville, then, should not be planted very extensively for home use, two or three fairly large trees being enough for most

places, a single tree only being planted in quite small gardens. When it is intended to grow Apples extensively for market, then the variety under notice may well be planted by the score or hundred, according to circumstances, many dwarf as well as standard trees being included. The advice often given to market the fruit direct from the trees ought certainly to be followed. It is too soft for storing, and being large, also cooking well, no great difficulty is experienced in finding a good market. W. I.

Shepherd's Seedling Apple.—I met with this very excellent variety recently in several cottage gardens at Messington, Surrey, where it is found as old standard trees. Shepherd's Seedling is a fine kitchen variety of handsome conical form, very firm, heavy, and a good keeper. On old trees—for I know nothing of its cropping quality on young

Apple Ecklinville Seedling.

trees—it is an abundant bearer, and I think equal to any others. In the district to which I refer the Apple is held in high esteem. It certainly merits planting as a first-class orchard variety.—A. D.

Fig trees in Surrey.—It may interest some of your readers to hear that in our garden (the soil of which is a very light sand) several Fig trees against south and south-west walls are ripening a second crop of fruit. The Figs are small, about the size of Walnuts, but very sweet.—C. M., *Farnham*.

Hambleton Deux Ans Apple.—When recently at Hackwood Park, Basingstoke, I noticed the extraordinary heavy crops very large old trees of this fine old cooking Apple were carrying, some having from 18 bushels to 20 bushels, and generally a very fine sample. Mr. Bowerman remarked that he had never seen the fruits finer or earlier, due no doubt to the abundant sun-heat of the summer, although the drought has been felt also. The variety is at Hackwood held in very high favour

for cooking during the late winter and spring, as it is one of the best keepers. This old Apple is probably more largely grown in Hampshire than elsewhere.—A. D.

APRICOTS IN FRANCE.

THE paper read by Mous. F. Jamin (p. 191) is most important and interesting, though it fails to inform English readers as to a question I have frequently asked in THE GARDEN as to the causes of the general inferiority of the Apricot in France. A good many have supposed that the varieties were inferior, and that, in fact, they were raised from seed, and that this largely accounted for the inferior quality of the fruit. Mons. F. Jamin finally disposes of this fallacy by informing us that French Apricots are mostly worked on the *St. Julien Plum*. Besides, the Royal, the Peach, the Blenheim and even the Moorpark seem to be grown, as well as other and more specially French varieties. True, the Apricot in France is grown in the open as a bush or dwarf standard tree, while in England it is grown on walls, and possibly our walls provide a better climate for Apricots than the open air in France, however superior the climate or larger the average of sunshine. This seems plausible enough at first sight, but it will hardly bear investigation; for though we can hardly ripen creditable Grapes on our walls in England, these ripen readily in France in the open air, thus proving that France without walls provides a climate for such fruit equal to England with brick walls of the most superior character. Giving up, then, the seedling and climatic theory of deterioration, we turn in other directions in search of the causes of the undoubted fact that French Apricots are far inferior to English. These are probably overcropping, inferior culture, early gathering, and the selection of the best for local or home use. One might suppose that the practice of cutting back the young wood annually to an average of four eyes would prove a sure physical antidote to overcropping, and it might were all or most Apricot fruit produced on the young wood of the previous year. But it is not,

and even this incessant pruning forces the dwarf standard and bush Apricots to become nests of spurs, as anyone may soon prove for himself who grows Apricots under glass in this country and prunes them annually on French lines. Overcropping, while reducing the size of fruit, also lowers its quality. From quality in this sense the very important factor of size is eliminated, though in ordinary cases size alone scores a fair number of points in determination of quality. But the point here and now is that the struggle for food among fruits if too severe lowers the quality as well as lessens the size of the whole, and this may partly account for the lack of colour, as well as flavour, in French Apricots.

As to the culture given, Mons. F. Jamin assures us that the trees thrive without any particular attention. The trees are at their

best at an age of from ten to fifty years. Neither does the soil become at all exhausted. Every year the trees which perish from old age or other causes are replaced by new ones, which always seem to grow in a very satisfactory manner. "In spite of the favourable conditions," Mons. F. Jamin adds, "it cannot be said that the yield of fruit is at all uniform in quantity or quality." There is no mention of mulching, manuring, watering, fruit-thinning when young, or all the rest of what is meant by liberal culture in England. That it is gathered early is proved by Mons. F. Jamin's paper, from which it appears that only superior samples are hand-picked and sold at superior prices. Growers who sell their crops off the trees get lower prices, but, on the other hand, they do not incur the expense of gathering nor of other items which tend to lessen the profits of those who pick and sell their own fruit. Can it be the Apricots are shaken *en masse* off the trees while yet so green as to bear such rough handling with impunity. The toughness and comparative tastelessness of all the Apricots I have eaten in France point to immaturity as the main cause of the lack of quality; and if so, it would surely pay the growers better to allow the climate which ripens Figs perfectly in the open to ripen Apricots into higher quality before gathering. But it seems that the French select their best samples—as the Chinese do their choicest teas—for local or home consumption. To make them good, infinitely better, for home consumption, it would be wise of them to avoid all the deteriorating causes here specified, and there may be others. So much trouble is taken with packing of Apricots in the boxes referred to, and in candying or crystallising Apricots in sugar, that it would pay the growers to have riper and more insouciant fruits to start with. And for jam-making, to say nothing of the addition of Marrows and Golden Gourds, it would be more profitable to grow the sugar in the fruit than to have to add so much cane or Beetroot sugar to preserve unripe or inferior Apricots or any other fruit. D. T. FISH.

Apple Peasgood's Nonsuch.—The fine fruits of this variety recently shown by Mr. J. B. Payne, The Palace, Wells, Mr. Woodward, of Barham Court, and others have called attention to the Apple, and among those who came to see Mr. Payne's fruit when exhibited at the Royal Aquarium was Mr. Peasgood, the raiser. It appears that when at school Mrs. Peasgood had an Apple given her, and she sowed one of the pips in a flower-pot, which in course of time grew and was planted in her father's garden. Some seven years or so afterwards she was married to Mr. Peasgood, and the seedling Apple tree accompanied her to her new home. In its fourteenth year the tree bore fruit, and its fine appearance being noticed it was exhibited by Mr. Peasgood at a flower show in Burghley Park, Stamford, some years ago. It was then sent to one of the meetings of the fruit committee of the Royal Horticultural Society, certificated under the name of Peasgood's Nonsuch, and eventually put into commerce. Mr. Payne reports that the tree in the Palace Gardens, Wells, which bore the fine fruit recently shown in London, occupies a south-west aspect, being grown against a stone wall 16 feet high, at the back of which is a terrace, which keeps the wall cold and damp, and no other kind of fruit has prospered there before. The dimensions of the tree from side to side are 17 feet, and it is 14 feet high, covering some 230 superficial feet. It is dwarf trained, fan-shaped, but the stock upon which the tree was worked is not known. The tree bore a large quantity of fruit in the early part of the year, but they were thinned out to sixty-two, all of which matured, not one weighing less than a

pound, and all beautifully coloured, as the sample shown in London testified. The tree was planted seven years ago, and from 1888 onwards fruit from it has secured for Mr. Payne first prizes at Taunton, Exeter, Bristol, Wells, Street, Weston, &c., and never once a second prize.—R. D.

Our fruit trees and drought.—Frequent mention of the singularly unseasonable flowering of Laburnum and similar trees, with an occasional outbreak of Apples and Pears, serves to show what might have happened to our fruit trees generally where they have specially suffered from the drought had a very heavy rainfall taken place during September. There seems to be now some fear lest the drought should leave the buds in such a starved condition, that they may not be fruitful next season. That so far is only conjecture, whilst had there been a heavy rainfall so as to lead to sudden and strong root excitement this autumn, it is but too probable that in many cases the then almost dormant buds would have been prematurely driven into bloom, and hope of a fruit crop next year would have been destroyed. So long as the buds remain at rest at least there is room for hope, and although we must admit that the early defoliation of the trees has resulted in the production of small or apparently imperfect buds, yet they may swell a good deal presently after rain comes (but all danger from unseasonable expansion is past), or they may not move at all till the spring, when a gradual swelling may precede blooming. In any case, so long as the buds are dormant they leave room for hope. It is very certain that only an abnormal winter's rainfall can compensate for the drought of the long summer. If that does not come, then our fruit trees may have to endure much severer root drought next year than they have had to encounter this season. The soil is now as dry as powder several feet down. There is little or no reserve of moisture, and the ground will require an immense rainfall to make good the deficiency.—A. D.

OUTDOOR PEACHES AND NECTARINES.

THE season, unpropitious as it has been for so many crops, has proved an excellent one for open-air Peaches and Nectarines. This has been proved everywhere, judging from the many autumn shows, where they have been staged in large numbers of excellent quality and fine size. The season, too, has been one of more than ordinary duration. Never before, probably, were Peaches gathered at such an early date as this year, an experience that will no doubt tend to more extended planting on outdoor walls, as well as a fuller measure of attention in the details of pruning, thin training, and timely protection of the blooms in spring. It is a well-known fact that in very many gardens good crops of Peaches and Nectarines can be grown now as well as they could be at any previous period if only due attention is given them at the proper time, but generally they have fallen into bad repute since so many are grown under glass, the seasons also being to some extent unfavourable. However, many will have reason to change their opinions from the experience the present season has taught, and certainly if wood maturity is any gain, the next year's crop should be a good one, if only the blooms are protected from frost and cold winds in some convenient way. Although good crops are the rule—and I have taken note of the Peach crop in several good gardens—I have not seen one of such uniform excellence as that in Lord Justice Lopes' garden at Heywood, Westbury. A lofty wall with a substantial glass coping is furnished with young trees, dwarf and standard trained, in several of the leading sorts, including Royal George, Dymond, Stirling Castle, Walburton Admirable, Violette Hâtive and Princess of Wales, which bore a full crop of extra fine fruit both in point of size, colour and flavour. The

crop was the more remarkable on account of the elevated position of the border, and the fact that no mulching or any protection to the roots was provided. The trees were kept clean and free from red spider by syringing in the evening, and at the present time are in as healthy a condition as could be wished. The trees which furnish this wall have only been planted some eight years, but it might be said they were strong and well furnished at the time. The Peach trees under the care of your correspondent "Practical" I have known for several years, in not one of which can I remember a failure to have occurred. This is attributable to proper care in pruning and training, and also abundant protection in the spring while the trees are in bloom. No glass coping is attached to this wall, a provision so much looked to as the first essential in their successful treatment outdoors in these days, and which is without doubt a very great aid in obtaining a reliable crop; still, this instance goes to prove that with a suitable soil, position, and treatment, walls may be profitably planted with Peach and Nectarine trees outdoors.

I could quote several instances in which these fruits are looked upon as reliable, and are given prominence to accordingly, but I have adduced sufficient in their favour. My experience, however, is that a southern aspect should be chosen for these trees in preference to any other, for while in some soils and situations they can be induced to fruit freely on either a west or an east wall, the greater certainty comes from a warm, sunny aspect, such as a south wall furnishes. On a west wall I have two trees, a Peach and a Nectarine, which, favourable as the season was and though protected, too, in spring, did not produce a single fruit. Although there may be other causes for this failing, it goes to prove somewhat conclusively that the position was unsuited to the requirements of the trees. The wood was not well matured last autumn owing to want of sunshine and perhaps a due thinning of the older as well as late growth, but while this argument may be advanced in this case with some weight, it fails when applied to trees on a southern exposure which had similar treatment and bore a very good crop of highly coloured and full flavoured fruits. An east wall would be better than a west if there is no alternative, because a greater length of sunshine obtains from this aspect than from an opposite one. Unless there is abundance of wall space, I do not consider it wise to plant late sorts, because in ordinary seasons they ripen imperfectly, or perhaps not at all, and when there is plenty of good Pears and late Plums, bad Peaches are not much valued. The earliest sorts are those which should claim the most space, even if there is plenty forthcoming from Peach houses. It is better to have them in quantity at a time when they are abundant indoors than to have a quantity when they are to some extent out of season. In most well-appointed gardens there is not often a glut, even should the outdoor fruits ripen during the same months as those under glass. Princess of Wales, Sea Eagle, Golden Eagle, Teton de Venus, and Lord Palmerston were fruiting with me in an unheated house last October, and so poorly flavoured were they, that all had to be stewed before they were considered fit to eat, and some of them, although earlier, are not much in demand now. Golden Eagle and Lord Palmerston will be destroyed directly their respective crops are gone and their places filled with others of better reputation.

Much may be done towards success during the next and subsequent years by cutting away

the old bearing wood directly the crop is gathered and fixing the shoots remaining thinly over the wall for the sun and air to act perfectly on them to mature and strengthen the dormant buds. If the wood is not ripened properly, there is a danger of the flowers setting badly even if they open well in spring, and a sparse crop thus brought about promotes at once an over-luxuriance, which often demands root-pruning to bring the trees again into a proper state of health and fruitfulness. Trees that annually bear an average crop seldom, or only in extreme cases, require to be root-pruned, because the requisite natural balance is maintained in fruit-bearing.—W. STRUGNELL, *Road Ashton, Trowbridge.*

Now that it is seen that the cultivation of Peaches against walls in the open air can be carried out successfully, there will, no doubt, be a further revival in their culture. This season success will have followed where the foliage has been kept free from insects, the plants duly supplied with water, and also cropped in proportion to the general health of the tree. Seeing a good set of fruit, and which, judging from the reports which have been lately published in THE GARDEN, appears to have been general, is not by any means a sure sign that the finish has also been equally satisfactory. It is sometimes asserted that over-cropping has to be indulged in to meet the heavy demands, and where this has been followed this season, the results, it is hoped, will have proved that this is entirely wrong. The fruits, in addition to being very small, will have ripened up prematurely, and just at the time when they should have been swelling off and finishing up into well-developed examples they will have dropped, or if caught before this has taken place and used for dessert, the flavour would be most insipid. It is through such mistakes as this that open-air Peach-growing has got into such bad repute. Insect pests also appear to have caused great havoc with the foliage in many gardens. Visitors, upon seeing our trees this season, have remarked as to their freedom from red spider, and this I entirely attribute to the frequent washings with a decoction of quassia chips and soft soap the trees received up till about the period of the commencement of the second swelling of the fruit.

Another cause of failure is, I think, in not allowing the trees to carry sufficient foliage. Thin training is all very well, but this can be carried too far. As long as each shoot has sufficient space accorded it, so as to be well exposed to direct light, this is quite sufficient, without having them 10 inches or a foot apart, as some people seem to infer is the better distance. I have noticed that trees which are disbudded down to this distance have not sufficient stamina or growing force to produce a crop of good sized fruit. I do not wish to be misunderstood or that I favour crowded growth, but the two extremes should be guarded against. Trees which have not been disbudded too heavily may now that the fruit is gathered have all shoots not needed for the furnishing of the trees cut clean away, to further assist in perfecting the growth for another season. Whether such trees will require root-lifting wholly or partially will entirely depend upon circumstances. Where the trees are healthy and not producing gross wood, leave them alone, but if unhealthy, with the foliage throughout the season of a decided yellow cast, then partial root-lifting will bring about a more satisfactory state of things. Before any root-lifting is attempted, take particular notice that the soil beforehand is in a well-moistened state, as if the roots are moved with the soil in a dry state the trees will decidedly receive a check.—Y. A. H.

Good Apples.—In the article on Lord Suffield Apple (9th inst.) it is stated that "the reliable free cropping and profitable early dessert Apple is yet to come." This is not alone true of early, but also of late kinds. If we take Cox's Orange as a standard of quality, we find that when gathered (even if look-

ing a heavy crop) the bulk of fruit is not much. This year it is best on the Crab stock. We want tender-fleshed Apples with the cropping qualities of Dutch Mignonne. I have tried Mabbot's Pearmain and Baumann's Reinette, &c., but none come up to the standard required. Lodgemore Nonpareil is one of the best late Apples, equal to Newtown Pippin, but is too small. It is pretty much the same with late baking Apples. Dumelow's Seedling is far ahead as to quality. When cooked it melts perfectly, and the juice turns into clear jelly when cold. The juice in many kinds leaves the solid pulp, and both are almost tasteless. Again, other kinds have a mealy pulp. The next to Dumelow's in quality I should say is Northern Greening. The Codlins are of very good quality, but the juice does not stiffen like that of Dumelow's. We hardly want any more varieties of cooking Apples unless nearly equal to Dumelow's. Dumelow's Seedling has many faults as to crop, unequal sized fruit, &c. The fruit is smooth and waxy, denoting its fine-grained flesh and liability to spot and blight, which results in its never being too abundant.—A. W., *Waterford.*

THE EFFECTS OF THE WEATHER ON DIFFERENT KINDS OF FRUIT.

It is interesting to note the various effects of excessive heat accompanied by the prevalent drought of this phenomenal season on our fruit crops and fruit trees. We may not learn much for future practice from a season which, as regards the weather, comes fortunately only once or so in a lifetime, unless it be an extra lesson on the benefits accruing from certain methods of culture conducive to the successful growth of most plants and trees in any season, such as deep culture (where practicable), free application of fertilisers early in the year, and mulching. The last applies chiefly to Strawberries, fruit trees and bushes, and especially to transplanted trees. Many a tree probably has been saved this season by a mulch put on in February while the soil was saturated with moisture, for even trees carefully planted last autumn have succumbed to the drought where watering or mulching has been neglected.

To commence with Strawberries as the earliest fruit, all the varieties suffered, and were comparative failures except Noble. The crop of Noble was very good, the berries being firmer and of better flavour than usual. Gooseberries could not swell up to a full crop, but ripened prematurely; even the bushes of Whinham's Industry, which suffered the least, were cleared of ripe berries a month earlier than usual. A great number of the bushes are now bare of leaves from the drought, which must have a prejudicial effect on the next crop. Where caterpillars have stripped the bushes there may be a crop next season, but neither early nor large, and that, I fear, will be the experience next spring, from the weakening effects of the drought. In an ordinary autumn a plantation of Whinham's is a beautiful sight, the foliage being of a strikingly rich colour, but nothing of that kind now. There is instead a desolate scene, the few leaves turning yellow as they fall. The moisture-loving Black Currant could not, of course, give us more than a light crop, and the bushes, although throwing out a few fresh leaves, have made little or no growth.

Early Apples, Red Astrachan in particular, had a half cooked taste when gathered, and soon shrivelled up. Worcester Pearmain is of grand colour and the quality extra good. Blenheim and some other winter Apples were gathered in August; Lord Suffield marketed in July, extra fine and a fair crop. A hot season suits Pears; the crops are unusually heavy. We had a fine show of Jargonelle and Pitmaston Duchess on some two-year-old grafts. Gansel's Bergamot on a south wall was gathered in the middle of August; proper season end of October. Knight's Monarch from standards ought to ripen this season; as a rule this Pear is useless. Black Hamburg Grapes on south wall a heavy crop, and, fortunately thinned, are ripening, the

quality being first-rate. Fruit of all kinds never kept worse, Pears especially requiring daily attention. We are now in the seventh month of drought; the pastures are as brown as the road, and, judging from the present appearance of the fruit plantations, the prospects of a full crop of fruit another season are very poor indeed.

Hereford.

E. W. B.

How to make a Strawberry bank.—It sometimes happens that there is an unsightly bank or useless incline facing south which it is desirable should be utilised. If in a convenient position, no crop will be found more profitable than early Strawberries. For this purpose the soil must be fairly good (if naturally poor enrich with well-rotted manure), and the bank, if steep, must be terraced, the soil being kept up with boards or slates. I am utilising for the purpose old tarred fences. If against a wall or very very steep bank the terraces may be 5 inches or even 4 inches wide, with a rise of 6 inches. Make the soil firm as you proceed, and drive in pegs or posts at equal distances to support the boards. Arrangements must be made for covering at night with some light material when the Strawberries are in bloom, or the chances of a crop may be destroyed by frost, and during very severe weather in winter protection of some kind will be advisable. Plant in rows 6 inches apart, a terrace a foot or more in width taking two or more rows. The present is the best time for planting, though February will do if plants are lifted carefully with soil attached. Runners of Noble planted now and well watered in should bear next season. If the situation is quite open and not overshadowed with trees the same plants may remain two years. Tomatoes properly trained to one stem at intervals of 4 feet or 5 feet would probably be no detriment to the Strawberry crop if allowed to run up the bank during the summer months after the Strawberries are gathered. These Tomatoes should be in pots, which induces early fruiting, the pots being inserted in the soil at the foot of the bank. To both Strawberries and Tomatoes when the fruit is swelling, a slight top-dressing of artificial manure, such as kainit and superphosphate or liquid manure, will be beneficial.—E.

ORCHIDS.

MORMODES PARDINUM.

I USED to grow Mormodes, Cynoches, and Catasetums in great quantity between thirty and forty years ago, and I have just received two flowers of the first from "J. M." for names. No. 1, a large flower, pale yellow, and destitute of any marks or spots, is Mormodes pardinum unicolor, and No. 2 is M. pardinum, the typical plant, which is much handsomer, having a dark yellow ground profusely spotted with rich brown. It is nearly sixty years ago since the species was first found in Mexico, and a few years later the variety was found by Ross when collecting Orchids for Mr. Barker, then of Birmingham. The Mormodes are easily managed, but they require somewhat different treatment to the vast majority of Orchids. In the first place they are all deciduous plants, and during the time that they are destitute of leaves they should be kept in a cooler temperature and quite dry. Before this treatment is commenced it should be ascertained that the growths are finished up, and that the plant is quite fit for the rest. In the spring months the plants should be taken in hand, turned out of the old soil, and the dead roots cut away. The pots should be exceptionally well drained, and for soil use good brown peat fibre and light turfy loam, mixing some chopped Sphagnum Moss with it. The bulbs when properly

trimmed should be placed on the soil raised in a little cone-like mound above the pot's rim, and tied to sticks in order to get them to stand until they form fresh roots. Stand them in the very hottest plant house. I have found that a good sunny place in the East Indian house suits them well, taking special care that the plants are not syringed. Shading should be provided for them during the very hottest part of the day. Now begins the most trying time for the plants, for when the roots begin to start they will require a liberal supply of water. Care must be exercised in giving this, so as not to allow it to fall upon the leaves or young growth, because as the spikes come up with the growth and emerge from it when it is about half grown, an accumulation of water settling in it will have a deleterious effect, often rotting the flower-spike in embryo, and perhaps the growth. At the same time a good moist air must be maintained. When the flowering season is passed and the growth is finished, water must be withheld in a great measure and a cooler atmosphere provided. This will tend to ripen the bulbs and to finish them off, so that by the time the leaves begin to fall the bulbs will be thoroughly ripe, when they will stand without shrivelling through the winter months and until the next spring potting. These plants are considered uncertain and unsatisfactory either owing to their treatment whilst growing, or by putting the plants away out of sight before the bulbs have finished up, thus causing them to shrivel. In either case the bulbs will break weak and the growth prove flowerless. If the plants are carefully tended, they will grow vigorously and flower annually. Some of the species are gratefully perfumed. Of these I may mention *M. luxatum*, its variety *eburneum*, and the beautifully coloured *M. Greeni*, whilst *M. pardinum* is remarkable for the medicinal odour which pervades it.

WM. HUGH GOWER.

Cattleya aurea (Cypher's variety).—A beautiful flower comes to me from Mr. Cypher, of the Queen's Road Nursery, Cheltenham, which well deserves a notice. The sepals and petals are of a soft cream colour, the petals having a marginal border of rosy purple. It is a very desirable and chaste variety, which Mr. Cypher tells me he has had about five years.—W. H. G.

Trichopilia marginata.—Flowers of this—the most beautiful of all the genus—come to me from Thomas Prettyman for a name. He says, "This is the second time of flowering this season, but this time it has only two flowers on a stem." It is a very lovely flower, white outside; the sepals and petals reddish crimson in front, bordered with white, into which the colour from the centre runs in an irregular manner; lip rich rosy carmine, changing to deep crimson in the throat and having a white border round the undulated margin. This fine plant has been figured as *crispa marginata* by Warner in "Select Orchidaceous Plants," i., t. 5, but *crispa* would appear to be merely a variety of *coccinea*, from which this plant is very distinct.—W. H. G.

Odontoglossum Uro-Skinneri album.—This appears to be the form sent me by Mr. Osborne from a plant that was raised from seed by him. I remember seeing the seedlings some few years ago before they had made any growth. After that they appeared to have grown rapidly, and many of the plants were sold by Mr. Stevens in his rooms in Covent Garden. One has just flowered with General Berkeley, who says that it is a probable cross between *O. Rossi* and *O. Uro-Skinneri*; but I cannot see the slightest reason to suggest any hybrid origin in it. The plant is exactly like *O. Uro-Skinneri* in its habit of growth, and the flower is in the sepals and petals normal in shape, keeled at the back, clear greenish yellow; lip clawed,

broadly cordate and of the purest white, having two fleshy ridges on the claw; the column winged. The lip is more than 1½ inches long and upwards of 1 inch wide. Is not this the first seedling *Odontoglossum* that has bloomed in this country? The plant that was raised by the Messrs. Veitch was the same as *Miltonia Bleuana*, and the *Odontoglossum* that proved to be a variety of *O. Wilckcanum* was flowered in France; but I think this seedling *Odontoglossum* raised by Mr. Osborne is the first one that has bloomed in this country.—W. H. GOWER.

Cattleya Aclandiae.—A beautiful form of this species is in bloom in the Orchid house at Kew. The flowers are not remarkable for size, but finely marked, the sepals and petals being richly blotched with crimson-purple on a yellow ground, the lip light purple, with deeper veins, and the column of a more intense colour.

GARDEN FLORA.

PLATE 929.

THE SQUILLS.

(WITH A COLOURED PLATE OF *SCILLA TAURICA*.)

AMONGST early spring-flowering bulbs the various species of *Scilla* are among the most important. Year by year they are becoming more

Scilla campanulata in the wild garden.

popular, and large quantities have been planted with a view to naturalising them in woods and parks. The kinds employed for this purpose are the different varieties of *S. bifolia* and *S. sibirica*, and there is no reason why others, such as *amœna* and *hispanica*, should not be used in the same way. *S. maritima* and *peruviana* are not here included, for, though hardy enough in some districts, it is always safest to have specially prepared places for their reception. Most of the kinds just mentioned are easily increased by means of offsets from the parent bulbs, but as in most cases this is a slow process, seed where procurable should be resorted to. *Scillas* are of easy cultivation and succeed well in pots. They delight in a well-drained sandy loam and an open, somewhat sheltered situation; if planted in damp or strong soil, they do not remain healthy. They require to be taken up every two or three years, sepa-

* Drawn for THE GARDEN by H. G. Moon, at Gravetye Manor, March 1, 1893. Lithographed and printed by Guillaume Severeys.

rated, and replanted. The bulbs do not like to be kept long out of the ground; if so, they get dry, and when planted do not thrive and produce good spikes of flower.

S. AMÆNA (the Star Hyacinth).—This is a handsome robust-growing Squill, which as regards outward appearance is simply an exaggerated *sibirica*. When full grown the leaves are about a foot long and pale yellowish green, forming effective tufts, which associate well in the mixed border or on rockeries with those of other plants. The flowers are dark porcelain-blue or violet, rather flat or turban-shaped, and borne on scapes about a foot high. For edging shrubberies this species is well adapted, and as the leaves keep their singular colour for a length of time, it helps to vary the dull green of the shrubs. It flowers in April, and is a native of the Levant.

S. BIFOLIA (the Early Squill).—This, though, perhaps, not so commonly met with as the Siberian Squill, is nevertheless quite as worthy of a place in our gardens. It seldom fails to produce its flowers a full fortnight before those of that species make their appearance, and, indeed, during mild winters and under favourable circumstances its welcome blooms may often be seen breaking the ground soon after midwinter if mild. As to position, that is immaterial, as it seems to succeed equally well in the open and under the shade of trees. One condition, however, is essential to its well-being, and that is, it must be left undisturbed to seed and increase as it likes. Of all the *Scillas*, *bifolia* has been perhaps the most prolific as regards varieties. Most of the other forms known in gardens are, without exception, advances on the type. *S. præcox* is a stronger grower than the common one, and has slightly broader leaves; the flowers, too, are larger and more abundant, and generally produced earlier. In *purpureo cœrulea* the ovary and base of the segments are rosy purple, gradually merging into blue, which becomes intense towards the tips, harmonising well with the black and gold-banded anthers. It is a free flowerer, and the blooms individually are nearly as large as a shilling. In the Taurian variety, *S. b. taurica*, shown in the coloured plate, the flowers are much larger than in *S. bifolia*, and, with the exception of the white base, greatly resemble those of some of the forms of *Chionodoxa Luciliae*. The flowers vary from ten to twenty on each scape, and

Scilla amœna.

the leaves of this fine variety are larger and broader than those of *S. bifolia*, and do not confine themselves to the bifoliate character. The white form of *S. b. taurica* is very scarce. *S. b. alba*, a pretty ivory-white form, has flowers not larger than those of the type, but they are freely produced. Others, many of which are in cultivation, are *candida*, *carnea*, *rosea*, *compacta*, *maxima*, *metallica*, and *pallida*, &c.

SCILLA TAURICA

S. NUTANS (the Wood Hyacinth), also known in gardens as *Hyacinthus non-scriptus*, is too well known to need detailed description, few gardens being without their patch of Bluebells. This is, perhaps, the only Squill in which the flowers are distinctly arranged on one side of the stem, thus giving it that gracefully drooping character which

Scilla nutans.

is so much admired. The common blue form is plentiful in many districts, but neither the rosy nor the white variety is found in any quantity, although both grow with the same freedom as the type. It flowers in May and June.

S. HISPANICA (the Spanish Squill).—This, known in gardens under the name of *S. campanulata*, is a native of Portugal and Spain. It is one of the very finest early summer flowering bulbs we have, and although for market work its white variety is preferred, the old form is still plentiful and likely to hold its own where well established. It is easily distinguished from all others by its distinct, bell-shaped flowers and rather robust habit. The leaves are about a foot long, an inch broad, and sharp pointed; the flower-stalk, which is about a foot in height, bears a profusion of pale blue flowers, but in others they are azure-blue, violet, pink, and pure white, all having more or less recurved edges. It flowers in May and June.

S. ITALICA (the Italian Squill).—This is remarkable for its pretty little rosettes of dark green lanceolate leaves, its pale blue flowers with darker coloured stamens, and the delicious fragrance which they emit early in the day. It rarely exceeds 8 inches or 10 inches in height, and though it will do well in a variety of soils, it seems to thrive best and increase most in a light, sandy loam sheltered from east winds.

S. SIBIRICA (the Siberian Squill).—This well merits the place which it has attained and which it has so long held—that of being foremost amongst dwarf spring-flowering bulbs. The peculiar porcelain-blue of its modest drooping flowers is quite unique at that early season, and mixed with Snowdrops they have a charming effect, while alone in large patches they are very striking. Wherever the soil is light and sandy this bulb may be had in perfection, either in the rock garden, in the flower border, or peeping from amongst the Grass by woodland walks, where it is

most effective. It is not so sportive as its near neighbour, *S. bifolia*; although a few varieties have been obtained, few are distinct enough to merit attention. *S. amœnula*, which comes a fortnight earlier than the type, seems to be the most distinct. The Siberian Squill is used extensively for forcing, which it seems to stand well, and is very ornamental in greenhouses early in the year. After forcing, instead of throwing away the bulbs, as is usually done, they should be planted out, where in the course of a year or two their usual vigour will be restored, when they may again be lifted and forced as before. By having three sets of bulbs, a continual succession for forcing may be kept up without expense.

Amongst Squills not generally found in gardens, but which are hardy enough in dry situations, may be named *S. peruviana*, a large species, with beautiful broad leaves, Yucca-like and very distinct; it stands well in sheltered nooks, or even in the open border in southern districts. The variety *Clusi* also stands well. *S. maritima* is properly a greenhouse species, but in the places indicated for *S. peruviana* it may be grown outside without hurt, though it rarely flowers. *S. lilio-hyacintha* is quite hardy, and well worth a place in the mixed border. *S. hyacinthoides*, *S. pratensis* (amethystina), *S. obtusifolia* (an Algerian species), *autumnalis*, *Aristidis*, *patula* and its various forms, including *cernua* and others, differ little from one another in general characters. D.

The Californian Fuchsia (*Zauschneria californica*).—Several times during this season I have seen this plant in a neighbouring garden, and it has always been very brilliant. No doubt the season has suited it, for it revels in sunshine, but in the place in question it was growing in a very poor clayey soil, and without any special care or attention. For several seasons, favoured with a free, warm, well-drained soil, I endeavoured to grow the plant under conditions where failure seemed impossible, but it grew about 6 inches high, and then the leaves began to turn brown and die back. In a healthy state it grows freely, commencing to bloom quite early, and continuing, as the shoots lengthen, to produce a profusion of brilliant red blossoms through summer and autumn.—A. H.

THE WEEK'S WORK.

ORCHIDS.

THE general operations will be much the same as last month. The shading will scarcely be needed on the *Cattleya* house now, and the other houses will soon do without as well, but I have seen mischief done to the plants by the sun shining out strongly after a few days of hot sunshine, and it is not well to take down the shading until it is seen that it will not really be again needed for the season. Cultivators have to be on the alert to see that sudden frosts do not set in after 10 p.m. Many nights I have stood considering for a quarter of an hour or so whether I should leave the damper in or pull it out an inch or two. This is a matter requiring more thought than many young gardeners care to give to it. There is not a very brilliant display of Orchids in any of the houses; therefore, the few plants that are in flower demand a larger share of our attention. In May we would not think much of the little *Lælias* of the *L. pumila* type, but they are very pretty when we can get them in the *Cattleya* house in the month of September or October. They seem to thrive with

a very small amount of peat and Sphagnum about the roots, and should be placed in teak baskets and suspended near the roof glass. They are often seen in a declining state, but this is owing in a great measure to the want of attention when the plants are growing. At that time they need a good supply of water at the roots, and if they are allowed to become too dry when making growth, the plants are injured thereby. Another thing they do not require is a high temperature, the cool end of the *Cattleya* house is best, or even a light position in the cool house during summer. They must also be kept quite free from insect pests. The white scale gets under the thin outer coating of the pseudo-bulbs and does much damage to them; in fact, this parasite would soon kill the plants if it were allowed to have its way. There are several distinct and pretty varieties in cultivation, some of them superior to the type; but the two most distinctly marked varieties are *Dayana* and *praestans*. *Cattleya marginata*, figured in Paxton's "Magazine of Botany," is merely a form of *L. pumila*. They require similar treatment. At present much less water is needed, although drying off does not suit them; in fact, much mischief is done to all the small-growing *Cattleyas* by inattention to watering. Gardeners cannot always find time to give that constant attention to basket and block plants that they ought to have, and this is very likely the reason why such plants are so unsatisfactory in many collections. As they are usually suspended from the glass roof, they are quite beyond the eye of their owner or the gardener in charge, and may be over-dry for hours and no one be aware of it. The plants on the side stages or in the centre of the house can be seen by anyone walking round the house, and it is very desirable to have a water-pot always within reach, and some rain water standing in pots or pans over the hot-water pipes, so that it may always be rather warmer than the temperature of the house. An Orchid as a general rule will not suffer so soon from want of water as a Cape Heath or some of the hard-wooded New Holland plants, but we do not want them to suffer at all, and for that reason even the most minute details of the work should not suffer neglect.

Heating, ventilating the house, and watering the plants are the three things that will demand the close attention of the cultivator now and for the next six months or more. The plants placed in the cool house for the summer will soon require to

Scilla patula.

be removed to the *Cattleya* house for the winter. This will, of course, depend a little upon the weather for the next few weeks, but it is just as well not to subject them to a low temperature and moist atmosphere; it is not a good preparation for the winter. The pretty little *Miltonia Phalaenopsis* is not so highly valued as it used to be. I have seen two plants sold in Stevens' rooms at 30 guineas each the one after the other. *M. vexill-*

laría is treated the same, and both of them would now be better in the Cattleya house. The *Masdevallias* of the *Chimera* type should also be removed to the same house. These singular plants are very liable to be attacked by red spider, which very often unobserved sucks the very substance out of the leaves, and when it is seen that they are discoloured, the mischief is done and it is too late. When cultivators are made aware of the insect pests that attack certain genera and species of Orchids, they are to blame if no effort is made to destroy the pests in time. Dipping the leaves in a solution of tobacco liquor, allowing it to drain off at the points of the leaves, and afterwards sponging them with clean water, will remove it. Yellow thrips also find a delightful resting-place on the fresh young leaves of these plants. See that they are thoroughly cleansed before being placed in the warmer, drier air of the Cattleya house. The pretty little *Masdevallia tovarensis* also requires the same treatment, that is, removal from the cool to the Cattleya house. As to insect pests, I do not remember ever to have seen any upon the leaves of this plant. I think it well to warn growers that in dipping or washing Orchids of any kind for the destruction of insect pests it is necessary to be careful that none of the mixture gets to the roots; the plants should be held over the mixture for half a minute, and then be laid on their sides to drain. I need not say that a little more care will now be necessary in order that no draughts of cold air blow directly upon the plants, and whenever the east winds are keen and cold, open the ventilators on the opposite side of the house. The cool house may stand without fire-heat at a minimum of 50° to 55°, the Cattleya house 60° to 65°, East India house 65° to 70°.

J. DOUGLAS.

HARDY FRUITS.

GATHERING PEARS.—Those who have treated all their varieties alike, that is to say, have gathered them all at much the same time, have in many cases erred greatly. Not only do Pears mature at different times, some, not necessarily non-keeping varieties, being fit to gather much sooner than others, but the same varieties growing under different conditions vary considerably in their time of ripening. Curiously enough, Marie Louise, Louise Bonne of Jersey, Autumn Bergamot, Winter Nelis, Beurré Diel, and a few others against walls facing north-east were ready to gather fully a fortnight earlier than the same varieties against south-west walls. Since gathering and storing of other October and November Pears commenced, Doyenné du Comice has swollen considerably, and so also have Glou Morceau, Ne Plus Meuris, and Josephine de Malines. There ought then to be no wholesale clearance of the trees, the fruit on each being well tested by lifting out of the perpendicular before gathering it. If the Pears part freely from the tree, the time has arrived for gathering and storing, while if the crop is heavy and the variety known to be a bad keeper, a portion of the fruit may well be gathered when the pips are only changing colour, and the rest when they are just brown, a longer succession of ripe fruit being thereby ensured. In some cases the change is rapid, and that is why the advice to test the fruit often is given, in order that no good fruit be lost by dropping. Those already stored ought to be very frequently looked over, as any damaged, however slightly, decay rapidly, spoiling other sound fruit they come into contact with.

RENOVATING PEAR TREES.—Very many large old trees do not pay for the valuable space they occupy. In some instances the varieties are worthless; in others they are worth preserving if only the trees could be made to produce presentable fruit. Supposing they are in fairly good health, regrafting inferior varieties with superior sorts is the quickest and best way out of the difficulty, the principal branches being headed back this winter and regrafted next spring. Where, however, there are large or, it may be, grand old horizontally-

trained or fan-shaped trees of, say, Marie Louise, Beurré Diel, Easter Beurré, Brown Beurré, Beurré Rance, Glou Morceau, Louise Bonne of Jersey, and such like against walls of any kind, and which of late years have failed to produce good fruit, steps should be taken to gradually restore these to a more profitable state. Much may be done in that direction by sawing off the old spurs piecemeal, their place being taken by short new ones, but the roots must also be taken in hand if the renovation is to be a complete success. In some cases the sole cause of the failure is a too deep root-action, the bulk of the roots being deep down in a clayey subsoil. After the buds are fully formed and just before the leaves change colour is a good time to commence restoring the roots and the border to a more satisfactory state, and this good work should be gone about in no half-hearted manner. At the same time it is easy to err in an opposite direction—doing too much at one time. If a large old tree is completely cut round and undermined, this may cause the leaves to flag badly, very feeble growth resulting in the next and following years; whereas, if only half the roots are done this autumn and the other half next year, no risks will be run and the remedy prove all that is expected of it. Commence by cutting a deep wide trench from the wall round to the front of the trees and about 6 feet from the stem. Novices and indifferent labourers are, as a rule, averse to opening a deep trench at the outset; but it is a saving of labour in the end, as it much simplifies the operation of well undermining the tree. Forks only should be used for undermining and separating the soil from the roots, this being persevered with till it is possible to reach and cut through any deep-running roots there may be directly under the stem of the tree. Many, or perhaps the majority of the strong roots found will be large, or 4 inches more or less in circumference. These should be unhesitatingly sawn through and the reserved portion brought up nearer the surface than heretofore. All the smaller roots should be also pruned and be relaid thinly in fairly rich loamy compost. What Pears, and indeed all other fruit trees, like is plenty of fresh fibrous loam, a very little well decayed manure, road trimmings, burn-bake, wood ashes, mortar rubbish and ground bones being added. In any case fresh compost, in which the extras enumerated figure, should be substituted for the stale soil, or it is not many fresh active roots that will form either this autumn or next season, the trees suffering badly, instead of being renovated, accordingly. Make the fresh soil firm, raising it well above the ordinary level if this can be done without unduly burying the stems, and the other half being similarly treated next year, a good and lasting improvement will be effected. Should this severe root-pruning cause the leaves to flag badly, resort to overhead syringing very frequently. Large old trees in the open may be similarly treated, only one half of the roots, however, being touched this autumn. When the mistake of undermining and cutting through the whole of the large roots at one time has been made, many years elapsed before the trees have recovered from the severe check given, some never being wholly restored to good health.

YOUNG PEAR TREES.—Many of these are still in a growing state, having restarted since the rains fell. Under these circumstances wholly lifting should be deferred for a time longer, though there is nothing to prevent a start being made when it is intended to only partially lift and root prune.

APPLES.—It is not often that pains are taken to restore large old trees of these to a more profitable state, but in some instances they would pay well for it. Especially ought large trees of Blenheim Orange to be taken good care of, as it is these, when in a fairly healthy state, which produce the bulk of the fruit grown of this excellent variety. Proceed on the same lines as advised in the case of Pear trees, only if the trees are very large no attempt should be made to get nearer than 4 feet from the stems. Young trees should be let alone till the wood is thoroughly hard and the leaves on the point of changing colour.

THE WINTER MOTH.—Where Apple, Pear, and Plum trees are liable to be attacked by the caterpillars of this moth, preventive measures ought to commence at once. The females, being unable to fly, commence to ascend the stems late in September or early in October with a view to depositing their eggs in the crevices of the bark all over the trees, this going on till near midwinter. Greased bands placed round the stems 1 foot or rather more from the ground check their progress and catch them wholesale. Greasing the naked stems will not do, as this has proved most injurious to the tree. What is wanted is strips of oiled or waterproof paper 6 inches wide, on these being spread to rather less than the whole width, a mixture of equal parts of cart grease and Stockholm tar, this being laid on rather thickly. The band should be made to completely surround the stems, and ought to be examined occasionally and the grease renewed whenever it is found dry.

W. IGGULDEN.

THE KITCHEN GARDEN.

ENDIVE.—In very many instances, on account of the dry weather, Endive is not in such a forward condition as in moister seasons, and if we could depend upon frosts keeping off, the plants would certainly be the better for being left undisturbed for a week or two longer. Unfortunately, frosts are likely to be very early this season, as we have already had some, but not sufficiently severe to do any damage. In the case of frost, some protection should be given by placing a light framework over the plants as a support to mats or oiled canvas. If the weather should remain open, the lifting of the forwardest plants might be deferred a week or two longer, of course affording adequate protection to these also in case of frost. The state of the weather in all cases should be the guide when to lift.

SUITABLE PLACES FOR STORING.—Damp is the greatest enemy to Endive, as once let the plants become affected, they very quickly rot off. The most suitable places for storing are high and dry frames, the floors of airy vineries or Peach houses where the plants can be freely exposed to light, or light and dry sheds. This last position might well be afforded to plants for earliest use, reserving the lighter and airy positions for the later plants. If sufficient rain has not fallen to well moisten the soil about the roots, it is advisable even at this late date to give a thorough watering, so that the plants can be lifted with a fair-sized ball of soil. The plants must be lifted with the foliage in a dry state. In the case of large plants, it would be better before taking them up to draw each up carefully together with the hands and tie with a piece of matting, cutting it away after they are placed in position. The plants must not be placed too closely together.

BLANCHING ENDIVE.—A portion of the forwardest may also be blanched as required where they are growing, by covering closely with clean flower-pots with the holes stopped up to exclude light, clean boards, slates or tiles. To further exclude light from these, the soil may be drawn up as a ridge along each side, or the whole may be covered with a mat. It is not wise to cover too many at one time, although in the case of plants blanched in the open where growing, decay does not set in so quickly as later on in the season. A dozen plants covered at weekly intervals are sufficient for an ordinary family.

LETTUCE.—Too much care cannot well be taken of Lettuce, especially in a season like the present, when in many gardens the supply up till now has been very short; in fact, in many instances the best Lettuces obtainable throughout the season are those which are turning in now. If the weather should remain fine and open, these, like Endive, might well be left undisturbed for a week or two longer, but if not, some, to guard against any emergency, must be lifted carefully with a ball and planted in frames, as during some seasons those which are left over in the open remain good for some time. In the case of the Cos varieties, before

lifting, each should be drawn up carefully and tied with a piece of matting, as on account of the brittle state of the leaves these would soon fall out and be broken. On all fine and dry days the lights should be drawn off, but they should be kept covered in case of rain. As the plants are bedded in the frame, a watering will assist in settling the soil.

WINTER LETTUCE.—Those plants which were planted with the intention of their forming the main winter supply must also now receive attention. The plants which were pricked out as I have previously advised in former calendars, so that they may be protected where grown, will be found to winter much the best, and the time has now arrived for the frames being placed over them, the lights being kept off on all fine days. If frames are not available then erect a temporary framework over them, as with a covering of mats or oiled canvas the Lettuce may be had in good condition as long as frost can be kept from them. If so desired the plants may also be lifted with a fair sized ball and planted in frames, taking care to water them in. The latest batch for late winter use will now be ready for pricking out into frames. The plants must be well elevated up to the light, and in the case of deep frames fill up with some open material before putting in the soil. A. YOUNG.

PLANT HOUSES.

STOVES.—**PLANT CLEANING.**—With abundance of other work it is just possible that plant cleaning has got somewhat behindhand. If this be so, the earliest possible attention should be turned to it now, otherwise as fire-heat increases insects will increase also and cause a lot of trouble. Fire-heat seems congenial to all the insects with which our plants are infested, in stoves more particularly than in other houses. For this purpose, the usual methods should be adopted which have in the past proved to be efficacious. At this season, however, I would recommend an extended use of the sponge amongst fine-foliaged plants; even if there be but a few insects the sponging of the foliage will do good in cleansing it of any dust and dirt that may have accumulated during the past few weeks, and that unavoidably. Every effort in particular should be directed against the mealy bug, also the various kinds of scale, and in order to reduce these to a minimum no labour should be spared or be considered as labour for naught. Between now and the turn of days it is possible to reduce these insects so as to be but little trouble afterwards if constant attention be given. Once well under hand the process of extermination in the case of the mealy bug is only a question of time. For this purpose I find nothing to surpass the Chelsea blight composition. I have written to this effect before, but it will bear repeating for the information of those who may not have given it a trial. When dealing with *Ixoras*, *Gardenias* and other shrubby or climbing evergreens a ready method is to provide a large shallow trough of zinc with a hole at one end or corner to allow the insecticide to drain away into a pail to be used over and over again. Our trough for this purpose measured about 6 feet by 4 feet and 4 inches deep, the expense of making being soon covered by the less amount of labour and liquid required to do the work effectively. Syringing is much more penetrating than dipping for all bad cases. Prior to using any insecticide, I would first syringe with hot water; as long as this is not uncomfortable to the hands it will not harm the plants, save in the case of the tenderest foliage. The hot water paves the way for a more effectual use of the insecticide, as well as being a cleansing medium itself. After all the work of a thorough cleaning has been accomplished amongst the plants, not forgetting the roof climbers, the house itself will without doubt be all the better for the same kind of attention. From now onwards we shall not receive any more light than is beneficial to plant life. The scum which has accumulated on the glass will go on increasing if not stopped in this way, and on the paint also.

TEMPERATURES, &c.—I never consider it advisable to drop the temperatures either by night or day too very early in the autumn. Up to within the past two or three weeks we have been experiencing unusually hot weather; a change now to the opposite would arrest growth too rapidly and be conducive to damping off amongst both flowers and foliage. What should be done is to slightly lessen the atmospheric moisture. This will be conducive to the ripening of woody growth and the hardening of that now being made in other instances, thus preparing the plants for the more unfavourable winter season to which we must now be looking forward. At the first, less moisture at night should be the rule. This can be managed without any harm to the plants, as the time has not yet arrived when severe firing is needed to maintain the desirable temperatures. The syringe should still be used freely at least once a day amongst plants that will stand it, as in the case of evergreens. The temperature at night should still rule in the average stove near about 70°, or at least 68°, and this will do for at least a month to come. In the daytime 80° to 85° will not be any too much, but a little air may with advantage be admitted now where in more growing periods none at all would be given.

There should also be a little more care exercised in the watering; plants which have hitherto taken water freely will not require so much if less growth is being made. To over-water now will put the soil into a bad condition for the rest of the autumn and winter. Some plants will be exceptions to this rule of less water, as in the case of pot-bound Palms, which must never be allowed to suffer, nor should evergreen Ferns in the same state at the roots. On the other hand, for such plants as *Clerodendron Balfourianum* and other deciduous climbers, as well as plants of perennial or herbaceous growth, as *Caladiums*, *Gloxinias*, &c., less water will be decidedly beneficial, for the sooner all of these can be got into closer compass the better for other plants that must have more room given them. In hardly any case will manurial stimulants be now needed, save in the case of the Palms alluded to and plants coming on for winter flowering, or pot-bound table and other small decorative plants. Pertaining to the watering is the condition of the water tanks; these at times are allowed to go longer without a thorough cleaning out than is desirable for the health of the plants. Large reserve tanks will probably still be low, and advantage should be taken of this to get the work done before heavy rains fall.

Blinds will not now be required, except in particular cases, as on propagating houses. The more light the plants can now have the better will it be for them. For my own part I never care to use blinds after the middle of September. An early opportunity should now be taken of getting the blinds thoroughly dried before unfixing them and putting them away for the winter. The only exception I would make to this is where the blinds are run down at night to save firing. Do not, however, let this be an excuse to use them in the daytime. Blind boxes to keep the blinds dry should be the rule in such cases, otherwise they will get rotten all too soon. Old blinds should at once be taken off the rollers and be kept by themselves for sundry purposes another year. New ones can then take their place in good time for use again.

JAMES HUDSON.

The Belladonna Lily, according to all accounts, seems to be flowering unusually well this year. The warm summer has evidently suited it and has awakened Mr. Miles' bulbs at Almondsbury. In my uncle's garden at Sutton House, Clifton Downs, where I am now staying, this Lily has flowered most profusely; the bulbs are in a border under the wall of a stove. They were planted some fifteen years ago and have never failed to flower, but this year they have surpassed themselves, and have borne 110 spikes, each carrying from five to nine blossoms. The bulbs were originally planted close to the wall. They have never been disturbed, have increased

in numbers, and are now spreading all over the narrow border. I believe some persons have much difficulty in flowering this Lily, but if it is planted in a sunny situation under a wall and left undisturbed, it is almost sure to do well and to give satisfaction. A mass of these bulbs in full flower is a charming sight, the delicate shape and colour of the blossoms contrasting so well with their long, dark, purplish-brown stems. Like all other flowers this year, the *Belladonna Lilies* are unusually early.—G. S. S.

KITCHEN GARDEN.

VEGETABLES ON HEAVY SOILS.

THIS season those who are in charge of gardens the soil of which is naturally heavy and retentive have had decidedly the best of it. In most cases where the subsoil is of a clayey nature drought can easily be defied, warmth rather than much rain being what is most needed. Hereabouts the soil varies surprisingly. A hundred yards from where I am located the subsoil is of a very gravelly or brashy character, but none of this is come across in the garden under my charge, a great depth of solid clay taking its place. During dull, wet summers I have frequently wished that we were on this higher ground, but this summer has effectually dispelled any lingering regrets there may have been, and once for all I say give me the clay. For months past and up to the present time it is possible to tell to a foot where the gravel ends and the clay commences, all vegetation on the former being literally burnt up, while that on the clayey ground is in a most satisfactory condition. Lighter soils resting on gravel or stones, in addition to being the first to suffer from drought, are equally non-retentive of fertility, and nothing short of increasing the depth by means of liberal dressings of marl or clay will effectually correct this state of affairs. It is, however, of heavy and not light soils that I am thinking and writing, and in particular of the state of the crops that have been borne or are being supported by them this season. If only the requisite amount of warmth can be transmitted to heavy soils it is astonishing what good crops they are capable of producing. According to my experience, many of us err or have erred in being over-zealous in changing the character of clayey ground. A wholesale removal of clay and the substitution of very light materials of different kinds may have answered well in some cases, but it is so much time and labour wasted in others. Bastard trenching, taking care to bring little or none of the clayey subsoil to the surface, abundance of strawy manure, vegetable refuse, and such like being forked into the bottom spit, is a step in the right direction, especially if the rainfall happen to be light during the winter, or not enough to badly saturate the ground, while ordinary trenching or the complete reversal of the spits is about the worst thing that can be done. A repetition of bastard trenching every third or fourth year gradually breaks up the clay and distributes it throughout the bulk, and we then have one of the most fertile soils imaginable. In my case there is not labour enough available for trenching beyond what varying the sites of the Celery trenches will do. It is my especial care not to interfere with our heavy soil at unseasonable times, and more particularly in wet weather. Laying as much as possible of it up roughly to the action of frosts, or else drying winds, sunshine and rain, results in its being well pulverised before

cropping is attempted, the avoidance of either very rotten manure and any obtained from cow-yards also being important points. When the surface soil, say to the full depth of a spade, can be got into a free working condition, a moderate amount of either horse manure or chemical manures, or the two together, in clayey soils will grow almost any kind of vegetables during most seasons. If they fail at all it is during a very wet season, and not during such as those experienced in 1887 and the present year. Could we be certain beforehand what kind of weather to expect there need never be a failure. For instance, if the old-fashioned plan of growing a variety of crops on raised beds be followed, the requisite amount of warmth would reach the roots during the dullest summers; and so well do some kinds of vegetables succeed on beds, say, not more than 5 feet wide, and only raised to the extent of what may be thrown on to them from the alleys, that I should always form these largely if in charge of a clayey garden in a low-lying cold position. So retentive of moisture and fertility are these heavy soils, that it is an easy matter to make them too rich, grossness in vegetables generally being the order of the day.

The spring and summer of 1893 have suited our garden admirably. There has been one, and only one, noteworthy failure, and that, unfortunately, was the main-crop and late Peas. These failed, not owing to anything being wrong at the roots, but rather because they cannot stand a tropical heat, the complaint of poor crops being general. Runner Beans, on the other hand, thrived admirably, though the flowers set none too well during the early part of the season. The spring-sown Onions, that failed so badly in very many instances, were the best I have ever seen. The seed was sown very early in March and germinated before the drought set in. The roots also matured early, and have been long since harvested and stored. Other root crops are quite good enough, while Potatoes have been lifted at the rate of one sack to the rod. The more moisture-loving Globe Artichokes have held out surprisingly well, good succulent heads being very plentiful at the present time.

Winter vegetables are stronger and better than I have seen them for a long time past. Brussels Sprouts 30 inches apart in rows 3 feet apart touch each other all round, the stems being extra stout and the sprouts abundant. Borecole of sorts is equally strong, and early Broccoli, as well as autumn Cauliflowers, are coarser than I care to see them. I am always afraid of growing Broccoli too strong, but, as a rule, they do not start away well when put out in close succession to Peas and Strawberries and without digging. This season, thanks to the extra warmth, they have done well and should stand through an ordinarily severe winter. Savoys and Chou de Burghley have grown too well and are earlier than I care to see them, and nothing could well present a more promising appearance than the breadth of Coleworts I have put out this season. Lettuces are as plentiful and good as during any part of the year, and there will be abundance in the open till severe frosts intervene. GROWER.

Two crops of Peas.—The following account of two crops of Peas (Chelsea Gem) grown in the garden here this season may not be without interest to your readers, and could only have happened in a season like the present. The first sowing was on February 10. They were raised in pots and planted out on March 18. They were fit for use on May 27, and the seed was gathered at the end of June. The second sowing took place on

July 14. The crop was ripe in the first week of September, and has only just been finished.—GRANVILLE LEVESON-GOWER, *Titsey Place, Limpsfield.*

Winter greens.—"A. D.'s" article on winter greens (p. 263) is evidence of the variableness this season of the state of the crops in widely separated districts. I recently inspected the crops of winter greens, and I never saw them in a more satisfactory state, the growth being both clean and vigorous. The soil being of a strong and holding nature is no doubt the cause of this, although good plants were put out, and this just after a heavy storm or two. Where plants have had to be rather heavily watered, the surrounding soil about the stems becomes baked and extremely hard, unless the precaution is taken after the plants become established to well stir it with the hoe. After the ground has been loosened, the plants start away at once, and are in marked contrast to others which have the roots bound up in hard soil. Where the plants are not making satisfactory growth, I should not hesitate even at this comparatively late date to stir the soil about the stems. Brussels Sprouts are making very satisfactory progress, although planted on unmanured ground.—A. Y.

Rapid growth of Peas.—When the ground is warm and moist, Peas, like most other vegetables, grow very rapidly. Often we hear of growers obtaining a crop in from ten to twelve weeks from the time of sowing, but it is not often one can obtain Peas with full pods in eight weeks from the time of sowing the seed. This year I resolved to try Chelsea Gem for autumn gathering. Accordingly I sowed three quarts of seed on June 24. The pods were ready for gathering on August 24, just eight weeks from sowing. It was not a question of gathering a few pods, but I gathered more than two pecks. From the weather being so hot and dry the plants only attained about 12 inches in height, and although the crop was not a large one, I found it came in very useful, and I intend trying this variety another year for autumn use. In this garden no late-sown Peas were a success, and the crop will be over very early.—J. C. CROOK, *Forde Abbey.*

Late sown Radishes.—In many places there is a demand for late Radishes for garnishing, &c. Every year I sow about the second week in September in a sheltered spot. The seed soon comes up. As the days shorten the plants grow more slowly, and what with more moisture and a colder air I get some most useful Radishes, and keep up a supply to well-nigh Christmas.—DORSET.

Cauliflower Midsummer-day.—I am surprised not to have seen any mention of this new Cauliflower in the pages of THE GARDEN, as undoubtedly it is a valuable kind. I saw in the gardens of Cotelstone House, Taunton, in the middle of last June large and perfect heads of the sort mentioned that were the produce of seed sown in the February previous. Of course, the plants were raised and brought on in heat and otherwise carefully treated. I am well acquainted with such sorts as Early Erfurt and Snowball, but Midsummer-day is quite distinct from them; the plants have no stems, so to speak, as the lower leaves almost touch the ground, and what surprises me as much as anything was the large size of the heads these apparently legless plants produced.—J. C. CLARKE.

Mildew on Onions.—It is astonishing to note the effect of mildew on our Onion crop in the generality of seasons. During the five years I have had charge of this garden I have never been able to secure a good crop of Onions till this year. In previous seasons, just as the bulbs began to form the mildew attacked them, and quickly arrested the growth. It is curious to notice this year how badly the Peas were affected with mildew, and although the Onions were growing beside them, it never affected these, and now we are harvesting a grand crop of good useful bulbs. I believe this fine, dry season is the reason for our having such a fine crop. The method of culture is just the same as in previous years. Some three

years ago I tried what effect sulphur would have on the mildew. One morning when the dew was on the leaves, I dusted them over with sulphur thickly. But this had not the least effect on them. I have come to the conclusion that it is a mistake to get Onions to make large, coarse leafage, as this encourages mildew.—J. C., *Forde Abbey.*

BRUSSELS SPROUTS.

THE past summer has been very unfavourable for the growth of these in all the southern counties. The soil having become so dry through the abnormally low rainfall in spring, it was with much difficulty that plants were able to make a start after being planted. However, where the land was in good heart and the plants were got out early, the few slight showers that fell in some places towards the end of May did much to establish them in their new quarters.

The plan I practise is as follows: The seed is sown thinly in shallow drills about 6 inches apart on a warm border at the beginning of April. I never make more than the one sowing. Should the weather be dry, as was the case this season, the ground is well watered and afterwards covered with mats to prevent it drying so quickly. When the young seedlings are bursting through the soil the shading is taken off and the ground dusted over with newly slaked lime; this has the effect of keeping off both birds and snails, and is also a preventive against the attacks of the Turnip fly. Growth is encouraged as much as possible by frequent waterings with weak liquid manure. This also encourages the plants to make fibrous roots near the surface, and as they are standing thinly in the seed bed they grow strongly. The ground on which it is intended to grow Brussels Sprouts should have a liberal dressing of manure in the autumn, then be deeply dug, leaving it rough till spring. It should then have a slight dressing of sulphate of potash forked into it, breaking the soil up fine as the work is done. Drills are then drawn 3 feet apart and 6 inches deep, along which the plants are put out when they are large enough, which is generally about the first week in June. The object of planting in drills is twofold, one being that the water does not run away from the plants when watering is done, the other that when the soil is levelled down it strengthens the plants and keeps them in an upright position. Before making the ground level, a dressing of soot is given along the drills, and when in full growth nitrate of soda at the rate of 2 lbs. to the square perch is sprinkled between the rows to be washed in by the rains. A second batch is planted about three weeks after the first, and these give a supply till quite late in the spring. In some places plants are raised on hot beds early in the season. This is good practice where an early supply is required for exhibition, but unless the plants can be put out at the proper time they do not make satisfactory progress. I have no difficulty here in getting good sprouts by the end of September, which is as early as they are usually called for, there being plenty of Peas, French Beans and such like green vegetables up till that time. Sprouts treated in the above manner will not fail to give satisfaction even in the worst of seasons.

H. C. P.

COARSE VEGETABLES.

"FRUIT GROWER'S" outcry in a late issue of THE GARDEN against the favour which some judges at fruit exhibitions bestow upon coarse fruit might well be extended to vegetables, as with these also large size would appear to be the ideal of perfection. It is only of late years that this inordinate size has been encouraged amongst certain classes of vegetables. This selection of coarse vegetables certainly affects but very little, if any, that greater body of cultivators who are not exhibitors, but there are certainly others who look to these exhibitions to show them what should be the ideal of perfection. One certainly does not begrudge the

recipients of the prizes their hard-earned honours, for they alone are not to blame. They know very well if size is needed to take the prizes, then this must be obtained.

The size of the Cauliflowers which are encouraged is simply enormous, and it is well known that when cooked they are almost uneatable, the flavour being so strong. Now if these huge Cauliflowers are not worth cooking, what is the use of growing them, or rather encouraging their cultivation by awarding them the best prizes at exhibitions? Like coarse Grapes, there is not the skill needed to produce them as in the case of the smaller and better quality varieties. This season, as vegetable growers know, is not a good one for Cauliflowers, at least for the smaller and better flavoured, but taking the generality of seasons, there is not a better quality variety for late summer use than the Walcheren. I daresay if well-grown Walcheren was placed in competition with others of large size it would hardly be looked at, let alone awarded a prize. I do not wish in the least to write disparagingly of Autumn Giant and other selections, as when grown not too large they are most useful and a good help to the gardener who has a vegetable supply to maintain, but I know which are the most appreciated when served up on the dining-table. These very large autumn Cauliflowers are the result of sowing in the autumn, wintering the young plants in frames and planting out at the first opportunity in the spring. It is also possible to get what is termed the early spring plants to a prodigious size by keeping them fed up with liquid manure, but I need scarcely add that this increase of size is at the expense of quality. Collections of vegetables would not have their merits lowered in the least by substituting Cauliflowers of the "old" type for others of huge dimensions.

Celery is another vegetable which is very often seen so large that the texture is positively coarse; in fact, the growers of it would hardly dare to send it to table. When such very large vegetables as these are encouraged, other kinds also have to be forced larger than they otherwise need be, so as to make the collection more even. This possibly may be the reason why there also appears to be a tendency to increase the size of Potatoes also for exhibition. This is a vegetable where size does not count even for market, and, as is well known, large Potatoes never find favour on the dining-table. It is only the medium-sized and shapely roots that should be encouraged, these being much the best in quality.

The fact that market growers have found out that the general public are much against large Tomatoes, and prefer those which run about four to the lb., shows an improvement in the public taste.

A. Y. A.

Prevention of the Onion fly.—Mr. Young (p. 225), in his article on the above, states "generally the plot intended for the Onions is that which was previously occupied with Cabbage or some of the Brassica family. Very likely it will have the refuse of the previous crop left on it for the purpose of being dug in . . . amongst such refuse the pupæ are apt to harbour." An old Cabbage bed would be the last place in which one would expect to find the pupæ of the Onion fly, and I was not aware that they had a relish for Cabbage roots. If it is admitted that the Onion fly hibernates in our Cabbage plots, there is no reason that it should not be present in every part of the garden. Why, then, should so much labour be recommended in forking, trenching, and applying gas lime, wood ashes, fresh slaked lime, salt, soot, petroleum, and quassia to this particular spot, whilst the ground surrounding it may be swarming? Neither of them will have the slightest effect on the Onion grub, and they may as well be put in any other part of the garden as in the intended Onion plot for what use they will be in preventing the Onion fly, as to my knowledge they have proved an absolute failure. I have enveloped the grub in fresh slaked lime and soot, and it has quickly wriggled itself out of it. Petroleum is admitted to be the

deadliest of all insecticides, but you may place the Onion grub on a flagstone, pour paraffin upon it, and it will readily glide out of it.—W. P. R., *Preston*.

TREES AND SHRUBS.

RHODODENDRON GLOXINIFLORUM.

THE charming Rhododendron which forms the subject of the annexed illustration was introduced by the late Mr. Robert Veitch, of Exeter, some thirty years ago, but is still almost unknown. The original plant was sold, and is now growing in the gardens at Whiteway, Chudleigh (Devon). A number of small plants may also be seen at the Royal Nurseries, Exeter, where Messrs. Veitch grow it in their ordinary Rhododendron beds without any protection whatever. It is of the Sikkim type, but as a plant much hardier than other kinds of that class, though in consequence of its early blooming habit the flowers are sometimes cut by cold winds in early spring.

Rhododendron gloxiniflorum at Whiteway, Chudleigh, Devon. Engraved for THE GARDEN from a photograph sent by Messrs. R. Veitch and Son, Exeter.

The plant at Whiteway House from which the photograph was obtained is about 9½ feet high, and measures 10 feet in diameter; it has been planted between twenty and thirty years, and is growing side by side with Rhododendron campylocarpum in an open spot sheltered only from the south and west. Mr. Nauscawen (head gardener to the Dowager Countess of Morley, Whiteway) informs me that *R. gloxiniflorum* never fails to bloom about the end of March or beginning of April, and that the flowers are so abundantly produced that its sheet of blossoms has often been mistaken for a mass of snow. The soil consists of peat and loam in about equal proportions. The flowers are in compact trusses, very large, Gloxinia-shaped, and pure white, with a few black spots in the centre. It is a most desirable variety, and should be in every garden. F. W. M.

The plumed Hydrangea.—There is evidently a bad form of this in existence which it is to be hoped will not become common. We have a group of several plants which had been neglected and had become quite large bushes. This spring they

were cut down to the ground, and they broke so strongly that a vigorous bloom was anticipated. There are fine heads, but of fertile or little inconspicuous flowers, with here and there one of the broad, flat-petalled kind that should crowd the whole cyme. It is poor and disappointing.

Leycesteria formosa.—I can quite bear out all that "T." says in favour of this flowering shrub, for at the present time it is one of the most noteworthy subjects which we have in the pleasure grounds. The secret of success certainly lies in its having free exposure, so that the wood becomes fully ripened. I find that it is not over particular as to the kind of soil it will thrive in, as we have several specimens growing in nothing better than solid clay intermixed with stones. The long bunches of purple or claret-coloured berries which follow quickly on the flowering really enhance its ornamental qualities. We have scores of plants springing up in various positions, and which must owe their origin to the deposit from birds, which later on become very partial to the berries. It is recommended as a capital covert plant on account of the berries, of which pheasants are extremely fond.—A. Y.

The Water Elder in fruit.—From mid-summer to mid-winter this shrub is delightful, and many are the questions put to me concerning it. It is possible to see its relationship with the Snowball Tree of our gardens when it is in flower, but all through the latter part of summer, and, in fact, right into the winter, as a berry-bearing shrub it has few equals, and all who see it are struck with its beauty and astonished when informed that it is a native shrub. Bushes by the waterside, as well as those in the woods, are quite laden with clusters of rich red berries which glow and glisten in the sun. It richly deserves bringing to the front, and it would be well if the shrub nurserymen would make it a stock plant, giving it preference to the abnormal globose-bloomed form that has no merit when out of bloom. It is not very long since an English nurseryman of great repute among shrubs was asked to supply a hundred plants of this. He was unable to do it, nor knew where to get such a number in a state fit to supply. Although tolerably common in woods in some districts, this does not minimise its value. In any case, most of those who see it laden with berries by the lakeside go away resolved to obtain and plant it in their gardens. This is the best possible testimony of its beauty and worth.—A. H.

ROSE GARDEN.

TEA ROSES IN POTS.

THE illustration of Niphotos and charming article on Tea Roses in pots (p. 209) are welcome. From personal experience and observation I do not remember a single planted-out Rose house to have turned out quite satisfactory. I have seen a goodly number more or less so, some of them of very considerable area, tastefully designed and most elaborately furnished with arches, trellises, pillars, &c. Several of them have also yielded fairly good crops of Roses, but with the exception of a few that have been mostly furnished with one or a few varieties, such as *Maréchal Niel*, *Niphotos*, *Gloire de Dijon*, *Catherine Mermet*, &c., the results have mostly been more or less marred through the partial failure of one or more of the many sorts with which the Rose houses or corridors may have been furnished. Unfortunately, there can be no question but that such pests as mildew and red spider are infectious. Let one or more permanent plants under glass be affected, and these maladies spread with amazing rapidity. It is all very well to answer that sulphur is a sure and certain cure for both. But Roses defiled with sulphur

are already three-quarters ruined or more. Fortunately, red-rust does not affect Roses under glass. How is this? And yet all three of these worst of Rose pests are atmospheric. But grow our earliest winter Roses at least in pots, and then the moment one is affected with red spider or mildew out with it. The leaves had better be carefully picked off and burned before the plants are removed lest a fungoid spore should be scattered or sown in pastures new. Thus by prompt removal these diseases would be all at once stamped out. The portability of Roses in pots also aids us in other respects. For example, it enables us to keep them as close to the light as may be, and also to regulate the heat in accordance with our wants and wishes. So long as the extremes of heat and cold are avoided, other circumstances being favourable, Roses will do almost equally well in different temperatures. From 40° to 70° is a wide leap of 30°. I do not say that it would be either wise or prudent, but very much the reverse, to suddenly take such leaps and bounds of temperature. But what rosarian will affirm after the three months of heat and drought of 1893, that 70° is the highest temperature that Roses will endure? And what rosarian who has gathered handfuls of good Roses in the open up to Christmastide will affirm that 40° is the minimum that Roses can endure to live and open into fragrance and beauty? "Ridgewood" says (p. 210) that from 55° to 65° is quite sufficient heat until the days are turned, and wisely leaves growers to determine the lowest temperature as well as the highest in accordance with their wants and wishes. With plants portable in pots growers hold the temperature of their Roses in their hands, and can to a very great extent check or force growth and bloom as they list. With well-ripened thoroughly prepared material and the prudent, yet powerful uses of heat and moisture to fit into the condition of the Rose plants, Roses every day in the year and all round are being gathered in growing numbers and perfection over wider areas every day. As to the preparation, there is only one point named by "Ridgewood" that might be better left alone, and that is the repotting of any plants that require it before they come into bloom. Let them bloom first, and pot them in mid-growth afterwards. It may be almost laid down as an axiom that the harder the root runs of Roses in pots, and the more matted the roots, the sooner and the more profusely will they bloom. I have no particular objection to any one of "Ridgewood's" selection of twenty grand Tea and Noisette Roses for pot culture, but how such an experienced rosarian could have left out Gloire de Dijon passeth my comprehension. But then doubtless he will reply that I have a craze for this Rose, which is quite true.

D. T. F.

AUTUMN-BLOOMING TEAS AND NOISETTIES.

As a general rule, all Teas and Noisettes with the exception of climbers are autumnal bloomers, but this season, owing to the exceptional weather in the south, we can also place many of the climbers under the above heading. Now that the National Rose Society have placed both Teas and Noisettes under one heading, it would be well to speak of them as one class; indeed, I think it most confusing to keep them separate, as they are so closely allied, that even our best and oldest growers do not agree to which section many belong. When the strong growers flower in the autumn they are very showy, and often put on tints which are not seen in the same variety during early summer

blooming. That grandest of old Roses, Gloire de Dijon, is as bright and deeply coloured as Bouquet d'Or, Kaiserin Friedrich and Mme. Béard also possess a much deeper and clearer colour. There are a few of the extra vigorous growers that almost always bloom well in the autumn; among them we may name Celine Forestier, W. A. Richardson and Ophiré. The first and last of these may be classed as certain autumnal bloomers. But it is when we come to the main section of the Teas and Noisettes that we so clearly see their immense value late in the season. What can possibly be handsomer than a bush of Marie van Houtte, with its quantities of bloom so exquisitely tinted with bright rose? In the early part of the summer this variety is a pure yellow, but in the autumn it is scarcely recognisable as the same sort. Anna Ollivier, too, very seldom produces any of the pale yellow, Mme. Hoste-like flowers we often see in the spring. We notice another peculiarity in Mme. Lambard. In the early part of the season almost all of the flowers are deep red, but as autumn approaches, the majority of the blooms come almost pure salmon in colour. All of the deep yellow and orange blooms have a much more intense shade in the autumn. One great advantage in the Teas over the Hybrid Perpetuals is their continuous growth, and as they always produce a crop of bloom upon this, we get fully three or four times the number of flowers from them. In the autumn we are very seldom troubled with green-fly or any other insect pest, the only enemy of importance being mildew. By syringing and lightly dusting over with flowers of sulphur, we may hold this in check to a certain extent; but as the causes of this disfiguring and crippling disease are entirely beyond our control in the open air, its rapid spread and disastrous effects are unavoidable. When Teas are exempt from this disease, their autumn display is one of the most charming and satisfying features in the garden, and it is extremely disappointing to have mildew set in just as a valuable crop of bloom is almost secured. This season the bulk of my autumn crop was well in flower before mildew appeared, but it is attacking the plants very severely now, and will probably prevent many more good blooms being produced. It is such a crippling disease, smothering and blighting the young foliage so suddenly, that a week will make all the difference between a good crop or none.

A list of varieties most suited for autumn blooming would include almost all of the fairly vigorous Teas, but I may name the following as being particularly good this season: Sunset, Anna Ollivier, Dr. Grill, Perle des Jardins, Mme. Lambard, Marie van Houtte, Mme. Falcot, and Mme. de Tartas. The last named is so seldom seen that I would call particular attention to it. Mme. de Tartas was sent out by M. Bernède in 1880, and is one of the freest growers and bloomers we have; in fact, I know of none more so. Through the summer the flowers are not bright enough in colour to meet with the approval of many, but towards the autumn they are of a clear red, almost as deep as the early blooms of Mme. Lambard. Quite little plants are blooming in the greatest profusion, and I recently saw on a wall a plant (about twenty years old) that was one mass of flowers. Of much the same habit as Marie van Houtte, but producing quite three times as many flowers, this old Rose is particularly grand in the autumn. I have counted as many as thirty buds upon a truss, and as each bud grows well away from the other, having a clear stem of 4 inches to 6 inches, it can easily be imagined what a quantity of bloom is available for cutting. Most Roses which produce large trusses seldom open more than one or two flowers satisfactorily, but this variety expands almost every bud. Although sent out over thirty years ago, I have only seen it in two private gardens. Those of the Hybrid Teas in which the Teascented blood predominates are also fairly good autumnal bloomers, but, unfortunately, many of these are subject to red rust and Orange fungus, a disease the true Teas are exempt from. When they escape this, the following half-dozen are

really good late in the season: Viscountess Folkestone, Augustine Guinoisseau, Camoens, La France, Grace Darling, and Caroline Testout. Among the Hybrid Perpetuals we also find a few which deserve mention, although they probably belong more correctly to the Hybrid Noisettes. I allude to Bonle de Neige, Mme. Francois Pittet, Mme. Alfred de Rougemont, and Coquette des Blanchés, all four of which are whites of different shades.—R.

—The true autumn Roses are the Teas, and at this season they are a long way ahead of their summer rivals. It is almost marvellous how they have endured the heat and drought. The whole season has been one long hot summer, beginning in advance of its time and extending altogether beyond its usual limit. With such heat individual blooms have been short-lived, but the never-ending succession kept up a display. In truth, the real autumnal bloom of many kinds is past, nor could it be otherwise. Never before have I seen such an abundance of Roses in August, as that month generally marks a slight break between the two great displays of summer and autumn. Everything, however, is about a month in advance of its usual date, and our annual autumnal feast of that best of Teas, Marie van Houtte, is no exception. The second display of this Rose is with us always greater than the first, and lately the sun-dyed brilliancy of the flowers has been strikingly beautiful. With all its constant beauty there is the fact that it is doubly as vigorous as many of the much vaunted Hybrid Perpetuals, and therefore surely everybody's Rose. I think, however, it likes a deep holding soil, as in lighter soil I have never observed it quite so good and full of substance. Whether for summer or autumn, Mme. Hoste has won its way by sheer force of high merit as absolutely the best pale yellow Tea Rose. Plentifully and often its flowers may be cut, and it is always first rate. The third display of the season is just beginning with this kind, and the same is true of Non. Edith Giffard, which is one of the very best Tea Roses in existence at all times and seasons. Anna Ollivier is full of lovely buds, just the thing for cutting, and it is one of the most characteristic Roses in a cut state, opening progressively in perfect form from day to day. Souvenir d'un Ami and its white counterpart are quite indispensable, and Jules Finger, still full of lovely flowers, has been one of the most faithful Roses of the year. The Dijon Teas are glorious this September on walls high and low, over fences, and as great scrambling bushes in their present wealth of blossom they suggest midsummer to those who do not know what Rose pictures are possible in autumn by the aid of Teas. Take Gloire de Dijon, Bouquet d'Or, Emilie Dupuy, and Mme. Berard, and put them in every conceivable position. They can hardly be wrongly placed, and autumn Roses will be plentiful enough. For picturesque effects a collection of anything is wrong if it must be confined to units. The reason that there are no Rose pictures in autumn in a great many gardens is because, though the best sorts may be present, their number is not nearly sufficient. To treat the Rose as a flowering shrub to brighten the garden and fill it with sweet odours, is the only way to discover its excellency.—A. H.

Do some Roses deteriorate?—I have frequently heard the remark that some varieties are not so good as they used to be. My own impression is that they are equally as good if treated with the same care as formerly. It is the vast improvements made among Roses during the last two decades which give many the idea that some of the old favourites are not so good as formerly. As an exhibitor of some years' standing, I can speak from experience of the much higher standard necessary to win with to-day compared with that of only ten years ago. Then we had to include John Hopper, Jules Margottin, La Reine, and many others which are scarcely ever seen on a stand now. Comparison can scarcely help being made between these and newer varieties, and owing to the great improvement in some of the latter, the former do not retain first place in our

estimation. There are very few old Roses which stand the test of time like the following half-a-dozen Teas: Adam (1833), Catherine Mermet and Devoniensis (1838), Madame Bravy (1818), Maréchal Niel and Niphetos (1844), and Souvenir d'un Ami (1846). The "old" Gloire de Dijon is comparatively new to these, having been sent out in 1853. Souvenir d'Elise Vardon was introduced during the same year, and this variety, with Catherine Mermet, has taken more medals for the best Tea Rose in the numerous exhibitions of the National Rose Society than any others. Among the Hybrid Perpetuals we find Marie Baumann, Charles Lefebvre, La France, Camille Bernardin, and Maurice Bernardin, all of which, if my memory serves me correctly, have taken this honour in their classes. As these are from twenty to thirty-five years old, and still hold their own against the cream of the hundreds introduced since, we may take it that they, at any rate, are not deteriorating. It is a question of a "survival of the fittest," and many old favourites are necessarily going to the wall and receiving less generous culture and attention as time goes on. One cannot help regretting the loss of some of these old Roses, but the spirit of the times demands that they should make room for improvements. A most gratifying thing to lovers of old Roses must be the feature introduced in the N.R.S. prize schedule during the past three or four years. I allude to the class for garden Roses, and which will revive many old favourites.—A. P.

Rose Aimee Vibert.—This charming old Rose, which has been in our gardens nearly seventy years, is classed with the Noisettes, and is somewhat tender. It never fails, however, and, like Lamarque, should the winter deal hardly with it and the first blooming be lost, it will soon send forth a forest of vigorous shoots which will be crowned with clusters of bloom. It is now very beautiful on a trellis, and I saw it in profuse bloom recently on a cottage wall. It is a great cluster Rose, much in advance of the summer cluster Roses, for whilst it flowers about the same time or a little later than they do, it also gives a second, and this year greater, display during autumn.—A. H.

Roses by the sea.—A good many Roses do well by the sea if they do not get an excess of salt spray, and if they, in seasons such as this, get a sufficiency of fresh water or house sewage at their roots. But the condition of many Roses on the east coast at the close of this dry season on September 18 is pitiable, and one of the saddest things about them is that they have perished or been crippled with heat and drought, and not with the salt brine. In some cases there are wrecks of what have been fine Rose plants almost close to the shore, with leaves and branches apparently as dead as if they had been passed through a fire. They have simply been left to their fate, and have perished from want of water. In other cases one finds Roses, and even the old scarlet and pink Monthly, in good health and bloom as near or yet nearer to the shore. At a glance one sees that one has been watered and the other not. It is probably no exaggeration to say that nine-tenths of the Roses and other plants—especially Rhododendrons—that have died or been crippled with disease this season, have suffered thus from lack of water. They have been starved rather than scorched to deformity or death. Roses by the sea may have been among the first victims, but thousands have followed suit far inland that a deluge from the sea would have saved.—D. T. F.

Polyantha Roses.—These and the miniature Provence and Fairy Roses are much alike in some respects. All of them produce small blooms, many of which are perfect in shape, while others are of rosette form. The closer growers are admirably adapted for pot culture, and when well grown are charming. The Rose frequently spoken of as Rosa Polyantha is more correctly described as Rosa multiflora. It has come to the front very much recently as a stock for Tea Roses. R. multiflora was introduced from Japan in 1827 and is a very rapid grower. The flowers are single and

produced in immense bunches. It is also known as Polyantha simplex. In 1886 M. Bernaix introduced R. m. grandiflora. This is of even stronger growth than simplex and the blooms much larger, often being 3 inches across. It is very strange that the tremendous growth of R. multiflora should have so persistently produced these very short-growing Roses when crossed with the Teas. Take Anna Maria de Montravel, sent out by Raimbaud in 1879. This is a cross between Polyantha alba plena and Tea Mme. de Tartas. It has entirely lost the strong growth of both varieties, but retains their great freedom of flowering, producing immense clusters of semi-double flowers of a pure white, often from thirty to sixty in a truss. Perle d'Or is another striking instance, being a cross between R. multiflora and Mme. Falcot. In this variety we retain the pointed bud of the latter, also a great deal of its colour—nankeen, with an orange-yellow centre, is a fairly accurate description. Gloire de Polyantha is more double and globular than its parent. Mignonette, colour deep rosy pink with a white base, is exquisitely scented, and one of the most perfect in this class. Ma Paquerette, Clothilde Soupert, Cecile Brunner, Golden Fairy and Kate Schultheis are all very pretty. Dr. Raymont, a Hybrid Polyantha, is a very fine purplish crimson and almost always in bloom. This resulted from a cross between the old R. multiflora and General Jacqueminot.—R.

THE FRUIT CROPS.

MIDLAND.

Coddington Hall, Newark-on-Trent.—The fruit crops in this district vary considerably, and are not, on the whole, satisfactory. The season opened with a grand promise, trees of all kinds being laden with blossom. In our own neighbourhood the spring frosts, of which we had a severe taste, did not actually cripple the expanding buds, although I believe that had not our own Apricots been protected with frigi domo instead of fish netting, the crop would have been lost. Of Apples and Pears, half and in some cases the whole crop fell to the ground. I am speaking of our district generally, as in our own orchards fruit is more abundant; in fact, the best crop we have had for years, although the fruit will certainly be undersized. Apricots are an abundant crop, but small. Peaches and Nectarines on open walls are an average, and I must here say a word in favour of the variety Amsden June. This is an excellent Peach for outdoors in the midlands, being ripe this year by July 6. It crops well, swells to a large size and takes on a delightful colour, whilst it is of good flavour. This Peach, I believe, belongs to the American section, but if it would retain its buds and crop as well indoors as it does out, it would be well for gardeners to substitute it for Alexander and Waterloo. Gooseberries and Currants were a good crop, especially the red variety; and Raspberries half a crop, owing to being nipped by a severe late frost when at a critical stage. Strawberries were under the average and the season of somewhat short duration. The advantage of having plants by the margin of walks for stock is more apparent this year than ever. Being more shaded and cool, runners have come early and strong, whilst even young plants on open quarters have produced them slowly, but much infested with spider. Plums are a medium crop generally in this quarter, but with us both Plums and Damsons are abundant. Our most prolific Pears on walls are Thomson's, Louise Bonne of Jersey, Marie Louise, Glou Morceau, Baurré Clairgeau and Winter Nelis; of Apples, Lane's Prince Albert, Lord Suffield, Duchess of Oldenburg, Cox's Orange Pippin, King of the Pippins, Stirling Castle, Cellini and Fearu's Pippin. Although the present year has been most trying, and in many instances productive of much loss to market growers, I am of opinion that it will ultimately prove of practical good by hardening and consolidating growth, leav-

ing less for autumn suns and winds to accomplish. We may therefore hope for an abundant crop in 1894.—JOHN CRAWFORD.

Barkby Hall, Leicester.—The Apple crops are generally good, but partial, some orchards having good crops, while others in the same neighbourhood are only moderate. The trees have suffered from the drought, causing an unusual number of fruit to fall. The Codlin moth has been very destructive in some orchards. Pears are only a moderate crop. Plums a good average. Apple, Pear, and Plum trees have not suffered so much from winter moth as usual, and where l'aris Green was used the injury is only slight in comparison with former years. Now that the rain has come trees are making good clean growths. Apricots on walls have very good crops, and the trees have stood the dry weather better than orchard trees. We have not had such good crops of Apricots for several years. Peaches also good, and the trees are doing well. Cherries good both in orchards and on walls. Gooseberries a very heavy crop everywhere. Currants, good crops of both Red and Black. Raspberries good. Strawberries were a very partial crop. Sir J. Paxton has generally failed in this neighbourhood, while Noble, as usual, gave good crops, and the flavour this year was nearly equal to that of the best varieties. The fruit of all varieties was small, and many plants were killed by the drought.

Peas have been the greatest sufferers amongst vegetables. In spite of heavy waterings they suffered badly from mildew. Late sowings are total failures. It is surprising how well Potatoes have stood the dry weather, and have made tops of average height both in the garden and field, with fair crops of tubers. I never remember to have seen so many failures in the Onion crop. Our own are very good, but the seed was sown as early as possible. Where sowings were late, crops are bad without exception. It has been a trying season for Celery, and many of the earliest plants have run to seed, due to a check from insufficient moisture. Lettuces bolted before hearing, but, as usual, those planted between the Celery trenches have done well. The highest reading of the thermometer was 93½° in the shade on July 2.—J. LANSDALE.

Euston Hall, Thetford.—The Apple crop is good, the fruit clean and well developed. Pears are an average crop. Plums, especially Victoria, are good on both standards and pyramids. Morello Cherries are very fine, but ripe much earlier than usual. Peaches and Nectarines are much over the average. Apricots over the average and very early, the fruit from south walls (August 5) having been already gathered. Small fruits an abundant crop, and Strawberries mulched early are quite up to the average. Raspberries were soon over and not so fine as usual. Nuts are hanging thickly on the trees.

Potatoes are looking well, except late planted ones, and any that have come under my notice at the local shows are quite equal to those of former years. Kitchen garden crops generally have not suffered to any great extent considering the long spell of dry weather.

The lawns, that during the drought looked as if they would never recover, are now fresher and greener than ever I remember to have seen them for the past twenty years.—W. Low.

Madresfield Court.—In such a season exceptional results may be anticipated. I never have seen crops so extremely partial or irregular. Certain positions seemed to have been affected by cold waves of frost during the flowering period. Madresfield lying low and somewhat damp suffered accordingly, but higher grounds and slightly sheltered from the east show full and heavy crops of fruit, although smaller than usual, probably owing to drought. A most remarkable feature was the extreme aridity of the atmosphere through March, April, May and June. Insect pests flourished accordingly, and gave constant trouble; in short, it was one of the very worst seasons I ever experienced. All one's calculations were upset and crops ripened prematurely. Peaches

were gathered outdoors on June 21, and Noble Strawberries were picked May 12, establishing a record not likely to be superseded. Apples and Plums are good average crops generally. Pears less so, having suffered heavily from attacks of that worst of all pests, *Diplosis pyrivora*, a small gnat fly which deposits its eggs in the calyx of the flower, and the larvæ eat their way to the core of the embryo fruit, causing it to fall prematurely. Apricots were never better or fuller crops. Cherries abundant, but small and soon over. Strawberries, early and midseason, small, but of excellent flavour; late kinds a failure, owing to intense heat and drought. Bush fruits fair crops on strong holding land. Raspberries small and soon over.

Vegetables, especially Peas, unsatisfactory.—W. CRUMP.

Caldecote Gardens, Nuneaton.—The fruit crops vary very much in this district. Apples are very good. Plums a moderate crop. Apricots a good crop, but rather small. Pears moderate crop, but vary very much, some trees bearing well, especially Marie Louise; others none. Dessert Cherries good crop, and Morellos very fine, bearing very heavy crops. Gooseberries very plentiful. Red, White and Black Currants moderate crop, but the trees much blighted. Raspberries a good crop, but fruit rather small. Strawberries a moderate crop, but soon over, owing to very dry, hot weather.

Early Potatoes a good crop and sound. Late Potatoes in this district are suffering very much from want of rain, and I am afraid the crops will be very much under average and tubers small. Onions a very good crop. Peas have been moderate, but soon over. Scarlet Runner Beans are bearing well, but are getting covered with red spider. The rainfall has been very light in this district this year; we have only registered up to August 29 9.44 inches, and everything is suffering through want of rain.—J. BOWLER.

Eaton Gardens, Chester.—Apricots in this district are a very good crop, the absence of late spring frosts favouring a good set, and where this has been followed up with plentiful supplies of water, there is abundance of clean, sound fruit. The Apple crop seems to be a somewhat varied one; in some places a good average, in others very slight. Here we have a good crop of all the cooking kinds, but a slight falling off in the dessert varieties; trees are remarkably free from blight and fruit clean and well formed. The following are among our best croppers: Worcester Pearmain, Cox's Orange and Ribston Pippin, Astrachan, Quarrenden, Lord Grosvenor, Stirling Castle, Cellini, Ecklinville Seedling, Annie Elizabeth, Golden Noble, Old Hawthornden, Mère de Ménage, Non-such, Kentish Fillbasket and Lord Suffield. Pears, speaking generally, are hardly half a crop. There was plenty of blossom on most trees, but it set very badly. The want of sun last autumn to thoroughly ripen the wood may account for this. Plums are a good half crop, but have been badly infested with fly this season. Strawberries were never worse in this district than they have been this year. A splendid show of blossom, but the scorching sun in May and June ripened them off prematurely and made the season for them one of the shortest on record. Damsons are largely grown around here. The crop in some places is fairly good, but the fruit very small, while the trees are completely covered with red spider. Cherries and small bush fruits, with the exception of Gooseberries, have been very good. Crops of all kinds are nearly a month earlier than last year.—N. F. BARNES.

WALES.

Brynkinalt, Chirk.—The fruit crop in this exceptional season is, generally speaking, very heavy, and the fruits smaller than usual unless they have been hand-thinned and had plenty of water, but I fear that in many gardens the water supply has been too scarce to allow the trees a sufficient allowance. Apricots set in abundance and are very good. Peaches and Nectarines are well cropped, although somewhat smaller in size

Apples, Pears, Plums, and Morello Cherries are very heavy notwithstanding the trying weather. Black Currants and Red Currants, Strawberries, and Raspberries have all been far above the average in quantity. In all cases fruit and vegetables have been from three weeks to a month earlier than usual.—J. A. WOOD.

Vaynor Park, Berriew.—The fruit crop here is a very good one, more especially Apricots, Peaches, Nectarines and Plums. These are plentiful, and promise to be excellent in quality. Cherries are an average crop May Duke being most abundant. Many of the Morellos and other varieties have dropped, as they suffered severely from the sun. Strawberries were a good average crop. Pears are below the average. Taking the Apple crop as a whole, I may say that it is about an average one. Gooseberries, Currants, and Raspberries are fair average crops. Walnut trees are bearing heavy crops, Filberts and Nuts being thin.—R. H. SMITH.

Glanafon Gardens, Taibach, Port Talbot.—The fruit crops this season have been very abundant and of good quality, though hardly as fine specimens are to be seen as in preceding years, except where water has been abundantly supplied. Gooseberries have given very good crops, the trees being remarkably free from the ravages of the caterpillar. Strawberries were abundant and the fruit fine, Laxton's Noble being our best in all respects this season. Apples are abundant and of good size, reaching perfection quite three weeks earlier than is usual. The trees look healthy. Pears have borne heavy crops, but the fruit has not been quite up to the average size. The trees look well. Plums are abundant; the trees look fresh and healthy where they have been well watered. The Cherry crop has been good. Peaches and Nectarines are fine and the crops good, particularly where the trees were well watered and mulched. The feature of this season's fruit crop is its comparative earliness. Bush fruit is almost entirely gone, and the fruit fully three weeks earlier than in ordinary years. Strawberries ripened early in May.

All vegetables have suffered greatly from the long-continued drought.—HENRY MORRIS.

Ruthin Castle.—Fruit crops good all round. Apples, Pears, Plums, Raspberries, and bush fruits being an abundant crop. Strawberries a good crop, but rather small. Fruit trees are clean and healthy owing to our abundant supply of water.

Vegetables good all round, especially Potatoes, which have been unusually early and very fine. These remarks about fruit apply to the district generally, but in many places where the water supply is deficient, kitchen garden crops have suffered from the drought.—H. FORDEB.

Dynevor Gardens, Carmarthenshire.—This is one of the best seasons that has been known in this district. Apples over average. Pears (early sorts) good, later kinds average. Plums over average. Peaches on walls outside very good. Figs on outside walls a good crop. Strawberries were heavy crops and good. Gooseberries heavy crop, but blighted in early season. Currants and Raspberries very good, but neither had a drop of water this season from February 26 to May 2; no rain then till July 8.

Vegetable crops are looking well; the only drawback was that Peas did not fill satisfactorily, but produced heavy crops. We, as a rule, trench a good part of our vegetable ground every year, which suits dry seasons.—JOHN M'DONALD.

Margam Park, S. Wales.—The season here from the beginning of March until early in July was the most extraordinary ever experienced. There was never sufficient rain to penetrate the soil during the whole of that period, and the drought and heat were excessive. All fruit trees came prematurely into blossom, and the early character was kept up all through. There was no frost or any other kind of bad weather to injure the bloom; consequently, the fruits all set freely. Strawberries were plentiful, but they had no

rain from the time the flowers appeared till the fruit was gathered, and were much below the average in size and soon over. John Ruskin was ripe first, and I have formed a high opinion of this sort as an early kind. Currants, Red, Black and White, were abundant and good. Raspberries were a capital crop, but the rows were mulched before the fruit began to swell. Gooseberries plentiful, but over by the time we have sometimes had them begin to ripen. Morello Cherries abundant and good. Pears better than they have been for some years. Apples a heavy crop and of fine quality, especially on trees that were not too prolific in 1892. Plums very heavy and good. The open-air Peaches are the best we ever had, but both those and the Plums were freely watered during the dry weather. Had it not been for this the Peaches at least would have been destroyed by insects. The heavy rains in the middle of July washed all the trees thoroughly, and they are now clean and in good health.

Vegetables were very deficient in quantity and quality all through the drought, but they are now almost as good as usual, as the great warmth in the soil caused the plants to grow freely as soon as the rain came. It was a new experience for me to sow, grow and gather the produce of Pea and other crops without their having a drop of rain during all their existence, but the labour that in ordinary times would have been devoted to lawn-mowing, weed-killing and such like was diverted to watering, and this, no doubt, saved many crops from being a complete failure. Potatoes have been exceedingly good, but second growth is threatened now, and this, I also fear, will prove injurious to many kinds of trees.—J. MUIR.

Slebeck Park, Haverfordwest.—Apples are a remarkable crop, all varieties carrying a very heavy crop of clean, good-sized fruit. The drought does not appear to have had any bad effect upon the trees. The fruit is much more promising this season than usual owing to the tropical weather. Pears are also a heavy crop, much above the average; all sorts alike. The fruit is of a good size and very clean. Cherries were above the average and of splendid quality; the finest crop ever seen in this district. This is not a good Cherry county, very few being grown. Owing to climatic or other causes we seldom get a crop, with the exception of the Morello. Plums are above average, especially the Victoria. All trees of that justly popular variety are loaded with fruit. Damsons are also a very heavy crop. With us they set too freely, and the fruit will be small in consequence. Small fruits were an abundant crop with the exception of Gooseberries, which were very much damaged by the caterpillar in nearly every garden in the district. Strawberries were a fairly good crop, but owing to the drought soon over, and with us they were quite a mouth earlier than usual. Peaches, Nectarines, and Apricots are not grown out of doors in this county to any extent worth mentioning, as it is only in a few favoured gardens that they succeed. On the whole this promises to be the best fruit season that has been experienced in this district for many years. It is surprising the amount of drought fruit trees will stand. From March 1 until July 19 we did not get sufficient rain to reach the roots of the trees.

Kitchen garden crops of all kinds have suffered severely this summer except where well watered. Onions and Cabbage were destroyed by the grub to a great extent, particularly on light soils. Early Potatoes were generally a very light crop. Late sorts, however, promise better.—GEO. GRIFFIN.

Quinta Gardens, Chirk.—Apples are a full average crop, Pears over the average, Apricots excellent, also Plums, Peaches and Nectarines. Small fruits are a good average with the exception of Gooseberries, which are poor and badly infested with spider. I never remember to have seen such a set of Apricots. We had to pull off ten for every one left on. Plums on walls much the same. Pears required a lot of thinning, while some of the other sorts of standard Apples will, I fear, be small owing to the great quantity of fruit. All fruits are of exceptional quality, and give promise of high colour and fine finish. Old standard Apple

trees of such as Lord Suffield, Stirling Castle, and Warner's King, are heavily laden, while newer sorts in the same orchard have been very poor. Lord Grosvenor and Saltmarsh's Queen are my best new kinds.—J. LOUDEN.

SOCIETIES AND EXHIBITIONS.

ROYAL HORTICULTURAL SOCIETY.

SEPTEMBER 26.

A BETTER meeting than that of Tuesday last or a more representative one could not possibly be desired. It speaks well for the enterprise of the trade, from whom the greater part of the exhibits came, that such a display should be made when London is comparatively empty. The only regret is that it was not patronised more than it was by Fellows and their friends. Of Orchids there was quite a good assemblage, with no dearth of variety or good quality. Dahlias made a considerable show of themselves, the Cactus varieties never having been shown all the season with the colours so intensified. This we have observed in other seasons at the end of September, but never so much so as on this occasion. This may probably account in some measure for the numbers of certificates awarded to new kinds, these being seen under the best possible conditions. Hardy flowers from the south coast were numerous, and a few good plants of decorative character were exhibited. Tuberos Begonias were shown in grand condition from Swanley, both single and double. From Woking came fine examples of the glaucous Spruce and Atlantic Cedar. Some excellent fruit was shown, the finest examples of culture being the Pine-apples from Frogmore, the Pears from Marston House, Frome, and the grand Melons from Gunnersbury Park. Some excellent dishes of Apples were shown, and also some fine examples of Onions and other vegetables from Swanley.

Orchid Committee.

A first-class certificate was awarded to—

CYPRIPEDIUM CHARLESWORTHII (Rolfe).—A distinct and decidedly novel new species, which cannot be compared with any other that we can call to mind. The plant is of dwarf habit, the flowers each having a remarkably fine dorsal sepal, extra large, measuring about 2½ inches each way, the colour a pale pink suffused with purple and having a lighter network towards the extremities; the petals are shaded with greenish brown, so also is the pouch, which is rather small. A greater novelty amongst the species of the Slipper family has not been seen for a long time. From Messrs. Charlesworth, Shuttlesworth and Co., Heaton Nursery, B adford, and 213, Park Road, Clapham.

Awards of merit were given to—

CATLEYA BLESENSIS (C. Loddigesii × *Lælia pumila*).—In this very pleasing and distinct-looking hybrid the sepals and petals much resemble those of *C. Loddigesii*, but the lip is of a vinous crimson-purple, with a yellow throat, beautifully fringed, the growth very free, and in habit quite intermediate. From Messrs. B. S. Williams and Son, U. per Holloway.

LÆLIA ELEGANS TURNERI (Ingram's var.).—A splendid variety, with flowers fully 6 inches across, the sepals and petals a deep rose-pink, flushed with purple, and the lip of an intensely deep velvety crimson-purple, the column partaking of the colour in the other parts of the flower, a fine Orchid. From Mr. Ingram, Elstead House, Godalming.

Botanical certificates were voted to—

BROWNLEA CERULEA.—A small terrestrial Orchid with pale blue flowers. From Mr. J. O'Brien, Harrow-on-the-Hill.

CATASETUM GNOMUS.—A most singular looking Orchid, with dark green sepals and petals; in no sense handsome, but remarkably novel, with a spike bearing thirteen flowers. From Mr. W. Cobb, Dulcote, Tunbridge Wells.

A cultural commendation was most deservedly awarded to—

DENDROBIUM PHALÆNOPSIS SCHROEDERIANUM VAR. **BEATRICE ASHWORTH**, with three extra fine spikes of great length, the lip dark vinous purple, the petals of a lighter shade, and the sepals almost white—a very fine form of this choice Orchid. From Mr. E. Ashworth, Harefield Hall, Wilmslow, Cheshire. Other good varieties of the same Orchid were shown by Mr. Ashworth.

From Mr. Statter, Stand Hall, Manchester, came *Cattleya Alexandra*, two spikes and four flowers of better colour than usual, with a deep rose-pink lip, the sepals and petals of a chocolate-brown and very glossy. Mr. Statter also had *Cattleya Parthenia*, also shown at the last meeting, and *Cattleya bicolor cœrulea*, which in its colour is a decided novelty, the sepals and petals being of a pale olive-green, the column pearly white, and the lip a pale clouded blue—a most singular combination of colours. *Cypripedium Arthurianum superbum*, a fine form was also included in this exhibit. From Messrs. H. Low and Co., Upper Clapton, came a small group of choice things well arranged, amongst which were *Vanda cœrulea* of beautiful colour, *V. Sanderiana* in good condition, and *V. Kimballiana*, a valuable Orchid for cutting, being so free and distinct. *Cypripedium tonsum* (good), *C. Harrisianum*, *C. L'Unique*, *C. bellatulum*, *C. picturatum*, and *Cattleya maxima* with its rosy lilac flowers were also included. Messrs. B. S. Williams and Son showed *Cypripedium amandum* in good order, and Messrs. Charlesworth, Shuttlesworth and Co. had *Cypripedium Morganæ*, *C. cœnanthum superbum* with other sorts, and a beautiful example of *Vanda cœrulea* finely coloured, splendid flowers of *Cattleya labiata autumnalis*, *Lælia tenebrosa* and a good *Oncidium* in *O. Gardneri*, a very fine form of *O. sarcodes* with the yellow lip distinctly marked with brown spots around the margin; a richly coloured *Vanda Sanderiana* was also included.

Messrs. Sander and Co., St. Albans, staged an attractive group, not large, but consisting of several choice kinds. From a cultural point of view the best of these were *Cattleya anrea*, with richly coloured flowers of fine size, and *Orcidium Jonesianum*, remarkably vigorous, the foliage in one case fully 18 inches in length. Three distinct forms of this beautiful autumnal Orchid were shown, each distinctly good. *Habenaria carnea* was again set up, and a distinct looking *Calanthe* called *C. curculigoides* with orange-yellow flowers; also *Aerides Rohanianum*, a species that comes near to *A. suavissimum*, but richer in its colour and larger. Several small flowering *Oncidiums* were included, as *O. pubes*, *O. bracteatum*, *O. tralliferum* and *O. Wentworthianum majus* with a long spike. Another pretty plant was *Phajus Woodfordi*, with lemon-yellow sepals and petals and yellowish brown lip. *Catasetum purum*, a pale yellowish green species, was also included. Messrs. Lewis and Co., Southgate, showed *Cattleya Johnsoniana* and *C. Ashtoniana*, hybrids between *C. Harrisoni* and *C. gigas Sanderiana*, both of which partake more of *C. Harrisoni* than of *C. gigas*; there are certainly some of the characteristics of the latter parent with the colour of the former, save in the lip of the last named hybrid, which has the rich crimson marking of *C. gigas*, the other hybrid being devoid of or but faintly stained with that colour. Mr. Thompson, Walton Grange, Stone, Staffs, showed cut spikes of *C. Alexandra*, pale and dark forms, one with richly coloured sepals and petals and a deeper coloured lip than usual. Mr. Brymer, Dorchester, sent *Cattleya Brymeriana*, after *C. Skinneri* in form, the inner part of the lip of a deep yellow, the outer portion of a rosy purple. Mr. Statter also showed a good form of *Cattleya Alexandra*, and Mr. J. O'Brien had *Satyrrium eriocarpum* and *S. membranaceum*. Mr. McArthur, The London Nursery, Maida Vale, arranged a small group in an effective manner, amongst which were *Cattleya Harrisoni* with fine deeply coloured flowers, *Vanda Sanderiana*, and *V. S. pallida*, with the upper sepals of nearly a pure white, the other parts of the flower also paler, a distinct variety. *Ceogyne Massangeana* with

long spikes, *Odontoglossum Alexandra*, *Cypripedium Ashburtoniæ* and *C. calurum* were as so shown also *Saccolabium cœleste*, a pale blue species with croet spikes, and *Stanhopea insignis major*, deeper in colour than the type.

Floral Committee.

First-class certificates were awarded as follows—

NEPENTHES MIXTA.—A splendid hybrid, raised at Chelsea, between *N. Curtisi* and *N. Northiana*. This must be classed amongst the finest kinds yet sent out, being a fitting companion to *N. Mastersiana*. The pitchers are about 10 inches in length, of a brownish pink ground colour, blotched and spotted with dark crimson and of unusually firm texture. Around the upper margin the colour is of a deep crimson or maroon. The plant bore six fine pitchers. From Messrs. Jas. Veitch and Sons.

AGLAONEMA ROTUNDUM.—A very distinct Aroid of dwarf Dieffenbachia-like habit, and a fitting companion to *A. costatum*, already in commerce. In *A. rotundum* the groundwork is a dark, glossy green, with marblings and blotches of silvery white, the leaves being leathery in texture, broadly ovate in form, and from 4 inches to 5 inches in length and 3 inches in breadth. From Messrs. Jas. Veitch and Sons.

DATURA CORNUCOPIA.—Of this new species a large plant was shown bearing well-developed semi-duplex flowers, nearly white, the inner part being white with a faint suffusion of violet, the reverse having deep violet splashings on a paler ground, the perfume peculiar to the *Daturas* being plainly discernible. This should prove to be a fine feature in the flower garden. From Messrs. Pitcher and Manda, Swanley, Kent.

Awards of merit were given to a number of Dahlias, the following being the varieties selected:

CACTUS DAHLIAS.—Mrs. A. Peart.—A creamy-white of true Cactus form and a full flower. From Mr. T. S. Ware, Tottenham. Edith Turner.—Another true Cactus with long petals, vermilion-scarlet shaded with purplish-violet, large flowers, very showy. From Mr. Charles Turner, Slough.

DECORATIVE DAHLIA GRAND DUKE ALEXIS.—A very remarkable and distinct flower of large size with long fluted petals, nearly white in colour with a slight suffusion of blush; a grand double Dahlia for the garden. From Messrs. Keynes, Williams and Co., Salisbury.

SHOW DAHLIAS.—Duchess of York.—One of the most distinct and beautiful kinds seen this season; the flowers medium in size, heavily tipped with deep rose-pink, the base of the petals of a bright terra-cotta shade. From Messrs. Keynes, Williams and Co. Mrs. Morgan.—A beautiful pale ground colour, deeper than Mrs. Gladstone, but after that well-known flower and larger, the petals faintly tipped with purple. From Mr. Charles Turner. Norma.—A bright terra-cotta, shaded with yellow and of fine form. From Mr. Charles Turner. Octavia.—A rich yellow, tipped with claret colour, distinct in its markings. From Mr. Charles Turner. Cherub.—A bright terra-cotta colour, shaded with orange, compact and full. From Mr. Pierre Harris, Orpington, Kent.

SINGLE DAHLIA.—Beauty of Watford.—A rich shade of yellow with brownish circle, resembling a Gaillardia. Mr. Darby.

POMPON DAHLIAS.—Sovereign.—A bright yellow self of medium size, full and free. From Messrs. Keynes, Williams and Co. Ceres.—A pale sulphur-yellow, and a fitting companion to the foregoing. Also from Messrs. Keynes, Williams and Co. Miranda.—With flowers of pale golden ground colour, tipped with claret. From Mr. C. Turner. Captain Boyton.—An intensely dark maroon self of good form. Also from Mr. C. Turner. Florence Woodland.—A golden ground colour, tipped with crimson, distinct in its shades. From Mr. T. S. Ware, Tottenham.

HELIOPSIS SCABRA MAJOR, with flowers of a deep golden-yellow and dark disc, a variety of sturdy and free growth. From Mr. B. Ladham's, The Shirley Nurseries, Southampton.

ALOCASIA CHANTRIERI.—A distinct variety, with long arrow shaped foliage and wavy edges, the

whole leaf faintly suffused with a silvery shading, the midrib and nerves of a lighter shade. From Messrs. J. Laing and Son, Forest Hill.

BEGONIA DUCHESS OF YORK (tuberous-rooted).—A splendid double variety, with immense flowers of a rosy crimson colour, the petals broad and reflexed. From Messrs. J. Laing and Son.

VERONICA HYBRIDA PURPLE QUEEN.—An extra dwarf and compact growing hybrid variety, with a profusion of dark purple trusses of flower, a valuable plant for boxes and massing for effect. From Messrs. J. Veitch and Sons.

Mr. Anthony Waterer, Knap Hill, Woking, sent some splendidly grown plants of *Abies pungens argentea* in beautiful character, with a glaucous silvery sheen over the entire growth, and of *Cedrus atlantica glauca* (the Silver Atlas Cedar), with most luxuriant growth and the same tints as in the *Abies* (these are both grand plants). From the same source came well-grown examples of *Andromeda floribunda* and *A. japonica*, with another exhibit of *Spiraea Bumalda* var. *Anthony Waterer* (award silver Flora medal). From Messrs. Keynes, Williams and Co. came a splendid lot of *Cactus* and other *Dahlias*, the former being remarkably characteristic of the name and of rich colouring. The finest of these were *Countess of Radnor*, Mrs. Masham, *Gloriosa*, *Miss Violet Morgan*, *Lady Penzance*, *Kynerith*, *Chancellor*, *Delicata*, *Countess of Gosford*, and *Bertha Mawley*. Excellent stands of show and fancy as well as pompons were also staged (silver Flora medal). A similar exhibit of *Dahlias* came from Messrs. J. Cheal and Son, Crawley; the pompons here embraced the best kinds, conspicuous amongst which were *Iolanthe*, *Lilian*, *Cecil*, *Admiration*, *Eva* and *Achilles*, and the *Cactus* *Countess of Radnor*, *Sultana* (distinct), *Robert Cannell*, *Delicata*, and *Duchess of York*. Amongst the singles were *Lowfield Beauty*, *The Bride*, *Yellow Satin*, *W. C. Harvey*, with several other good kinds in each section (silver Flora medal). From Messrs. J. Laing and Son came a beautifully grown collection of decorative fine-foliaged and flowering plants, which included many excellent things, as *Saxifraga sarmentosa tricolor superba*, *Dracena Doucetti* (good), *Crotons* Mr. Bause and *Miss Lucien Linden*, two fine and distinct broad-foliaged kinds of rich colour; *Strobilanthes Dyerianus* (fine), and *Pavella borbonica* were all shown well. Of flowering plants there were several tuberous *Begonias* (double kinds), *Baroness Burdett Coutts*, a salmon-pink, being one of the best (silver Flora medal).

Mr. B. Ladhams had a splendid collection of hardy herbaceous cut flowers of particular interest; prominent amongst these was a grand lot of the new perpetual *Pink* with fine flowers. Other good things were *Funkia grandiflora*, *Echinops ruthenicus*, *Pentstemon John Thompson* (a deep crimson), *Static incana*, *Erigeron speciosus superbus*, *Liatris pycnostachya* in superior condition, *Chrysanthemum maximum*, *Linum campanulatum grandiflorum*, *Scabiosa caucasica*, *Helianthus Soleil d'Or*, with *Gaillardias*, *Coreopsis*, *Rudbeckias* and *Delphiniums* (silver Flora medal). Messrs. Cannell and Sons exhibited a very fine lot of cut blooms of tuberous *Begonias*, a single amongst which named *Fashion*, of an orange-yellow colour, is quite distinct. Several fine doubles, very large, were also shown in various shades (silver Banksian medal). From Mr. Rawlings, of Brentwood, came show and fancy *Dahlias*, the best of which were Mrs. Gladstone, *Maud Fellowes*, *Peacock*, *Colonist* and Mr. Glasscock (silver Banksian medal). Messrs. Veitch and Sons exhibited a splendid basketful of *Amasonia punicea* in beautiful condition, it being intermixed with *Phrynium variegatum* profusely variegated. Mr. Owen, Maidenhead, showed *Canna Comtesse de l'Etoile* with yellow flowers spotted orange and of good size. Mr. Jones, Lewisham, had *Fuchsia triphylla carminata*, a pale coloured form; and Mr. Aldridge, Petersham, Richmond, sent a seedling *Aster* with nearly white flowers and of free growth. Messrs. H. Low and Son showed *Lilium nepalense*, a singular and distinct variety in good condition, the flowers having a dark maroon centre and a broad margin to each petal of yellowish green.

The first prize for twelve spikes of *Gladioli* was awarded to Mr. J. C. Tandy, Warkworth, Northumberland, and included some very fine spikes of *Enchantress*, *Grand Rouge*, *Atlas*, and *Corinne*. The same exhibitor was awarded the first prize also for twelve English raised seedlings, neither of which was worth notice for superior quality, the spikes being thin and meagre looking. The craze lately shown in withholding the first prizes might in this case have been done for a palpable and just reason.

Fruit Committee.

There was a number of exhibits before this committee, some excellent collections of Pines, Pears and Melons being shown.

An award of merit was given to—

APPLE WEALTHY.—An American variety, above medium size, of a dark red colour, with soft mealy flesh. Its only merit is its colour, the flavour being certainly poor. From Mr. E. Molyneux, Swanmore Park, Bishop's Waltham.

A very fine dish of nine fruits of *Doyenné du Comice* Pear was staged by Mr. Iggulden, Marston House Gardens, Frome. This was a remarkable exhibit from trees grown in a heavy clay soil. The fruits were very clear and of great size (bronze medal). Mr. Iggulden also contributed thirty dishes of Pears of great excellence; indeed, several of the varieties were equal to orchard house-grown fruits, the finish being perfect. The best were *Doyenné du Comice*, each fruit over 1 lb.; *Pitmaston Duchess*, very fine; *General Tottleben*, *Glou Morceau*, *Van Mons Leon Leclerc*, *Durondeau*, *Beurré Clairgean*, *Doyenné Boussoch*, *Easter Beurré*, *Brown Beurré*, *Marie Louise* and *Huyshe's Prince Consort* (silver Knightian medal). From Mr. Thomas, The Royal Gardens, Windsor, came eighteen very good *Queen* and *Smooth Cayenne* Pines of nice shape. This was an interesting exhibit and well deserved the silver-gilt Knightian medal awarded. Messrs. Cannell and Sons, Swanley, occupied a large space, showing a collection of Apples and a large and varied collection of vegetables. The best dishes of Apples were *Col. Vaughan*, *Scarlet Nonpareil*, *Cox's Orange*, *Queen Caroline*, *Emperor Alexander*, *King of the Pippins* and some seedlings. The vegetables comprised a basket of *Anglo-Spanish Onions* of great weight; some excellent *Somerset Hero*, *Ailsa Craig* and *Wroxton Onions* grown naturally; fifty dishes of Potatoes, the best being *Victory*, *Satisfaction*, *Chancellor*, and some enormous tubers of *Eynsford Mammoth*; some good *Ladybird* and *Criterion* Tomatoes, *Autocrat* and *Colossus* Peas, &c. (silver Knightian medal). Mr. Reynolds, Gunnersbury Park, Acton, staged twenty Melons, mostly of the *Hero* of *Lockinge* type. The fruits were larger than he usually shows, but that may be owing to the favourable season. The fruits were highly coloured and fit for table (silver Banksian medal). Mr. J. Chinnery, Downton Castle, Ludlow, sent some very fine *Lord Derby*, *Alexander*, *Mère de Ménage*, *King of the Pippins* and *Cox's Orange* Apples, *Marie Louise* Pears and *Plums*, the best being *Coe's Golden Drop*, very fine, *Pond's Seedling* and *Reine Claude de Bavay* (silver Banksian medal). Mr. Dibben, Tilgate Manor, Crawley, sent a good collection of Pears, some twenty-six varieties being staged. The best were *Pitmaston Duchess*, *Louise Bonne de Jersey*, *Marie Louise*, *White Doyenné*, very good; *Beurré Bachelier*, *Van Mons. Leon Leclerc*, *Conseiller de la Cour*, and some stewing varieties (silver Banksian medal). Mr. A. H. Rickwood, Fulwell Park, Twickenham, staged a large collection of Apples and Pears, having some nice dishes of *Colone! Vaughan*, *King of the Pippins*, *Wellington*, *Tibston* and *Frogmore Prolific* Apples; *Pitmaston Duchess*, *Durondeau*, *Gansel's Bergamot*, and *Catillac* Pears (silver Banksian medal). Mr. J. Crook, Forde Abbey Gardens, Chard, sent a small collection of Apples and some good *Coe's Golden Drop* and *Transparent Gage* Plums. Mr. Goldsmith, Leonardlee, Horsham, contributed a very good dish of *Pomegranates*, large and highly coloured. Mr. Lye, Cliffe Hall, Market Lavington, Wilts, sent a green flesh seedling *Melon*, but of no merit. A

large white-fleshed *Melon* was sent by Mr. McGrigor, Knightsbays Court, Tiverton, Devon, and a dish of *Duke of Albany* *Pea* came from Mr. Palmer, Andover.

The lecture by Mr. Iggulden on the "Causes of Failure in the Culture of the Eucharis" was very interesting. At the commencement the lecturer stated he did not intend to go at great length into the question of the mite or the pests that attack this plant, but the cause and a few words as to its remedy. Everyone will admit that of late years there have been more failures, and these were put down to the mite in most cases. All the trouble was not owing to this cause, as many who had grown these bulbs well previously often failed even when a fresh stock was secured. He gave an instance where some plants of grand proportions a year or two ago were now a total wreck. This was put down to the mite, but he differed, and would put it down to other causes, one being a too free use of the water-pot, as he thought there was no surer method of destruction than pouring on the bulbs large volumes of cold water. In dull weather the bulbs could not absorb this moisture; hence the beginning of failure and so-called disease. Mealy bug he felt certain was a sure cause of many failures, as once this pest got a hold of the plants it was difficult to dislodge. Often the destruction of the bug was the ruin of the plant, as the strong measures taken to destroy the pest were too much for the tender growth. It was often stated the *Eucharis* would produce three crops of bloom in one year, and to do this the plants were subjected to extremes of heat and cold, also drought. These extremes were often the cause of failure, as the bulbs had not time to build up a store of nourishment before they were called upon to produce a succession of bloom. Excessive drying off was also detrimental. He would advise a partial rest by lowering the temperature, but he found that the bulbs did best when kept in a growing state. Some growers to obtain large specimens over-potted; this was a sure cause of failure, as once decay of roots set in there was a difficulty in arresting its progress. Another source of failure was hard shaking out of bulbs when in full vigour. This was done at times to get the bulbs to grow more quickly, but it was harsh treatment, as the loss of the succulent leaves and roots was the beginning of failure. Bottom-heat was recommended by some growers, but he did not advise it. Of course, with weak attenuated bulbs extra warmth to produce root action may be desirable, but a strong, vigorous growth was better without bottom-heat. He did not recommend a fancy compost. Excessive use of manures tends to decay, and the fresh roots coming into contact with sour soil soon went wrong. He advised good yellow loam with a portion of bone-meal with ample drainage. Some could not always get the best loam, but his plants thrived well in what might be termed hungry loam with some old lime rubble added. He advised care in watering, using clear rain water, carefully watering during the first six weeks after repotting, and if it was found the plants did well in one house or position, he would be slow to shift into others. Many good growers had found out this as a cause of failure, as often in old or low houses plants thrived well, as in these there were small panes and partial shade; whereas in modern houses there were too much light and a drying atmosphere. The *Eucharis* likes plenty of shade. He had a large plant of *Stephanotis* covering the roof of the house in which he grows the *Eucharis*. He advised watering with clear soot water, this keeping the soil sweet. Watering with thick liquid manures closed up the pores of the soil and was the cause of much mischief. His plants stood on a staging resting on coal cinders; this latter retained the moisture and the staging gave free drainage. He also syringed the ashes with and the underside of the leaves clear soot water. He condemned the use of strong insecticides for washing or dipping. If at all dirty, sponging with tepid water with a very small portion of soft soap

in it was sufficient to remove the dirt or insects of any kind. Resting before the young leaves have matured their growth was not advisable, as this caused decay and a check to roots in an active state. To sum up, he contended that good culture was the best remedy against disease, and if a check was necessary to produce bloom, lower the temperature. He advised having plants in various stages if a long succession of bloom was required. He had plants in bloom at this time with nine large flowers on a spike; these he never rested.

Professor Cheshire went into the question from a scientific point of view, and stated his conclusions were the same as those of the lecturer. Disease, he said, was brought on by excessive moisture and extremes of heat and cold.

GARDENING AND FORESTRY EXHIBITION, EARL'S COURT.

SEPTEMBER 27, 28 AND 29.

THE competitive classes at this, the last of the series of shows for this season, were confined to fruits alone, the plants and cut flowers being therefore shown in the miscellaneous classes. The feature of the show on this occasion was undoubtedly the grandly grown and superb collection of *Nepenthes* or Pitcher Plants contributed by Messrs. J. Veitch and Sons, of Chelsea. From the same source have come in other years some remarkably fine exhibits of this family, but on no occasion have they shown a finer selection than this one, the plants clothed with pitchers of fine size. Twenty-five varieties were exhibited, twelve of which were hybrids and the rest species or variations of species. Prominent amongst the hybrids were *N. Mastersiana*, both the light and the dark varieties being represented by large plants having about three dozen pitchers on each; *N. mixta*, shown on the previous day at the R.H.S. and described in the report of that show, was again staged, and it was a peer among its fellows. *N. Dicksoniana*, another splendid hybrid, a grand specimen with twenty large pitchers, was a fine feature. *N. Chelsoni*, an extra fine hybrid; *N. Dominii*, another well-known one; *N. Curtii*, *N. intermedia*, large and fine, with numbers of its pitchers; *N. Morgania*, a choice kind; *N. cylindrica*, with large yellowish green pitchers; *N. Wrigleyana*, with large and distinct ones, and *N. Sedeni*, with its neat little pitchers, comprised the list of hybrids. Of the species there were *N. Burkei* and the variety *excellens*; the former distinct and fine, the latter a grand form of it, with its pitchers of rich markings; *N. Curtisi* and the form *superba*, the latter with pitchers of extra length and well developed; *N. Northiana*, one of the rarest of species, with pitchers of grand size and remarkably distinct; *N. bicalcarata*, with its brownish red pitchers. *N. hirsuta glabrescens* and the form called *rubra* were both in good condition; so also were *N. Hookeriana* and its variety *elongata*, both with large and finely marked pitchers. The well-known old *N. Rafflesiana* was in good condition; so also were *N. ampullacea vittata* and the major form. These complete the list, forming one of the most attractive exhibits seen this season. The gold medal was never more worthily awarded than to this exhibit.

Messrs. Veitch and Sons also exhibited several new and rare plants, Orchids, *Rhododendrons*, with cut hardy foliage well advanced in the autumnal tints. Of Orchids, which consisted chiefly of hybrids, there were *Cypripedium T. B. Haywood*, with fine flowers; *C. oenanthum superhum*, having a profusion of flowers; *C. Niobe*, very distinct; *C. Mrs. Charles Canham*, the flowers large; *C. Bellona*, and one of the most recently raised hybrids, *C. Aphrodite*, a choice kind, with *C. Brysa* formed a good exhibit. *Cattleya porphyroplebia*, a distinct cross between *C. superba* and *C. intermedia*, and *Catasetum Darwinianum*, which comes close to *C. Gnomus*, if not identical with it, completed the Orchids. The javanico-jasminiflorum *Rhododendrons* were represented by both cut trusses and flowering plants, the trusses being

large and the varieties distinct and showy; the plants were dwarf and carried fine trusses. The hybrid *Streptocarpus* were exhibited as plants on this occasion, and they are thus even more attractive and pleasing than when put up in bunches as cut flowers, the distinct colours thus being more clearly seen. *Amasonia punicea* and *Phrynium variegatum* were again shown, as on the previous day, still in good form; so also were *Veronica hybrida Purple Queen* and *Aglaonema rotundum*, *A. costatum* being added and in excellent condition. *Strobilanthes Dyerianus* was represented by plants well coloured. *Vriesia leodinensis*, *Pandanus pacificus*, a massive species with bright green foliage, and *P. Baptisti*, devoid of spines, were also shown; likewise *Begonia Arthur Malet* in good form. A large number of cut specimens of ornamental shrubs with richly coloured foliage and trees with the autumn tints well advanced were also contributed; these were a study in themselves, the best being *Rhus glabrescens*, *Euonymus atro-purpureus*, *Acer vittatum*, *A. palmatum sanguineum*, *Cornus sanguinea alba variegata*, *Ligustrum ovalifolium*, and *Cornus mas variegata* being a few of the best kinds.

Mr. Anthony Waterer, Knap Hill, Woking, again showed the beautiful examples of *Abies pungens argentea* and *Cedrus atlantica glauca* which in the position chosen for them were seen to better advantage than on the previous day at the Drill Hall meeting. Messrs. J. Cheal and Son, Crawley, showed Dahlias in large numbers of all sections, the same as at the Drill Hall with others added thereto; the central group of Cactus varieties was a most effective arrangement. A boxful of a new Cactus Dahlia called *Duchess of York*, the flowers of medium size and of a rich terra-cotta colour, was much admired for its distinctive character. Messrs. Keynes, Williams and Co., Salisbury, had a similar exhibit to that of the previous day of all classes of Dahlias, the Cactus section being particularly strong, and still quite fresh and bright. Mr. Rawlings, Brentwood, showed some good flowers of show and fancy kinds. Messrs. Cannell and Sons made a good and brilliant display of tuberous Begonias, which were fully noted in the R.H.S. report. Mr. R. Dear showed *Venidium calendulaceum multiflorum* (*Vilmorin*), and it was duly honoured as a new plant. The habit is remarkably dwarf (5 inches) and compact, being also most profuse in flowering, but not yet at its full beauty; the flowers pale yellow and single.

Messrs. W. Paul and Son, Waltham Cross, contributed a magnificent exhibit, in all ten boxes, of cut Roses, the most prominent amongst which were *W. A. Richardson*, *Boule d'Or*, *Princess May*, *Ulrich Brunner*, *The Bride*, *Francisca Kruger*, *Mme. Lambard*, *Horace Vernet*, *Miss Ethel Brownlow*, *Mme. de Watteville*, *Danmark*, *Mrs. J. Laing*, *Christine de Nougé*, *Duke of York*, *La France*, *Boule de Neige*, *J. B. Varonne*, and *Hon. Edith Giffard*—in all a most instructive feature and good guide for reliable autumn kinds.

Fruit.

Good as was the fruit staged last year here, it is questionable if ever there were so many grand dishes of fruit as on this occasion. Some of the dishes of Apples were superb and of higher colour than usually seen, no doubt owing to the favourable ripening season. On this occasion the tent was filled to overflowing with the competitive classes, and the large and miscellaneous collections were staged in the main building, occupying a large amount of space. Several well-known trade exhibits could not be received owing to the want of space, being entered too late. Messrs. Veitch staged a very choice collection of hardy fruit, obtaining the premier award. Messrs. Bunyard, Cheal and W. Paul and Son followed closely with similar collections, and there were also some very fine Grapes, Melons and vegetables staged.

A first-class certificate was awarded to—

PEAR BEURRÉ FOUQUERAY.—This partakes of the character of *Marie Louise d'Uccle* and *Duchesse d'Angoulême*, but is superior in flavour to the latter and a fruit of noble proportions. It is stated to be very hardy and most prolific, a valu-

able addition to the list of good dessert Pears. From Messrs. Veitch and Sons.

Open Classes.

In the open classes there was a spirited competition. Mr. Bunyard was first for twenty-four dishes of dessert fruits, and here was seen one of the grandest lots staged, not a bad dish being shown. Mr. H. Berwick, The Nurseries, Sidmouth, Devon, was second, having large fruits, but not so even or well coloured. In this collection were fine dishes of *Gravenstein*, *Fearn's Pippin*, and *Scarlet Pearmain*. In the open class for forty-eight dishes of cooking Apples there was a close competition; indeed, this was the best exhibit in many respects, as here were seen fruits rarely staged, the favourable season having been good for the shy bearers. Mr. Bunyard secured the premier award, having fine fruits, very even and splendidly finished, his dishes of *King of Tompkins Co.*, *Cox's Pomona*, *Gold Medal*, *Peasgood's Nonsuch*, *Cellini*, *Sandringham*, *Beauty of Kent*, *High Canons*, *Annie Elizabeth*, *Emperor Alexander*, and *Tyler's Kernel* being perfect specimens; second, Mr. Woodward, *Barham Court Gardens*, *Maidstone*, with only a point or two behind the first lot, his back rows of fruit being very fine. Mr. Scott was third with smaller fruits, but a meritorious collection. The English Fruit Co., Hereford, received an extra award in this class for a good lot of highly coloured fruits. For twelve dishes of dessert Apples, Mr. Bunyard took the lead with a fine collection, Mr. G. Woodward being a close second, his dishes of *King Pippin*, *Ribston*, *Cox's Orange*, and *Adams' Pearmain* being very fine. For twelve dishes of cooking Apples, the awards were reversed, Mr. Woodward coming in an easy first with twelve of the finest dishes ever put up; second, Mr. Bunyard, with good varieties, but smaller than the first lot. There was only one competitor for the table of hardy fruits arranged for effect, Messrs. Rivers, *Sawbridgeworth*, securing first prize for a grand collection tastefully arranged, having a selection of Apples, Pears, Peaches, Strawberries, Plums, Damsons, Crabs, Currants, Raspberries, Nuts, Medlars and a choice lot of seedling Pears, Peaches and Apples. In the Pear classes there was a great number of competitors and very few poor fruits. Mr. Woodward secured the premier award in the large collection, having grand fruits; second, Mr. G. Goldsmith, *Leonardslee*, *Horsham*, with fine fruits, having very heavy *Durondeau*, *Marie Louise d'Uccle*, *Doyenné du Comice* and grand *Glou Morceau*. Mr. Iggulden, *Marston House*, *Frome*, was third, his back row of fruits being remarkably fine, an extra award being given Mr. Allan, *Guntun Park*, *Norwich*. For twelve dishes, Mr. Offer, *Handcross Park*, *Crawley*, was first; second, Mr. Smith, *Presdale Gardens*, *Ware*. There were only three lots of orchard-house fruit staged, and in these there was outside fruit, stewing Pears being shown. Mr. Bunyard was first with a highly-finished collection; second, Messrs. Rivers. For three dishes of dessert Apples, there was a large number of exhibitors, Mr. Woodward being a good first, having a superb dish of *Washington*; second, Mr. Hall. For the same number of cooking fruits, Mr. Nicholson was first, having fine *Gloria Mundi* and *Warner's King*. The early season had exhausted the *Nectarine* crop, only two inferior dishes being staged and no awards given. Some very fine Peaches were staged, Messrs. Woodward and Rivers taking the awards in the order named. In the single dish of Peaches, Mr. Fairweather, *Bifrons Park*, *Canterbury*, staged very fine fruit, Mr. Woodward being second. There was only a limited lot of Plums, Messrs. Rivers staging three dishes of seedlings of nice appearance, and *Monarch*, *Coe's Golden Drop* and *Autumn Beauty* in the class for six dishes.

The Amateur Classes

were strongly contested, some very fine dishes in most of the classes being staged; for twenty-four dishes of Apples, eight dessert and sixteen cooking, Mr. Woodward was an easy first; Mr. Goldsmith was second with smaller fruit. In the class for twelve dishes, including four dessert varieties, there were eight collections, Mr. Goodwin, *Maid-*

stone, being first. For six dishes dessert, Mr. Chambers easily secured first place with fine fruits, having a fine dish of Nanny Apple; second, Mr. Potter, St. Clare, Sevenoaks. For six cooking Apples, Mr. Minifie, Sidmouth, Devon, was first with large fruits. For twelve dishes of Pears there was a great number of dishes staged, only one poor collection being put up, Mr. Goldsmith being first with very heavy fruits, followed closely by Mr. Allan. For six dishes there were ten collections, Messrs. Wiles, Dean, and Slogrove taking the awards.

Vegetables

were well shown. For twelve kinds to fill a space 6 feet by 3 feet, there were no less than seven lots, mostly good, the best being staged by Mr. Wilkins, Inwood House, Dorset. He had splendid Cauliflower Autumn Giant, Intermediate Carrots a trifle too large, Student Parsnip, Leeks, Main-crop Onions (immense bulbs), London Hero Potatoes, Celery, Perfection Tomato, Snowball Turnip, Empress of India Peas, Beet and Artichokes. Mr. Waite, Esher, was second with smaller examples, but very choice. Collections of Tomatoes were very fine, not such coarse fruit being staged as is sometimes seen. Mr. Ryder, Orpington, was first, having very fine dishes of Perfection, Trophy, Ham Green, Mayflower and Dedham Favourite, the Frome Fruit Company, Somerset, being a close second with grand fruits of Veitch's Ladybird, Potomac, Early Ruby and Ignatum. In the single dishes of red, Mr. Ryder was first with Perfection.

In the miscellaneous classes there was an enormous quantity of fruit staged, Messrs. Veitch taking the lead in the fruit collections, securing the highest award, a gold medal. They staged nearly 300 dishes of fruit of high colour and large size. Mr. Bunyard followed closely, having a great number of dishes, consisting of the best known kinds and some of the newer varieties both in Pears and Apples. Some heavily laden cordons formed the centre of the group, these being much admired; these were flanked by two dozen large baskets of fruit of great size (silver-gilt medal). Messrs. Cheal, Crawley, staged an enormous collection of choice Apples and Pears, having 200 dishes of Apples and Pears and fourteen flat baskets. The Pears were remarkably fine and the Apples of great weight and beautifully coloured (silver-gilt medal). Messrs. W. Paul and Son, Waltham Cross, staged a large collection of Apples and Pears with a background of Roses. This was much admired, the fruits consisting of leading varieties (silver-gilt medal). Messrs. Laing, Forest Hill, contributed a smaller collection of Apples and Pears, consisting of well known varieties (silver medal). Messrs. W. Innes, Littleover, Derby, staged two dozen good bunches of black Grapes, chiefly Alicante, Gros Colman, and Barbarossa (silver-gilt medal). Mr. C. Terry, Tatton Park, Knutsford, sent one dozen Pine-apples, some nice Queens being staged (silver-gilt medal). Messrs. Deverill staged a very large collection of their well-known pedigree Onions of great size and perfect finish (silver-gilt medal). Mr. Berwick, Sidmouth, had a good collection of Apples and Pears (silver medal). Messrs. Cannell staged the collection shown at the R. H. S. the previous day (silver medal). Messrs. Spooner, Hounslow, had a nice collection of hardy fruits (silver medal). Mr. Salmon, West Norwood, had a very good lot of vegetables (silver medal). Mr. Reynolds, Gunnersbury, Acton, staged the twenty Melons shown at the R. H. S. meeting on Tuesday (silver medal). Messrs. Rivers had a very fine collection of Grapes, consisting of Mrs. Pearson, Muscat of Alexandria, Gros Maroc, Mrs. Pince, Lady Downe's, Black Alicante (silver medal). Mr. Watkins, Hereford, staged a beautiful collection of hardy fruits, the Apples being remarkable for their high colour (silver medal). Bronze medals were given to Mr. Rickwood, Twickenham, for hardy fruit; Mr. Le Pelley, Ruspur, Sussex, for Grapes; Mr. Dibben, collection of Pears; Mr. Hester, Plumstead Common, for collection of hardy fruits; Mr. Strong, Essex, for collection of Tomatoes of good varieties; Mr. Goldsmith, dish of Pomegranates; Mr. Gregor, for

Pears; Mr. Mancey, Red Hill, for Pears of enormous size, ten weighing 17 lbs. 6 ozs.

A full prize list will be found in our advertisement columns.

NATIONAL CHRYSANTHEMUM SOCIETY.

A MEETING of the floral committee of this society was held on the 27th inst. at the Royal Aquarium, Mr. G. Gordon occupying the chair. Although the exhibits were few in number the quality was of a high order, and seems to promise much for the meetings later on. Mr. Godfrey, of Exmouth, staged a new seedling, Devonshire Lass, a large, white incurved Japanese flower, tinted yellow, but rather flat; also Mme. Edouard Rey, another of the same type, colour deep purple with a pale reverse. Mr. N. Davis exhibited a new Japanese called Il. Shoesmith, a very fine yellow flower of good size, similar to a priurose Mme. Marie Hoste. First-class certificates were awarded to—

PRESIDENT BORREL, a grand Japanese flower of great size and substance, raised by M. Ernest Calvat. The colour is a deep purple-amaranth, with a golden reverse, and petals of great length. Shown by Mr. Rowbottom.

GUSTAVE GRUNERWALD, described in our report of the previous meeting, was again brought up as a decorative variety in accordance with the wish of the committee. Shown by Mr. N. Davis.

MRS. C. B. MYERS, a fine Japanese variety, with drooping florets, colour white, tinted greenish yellow. A full sized, deep flower of capital form. Exhibited by Mr. Owen.

The weather in West Herts.—Until to-day (Wednesday), the past week has remained unseasonably cold both during the daytime and at night. On Friday in last week the temperature in shade rose only to 54°, while on five nights the exposed thermometer showed readings below the freezing-point, and on the coldest of these (Sunday) 4° of frost was registered by it. In my own garden no damage was done by this frost. Rain fell on five days of the week, and to the total depth of rather more than a quarter of an inch. The ground remains perfectly dry, no rain water whatever having come through the 2½ feet of soil in either of my percolation gauges for a week. On Sunday the sun shone brightly for over nine hours.—E. M., *Berkhamsted*.

Lilies from Colchester.—We send you a box of cut Lily blooms, taken mostly from plants growing out of doors, viz., *speciosum* Krätzeri, s. *Melpomene*, s. *macranthum*, and *tigrinum* Fortunei. Owing to the persistent drought, Lilies have had a bad time of it; their flower-spikes are short and the substance of the blooms thin where grown out of doors in the open. As regards pot culture, where moisture has been freely given it is quite different, and the blooms and spikes are very good. We have also included blooms of *Lilium neilgherrense* and *L. Henryi*. *L. neilgherrense* has flowered very freely with us and very early, but requires the aid of glass both to start it and to finish its growth. Imported bulbs, received late in spring in a shrivelled, poor condition, plumped up rapidly, started well to our surprise, and have now flowered freely, much better than could have been expected, thus showing that it is really a very vigorous Lily under proper treatment, but a cold, sunless summer is against it. The scent is very peculiar, like honey. *L. Henryi* has been grown by us both in pots out of doors and in the open ground. It is a grand doer. We received our bulbs from China in the middle of March last. They soon began to show above ground, and broke with us some six weeks later than those established at Kew. They are now in full flower some six weeks later than those at Kew. This Lily has evidently a very hardy constitution, and can stand drought well. It roots very freely, has dark green foliage and numerous flowers. It is, from these points

and from its novel colour, a grand Lily for the hybridiser. There are two points about this new form that we wish to dwell upon: Its very beautiful, broad, dark green central axes translucent like deep sea water, and the number of large processes of an orange-yellow colour which fringe these green axes.—WALLACE AND Co., September 20, 1893.

Apple Court Pendu Plat.—This is a pretty little Apple and keeps well, but the quality is not sufficiently good for dessert. When we have such varieties as Lane's Prince Albert and Wellington, which are of large size and keep equally as well, the small Apples on slow growing trees like Court Pendu Plat are scarcely worth cultivating.—E. W. B.

Proposed testimonial to Mr. Thos. Manning.—It has come to the knowledge of several head gardeners, through the press and otherwise, that Mr. Manning, who has been for nearly half a century so intimately associated with Messrs. James Veitch and Sons' establishment at Chelsea and elsewhere, is about to retire into private life, and the enjoyment of a well earned rest. The present is considered to be a fitting opportunity of offering to Mr. Manning some slight testimony in recognition of his courtesy and invariable kindness to gardeners on all occasions. Should any reader of THE GARDEN desire to avail himself of this opportunity of showing his appreciation of Mr. Manning's good qualities, the undersigned will cheerfully acknowledge any contributions that may be sent. Subscriptions, not to exceed 10s. 6d. each, will be received by the treasurer, George Wythes, Syon House Gardens, Brentford, London, W., or the hon. secretary, James Hudson, Gunnersbury House Gardens, Acton, London, W. By request the list is kept open till October 7.

Names of plants.—*W. J. Mitchison*.—*Ruellia macrantha*.—*C. Clarke*.—*Odontoglossum Lindleyanum*.—*G. B.*—*I. Cyrtium Fortunei*; 2, *Asplenium furcatum*; 3, *Adiantum assimile*; 4, a *Salaginella*, too shrivelled; send again and dry flat; 5, send better specimens; 6, *Adiantum Meritzianum*.—*H. M.*—1, *Anemia adiantifolia*; 2, *Mohria thurifraga*; 3, *Asplenium Selosi*.—*G. Archer*.—1, *Retinospora leptoclada*; 2, *Thujopsis dolabrata*; 3, *Abies canadensis*.—*C. James*.—1, *Cattleya aurea*, good variety; 2, *Laelia elegans prasiata*; 3, *Odontoglossum Schlieperianum*.—*J. Elliott*.—1, *Pulmonaria officinalis*; 2, send again; 3, *Atriplex littoralis*.—*C. Ames*.—1, *Miltonia Peetersiana*; 2, *Oncidium Jonesianum*; 3, *Lycaste Skinneri*, light variety; 4, *Lycaste Skinneri*, dark variety; 5, *Aerides snavissimum*.—*I. of W.*—1, *Habrothamnus elegans*.—*Col. Paget*.—*Paulownia imperialis*; the growths sent represent future flowers, which will open if late spring frosts do not injure the buds. —*Blackadder*.—*Lavandula Stachys*.—*H. Baverstock*.—*Plumbago Larpena*.—*Reginald Kelly*.—Kindly let us see flowers.

Names of fruit.—*H. S. Nevill*.—1 and 2, not recognised; 3, King of the Pippins; 4, Ribston. —*I. of W.*—1, *Fondante d'Automne*; 2, *Beurré Bosc*; 3, *Beurré Hardy*; 4, *Bleuheim Orange*.—*R. C. Coode*.—1, King of the Pippins; 2 and 4, *Blenheim Orange*; 3, *Fearn's Pippin*; 5, *Cox's Orange Pippin*.

"The Garden" Monthly Parts.—*This journal is published in neatly bound Monthly Parts. In this form the coloured plates are best preserved, and it is most suitable for reference previous to the issue of the half-yearly volumes. Price 1s. 6d.; post free, 1s. 9d. Complete set of volumes of THE GARDEN from its commencement to end of 1892, forty-two vols., price, cloth, £30 12s.*

"Gardening Illustrated" Monthly Parts.—*This journal is published in neatly bound Monthly Parts, in which form it is most suitable for reference previous to the issue of the yearly volumes. Price 5d.; post free, 8d.*

"Farm and Home" Monthly Parts.—*This journal is published in neatly bound Monthly Parts, in which form it is most suitable for reference previous to the issue of the yearly volumes. Price 5d.; post free, 8d.*

"Hardy Flowers."—*Giving descriptions of upwards of thirteen hundred of the most ornamental species, with directions for their arrangement, culture, &c. Fifth and Popular Edition, 1s.; post free, 1s. 3d.*

"The Garden Annual" for 1893.—*Contains Alphabetical Lists of all Branches of the Horticultural Trade. The Lists of Gardens and Country Seats (containing over 9000) have been very carefully and extensively revised, and are admitted to be the most complete ever published. Price 1s.; by post, 1s. 3d.*

All of our readers who are interested in the improvement of cottage homes are invited to help us to make Cottage Gardening known. It is published at the very lowest price to meet the wants of those for whom it is intended, and copies will be sent for distribution, free, by the publishers, Messrs. Cassell and Company, La Belle Sauvage Ludgate Hill E.C.

No. 1142. SATURDAY, October 7 1893 Vol. XLIV.

"This is an Art
Wh'ch does mend Nature: 'chang' it rather but
THE ART ITSELF IS NATURE. — Shakespeare.

ORCHARD AND FRUIT GARDEN.

APPLES FOR MARKET.

IN face of the extremely low prices realised for certain varieties of Apples this year, it may be worth some little trouble on the part of intending planters to study which kinds are likely to prove the most valuable in the future. Ecklinville Seedling is such a great bearer, and the fruit attains so large a size, that it has been extensively planted, and, judging from my own experience, many will wish they had planted it in smaller quantities. Various salesmen, both in the north and south, informed me that they had more difficulty in disposing of Ecklinville than any other sort. Being a soft Apple, it does not travel well, arriving in the market in a more or less bruised condition, and this season decay has set in almost immediately at the bruised parts, and buyers have fought shy of it after purchasing once. The good old Keswick Codlin is a favourite with many, but this I have always considered the most unprofitable variety I grow, for though it is most prolific, the average value is not more than 6s. per cwt. after deducting 1s. 6d. per cwt. for carriage, portage, and commission. This does not leave much profit for the grower when all home expenses are considered. There are many excellent kinds that are very popular with consumers (of the upper class) which will never pay to plant for market—for instance, Ribston Pippin, American Mother, &c., and it is important that growers should grow only a few varieties of good quality, large size, and handsome appearance. These, if marketed on proper principles, will not only pay well, but realise more than the best from the States or Canada. The following varieties have proved all that could be desired for market on our light sandy soil: White Transparent is a valuable early Apple, ripe about the end of July, first-class for cooking or dessert. The tree is a vigorous grower and very prolific. Coming into use so early, the fruit is a welcome change from Rhubarb and Gooseberries for tarts, &c.; consequently it has always sold at good prices. A capital successor is Duchess of Oldenburg. Like the preceding, it is of Russian origin; consequently it is hardy, and the tree a very free cropper. The fruit attains a fair size and most beautiful colour, causing it to sell freely. It must be carefully packed, as it is rather soft. Worcester Pearmain is so well known as a most prolific variety and producing such beautiful fruit, that any further description is unnecessary, beyond stating that the demand exceeds the supply every year. In spite of glutted markets, Worcester Pearmain has been in great demand this season, and for selling in large manufacturing centres no Apple equals it. Lord Suffield cankers so badly on some soils, that it cannot be universally recommended. Neither can Lord Grosvenor, as it produces so many small or malformed fruit here. A variety that promises to excel either is Cardinal. It comes into use about the same time as the two last named; the fruit is as large as Warner's King, with a bright crimson cheek, and is produced in

abundance. I have had many fruit's measure 18 inches in circumference. So far there is no sign of canker, and the growth of the tree is erect, sturdy, and covered with fruit-buds. Yorkshire Beauty answers admirably on our soil, bearing heavy crops of fruit. It always sells well, owing to its attractiveness. One of the largest fruit salesmen in the north informed me a few days ago that it sold better than any other variety in his market (Manchester). Pott's Seedling realises a fair price, and as the tree is an enormous cropper and the fruit large, it is worth planting; for smoky districts it has no superior. Frogmore Prolific crops heavily and is a desirable variety, but care should be exercised, as it will not answer on all soils. My favourite Apple is Lane's Prince Albert, which does splendidly here, producing immense crops of heavy fruit, which may be sold at any time from the end of September to the end of March, according to the state of the markets. A very good companion is Bramley's Seedling; fruit large and keeping well, tree a free bearer. King of the Pippins is excellent for market, and the following newer varieties promise to be a great acquisition, viz., Wealthy, Benoni, Bismarck, Gascogne's Scarlet, and Sandringham, all of which have so far carried good crops of handsome fruit. W.

Strawberry Laxton's Competitor.—This is worthy of a trial. The fruit is large and it has stood the drought fairly well. It comes in just after Noble, and though not so prolific either in producing runners or in fruiting on the young plants as that variety, it is hardy, very robust and a fair cropper when the plants once get well established. It should have plenty of room on good soils.—E. W. B.

Top-dressing Strawberries.—Plants of more than one or two seasons' growth are greatly benefited at this season of the year by a good top-dressing. This has especial reference to light or thin soils, or where the plants are apt to suffer much from drought. It will have been noticed that the older ones were the first to collapse during the past season. To obviate this or to lessen it considerably, a top-dressing of suitable compost will be found of great benefit, this assisting in the formation of surface-roots near the collar of the plants. It will also have been observed that as Strawberries grow old, hard woody stems are formed, and it is these which are the first to collapse under a heavy strain of bright sunshine and drought. In very many cases the plants quickly flagged, and when this was the case, all hopes of securing a crop of fruit had passed. Before adding the top-dressing the surface should be very lightly pricked over, but not deep enough to disturb roots. A dressing of soot should be first applied. The top-dressing should consist of burned garden refuse, some well decayed manure, and any other soil that may be at hand. Old Melon and Cucumber soil, surface soil from Vine borders, or anything similar is what is needed, the whole being mixed and spread over the surface, working it also well in about the crowns. If a depth of 2 inches or thereabouts could be given, it would be both labour and material well spent.—Y. A. H.

Quality in early Pears—By early Pears I do not mean those extra early varieties such as Jargonelle, Doyenné d'Ete, &c., but the varieties which are timed to ripen throughout September and October. These include Williams' Bon Chrétien, Beurré d'Amanlis, Souvenir du Congrès, Louise Bonne de Jersey, Fondante d'Automne, Mme. Treve, Flemish Beauty and a few others. The question is, which is the best method of growing these so that the quality may be so improved that they will be appreciated? According to my experience and observations in some other gardens, the quality of these varieties is best brought out by growing them in the open and away from the shelter of walls of any kind. I know it is some-

times recommended to grow them against an east wall, but in this position they do not receive sun enough. When the varieties mentioned above are grown in the open they receive the full benefit of the sun with a free circulation of air. Far better is it to occupy the space where either of the varieties are growing against a western or southern aspect with later varieties. Williams' Bon Chrétien and Souvenir du Congrès are certainly never so good in quality as when the fruits are produced from trees in the open, either standard or bush, and it is the same with that excellent hardy Pear Beurré d'Amanlis. Flemish Beauty, again, is excellent in quality this season. It is of no use to grow it against a wall; in this position certainly the fruits grow to a large size, but the quality is very poor. It is only since I took to growing it in the open that it has become satisfactory. The only two varieties which are improved by the protection of a wall are Beurré Hardy and Beurré Superfin, but on favourable soils and districts in the southern counties these are excellent in the open.—Y. A. H.

NOTES ON LITTLE KNOWN APPLES.

ALTHOUGH there is a very great number of sorts of Apples in cultivation, we cannot have too many provided they are worthy of attention and are a distinct gain when grown. Some sorts will succeed capitally in one county, while the same kinds will be looked upon as worthless in the next. A striking instance of this has just come under my notice. Here

BENONI is considered well worthy of extensive planting, so well does it crop and colour, while its habit of growth is all that could be desired, upright, and not too rampant. The fruit resembles King of Pippins very much in appearance, but is not quite equal to it in point of quality. It, however, has another virtue in that it ripens just when there is a dearth of dessert kinds ready for use. The early summer sorts, as Red Astrachan, Devonshire Quarrenden, and Irish Peach, are past, while such as Worcester Pearmain and King of the Pippins are not ready for use. In Kent, I am told it does very badly.

WEALTHY is perhaps, next to Peasgood's Nonsuch, the most shapely Apple we have. I have today gathered one fruit from a small tree bearing six others, which measures 1 foot in circumference and 3½ inches high. It is richly coloured all over, and certainly deserves attention in every respect.

CARDINAL, or, as it is sometimes named, Peter the Great, is an early ripening variety that must be valuable for market, as it is ready for use so early and of such a taking appearance. With me, however, its cooking qualities are not of the highest merit.

COUNSELLOR, or what is perhaps the more correct name, Greenup's Pippin, and by some named Yorkshire Beauty, is decidedly a handsome Apple. The fruit is large, smooth, deep yellow, with a deep flush of colour on the sunny side. It is a free bearer, and, what is of equal importance, its cooking quality is of the highest. It is one of those white-fleshed kinds that resembles a ball of flour when roasted, and yet firm. The smallest collection should include this.

BAUMANN'S RED REINETTE is one of the small or medium-sized dessert kinds, with exceedingly red skin, rendering it a showy and handsome Apple. It is a capital keeping sort and one of those desirable kinds in point of habit of growth, occupying but little space, the branches growing erect.

THE SANDRINGHAM is a somewhat new Apple, of free growth, bears well, and is most peculiar in point of colour, being a dense green until it changes to yellow after being kept some time. It is a late Apple of much promise.

QUEEN CAROLINE is of medium size, of exquisite shape and pure golden yellow even when hanging upon the tree. It is not a rampant grower, but is well adapted to a small garden.

HOLLANDBURY.—Those in search of an extra large Apple should cultivate this. From a two-year-planted tree I gathered twelve fruits, one

weighing just over 1 lb. In some districts it bears abundantly. A tree of it in this neighbourhood last year produced fifteen bushels of well coloured fruit.

GOLDEN SPIRE is a capital Apple to grow in a small garden where space is limited. It comes into use along with the early Codlins, as Lord Suffield and Lord Grosvenor. Golden Spire has an advantage, however, over those named in the matter of its keeping qualities, as fruit of it will last sound up to Christmas. The tree is of rather weak growth and needs spurring in rather closely to strengthen the branches. As it crops so freely, this method of pruning is suitable.

BRAMLEY'S SEEDLING is likely to take a high position amongst late varieties when it becomes better known. It is only within the last few years that its merits have been generally recognised. In constitution it is all that could be desired, and so it is in the matter of cropping. I know of no better sort to plant as a standard where late Apples are required and the position is at all exposed. In a young state also it bears freely. Fruits each nearly 1 lb. in weight I gathered this year on trees but three years from the graft. In strong soil it behaves admirably; the weight of fruit brings the branches downwards, keeping the middle of the tree open.

PINE-APPLE RUSSET is an Apple with a flavour peculiarly its own. As a mid-season dessert variety it is valuable, being ready for use at the end of September or early in October. It is of vigorous growth and does not fruit freely in its young state, but does so when well established.

SCHOOLMASTER is an Apple well adapted for small gardens, as it is not a rampant grower, bears freely and is of good cooking quality. The fruit is not extra large, and has a pleasing yellow skin with just a little colour on the sunny side. In strong soil the tree should be planted on a mound to ensure better drainage during the winter.

THE QUEEN is disappointing in some respects, being a little too flat in proportion to its width, which detracts from its appearance as a market Apple. In point of growth, cropping and quality it deserves high praise.

NANNY is much grown in this county and Sussex; it is an excellent dessert Apple, ripening as a rule in October, but this year it was ready for use in August, so peculiar has been the season. The fruit is of medium size, much resembling Ribston Pippin in flavour. It is an Apple worthy of extensive planting.

HARVEY'S WILTSHIRE DEFIANCE is seldom met with in private gardens; it grows to a large size, golden yellow skin with white flesh, an excellent cooking Apple. In form it is decidedly remarkable, having as it were five sides or parts.

TYLER'S KERNEL belongs to the section of conical-shaped fruit. The tree requires a good deal of attention in root pruning in its young state, as it is a vigorous growing kind.

Not only does the situation have a direct influence on certain sorts, but the soil is an important factor in the success or otherwise of certain varieties. Although some Apples will flourish in a heavy soil, many sorts are unable to bear the cold which soil of this character is liable to during the winter and spring. So much does it affect their maturation, that shoots made one season are killed during the succeeding winter. Where soil of this kind has to be dealt with, extra care in planting must be exercised; the trees should be raised above the level, their roots kept as near the surface as possible, just sufficient soil being laid over them to prevent their being injured by drought or otherwise.

E. M.

Bishop's Waltham.

The propagation of Strawberry plants.—This has been one of the worst of seasons for the production of runners, but if you have a limited quantity of any new or valuable variety which it is desirable should be increased with a view to growing an extended area speedily, it is quite possible to propagate a large number of runners in-

dependent of the weather by taking some care. First of all the plants should be put out, say 2 feet apart in rows, any time before Michaelmas, or, if laid in a sheltered position this autumn, they may be removed with soil attached next February, and 6 feet will be none too much between the rows. The richer the soil the better, and as moisture is essential to success, a mulch of rotten manure over all the ground will prove beneficial. No other kind should be near, or if near, it must be divided off with slates or boards, for it is of importance that not a single plant of any other variety should get mixed with it. As the runners push out in spring they should be pegged down, or, better still, covered with a little soil at the joints, and in a dry time watering must be done thoroughly and systematically. Weak liquid manure is very beneficial, and there need be little fear of giving the plants and whole bed too much in a season like the present. When the runners are spreading and rooting, weeds must be pulled up—never hoed, and if you wish to have the greatest number of plants, the bed should not be disturbed before winter. The runners are planted out in February—the best month of the whole year for planting on a large scale, and if the original bed is required for bearing, the strongest plants may remain at proper distances. By this method I succeeded, when Noble came out first, in raising 2000 runners from fifty plants. The original plants were purchased at Michaelmas, laid in for the winter and planted out carefully in April; so that if your land is not ready, or the weather or other circumstances prevent, it is possible with this prolific variety to plant runners for fruiting or propagation at any time up to the middle of April, provided due care is taken in the lifting and watering.—E. W.

Pear Williams' Bon Chretien.—This is generally classed as a not very frequent bearer, but this, I think, is on account of growing it either on a wall or as a closely pruned in pyramid or bush tree. As a standard, under which form of culture it has more head room, it is a much more frequent and regular bearer, freedom of growth being much in its favour. As a freely grown bush, it is also much more satisfactory, especially if care is taken to thin out crowded branches in the autumn. This has been a good season for this Pear, it being much more melting than usual, especially where care was taken to gather the fruits before they changed colour. It will ripen up better than any other variety, even when gathered two, or even three weeks before it is supposed to be ready; consequently its season may be prolonged for a much longer period.—Y. A. H.

Pear Louise Bonne of Jersey.—This is one of those fine Pears which for September or early October use has few equals. In some gardens it is no infrequent occurrence to see several very old trees trained to walls on various aspects, although I do not consider it by any means an ideal variety for a wall, the quality not being nearly so good as when cultivated in the open. Grown under this latter form either as a standard or a bush on the Quince stock, and not allowed to hang too long before being gathered, it is really a delicious fruit, and, what is better, it does not go off nearly so quickly as the majority of early Pears. Where planters are on the look-out for fruit trees to plant for effect as well as utility, Louise Bonne of Jersey will be found suitable. As a standard it takes on a pyramidal form and towers upwards, its heavily-laden branches of ruddy-checked fruit showing up conspicuously. After the fruit is gathered there remains the highly coloured, bronzy crimson foliage.—H.

Storing Apples.—From all parts of the kingdom the same accounts are to hand—most abundant crops of Apples. Old trees that had long been given up as useless, young ones only recently planted, or those in their prime, are all loaded with fruit, and, as a matter of course, Apples at the present time are only realising low prices in the market. It is surprising, with the quantity grown in all directions, that they realise as much as they

do, considering that varieties which should be kept for mid-winter supply are gathered and sent direct to the market for present use, thereby forcing down the price of sorts that must be used lower than they otherwise would be. I have lately seen in quantity Blenheim Orange, Wellington, Lane's Prince Albert and other good keepers which only need storing for a few weeks until the glut of the midseason sorts are over. I fear that many have an idea that some very elaborately constructed fruit rooms are necessary, with tiers of shelves, &c., for laying the fruit out in single layers; whereas, this sort of thing is not only not required, but is by no means the best means of keeping Apples crisp and juicy until mid-winter or even far into the spring. My plan is to sell all early and midseason varieties either direct from the tree or after they have been gathered about a fortnight, and only to store those that will keep for some time. It is a mistake to gather these too soon, for if some drop, it is better to utilise them as windfalls than to spoil the whole crop by premature gathering. By leaving until fully ready for storing, all maggot-eaten fruit will have dropped and nothing but sound fruit be left. These if gathered with care and put into barrels, boxes or bins, or even into large heaps covered with straw, will keep far better than on elevated shelves. It is useless expecting townspeople to store fruit or anything else, as the space at their disposal only allows them to live from day to day, and the storing must be done in the country. It is playing into the hands of the foreigner and importer to rush late Apples on the market and sell them for little more than half their value.—JAMES GROOM, *Gosport.*

COARSE FRUIT.

"FRUIT GROWER'S" most sensible remarks on this (p. 240) are, unfortunately, very far from being out of date. Since the sensible test of tasting as a test of quality has fallen into abeyance, size has had the cream of many great shows. Of course, it was very trying to exhibitors to have their choice fruits hacked out of selling form or value through the testing and tasting of jurors, who insisted that the proof of the fruit, as of the pudding, lay in the eating of it. Occasionally, too, the tasting was carried to extreme, as once at a great show at Manchester, when all that remained of a first prize Melon exhibited by me was a few slices of rind and fewer seeds; but the quality was so superb, that the jurors, and their friends could not resist the temptation. But generally careful tasting does not involve demolition or serious disfigurement. Of course, it lowers or destroys the selling value of the fruit; but what of that? The honour of prizes, to say nothing of their value in hard cash, is supposed to be a sufficient compensation for the loss of or injury to the fruit. I do not deny that not a few of our most experienced judges may award prizes according to merit without tasting it there and then, but such awards of precision can only be arrived at through a long series of previous tasting and the most careful assessment of the character and condition of the fruit before the judges; hence, judging by appearance is far more difficult and needs a larger stock of fuller, riper knowledge than judging by direct cut and taste on the spot. The fruit is saved, its selling value preserved at the cost of the jurors' brains, and at a greatly increased risk of failure. That is assuming that the jurors are familiar with the merits of special varieties and with their appearance when in the most perfect condition. For example, such judges will be in little danger of confounding the bloom, colour, size, and quality of such Grapes as Hamburgh, Alicante, Gros Maroc, Madresfield Court, Muscat of Alexandria, Foster's Seedling, or Buckland Sweetwater. No experienced judge

would pit the special merits of either of these Grapes one against the other, as is so often done, to the great wrong of exhibitors and the serious discouragement of horticulture. To make my meaning clearer, I may say that there are some judges who will place almost any Muscat Grapes before the very best and white Grapes of any other sort, and who have such a craze for bloom, that they will place indifferent Alicante, Lady Downe's, or any other sour Grape over the heads of the most luscious Hamburgs. Bloom, as a rule, is prodigiously overrated, and yet all experienced cultivators are well aware of the fact that its maximum amount or density is seldom found abreast of maturity—that is, quality. A certain, I had almost written a considerable, amount of acidity is well nigh inseparable from the heaviest coating of bloom, and yet how many award prizes to Grapes for bloom chiefly. Doubtless it is beautiful in its way, and may even indicate careful finish, handling, and carriage, but it is at best but a flimsy as well as an evanescent basis of quality. And as for big Peaches, where shall we find any to beat in flavour the Royal George, Noblesse, or Grosse Mignonne? I agree with "A Fruit Grower" that judges of late seem to have had a craze for size among Apples, Plums, and Pears, especially Plums. It is marvellous to have seen the high place given to Pond's Seedling, Prince Englebert, Diamond, White Magnum Bonum, and Goliath, in open classes of Plums, while the luscious merits of Coe's Golden Drop, Jefferson, Kirke's, Oullin's Golden, and the Gages, Green Transparent, &c., seem to have been overlooked or underrated. A good deal of this might easily be prevented by the classification of Plums into the two classes of cooking and dessert, while simple tasting in open classes would give a fair chance as against size. D. T. F.

FIGS FOR FORCING.

I HAVE much pleasure in supplementing my note on the above, as requested by "D. T. F." (p. 253). I only mentioned two kinds of recent introduction in my note because many growers of this fruit have not had an opportunity of testing the value of these varieties. The note by "D. T. F." finishes with the remark that good culture is the best preventive of dropping, and I agree with it. Some varieties are worse than others in this respect, but under pot culture there is a certainty of a crop, provided there is attention to details, as under pot culture several kinds succeed which are otherwise useless. I am of opinion that there are few crops which better repay good culture than Figs, as good fruit may be had eight months in the year. It is not wise to allow forced plants to continue to fruit and exhaust themselves if required to force early the following season, as a certain amount of rest must be given.

With regard to "D. T. F.'s" question as to the merits of the older varieties, I would place Brown Turkey at the head of the list for most purposes. I admit it does not come first on the list for flavour. I would give Bourjassote Grise or Monaco Bianco the preference for flavour, but the latter are not so reliable as Brown Turkey. In placing Brown Turkey in so exalted a position I may be taken to task. From close observation I am of opinion there are other points to be considered. Are there not various forms of this variety, some far superior to others? Indeed, I have seen so-called Brown Turkey small and even third-rate as regards flavour. We have an old tree planted at the back of a vinery that gives mag-

nificent fruits, and in quantity, whilst its near neighbour is much inferior in every way. Of course we do not perpetuate the stock of the latter, but being large trees one cannot get rid of them in a hurry. In this case soil cannot have any influence on quality, so that, as previously remarked, there are good and bad varieties of Brown Turkey. I fail to see any difference in any way in the last named and Lee's Perpetual and Osborn's Prolific. Mr. Barron, who grows this fruit to the greatest perfection in pots at the R.H.S. Gardens, Chiswick, classes them with Brown Turkey, and he has tried nearly seventy kinds, so that with its numerous synonyms the original stock may have deteriorated in places, and under the circumstances it is best to get trees from a good source. Our next most useful Fig is the White Ischia. There is a serious objection to this variety on account of its small size, but the tree is very prolific, the fruit of first-rate quality and early. It is a shy first cropper if the wood is not hard stopped and plenty of light allowed. We have trees of this kind which have no doubt been planted nearly forty years that bear enormous crops; this is also a grand variety for pot culture. I do not consider the Black Ischia of so good quality as the white, so do not grow it in quantity. Early Violet I do not care for, owing to its small fruit and inferior flavour, though it is a great bearer under pot culture and a good forcer. I prefer the Black Marseilles, a small fruit, but richly flavoured. White Marseilles is a good forcing Fig either in pots or planted out, and was one of our most useful pot varieties. Of late I have not grown it, as the St. John, one of the newer introductions, proves a better fruit, being richer and not so watery as the White Marseilles, and more prolific. I gave Nebian a trial last season; it is a large showy Fig with a deep green skin and bright red flesh, very rich and free bearing, but it is useless to force it early. The fruit also splits badly. Brunswick, a variety "D. T. F." mentions, I can recommend for early forcing in pots. It is a Fig of great merit, but second-rate in quality. It is excellent for a warm wall in the open, where this fruit succeeds. I grow the early trees in 12-inch to 14-inch pots, and keep them dwarf, as I force the pot trees in small pits, and by propagating or purchasing occasionally newer kinds I keep up a succession of young trees. Plenty of good yellow loam well mixed with old mortar rubble is a good compost, using manures sparingly in the soil. Firm potting and plenty of food in a liquid state when in fruit are essential. I never saw pot trees look better than they do this season, the wood being well ripened and a mass of fruiting spurs and shoots. These are now standing in the open, the roots being protected from heavy rains and frosts. G. WYTHES.

Apple Annie Elizabeth.—Even in this bountiful season of Apples there are some varieties which show up conspicuously. The above-named variety is one of them. This has done well with me this season both on young standards and freely grown bushes. As an orchard standard to produce fruit for storing for late use it is one which I can well recommend.—Y. A. H.

Apple Gibbon's Russet.—This, to my mind the finest of all midwinter or late-keeping Apples, I must again refer to in order to put "D. T. F." right as to what I may have left unsaid in any previous notice. I never intended to convey the idea that placing the fruit in a close drawer for a period was for any but the one purpose, viz., the getting the fruit's most unique perfume. As regards the term "Cherry Brandy Apple," this needs supplementing, as the fruit was known in other localities as "Syrup and Brandy."

The Apple is highly coloured this year in old orchards where the soil rests on limestone, but the trees are worn out.—W. BAYLOR HARTLAND, Cork.

Apple Peasgood's Nonsuch.—In my note on the above-named Apple (p. 273) a curious mistake occurs. I am made to say, when recommending it for standard culture, that the fruits are "not so large as those produced from the more highly 'cropped' bush trees." The sentence should read "more highly 'cultivated' bush trees."—A. YOUNG.

Apple Hambleton Deux Ans.—"A. D.," in his interesting article on "Old Apple Trees," refers to the Hambleton Deux Ans as being a most valuable late Apple, a statement I quite agree with, that is, when produced from trees growing on a warm soil in a favourable climate. During the spring months it is of excellent flavour.—A. Y.

Russet Apples.—Never have I seen or tasted better Russet Apples than in Herefordshire, where the trees were growing on a warm site, the soil overlying the old red sandstone formation. Here on a clay soil the Russet Apples will not thrive nearly so well as they used to do there, and this I find is a general experience on cold soils. The Brandy Apple or Golden Harvey, as spoken of by "D. T. F.," is a beautifully flavoured little Apple. Both Royal Russet and Golden Russet are excellent varieties on suitable soils, but I think the palm must be given to Egremont Russet, which is a beautiful looking Apple and of excellent flavour. It is hoped that planters will not neglect the Russet Apples where they can be grown well.—Y. A. H.

GRASS DRIVES AND WALKS.

IN the larger country places the often noble opportunities for beautiful woodland drives are not always seized; it is often because people have the primitive and wholly inartistic idea that the proper way to make a drive is to plant two or four lines of trees along it. These are usually planted far too close at first, and as the trees are in nine cases out of ten never thinned in time, the whole thing ends in a gloomy tunnel without air, light, shade, or life. Even where the avenue is not the "leading feature," drives through woods and parks are too narrow! Noble effects might be got by breadths of low covert or fern on each side of the drives. These drives should take the lines of easiest grade and the best for views where possible. There is no reason why they should not pass under trees here and there, but generally a better effect is got by keeping the stately groups and trees a little off the drive itself, and having fine groups of hardy shrubs and carpets of things as a foreground to the woodland picture.

Here and there, as at Penrhyn, we have seen beautiful gardens of wild Ferns coming near the drives, and there is a lovely example at Powys of the value of our native plants in the foreground of a really picturesque drive. But by a little forethought we might easily get finer things in this way—Fern, Heath, Foxglove, or Willow Herb, wide sheets of large Ferns with breaks of wild Roses, large and rambling colonies of Sweet Brier, lovely fields of native Heaths, double Furze, as well as the common kind, Broom on warm banks and hills, Partridge-berry for the hollows and half-shady places, and a host of beautiful things that would spread about and give excellent covert and pretty effects. Of regularly formed

drives and roads there are three times too many in most large country seats. We mean those of gravel, flint, or other stone. It is very good economy to reduce them to the needs of the place. All places are uglier for being beset with gate lodges, usually ugly in themselves, and leading to needless cutting up of beautiful ground, increase of gates, and the springing up of the iron fiend in every direction. As the artistic and true way is to reduce as much as possible these needless drives, either made through vanity, or to save five minutes, let those we keep be as good in grade and view as we can make them, and have many pictures by them.

GRASS WALKS.

What we never have enough of is grass walks and drives. When we want a way merely for our own pleasure or convenience, by far the best thing is often a grass drive or walk through pretty woodland scenery, park, hill, or by stream or river. A delightful privilege which English gardens have and few others possess is that of having grass walks of the finest texture and verdure. At Holwood, in the late Lord Derby's time, it was pleasant to see the great range and the delightful charm of the grass walks there. Around our houses we must have good firm walks; but once free of the house and regular gardens, one may break into the graceful lines of grass walks without injury to anything. Some say that they like dry walks in winter. The gravel walk is not much drier than a well-made grass walk, but as people use their gardens in summer most, it does not matter so much. Even in heavy soils grass walks may be delightful throughout the greater part of the year, and on dry soils grass walks are as dry at all times as those made of gravel.

It is not only the effect of grass walks that is in their favour—they are a great economy. These grass walks can be cleaned with one-fourth of the labour which the gravel walks take. In many gardens, where there are now gravel walks, a much better and happier effect would be got by good turf walks. But, free of the garden, it is rather in the rougher parts of the pleasure ground and about the park that grass walks are made with the best results. They should be taken in the most picturesque and interesting lines. The line of ground should be studied both for ease in walking and mowing, and for the sake of the best views. Nothing in gardening rewards us so well as well-considered grass walks. To reduce gravel walks to the necessary area, grass walks in many positions where gravel walks are used enable us to do this. If, as we hold, the walks about the house are reduced to the often strictly necessary dimensions, it is surprising how much the old and wearisome trouble of hoeing is done away with. The toilsome labour of ripping up walks, raking, and hoeing seen in so many gardens need not, happily, go on. It only makes matters worse by softening the walks for the weeds, and is a serious labour for the men in the hottest season.

Having got our grass drive or grass walk, what shall we place beside it? Our common British plants are as fair as any others. Sometimes we see as beautiful groups of Fern, Heather, Thorn, and Bramble as one could see in any country. Still, those who care for the plants of other countries have a charming opportunity of adding other pretty things to our own wild flowers.

There is a great difference in places as regards wild flowers and beautiful effects from native shrubs. Some may be full of beautiful shrubs and trailers; others have very little. What a place has in this way depends upon the cultivation and the quality of the land and other conditions which need not be gone into—it is enough to know these differences exist. Where the natural vegetation is poor, there is all the greater need for adding beautiful things of easy naturalisation. Our wood Anemone is pretty in the fields and groves in spring, but the blue Apennine Anemone, which is quite hardy, gives us a wholly distinct and charming colour; and so with many other things. Then the high mountain plants of the Alps of Europe, to whose flora these and many other early flowers belong, give us a precious gift in earliness. The Crocus, early Narcissus, and the Scilla all come before our own vegetation is awake, while nearly all are as hardy as our own native flowers. Then there are the many hardy climbers which, if we care to put them about or against trees, would be quite as beautiful as any native climber, of which the number is small. The Indian mountain Clematis is hardy and as easy to establish as our native Clematis, while we think it is much more beautiful; in fact there is no end to the beautiful exotic things one may add to our own flora in such positions.

The prettiest group of shrubs we ever saw was an immense group of the common *Barberry* in fruit at Compton Winyates, weeping down with glowing colour.

Much may be done in the direction of grass walks to take them not only where the views and landscape charm us, but also where the native flora shows itself best. Very often our common Ferns in the west country and in moist districts make themselves great ferneries which ought to be seen. The idea that the fernery can only be made with heaps of old stone or other rubbish is too absurd to be worth disputing. The plants rarely ever grow in that way, and certainly not the most vigorous and effective of Ferns which make evergreen covert and give such cool and beautiful effects. There are also a number of fine hardy North American and other Ferns tempting us to naturalise them, but for all artistic ends our native Ferns are sufficient as far as effects by drives are concerned.—*Field*.

THE "FLOWER GARDEN" AT KEW.

WE hope the improvements so manifest as regards hardy flowers in many parts of the pleasure grounds at Kew will not stop at the flower garden in front of the Palm

house. Two large beds of common Beetroot form the central feature of this, and masses of flowerless Pelargoniums and dots and stripes of red and blue are not worthy a place as a flower garden in the Royal Gardens at Kew. If the idea exists that a garden in such a position cannot be made beautiful through the aid of nobler types of vegetation, it is quite erroneous. That is a position above all others in which beautiful things, gracefully grouped and well grown, would tell best. The scarlet Pelargonium in the dry soil of Kew is as well worthy of a place as any other flower, but it is only one of the many beautiful things that should find a summer home there. Some of the prettiest beds of half-hardy flowers in the parks might well find a place here, and are far before the Beetroot, &c., of the present year. In such a flower garden it would be well to use the best of the half-hardy flowers also. Moreover, where the collection is so rich in sub-tropical and other half-hardy Palms, Oranges, Oleanders, Datura, and many beautiful plants which enjoy, and are all the better for, a sojourn in the open air during the summer, it would be well to make artistic use of them, and put them in groups not only in the flower garden, but also in the unused parts of that waste of gravel around the Palm house.

So, too, that piece of water between the museum and the Palm house should be a garden of handsome water flowers which to Victoria regia house in the world would equal in beauty. Not only Water Lilies and beautiful water flowers of the northern world have we to enrich such water now, but, owing to our friend M. Latour-Marliac, we have a noble series of hardy hybrids, groups of which in such a position would give delightful pictures. The unclean water-fowl should be taken somewhere else—to the Zoo, perhaps. The banks of this water should be planted with the many fine plants, such as *Spiraea venusta*, which delight in the waterside, flower at the same time as the Water Lilies, and would form with them a garden worth seeing. The flowering herbaceous plants for the waterside are numerous and handsome, and, seen in bloom at the same season as the Water Lilies, give effects which few people have any idea that gardens are capable of. Then, after the Iris and Globe Flowers, and other handsomer flowers of the waterside, there are many plants with fine habit, as the Gunnera, great Reeds, some hardy and free Bamboos, Royal Ferns, great Water Duck and Bulrushes, and the more graceful and smaller Reeds, Arrowheads and Reed Mace. We not only wish these things for themselves, but for the good it would do in the minds of the many people who see Kew. Unhappily, the idea that a flower garden can only be formed of a few things in a stiff way is still very common even in the "fine places" in the home counties, and a real flower garden at Kew would do much to dispel it. Thousands of gardens would be influenced for good if the right thing were done in the flower garden at Kew; and it is very easy to do it there.

W. R.

POWIS CASTLE.

OF the many gardens we have seen, very few give us the pleasure of Powis—first, because of its noble drive through great Oaks with breaks of Fern between, so unlike the dark inartistic avenue which spoils so many places. The light and shade and the noble forms of the trees, and also their contrast with fine-grown vegetation, make them ten times more beautiful than any primly set-out avenue. The flower garden itself is very beautiful, partly owing to its position, which is that of a real terrace garden—*i e.*, the ground falls so steeply, that terracing is necessary. These terraces were, as they should be, wreathed with Clematis and beautiful with shrub, and flower, and life, a picture of what a flower garden should be.

A friend who has recently visited Powis sends us the following description of the garden and grounds:—

Powis Castle, Welshpool. Engraved for THE GARDEN.

masonry for the formation of the highest of the three terraces. Glancing over a balustrading from the castle level on to the terraces beneath, the scene is gorgeous, and we are struck at once with the harmonious blending of the flowers and their surroundings, and one very marked improvement we note has of late been made in this respect, namely, the substitution of a warm red gravel on the paths for a very cold and ineffective grey material. A very happy idea has been adopted in regard to colours, the three terraces having each its predominating colour, viz., the lowest white, the middle yellow, and the highest purple; not that other colours are excluded in either case, but these characteristic tones are maintained all through.

Entering the lower terrace by means of a winding pathway, and through an entrance in a pathway of stately Yews, the effect is dazzling. A broad pathway runs from end to end of the terrace, deviating only where it encircles an oval bed on a broad platform in the middle,

for edging and the same white Pansy, backed by the old Vesuvius Colours, then a broad band of Flower of Spring Geranium and a band of Lobelia cardinalis intervening between these and clumps of Tritomas, Dahlias and other sturdy subjects, with an elevated vase in the centre, from which *Tropæolum canariense* gracefully depended. To the back of this bed is a conservatory-fernery, the roof of which forms the pathway of the next terrace. This house was occupied by some interesting plants and Ferns. In another bed to the front of the oval we notice a very pretty though simple arrangement, consisting of H. Jacoby Geranium (crimson) and a good white Geranium dove-tailed into it, backed by yellow Calceolaria. Although design and method are abundantly apparent, there is no air of formality in any of the arrangements, the stiffness of lines, &c., being quite broken by the Clematis, &c., already mentioned, supplemented by Roses, standard and dwarf, Sunflowers, Solidagos, Golden Arbor-vite, Silver Elders, Irish Yews, Hollies, Japanese Maples, Tree Peonies, Tobacco plants, &c. The walls of this terrace are furnished with Roses, Clematises, Pears, Peaches, Nectarines, &c. In the latter cases crops have been exceptionally good this season and the trees are in capital condition. On the next terrace are some more fruit trees on the walls, and more Roses too, and, what is not seen every day, a fine plant of Pomegranate, which flowers freely every season. Magnolia conspicua, too, is good. There are also fine plants of Wistaria sinensis. This terrace is considerably narrower than the first and differently arranged. From the centre to one end, the higher side of the walk is finely planted with Carnations in splendid variety and rudest health. The other side contains among other herbaceous plants Gladioli, &c., and a capital representative collection of Helianthus. Extending from the centre in the opposite direction, among a number of closely clipped Yews and a few remarkable specimens of Irish Yew, are Dahlias in large quantities, Roses, tall growing herbaceous plants, with semi-circles, the band of which is formed mostly of Coleus and Flower of Spring Geranium, and the interior filled with one subject in each space; sometimes tuberous Begonias, which do well, Geraniums in colours, fine-foliaged Geraniums, &c., the semi-circles at intervals on both sides creating quite a striking effect. I had almost forgotten the early-flowering Chrysanthemums and the Fuchsias, which are doing splendid service here; also the clumps of Pampas Grass that add considerably to the general effect.

Powis Castle is a few miles inside the Welsh border, and close to the old town of Welshpool. It occupies a most commanding and picturesque position on the crest of a bold eminence, from which the several passes in and out of the Principality can be seen, a fact of great importance in the old days of feudal strife. The extent and variety of the views obtained from the castle heights are charming in the extreme. The Breidden Hills tower majestically in the distance in the direction of Salop, and the windings of the Severn carry the eye through the fertile valley away into the several Welsh ranges in the opposite direction. As the original name, "Castell Coch," signifies, the castle is built of red sandstone, and the formation upon which it is founded is of the same material. The terraces, too, of the famous hanging gardens are literally hewn out of this red rock, which forms the walls, for the most part unaided by masonry. Indeed, an artificial height is given the castle by the great depth of its foundation being cut away nearly perpendicular from the

and on either side broad borders are richly and tastefully furnished in charming variety. A feature of this terrace has been for years a number of dome-shaped trellises 8 feet to 10 feet high covered with Clematis Jackmanni, and recently the effect has been heightened by the introduction of many more trellises and other light-coloured varieties of Clematis. Here and there a blaze is produced by the aptly called Flame Flower (*Tropæolum speciosum*), which is induced to cover a few branching sticks loosely, and to suspend therefrom in graceful festoons of brightest colour. Pyramids of Sweet Peas are very noticeable, too, among the wealth of the most deserving perennials and choice annuals which back up the bedding style proper, the latter consisting of a very dark and dwarf Lobelia as an edging, behind which is a very fine white tufted Pansy, backed again by West Brighton Gem Geranium. This arrangement is carried throughout this terrace with the exception of the centre oval bed referred to, which has also the same Lobelia

Ascending to No. 3 terrace, we find still further surprises in store. Beds of Geraniums worked in four distinct colours, and the beds themselves in pairs, prepare us for more formal designs which we find in several distinct beds of pretty and effective colours, worked with Lobelia, Alternanthera of sorts, Mesembryanthemum, Sedum, Echeveria, &c. The most effective bed to our mind and according to the expressed opinion of our genial guide was a round, somewhat large bed with a groundwork of *Tropæolum Mrs. Clibran*, with an edging of purple Pansy and a light dotting of a somewhat dark coloured Fuchsia. The lovely warm golden colour of the *Tropæolum* in such a mass was very effective. Cactus Dahlias are evidently favourites at Powis Castle, and are represented by a very fine collection. Among other things not already enumerated the following are conspicuous: Scabious in good variety, Love-bleeding (red and white, the latter being a favourite of Mr. Lambert), Everlasting Flowers

of all kinds, Centaureas, Convolvulus, Mari-golds, Asters everywhere, Stocks, &c. The varieties of Geranium principally used are Lord Eversley, Queen of the Whites, Ferdinand de Lesseps, Henry Jacoby, Flower of Spring, Vesuvius, West Brighton Gem, Avalanche, Master Christine, Black Douglas, Lady Cullum, Prince Silverwings, Sophia Dumaresque, &c.

Several of the large Yews that skirt the castle have recently been pruned in considerably, thus affording views long hidden. Much judicious thinning and pruning have been well carried out of late both among these fine old Yews and other trees. Among the former splendid trees there is one whose branches had overgrown the path, and by continual clipping has become quite a summer-house, wherein a seat has been placed, which doubtless is much resorted to as a curiosity as well as a shade. Leaving the flower garden by the opposite end from which we enter, we pass some useful pits and houses for the propagating and storing of the immense quantities of bedding plants necessary in such a garden, and one old structure we find has been considerably altered and improved by replacing flues with hot water, &c., and here we find a splendid young plantation of Vines, among them being some of the recent new varieties. Underneath, on stages and in specially designed wall pots, are a capital lot of Maiden-hair Ferns much in demand for decoration.

From here we are conducted by the end of a pretty dingle into a fine woodland called the wilderness, which is for the most part on a sunmit running parallel with the hill on which stands the castle. Immense trees are luxuriating here, and in the shelter afforded by them are clumps of Azaleas, Rhododendrons, Skimias, &c., of quite unusual dimensions. Much has been done here during the last year in the way of thinning and opening out of glorious views to the opposite hills, &c. A grand view of the fine old Castle of Montgomery has thus been obtained, and more remains to be done when time permits. In the kitchen garden there are fine breadths of Strawberries, and quantities of these in pots for forcing. Here, too, is a fine hatch of Calla æthiopica and Calla Little Gem, the latter flowering, and both promising abundance of bloom later on; Solanums also planted out and loaded with berries. A large plantation of Cabbages; Ellam's Early, Battersea and Heartwell are planted 1 foot apart. During early spring every other is cut away, allowing the remaining ones 2 feet space each way. Batches of Bouvardias and other winter-flowering stuff in frames, and particularly a fine lot of Cyclamens, are in splendid condition, and batches of Amaryllis are equally good. Gardenias plunged in cocoa-nut fibre and useful batches of Poinsettias, Carnation Souvenir de la Malmaison, winter-flowering Begonias, &c., are all in the best possible condition, awaiting their own times of flowering. The old vineries are being renovated piecemeal, a policy that secures a crop during the renovating process; indeed, a crop of Grapes here is quite indispensable. The newly-planted Vines in these several vineries are making good progress notwithstanding the crowding occasioned by a stock of fruiting canes in pots that have done excellent service by the weight and quality of their produce. There is a lean-to house in two divisions for the early batches of pot Vines, from which Mr. Lambert secures a remarkable succession of crops in addition to Grapes. Whilst Vines occupy the centre bed, Strawberries crowd the stages near the glass front and back, giving way in their turn to Tomatoes, which share the roof space with the Vines,

until the latter in their turn are after fruiting consigned to other quarters. Then the bed is filled with fibre or other plunging material for the reception of a splendid batch of Amaryllis, the Tomatoes being kept on during winter, and French Beans, &c., filling whatever gaps there may be until the Strawberries, &c., demand their own place again. Pines, embracing Queens and Smooth Cayennes, are in the most perfect health.

Miscellaneous plants for decorations fill several houses, Calanthes being particularly good in one of these structures. A fine lot of early-flowering Chrysanthemum Mme. Desgrange was carrying quite large blooms under the shelter of some old lights that were raised on stakes, leaving the front and sides open, and a little further along some hundreds of the later kinds in bush form for cutting, beyond these being several hundreds more of dwarf, stout, healthy plants for the production of large blooms.

STOVE AND GREENHOUSE.

BOUVDARIAS.

As flowering plants for the greenhouse the different varieties are very valuable, and where there is a demand for the choicer class of flowers for button-holes, sprays, wreaths and similar purposes, Bouvardias are extremely useful. Blooms of them can be had to a limited extent almost throughout the year, but their regular season of flowering is in the autumn and winter, when, of course, they are more appreciated than at any other time. For winter flowering the cuttings are usually struck early in the spring, potted off as soon as rooted, and grown on during the summer months. Different methods are followed by cultivators, for by some the plants are kept altogether in pots, and by others planted out in a frame (under which conditions they will grow with great freedom) and carefully lifted and potted in the autumn. When this last is carried out, the plants should be kept close and shaded from very bright sunshine till they have recovered from the check of removal. The nurserymen that grow Bouvardias in large quantities, as a rule, keep them altogether in pots, for neat flowering specimens may be had in pots 5 inches in diameter; whereas, if planted out they would receive so great a check to get them into pots of that size that the plants would suffer greatly, and large pots are, as a rule, not appreciated by buyers. Large specimens for conservatory decoration where pot-room is no object can be grown well on the planting-out system, and so can those needed for the supply of cut blooms. For this last purpose if the old plants are in the spring, when all danger from frosts are over, planted out in a warm prepared border, they can in an ordinary summer be depended upon to give a good sprinkling of flowers, which are very useful, for even with the wealth of bloom at that season, Bouvardia flowers are sure to be appreciated. With the advent of the first double-flowered variety, Alfred Neuner, this section of Bouvardias was thought to have a very great future before it; but Alfred Neuner still remains the only one of this class grown in any quantity, for the second that made its appearance—the pink-flowered President Garfield—was not sufficiently decided in tint to make much headway; while the bright-coloured forms with double blossoms—Hogarth fl.-plena, Thomas Meehan, Sang Lorraine, Victor Lemoine, Triomphe de Nancy and the yellowish flavescens fl.-plena—have never been grown to any great extent. Of single kinds with white blossoms, Humboldtii corymbiflora, a somewhat upright, vigorous-growing form, with long-tubed, Jasmine-like blossoms that are most deliciously scented, is good, the only drawback being that the tube of the flower is weak, and from its length

liable to be broken. The variety Purity is of dwarfer habit and with a shorter tube to the flower than the preceding, and altogether it is well worth the award of merit bestowed upon it by the Royal Horticultural Society on October 14, 1890. Other whites belonging to the hairy leaved scentless class are Bridal Wreath and Vreelandi, both of which are, however, liable to become tinged with pink. Of bright-coloured blossoms far and away the best is President Cleveland, but other good ones are elegans and Dazzler. The salmon-pink sport from President Cleveland—Mrs. Green—is, except in colour, the counterpart of its parent; while Priory Beauty and rosea multiflora are also good pink-flowered kinds. The sulphur-tinted flavescens adds variety, while two species, triphylla and leiantha, are both pretty bright-flowered kinds.

H. P.

Tabernæmontana coronaria flore-pleno.

—The genus Tabernæmontana is a pretty extensive one, but very few members of it are in cultivation, and that above mentioned is, as a rule, the only one to be met with in gardens. It is a very beautiful stove shrub, with pure white, sweet-scented blossoms, not so large and double as those of a Gardenia, but more like those of one of the Oleanders. The oblong-shaped leaves are of a dark glossy green, which serves well as a setting to the pure white blossoms. The typical form with single flowers is also very pretty. This Tabernæmontana has been known in this country for more than a century. It is often seen in a by no means flourishing state, owing in some cases to overpotting (for this must be especially guarded against), and in others to being drawn up in a shaded place. Given much the same treatment as a Gardenia it will succeed perfectly, and produce its pure white blossoms in great profusion. If in pots a compost of good loam and peat or leaf-mould with a liberal dash of sand will suit it perfectly, and in potting thorough drainage must be ensured. Plants grow freely during the summer, and thoroughly ripened by full exposure to the sun afterwards will flower well in the spring, but its season of blooming is not limited to any particular period of the year, for I recently saw some good examples in flower.—H. P.

A hybrid Amaryllis, a cross between A. Belladonna and Brunsvigia Josephina, is flowering in the frames against the economic house at Kew. We admire greatly this splendid cross, and hope that this good work will not be discontinued, as the hybrid is a distinct gain to the garden. It is quite different in general aspect to the well-known Belladonna Lily, of which there is a perfect forest of spikes, near the same place. The great distinction is in colour, the hybrid bearing smaller flowers, but they are of a brilliant rose-purple, very rich and striking, and appear to have larger heads, whilst the scapes are taller, and the colouring is more of a glaucous tone than the rich chocolate of the Belladonna Lily. Such a brilliant flower should be more known, as it would look well in pots, but a mass of it in the garden at this season would create a superb effect. The only disadvantage is that the position must be warm and sheltered.

Notes from Gunnersbury Park, Acton.—There have been seasons when Amaryllis Belladonna has flowered better at Gunnersbury Park than in others, but this year it may be said to have established a record, so freely has it bloomed. The dry spring proved favourable to ripening the bulbs, and as a result a greater number of flower-stems has been put up, each carrying a large umbel of flowers of fine colour. No doubt some liquid manure is given during the spring and early summer when growth is being made. In one of the cool houses the beautiful Carnation Mrs. Leopold de Rothschild is now to be seen at its very best. It has been described as an improved Miss Joliffe, and it certainly partakes of its free bushy growth, but in point of colour the blossoms open a blush-pink, but change to a soft rose; the flowers are thus not only deeper in colour, but larger in size, sweetly fragrant, and do not burst the calyx to any

serious extent, and only when old. Plants from cuttings struck a year ago are seen with specimens two years and three years old, and all bloom freely, but the finest flowers are on the young plants. On the roof of a stove can be seen *Allamanda Williamsi* mingling with *Dipladenias*, and forming a pretty sight. The deep yellow colour of this fine species is particularly noticeable, and being so free blooming is a great acquisition as a stove climber as well as an exhibition specimen. In another stove house can be seen *A. Hendersoni* completely filling the roof interior. It is still almost a sheet of yellow, though past its best. *Ixoras* grown for cutting have been a great feature, and are still throwing up from vigorous quarter specimens numbers of trusses of bloom. *Vanda teres* has been very fine planted out at the east and west ends of a range of houses so as to be near the glass. The plants at the west end have flowered more freely.—R. D.

Monstera deliciosa.—Will any reader tell me whether *Monstera deliciosa* can be kept in an ordinary greenhouse during the winter, or whether it requires stove heat? I had a fine specimen of the *Monstera* given me this summer which has fruited. I would like to know if it usually does so in this climate.—L.

* * * An ordinary greenhouse is barely warm enough to keep this plant in safety through the winter. Provided the temperature could be kept at about 50° as the minimum, it would be considered tolerably safe for it. The better way would be to keep the plant correspondingly drier at the roots as the temperature declines; then by the time severe frosts are anticipated in the usual course it will withstand with greater safety a lower temperature. In a greenhouse that is only kept at 45° at night the *Monstera* should have the warmest place that can be given it, made all the more secure by a covering thrown over the glass outside. Rather than water to any extent in the winter I would advise that the leaves be sponged occasionally, but it would be better even for a few of the older ones to fade or shrivel than to risk the loss of the roots by an excess of moisture. As a further protection still the pot in which it is growing might be stood into a box or tub, the intervening space then being packed with cocoa fibre or other dry material that would act as a protecting medium, preventing the soil within the pot from becoming so excessively cold. The plant should be so stood if possible as to allow a fair distance between the leaves and the glass; if too near, there will be more risk of injury to topmost foliage and the points of the shoots. Do not on any account repot the plant before next April or May when active growth recommences. During such a summer as the present the *Monstera* would fruit in the open air in warm situations, but it is comparatively rare for it to do so. Finer and better developed fruits in every way are obtained only when the plant is grown in a warm house. If it is possible to keep the plant in question in a house with a night temperature of 55° in cold weather, it will be far better to do so, and more moisture which is congenial to its healthy growth can then be given it.—G. A.

Eulalia gracillima.—This forms a very pretty pot plant and one that is likely to become more popular now that Grass-like plants are so much grown. This form is a less vigorous grower than either of the better-known kinds, the leaves being a good deal narrower and more gracefully recurved. The colour of the leaves is bright green, with a comparatively broad stripe of white down the centre of each—a style of variegation by no means common. So pronounced is this white stripe, that this form is sometimes called *E. gracillima univittata*. Very effective little specimens may be had in pots 5 inches or 6 inches in diameter, and in this way they are useful for decoration.—H. P.

Sweet-scented Pelargoniums.—It was a rare treat to have these old favourites presented in such size and perfect form as they were by Mr. Hudson, of Gunnersbury House, at the recent shows at the Agricultural Hall and Earl's Court. A renaissance of these scented or so-called Cape

species of *Pelargoniums* is indeed welcome to all lovers of these showy and useful plants. It is feared that not a few of them, especially the semi-bulbous *Pelargoniums*, have dropped out of cultivation. But in such good hands as Mr. Hudson's there is little fear of the popularly known Oak-leaved section suffering a similar fate. In fact it is doubtful if any cultivator has ever forced these plants into such extraordinary vigour before. One of the most striking of them all, *P. filicifolium odoratissimum*, used to be grown under the name of *glaucum* or *glabratum*, owing to its sticky qualities pointed out by Mr. Wythes (p. 256). This also used to be considered rather milky, and assuredly such plants as those exhibited by Mr. Hudson would have astonished the late Mr. Beaton, of Shrubbyard, who did more in his day to grow these beautiful plants successfully alike out of doors and in than any other cultivator. I agree with Mr. Wythes' estimate of the great popularity of these fine plants at the Agricultural Hall, Islington. While admiring all the forms, perhaps the standards were the more striking, though the fan-trained plants would form useful furnishing for fireplaces, windows, or other recesses. These sweet-scented *Pelargoniums* are also admirable for the clothing of vacant walls in conservatories or corridors, and in not a few gardens of the old-fashioned type most vacant spaces in houses or corridors were furnished with Oak or other leaved *Geraniums*. These and other Cape *Pelargoniums* often had one or more houses to themselves where quantities used to be grown specially for cutting. In those days, not so far off as they may seem, no bouquet or basket of flowers was considered complete unless plentifully perfumed with the foliage of Cape or other sweet *Pelargoniums*.—D. T. F.

Browallia elata for winter.—In the autumn and winter blue flowers are not too abundant, more especially for cutting from. This plant, although only an annual, is a most useful blue-flowered plant to cut from. It is of the easiest culture and may be had in bloom the greater portion of the year, provided seed is sown at several different times. I find it most useful during the autumn and winter months. Last year I had it in bloom through the winter and till March in a warm greenhouse. When the plants are nicely grown they are useful for placing in vases in light rooms. Any plant that can be grown in a few months and that has such useful qualities should be better known. I find the best way is to sow a little seed in July. When strong enough, prick out the seedlings, putting three round a 3-inch pot. Place in a close frame for a few days, after which they are removed to a warm spot in the open air. When the pots are full of roots, they are potted into 4½-inch, 6-inch or 8½-inch pots, as the case may be. They are then placed in a cold frame, and when the weather becomes too cold and damp, removed to a greenhouse shelf, using every effort to keep them dwarf. Should a few be needed early, they are removed into a house with a temperature of 50° by night. The plants should be pinched according to the size they are needed and time they are wanted in bloom. This *Browallia* is not particular as to soil. I use loam and old Mushroom manure and sand, two parts of loam to one of manure, adding sand enough to keep it open.—DORSET.

Begonia fuchsioides.—While some classes of *Begonias* have at the present day attained a high degree of popularity, others are allowed to a great extent to pass unnoticed, and among these last must be mentioned *B. fuchsioides*, which is a really handsome species, though the individual blossoms are but small. It is one of the fibrous-rooted section, and in a warm greenhouse will, under favourable conditions, reach a height of 6 feet. This *Begonia* is, for such a structure, one of the best pillar plants that we possess. The leaves are ovate, about 1½ inches long, of a deep shining green when mature, though in a young state they are tinged with red. The bright scarlet flowers are borne in large drooping panicles, and where favourably situated will keep up more or less of a succession for a considerable period. Several of this class of *Begonias* are well worthy of a passing

notice, especially all the forms of *B. semperflorens*, which are, however, now rapidly coming to the front; *B. Haageana*, whose large bluish coloured flowers are borne nearly throughout the year; *B. corallina*, with tall wand-like shoots, from the upper part of which are produced large drooping clusters of coral-red blossoms; *B. glaucophylla*, a good basket plant with flowers of a reddish salmon tint; *B. manicata*, whose leaf-stalks are clothed with whorls of large scale-like hairs, while the small flowers, which are borne in large branching panicles during the winter, are pink; *B. nitida*, with large glossy green leaves and pink blossoms; *B. weltoniensis*, still one of the best; *B. Carrieri*, white; *B. insignis*, pink; *B. ascotensis*, silvery bluish; and *B. Gloire de Secaux*, with handsome bronzy foliage and large pink blossoms. This commences to flower by the early days of the new year, and is one of the best fibrous-rooted *Begonias* in cultivation.—H. P.

Curcuma Roscoesna.—There are several species of these Ginger-worts in cultivation, but many of them greatly resemble each other, and that named above is one of the best, while it forms a very pretty flowering plant for the stove. It usually blooms towards the end of the summer or in early autumn, though blossoms are occasionally produced earlier in the year. It is well worthy of consideration for its foliage alone, as the large Cana-like leaves are very handsome, but its beauty is still further enhanced when they are supplemented by a distinct and showy spike of blossoms. The inflorescence is totally distinct from anything else in common cultivation, by far the showiest portion being not the flowers themselves, but the large bracts, which to a great extent hide the blooms. These bracts are of a bright reddish orange tint, and retain their beauty for a considerable time.—H. P.

SHORT NOTES.—STOVE AND GREENHOUSE.

Salvia compacta splendens.—This variety is well worth a note. In the temperate house at Kew are several fine plants of it smothered with large, brilliant scarlet flowers, which stand out well from the deep green leafage. It is a remarkably showy pot plant, and very bright at this season of the year in greenhouse or conservatory.

Begonia corallina.—This is a very striking object at Forde Abbey. It is growing in a Fern house, trained up under the roof, where its bunches or racemes of rich coral-red flowers hang down in great profusion. It is not a good thing to travel when cut, but at home the flowers are very beautiful when used for vase decoration. Close by the pale-flowered *Begonia nitida alba* was also most pleasing and blooming freely.—D.

Begonia Martiana gracilis is a very beautiful kind in bloom in the stove at Kew. The plant is not large, but sufficiently so to enable one to judge of its character, and a fine specimen would be distinct and unusually handsome. The leaves are of the deepest possible green, which brings into bold relief the clear pink coloured flowers, shading off to white towards the base of the segments. They are about the size of a halfpenny and borne freely.

Bouvardia at Kew.—The *Bouvardias* in the temperate house at Kew are well worthy of note. All the leading kinds are grown in pots, and some of the plants are of large size. We made note of a few kinds, and one of the best is the well-known *B. Humboldti corymbiflora*, which was a remarkably fine specimen, about 3 feet in height and almost as much through, whilst the flowers were freely produced. *B. Vreelandi*, Mrs. Robert Green, with salmon coloured flowers, and *President Cleveland*, bright scarlet, are also grown well.

Witsenia corymbosa is one of those fine old plants that have disappeared in a great degree from gardens. We saw it in bloom a few days ago, and it is difficult to tell why such a pleasing blue-flowered plant should have almost dropped

out of cultivation. The *Witsenia* belongs to the Iris family, and we can trace a likeness to them in the tufted character of the leaves, which are very much like those of some of the Irises, whilst the flowers are produced in autumn, when they are highly appreciated, as then one requires some relief from *Chrysanthemums*, *Cyclamens* and a few other things which fill our greenhouses. It was introduced from the Cape in 1803, and perhaps something is due to its rather difficult culture as to why it is not more grown in English gardens. The flowers which are produced plentifully, are of a bright and most pleasing blue colour.

ORCHIDS.

AERIDES SUAVISSIMUM.

This belongs to the same set as the well-known *A. odoratum*, and it has from time to time appeared in various gardens under different names. "H. H." sends me a short spike, cut from the base of a branching raceme, with beautifully coloured flowers. The plant, I am told, is between 3 feet and 4 feet high, and it has borne three spikes this season, each carrying a spur or short branch from the base of the main raceme, which was about 2 feet in length, thickly set with its very fragrant flowers. This plant appears to have been introduced many years back by the Messrs. Loddiges, of Hackney, with whom it first flowered nearly fifty years ago, but nothing definite is recorded of its native habitat. The Messrs. Loddiges said they received it from the Straits of Malacca, but from what island it came no one can say, and up to the present time I believe we still remain in ignorance of the precise locality whence it was brought. The plant used to be cultivated far more, say thirty years ago, than it is now. Indeed, such was the case with many other species belonging to the distichous leaved sections, as *Aerides*, *Saccolabiums*, and *Vandas*.

Aerides suavisimum enjoys a fair share of heat and moisture when growing or in the summer season, for although it continues to grow a little through the winter, the temperature should be let fall to 60°. I do not like the glass to fall lower where these plants stand, although I have had *A. odoratum* stand a few degrees lower and flower well the next season. The pots this plant is put into must be nearly filled with drainage. It should be put into some clean fresh Sphagnum, and should have an abundant supply of water during the summer both from the watering-can and also overhead. When the dull days come round the syringe may be laid on one side, and less water must be given from the watering-can, only just sufficient being administered to prevent the leaves shrivelling. Less water must also be put upon the floor and stages and the air generally kept dry.

W. H. GOWER.

Oncidium phymatochilum.—This is not a new species, for it has been known about fifty years. It was for a long time thought to be of Mexican origin, but it was at last sent from Brazil by M. Pinel. It bears an erect scape several feet in length, which is paniculate, the flowers numerous, with the sepals and petals of a greenish yellow, spotted on the face with deep orange, the lip white, having a yellow crest, round which are some red spots. The plant has been termed a hard one to cultivate successfully for any length of time, and I think, perhaps, this has been from not having it well drained. It does not like much soil about its roots, neither does it thrive if any water is allowed to lie about it. For this reason it does best upon a block of wood. It thrives at the cool

end of the *Cattleya* house with a moist atmosphere when growing, but does not like syringing overhead. If grown upon wood it requires extra care to bring it safely through the resting season.—*Orchid Album*, p. 470.

Cymbidium Lowianum.—This beautiful species was introduced from Burmah about sixteen years ago by Mr. Stuart Low, and some two years afterwards it flowered with and was exhibited by its introducer before the committee of the Royal Horticultural Society, and received a first-class certificate. On account of *Cymbidiums* being such robust growers, many persons have been induced to feed them with liquid manure, and in many instances ill effects have been produced by this course of treatment. When growing, the plant likes the temperature of the *Cattleya* house, with a nice moist atmosphere, but when at rest a temperature of 50° will be ample with a drier air.—*Orchid Album*, p. 471.

Ornithocephalus grandiflorus.—This has not been seen much in cultivation, because these small-flowered Orchids do not find great favour with growers. One striking exception is to be found in Sir Trevor Lawrence's collection, where Mr. White devotes much care and attention to these kinds. The plant was first found by Gardner in Southern Brazil nearly sixty years ago. It is best grown in a small shallow basket or pan, so that it can be suspended near the roof glass. These must be thoroughly drained, using for soil peat and chopped Sphagnum Moss.—*Orchid Album*, p. 472.

SHORT NOTES.—ORCHIDS.

Stanhopea platyceras.—This plant is again flowering, so I am informed by Mr. F. Lidderdale, of White Hill, Berkhamsted, in his collection, the flowers lasting about three days.—W. H. G.

Cattleya citrina.—This, figured in the "*Orchid Album*" (p. 469), is a very beautiful *Cattleya*, and the only species which has yet been found in the Mexican territory, although the allied genus *Lælia* is present in great profusion in that country. It first flowered in the Duke of Bedford's collection at Woburn Abbey. Mr. Williams recommends it to be grown in a shady position in the *Cattleya* house, wintering it in the cool house with the *Odontoglossums*.

Oncidium Lanceanum.—H. Dalruple sends two flowers of this species, which was figured in *THE GARDEN*, Vol. XXIX., t. 539, asking if the two are the same species. No. 2 is the typical plant, having a deep purple lip, and the flowers have a rich perfume, which resembles vanilla. No. 1 is the variety known as *Louvrexianum*, which has the front lobe of the lip white, passing into rose, and from that into violet-purple at the base. It has the same fragrance as the typical form. This plant requires the very hottest house. Give shade and an abundant supply of water.—W. H. G.

MARKET GARDEN NOTES.

I HAVE an indistinct remembrance that *Fuchsia fulgens* was at one time grown for market, and was rather a favourite in Covent Garden. To the younger generation of market growers it appears to be unknown, and some nicely grown little specimens that were brought this season into Covent Garden were regarded in the light of a novelty, and were quickly sold. The man who had the happy idea of re-introducing this old *Fuchsia* to the London markets is so far satisfied with his experiment, that in the forthcoming year *Fuchsia fulgens* will probably be offered in quantity. Purchasers are always on the look out for something new or distinct, and I should not be surprised if *Fuchsia fulgens* becomes for several years at least rather popular. *Amaryllis Belladonna* has been much in favour this year. The peculiar colour of the blooms happen to be very popular just now, and for that reason they have met with a ready sale. They are

mostly imported, coming, I believe, from the south of France. It is curious how the fashion as regards colour changes now-a-days. A soft shade of pink appears to be most in favour at present, and any flower that possesses this particular tint commands a quick sale. Florists are sometimes puzzled to meet these changes, especially in provincial towns, where the choice of flowers is more limited than in the metropolis. I know of an instance where a lady will just now have no flowers for room decoration that is not of this particular shade. When Baroness Rothschild Rose can be had, it is used in preference to anything else, but at this season it is very difficult to get anything that will supply its place.

The first consideration now is whether a flower will harmonise with the decorations of an apartment or with ladies' attire, so that for a season or two some particular variety of Rose, Carnation, or *Chrysanthemum* will be in high demand, but which at other times gets no special attention. The pink Everlasting Pea is a case in point. Two or three years ago it was very popular; this year one cannot get rid of the blooms. "They will not go with anything," a florist remarked, meaning that the rosy pink blooms will not harmonise with the colours used in dress materials and room decoration. *Freesias* have already made their appearance in Covent Garden—an unprecedentedly early date for this flower. They came, presumably, from that paradise for tender huldous flowers—the Mediterranean shore. *Richardia albo-maculata* (the variegated *Arum Lily*) is coming at length to the front. Market growers have strangely neglected what is probably one of the most useful decorative plants we have. The blooms are much smaller than those of the ordinary form, but it is as a fine-leaved plant that it will be cultivated for market. Under ordinary culture the leaves die off in late autumn, but if required for winter use the bulbs can be kept dry through early summer, and if potted up in July and August and kept in a genial temperature, they will remain in good condition all through the winter. One man is now so impressed with its merits, that he will not part with a single plant till he can number his stock by thousands. Some excellent Strawberries were brought into Covent Garden a few days ago, probably the produce of early forced plants put out in the open ground.

J. C. B.

FLOWER GARDEN.

MICHAELMAS DAISIES.

HOWEVER it may be in the south of England, Michaelmas Daisies here in Cheshire, in spite of prophesyings that they would be over before Michaelmas, are no earlier than usual, and are true to their popular name in their time of flowering. Most of them are at their best in this Michaelmas week, though some late kinds, such as *turbinellus*, *Diana* and *Archer Hind*, have hardly yet opened a flower. It is an agreeable novelty to be able to speak of them by names which convey a definite meaning to all gardeners who have given their adherence to the classification adopted at the Chiswick conference, and we ought all of us to hope that the botanical affinities of each kind will not again be called in question for a generation. It matters little to a gardener whether the characters of a plant come nearest to *A. lævis* or *A. Novi-Belgii* or *A. versicolor*, provided all of us agree to call the same plant by the same name; but it must not by any means be supposed that finality has been reached in Michaelmas Daisies. Those who are interested in the flower hope that the collection exhibited at Chiswick two years ago was only the beginning, and that the race of perennial Asters is destined to develop great improvements in the near

future. It is probable that many varieties, better in their kind than anything shown at the conference, were already in existence then. Some of the specimens there selected as first-class had been raised from seed only two or three years before, amongst them W. Grant and J. Wood. The flowers of one now called Areturus were sent to me whilst the conference was sitting. It was found in a garden near Scarborough, and is one of the finest Asters known. What its botanical name is I do not care, but the plant grows 6 feet high with glossy black stalks, dark green leaves, and large dark purple flowers, and the habit is in every way excellent. As for other novelties, I have selected twenty or thirty out of some thousand seedlings sown in the spring of 1891. Some of them are new in colour, but none of them have yet been judged or named. I hope many other gardeners are growing Michaelmas Daisies from seed. If the plants have flowered earlier than usual in the south of England, it will be a good opportunity for saving seed from some of the best of late-flowering kinds, such as Archer Hind, which has seldom ripened seed here. Amongst those which I have found most satisfactory as seed parents I may mention Diana, of which the seedlings, if not crossed, come very true to name—versicolor, Antigone, and Harpur Crewe, and John Wood, of which a large crop of seedlings sown in the open air last February is now beginning to flower. Perhaps the best colours and best formed flowers in the Novi-Belgii class come from a variety called decorus, which name I think was retained at the conference; it is of moderate height, full round flower, and broad disc. I have other seedlings, of which the mixed parentage is obvious; for instance, crosses between levis and cordifolius, with large flowers, dense upright branches, and gigantic stature of 7 feet or 8 feet. These, however, are not quite first class, but distinct in habit and appearance. Everyone who can save good seed of it should raise Aster Amellus, the prince of the whole genus. I have come to the conclusion to which I think Mr. Dewar came, that the distinctions, whatever they are, between Amellus and bessarabicus disappear in cultivation, and that the name bessarabicus had better disappear from gardens also. If distinct varieties of Amellus can be established, let them have garden names, but unless botanists will tell us definite characters by which to distinguish the variety bessarabicus—and they did not tell us them at the conference—the name is only confusing. No doubt seedlings of Amellus vary much in merit, especially in respect to colour; they are more or less good in proportion to the mixture of red with the blue, and a red-purple variety sold as Amellus ruber ought to be consigned to the rubbish heap. A true blue Amellus is within easier reach of gardeners than a true blue Primrose, and ought soon to be raised. It is remarkable how the colour of this Aster varies in different lights, sometimes appearing to be quite blue. A pure white A. Amellus is a thing to be longed for, and will probably be found some day.

In one part of the outside of my garden, separating it from the grass park, is a row of hurdles 70 yards long, and lined with rabbit wire; a walk of coal ashes runs between this fence and a long border. In these coal ashes against the hurdles a row of Michaelmas Daisies grows admirably, and now makes a fine show. There is, of course, a wide and deep ditch outside to prevent the cattle grazing on the flowers, and as this secures good drainage, the plants are a picture of health and vigour. The difficulty I have is not to supply enough

plants to make such a row, but to choose amongst the endless candidates for the honour of a place. A hundred plants quite fill the distance, and they are this year all two-year-old seedlings, marked for selection last year. Half of them or more will be eliminated next spring, to be replaced by this year's selection of seedlings. In this way vacant fences or sides of shrubberies are made to do duty as trial grounds. No one, until he has tried, knows how easy it is to add improvements to a collection of Michaelmas Daisies in this way.

Few of the varieties of Aster are exacting in their requirements, but some of them have likings. For instance, the cordifolius section prefer shade, being easily burnt up in hot sun, whilst the varieties of versicolor do badly in shade. The dwarf gem of this class, versicolor nanus, which was not appreciated at the conference, is worthy of special care in this way, being easily spoilt by autumnal over-growth. It makes an excellent edging, alternating with the later autumn purple Crocuses, such as C. medius and C. longiflorus, and produces dense bunches of white flowers, rising 6 inches from the ground and lasting through October. All

Liliun Martagon album. Engraved for THE GARDEN from a photograph sent by Mr. R. A. Jenkins, Highgate, London, N.

these grow on the very same margin on which Chionodoxas and spring Crocuses flowered in March, and they do not interfere with one another.

C. WOLLEY DOD.

Edge Hall, Malpas.

Dahlias at Colchester.—One of the best collections of this autumn flower we have seen this season was in the nursery of Messrs. D. Prior and Son, of Colchester, where many things are grown besides Roses. Of the Cactus section, now so popular in gardens, the four more conspicuous varieties were Delicata, Panthea, the colour a brilliant reddish salmon; Mrs. Tait, white, the petals serrated; and Lady Marsham, bright salmon. The show section is also grown largely, but one wants only a few kinds unless a large collection is desired. One of the most distinct was Georgina, the flower large, but not too much so, and creamy white in colour; whilst others of note were Walter H. Williams, bright scarlet, surpassing all others of that colour; Earl of Radnor, intense plum colour; and Mrs. Gladstone, delicate blush, a model in shape; whilst the best fancy

was Lottie Eckford, a white flower striped with purple. Two good singles were James Scobie, one of the best of this section, the flowers finely striped, and Negress, deep velvety maroon almost black.

THE WHITE MARTAGON LILY.

The white Martagon Lily is one of the most distinct of the family, and if given a suitable soil and position there are but few of its relatives that excel it in beauty, hardness, or freedom of bloom. No one who has seen the graceful spikes of chaste wax-like blooms of snow-white purity thrown up by this Lily can deny its beauty, while as to hardness, all the bulbs which I planted in the autumn of 1890 survived the abnormally long period of severe frost which ensued, although they were not afforded any protection, and bloomed freely in the following summer. As to the free flowering qualities of the subject of this notice, suffice it to say that three bulbs in my garden after being planted as many years ago gave me no less than 167 blooms this June, two of the stems carrying forty-two and forty-nine blooms. The annexed illustration is from a photograph taken last year of the same specimens which gave me ninety blooms, the finest spike carrying thirty-one buds. This was the second year after planting. Even in the summer immediately after planting the Lilies sent up forty blooms. This I attribute to their being moved early in September, for if planted late in the year, most of the Martagon section refuse to bloom in the ensuing summer. So convinced am I of the advantage of early planting, that, finding it necessary to remove my bulbs before next March, I resolved on lifting them early this August, and on the 5th of that month I planted them at Great Houghton Hall, Northampton. If the plants (which are the original three bulbs planted in my garden in 1890) bloom well during next summer, my theory of early moving would seem established. Anyhow I hope to send a short account of the results to THE GARDEN next June. I find that this Lily does best in good deep soil well enriched with leaf-mould, and without manure or sand. As the above-mentioned soil suits such plants as Anemone sylvestris and Lily of the Valley to perfection, I have carpeted the ground with them, and they serve to keep the soil cool during the summer, while in May they furnish me with countless flowers. The bulbs of the white Martagon increase very slowly, and this accounts for the high figure at which this Lily is usually sold. They do best planted 3 inches to 4 inches deep.

Highgate.

R. A. JENKINS.

Euphorbia pilosa.—A short note on this plant may be not out of place. I have lately heard two counter statements about it made by amateur gardeners, one saying that she brought it from Hyères, and that it is tender, but ornamental and seeds freely; the other that it is a native plant and not ornamental at all. *E. pilosa* of Linnaeus is included in the "British Flora," being found in two spots, one near Bath, the other in Sussex, but Bentham considered it certainly not indigenous. I have seen it growing near Biarritz and Bayonne, but in Godron's "Flore de France" we have a very full summary of its distribution in France, and it does not extend there eastward of the Rhone, so is not found at Hyères. It reappears, however, in Eastern Europe, extending into Central Russia, so there can be no doubt of its complete hardness. I have grown it for about twenty years, and the first plant I had is still flourishing where I first put it, not having spread at all. It dies down to the ground in winter, and in April makes a branching

growth, having the upper leaves and bracts of a rich gold colour as bright as a large double Daffodil, which lasts for three months. In early autumn it becomes as scarlet as a Virginia Creeper. I consider it very ornamental both early and late, and visitors to my garden have frequently asked for a plant, which I have seldom had to give them, as I never could increase it except by cuttings taken off to the base in early spring. The portrait in Sowerby's "English Botany," in which the whole plant is coloured dull green, gives no idea of its merit as a garden plant.—C. WOLLEY DOD, *Edge Hall, Malpas.*

Tritoma McOwani is one of the dwarfiest of the Tritomas. We noticed a quantity of it in bloom a few days ago in the Long Ditton nursery, the flowers of a distinct orange-red colour. It only grows about 18 inches in height, and should be in every choice collection of hardy plants. The leaves are between 1 foot and 2 feet long and narrow, and if the flower-heads are small, they are showy through their distinct colouring. It is more suitable, therefore, for the rockery than beds or borders. The variety *longiflora* is so named from its longer flowers, and one finds this Tritoma catalogued as *T. rigidissima* and *T. maroccana*. A very pleasing Tritoma is named *T. corallina*, which is a hybrid between *T. McOwani* and *T. aloides*, and raised by Deleuil, of Marseilles. It has the character of both parents, and is a good garden plant.

Eomecon chionantha was still in bloom a few days ago on the Kew rockery. A coloured plate was given of it in THE GARDEN, January 26, 1889. It is a native of China, from whence it was introduced about the year 1884. It belongs to the Poppyworts, and when grown in groups or colonies, forms a very charming plant during the summer and early autumn. The flowers at first sight are not unlike those of the Japanese Anemone, but much smaller. They are pure waxy white, relieved by a central tuft of yellow stamens. The soil best suited for the Eomecon is a moist sandy loam, and on the lower parts of the rockery the plants will succeed to perfection, producing a wealth of leaves, with the flowers appearing above them. A ready mode of increase is by seed or division of the roots.

THE FLAME NASTURTIUM.

(*TROPEOLUM SPECIOSUM.*)

NOTES which appear from time to time on the above-named plant indicate that it is a difficult thing to establish in many places, and a variety of causes has been mentioned as leading to failure. On June 9 last year I planted in different parts of the garden several pieces, which had been sent to me from Scotland. These pieces mostly had shoots about 3 inches or 4 inches long, and thick, fleshy root-stems double the length of the shoots. To the goodly proportions of the roots I attribute the first step towards success, and the care which had been taken in packing the pieces in damp Moss was another great help. No special preparation of the soil was made, but care was taken to choose shady positions for planting. All but one lot has done exceedingly well, especially when the present dry season is taken into consideration. The lot which failed to make satisfactory progress was planted in a rather dry spot, and with coarse Grass, &c., growing almost close up to the plants. The lots that have done best were those planted in a fairly damp position against walls facing a little west of north, where they get a little sunshine in the afternoon. Another lot was planted against a west wall, shaded on the south by a Holly bush, and on to which the western sun shone through a large Cedar that stands some distance away. The success of these last-mentioned plants is especially a pleasant surprise, as the site is a dry one, close to a gravel path, and more than one thing has refused to grow when planted there. The *Tropæolum*, however, has sent up a dozen or more strong shoots, which are now beautifully in flower, and thinly cover a big window in the prettiest way

imaginable to a height of over 8 feet. A photograph enclosed with this shows one of the lots planted in a damper position, and here it has taken possession of the horizontal branches of a very old Duchesse d'Angoulême Pear tree, which never has any fruit on that side of the wall, but which bears well on vertically trained branches brought down the other side. Several gnarled old spurs of the Pear tree surmount the wall, and these again are topped by the long, straggling growths of a Devonensis Rose rising to quite 9 feet high. The *Tropæolum* has gone to the full height of these, and many of the shoots have bent over and come downwards again another 3 feet, and for more than two months it has been quite smothered in flowers—a very brilliant object. The photograph was taken on July 17, since which time the plant has made a great deal of progress. It does not do justice to the plant, the leaves and flowers of which are too small and too numerous to stand out distinctly. The earlier flowers have been succeeded by berries which when ripe are of a lovely azure-blue colour, with the tone and brilliancy of a lapis lazuli stone.

J. C. TALLACK.

FLOWER GARDEN NOTES.

FOLLOWING on the remarks of last week, which treated of some few herbaceous plants that had done very well this season, I may note some annuals, or at any rate plants treated as annuals, that have either scored a success or that have promised sufficiently well to warrant another year's trial. Beds or borders that are to be devoted to anything special in this way should have a good dressing of short manure and be broken up in early winter to ensure not only a deep rich tilth, but a fine well-pulverised surface for another spring. Such a preparation, especially in a season like the present, is of immense advantage as compared with the system of leaving the preparation until just before sowing. Apropos of annuals, I was very much interested in the account of an experiment with a vast number of varieties in order to determine not only their free-flowering properties, but to make accurate observations as to the relative duration of season. The peculiar season was all against such an experiment, and it is to be hoped, therefore, it may be repeated, as it is likely to be of great service in flower garden operations.

Seedling Hollyhocks have been remarkably good this year. Sown where they were to flower, and thinned out to the number of plants to form the required line or clumps as the case may be, they have formed a good background for smaller subjects or associated well with the bright foliage of small coniferæ or large deciduous shrubs. The new shades of colour in *Convolvulus major* are very beautiful, and the plants themselves admirably adapted for those old-fashioned raised beds still to be found in some gardens, also for large sloping borders. Here their effectiveness may be increased by the occasional insertion of small mounds of twigs from Pea boughs, which, when covered with hine and flowers, will help to make a nice undulating surface. Passing through the flower garden in the evening, the remarkable contrast in the habits of different flowers is borne out in beds of *Convolvulus* and Sweet Tobacco; the one closed for the night, the other with fully expanded flowers charging the air with delicate perfume. I gave *Phacelia campanularia* a trial in the flower garden this year on account of its colour, but it will have to retire to the wild garden. It is a rich and telling shade, but too short-lived for prominent positions. *Nemesia strumosa* must have another trial. The *Godetias* must take rank among the most enduring of the annuals; a very handsome bed can be made with these in four or five varieties, with an occasional *Retinospora* or *Cupressus* among them as dot plants. They are also useful for cutting, standing a long time in water. Whilst on the subject of useful plants easily raised for cutting, I should like to say a good word for the varieties of *Gomphrena* (the Globe Amaranth). They do not come in strictly as outdoor subjects, and yet well-grown

bushes make nice verandah, porch or house plants, and the value of the flower in a cut state is well known. The purple is the most striking and serviceable variety, at any rate as a pot plant. Dwarf Petunias, double Zinnias and East Lothian Stocks have been so satisfactory, that they will be grown next year in greatly increased numbers. The Stocks are already fairly well advanced and will shortly be pricked out into winter quarters, whilst early sowings will be made in the spring of 1894 of the Zinnias and Petunias to get them early into flower. Good dot plants for the dwarf Petunias are the whitest of the Eucalypti or the variegated Abutilon. The housing of Violets will receive attention this week; they have required a lot of extra care this season in the way of occasional soakings of water and additional mulching, but are now very good plants. With careful lifting and planting, a good soaking of water, and a little shade for a few days if the sun is bright, they will soon become established in their new quarters. We are fortunate in having a flow and return pipe in the pit devoted to their culture, and as a consequence are not troubled with damping.

Outdoor Chrysanthemums under skeleton frames intended for cutting have been tied and cleaned and given a dusting of sulphur where necessary. They will not be so good as usual this year, as we have been able to give only a small quantity of water, but they will doubtless furnish a very fair supply of cut flowers. What are known as October flowering varieties, such, for instance, as l'Ami Conderchet, Achievement, Sœur Melanie, William Holmes, Lady Selborne, and Mme. Dufosse amongst others are most useful for this purpose. If a slight protection in the way of tiffany is given them, very few of the flowers will be lost even in the event of an early and somewhat severe frost. All tender plants in pots in the way of Palms, Ficus, Grevilleas, and anything of a similar nature must come under cover if ample means for protecting outside is not available. We also make a practice of getting in on the shelves of a vinery or Peach house from which the fruit has been taken a good supply of zonal Pelargoniums (doubles) in pots that have done duty in various positions in the flower garden through the summer months; they furnish a capital lot of cut flower for a considerable time, and are very handy in connection with a few light Palms and some variegated *Aspidistra* in forming little indoor groups for dwelling-house or church, contributions for the latter in connection with the harvest festivals being pretty general at this season. We have gone through the beds of Marguerite Carnation this week, and, selecting nice sturdy, bushy plants with a goodly supply of buds, have lifted them carefully and potted in 6-inch pots, using a compost of three-parts road sidings and one of horse droppings rubbed up rather fine. A frame under a north wall will suit them best for a few days, when they can be transferred to a light, airy house. In any list of the most useful plants for universal culture I should most decidedly include this race of Carnations. Anyone with a tiny house can get the seed up early, and as a consequence early-flowering plants, whilst the same house will afford to the plants lifted in the manner above indicated ample shelter to keep them in health and flower until, say, the middle of December. E. BURRELL.

Claremont.

East Lothian Stocks.—I am sure that anyone who may once have grown these will always make a point of so doing. They fully merit all that has been said of them in previous numbers of this paper. Sown in late summer or early autumn and kept under glass through the winter and early spring, they yield a rich supply of flowers. In Scotland I believe these Stocks are much grown, but in the southern portions of the kingdom they are seldom employed in this way. In this district I never saw but one lot of them, and the grower learned his trade from a Scotch gardener. I thought that I had never seen a fairer picture of floral beauty than offered by a mass of the pure white variety. Anyone who may

be growing for profit and is not quite decided what to fill up with for the spring markets cannot make a mistake in growing a house of Lothian Stocks. They make very fair and sometimes really good prices—much better often than those obtained for what are termed choice flowers. Everyone likes Stocks, and to many they come thus early in the year as a delightful surprise. The white one makes, as a rule, the best price.—J. C. B.

—The remarks about East Lothian Stocks in your issue of September 16 from the pen of "D. T. F." brought to my mind the magnificent lot I lately saw in the nurseries of Mr. John Forbes at Hawick. They were in six different varieties, viz., crimson, purple, white, scarlet and white, and crimson wall-leaved. These show how well the East Lothian Stocks are adapted for massing in beds where distinct colour is wanted. Another point which struck me when looking at them was the very small percentage of singles.—D. S.

Aster Amellus bessarabicus.—This is certainly one of the best of the Michaelmas Daisies, being really good in colour. There is nothing quite equal to it for supplying cut flowers at this time of year. Although we can ensure an abundance of white and yellow flowers in autumn, those that approach blue are much rarer. I am going to work up a stock of it for cutting from, as I find that the fine tint of this Starwort is much admired. For harvest decorations or any purpose where showy flowers in quantity are necessary, this Aster is well fitted, and the same may be said of all the members of the family.—J. C., *Byfleet*.

OUTDOOR BEGONIAS AT FOREST HILL.

THE present year has not proved favourable for tuberous Begonias in the open, the brilliant sun scorching the foliage and preventing the plants flowering so freely, as in more humid seasons. In the Forest Hill Nurseries of Messrs. J. Laing and Sons a very fine break of outdoor varieties plainly shows the great value of the plants for the enrichment of the garden through the summer and autumn months. Upwards of 400,000 plants are bedded out, and the colours, or at least shades of one colour, are kept distinct, the effect being unusually fine, rich and striking, evidence that when judiciously planted, splendid contrasts may be obtained. The light and dark crimsons are remarkably rich, and a bold mass of either shade would be welcome in the garden, and the same may be said of the rose, yellow, salmon, bronze and scarlet colours. The white-flowered kinds are very pure, and when associated with the variegated *Dactylis* make a delightful bed. All the kinds here are the outcome of most careful hybridising, and are very true to colour. This is a great gain, for one can by getting seed of a certain colour be fairly certain of securing a large percentage of varieties true to that colour, and the few "rogues" can be easily eradicated. This is a great advance in the culture of the tuberous Begonia, which is one of the easiest plants to grow, and is in beauty in all except very hot seasons.

The careful observer will see in the lines of plants at Forest Hill a great difference between the tuberous Begonia of to-day and a few years ago, not only in the colours of the flowers, which vary from the softest blush to almost black, so deep is the shade of maroon, but also in the habit of growth. This is dwarf and compact, and the flowers are produced well above the leafage, thus being displayed to the fullest advantage. One sees few of the leggy specimens that were frequent not many years ago. The seed of the large mass of plants in the open here was sown in the second week of January, and the seedlings potted on in due course until they were put out the second week in June, a week later than usual. All the varieties seem to be much alike as regards freedom of flowering. During the past few days the Begonias have improved greatly, and if severe frosts keep off we may expect a gay show until quite the end of the month, as in many gardens, public or otherwise,

they are now the brightest things in the various arrangements. The tuberous Begonias in the houses at Forest Hill are still beautiful, but we need not make further notes upon them, as they were dealt with in THE GARDEN when in perfection in early summer. We were pleased to see at Forest Hill several varieties of that fine bedding Begonia, *B. semperflorens*, of which *Crimson Gem* is one of the more effective forms. There is, we feel sure, a great future before this type for bedding, as it has been largely planted. The flowers are crimson and produced in great profusion, whilst the leafage is of a dark green, a rich contrast of two decided colours. Even in spite of the great heat and brilliant sunshine *B. semperflorens* has not been affected in the least. The plants are also very useful for pots and easily grown.

DELPHINIUMS.

THESE are particularly easy to cultivate and form one of the most showy features in the herbaceous border; indeed, there are few subjects which will give so much bloom and for so long a time as the Delphinium.

The propagation of named varieties should be taken in hand at once. There are two methods of increasing stock of any particular variety, viz., division of the crowns and by cuttings. I prefer the latter, and am now busy among my own plants. The best cuttings are obtained by cutting away the older growth now that bloom is over. At the same time the best of the seed may be secured, Delphiniums being very rapidly increased in this way. Having cut down the older wood about a fortnight ago, the crowns are now pushing out a number of fresh growths that are not nearly so strong and sappy as those produced in the spring; consequently they are much better suited for propagation. But this is by no means the only advantage of propagating in the autumn instead of leaving it until spring. In the latter case the growth is not so suitable, the plants do not make a flowering clump the first season, and you also cut away the earliest and finest spikes of blossom when removing spring growth for cuttings. When the autumn growths are 3 inches high, cut them off as close to the crown as possible and insert in 3-inch pots of sandy leaf soil and loam. Place them in a cold frame, keep them close and occasionally sprinkle to avoid flagging. Every cutting will strike, and if kept in a frame until spring, each one will make a fairly good clump the first summer, being in perfection the second season. Division of the roots is also best done in the late autumn; this does not check the plants so much as when left until early spring. A rich and deep loam will grow Delphiniums to perfection. Planted in masses or in small groups in the shrubbery in conjunction with a few Lilies, their bold and immense spikes of blue are very conspicuous. Slugs are their chief enemies and are very destructive early in the spring. They eat the young shoots directly they push from the crown. A little fresh lime or soot sprinkled over the crowns occasionally, particularly from February until March, will help prevent their attacks. R.

Bedding plants and the drought.—Our beds here are very exposed, the soil also being of a heavy nature, yet the following things have done well, viz., *Tagetes*, *Coleus*, *Heliotrope*, *Iresine*, *Petunias*, *Alyssum variegatum*, several sorts of *Geranium*, *Lobelia*, *Alternanthera*, *Ricinus*, *Begonias*, *Ageratum*, *Mesembryanthemums*, *Cannas*, and *Fuchsias* have not been satisfactory. Of course, constant watering was the order of the day until rain came.—A. J. LONG, *Wyfold Court, Reading*.

Cactus Dahlia Mrs. A. Peart.—This variety is well worthy of note and likely to be much grown for cutting. It is the nearest approach to a pure white Cactus variety, the flowers of the true shape—that is with pointed petals narrowing towards the apex, and if not quite pure, of a

creamy white tint touched with citron-yellow in the centre. It has been exhibited on several occasions by Mr. T. S. Ware, of Tottenham, who had a large bunch of it at the recent show at Earl's Court. We hope it is free flowering, as then it would be certainly valuable for cutting, as a good creamy white Dahlia of pleasing shape is an acquisition. This variety, *Lady Penzance*, clear yellow, and the lovely salmon-rose *Delicata* are an exquisite trio of Cactus Dahlias.

Primula obconica.—One of the most enthusiastic admirers of this Primrose is Mr. J. Crook, of Forde Abbey, who not only grows it very largely, but has also devoted much time to cross-fertilising it with other kinds, with some amount of success. There is in several plants now in flower ample evidence that the *sinensis* blood is operating. Blooms of much larger size and of a much deeper colour have already been obtained, also there is in some distinct evidence of fringing of the edges, so marked a feature in the *sinensis* varieties, and further there are in some very marked lemon eyes, and in several cases these have a distinct circle of a dark colour surrounding them.—A. D.

Seedling Aster Amellus.—When visiting the Royal Nursery, Slough, recently I was much interested in a bed of seedlings of this fine European species. It was an illustration of the fact of differences in seminal varieties, for a large bed showed variations in colour, in the size of the flowers, and breadth of petals, and also in height, while the tints ranged from a pale silvery hue to purple. There was nothing in the seedlings that could be regarded as superior to the type or its fine varieties *bessarabicus* or *major*, but they were full of interest, the dwarf, compact habit of some being particularly noticeable. Among the many Michaelmas Daisies which find a place in collections *A. Amellus* can still hold its own, and a number of plants in small pots plunged in a tan bed was a really striking sight. This Aster does remarkably well treated in this way, and grown in pots it might be employed for decoration in many ways. There is every promise that perennial Asters and also other plants not prone to seeding freely will produce a good deal of seed this season, and so opportunity will be afforded to sow, as the raising of seedlings is a most interesting study.—R. D.

CHRYSANTHEMUMS.

CHRYSANTHEMUMS PLANTED OUT.

IN growing Chrysanthemums on the planting-out system for cut blooms, I have always considered a regular and plentiful supply of water in hot, dry weather indispensable. An experience this season has caused me to modify my ideas on this subject very considerably. In April, having some old stools of a late kind or two in hand, I parted them and planted them out. Having been wintered in a cold frame and the lights being drawn off as soon as the hard weather broke, they had made but little growth and the shoots were naturally very hard. When planted they were watered in, and once a week later. From that time to the present date they have never been watered, and during the past six months we have not had sufficient rain to moisten the ground more than an inch in depth, the heat being at times terrific. Under such circumstances I should have expected the foliage to turn yellow at the base and the plants generally to have made hardly any growth. On the contrary, the foliage is of a rich green from top to bottom—the very picture of health. Naturally, the plants are not so tall and gross as would have been the case had they been watered, but the wood is so firm and well ripened, that I have no doubt they will produce good blooms. Sometimes on the planting-out system the growth is too gross, especially when the ground is in good heart. I have never found that the blooms are better or more numerous when the plants run up tall but, on the

contrary, that more compact specimens are most satisfactory. With the soil in good condition, deeply stirred and given a mulch of short litter, I am of opinion that very little, if any, water would be needful, especially on soils of a rather heavy nature. If on a light soil like mine, plants will come through such a season as this without water fairly well, it is certain that in ordinary years they would do very well if not regularly watered. The earlier the young plants are put out the better. If they can be got out the first week in April they get good hold of the ground by the middle of May, about the time that the first burst of hot weather may be expected. For this way of growing *Chrysanthemums* division of the old stools is the easiest mode of propagation. They can be packed away closely in frames in light mould, and if the lights are pulled off on all favourable occasions the young growths will be almost as hard as those of the hardier kinds that remain in the open all through the winter. When putting them out, it is better to pinch them back to about three eyes so that the first growths are made in the open, as they are then not likely to suffer from cold winds and frosty nights.

As regards quality of bloom, I have never seen any difference when propagation is effected by division or from cuttings. I have tried both ways, and grown the plants side by side under identical conditions, with the result that both sets of plants gave blooms similar in quality and quantity. If cuttings are put in, say, at the latter end of January or beginning of February, they must necessarily be hardened off after having been in the confined atmosphere of the propagating frame, and it is hardly safe to put them in the open before May. During that month a lot of attention is necessary if the weather happens to be hot and dry, or the foliage will turn yellow and the plants will get a check from which they take some time to recover. Some kinds naturally form a mass of fibrous roots, so that they can be taken up with a ball of earth to them, but this is not the case with the bulk of them. In light soils it is especially difficult to keep any amount of earth to the roots. Such varieties as *Boule de Neige* and *Golden Gem* have a tendency when planted out to make a few coarse roots, so that when lifted there is little but roots and foliage to take indoors. Naturally there is a severe check, which must be minimised as much as possible, or the greater portion of the leaves will drop before the blooms can expand. When the plants are housed they must be well watered in, and if the weather is fine they will need watering every other day until they get well hold of the soil. They must also be drenched overhead with the syringe several times daily. However much they may flag in the daytime, they will not sustain any serious check if they revive again during the night. *Elaine* is the worst *Chrysanthemum* I know of to deal with in this way. Being an early blooming kind, it has to be got in while the sun has still much power. What with the heat of the sun and the parching air it is rather difficult to keep the foliage from wilting. Only great care for a month till new roots form can ensure the plants against much injury. In the case of such early blooming kinds it is impossible to get flowers of fine quality by this method of culture, and for this reason some who grow *Chrysanthemums* largely in this way make an exception in favour of *Elaine*, and keep the plants in pots all through the summer. As this variety is so largely used for wreath-making and church decoration, it is not so much size of blooms as purity of colour that is required. Very large blooms are not so suitable for wreaths and crosses as medium-sized ones that are up to the mark in form and colour. For the London markets, the varieties that yield an abundance of flowers of this description are most valued. In their respective colours, *Golden Gem*, *Cullingfordi*, *Boule de Neige*, and *Mlle. Lacroix* may be said to realise the needs of the florist. It is only occasionally that they require blooms that in any way approach the exhibition standard. Nearly all the late blooming kinds will yield nice marketable flowers by the rough and ready way of growing now generally practised in market gardens. If

housed early in October they have time to get hold of the ground by the time the buds open. I have never found any difficulty with plants that bloom in the middle of December, but there is some uncertainty when one wishes to extend the season up to February. I find that the defoliation which inevitably takes place during December seriously affects the expansion of the buds, and as the year approaches its end the roots come into a more or less torpid condition. In private gardens, where the plants can have ample space, the effects of short days and decreasing light are not so marked, but growers for profit, anxious to make the most of their space, pack their plants so closely, that there can be but little circulation of air among the leaves. In a mild winter, when the ventilators can be almost daily opened, the foliage will remain till the new year in fair condition, but in severe ones, such as the last, the greater portion of the leaves turn yellow by that time.

J. C. B.

Chrysanthemum Mme. C. Desgrange and the yellow sport *G. Wermig* are grown out of doors well and with fine effect by Mr. C. Gibson, Morden Park. A number of plants, with the colours alternate, is trained against a low fence alongside the path leading to his house. Being on the main road, it can easily be seen that this floral treat is appreciated by passers by. Of course the plants have been well cared for in the matter of water, and no disbudding has been done. The little hedge of bloom is a perfect mass, and no more than 2 feet high. In parts of the garden proper of Morden Park, these well-known early kinds are planted pretty extensively for the supply of cut blooms in quantity. When grown as they are here in well manured ground and constantly supplied with water, these *Chrysanthemums* are not the least useful or indeed beautiful among hardy plants.—H. S.

Chrysanthemum Mrs. G. Rundle is grown at Morden Park in a manner not often seen. The plants are allowed to grow to a natural break in the first place, as in the case of those grown for exhibition blooms. This gives them stems about 1 yard high; afterwards they assume a natural habit and are not pinched or the blooms thinned in any way. The result is on each plant a multitude of shoots covered with flower-buds, which will ultimately make a fine head of bloom. For mixing with *Palms*, *Camellias*, &c., in large conservatories such plants are very useful.—H.

Chrysanthemum White Vivian Morel.—A pure white bloom of the type was exhibited by Mr. Agate at the National Society's show the other week. It is claimed to be a sport. Whether or not it is properly fixed remains to be seen, but I feel rather dubious about accepting these white flowers from pink varieties, as it has so often been proved that they are no other than results from early bud selection. Any way the particular bloom under notice is the best yet seen at an exhibition, and I hope it may continue white and be seen in the ordinary season (November). If that be the case, a great acquisition is in store for the many growers of the *Chrysanthemum*.—H. S.

Chrysanthemum Mr. E. Rowbottom.—This new kind, which obtained a certificate from the National *Chrysanthemum* Society, will, it is safe to predict, become a favoured variety for early blooms. The colour is a rich pleasing yellow and the bloom of a light, feathery character. It is especially free flowering, the specimens that were shown, which were about 5 inches in diameter, being cut from a plant that bore a dozen flowers. Although exhibited by its namesake, Mr. Jones, of Lewisham, can claim the credit of raising it from seed.—H.

Early *Chrysanthemums* are certainly increasing in favour, but more varieties of stronger colour would be welcome. The shades of colour are in many cases weak and lacking in variety. Unquestionably the most beautiful kind that has been raised of recent years is *M. Gustave*

Grunerwald, which has been called a pink coloured *Mme. Desgrange*—not an inapt comparison. The flowers are about the size of those of that type, and of exquisite colour—pink, melting away to white. At Kew we noticed that several early-flowering kinds are planted in masses, and they assist greatly to make the garden gay at this season. *Mme. Desgrange* is a mass of flowers, and other varieties are in full bloom. One is *Précocité Japonaise*, the flowers rose passing to crimson in the centre, whilst the other is *Précocité*, the flowers yellow. Both are very dwarf, dense in growth, and remarkably showy. Healthy groups of such fine single varieties as *Miss Rose* are smothered with buds. We hope to see the September and early October blooming varieties of *Chrysanthemums* grown largely in all good gardens.

Seedling Chrysanthemums.—Among the many interesting things connected with the *Chrysanthemum* to be seen at Morden Park is a batch of promising plants from seedlings raised in Algeria. From this source came *Gloire du Rocher*, a Japanese sort of great repute, and the new light yellow of last year, *Le Prince du Bois*. It is not too much to expect that Mr. Gibson will obtain something equally valuable this year.—S.

GARDEN FLORA.

PLATE 930.

THE SMALLER-FLOWERED CAMELLIAS.

(WITH A COLOURED PLATE OF *C. SASANQUA*.)

NOTWITHSTANDING the great number of garden varieties of *Camellias* that are now in cultivation (nearly all of which are double-flowered forms originating from *C. japonica*), there are very few distinct species, and of that limited number the giant of the genus, *C. reticulata*, has been illustrated by means of a coloured plate in *THE GARDEN*, June 14, 1890. The present plate represents *C. Sasanqua*, and it is so well portrayed thereon, that little need be said concerning its general appearance. The neat, freely-branched habit of growth, small leaves, and flowers to match, are all widely removed from those of the forms in common cultivation, and as a conservatory shrub it is both handsome and distinct, while Messrs. Veitch say it has at Coombe Wood proved itself to be much hardier than the ordinary *Camellias*, and also sets its buds more freely. A first-class certificate was awarded this *Camellia* at a meeting of the Royal Horticultural Society, on December 13 last year, when it was exhibited by Messrs. Veitch, who also showed a double white form of the same species. The plants then exhibited are said to have flowered in a cool house, which at that time of the year is especially noteworthy, and if this early flowering feature is permanent it will be an additional point in favour of this pretty little *Camellia*. It should make a good wall plant in favourable situations, and it will doubtless be employed by the hybridist, for between this species and some forms of *C. japonica* a very desirable class of *Camellias* might reasonably be anticipated. *C. Sasanqua* was found in Japan by Thunberg about the latter part of the last century, and was soon introduced into this country, but it is now quite a rare plant, though Messrs. Veitch are, I believe, busy working up a stock. There are several different forms, some with single and others with double blossoms, while I am acquainted with one plant that has the foliage prettily variegated. The leaves of this species

* Drawn for *THE GARDEN* in Messrs. Veitch's nursery by Gertrude Hamilton. Lithographed and printed by Guillaume Severeys.

Camellia japonica

are said to be used for the adulteration of Tea, and from the resemblance they bear to some forms of the Tea plant (itself now regarded as a Camellia), such adulteration would be difficult to detect. Four years ago two single-flowered varieties of Camellia were illustrated in THE GARDEN as Japanese Camellias, under which heading several forms were distributed by one of our leading nurserymen, and their appearance would suggest that *C. Sasanqua* had played a part in their production. The mere fact that single or at most semi-double Camellias are grown for sale serves to show the great difference that takes place in public opinion, for some years ago single-flowered forms of Dahlias, Chrysanthemums, and other subjects as well as Camellias would have been consigned to the rubbish heap, whereas now they have many admirers and are grown to a considerable extent. Where *C. Sasanqua* is employed for furnishing a wall out-of-doors, a south position should if possible be chosen for the purpose, in order that the wood may be thoroughly ripened.

CAMELLIA THEIFERA, the second to mention of these smaller growing species, is the well-known Tea plant, which is more generally met with under the generic name of *Thea*, though by the latest botanical authorities it is now included in the genus *Camellia*. The flowers of this are white and about a couple of inches in diameter, being composed of five spreading petals. As a flowering shrub this is not nearly as showy as some of the other Camellias, but still the pure white blossoms are very pretty when nestling among the dark green leaves. There are several forms in cultivation, selected, however, more from an economic point of view as Tea producers than for their beauty as flowering shrubs. Of the Tea plant there is a variety with variegated leaves.

Other species of *Camellia* are—

C. EURYOIDES.—A small-growing, white-flowered kind, said to be employed as a stock for grafting purposes by the Chinese, and though introduced in 1822, I am not aware that it can now be obtained in this country.

C. ROSEFLORA is very much in the way of *C. Sasanqua*, and apparently but a variety of it.

C. OLEIFERA.—Flowers white, 2 inches in diameter. This was at one period in cultivation, but does not appear to be so at the present time.

C. JAPONICA, so well known as the old single red *Camellia*, has given rise to an endless list of cultivated varieties, and is in itself a really handsome shrub, the foliage being more robust and of a richer hue than in most of the double-flowered forms. This *Camellia* is used as a stock on which to graft the others, and though seeds are rarely produced in this country, they are often imported, and when they germinate soon form stocks fit for grafting; while, singularly enough, it strikes root readily from cuttings, while the common forms are very difficult to increase in this way.

The flowers of the garden varieties differ a good deal in shape, there being the regularly imbricated bloom as well as the Anemone-flowered group; while a few, particularly *fimbriata alba*, have the edges of the petals fringed. T.

Ivy-leaved Pelargoniums at Swanley.—The zonal Pelargoniums are amongst the chief flowers grown by Messrs. H. Cannell and Sons in their Swanley nursery, but the Ivy-leaved section is also well represented. The double kinds are remarkably fine, and we made note of a few of the more beautiful. One of the finest is *Beauty of Castle Hill*, which bears very large flowers of a bright rosy colour, with a dark blotch on the upper petals. It is vigorous and very free blooming. *Rycroft Surprise* is another fine addition, a cross, we believe, between *Mme. Thibaut* and *Souv. de Chas. Turner*. We have previously noted this fine variety in THE GARDEN, and it is certainly unsurpassed for freedom and brightness of

colour, the flowers being of a salmon-pink shade. *Liberty*, pale magenta; *Edith Owen*, best described as rose-magenta, but not a dead colour; *Flambeau*, scarlet; *Galilee*, rose-pink, very free, and of excellent habit; and *Souv. de Chas. Turner* are all worth growing. The last mentioned is one of the finest of this section, the flowers rich rose-pink, and borne in large trusses, whilst individually they are larger than in any other variety. To these may be added *Beauty of Jersey*, very free, and of excellent habit, the flowers scarlet, touched with purple; *Jeanne d'Arc*, white, suffused with a lavender tint; and *Mme. Thibaut*, deep pink. There is also a fine collection of single kinds, two of the finest being *Masterpiece* and *Victoria*. The former has rich crimson-magenta flowers, borne with great freedom, whilst those of the latter are rose-pink.

THE WEEK'S WORK.

ORCHIDS.

It may be thought tedious by some were I to enlarge upon the importance of attending well to the heating of the houses at this particular period of the year, but it is of much importance that sudden

Camellia japonica anemoneflora.

falls of temperature should not take place in the houses even if it should happen that there may be a sudden change in the external atmosphere; we have already had those sudden changes within the last few days. It is even more likely that we may get such changes in October. It is generally towards morning that the frost is likely to take effect, and as we are now entering the period when sudden falls of temperature may happen, it is well that the treatment of the houses should be given when the thermometers show a lower temperature than they ought in the morning. When the temperatures happen to be very low in the morning my advice is, do not sprinkle any water about, keep the doors and ventilators close, and make up a sharp fire, being careful not to put on much fuel. One can have little or no control over a fire when the grate is choked full of coke or coals, and as the object is to get up the temperature quickly, a moderate-sized fire is best for the purpose; and not only so, but should the sun shine out brightly, it is much easier to damp up a small or moderate fire than a large one, which would have become a glowing mass rather too late to do any good, and with the sun shining brightly would do much harm. It may be taken for granted that the less artificial heat that can be used the better in any department; but we have passed through such a hot period, and that so recently, it would certainly for a time at least be better to err on the side of the

temperature being 2° or 3° too high rather than too low. The effects of cold at this season of the year are seen on the foliage of some Orchids when it is not far removed from the glass. The temperature of our own warm house fell below 60° on several cold nights, owing to the plants having to be removed into another house during painting, and the leaves of the deciduous *Calanthes* show that they do not like it. The time has arrived when the foliage will naturally decay, but it has become blotched and marked in places with decay rather too early, showing, I think, that it would be better if the temperature did not fall below 65° at this season. Other plants, although they do not so unmistakably show its effects, may feel it. All the beautiful species and varieties of *Phalenopsis* are easily injured by being exposed to a temperature below 65°, more so if the atmosphere is ever-moist, because "spot" is engendered under those conditions, and this disease causes much consternation amongst growers. Although I write about it as appearing in collections, I can truly say that during the thirty years I have had charge of Orchid collections, it has never once showed itself on plants under my charge, and I fancy it is getting less common than it used to be. This is doubtless owing to two things: first, greater knowledge of the requirements of the plants, and, in the second place, better houses to grow them in. I well remember the late Mr. Dominy, who had for so long a time charge of the Orchids at Chelsea, telling me that *Vandas* and some other Orchids had never succeeded so well in the new houses where large panes of glass were used. He fancied that the small panes and sash bars about 6 inches or so asunder were the best for Orchids. They were the best for engendering "spot" in the winter time, but I do not fancy they are the best for the general culture of the plants. Old growers doubtless can remember many handsome specimens of Orchids, especially *Aerides*, *Vandas*, *Saccolabiums*, &c., such as are now seldom seen, but in those days Orchids were few, and handsome specimens could be counted on the fingers of one hand, and everybody heard of them. Now they are plentiful in every public and private collection, and although I must be classed with the old growers, I have no hesitation in saying that the general health of all the leading collections is far in advance of what it used to be in the "good old times" of small panes of glass and sash bars placed closely together.

Those who are having their houses repainted, as we have had this year, should not only be careful to see that the plants are made thoroughly clean before being placed in the house again, but it is much better not to be in a hurry to get them back again after the painting is finished. I fancy the smell of the paint is as bad for the plants as it is objectionable to ourselves; besides, it is in every way better that the paint should be thoroughly hardened before the house is shut up. I have allowed a full week for the house to be empty after the painting was finished. During that time the pipes have been heated and the ventilators open night and day. It is better to make sure in a case of this kind. I well remember some twenty years ago one of our best Orchid growers getting a fine collection of *Cattleyas* into bad health owing to their being placed too soon into a freshly painted house—at any rate, I could never see any other cause for it; they were without exception pictures of health before the house was painted, and they never did any good afterwards. I am well aware that other causes might be at work, such as change of temperature in the removal of the plants from one house to another, but under careful management this ought not to happen. The careful cultivator will pay extra attention to his plants when painting is going on, and I may add that the fumes of paint from the pipes is even worse than that from the woodwork. The pipes should be heated when the paint is being applied, and if kept heated for a few days afterwards with an empty house and the ventilators open, there is not the least cause for

anxiety. I have found that keeping *Cymbidium Lowianum* rather pot-bound does it no harm, and if the plants get occasional doses of weak manure water the leaves still retain their healthy green colour. Some of our large specimens have been in the same flower-pots for two and three years; it is, therefore, quite time that they should be re-potted, and this will be done in a few days, using good fibrous yellow loam, a little good peat, sand, and decayed manure. Attention should be given to the *Bolleas*, *Pescatoreas* and plants of this class. See that the leaves are quite free from red spider, and that the plants are kept near the glass roof in a moist equable temperature of about 60°. As many of them will be in growth the state of the atmosphere and temperature of the house is important.

J. DOUGLAS.

THE KITCHEN GARDEN.

CARDOONS.—The blanching of these must now be proceeded with. The plan of earthing at intervals is not the best, one earthing up about now being sufficient to ensure well-blanching produce. Care, however, has to be taken that the plants are perfectly dry before being confined, as if this is neglected the chances are the stems will decay. Any small leaves or suckers clustering about the base must be removed. Being of strong growth, the outer leaves must be gathered well up together, and then with some well-twisted hay-bands commence to bind the stems well around from the bottom, binding closely up to within a foot of the top. This being finished, the whole must be well banked up with soil, bringing the sides up sharply, and making smooth with the back of a spade so as to throw off wet. Any strong flowerless growths of *Globe Artichokes* which were reserved and prepared for *Chards* should now be treated in the same way as *Cardoons*, there being but little if any difference when cooked.

YOUNG CARROTS IN FRAMES.—On frames in which young Carrots were sown for maintaining a supply during the winter months the lights must now be placed so as to keep them free from cold autumnal rains, and also frosts. Where a sowing was made on a south border for the same purpose, the *Bracken* or litter covering should be left off until protection from frost is necessary.

STORING ONIONS.—Where the Onions were not spoiled by the *Onion fly*, good crops will have been secured and also harvested in fine condition, the bulbs being now very firm and clean. But to necessitate their keeping sound and good throughout the winter, it is very essential that they should be stored well and in suitable quarters. If the bulbs are stored where they may be under the influence of warmth and also close, they will not be long in starting into growth, when, of course, their keeping properties will be much impaired, damp also being an enemy to guard against, this causing decay. The best position is a cool and airy loft where they will not be subjected to frost, laying the bulbs out thinly. The bulbs keep the longest when they are roped, and where the crop is short this will be found to be the best means of preserving them so as to prolong the supply. Where there is not a good store, the "ropes" may be hung up in an open shed, and then during severe frost they may be taken down and placed away from harm, to be replaced again after the frost has passed away.

PRICKING OUT CABBAGE PLANTS.—The plants of the succession kinds of Cabbage, such as *Enfield Market*, *Nonpareil*, or any other approved kind, may be planted out into their respective positions directly they are fit, these forming a good succession to the early varieties recommended to be planted in a former calendar. In the case of ground not being ready, the young plants should be pricked out into nursery beds to come in for spring planting, as if left as they are in the seed bed they become overgrown, and in this state are apt to suffer if a severe winter should come upon us. It is also advisable to prick out a bed of any small plants left over from the earlier plantings for filling up any gaps in the spring.

MUSTARD AND CRESS.—The season is now past for raising this under cool conditions. A succession in most cases being a necessity, the sowings should take place at not less than weekly intervals. Although such a simple crop, there are often failures with it, decaying sometimes just before ready for use. This is mainly on account of using exhausted soil, which probably has produced a crop or two previously. The soil must be rich and light, and also fresh, and then there is no difficulty if given sufficient warmth and moisture. Ordinary cutting boxes are the most suitable, these being filled with soil, the rougher being placed at the bottom with a layer of fine for the surface. A gentle watering should be given previous to and after sowing. It may also be necessary to add that the seeds should be pressed in. Shade heavily, as darkness is essential both for regular germination and securing a sufficient length of stem. When ready for use remove to a cooler position.

A. YOUNG.

PLANT HOUSES.

EARLY BULBS.—ROMAN HYACINTHS.—Where the bulbs have been obtained and potted or boxed up early as advised, the forwardest will now be well advanced in growth both at the roots and upwards. In our case the shoots are fully 3 inches in length; these with a little steady warmth will soon be in flower to commence the season. After a few boxes have been thus brought for the very earliest, the others will follow from the earliest started ones in the cold frames without any difficulty whatever. We have moved the early boxed ones under cover for several days; in doing so we found that the roots had already penetrated into the ashes beneath. This fact proves that they will come on well with but little inducement. It is useless to attempt to force early when good root action has not taken place. Nothing is more conducive to failure, and if this does then occur, it is not fair to blame the quality of the bulbs when the fault lies nearer home. Look to it that none suffer for want of water; the roots will not work kindly in the soil if it be on the dry side, and this may possibly happen where the rainfall has not yet been sufficient to thoroughly penetrate to the bulbs and their surroundings. If any bulbs have not yet been potted up no time should now be lost in getting the work done, otherwise the bulbs by later exposure will be weakened in growth; even if not wanted until the turn of days, it is better to pot up and then keep them quite cool.

OTHER HYACINTHS.—The general stock of these should now be got in, as, in the other case just quoted, these also will be none the better for remaining out of the soil any longer. One of the best successions to the *Roman Hyacinth* is the *straw-coloured French*, the value of which is not yet fully realised. It will come into flower very well for *Christmas* if potted at once, although I would prefer to have had it done a fortnight or three weeks back; thus it will be a fitting companion to the later *Roman*. The older type of *Hyacinths* for forcing for *Christmas* should at once be put in; in fact, it is now rather late for early work if time be allowed for rooting. The earliest kinds can be easily chosen from a good bulb catalogue; these bulbs it will pay to order by the dozen far better than only having one or two of each sort. Choose the best and depend on these after having secured the desired colours. No fault can be found that the early sorts are in any sense dear ones to purchase, and as these prove of the greatest value through *January* and *February*, they should not be lightly passed over. In potting these and the later sorts at one time, each should be kept separate from the other, so as to save future trouble. The early ones may well be potted up in *trebles*, thus producing a far better effect. For this purpose 6-inch pots are the best ones to choose, a saving of pots and room also being thus effected.

OTHER BULBS.—These, as *Tulips* and the *Narcissi*, should also be got in at once; good sorts of each should be depended upon. *Keizer Kroon*, *Vermilion*

Brilliant, and the old *Tournesol* are not easily surpassed for utility amongst the former, nor are *Grand Monarque*, *Gloriosa*, and *Soliel d'Or* of the latter. Do not lose sight of such fine kinds as *Bazelman major*, but unfortunately it is still dear. The *Daffodils* should also be potted or boxed up without any further delay, more particularly if they are intended for early forcing. These are as likely to fail as any bulb, when forcing is attempted, if the roots are not well in advance. Where such as *Crocus* and *Scillas* are found to be of service, as in the conservatory or elsewhere, these also should be attended to. They both make a beautiful display when in flower, giving colours not obtainable so easily in other things.

LILIUM HARRISI.—The earliest bulbs are already to hand from *Bermuda*, and no time should be lost in securing them for early flowering. In any case I would prefer to get them in at once to save injury by exposure to a dry atmosphere. These will often start into growth of their own accord if not kept quite cool; this is no more desirable in their case than in others already instanced. It is a mistake to use large pots for this *Lily*. What are termed small 32's or large 48's are amply large enough for the best of bulbs when potted singly. In larger pots with more soil there is the risk of too much water being given them, the roots consequently suffering long before their work is done, the flowers thereby being weakened.

LILIES OF THE VALLEY.—The earliest of these will soon be to hand; then if extremely early flowers are desirable they should be potted at once when they can be started; otherwise I prefer to let them rest awhile after being potted up. As a rule I think *Christmas* is quite early enough to have them in flower. Do not in any case let the single *Berlin crowns* be exposed after their arrival, otherwise the roots will be weakened beyond recovery. Immediately they are received it is not at all a bad plan to dip them into water for a few hours and then plunge in soil or *cocca fibre* refuse to keep them moist until potted.

FREESIAs.—None should be left out of the soil any longer now. If not wanted for forcing it is all the same, the small tubers suffering, with a tendency to shrivel if left exposed. Pot up and keep quite cool is the better plan. Early potted ones, I note, are already several inches high, but for these a cold frame will still be good enough for weeks to come.

JAMES HUDSON.

FRUIT HOUSES.

MELONS.—Without being actually in great demand, a few late *Melons* are yet very serviceable, being a welcome addition to the more than ordinarily meagre list of dessert fruit. In order to keep the latest formed fruit swelling freely, rather high temperatures must be maintained, 70° being the lowest figures permissible during the night, with a slight increase in the daytime. Keep the soil uniformly moist, liquid manure being applied occasionally, especially where the roots are much confined. Remove all superfluous shoots and sling up the fruit at first by means of ties at the stem, a few strings or strips of *raffia* being passed under and round the fruit a short time before the ripening period commences. When nearly or quite all the fruit are fully grown and are on the point of colouring, give rather less water at the roots, but at no time permit the soil to become dust-dry. Remember also that the fruit nets most perfectly when not unduly shaded by foliage. Late fruit keeps very much longer after it is ripe than do *Melons* cut earlier in the season. If cut before they are either cracked or on the point of separating from the footstalks, they will keep well for three weeks or a month in a dry fruit-room and be found good to eat at the end of that time. *Hero of Lockinge* and *Blenheim Orange* are among the best keepers.

CUCUMBERS.—Where red spider has been kept in check, plants put out in ridges in well-heated houses some time in July or early in August will very probably be nearly or quite as productive as

at any time previously. If it is desirable that they should be kept in a bearing state for some time longer, rather light cropping ought to be the rule, nearly or quite fully-grown fruit in particular being kept closely cut. Cucumbers are certainly at their best when used quickly, but will at this time of year keep fairly well if stored in a cool room with only their footstalks in water. Cut out exhausted growths and allow some of the clearer young shoots to extend freely before stopping, this stimulating root-action and is also the means of getting a number of fruiting side shoots. If the reserved older leaves are syringed with water in which a handful of flowers of sulphur has been mixed, this effectually checks the increase and spread of red spider. Overhead syringing should be resorted to only on clear days towards noon, and much less water at the roots than heretofore should be given. There is no necessity to ventilate at any part of the day, both old plants and younger ones thriving best when the house is kept constantly close. The night temperature ought not to fall below 70°, and a fair amount of atmospheric moisture should be kept up by means of damping down the walls and floors occasionally. Quite young plants that are to bear fruit during the winter ought especially to be lightly cropped. After the trellis is thinly covered with haulm practise close stopping of side shoots, one, or at the most two joints being left to all that there is good room for. A brisk heat and moderately moist atmosphere being sustained, root action will be brisk, quite filling the lumps of fibrous loam given occasionally by way of a top-dressing with fibres. Very much depends on this root activity, and the loam ought always to be as coarse and open as possible.

STRAWBERRIES IN POTS.—This season there ought to be few or no plants not well established, but if from any cause the final potting was late or the plants are very weakly, it is advisable to do something towards assisting them to mature their growth. All that stand in need of it should be placed in cold pits or frames, being raised well up to the glass, freely ventilated, and not allowed to become dry at the roots. It is yet somewhat early to store Strawberries in pots in rough pits or frames, but all should be moved with a view to preventing roots from leaving the pots, being also cleared of runners and weeds if any. If a single strong crown is preferred to two or three, it is not yet too late to remove all but the stoutest, and the latter will plump up more strongly accordingly.

LIFTING FRUITING STRAWBERRIES.—A considerable number of plants that fruited in the open early last season, in addition to those that were turned out from forcing houses, have borne, or are bearing good second crops. So heavy are these late crops, that it would pay well in many cases to lift a number of plants in order that the ripe fruit may have a chance of swelling and ripening under glass. Heavy rains having fallen, the soil may have become well moistened, otherwise it will be better to use the watering pot freely before lifting rather than attempt remoistening the hard, dry soil subsequently. They should be dug up with a moderately large ball of soil about the roots, and be placed in pots that will hold them without a severe reduction being necessary. What little fresh soil is needed ought to be rather rich. The smaller pots may be set on shelves in Peach houses and vineries, the fruit ripening well in these or other cool, light quarters. Some of the plants may need 10-inch pots, and these can be arranged in the front of fruit houses generally.

STORING LOAM.—After enough rain has fallen to well moisten turf, and before it becomes saturated, is the time to cut and store for future use. Very often there is no choice, fruit growers in such cases having to do the best they can with available material. For Pines it is of the greatest importance that a good brown fibrous loam should be forthcoming, nothing but the thin strip of turf from an old, well-drained pasture being really suitable for these. It ought to be cut and stacked, grass downwards, apart from the rest, and if kept fairly dry should be in prime condition for use

next spring. Also cut and stack turves not more than 2 inches thick for Vines, Peaches, Cucumbers and such like. A rather strong loam best suits the first-named, and in fact most other fruit trees, but Cucumbers should have soil with little or no clay in it. Melons, on the other hand, thrive best in a solid root-run, fibrous loam not being indispensable in this case. In many instances the soil immediately below the top strip of turf would suit Melons well, and could be dug in quantity, ordinary garden soil being substituted and the turf restored to its original position. If the removal of turf is objected to, and it is a very common occurrence, the same plan might be adopted when fresh loam is required in quantity for other purposes. The turf should be pared rather thinly, and it will then be possible to dig a thin layer of fairly fibrous loam from underneath. Rather rich fibrous loam answers best for top-dressings, and if a thin layer of good farmyard manure alternates with the turf in a stack, this will improve it considerably. Soil generally should be stacked where there will be no likelihood of its becoming saturated by stagnant water, and where also the roots of Elms or other forest trees cannot reach it. A hard, dry bottom is preferable.

PRACTICAL.

ROSE GARDEN.

ROSES AT COLCHESTER.

THE present year, although exceptionally trying for the flowers of Roses, has not affected the plants. We are surprised at their healthy and vigorous aspect, rewarding us at this late date with a profusion of bloom. It is the Tea section in particular that is most noteworthy, and when in the nursery of Mr. B. R. Cant at Colchester a few days ago the plants were in full beauty, giving promise of continuing in that condition for several weeks. Roses this year have proved most quixotic. The calculations of exhibitors have been entirely upset, and in Essex—in fact the eastern counties generally—the flowers at the time the shows were in full swing were not in perfection. Those who care little for shows do not grumble at this, as the autumn display is highly enjoyable. The nursery of Mr. B. R. Cant stands on hilly ground, overlooking, so to speak, the town of Colchester, and here on this exposed breezy spot the Roses flourish in a way seldom seen in other parts of England. Of course the highest culture is given, and at an interval of a few years the position is changed, whilst the soil is of deep, strong character, with the result that the Roses are in the rudest health. All classes are grown, and especial attention is being given to the garden types, as the Provence, Moss, Bourbon and others, which are increasing greatly in favour. We have only to visit an exhibition to know this, and the splendid bunches of flowers are amongst the most pleasing features. The Roses are for the most part upon the Brier stock, and Mr. Cant gives preference to the cutting Brier.

It is the Tea section that we may first mention. Jean Ducher has proved one of the best varieties this year, and though a comparatively old Rose, having been distributed by Ducher in 1874, it is of note, the plants strong in growth, and the flowers of a charming yellow shade, suffused with salmon, which is touched with rose in the centre. Marie van Houtte is also superb this year. It is interesting to note the behaviour of certain varieties placed under similar conditions. Mme. Pierre Guillot, one of Guillot's most recent additions, is evidently of no good for England, at least in the eastern counties it refuses to bloom with freedom, the flowers developing far better under glass. Sappho, raised by Messrs. Wm. Paul and Son, is a splendid variety as seen here, a good garden Rose, exceptionally free, the flowers of an apricot colour, suffused with rose, passing to rich yellow in the centre. Very beautiful is the variety Mme. Bravy, which is a very old kind. It was sent out by Guillot as far back as 1848, the flowers of charm-

ing shape, white, suffused with delicate pink in the centre. It is still one of the best of the Tea-scented varieties. Princess of Wales, one of the late Mr. Henry Bennett's seedlings, was in full bloom, but it varies greatly in colour, sometimes almost a rich rose; the characteristic colour is deep yellow in the centre of the flower, the outer petals touched with rose. Rows of Rubens are worth noting, and also of the variety Souvenir de S. A. Prince, which is placed against Catherine Mermet, its parent. There is no difference between the two except the important one of colour, the sport being white, the flowers large, full, and of great value for cutting. A Rose that will be useful in the garden is Grand Duc Guillaume de Luxembourg, to give its full name, but an abbreviated form of this is essential. French raisers seem afflicted with a mania to give names to their novelties of inordinate length, but no greater mistake can be made. This new Tea Rose will not, we think, be of much account for exhibition, but the rosy-coloured flowers are bright, produced freely, and the plant is compact and vigorous. It was raised by Souper and Notting.

In a field of several acres is a splendid piece of standards and half-standards, and it may be useful to our readers to give an indication of the most successful varieties in this form. Amongst Hybrid Perpetual varieties, Merveille de Lyon is one of the finest. It is a splendid Rose and makes sturdy half-standards, the large flowers of a creamy white colour touched with rose. Of course, Mrs. John Laing is of note, but this seems to succeed under all forms. La France did not bloom well in the summer, but it is very beautiful just now; whilst a note may be made of the popular Maréchal Niel as a half-standard, a large break of this kind being in bloom. It makes a better climber for the conservatory or greenhouse when grown as a half-standard than as a dwarf. When visiting Mr. Cant some time ago we mentioned Suzanne Marie Rodocanachi, raised by the celebrated Verdier. It was very beautiful in late September, and also flowered freely during the summer months. The flowers are clear shining rose in colour, bright in the garden and useful for exhibition. Curiously this year the dark Roses have been in perfection, and kinds that seldom prove satisfactory were in superb condition, such as Pierre Notting, of intense colour, rich crimson, touched with a purplish tone. One would suppose that the dark Roses would have been burnt up by the fierce sun, but such is not the case. The only reason why this type fails in warm countries is the scorching of the petals through excessive heat, but in the height of the show season the dark Roses were the most beautiful, in spite of tropical sunshine. We think that the experience of Mr. Cant is general. There has been much discussion respecting the American kind named Waban, a Tea-scented variety, but it is not thought much of here. The flowers are pleasing in a way and the crimson colouring is bright, but it is not a Rose for general cultivation. Perhaps a more lengthy trial of it will produce a better impression. Mme. de Watteville, a Rose which is of delightful beauty when in true character, was sent out by Mr. Cant and raised by Guillot. It is not so satisfactory as one would like this year, although on half-standards we saw some very good blooms, but they are not constant. Such favourites as Mme. Lambard, Anna Ollivier, Souvenir d'Elise, Mme. Hoste, Mme. Cusin, which is, unfortunately, inclined much to mildew, Luciole, Ethel Brownlow, Amazone, the Hybrid Tea Angustine Guinoisseau and Isabella Sprunt are very beautiful.

Nothing except Roses have a place in this nursery, and every style is grown. We were pleased with a fine break of climbing kinds, including many that are little known as yet in gardens. One of these is Henriette de Beauveau, one of Lacharme's acquisitions, and sent out in 1887. But it is not often seen, although a very fine climber, strong, free and useful either under glass or in the open. The flowers are rich yellow, full and very sweetly scented. Mme. Berard is of the Dijon type, but it is difficult to eclipse in general excellence the old Gloire de Dijon, a Rose for every garden, and

without rival for freedom, fragrance and bardness, in spite of what some writers aver, that there are other superior kinds. It would be interesting to know their names. A strong growing climber comparatively little known is the Tea-scented Duchesse d'Auerstadt, one of Bernaix's acquisitions. The flowers when in the bud are deep yellow, but on expansion get a tinge of nankeen colour. It may be recommended for the sake of variety amongst climbers, because, however beautiful a certain kind may be, it should be varied with others. W. A. Richardson was superb for colour, and L'Idéal, raised by Nabonnand, was bright with many flowers. It is exquisite in the bud, but the flowers are thin when fully expanded, the colour, however, being yellow and crimson shaded, touched with gold. It makes a strong rambling growth. One of the most recent additions to the Gloire de Dijon type is Kaiserin Friedrich, which was raised by Drogemüller. It is distinct, but resembles most closely Mme. Berard, the flowers yellow with a tinge of apricot in the centre, a few petals perhaps tipped with rose. Judging from the specimens here, it is of strong growth. Climbing Niphetos has become a thoroughly well established climber, and it was very beautiful at Colchester. When first sent out by Messrs. Keynes, Williams and Co., we thought it too close to Niphetos itself for any award, but the climbing habit is very pronounced, whilst as regards freedom and beauty of flowers it is identical. A very welcome climbing Rose is Climbing Perle des Jardins, which is most suitable for walls or under glass. It has bloomed remarkably well this year, and is a sport from Perle des Jardins. A Rose that has been exhibited frequently this year is Gustave Regis, a good variety for a wall and of vigorous growth. The flowers are nankeen-yellow, and in the early summer the buds are very long, but not in the autumn. A new Rose that has not yet bloomed at Colchester is Climbing Souvenir de la Malmaison, sent to Mr. Cant from Mr. Bennett, of Australia, where we believe it originated. It is described as a vigorous climbing sport from the old Souvenir de la Malmaison, and if it is as fine in other respects will be a valuable novelty.

A Rose that has been exhibited on several occasions remarkably well by Mr. Cant is Gustave Piganeau, one of Pernet and Ducher's finest seedlings. The flower is of immense size and almost faultless for exhibition, its colour being perhaps best described as a deep shade of carmine. It promises to be as useful as Ulrich Brunner, which became a favourite at once. Three other Roses may be mentioned, and one is Mons. de Morand, sent out by Schwartz in 1891. The flower is large, and the colour deep velvety crimson. Judging from the plants here, it is a thoroughly good kind. Gen. Baron Berge appeared about the same time, and is one of Pernet père's additions. This will prove, we think, a good dark Rose for the garden, the flowers bright red and very free. It is a good grower. Amongst Teas a very fine Rose of comparatively recent date is Ernest Metz, a variety highly prized in the garden and exhibition, the flowers soft carnation-rose, which deepens in the centre. They are held on a sturdy stem, and useful for cutting. A bed of it in the garden is full of charm, and the plant blooms well through the autumn.

The Manetti stock is not in great favour at Colchester, as we have previously remarked, but a large break is on this stock, and the varieties comprise twelve of the most useful garden Roses in cultivation. We give the names, as such a short and select list might prove of value to amateurs who want only a few kinds. They are the old, but still worthy Alfred Colomb, A. K. Williams, Charles Lefebvre, Gustave Piganeau, La France, Marie Baumann, Merveille de Lyon, Mrs. John Laing, Suzanne Marie de Rodocanachi, Ulrich Brunner, Prince Arthur, which was raised by Mr. B. R. Cant, and Jeanne Dickson, raised by Messrs. A. Dickson and Sons, a splendid variety, the flowers large, silvery rose in colour, and very fragrant.

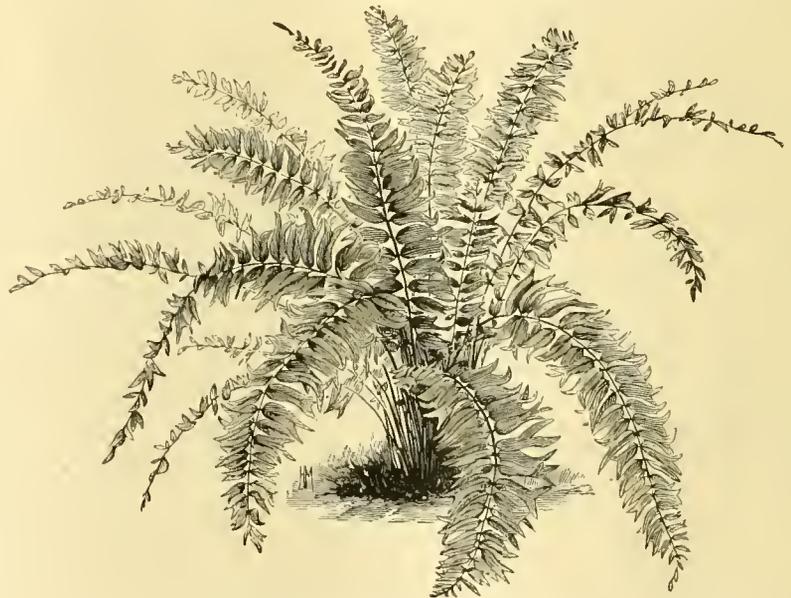

An important and fast-increasing class of Roses is that called the Hybrid Tea-scented, but this

section is getting much mixed, some of the more recent additions being as like a Hybrid Perpetual as a Tea. But we place all kinds under this heading that are so arranged in the best catalogues. The Hybrid Teas this year have been in most places a complete failure, with the exception of the varieties Grace Darling and La Fraicheur; but at the present time they are making amends for their behaviour earlier in the season, several kinds blooming very freely. Grace Darling, which is one of Mr. Henry Bennett's best Roses, is a thoroughly good variety for gardens. It commences to bloom early and is one of the last to cease, whilst weather seems to have little influence upon it. The flowers are full, creamy white, lightly touched with rose, and the petals are margined with the same shade; whilst both leafage and growth are exceptionally robust. Mr. Cant praises La Fraicheur highly, and plants on the cutting Brier are very fine, whilst in pots it is first-class. The flowers are of a rosy shade touched with carmine, and the buds long, expanding into a full handsome bloom. Lady Henry Grosvenor, quite a new Rose, is especially recommended for pots, and its blush-white colour is certainly pleasing. One of the more famous acquisitions to this section is the variety Caroline Testout, a very beautiful Rose, and the plants

upon this stock and in rude health. Near Mr Cant's residence are some noble bushes of well-known kinds, which show the beauty of the Rose when advanced in age, large standards covering much ground and giving hundreds of flowers.

MILDEW ON ROSES.

THIS disease has come on very suddenly—in fact during the last week my plants have become smothered with it. Of the two, I think the Hybrid Perpetuals upon the Brier stock are most affected. There is no disease more annoying or destructive among autumnal Roses than mildew, and, unfortunately, the last few weeks have been greatly in favour of its development. The nights have been exceedingly cold for the time of year, and when these are contrasted with the hot days we discover a serious difference between the two temperatures. In some respects it is very seasonable, for no one who has given a little trouble and observation to the matter can doubt but that plants grow much more during the night and early morning than they do throughout the remainder of the day. Now as we do not want much more growth colder nights are beneficial, while the fine

Nephrolepis davallioides furcans.

were blooming with great freedom. Each row was bright with colour, the flowers large, reminding one something of those of La France, and soft pink, in which there is a suspicion of salmon shade. It will, we think, become much grown both for the garden and exhibition. Viscountess Folkestone, one of the most beautiful of Bennett's Roses, has not been so good this year as usual. It requires cooler weather, but it is a Rose that should be in every collection. The flowers are very beautiful early in the season, and even now are satisfactory, whilst the cream-white colour, touched with a delightful salmon-pink shade, is unsurpassed. A group of this should be planted, as in this way one gets the full beauty of the large, informal flowers.

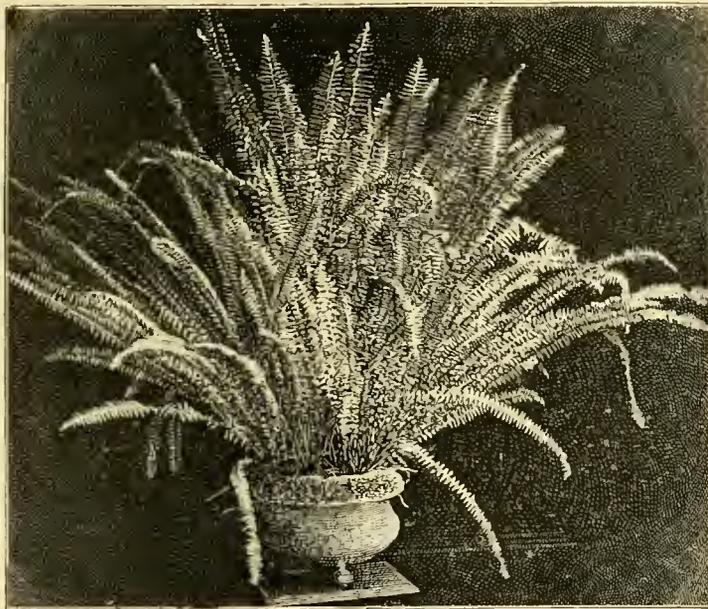

Much is said and written against the De la Greferaie stock, but for a certain class it is of value. A large break in Mr. Cant's nursery is upon this stock, but only used for the very strong growing climbers. Perhaps they are no better on this stock than on the Brier, and if matters could be reduced so that only one stock is used, so much the better for gardening. Such very vigorous varieties as l'Idéal and Homère were in marvellous health upon this stock, the last-mentioned variety in particular, which we have never seen so beautiful in the autumn months. That splendid trio, General Jacqueminot, Jules Margottin, and Gloire de Dijon, are

and dry autumn is ripening the wood of Roses in a splendid manner. But it is owing to these extremes of temperature that mildew has increased so rapidly during the past fortnight. Mr. Mawley's interesting note upon the "Weather in West Herts" is very similar to that experienced in mid-Sussex. More than once last week the temperature reached 100° in the sun, and upon two occasions there was slight frost in the morning, with a dense and very cold fog on Friday. Whether indoors or out, plants that are so subject to mildew as the Rose cannot stand these sudden changes. That this is one of the chief causes of mildew has been noticed over and over again, and we find yet another instance this season. All through the hottest part of the summer, when both day and night were proportionately warm, we did not suffer from mildew, but early in the season, when the temperature was fluctuating considerably, we were threatened with a severe attack. It is already very general upon Roses in this district, and autumn crops of bloom are greatly damaged. The parasitic character of mildew robs the plant of all life and energy, while at the same time it chokes up the pores and arrests all development of foliage. There is no remedy really worth the trouble for outdoor application in the autumn, but in the spring and early part of the summer remedies are

necessary. You cannot possibly kill and prevent the recurrence of this disease upon Roses in the open border late in the season, the chief causes being so entirely beyond our control. But where it has attacked plants under glass measures should be taken to eradicate it and prevent its spreading. I have already pointed out that the chief causes are the extreme variations in the temperature. We can remedy this under glass, and with care, combined with a few simple remedies, mildew may be prevented from doing much harm. At night time, so long as we are favoured with such extremes of temperature, it will be found much better to close the house, opening again about 7 or 8 o'clock in the morning. In the case of plants that are almost ripe, and which are not intended for early forcing, I am not much alarmed at the presence of a little mildew, and would rather open the houses sooner than risk the too premature excitement of their wood. In this case a stronger solution of the insecticide I will presently name may be used when all of the foliage is off. Some authorities state that the spores of this fungoid disease remain in the soil. While not disputing this fact, I am certain they will not germinate unless it be under favourable conditions, and as it is, or should be, the aim of all growers to avoid this,

syringing the plants, otherwise the bulk of the paraffin will be at the top and the sulphur at the bottom of the solution. This is a splendid remedy for mildew, and can do no harm. Use it freely, bringing the whole of the wood and foliage into contact with it, and applying it immediately mildew appears. The sulphur and paraffin are death to all mildew spores they come into contact with, and at the same time they leave the foliage clean and in a disease-resisting state. I have tried many remedies, but this is the cheapest and most effectual I have yet met with. Not only is it deadly to mildew, but it kills green-fly, red spider and thrips.

In mentioning the chief causes of mildew, I did not give sufficient attention to watering. Sudden atmospheric changes are only little more injurious than the same extremes in moisture. We are occasionally reminded of this very forcibly. One may have been watering a few plants in order to throw more size and colour into an exhibition bloom. When this has been secured, less attention is oftentimes given to the plants, and mildew attacks them much more than those which had no artificial watering. Under glass, too, we find neglect in watering has a great influence upon the appearance and spread of mildew. Whether it be

Nephrolepis exaltata.

and also bearing in mind that a few of the spores are certain to be in the soil, and are capable of such rapid reproduction, I fail to discover any advantage in lessening their number now. This is only referring to ripe plants. When young growth commences again, we must avoid giving the spores any opportunity to germinate, and if the following solutions be used as directed, with careful ventilation and watering, I have very little fear of mildew under glass.

I find the cheapest composition to be good soft soap boiled for about ten minutes, and immediately it is taken off the fire I add a wineglassful of paraffin to every pound of soft soap, also about the same quantity of flowers of sulphur. Stir the whole together, and give it a few turns at intervals while cooling. I have given the amounts in the above form to simplify matters, and if a gallon of water be used when boiling each pound of soap, the result will be ample for making 12 gallons of solution. More or less may be made, but it will be best to manufacture enough for more than one application, as it will keep good for a long time. Before adding any of the mixture to a larger quantity of water it should be thoroughly stirred together. The same precaution should be taken when

a check afforded by drought or from sudden atmospheric changes, the result is much the same; the tone of the plant is lowered, and consequently any disease gains an easier footing. Most of the advertised insecticides will check mildew, but when used at the strength recommended they are somewhat expensive. They may, however, be considerably improved by the addition of more sulphur and a little paraffin when used for the purpose under notice; in this case half strength of the original insecticide will be sufficient.

RIDGEWOOD.

Roses for exposed positions.—In reply to a query upon p. 294, I would suggest that the following varieties be used. Roses with a bushy habit would be preferred, so I propose dividing the list into two sections—extra vigorous growers, and those with a dwarf and more compact habit. For my own part I should choose the vigorous growers, and train the shoots horizontally right and left of each stool. By doing this the fence will be covered more quickly. Strong growers.—William Allen Richardson, orange and apricot; Miss Glegg, white; Aimée Vibert, white; Reine Marie Henriette, red; Dundee Rambler, blush white; Mme.

A. Carrière, white, with a yellow base; Gloire de Dijon, buff; Rêve d'Or, yellow; Mme. Chauvry, copper and nankeen; Mme. Berard, buff and orange; l'Idéal, coppery orange and peach; and Gloire de Bordeaux, deep rose. All of the above are very hardy, and will afford a good variety of colour. They may be planted 12 feet apart and trained to meet one another. A long iron fence in my neighbourhood is completely clothed with the four first varieties I have named. As the plants will be much exposed, together with the fact that frost is more injurious near to water, I would advise allowing them to grow at will, simply removing a portion of the oldest wood late in each spring. For growers of more compact habit I would choose the following dozen as being very hardy and free bloomers: Annie Wood, deep scarlet; Baroness Rothschild, delicate flesh; Dr. Bailon, deep carmine; Dupuy Jamain, bright cerise; General Jacqueminot, deep scarlet; Francisca Kruger, copper and peach; Goubault, rosy pink; Homère, rose and flesh; Mme. de Tartas, bright rose; Captain Christy, clear flesh; the common blush China Mrs. Bosanquet, pale creamy flesh; and Souvenir de la Malmaison, white and flesh. Three feet apart will be none too close for the above if the fence is to be clothed as soon as possible. If a few more of the darker coloured kinds are wanted than can be found among the climbers, they may be selected from the list of shorter growers, the relative distances apart recommended for each being observed.—R.

FERNS.

NEPHROLEPIS.

I AM asked by Mr. Watson, a reader of this paper, to say a few words upon these Ferns. The falling pinnae and the bare stems he complains of are the result of dryness at the root. The genus has a very wide distribution, being found in both hemispheres. Some of the kinds are useful for planting in the stove fernery, while many of them form excellent specimens for pot culture. They also make beautiful objects when grown in hanging baskets. Water must always be given in abundance, as well as plenty of moisture in the atmosphere, for by this means I believe the long creeping roots and youngshoots obtain a great amount of sustenance. Although these plants require such a large amount of water, they do not like it to be about them in a stagnant manner, so that it becomes specially requisite to provide ample drainage, using for soil two parts good loam, one part leaf-mould and one of peat, the whole made sandy and thoroughly mixed. The following kinds are well deserving the attention of Mr. Watson, or, indeed, any grower and lover of Ferns; all of them like stove heat:—

N. BISERRATA.—This, which appears to be very widely distributed, is a fine strong-growing plant, admirably adapted for a pot specimen. It makes large fronds from 2 feet to 4 feet long, and indeed Col. Beddome records them double that length; pinnae some 5 inches or 6 inches in length and about an inch in breadth, both surfaces tomentose when young, but with age becoming smooth and deep green.

N. DAYALLIOIDES.—Another kind which, like the one previously named, succeeds best when grown as a pot plant. The fronds, which are some 3 feet or more in length, are arching, the pinnae large at the lower part of the frond, but in the upper part they are contracted. It is one of the best and most handsome Ferns for the stove decoration or for public exhibition. This fine plant is said to have been introduced from Java about forty years ago by the Messrs. Rollisson, then of Footing. The cut herewith represents a form of it called furcans.

N. ENSIFOLIA.—In this plant we have a remarkably fine and useful kind for the fernery. The fronds grow from 2 feet to 4 feet long, having broad pinnae about 4 inches in length and bright green; these are borne upon a very slender rhizome and are pendent.

N. EXALTATA.—This is the one which Mr. Watson encloses for a name. It is the one most commonly met with, and it is as widely distributed. When grown in the stove with arching fronds from 3 feet to 5 feet in length, and bearing upwards of 100 pairs of pinnae, which vary in length from 1 inch to 1½ inches and pale green in colour, it is one of the most beautiful kinds.

N. FALCIFORMIS.—This is more suitable for a pot specimen, because its fronds are more erect in growth. I have only seen this plant with fronds some 2½ feet long and 4 inches broad in the widest part. The lower pinnae are sterile. The sori are large, forming a decided ornament. It comes from Borneo.

N. HIRSUTULA is a species not commonly met with, a great many associating it with *N. exaltata*, from which it is quite distinct. It is erect in habit, from 18 inches to 2½ feet long, and 2 inches to 3 inches broad; the rachis clothed throughout with bright ferruginous hairs, and the pinnae also covered more or less with short ones of the same colour. This plant one of the most beautiful of the *Nephrolepis*.

N. PECTINATA is a small-growing and exceedingly pretty Fern. I have received specimens from J. Reynolds, some of which are forked at the top, which is quite unusual. The normal form of the plant is to have a frond from 1 foot to 3 feet in length, and about 1 inch in width, the pinnae being set very close and bright green. It is a grand plant for the rockery.

N. TUBEROSA.—This is an evergreen plant which makes tuberous roots, and hence it has been confounded with *N. undulata*, from which, however, it is quite distinct. It is an excellent basket Fern, and produces pendent fronds some 18 inches or 2 feet long and deep green. It much resembles a gigantic form of *N. pectinata*.

N. UNdulATA is a very pretty species, quite distinct from any other which we have in cultivation, and it is admirably suited for basket culture, being deciduous. The fronds are usually from 1 foot to 2 feet long and between 2 inches and 3 inches wide. The brown sori make it a very showy plant, the upper side being light soft green. Care must be taken not to dry it too much during the resting season. W. HUGH GOWER.

THE LITTLE TREE FERN OF HONG-KONG.

(*BRINEA INSIGNIS*.)

AMONG some specimens of Ferns named by me last week for "Globe Trotter" I omitted one or two. One which he thinks is *Branea insignis*, after careful examination, I consider a narrower form than usual of *Blechnum orientale*, which is a somewhat common Fern throughout India, but I am unaware if it is found in the island from which the *Branea* was first introduced, and which, with the Khasya Hills and one or two other places on the Indian territory appear to be the only places where it is to be found. *Branea insignis* is a very elegant plant, which a few years ago I was glad to see had been obtained from spores, and was becoming somewhat widely distributed, but during the past year or two it has apparently died out. I should like to have the experience of those who have raised these young plants from spores, because, although I have raised many thousand Ferns in this way, I never got this one beyond the prothallium state. Not a frond was produced from them, and I utterly failed to raise young plants of this species. Of the Fern sent by "Globe

Trotter," I have raised many from time to time, although I think it is one of the rarer species of *Blechnum* in cultivation. One particular point of distinction is that in this plant the pinnae are sessile and adherent, whilst in *Branea* the pinnae have a truncate base. *B. insignis* is a highly interesting plant, and I have had it with stems 3 feet and 4 feet high which had been imported from its native country (Hong-Kong). I have never seen the Indian form in a living state. The stems are stout and very much like a *Lomaria*, as indeed is the whole plant; the fronds are some 2 feet or more in length, having opposite, somewhat narrow pinnae of a rich green, which in the fertile frond are much contracted, so that the under side is entirely covered with the sori. The plant grows well if potted in a mixture of light turfy loam and peat made sandy, with good drainage. It enjoys a good amount of heat and a moist atmosphere. I do not know the spots this plant grows in naturally in Hong-Kong, but I have found that it likes shade. I believe in its Indian habitat it grows from 3000 feet to 4000 feet altitude. W. HUGH GOWER.

KITCHEN GARDEN.

DEEP CULTIVATION.

IN this long season of drought and bright sunshine it will have been noticed that those soils which were the most deeply worked, and especially those of a gravelly or light nature, held out surprisingly well, whilst in others which were but lightly worked there was the greatest difficulty imaginable in enticing the various subjects to grow. Even where there was an ample supply of water the returns were anything but satisfactory, and not to be compared to others produced from well or deeply-worked soils, and without any water, or but little being applied. I have long been of the opinion if those people who are responsible for the cropping of a kitchen garden were to bestow more pains in the proper working of the soil, there would be far less need in having recourse to the watering-pot upon a spell of dry weather occurring. That this has been an exceptional season I must admit, but this does not lessen the necessity for attending to the proper working of the soil. With ground deeply worked, the roots of course can penetrate more deeply than they otherwise would where there is only a few inches of loose surface, with a hard subsoil beneath, and which during a dry season is harder still. To secure an ample depth of good fertile soil capable of supporting the various crops that have to be produced, there need be no necessity to go back to the old system of trenching formerly in vogue, and that of turning over the soil two or three spits deep, placing the bottom to the top irrespective of the condition it was in. Not a few kitchen gardens have been absolutely ruined for the production of good vegetables for at least two or three years, or until the bottom soil was returned again to the surface. Much valuable time may, therefore, be lost by going about this work in a haphazard manner.

For the majority of soils, more especially those which have been only surface worked, what is known as bastard trenching would be much the better system, as by this method the best surface soil is kept at the top, and the bottom soil improved by well working this over and adding any material which may improve it.

Besides manure, road scrapings and trimmings from roads will form an excellent addition, but to be used only in a dry state. Garden refuse of any kind may also be added with advantage. The mode of bastard trenching has been previously explained in THE GARDEN, but for the benefit of younger readers it may be necessary to add that this form of trenching is managed by marking out a straight trench from 30 inches to even 3 feet in width, and taking this out to the depth of the spade or fork and also the shovellings. This must be wheeled to the far end of the plot where it is intended to finish. The bottom trench must now be well broken up, going as deeply as possible, afterwards forking in any material it is desired to add, also spreading a layer of manure on the surface. The top portion of the next trench is now placed on this, and the bottom served in the same manner until the whole plot is finished. A depth of well-worked soil will now be secured from 20 inches to 2 feet in depth, and being laid up to the pulverising influence of winter frosts will have settled down by cropping time in the spring into a fair depth of well-worked soil. There are other soils which are undoubtedly improved by working some of the bottom soil to the top, and this in those old gardens which have been cropped and manured for years.

The reason generally given for not attending to deeper cultivation is want of labour, and a good reason it is too, as labour is none too plentiful in the majority of gardens. This season may prove an exception, as on account of the general earliness of the season, time may be found to commence such work at once, and in a month or two, two or three men would get over a good extent of ground. Very light or gravelly soils, and which are not likely to be injured by working during the winter, may certainly be operated upon during the whole of this time. During frosty weather I have been enabled to keep men at work by laying a covering of litter over the surface, and where such can be managed, the labour necessary for the work is hardly felt, as other work at these times is not very pressing. It is quite evident that if we are to have a recurrence of these dry seasons, nothing short of deep cultivation on light soils will produce satisfactory crops and lessen labour in watering. A. YOUNG.

Vegetables at The Quinta, Chirk.—Early Potatoes are good crops and of splendid quality, the second earlies being good in every way. Field crops look full of vigour and promise well for heavy supplies. Early Peas, Potatoes and Cauliflowers were quite a month earlier than usual. Early Peas lasted a short time owing to the exceptionally hot, dry weather. Onions and Carrots at one time looked like failures, but since the rain came they have improved wonderfully. It has been uphill work getting winter stuff into their quarters, but on the whole since the rain the plants are doing well.—J. LOUDEN.

Blanching Celery.—When looking through the gardens at Inwood House, Blandford, recently, I observed that Mr. Wilkins had a large number of early sown plants unearthened, but were bound up with paper bands and also largely enclosed with round drainpipes. This practice is an old one, and specially so for many years in Lancashire, from whence it seems to have been carried south. That by this method, and it is not at all a troublesome one, the brightest and cleanest stems can be cut there can be no doubt; in fact, no Celery blanched by soil, however carefully, can equal on the exhibition table those stems that have been paper-blanching. As to how far such Celery may have the sweet, nutty flavour that fine dry earth imparts I cannot say, that is a matter for experts to

determine, but Celery on the show table is not tested for flavour. Later only such as have been blanched by earthing is possible, as plants paper-bound would suffer materially in hard weather. There is an advantage about the paper blanching that is not found in earthing. The plants can be fed by liquid manure up to the last moment if it be desirable. On the other hand, air cannot be so thoroughly excluded from the stems as is the case when earthing is done well.—A. D.

Autumn young Carrots.—I was particularly pleased to see at Claremont just recently a large bed of young Carrots from seed sown in July. The roots had been moderately thinned, and were just becoming of the right size for pulling and cooking. Mr. Burrell was in the spring much troubled with Carrot maggot, and the excessive dryness of the soil promoting slow growth and rather hard irregular roots, and therefore the particular necessity to sow again. No doubt there, as should be the case everywhere, a July sowing has become now a regular practice. Such a bed as this will give soft, tender Carrots up to Christmas, indeed pretty well all the winter, if what be left in December is protected from severe frost by a little covering. One of the best Carrots for this purpose is the Long Horn or Early Nantes, also known as the Early Champion, a fine variety for early as for July sowing.—A. D.

Dwarf Perfection Parsley.—I had not seen this in any private garden until the other day Mr. Burrell drew my attention to a bed of it at Claremont, where it exhibited just the same admirable character seen at Reading. It looks as if it were the product of a cross between a good strain of treble curled and the Fern-leaved. It is a distinctly dwarf form, the plants forming compact and very handsome bunches of very green leafage, which is finely cut or lacinated and very pleasing. The fine leafage and rich deep colour form specially good features in the variety, for most of the best double curled strains are too light in colour. This dwarf Perfection Parsley is evidently very constant and hardy.—A. D.

THE FRUIT CROPS.

WALES.

Bodnant, Eglwysbach.—I am pleased to be able to report most favourably upon the fruit crops in this neighbourhood. Apples are abundant, and thinning has been resorted to wherever possible, whilst the quality is excellent. Pears are an average crop of fair quality. Plums a very heavy crop and of fine quality. Apricots a fair crop of fine fruit. Morello Cherries are heavily laden. Strawberries were under average, and the fruit poor through lack of moisture. Currants were plentiful, but of medium quality. Gooseberries a full crop of fair fruit. Raspberries average crop, and the fruit good. Old Walnut trees appear to be well cropped. We only registered about 5 inches of rain between March 1 and the last day of June. Most of the trees rest on a clay subsoil, which may account for present state of crops.—J. SAUNDERSON.

Cardiff Castle.—This has been one of the hottest and driest seasons I ever remember. The rainfall in March was 35 of an inch, which fell on six days, and the fall in April was still less—25 of an inch, which fell on three days. The rainfall in May was 2.49 inches, but owing to the long-continued drought and the prevailing hot weather it soon evaporated, and vegetation was little benefited by it. The fall in June was very low, .60 of an inch, with a high temperature and bright sunshine which dried up the ground to a considerable depth, causing vegetation to suffer severely. The rainfall in July up to the time I write (July 24) has been 4.24 inches. The ground has had a good soaking, and the fruit trees a good washing. The insect pests have mostly disappeared, and the trees are assuming a fresh, healthy appearance. All kinds of fruit trees flowered freely this year from a fort-

night to three weeks earlier than in most seasons. The weather was favourable during the time they were in flower, and the fruits set well and swelled away freely until the trees began to feel the effects of the drought, when the Apple trees got infested with red spider and the fruit began to drop in great quantities, and it continued to fall, more or less, until the rain came. Apples, Pears, and Plums are plentiful in this district, and in many cases the branches have had to be propped up to keep them from being broken by the great weight of fruit, which is swelling rapidly since the trees have had plenty of moisture at the roots. Strawberries, mulched early in the season with rough stable litter, withstood the drought well, and produced a good crop, which began to ripen three weeks earlier than in ordinary seasons. Scarlet Queen ripened first, fully eight days before Noble, both growing side by side on a south border. The fruits are not so large nor so fine looking as those of Noble, but they are firmer and of better quality. Gooseberries, Raspberries, Black, Red, and White Currants have been plentiful and good in this district. The Vines in the vineyards at Castle C. ch., Swanbridge, and St. Quinten's Castle are covered with fruit, and the plants never looked better; the hot dry season seems to have suited them, the foliage is clean and healthy, and the young canes of this year's growth are stronger than ever I remember them before. The bunches of Grapes are large, and the berries are as forward now as they generally are at the end of the season. If the weather proves favourable there will be a full vintage this year of many tons.—A. PETTIGREW.

Gogerddan, Aberystwith.—The fruit crops in this neighbourhood are very good, Apples, Plums, Cherries, and Gooseberries being above the average. Pears are an average crop, also Currants, but Apricots are under, and Strawberries were dried up owing to the hot weather we have had. The crops are about three weeks earlier this year than usual.

Potatoes look well and show no signs of disease. The crops here are better, on the whole, than for many years past.—J. VEAREY.

Pen-y-wern, Aberystwith.—The fruit crops in this district are, on the whole, very good. Apples are a very heavy crop, in many cases the trees being weighed down. Of course, in such cases the fruit is small, but on trees where the crops are not too heavy it is a very good sample, quite up to the average. Pears are also a very good crop, Williams Bon Chrétien, Marie Louise, Josephine de Malines, and Marie Louise d'Uccle bearing heavy crops, while most other sorts are of a good average size. Plums of all kinds are an enormous crop. We have had to thin the fruit heavily, but it is rather below the average size. Damsons, like the Plums, are a very heavy crop, but the fruit is small. Gooseberries have been a heavy crop, but quantities have been spoiled through caterpillars destroying the leaves on the bushes. Black and Red Currants have not been so good as usual. Black Currants in some cases were shrivelled up, no doubt through the dry weather. The first Strawberries were very good, Noble being very fine, the late crop not being so good, the latter part having failed altogether. I planted strong runners of Noble in November, gathered fine fruit on May 9, and continued to do so for some time; in fact, they were better than two-year-old plants in the same garden. Raspberries have not been quite so good, the dry weather seems to have affected them, and Black Currants have suffered more than any other fruit. Morello Cherries are much above the average. One thing is very noticeable in all fruit trees, the growth is very weak; the shoots of all are very much shorter than usual. On the whole I do not consider that the fruit crop has suffered in the least by the long spell of dry weather that we have just gone through. All crops show signs of early ripening, Damsons being quite three weeks earlier than usual.—GEORGE GRIFFITH.

Park Gardens, Pontypool.—Apple, Pear, and Plum trees have been making a remarkably healthy growth since the rain set in, also Peaches,

but these and small fruits suffered considerably from red spider previous to that time.

Vegetables with some exceptions have been fairly good. Broad Beans a total failure in most gardens in this district owing to blight. Early kinds were remarkably good, and late varieties are very fine in appearance. Early Turnips scarce, owing to the hot weather and fly, whilst Carrots also have suffered.—J. LOCKYER.

Penrhos.—Owing to the continued drought the fruit crops in these gardens and locality are hardly worth taking account of. All kinds of fruits are quite a month in advance of other years. Apples are the most satisfactory, especially the early kinds, which are a very fair crop. Pears very few. Morello Cherries are also a very fair crop. Plums are good on trees of the most free-bearing kinds. Gooseberries and Currants excellent. Strawberries and Raspberries were small; in fact they ripened prematurely.

All kinds of vegetable crops have suffered severely from the drought. Potatoes rather smaller this season, but quite free from disease.—F. W. EVERETT.

SCOTLAND.

Alloa House, Alloa.—Apples, Pears and Plums are a good average crop. Peaches and Nectarines have done very well under glass, but are very little grown outside. Cherries a good average, and bush fruits, such as Black and Red Currants and Gooseberries, have been very abundant and of first rate quality. The same remark applies to Raspberries, which have been exceptionally good. Strawberries, owing, I believe, to the dry, hot season, have been, if anything, under average.

Vegetables have been a splendid crop. Peas abundant, but of course short in the straw. Cabbages, Cauliflowers, and French Beans are excellent. Potatoes are looking very well and no appearance of disease as yet. Upon the whole the splendid season we have had has resulted in a decided improvement, as far as garden produce is concerned.—THOMAS ORMISTON.

Munches, Dalbeattie.—The crops of the present year are the best I have seen in this neighbourhood. I have never seen finer Strawberries, although the crops did not last long owing to the later flowers being rendered abortive by the drought, but the fruits were larger and better flavoured than has been the case for several years. The first dish was gathered this year on June 5, and last year the first dish was sent to table on July 1. President, Sir Joseph Paxton, Ruskin, and Noble all came in at about the same time here; if anything, President and Ruskin were in advance of Noble grown under similar conditions. For pot work I find Noble crop better and ripen earlier than any of the others mentioned. Cherries were a good crop and ripened earlier than usual, a large proportion being devoured by birds and wasps, the latter pest being much in evidence this year, attacking every variety of fruit as it approached ripeness. Gooseberries were very abundant, but the fruit was under the average size, and ripe about a month earlier than last year. The crop finished six weeks earlier than last year, a large percentage being devoured by wasps. Red, Black and White Currants bore a splendid crop. Raspberries were a good crop of nice sized fruit, but the later fruits were devoured by wasps. Apples are a splendid crop on healthy trees. We have examples of Warner's King measuring from 11 inches to 13½ inches in circumference. On very old orchard trees there is a heavy crop of undersized fruit, but totally spoiled by maggots. The above applies to a grass orchard, from which I do not think you could gather a single sound Apple. Pears are not such a good crop, nor are the fruits so fine as I have seen here. Plums very abundant, especially Gages, Victoria and Kirke's. Filberts and Nuts below the average.—A. MURRAY.

Hopetoun Gardens, South Queensferry.—Apricots are a good crop, and the fruit of fine size on young trees. Cherries abundant. Victoria

Plums a failure on walls, but a fair average on standards. Pears on walls a fair average, but will be small; standard Pears a failure. Apples about half a crop, Lord Suffield and Keswick Codlin being the most prolific. The failure in the Apple crop around here I attribute to the cold, unless summer of last year, the wood being badly ripened, and although the trees bloomed well, there seemed to be a want of vigour to carry on the fruit. Strawberries were plentiful, although the gathering season was shortened by the long spell of dry weather. Red, White, and Black Currants abundant. Raspberries and Gooseberries also plentiful. Filberts almost a failure. Peaches are not grown outside.—JAMES SMITH.

Haddo House.—The fruit crops in this district are variable. Apples on standard trees are in many cases a complete failure. Though the weather was fine when the trees were in blossom the fruit did not set. The dry, hot weather which prevailed at that time may have had something to do with the failure. I am inclined to think the wet autumn of last year was the cause, the fruit buds not being well matured. Young Apple trees on walls have a fair crop. Pears on walls are a fair crop. Plums on walls are a very heavy crop, in many cases two-thirds of the fruit set having to be thinned out. Cherries are also a good crop. Gooseberries and other small fruits would have been a good crop, but in most cases they have suffered severely from the attacks of green and black fly. Strawberries were a fair crop and of good quality. Raspberries rather a poor crop.

Vegetables in general have done fairly well. Cauliflowers, Onions, and Carrots suffered severely from the heat and drought, but since the rain came they have improved very much. Potatoes have done exceedingly well, being also of excellent quality. Peas have also done well, and although the heat and drought were very trying during the months of May and June, crops of all sorts are rather above the average.—JOHN FORREST.

Dumfries House, Greenock.—Strawberries were an average crop. Cherries excellent. Gooseberries average. Red, Black, and White Currants good. Plums excellent, also Apples; whilst Pears are an average.—N. MCKINNON.

Altrey, Forres.—The fruit crops here and in the immediate neighbourhood are about an average. Apricots, Peaches and Plums on walls are a good crop and ripening up well. Early Cherries were good; Morellos almost a failure. Apples very good on young trees, also on walls; old standards almost a failure. Pears here quite a failure, but in the lower-lying district an average crop. Strawberries in general very poor. None of the late varieties set their fruit, owing to the severe drought in May and June. Small fruit, such as Currants, Raspberries and Gooseberries, abundant. Crops of all sorts are fully a fortnight earlier than usual.—A. CHRYSTALL.

Balcarres.—The fruit crop in this district has been very good. Strawberries in the early part of the season were small and soon over. Elton Pine has been very fine. All the small or bush fruits have been very good. Apples are a good crop, but Pears only half a crop. Plums very heavy. Peaches good, also Apricots; whilst Morello Cherries are extra heavy. All fruits are three weeks earlier than usual.—EDWARD TATE.

Coltness, Wishaw, Lanarkshire.—The gardens here are situated in the midst of the Lanarkshire coal-field; altitude 465 feet; soil heavy and retentive, with the inevitable subsoil of stiff clay, overlying mineral. As these conditions demonstrate, the soil and situation of the gardens here are not at all favourable for the successful cultivation of orchard fruit. The past warm summer has, however, been very suitable for most kinds of small fruit. Raspberries and Black and Red Currants have done remarkably well. Gooseberries very good; some varieties much troubled with green-fly. Strawberries good in quality, but season somewhat short. Apples about half a crop. Pears and Plums we do not grow out of doors here but

they are doing well in the orchard house, as also Peaches and most other indoor fruits. The Clyde orchards being in the immediate neighbourhood, I herewith give you a short account of the conditions of the fruit crops there. These orchards are situated at a much lower level than this, and are mostly on the sloping banks of the river Clyde. The soil is also much lighter, and they in consequence have suffered very severely from drought this dry season. Strawberries were a short crop, Vicomtesse Héricart de Thury, Elton Pine and President being the kinds grown. Newer sorts have been tried, but have not proved so profitable as these old kinds. Hundreds of acres of Strawberries are grown. Plums are only half a crop, the trees having suffered much from green-fly. Victoria Plum has been planted in thousands during late years, it being found the most reliable variety for market. A few acres of Orleans and Magnum Bonum are also grown. Pears are a good crop. A great many varieties of these are grown, such as Early Crawford, Hessel, Moorfowl's Egg, Auchen, &c. Apples are a fine crop and much superior in size and quality to what they have been for a number of years back. Other small fruits are a fair crop, but very unremunerative to the growers, the prices being very low. These orchards present a beautiful spectacle in the early season when in flower, the whole valley being draped in white with the blossom of the Plum, Pear, and a little later with the pinkish bloom of the Apple.—J. GRAHAM.

Brechin Castle, Forfarshire.—The fruit crop generally may be called a fair one. Apples and Pears are under the average. Plums an average crop. Late Strawberries a good crop, but early sorts rather short. Raspberries, Gooseberries and Currants are abundant.

Vegetables generally have done well. Early planted Cauliflowers inclined to button with the dry weather. Peas a good crop with shorter straw than usual. French Beans much better than they have been for years. Potatoes a heavy crop and of good quality, and as yet no appearance of disease. Although spring and early summer were dry, the drought was not so much felt here as in many other gardens.—W. McDOWALL.

Moy Hall, Inverness-shire.—Fruit crops here and in the surrounding neighbourhood are generally good with the exception of Apples, which are under the average. Gooseberries, Currants and Raspberries are an abundant crop. Strawberries excellent, but their season was short owing to the hot and dry weather. The caterpillar and fly made great ravages among our bushes.

Potato crops, both early and late, are looking well, the earlier sorts, which we are lifting for present use, being excellent as regards quantity, size, and quality, and we have not yet seen signs of disease. The exceptionally fine season which we are passing through suited this district admirably, owing to the cold subsoil and high altitude.—D. RHIND.

Edmonstone, Midlothian.—Apples promised well when in flower and set satisfactorily, but the fruit has dropped considerably, and only a very small crop will be gathered. The cause of this, I believe, is that last season's wood never properly ripened. Canker is making sad havoc, and during the last few years getting gradually worse. Almost all the trees are affected. Red spider is also very bad. Pears are a very poor crop. Apricots, one of our best sorts—Moorpark—is barren, some of the other kinds bearing a good crop. Peaches (outside) are a very small crop with the exception of Rivers' Early, and this is of no use here, every fruit being split and dropping off. We incorporated lime rubbish in the border, but this does not appear to have done any good. This failing is a great pity, as in a late season and locality it would otherwise have proved a great acquisition. Plums always do well here, and are an average crop. Cherries not many grown, Morello very good. Of Strawberries, we have not had a smaller crop for twenty years. We grow Laxton's Noble, Duke of Edinburgh, President, and the never-failing Garibaldi. Without the latter our crop would have been almost nil.

Of Currants, the Black are of good quality, but rather thin; the Red are very poor here, and mostly grown on walls. In May they were completely smothered with aphides. Gooseberries always do well on the heavy loam here, and have been a very good crop. Whinham's Industry is one that everybody should grow; it has very large red berries of fair quality, and there is always an immense crop. In some gardens where neglected, aphides completely destroyed both bushes and fruit. On a dry gravelly garden close by we advised the bushes to be burned, as there was not a leaf on them.

Vegetables upon the whole are very poor, although at the commencement of the season, due to the very dry weather, we were much troubled with insect pests. Maggots were very destructive on early Cauliflowers and Cabbages, which, however, are doing very well now and making up for lost time. Peas, Broad and Kidney Beans are extra good; the latter came on very early this season. Vegetable Marrows are a great crop.—JOHN GRAY.

Whittinghame, Prestonkirk.—In this district the present season is a very bad one for hardy fruit. There was an abundance of blossom and it seemed to set fairly well, but the long spell of drought we experienced during the months of March, April, and May caused the greater part to drop off. Apricots, Pears, Plums, and Cherries are a very poor crop. Morello Cherries are an average crop, and such kinds of Apples as Keswick Codlin, Stirling Castle, Lane's Prince Albert, Ecklinville, Warner's King, Lord Suffield, Lord Grosvenor, Peasgood's Nonsuch, Northern Dumpling, Professor, Golden Spire, Maltster, and East Lothian Seedling are bearing fair crops. Some of them indeed have good crops, but all other kinds grown here are a failure. Strawberries and Raspberries were a poor crop and soon over. Red and White Currants are an average crop, and Black Currants abundant. Gooseberries a fair crop. No Peaches or Figs are grown outside here. Altogether we cannot but regard this season as one of the worst fruit years we have experienced.—JOHN GARRETT.

Glamis Castle, Glamis, N.B.—The crops of fruit are abundant and of good quality in this district. Apples showed a splendid lot of bloom, and are a heavy crop and promise to be of good quality, such varieties as Lord Suffield, Stirling Castle, and Northern Greening being the best. Pears are a partial crop, a few kinds only bearing a light crop of clean, healthy fruit. Plums generally are over the average, the best being Victoria, Pond's Seedling, and Magnum Bonum. Apricots and Peaches outside are fair. Cherries are a medium crop, the fruits large and fine. Morellos are not so good and the trees here are gumming badly. Small fruits are a heavy crop in most places and of fine quality, though there are complaints regarding red spider on Gooseberries, owing no doubt to the absence of rain in the early part of the summer. Strawberries of the earlier varieties were of fine quality, but their season was short. The late varieties are of fine quality and an abundant crop. The season is fully a fortnight earlier than usual, and noteworthy for the absence of late spring frosts so prevalent in this district.—THOMAS WILSON.

Duff House, Banff.—I have pleasure in stating that the fruit crop in this quarter has been exceptionally good, being the best I have seen here during the last fourteen years. All small fruits are a heavy crop with the exception of Strawberries and Cherries. Apricots, Pears, Plums, and Apples very heavy, especially the following sorts: Large Early Apricot, Jargonelle, Williams' Bon Chrétien, Autumn Bergamot, and Muirfool's Egg Pears; Victoria, Jefferson, Kirke's, Coe's Golden Drop, and Oullin's Golden Gage Plums; whilst of Apples, Lord Suffield, Hawthornden, Oslin, and Melville Pippin are the best sorts here.—J. BRANDER.

Newbattle, Dalkeith.—The show of blossom here this spring was magnificent, and gave promise of a good crop all round, and this would have been the case had the rain come in time. Strawberries set well, but did not swell for want of moisture, the consequence being that we had only half a

crop, and very soon over. All bush fruits were good, especially Red and Black Currants. Gooseberries were a heavy crop, but very much damaged with aphids. Raspberries good both in quantity and quality. Apples set well, but were very much reduced during summer, some kinds failing altogether. Still, a fair crop is left. Cherries good. Plums are an average crop on walls. Standard Victorias very fine; whilst Pears on walls are quite a picture of fruitfulness.—A. McDONALD.

NOTES OF THE WEEK.

Sweet Pea Primrose.—This as sent us by Mr. Smith, of Daisy Hill Nursery, Newry, is a charming kind, and is very distinct and pretty in colour.

Cornus florida has quite a comforting look now so few bits of colour being left us. But I think a few days ago the pearly look of the under leaf was still prettier.—M. R.

Colchicums and autumn Crocuses are flowering well in the nursery of Messrs. Barr and Son, Long Ditton. A large collection of each is grown, comprising many beautiful things too little seen in English gardens.

Cytisus longispicatus.—A bunch of this comes from Daisy Hill Nurseries, Newry, and a very graceful Broom it is, with long slender spikes of soft yellow flowers. It resembles that beautiful kind *C. nigricans*.

Colchicum autumnale album is just at its best here now, and is a very effective plant in a good-sized clump at the edge of a mixed bed. Considering the delicacy of the individual flowers, it is wonderful how long such a clump lasts in bloom.—E. A. B., *Myddelton House, Herts.*

Fuchsia fulgens.—When this grand old Fuchsia does well outdoors it is a plant very hard to beat for beauty as well as for interest. At Inwood House, Blandford, I saw some plants of this Fuchsia growing in the ordinary border outdoors and blooming freely.—D.

Royal Horticultural Society.—The next show of fruits, flowers, and vegetables will take place in the Drill Hall, James' Street, Victoria Street, Westminster, on Tuesday, October 10, when prizes are offered for hardy herbaceous perennials. At 3 o'clock, Mr. W. Crump will lecture on Pears.

Hardy Cyclamens.—These have flowered well on the rockery this season. Some bulbs sent from Cannes three years since have become well established. It may not be generally known that the flowers are very sweetly scented. A fairly strong soil to which is added leaf soil and old lime rubble grows the plants well.—E. M.

The Flame Flower.—This grows and blooms brilliantly on a north wall at Forde Abbey. The soil is fairly deep and retentive and the position cool. These seem to be conditions specially favourable to the growth of this *Tropæolum*. It is a matter for surprise that it is not much more frequently found in gardens, but it may be due to some occasional difficulty in getting it established.—A. D.

Crocus speciosus and its variety *transylvanicus* are flowering together with me this season. The latter, I believe, should be decidedly the earlier. There is but little difference between them. The variety is a rather bluer flower and the veins are not so well marked. *C. zonatus*, I am sorry to say, is already over. A *Belladonna Lily* pushing through a mass of *Plumbago Larpentæ* forms a very beautiful combination.—E. A. BOWLES, *Herts.*

Begonia semperflorens Vernon.—This variety is evidently the same, or nearly so, as is the popular bedding kind *atropurpurea*. It has been used with striking effect both at Forde Abbey and at Mr. Davis' Begonia nursery at Yeovil this season for massing. Plants from seed as these were grow some 2 inches or 3 inches taller than if from cuttings. The most pleasing effect is obtained when

thinly planted on a carpet of dwarf blue *Ageratum* or *Cannestus* of *Hopetoun* tufted Pansy.—A. D.

Erigeron speciosus.—There are few, if any, plants likely to excel this useful dwarf perennial in hot seasons. It is effective in mixed borders, growing about 15 inches high, and bearing a quantity of small violet flowers with yellow disc from early summer until the winter. The past long spell of drought has had no apparent effect upon it. It is readily increased by division or seed.—C. NEWITT.

Colchicums.—*C. speciosum* has been very fine with me this year, and is still (September 28) a beautiful object, although the cold at the end of last week damaged many of the blooms. I noticed two beautiful new forms of this, the grandest of the Colchicums, at Messrs. Backhouse's, York, last week, one named *C. s. roseum*, a most beautiful rosy purple, and with enormous flowers; the other pure white, and quite the most beautiful Colchicum I have ever seen.—E. A. BOWLES.

Lady Ardilsun Anemone.—I am sending some blooms and buds of a seedling Anemone *japonica alba* var. *Lady Ardilsun*, raised in 1892. It is strong and robust, with large glossy green foliage, and a very free bloomer, as you will observe by the sprays enclosed.—A. CAMPBELL, *Ashford Gardens, Cong, Co. Galway.*

* * * A semi-double form, often with little claw-like petals clasping the stamens. Some of the flowers are over 3½ inches across, white, delicate lilac outside, the buds also tinted with lilac.—ED.

Zauschneria californica.—This plant has bloomed continuously with me for the last two months, and is still smothered with its bright drooping flowers. It is one of the best dry weather things we have for the rockery. Here there is no necessity to protect in any way during the winter, as it is perfectly hardy and increases readily, the creeping sucker-like roots throwing up an abundance of stocky growths, which if dug up carefully at almost any time of the year seldom fail to grow.—E. M., *Swanmore Park.*

Calopetalon ringens.—"B. M." sends a specimen of this plant for a name, saying it has been raised from seeds sent him by a relative from Western Australia as a scarlet Honeysuckle. It is upwards of thirty years since I have seen this plant. It is a slender growing greenhouse climber with entire dark green leaves, the slender stems terminated in corymbs of flowers which are not bright enough to deserve the name of scarlet, being of a somewhat dull red, the tube of the flower pale yellow. They are not fragrant. The plant does not belong to the Honeysuckle family. I do not think it will ever make a showy plant for the greenhouse.—W.

Single Cactus Dahlias.—We have received a large gathering of single Cactus Dahlias from Messrs. Dobbie and Co., Rothesay. The flowers are quite single, but preserve a characteristic shape, similar to the Cactus type, the segments pointed, narrow, and distinctly twisted. The colours are very varied and beautiful, varying from deep yellow to rosy purple. A few of the best kinds sent comprise Robert Burns, dark purple magenta, but not a dead slaty tone; Maid of Bute, rose; Meg Merrilies, yellow; Guy Mannering, rosy pink, petals shading off to yellow towards the base; Isabella Vardon, bright reddish orange; and Lucy Ashton, creamy white.

New Pear Beurte Fouquieray.—I saw this Pear a few weeks ago at Messrs. Veitch's Langley nurseries, and was not surprised to see it certificated recently. It is of large size and an immense bearer, as a number of small bush and pyramid trees were heavily laden. This variety was on the Quince stock, and it is stated to bear our variable spring climate when in bloom much better than other Pears. It is of French origin, and in ordinary seasons fit for use from October to November. Even at this early date the flavour is rich and the fruit very juicy. In shape it is somewhat like *Duchesse d'Angoulême*, and much resembles *Marie Louise d'Uccle* in colour. This will undoubtedly be an acquisition, as its free bearing

properties will make it valuable. It is grown in various forms, the best fruit I saw being on pyramids grafted on the Quince and nearly 1 lb. in weight. I should say from its appearance it would be a good tree for cold districts or for heavy clay soils.—G. WYTHES.

* * * This variety was shown by Messrs. Veitch at the Pear conference at Chiswick in 1883, and it seems strange that we have heard nothing of it since.—ED.

Shrubby Veronicas are a feature of interest in the Swanley nursery, and it is a pity that such free-flowering and sturdy-growing plants are not more grown in gardens. At one time they were fairly popular, but during recent years they seem to have fallen quite into the background. In the more southern districts of England they are quite hardy if the position is moderately sheltered and the soil not too cold and heavy; but even if they cannot be grown in the open, they can be enjoyed under glass as pot plants. If planted out in the summer, they may be lifted before frosts occur and will go on blooming in the winter months. There are many varieties at Swanley, but three of the finest are unquestionably *Bolide*, which produces red-coloured flowers, the plant of good habit, and the two new kinds *Eveline* and *Reine des Blanches*. The former has rose-lilac flowers, a distinct and pleasing shade of colour, whilst those of the latter are pure white.

Plumbago Larpentæ.—I often hear people complain, as does Mr. Wood (p. 254), that this lovely *Plumbago* is a shy bloomer, but I fancy it is not only the short summers that are to blame, but that it is not often planted in a warm enough corner. It spreads so rapidly, that one is obliged to think twice before planting it among choice things in a specially favoured nook, but I am sure it is worth a good place. One clump I have has never failed to flower for the last three seasons, although before then, the kind donor thereof tells me, it never bloomed with him. I put it at the foot of a south wall in a border in front of an orchard house; it gets cut right down every winter, but comes up apparently none the worse and very early owing to its warm position. This year it opened flowers the second week in July, and is still covered with bloom, and has been a mass of blue during that time. I should say a hand-light early in March, to help on the first growths of the year, would in most positions cause it to bloom long before the frosts come.—E. A. BOWLES, *Waltham Cross, Herts.*

PUBLIC GARDENS.

THE BOTANIC FROM A KEW POINT OF VIEW.

MR. WATSON, of Kew, has a very unfriendly note in an American paper about the Botanic Gardens in the Regent's Park:—

The Royal Botanic Society of Regent's Park is in a tottering condition, and is like to fall. Its finances are in a hopeless state, and its work during the last few years has been such as is not likely to win much sympathy either from horticulturists or botanists. The general feeling is that there is no need for a botanical collection in Regent's Park, when all that can be desired is to be seen and obtained a few miles away at Kew. On the other side, the assistance the society has tried to render to horticulture by means of exhibitions has been almost superfluous now that the Royal Horticultural Society is in vigorous activity again. It would appear, therefore, that London does not require such a society as that which has for so long held its meetings in the enclosure at Regent's Park. The suggestion that the Botanic Gardens should be recovered by Government and added to the park appears to be the best course. It is scarcely likely that the £18,000 debt of the society will be subscribed by a public unable to see the utility of the work done by the society in recent years.

We cannot see that the failure of the Botanic would do any good to Kew or any other garden. The more we have of such places and the more distinct they are from Kew the better. No doubt the Botanic would be better and more charming under more spirited management and better fortunes, but all societies of the kind have a habit of getting into ruts and staying there.

Financially, the past two years have not been so good as could be wished, but probably these bad times and the destruction of our agriculture, and to a great extent of country gentlemen's fortunes, has not been to the benefit of the country generally.

The following particulars may be of interest:—

The debt is the capital held by Fellows of the society, and only £100 allowed to each Fellow. The large cost of laying out the gardens has not been estimated. The cost paid for buildings alone has been over £23,000, and in prizes to exhibitors £55,000.

Students, three months each, free, year up to end of September	1893	743
Whole year	1855	32
"	1865	175
"	1875	364
"	1885	706
"	1891	808

Cut specimens, year, average 47,000; also rambling clubs, schools, societies occasionally.

We think the Botanic should make much less of its botany and more of its gardening. The wretched "botanical department" should be swept away, the ground turfed over, and the plants really worth it put in groups in bold beds on the turf, and any other changes made to add to the beauty of the garden—much marred by an ugly herbaceous ground. The society is not endowed or fitted for the teaching of botany, and it should leave that to gardens liberally supported by the State.

There are also certain instruments and apparatus for measuring wind and water, we believe, exposed in what might be the prettiest part of the garden, and these are too ugly for a London graveyard. They disfigure the prettily designed little garden, and should be removed.

LONDON TREES.

The following letters in reply to that of Sir Herbert Maxwell which we quoted in THE GARDEN of September 23 (p. 293) appeared in the *Times*:—

Your correspondent Sir Herbert Maxwell does well in calling attention to the Ailantus glandulosa in his remarks on London trees. It is one of the very best trees for the soil and climate of London, and will in time grow to the height of 40 feet or 50 feet. So vigorous is the growth in a young state that it will often make a shoot of 6 feet in a single year. The leaves are large and handsome, 3 feet or more in length, with a thick midrib, on each side of which are arranged in pairs some twenty or thirty lance-shaped leaflets. I have a specimen of this tree in my garden nearly 50 feet high, which is the admiration of everyone who sees it. When the late Major M Kenzie was about to plant the trees on the Thames Embankment I remember discussing with him the merits of this tree for that position. It was, however, decided, properly I think, that the beautiful, but massive foliage would be torn and disfigured by the strong currents of wind often prevalent there. In fairly sheltered positions no tree is handsomer or more appropriate for cities and large towns, as it is very hardy and will grow anywhere. Many trees which flourished in London some thirty or more years ago no longer thrive there, owing to the increased volumes of smoke and various noxious gases; but there are still many trees and shrubs which, owing to

believe, principally to the structure of their leaves' seem to set these influences at defiance, and the Ailantus is one of the most valuable of them. Planes, Poplars, and Robinias (the latter usually called Acacias) are proved London trees, and there are many varieties of each far preferable to the old-fashioned and beautiful but unsuitable English and foreign trees still injudiciously planted.—WILLIAM PAUL, *Waltham Cross, Herts.*

May I add a word of caution to Sir Herbert Maxwell's praise of the Ailantus as a London tree? The foliage has all the beauty and endurance he claims; but, to use the words of an American authority, Mr. F. B. Hough, "the male flowers have a nauseating odour that renders this tree undesirable for cultivation near dwellings." I think I am right in adding that not many years since most of the Ailantus trees in New York were grubbed up on account of this offensive character. It is a tree also to be handled with care on account of the acrid juice of its bark, which has been known to cause poisoned hands among woodmen and gardeners.—J. L. P., *Marlborough.*

The public park at Dewsbury, known as the Crow Nest Park, which contains 76 acres, and which the corporation purchased for £20,000, has lately been opened.

Open space for Bolton.—The Parks Committee of the Bolton Corporation have decided to lay out a piece of land in Bradford Street, given by the Earl of Bradford, for recreation.

Proposed park for Manchester.—The Manchester Corporation are negotiating with the owners with a view to purchasing 134 acres of the Booth Hall Estate, including the picturesque Boggart Hole Clough, for the purposes of a cemetery and an open space.

Private gardens at Hampton Court.—With the approval of the Queen, about four acres of private gardens at Hampton Court Palace, which have hitherto been maintained out of the privy purse, but to which the public have for many years had free access, are about to be transferred to the management of the Board of Works, and the expense borne by the parliamentary vote. The orangery is to be repaired and redecorated, and, together with the lawn in front, will be set apart specially for the use of the private residents of the palace.

Iron spouting to garden shed (*L. R.*).—You will understand that all iron which is not galvanised requires protection from the weather by painting. Had your guttering been painted about twice since it was fixed, it would be good to-day. It matters not how good the iron is, it will not stand against the weather unless painted or galvanised. Cast-iron guttering will stand much longer than wrought iron, as it is nearer the natural iron ore; even that will not stand long without being painted. We can hardly see that it is the fault of the iron. No doubt the guttering was thin; still the painting would have protected it from rusting away. You will see that there are drawbacks to the use of iron in spouting and roofs. Much of the money now spent in iron roofs is wasted.

The weather in West Herts.—During the past week the temperature has been, on the whole, above the average for the time of year. There, however, occurred one cold night when the exposed thermometer indicated a reading slightly below the freezing-point. At both 1 foot and 2 feet deep the ground is at the present time 2° warmer than at the same period last year. A little water came through the heavy soil percolation gauge on Friday and Saturday in last week, but no measurable quantity has come through the light soil gauge for nearly six weeks. September was the eighth unseasonably warm and the seventh unseasonably wet month that we have had this year in succession. In September rain fell on thirteen days, and to the total depth of little more than 1 inch, which is considerably less than half the average quantity for the month. Since February

only 8 inches of rain have fallen here, the mean amount for the same seven months in the previous thirty-seven years being 16½ inches. In 1879 the total rainfall for these seven months was 26 inches, or more than three times the quantity measured in 1893.—E. M., *Berkhamsted.*

Autumn flowers from Newry.—The autumn flowers must be very beautiful in Ireland now, judging from the varied gathering Mr. Smith has sent us. Sweet Peas of such pure soft colours as Delicata and Conntess of Radnor will always be appreciated. Tall and brilliant Lobelias, including the true cardinalis and vivid newer forms, are very striking. *Gardoquia betonicoides* is a welcome fragrant plant, and besides there are Michaelmas Daisies, Poppies, Colchicums, and a bunch of *Rudbeckia subtomentosa*, yellow stars with chocolate discs, smelling sweetly like new mown hay, also other things spoken of elsewhere.

Mr. F. L. Ames.—This well-known American amateur gardener died, we regret to hear, suddenly a few days ago. He was a member of various horticultural societies, and possessed a unique collection of Orchids.

Names of plants.—*G. B.*—5, *Juniperus Sabina* variegata.—*C. Johnstone.*—1, *Pavonia Wioti*; 2, *Manettia micans*; 3, *Dipladenia Harrisii.*—*C. M. E.*—1, *Diplazium plantagineum*; 2, *Cibotium Barometz*; 3, *Anchistea virginica*; 4, *Doryopteris palmata*; 5, *Goniophlebium loriceum.*—*Thos. Wells.*—1, apparently *Nepenthes intermedia*, a garden hybrid; 2, *Cyrtoceras reflexum*; 3, *Amaryllis reticulata*; 4, *Zygopetalum maxillare.*—*William Kerr.*—The one flower, *Cattleya Harrisonia*, the spike, *Cattleya guttata*; they must not be potted until the spring; now is the time for flowering.—*J. Reynolds.*—1, *Nephrolepis pectinata*; 2, *Lastrea lirta.*—*H. H.*—*Acerides suavissimum* noble.—*E. Semper.*—*Salvia Hormiumum.*—*James Finch.*—1, *Plumbago zeylanica*; 2, *Plumbago Larpente.*—*F. W. Everett.*—*Araujia albens.*—*T. B. D.*—Varieties of *Calluna vulgaris*: 1, *alba* (white); 2, *carnea* (pink); 3, *floro-pleno* (double-flowered).—*Plant.*—1, *Aspidistra lurida variegata*; 2, please send in flower; 3, *Retinospora plumosa*; 4, *Cupressus Lawsoniana*; 5 and 6, forms of *C. Lawsoniana*; 7, *Retinospora pisifera.*

Names of fruit.—*Mrs. Smithers.*—Cornish Gilliflower.—*B. Wells.*—17, *Bess Pool*; 18, *Wadhurst Pippin*; 35, 36, too much out of character; 37, *Tyler's Kernel*; 34, *Queen Caroline.*—*Fruit in shallow box.*—Pear is *Duchesse d'Angoulême.* Apples: 1, *Ribston Pippin*; 2, *Ecklinville Seedling*; 4, *Royal Russet*; 5, *Wellington*; 6, *Hambledon Deux Ans.*—*W. Carr.*—Cornish Gilliflower.—*J. P.*—1, *Norfolk Beaufin*; 2, *Bess Pool.*—*W. Newton.*—1, *Souvenir du Congrès*; 2, *Duchesse d'Angoulême*; 3, *Marie Louise d'Uccle*; others rotten.—*Kentley.*—33, *Ribston Pippin*; 34, *Duchesse d'Angoulême*; 37, *Round Winter Nonsuch*; 40, *Winter Peach*; 50, *Fondante d'Automne*; 90, *Marie Louise d'Uccle.*—*Yarb.*—Undoubtedly small fruits of *Ribston Pippin.*—*W. F. B. B.*—Long Pear is *Calebasse Bose*, the other *Suffolk Thorn*; Apple is possibly *Cox's Orange Pippin*, but rather too small to properly identify.

"The Garden" Monthly Parts.—This journal is published in neatly bound Monthly Parts. In this form the coloured plates are best preserved, and it is most suitable for reference previous to the issue of the half-yearly volumes. Price 1s. 6d.; post free, 1s. 9d. Complete set of volumes of THE GARDEN from its commencement to end of 1892, forty-two vols., price, cloth, £30 12s.

"Gardening Illustrated" Monthly Parts.—This journal is published in neatly bound Monthly Parts, in which form it is most suitable for reference previous to the issue of the yearly volumes. Price 5d.; post free, 8d.

"Farm and Home" Monthly Parts.—This journal is published in neatly bound Monthly Parts, in which form it is most suitable for reference previous to the issue of the yearly volumes. Price 5d.; post free, 8d.

"Hardy Flowers."—Giving descriptions of upwards of thirteen hundred of the most ornamental species, with directions for their arrangement, culture, &c. Fifth and Popular Edition, 1s.; post free, 1s. 3d.

"The Garden Annual" for 1893.—Contains Alphabetical Lists of all Branches of the Horticultural Trade. The Lists of Gardens and Country Seats (containing over 9000) have been very carefully and extensively revised, and are admitted to be the most complete ever published. Price 1s.; by post, 1s. 3d.

All of our readers who are interested in the improvement of cottage homes are invited to help us to make Cottage Gardening known. It is published at the very lowest price to meet the wants of those for whom it is intended, and copies will be sent for distribution, free, by the publishers, Messrs. Cassell and Company, La Belle Courway, Ludgate Hill, E.C.

"This is an Art
Which does mend Nature: change it rather, but
THE ART ITSELF IS NATURE."—*Shakespeare.*

KITCHEN GARDEN.

AMERICAN TOMATOES.

THIS season, thanks to the kindness of Prof. Bailey of the Cornell University, New York, I have had a good opportunity of testing the merits of most of the best American-raised Tomatoes as well as older ones again both under glass and in the open. A better or more favourable summer for bringing out their good qualities could not well be had, and it is very doubtful if such excellent crops in the case, more especially of open-air plants, were ever grown in this country before. Most of the sorts tried were recommended for the open, and I was warned not to expect too much of any of them under glass. So far, results have not exceeded or hardly come up to expectations, that is to say, nothing very far superior to the best English-raised varieties have been discovered, though it is very questionable if we have anything placed to our credit that will produce such heavy crops in so short a period as Early Ruby. So freely does this variety set and to such a size does the fruit swell, that the plants cannot well be induced to continue growing and fruiting strongly, and it is not, therefore, one of the best for training up roofs, extra long stakes, or strings. It is very suitable for growing where the house room is limited, and will stand, in fact requires, high culture, that is to say, plenty of feeding after the crops are beginning to swell. Early Ruby is also good for planting against sunny walls, being one of the first to give ripe fruit in the open while the crops are heavy. Curiously enough, it is not affected by the "black spot," a disease which has been very prevalent this year. The fruits of Early Ruby are nearly all of medium size, somewhat flat and slightly ribbed, the colour being a bright red and the flavour fairly good.

Ignotum is newer to this country, and it is doubtful if it will ever be extensively cultivated by us, though in America it has proved to be the very best of all for open air culture. No other variety yielded such heavy crops as this when tried against all comers at the Cornell University and other trials, the shape of the fruit and quality being also satisfactory. I have grown it under glass and in the open, and in each instance it did not surpass several English raised varieties growing alongside. It is a moderately strong grower, but sets none too well under glass. The fruit attains a fairly large size, is smooth, round or ball-shaped, and differs from our Perfection in its paler shade of red colour. The quality is good both in the case of fruit grown under glass and in the open, and I like it well enough to give it yet another trial. This season Tomatoes generally have done well, and it may prove that Ignotum will come more to the front during a less favourable summer.

In Livingstone's Stone I think we have a decided improvement on the best selection of Perfection. The fruits are of the same good form and colour, but of greater depth, this giving it a greater value in the eyes of exhibitors accordingly. It appears to possess a strong constitution, or quite equal to that of Perfection, and

the fruits set with freedom. Even this introduction seems to have been anticipated on this side of the Atlantic, as we hear of selections from Perfection that answer to the description of Livingstone's Stone.

Paragon, Livingstone's Perfection, Mayflower, and Autocrat are all more or less like our Perfection, or at any rate are not sufficiently distinct to be kept apart. Puritan is a slight improvement on all of them in weight, many of the fruits also becoming slightly ribbed. Cardinal, however, is a smaller fruited form, but does not crop sufficiently heavy. The fruits are of perfect form, a rich cardinal-red in colour, and good in quality. Canada Victor, again, is scarcely worthy of being retained, and the Trophy, one of the oldest of American varieties, is now-a-days rightly considered too coarse. Not so another old favourite—Hathaway's Excelsior. The latter is a good type of Tomato for market culture, the fruit being of medium size, perfectly smooth and round or ball-shaped, and of a lively red colour. These then who have good selections of Hathaway's Excelsior will do well to cultivate it extensively.

The foregoing are all of what we consider the right shape, size, and colour, but in America they are less particular as to colour. Several of the most extensively cultivated varieties, and of which I hoped great things, really proved most disappointing, owing to the colour being of pink or pinkish red shade. No matter how richly flavoured or how well formed a fruit may be, it finds but little favour if the colour is other than a rich red. Especially is this the case when the fruit has to be sold, the prices fetched by the pinkish red fruit being invariably much below that realised on the same day by the rich red Tomatoes. After reading an account of what had been obtained from a given number of plants of Ithaca, I was naturally anxious to give this variety a trial. It certainly is a good cropper, though not any better in this respect than Dedham's Favourite and the colour is the same, quality also being good. Potomac again is another of the despised pinkish, or rather in this case purplish red forms, but all the same is a distinct and fairly valuable variety for open air culture especially. With me nearly all the fruits attain a fairly large size, are not particularly ugly, while the quality is extra good. Mikado, and which has been grown in this country for several years, produces larger fruit, and the foliage is broader. This also is of excellent quality, very few varieties equalling it, but it is too big and rough for us. The Americans will likewise do well to discard this and other forms of the same colour, that is if they wish to control the markets with their bottled or canned fruit. Ponderosa or Royal Sovereign, as it has been re-named with us, seems to have pleased the fruit committee of the Royal Horticultural Society, and just suits one at least of our leading exhibitors of vegetables, yet it is a great washed-out-looking thing and not worth either house or garden room. A very different description applies to Dwarf Champion. The latter is of very sturdy habit of growth, the leaves very broad, yet compact, and the fruit produced with moderate freedom, of medium size, perfect in form, of a deep purplish red, and of excellent quality. Potato Leaf greatly resembles Mikado, and will not be grown again.

There is also a prejudice against yellow Tomatoes in this country, but the American introductions ought to have dispelled some of this. As far as the old, large, yellow is concerned, I can quite understand the objection, as this is a poor, flavourless thing, but in Golden

Queen or Golden Sunrise, for they apparently are synonymous, we have a variety little inferior to most red-fruited sorts. What I have grown several seasons in succession has been under the name of Henderson's Golden Sunrise, and it has proved of much the same habit as Perfection, the fruit being nearly as large, of equally good form, of a rich yellow in colour, and of fairly good quality, acidity not being altogether wanting. Golden Trophy is of the same habit of growth as Trophy, the fruit also large, but of no value.

W. IGGULDEN.

VEGETABLES AS GROWN.

THE very extensive and interesting collection of vegetables which Messrs. Cannell and Sons set up both at the Drill Hall on the 26th ult. and the following day at Earl's Court deserves more than a passing notice, because vegetables have not hitherto been regarded as a Swanley speciality, and also because there was no pretence to exhibit these products other than as grown under ordinary culture. So far was this idea exemplified, that some of the least valuable kinds were rather indifferently represented, and these naturally enough met with adverse criticism. On the other hand, the Potatoes, Onions, Carrots, Cabbages, Cauliflowers, Tomatoes, &c. were of their kinds excellent, and showed that if but ordinary care be bestowed on these products, very good samples are easily obtained. But it may be pleaded that cultivation is not everything, and that selection of seed stocks is a matter of some importance also. That is a seedsman's view which merits all consideration, and it is one on which not only Messrs. Cannell and Sons, but every other seedsman is entitled to lay full weight. With very few exceptions the Swanley vegetables did not exhibit any attempt to display mere size. Only one lot of Onions were unduly large, but the bulk of the samples served to show what large, firm, enduring bulbs can be got from ordinary culture if the soil be good and the plants well thinned early. Yet, whatsoever may be the keeping or non-keeping properties of the giant show Onions, at least all ordinary grown bulbs should keep remarkably well, for seldom have they ripened off earlier or better than this season. The Wroxtons of the Swanley collection averaging 6 ozs. to 7 ozs. were perfect, and better could hardly be conceived. A very interesting dish in the collection was Pea Autocrat; the pods were not large at this season of the year, but very full of Peas literally as green as grass. I heard this excellent Pea well spoken of when recently at Inwood House, Henstridge, where Mr. Wilkins produces his giant show vegetables. Its colour is a strong point in its favour, and we like Peas to be green when so called, and not white, as they are so frequently. Not the least value of such a collection of vegetables as that referred to is found in its reliability. The constant exhibition of varieties or kinds that have been produced under high class conditions of culture naturally misleads, and the on-looker as naturally observes, "I can never obtain samples like these in my garden;" but when he turns to a collection of ordinarily grown vegetables, he recognises at once their natural characteristics, and is satisfied. I am not at all for assuming that ordinary culture signifies poor or inferior culture. That is not so. By ordinary culture I mean cropping under such conditions as that samples most suitable for domestic use may be obtained in the greatest abundance and with appreciable profit. Nearly the whole of the Messrs. Cannell's collection was grown on the Eynsford farm literally under field culture, and under conditions less favourable, especially during the recent dry season, than are found in ordinary gardens. That fact renders the exhibit all the more meritorious, because if good vegetables can be so produced, it should be easy for anyone else to have good samples. I have been much surprised to find generally how wonderfully good vegetables have been out in the open or field allotments. That is

less due to heavy manuring, for that cannot be, than to deep working of the soil and to the cooler atmosphere which exists in open areas. Those conditions largely exist at Eynsford, and they are worth more consideration than they usually receive in places, for too often vegetables have to be grown in soil that is excessively enriched and super-heated because of the neighbouring trees and walls. As to seed stocks, there is a good deal of rivalry in these days amongst seedsmen and growers to get the best, and immense pains are taken to have them. That is good practice, and the gardening public get the benefit of it. No firm has a monopoly in this respect, and if I find one gardener believes in one seed house, another has implicit faith in a second, so that it is evident all are now putting into commerce high-class stocks. A. D.

NOTES OF THE WEEK.

Caryopteris mastacantha.—This is looking so pretty now, and I send you some. It flowers at an acceptable time.—M. R., *Liphook*.

* * Very charming, the flowers of a pleasing blue colour.—ED.

The American Virgin's Bower (*Clematis virginiana*) is a really desirable and vigorous climber, flowering so freely and so long after our own native kind is past. It will festoon a hedge, go up a tree, or do anything that our own can do.—T. SMITH, *Newry*.

Trachelium Rumelianum of which I send you a specimen, is quite the daintiest alpine plant in flower now; in habit, in colour and profusion of bloom there is nothing like it; besides there is no doubt about its hardiness, it having withstood the rigours of last winter unhurt.—T. SMITH, *Newry*.

Lavatera maritima is a pretty malvaceous plant. The flowers are about the size of a florin, white, faintly tinged with lilac, and having a dark spot at the base of each petal. These petals contract at the bottom, leaving a space between each through which the calyx shows, thus forming a green star in the centre, a rather singular effect. It appears to require warm greenhouse treatment.—J. M., *Charmouth, Dorset*.

Lilium auratum in Ireland.—I send you a photograph I had taken of a group of *Lilium auratum*. The group was more beautiful about a fortnight after this photograph was done, as some of the taller spikes were in bloom too.—H. BOSCAWEN.

* * One of the most beautiful and picturesque photographs we have ever seen, and showing a remarkable example of Lily growth. We hope to engrave it.—ED.

Lobelias from Newry.—The Cardinal Flower is one of the most brilliant things of late summer and autumn, and the varieties are happily becoming more numerous. There are none better than Firefly, which Mr. Smith sent out a few years ago, but he sends spikes of three more distinct kinds named Magenta Queen, Vermilion and Rosea, the names descriptive of the colour, but Rosea is very soft and charming.

Pear Pitmaston Duchess.—It may interest some of your readers to know that I gathered this week thirty-three Pitmaston Duchess Pears off one tree. I weighed six and found them 10 lbs., and twelve weighed 18 lbs. I thinned the tree very slightly, or I am sure the weight of each Pear would have been larger. Twelve fruits of Pitmaston Duchess weighing 17 lbs. 5 ozs. took the prize at the Royal Horticultural show last month.—HENRY HOWARD, *St. Asaph, N. Wales*.

Pyrethrum (Chrysanthemum) uliginosum serotinum.—In the gardens at the Belvedere, Vienna, I noticed this growing with bog plants. I am told that in Hungary this *Pyrethrum* is to be found in masses in places which are flooded for some time during the summer.—LOUIS KROPATSCH, *Vienna*.

Chslons barbata is now in fine condition. I send you a spike 3 feet in length to show how

beautiful it is. The plants flowering now are from seeds sown in the spring.—T. SMITH, *Newry*.

Pear Marie Louise in Kildare.—Mr. Bedford sends us from Straffan some beautiful specimens of that most excellent of all autumn Pears grown in England, Marie Louise, with the following note: "The fruits are from the tree that was photographed two years ago in THE GARDEN, but it carried double the number of fruits this year. We had not a single failure with any kind of fruit this year; all were good both in quantity and quality." We wonder how anybody can grow Pears like Beurré Clairgeau, or any inferior kind, in the presence of such a fruit as Marie Louise.

Begonia Martiana gracilis.—I see you have a note of commendation for this pretty plant. I send you sprays of *B. Martiana grandiflora* and *B. M. pulcherrima*, the first growing about 2 feet high, the latter not so tall. Both were outside all summer, and I expect you to admit that the stove-grown plants you referred to lose by comparison.—T. SMITH.

* * All the forms of these Begonias sent us by Mr. T. Smith, of Newry, are extremely pretty, and deserve the attention of flower gardeners. We have seen one form used with fine effect by Mr. Dick in the Phoenix Park gardens.—ED.

The Royal Gardeners' Orphan Fund.—Intending subscribers are respectfully reminded that the collecting cards recently issued amongst the gardeners and general nursery trade throughout the country should be returned during the course of the ensuing month. It may be again stated that every 5s. collected will secure a vote for the next election, and every £5 a vote for life. It is earnestly to be hoped that a very liberal response may be made to this appeal in order to meet the requirements of the present year. Collecting cards may still be obtained on application to the hon. secretary or any member of the committee.—A. F. BARRON, *Hon. Sec.*

Gladiolus oppositiflorus.—This species was re-introduced by the Royal Gardens, Kew, in 1892, and in larger quantity by myself in May and June of this year. Apart from its qualities for hybridising, it is one of the most charming of the whole tribe. It is a stately plant of 5 feet to 6 feet high, with spikes often 2 feet long. Many flowers open at once and remain in beauty for several days. On one spike I counted as many as twenty-two flowers open at the same time. They are of medium size, white to deep rose, with a few purple streaks. The delicacy of the various shades cannot be described. It will grow here, and no doubt when better known will become a general favourite.—MAX LEICHTLIN, *Baden-Baden*.

Old Apple trees at Tachbrook.—Ten years have elapsed since the readers of THE GARDEN (Vol. XXIV., p. 191) enjoyed a description of these fine trees from the pen of Canon Kingsley's widow, and although the writer has passed away, the trees bear out her words, and "look as if another hundred Mays might still see their pink and white buds opening to the spring sun." The crop of fruit this year has been large and good, and the new and healthy shoots testify to the vigour of the trees; indeed, the gardener, Mr. Taylor, told me to-day that they are more vigorous now than at any time during the twenty years they have been under his care. If any lover of herbaceous plants makes a pilgrimage to see these trees, let him persuade Mr. Taylor to take him to his cottage garden—it is easily done—where he will see many a good plant, and may marvel, as I did, how such wealth can continue if all visitors are treated with the same liberality that I experienced.—HENRY BUCKLEY, *Leamington*.

* * A very fine fruit was sent which is similar to Warner's King.—ED.

Vitis heterophylla humulifolia.—This creeper is very beautiful this year, the trailing shoots being covered with the sky-blue berries. We have a very fine specimen on a wall facing west, and it rarely fails to fruit. This season it is a mass of berries, and makes a lovely object for covering a bare wall. There are fewer berries at

the top of the wall, owing to the gross growth, the lower portion being loaded, and the fruit is borne on the more slender branches. Some time ago a note appeared in THE GARDEN, complaining that this creeper failed to fruit. I believe it requires restricting at the roots, otherwise it rarely fruits. Our plant is in a very small border, and only allowed to cover a certain space. It receives no shelter, being perfectly hardy, and no special treatment is given.—G. WYTHES.

Begonias at Chiswick.—These plants look remarkably well after the late rains, the beds being a mass of rich colours. At Chiswick may be seen several really good and distinct things. The beds of *B. semperflorens atropurpurea* are of special note. The flowers are of a dark shade, and the leaves quite bronzy in colour. There are several forms of this Begonia, varying only slightly in the colour of flowers, some of a rosy shade, others nearly pure white. Vernon is a very fine type, rich and attractive. From seed may be had various shades, but the orange colours will predominate. Those who wish to have a distinct break away from the tuberous-rooted section would do well to note this type of Begonia for next season, as a stock is readily obtained from seed, and the growth is erect and the foliage thick and leathery. The plants may almost be termed perpetual flowering, as they are always in bloom. *Atropurpurea* stood the severe drought during the summer months better than many others. The plants were mulched after planting, and given a thorough watering twice a week.

Grapes on open wall at Chiswick.—A most interesting collection of Vines is grown on a south-west wall at the R.H.S. Gardens, Chiswick, Mr. Barron having planted a number to test their fruiting qualities in the open, and certainly this is the right season for such experiments. Though the berries are not so large as those of indoor fruits, the flavour is all that can be desired both in the black and white varieties. Of course it is no new thing to have Grapes in the open, but it rarely occurs that one can obtain them so well finished both as regards size and colour. Royal Muscadine is in perfection, the berries firm, juicy and very sweet. Chasselas Rose, another form of the Royal Muscadine, is excellent, and a variety less known perhaps is Miller's Burgundy, the black fruits suffused with a beautiful bloom, the berries small and very sweet, whilst the bunches are smaller than those of the above varieties and very compact. There are others of American origin, some of considerable merit. One can still cultivate these fruits in the open, although I fear of late years they have been little grown owing to glass erections being more plentiful, but even for decorations the Vine is very charming. Here may be seen some arches over walks festooned over with various kinds of Vines bearing very freely, and certainly no better method can be adopted.—G. WYTHES.

Notes from Dorset.—There is little doubt but your columns will soon teem with accounts of the effects of the past remarkable summer. The following notes taken at random may not be without interest. *Cleome pungens* on a perfectly open border has flowered well and nearly ripened seed. *Vitis humulifolia* is covered with its turquoise berries. *Colletia cruciata* will in a few days be a sheet of greenish white with its small flowers. *Mandevilla suaveolens*, planted in a conservatory border and allowed to ramble outside through a side ventilator, is maturing its clusters of slender seed-pods, which are a foot in length. *Abutilons* which I have a large number, have seeded in the greatest profusion. Apples and Pears are nearly double their usual size besides bearing a heavy crop. In the fields the Oaks are swaying beneath the great weight of acorns. Many Ash trees now denuded of foliage appear at a distance in full leaf by reason of the great crop of keys. The ground beneath the Horse Chestnuts is literally covered with the great fallen burrs, and the enclosed seeds are of enormous size. Hollies are already scarlet with the glow of their winter fruit.—J. M., *Charmouth, Dorset*.

TREES AND SHRUBS.

THE WISTARIA IN JERSEY.

THIS *Wistaria* is growing over a yard wall facing south, but getting but little sun, the house in front almost entirely shading it. It grows perfectly wild, and when in bloom is most effective. I presume its luxuriant growth is owing to the mildness of the climate.

S. BOWEN.

Millbrook, Jersey.

Robinia and the dry weather.—The common False Acacia (*Robinia pseudacacia*) has resisted the excessive drought of the present season better than most trees, and consequently it may be seen in many cases with the foliage in good condition, while most of its associates are almost

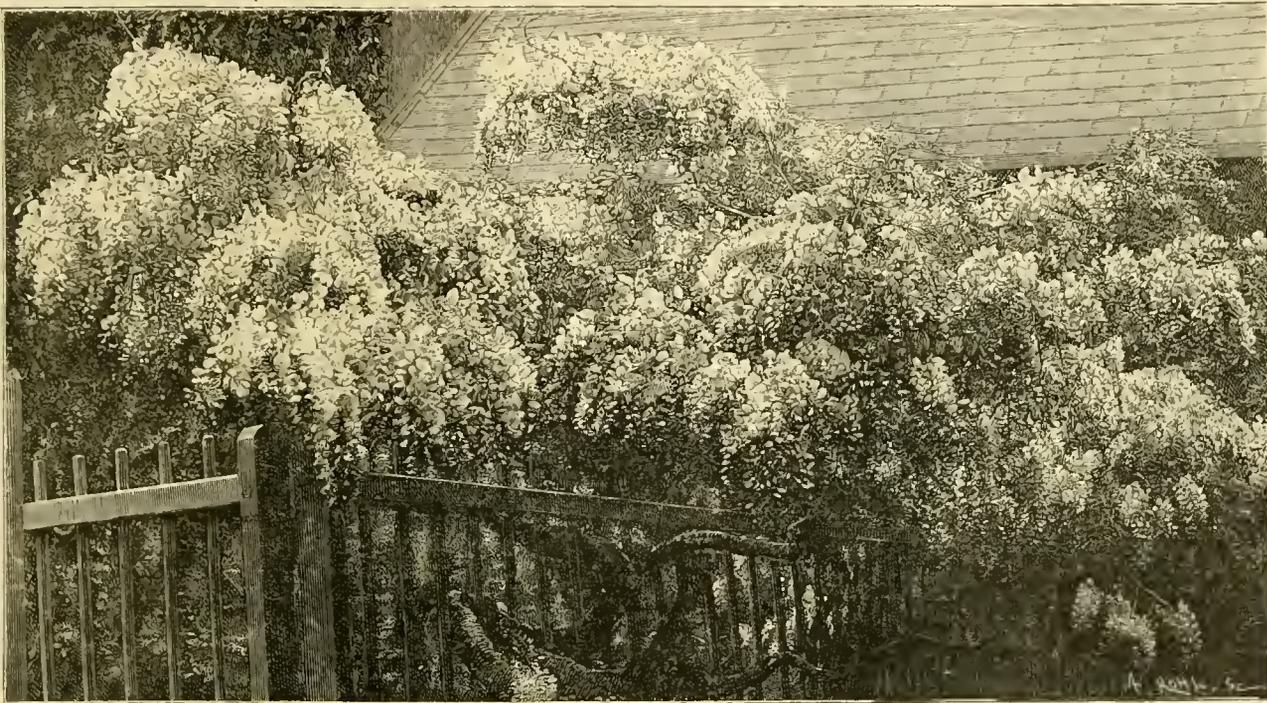

the foliage is a good deal lighter, added to which the branches are more slender, thus combining to form a really handsome specimen. Such varieties as this and the golden-leaved form, with their light and elegant appearance, are widely removed from the close, round-headed kind *umbraculifera*, the erect Lombardy Poplar-like *fastigiata*, or the curiously gnarled *tortuosa*. This by no means exhausts the list, for there are among others *crispa*, *pendula*, *latifolia* and *monophylla*, whose distinctive characters are indicated by their respective names. From a floral point of view, *Decaisneana* and *semperflorens* are very noteworthy, the former having pinkish blossoms, while *semperflorens* will continue to bloom for a very long time.—T.

Berberidopsis corallina.—This is a very pretty climbing or rambling shrub, and one that is quite distinct from anything else in our gardens. The leaves, which are 3 inches or 4 inches long, are dark green and of a leathery texture, while the edges are furnished with spines. When growing freely the evergreen foliage is very ornamental,

by many, while it may be pointed out that there is a second, though not a well-known form in gardens under the varietal name of *aureo-variegatum*. This has not the rich golden hue common to some variegated shrubs, but instead of the clear pure white of the older kind, the leaves of this are variegated with yellow, which is more pronounced than in the older ones. The arrangement of the variegation is about the same in both forms.—T.

JAPANESE OAKS.

ALTHOUGH poorer in species and less important in the number, size, and value of individuals than in Eastern America, *Quercus* furnishes one of the principal elements of the forests of Japan. The types are all of the Old World, and there is nothing in Japan which corresponds with our Red, Black, or Scarlet Oaks, or with the Black Jack, the Willow Oak, the Shingle Oak, the Turkey Oak, the Spanish Oak, the Water Oak

Part of fence covered with *Wistaria*. Engraved for THE GARDEN from a photograph sent by Mr. S. Bowen, Lansdowne, Millbrook, Jersey.

leafless. That small form, the round-headed variety, *umbraculifera*, which is often planted in formally arranged gardens (sometimes in too great a number), shows this peculiarity in a very marked manner, and as late as September 23 I saw a row of this, in a very dry spot, which had not commenced to change colour, though everything else in the neighbourhood was showing the effect of the drought. This habit of resisting a long continued spell of dry weather is shared by many other Leguminosae, most of which have deep descending roots that serve them in good stead during such a season as the present. Another tree, *Sophora japonica*, is particularly noticeable in this respect, and of shrubs, many of the Brooms, *Furze*, *Coluteas* (or Bladder Sennas), *Caraganas*, and other things stand out conspicuously.—T.

***Robinia pseudacacia angustifolia* elegans.**—Though to a certain extent handicapped by such a formidable name, this is a very desirable variety of the False Acacia, and one that should be borne in mind in making a selection from the numerous forms now in cultivation. It is altogether a far more elegant tree than the type, the leaflets being much narrower, and consequently

but it is the flowers which form the most striking feature of the plant. They are globular, and hang on long slender stalks in little clusters from the upper parts of the shoots. The colour of the flower is a bright coral-red, a tint little represented among outdoor plants. It was introduced from Chili in 1862, and, in common with many other subjects from the same region, it is hardy in some parts of this country, and in others needs a certain amount of protection. In the neighbourhood of London the shelter of a wall will as a rule enable it to pass through the winter, but where it cannot be induced to thrive in this way it may be grown as a cool house climber. When so treated, a light airy position must be assigned it, as if drawn in any way it cannot be depended upon to flower freely. An established specimen will often bloom throughout the greater part of the summer and well on into the autumn.—H. P.

Negundo frexinifolium aureo-variegatum.—The ordinary white variegated *Negundo*, or *Acer Negundo* as it is sometimes called, is one of the commonest shrubs to be met with in gardens; in fact, it is often overdone by the planter. Still, judiciously placed, it is very effective and admired

or the Pin Oak, the Blue Jack, or with our Chestnut Oaks. In the north and on the high mountains of Hondo there are four White Oaks, and in the south a number of species with evergreen foliage of sections of the genus, which are not represented in the United States. In the south, too, there are a couple of deciduous-leaved species with biennial fructification of the Turkey Oak (*Quercus cerris*) sort.

The best known of the Japanese Oaks to European and American planters is

QUERCUS DENTATA (the *Quercus* Daimio of gardens).—This tree is remarkable for the great size of its leaves, which are often a foot long and 8 inches broad, and for the long, loose, narrow, chestnut-brown scales of the large cup which nearly encloses the small pointed acorn. In Central Hondo this tree is only found on the high mountains, and it is not at all common, but in the extreme northern part of the island it appears in great numbers on dry gravelly slopes, at no great elevation above the sea. Here, apparently, however, it does not reach the size it attains farther north, and the finest trees we saw were on the

gravelly plain south of Volcano Bay and in the neighbourhood of Sapparo. Although *Quercus dentata* grows to the height of at least 80 feet and forms a thick trunk more than 3 feet in diameter, it is not an imposing or handsome tree in its maturity and is only beautiful in youth. Old trees lack symmetry and the appearance of strength, and are sprawling in habit, without being picturesque. The bark is rather dark for a White Oak, and not unlike that of our Rock Chestnut Oak (*Quercus Prinus*); it is valued for tanning leather, but the wood is considered worthless. *Quercus dentata* appears to be the only deciduous-leaved Oak cultivated by the Japanese, and small trees are common in the gardens of Tokio and other southern cities, where, however, it seems to languish. A variety (*pinnatifida*), with deeply divided leaves, is cultivated in the Botanic Garden at Tokio, and has, I believe, been introduced into Europe. In Central Yezo, two noble White Oaks,

QUERCUS CRISPULA AND *QUERCUS GROSSE-SERRATA*, form a considerable part of the forest growth. The Dutch botanist Miquel considered them forms of one species, but Professor Miyabe, who has had the best opportunity for studying these trees under the most favourable conditions, believes them to be distinct in their fruit, although similar in foliage. His view, too, that *Quercus grosseserrata* cannot be specifically distinguished from the Saghalin and Manchurian *Quercus mongolica*, will probably be found to be correct. *Quercus crispula* appears to range farther south than *Quercus grosseserrata*, which extends north to the Kurile Islands, and was not recognised by us in Hondo. In the Nikko Mountains, on the road to Lake Chuzenji, we saw fine forests of *Quercus crispula*. In Central Yezo, where the two species grow side by side on the hills, on low ground, near the banks of streams, *Quercus crispula* appears the more common tree. Both have leaves resembling in colour and texture those of the common Oak of Europe. The bark is pale, or sometimes dark, and scaly, and both species under favourable conditions rise to a height of 80 feet to 100 feet, and produce stems 3 feet to 4 feet in diameter. Both are timber trees of the first class, and both, should they thrive in this country, may be expected to add beauty and interest to our parks and plantations. The smaller, shorter acorn of *Quercus crispula* appears to offer the only character for distinguishing the two trees; in their port, bark and foliage they were indistinguishable to my eyes. The fourth Japanese White Oak,

QUERCUS GLANDULIFERA, ranges in Yezo nearly as far north as Sapparo, although it is only south of Volcano Bay that it is really abundant. This, the common Oak of the high mountains of Central Japan at elevations over 3000 feet, is probably the most widely distributed species of the empire; it is a pretty tree, rarely more than 30 feet or 40 feet high, although on the hills above Fu-kushina, on the Nagasendo, we saw specimens nearly twice that height. The leaves are pale or nearly white on the lower surface, and from 1 inch to 4 inches in length. The acorns are small. Like many American Oaks, this species varies remarkably in the size of individuals, and in some parts of the country traversed by the Nagasendo we found plants only a foot high covered with acorns. This Oak was sent to the Arnold Arboretum many years ago from Segrez by Monsieur Lavallée. It is perfectly hardy here, and has flowered for years, although it remains a bush, and makes no attempt to grow into a tree. Of the other deciduous-leaved Oaks,

QUERCUS SERRATA, one of the most widely distributed of the Asiatic species, ranging, as it does, from Japan to the Indian Himalaya, is common in dry soil near the coast below Yokohama and on the foot-hills of the mountains of Central Hondo. It is a small tree, 20 feet to 40 feet high, with a slender, black-barked trunk and beautiful dark green leaves. In Japan this tree appears to spring up in waste lands in great numbers; it is only valued for the charcoal which is made from it.

QUERCUS VARIABILIS, a nobler tree of the same general character, we only saw in the grounds of a temple near Nakatsu-gawa, on the Nagasendo,

where there were specimens fully 80 feet high, with tall straight trunks 3 feet or 4 feet in diameter, covered with thick, pale, corky bark, which is sometimes used by the Japanese for the same purposes that we use the bark of the Cork Oak. The leaves are less coarsely toothed than those of *Quercus serrata*, dark green and lustrous above and pale, or nearly white, below. From *Quercus serrata*, too, it differs in the smaller cups and in their shorter, thicker scales. A number of plants have been raised in the arboretum from the acorns which we picked up under these trees, and if they are not hardy here in New England, they will certainly thrive in the middle States.

It is impossible to know whether many of the

EVERGREEN OAKS

which we saw in Japan were growing naturally or had been planted. In the gardens and temple grounds of Tokio, Yokohama, Kioto and other southern cities evergreen Oaks are the commonest trees, but we did not see them growing in the forest except near temples. The species most frequently seen in Tokio and Yokohama are

QUERCUS CUSPIDATA AND *QUERCUS GLAUCA*. They are both large and beautiful trees, said to be particularly conspicuous in early spring from the bright red colour of their young shoots and new leaves, which at that season make a charming contrast with the dark and lustrous green of the older foliage. They should be introduced into our Southern States, where, probably, all the Japanese evergreen Oaks will flourish. The wood produced by *Quercus cuspidata* and *Quercus glauca* does not appear to be valued in Japan, but the acorns of the latter are of considerable commercial importance, and are cooked and eaten by the Japanese.

QUERCUS ACUTA, which is also much planted in Tokio, we saw growing to the height of more than 80 feet, with *Quercus variabilis*, in the temple grounds at Nakatsu-gawa, and also near the temple of Higane, near Atami, on the coast. It is a noble tree, with dark green, thick, and lustrous leaves. This noble tree has been introduced into English gardens, with a number of other evergreen Japanese Oaks, through the efforts of the Messrs. Veitch, who obtained it some years ago from their collector, Maries. But the finest Oak tree, and perhaps the finest tree which we saw in Japan, was a specimen of

QUERCUS GILVA in the temple grounds at Nara, where there are a number of remarkable specimens of this beautiful species. The largest of these Nara trees was probably 100 feet high, with a trunk covered with pale scaly bark, which, breast-high from the ground, girthed just over 21 feet; it rose without a branch, and with little diminution of diameter, for something like 50 feet, and then separated into a number of stout horizontal branches, which had not grown to a great length, and formed a narrow, cylindrical, round-topped head.

Of the other Japanese Oaks, *Quercus Thalicca*, *Quercus Vibrayana* and *Quercus glabra*, we only saw occasional plants in gardens. The *Quercus lacera* of Blume we did not see at all.—C. S. S., in *Garden and Forest*.

Balbisia verticillata (*James Exall*).—This is the name of the flower you send, which you say "is from a plant which has been grown in a pot in a cold house." It is a half-hardy shrub from Peru, and was introduced to this country by Messrs. Veitch and Sons, of Chelsea, about twenty years ago. I have not seen it much, but I do not think it was a new plant, for once before in the early part of the century it was introduced to this country from Chili. The flowers resemble those of a *Hypericum* in shape and colour, being nearly 3 inches across and rich golden yellow. This is the time for its flowering, and I advise the sender to increase the plant, and to try it as an outdoor shrub, selecting a dry, well-drained and somewhat sandy situation for it.—W. H. G.

ROSE GARDEN.

THE ROSE SEASON OF 1893.

SELDOM has a year opened with greater promise to rosarians than did the present one, and to some few, more especially those with gardens in the northern parts of England, Scotland and Ireland, the promise has been fulfilled, but the expectations and hopes of those of us who live in the southern counties have been somewhat upset by the extraordinary drought and heat. I wrote to THE GARDEN a letter which appeared in the issue of March 25, in which it was stated that up to that period of this year we had enjoyed typical weather, but the dust of March was not followed by the showers of April, and, in fact, barely 2 inches of rain fell in most parts of England from that time till the month of July, by which time the Rose season for the majority of growers was over.

I shall not trouble you with a discussion on the trials and worries incidental to a season in which insect life naturally became rampant, but some of the drawbacks which the early activity of caterpillars, &c., would have intensified were obviated by the fact that in consequence of Rose trees starting into full growth quite a month in many cases before their usual time, a great deal of this early growth had to be cut away and the trees very hard pruned, the insect life just then becoming rampant in the upper shoots being thus disposed of and relegated to the obscurity of dust-heaps. Theories as to correct dates for pruning were as a matter of course, totally upset by the weather, and there were few Rose gardens where all Rose trees were not pruned by the second week in April. The question which soon became one of urgency was as to whether watering in the early stages of growth was judicious or otherwise. Those who favour the belief that plant life cannot have much vigour without a certain amount of moisture soon took to the pumps or the garden hose, and I know that in most cases others who habitually decry this method finally took to watering vigorously—in some instances too late to benefit their trees or retard the undue rapidity of bud-development of a weakly character. I believe to this neglect or the inability to obtain sufficient artificial watering power we may ascribe in great part the effacement this year of some of our great Tea amateur exhibitors.

What, however, was a source of great damage to the south was of advantage to the cooler region of the north, and the year 1893 will be remembered amongst rosarians as a year of triumph for all the great growers in the northern parts of the United Kingdom. By the liberality of the executive of the Gardening and Forestry Exhibition at Earl's Court, and by the early appreciation of the position and prompt action of the executive of some of the Rose societies in the south of England (notably those of Ryde and Newport, Isle of Wight, Reigate, Hitchin, Sutton, Windsor, and one or two other places) there were early Rose shows fixed, and those with later dates altered their arrangements, thereby enabling many to show their flowers who would have been unable to do so later, their best period of blooming being over by even June 28. I believe I am stating what is strictly accurate when I say that even on June 28 the great Colchester growers and Mr. George Paul were principally exhibiting flowers from maiden plants at the Earl's Court show, and that even then, so early a date in ordinary seasons for many growers, there was great doubt about their being able to show at the N.R.S. Crystal Palace meeting from maiden plants on July 1. In the earlier meetings, notably those of June 14 and 28 at Earl's Court, and June 24 at Reigate and also at Sutton and Windsor, Messrs. Benj. Cant and Frank Cant showed in all classes in their usual splendid form, and Messrs. Prior and Son (another Colchester house coming rapidly to the front) were also able to take the premier place in the Tea class at Earl's Court on June 14; but as the month of June closed, fortune favoured the north, and the name of Hawkess became synonymous with that

of victory on almost every occasion. Moreover, their success was not gained by want of competition, but won by sheer merit. At Reigate, in my opinion (as I have stated elsewhere on other occasions), the best general Rose show of the year was held. Messrs. Harkness were even then (June 24) able to show what their prowess would be later on, as although they were defeated in a splendid competition by Mr. Frank Cant in the class for forty-eight varieties, they won the first prize for trebles in a competition of eleven exhibits of the greatest growers of England. At Hitchin on June 26, at Earl's Court on June 28, at the N.R.S. meeting at the Crystal Palace on July 1, and at Worksop on July 13 they were literally invincible, and although at Worksop they had to meet such competitors as Messrs. Dickson, of Newtownards, and the northern growers, Messrs. Mack, Croll, and, I think, Cocker, they continued their victorious career unchecked, and I am told their success in 1893 is a "record." A word of praise must also be given to their principal competitors at Worksop, Messrs. Dickson, who pressed their Yorkshire opponents very hard. Messrs. Dickson achieved at the National Rose Society's great meeting on July 1 a feat never before recorded, viz., that of taking two gold medals for new Roses, and if they had done nothing else this year or had been unknown, this alone would have made them famous.

The show at the Crystal Palace this year was what your readers can only have anticipated who read the letters of last winter which I wrote you on the probable effect of a season such as we have chanced to go through. There were redeeming points such as the one exemplified by Messrs. Dickson's victory and by the superb exhibits of a few of our great amateurs, notably those of Mr. Foster-Melliard, of Ipswich, who this year has taken the place of late years occupied by Mr. Burnside and Mr. Hill Gray as Tea Rose champion. Mr. Foster-Melliard's exhibits were worthy of his great reputation, and both on June 20 and July 1 he showed flowers which can be truly said to have been quite exceptional in any season. He also took the N.R.S. medals at both of their early meetings for the best individual flower shown in the Tea classes. Mr. Lindsell, of Hitchin, at all the early shows also maintained his position of champion rosarian of England, which he has now held for four years, and although the present season by no means favoured him, he was, as usual, well to the front at all the earlier meetings, as well as at the Crystal Palace—other amateurs who also showed well at the Crystal Palace being Mr. Pemberton, of Havering, and Mr. Machin, of Worksop. Later in the season these two gentlemen won many prizes, Mr. Machin's successes in the provinces being quite phenomenal in number and value. He is steadily advancing to the summit of the rosarian's ambition, and should make a bold bid for the championship within the next year or two. The amateur (championship of the northern or provincial meeting this year went to a young rosarian of great promise, Mr. A. Whitton, of Bedale, who has learnt his lesson from the great Yorkshire firm of Harkness, who may be congratulated on so apt a pupil.

Amongst professionals, the north naturally has come very prominently to the front, and the exhibits of Messrs. Mack, Cocker and Croll have been numerous and very creditable in every respect. I believe that Messrs. Cocker have the credit of beating Messrs. Harkness for the only cup they lost in the competitions of 1893—a fact of importance in a year that Yorkshire has been the invincible county. While giving its due meed of praise to the north, we must also give credit to others who have shown well on many occasions, and I may instance Mr. George Mount, of Canterbury, Messrs. Burch, of Peterborough, Messrs. Prior and Son, of Colchester, and Mr. Merryweather, of Southwell, as having been very successful at many meetings throughout the season. Messrs. Paul and Son, Mr. Turner and Messrs. Wm. Paul and Son have also shown in splendid form, although the latter never shows for competition. I may specially mention here the exhibits Messrs. Paul and Son had at Croydon when

they took the principal prize, their beautiful exhibits at Sutton and their superb exhibit at Earl's Court of garden Roses on June 28. Mr. Turner's Rose *Crimson Rambler* has been one of the sensations of the year, winning a N.R.S. gold medal at the Crystal Palace, and being shown to admiring crowds at many places; but at no place was it more effectively and artistically staged than at Reigate. Mr. Turner has also shown Roses well in competition, his exhibits at Earl's Court being, with Mr. Wm. Paul's, the mainstays of the beautiful flower shows held there.

The most splendid Roses of the year have been the darker varieties. It has been generally thought that light varieties do well in a season of the character such as we have had in 1893, but this year it has not been so, save with two exceptions which I shall presently instance. The Rose of the year has certainly been *Horace Vernet*. It has been shown superbly by all growers of standing who cultivate H.P.'s—of course, the bulk of rosarians—but I may specially instance amongst its greatest exponents in 1893 Mr. Frank Cant, Messrs. Harkness, Mr. Benj. Cant, Messrs. Dickson, and Messrs. Paul and Son, in whose exhibits there have been many splendid specimens of it, and it has been well shown amongst our amateurs by Mr. Lindsell, Mr. Orpen, Mr. Pemberton, and Mr. Romaine. It is a difficult Rose in most seasons, but there is no Rose superior to it when it comes so good as in 1893. *Prince Arthur* and *Earl of Dufferin* (respectively raised by our native rosarians Messrs. Benj. Cant and Messrs. Dickson, of Newtownards) have also been exceptionally good. *Earl of Dufferin* is, like *Horace Vernet*, a most difficult Rose, but also, like it, superb when it can be staged at the right moment. One light coloured Rose of 1893 I should wish to specially name, the new variety brought out by Messrs. Dickson, and named *Mrs. Sharman Crawford*. This Rose took a gold medal and the first prize for twelve blooms of one variety at the N.R.S. show on July 1, the exhibits being of very exceptional merit. If this Rose can only be grown in this country with half the vigour and beauty of the examples which took high honours on July 1 it will be one of the Roses of the century. It has every advantage of colour, form, and scent; the colour approaches the tint of the lovely *Mme. Gabriel Luizet*, than which there is nothing more beautiful. Another light Rose which has done well and been frequently well exhibited is *Mrs. John Laing*. It took the N.R.S. medal for Mr. Pemberton at Worksop, for Mr. Romaine at Windsor, and I got two medals for one specimen at Croydon, at other places also, and notably by Mr. Mount, of Canterbury, it has been splendidly shown. Although its colour is unreliable, when this Rose comes true it is unsurpassed amongst the lighter varieties.

Whatever drawbacks the drought may have occasioned, there is one advantage in a dry and hot summer. Those plants which have survived the trying heat of June, July, and August will have splendidly ripened wood. Let us, therefore, hope that the Rose season next year will give a fair chance to all, and that the hopes formed early in 1893, but somewhat upset by the abnormal heat, may be realised in 1894.

Croydon.

CHARLES J. GRAHAME.

Red Tea Roses.—I quite agree with Mr. J. C. Clarke that red or purple Tea Roses are half spoilt. Still, if we are to have such coloured Teas we may as well add as many other good qualities as we can, such, for example, as the fragrance of *W. F. Bennett*. I still, however, think that the latter is one of the best of the coloured Teas, which Mr. Clarke, "A. H.," and others will say is not much after all.—D. T. F.

Rose Aimée Vibert.—It is gratifying to find "A. H.," who eagerly welcomes all good new Roses, sparing a note for this chaste old favourite in a recent issue. I would like to add how very much harder it is than *Lamarque*, and to have "A. H.'s" opinion as to the merits of the climbing and common—it seems a sacrilege to call it the

common—variety of *Aimée Vibert*. The climber in my experience runs further, but can hardly be said to fare better or grow more beautiful. I long to mass and mix thousands of this charming and graceful old white Rose with Turner's new *Crimson Rambler* or other brilliant and free-growing and flowering Roses.—D. T. F.

— I never saw this Rose flowering so freely as this year. In spite of the exceptionally hot and dry summer, a plant of it 20 feet high growing against a south wall has been and is now a mass of bloom, although not watered at all. As an autumn-flowering and hot-weather Rose this deserves more attention than it receives.—E. M.

GARDEN WALKS.

NOT a little of the enjoyment to be got out of a place depends upon the arrangement of the walks and the condition they are kept in. No general rules as to where the walks should be located can possibly be laid down, every place having its own peculiar conformation, needs, and points of interest. A certain number are absolutely indispensable, but in very many instances there are far more than are required either for utility or ornament; in fact not a few pretty little pleasure grounds and gardens are greatly disfigured by the superabundance of gravel walks more especially. Either there are too many or they are too straight and formal, or else gravelled walks are made where a firm turf-covered path would be far more enjoyable in every way. Straight walks may be correct enough in connection with house fronts, terraces, and the borders formed at the base of these, and straight avenues and central walks are a feature in many places, especially where these lead up to a landmark of some kind, but in nearly all other situations a perfectly straight walk is most objectionable. It is the winding walks with ever varying views, or which approach nearer objects of interest, that are the most enjoyable, and it would really seem that it is these that amateur or inexperienced landscape gardeners find it very difficult to lay down. Their idea of a perfect walk would appear to be something as straight and as level as possible. Such may suit invalids very well, and that is the most that can be said in their favour. Instead of imitating a railway cutting on a small scale it is far preferable to let the walks rise and fall much as the surrounding ground undulates, this being both the more artistic and more economical arrangement. A dead level is the most wearisome of road or country to travel over, and the same rule holds good in the case of walks. Cuttings may, however, be necessary in some instances in order to modify very abrupt descents, and if the banks are turned to good account, these may be a feature rather than otherwise in the pleasure grounds, and it is not these that are found fault with. No greater disfigurement than a perfectly straight walk where a winding, undulating path might be substituted could well be planned, while to make matters worse these too often cut up an expanse of turf where no walk of any kind is either necessary or desirable. If gravelled walks there must be, let these fringe the pleasure grounds, the turf, for which English gardens are noted, being kept as nearly intact as possible.

Walks may be laid down in the plans and through the grounds correctly enough, and yet not be enjoyable at all times owing to their faulty construction. If they cannot be used in wet weather or after a frost, of what use are they? They may be properly drained, the gullies in steep walks being sufficient in number—and the gratings connected with these be kept properly cleared—to keep the gravel from being washed away, and yet be imperfect. So-called binding gravels are, as a rule, unreliable. While the weather is favourable they give a good finish to a walk and are also pleasant to the feet, and it is a pity they are not more durable. The way out of the difficulty with many is to face over the walk either with fine gravel, and which in some few cases is not harsh to tread upon, especially that

procured from the seaside. Of late years, however, "chippings" have taken the place of both faulty binding gravel and the pea-like gravel obtained from the coasts, said chippings being in many cases hard stones cracked up finely by tramps, who patronise casual wards, doing this work instead of, as heretofore, picking oakum. This form of surfacing is not particularly expensive unless hauled a considerable distance, always looks clean, can be walked upon in all weathers, and is very durable. All the same, it is far too coarse and harsh to the feet. If loose gravel is used as a surfacing, it ought always to rest on a well-prepared foundation of coarse stones, with a middle layer of similar material of a size that would pass through a 1-inch mesh sieve. Fine waste from stone quarries is preferable to chippings, and if this is passed through a quarter-inch circular-wired sieve, the coarser parts going underneath and that which passes through the sieve being used as a surfacing, there will be no harshness about it, and the walks could be passed over in comfort during wet as well as fine weather, frosts having no prejudicial effect. Where binding gravel is freely used, weeds and Moss most abound, this necessitating, or at all events, leading to the fine gravel being turned every two or three seasons. Now that the application of weed-killers has rightly become so very general, gravel walks of all kinds are very simply and cheaply kept in a clean state, and these do not make them so damp and rotten as used to be the case when salt was largely used as a weed destroyer. As far as kitchen gardens are concerned, the walks ought to be both few in number, straight, and well made, binding gravel being of little service in these places. Much wheeling quickly wears out the best made gravel walks, and when the latter lick up badly, owing to the presence of too much clay in the binding gravel, nothing can be more miserable to deal with. Clinkers and a good surfacing of ashes well rolled in would in many instances be of better service than gravel, while asphalt, and which could either be made on the place or procured ready mixed from the nearest gas works, is preferable to all other forms of kitchen garden walks. Especially is asphalt necessary where the walks are steep, the finer material on steep gravelled paths being liable to be washed to the bottom of a garden whenever heavy storms of rain are experienced. Staffordshire tiles or thin stone are the most suitable for edging asphalt walks, the tar not unfrequently killing much of the Box alongside them. All things considered, imperishable edgings are to be preferred in the kitchen garden, no matter what material may be used in the construction of the walks.

The question yet remains to be answered, Why should gravel walks so often be formed where good turf would answer as well, or, according to some people's ideas, even better? Give a number of visitors to a garden the chance of walking either on a gravelled walk or a strip of turf, and the latter will be selected by a great majority of them. So much is this the case, that when the public are admitted to private places, every precaution is frequently taken to keep them off the turf. The latter will certainly not bear the strain of much traffic in all weathers, but is fully equal to the strain in very many situations where gravel at present reigns supreme. If the ground is well drained, the turf being perfectly level with a good bottom, the Grass also being kept closely shorn, there is nothing more enjoyable to walk upon in hot weather, and in not a few instances it is not so damp to the feet during the winter as a smooth gravel path would be, the disagreeable licking up common to the latter also being avoided. Especially are turf-covered walks desirable in the fronts of or between herbaceous and other flower borders both in the kitchen garden and out of it. I. M. H.

Erythrolæna conspicua.—This very effective giant Thistle from Mexico has been flowering very well on a new piece of the rock garden here, where I placed it to cover an unoccupied portion. The flowering stems have been over 8 feet in height,

and the flowers, as the photograph will show, have been numerous and most graceful. They are brilliant in their colouring of a bright scarlet, shading to crimson as they ripen. The plants have been in flower over two months, and are still quite fresh and bright. The leaves are immense, of a dark glossy green. Altogether the plant is one that arrests attention and elicits great admiration. Two other plants which I placed in good ordinary border soil only succeeded in producing two or three leaves all through the summer.—W. D. R. D.

FLOWER GARDEN.

FLOWER GARDEN NOTES.

THE gradual increase in the number of herbaceous borders and the long-continued supply of flowers obtained therefrom are doubtless partly responsible for the general desire to do something in the way of furnishing beds in the formal garden for the winter, and so obviate the nuisance of looking on nothing but bare earth for some eight months out of the twelve. Spring gardening has, we know, been carried out thoroughly and satisfactorily many years back at such places as Belvoir, Cliveden and Castle Asby, but it is only lately, with possibly the more extensive knowledge of the merits of tufted Pansies, Polyanthuses, and Daffodils, that the majority of gardens both large and small have more or less adopted the system. Small conifers are almost indispensable in this winter gardening, a trifle formal perhaps, but then the foliage always looks bright and healthy; and of how many so-called hardy evergreen shrubs can the same be said if they have to experience winters like that of 1891 and 1892? In the employment of conifers for this purpose it is necessary to guard against over-planting, as too many in any one bed give a heavy appearance. No very formal things, as the Yews, the upright Cupressus and the golden *Arbor-vitæ*, should be tolerated. There is a wide difference between a light, graceful *Retinospora* and the golden form of *Taxus fastigiata* or the severely formal *T. adpressa*. Into the very many plants suitable for present planting it is hardly necessary to enter. Hardy carpet plants alone are in considerable variety and the enumeration of the same is not advisable. They are easy of culture and can be used to meet individual requirements; so, too, such things as *Silene*, *Myosotis* and *Limnanthes*. The two former may act as a carpet to beds of Tulips and make in this way a very pleasing show if the bulbs are not planted too thickly. Considerable difficulty has been experienced this season in obtaining tufted Pansy cuttings; indeed, on light sandy soils the supply is very short. As good bedding varieties of the true tufted type are forthcoming and a bountiful supply obtained by division, we shall be comparatively independent of cuttings, but at present many really excellent varieties are too much allied to the Pansy in habit to split up freely into countless little plants. Sorts comparatively new to us, and which were planted for the first time last autumn, have furnished the best supply of cuttings, for the reason that the ground was well done for them and they have been less affected by the drought. Four sorts, viz., *Crimson King*, *Mrs. Bellamy*, *William Niel*, and *Duchess of Sutherland*, will occupy the greater part of a large bed round plants of *Retinospora plumosa*, intervening spaces being filled with *Veronica incana*. The centre of another bed will be *Bullion*, shaded off at either end with *Ardwell Gem* and *Sylvia*, or *Duchess of Fife* if sufficient of *Sylvia* is not forthcoming. *Polyanthus* seed did not, I believe, come up any too well this spring, but by soaking shallow drills and shading for a time we were successful in securing an excellent plant of a very good strain. The seedlings were transferred to a good north border as soon as they could be handled.

It is a great mistake, by the way, to leave them too long in the seed bed, and they are now capital stuff, each with some fifteen to twenty leaves. No

single flower is more extensively used for spring gardening than the *Polyanthuses*. They were not seen at their best this year in the majority of gardens, the drought and persistent attacks of sparrows crippling both plant and flower; but in the spring of 1892 they were magnificent, and no finer display of colour was obtained all through the season than large beds of the sulphur and crimson-flowered dotted over sparingly with scarlet *Pottebakker Tulips* and the vigorous *Star Daffodil John Bull*. The breaking up and relieving the flat surface of beds as shown here and above in the case of Tulips with *Forget-me-nots* or *Silene* is, I think, one of the best new departures in spring bedding. If there is an inclination to utilise some of the most suitable of herbaceous plants as permanent subjects in the formal garden, many things named above will associate with them for winter and spring, to be in their turn removed for other things. The pink *Silene*, for instance, is seen to great advantage among clumps of *Mrs. Sinkins*, *Her Majesty*, or the *Pheasant-eyed Pinks*, and these make an admirable carpet through the summer months for bold plants of any dark free-flowering *Fuchsia*, clumps of bronzy-leaved *Cannas* or *Ricinus Gibsoni*. Again, no objection can be raised to occasional clumps of good *Pyrethrums* or some of the *Spiræas* among either spring or summer bedding; the foliage is nearly always attractive if they are not in flower. For large beds where a bold mass of colour is required, there are few better things than a good strain of *Wallflower*. I generally sow four varieties, two colours in the dwarf and the same in the taller strains. It was a very dry seed time this year, so they were put in on a north-west border, the shallow drills, as in the case of *Polyanthus* earlier in the year, being well soaked previous to sowing.

TRANSPLANTING HERBACEOUS THINGS.—It is somewhat early in the year to write on this matter, but I should like to note that extra care should be taken in the operation this season, and that all transplanted stuff should have a well-prepared site ready for its reception. It is more than probable after such a season that nearly all growth will come away in a weakly, spindly fashion, and a fillip will be necessary to counteract the imperfect root action consequent on the lack of moisture. Earlier in the season I mentioned the crippling of *Starworts* by rabbits, and with the view to prevent a recurrence of the disaster I have decided to get them to a safer spot, and already started lifting some of the early-flowering section as represented by *Amellus*, *corymbosus*, *paniculatus* *Dot.*, and some of the *Novi-Belgii*. The great mass of the ball of each plant except just round the sides is simply as dry as powder, and a lot of roots are practically withered up. No good can come of leaving these longer in the ground, so we shall continue lifting, cut away the bad stuff, soak the clumps well, and replant in a compost that is likely to suit them well. E. BURRELL.

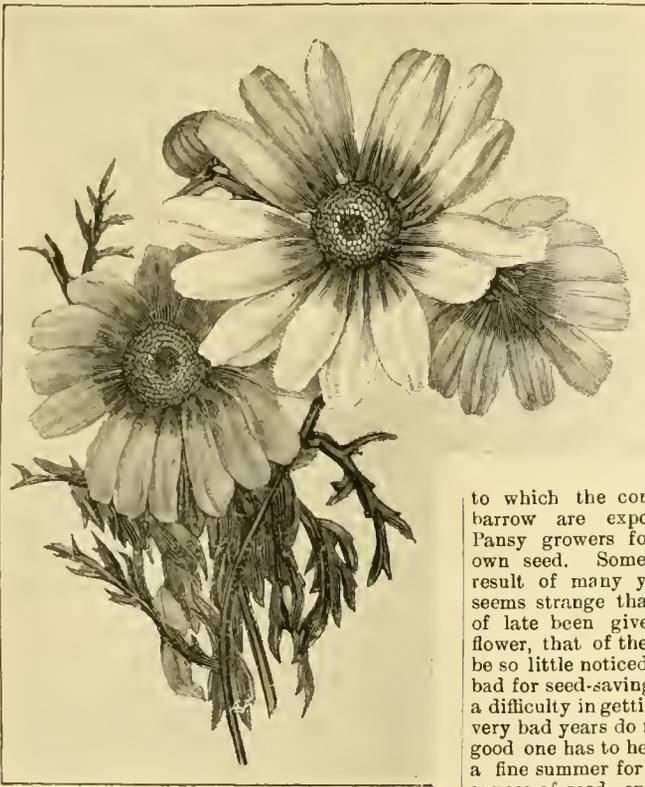

Claremont.

Hardy and tender flowers—"People are getting tired of choice flowers," a florist remarked lately, and added that if simple hardy things, such as *Pinks*, *Stocks*, *Gaillardias*, *Anemones*, &c., could be had through the winter months, many would rather buy them than the choicer flowers that furnish our markets at that season. However that may be, it is certain that there is at the present time a much greater demand for hardy flowers than was the case a few years ago. I should say that for one acre given up to hardy flowers for cutting twenty years ago there are 100 at the present time. The florist above alluded to said we cannot have too many *Daffodils*; everyone wants *Daffodils* as soon as their season comes round, and it is a fact that they come into the London markets in such quantities that would within my remembrance have been thought incredible. At times *Covent Garden* seems full of them, and yet I doubt if ever a bunch remains on hand. If a similar quantity of *Azaleas* or *Pelargonium* were brought in, I doubt if even at a low price they could be got rid of. I have many times

heard gardeners say that the hardy flower border was held in greater esteem than the contents of the glasshouse. One reason for this may be that flowers that have to be cultivated in glasshouses are much more common than formerly. I remember the time when a bunch of flowers in winter was too great a luxury for people of moderate means, but owing to the wonderful development of Chrysanthemum culture and the large importations of flowers from France at an early period of the year, the florists' shops can be well furnished throughout the duller months. Even Orchid flowers can at certain seasons be bought at very moderate rates. Flowers that some years ago were only to be found in the gardens of the wealthy now find their way into the florists' hands in quantity.—J. C. B.

CHRYSANTHEMUM CORONARIUM.

This is an annual species, native of Southern and Eastern Europe, and well known as a sum-

Flowers of the Crown Daisy (*Chrysanthemum coronarium*).

mer inhabitant of our gardens. There are innumerable forms, both single and double, and they afford a considerable range of colouring varying from white through all shades of yellow and orange, while some exhibit discoid orange markings on the florets that render them still more ornamental. It seems to be a widely distributed plant in nature, and is said to be grown as a pot herb in China and Japan.

C. coronarium and its European ally, *C. carinatum*, are both well known as easily grown hardy annuals in the flower garden, and they are so showy, that one all the more regrets that our own golden Corn Marigold (*C. segetum*) has not been taken in hand and improved as a garden annual, since it possesses a far harder constitution than either of the above exotic kinds, and often goes on flowering most of the winter on warm dry soils. F. W. B.

PANSIES FOR MARKET.

WHEN one sees three or four acres of land with long ranges of frames given up to Pansy culture, one is able to form a pretty fair idea of the popularity of this hardy flower. How many plants are sent to market and disposed of in other ways in the course of the year it would probably puzzle the owner himself to say, but there they are in countless thousands in various stages of growth—frames filled with them just coming into bloom to be succeeded by long beds of sturdy little specimens that have passed the winter without protection. The Pansy grower's season is not a long one, but he manages to lengthen it considerably by advancing a portion of his stock through giving protection during the winter. Artificial warmth is not employed, as it would not do to rob the plants to any extent of their naturally hardy character. With shelter from heavy rains, snow and cold winds, they remain fresh and green, and make a certain amount of growth during the winter months. On mild days the lights are pulled off, and this exposure keeps them dwarf and hardy.

The first blooms that come on them are very large and fine in colour. As soon as one bloom is expanded the plant is ready for sale, and is taken to Covent Garden Market or sold on the place to flower hawkers. The Pansy is a great favourite with these men; it comes at a time when the owners of small gardens are beginning to think of furnishing their flower beds, and being so easily propagated, growers can sell at low rates, and this places them within the reach of flower lovers of limited incomes. The hawker can load his barrow with Pansies at the cost of a few shillings, and, unlike the majority of flowers grown for market, they are not much affected by the changes of weather

to which the contents of the flower hawker's barrow are exposed in the spring months. Pansy growers for profit as a rule save their own seed. Some have very fine strains, the result of many years' careful selection, and it seems strange that whilst great prominence has of late been given to French strains of this flower, that of the London market grower should be so little noticed. Some years are conspicuously bad for seed-saving. In a damp summer there is a difficulty in getting enough good seeds, but as two very bad years do not often follow each other, the good one has to help the bad one. This has been a fine summer for seeding. I have saved several ounces of seed, enough to bring me through the next two years if I do not save any next season. Pansy seed does not, fortunately, quickly lose its vitality. Two-year-old seed comes up almost as well as when sown the first season after gathering. July is the month for sowing, and to get good strong marketable stuff one must not be later than the middle of the month. The young plants ought to be dibbled out by the middle or end of August, so that they get sufficient root-hold to ensure them against the effects of frost-heaving. The ground is fallowed for them, thoroughly worked and made fine before planting, some growers making a practice of working in a dressing of soot, so that the plants get the benefit of it at once. In October a surface-stirring is given. A few of the so-called bedding Pansies are grown, but these are propagated by cuttings or division. The old Cliveden Purple and Blue King are still in favour, the latter, owing to its fine colour and compact, free-flowering character, being largely grown. J. C. B.

China Asters at Eynsford.—Although this has not been a good season for Asters, the plants at Eynsford are very satisfactory, but not quite so

strong as in more favourable years. Annuals generally have not succeeded this year, and the results are curious at Eynsford, some inferior, others evidently enjoying the hot, dry season. The broad masses of China Asters grown here show how splendid the flower is for creating masses of colour, and there is a great variety of kinds in the collection. The mixed colours show many splendid shades, but by far the most effective are the kinds grown in distinct colours, which produce a remarkably rich and striking effect. It would not be easy to find better strains, the seed home-saved and each section represented in perfection. It would require much space to deal separately with each phase of the China Aster, as every class has a great range of colour, varying from white to deepest purple. Amongst the most beautiful are the pompons, which provide delightful colours, such as scarlet and rose-carmine, besides many other tints. The pompons are especially useful for cutting, as the stems are of moderate height, and therefore may be more conveniently cut than those varieties which are of such conspicuously dense and dwarf habit. The Victoria Asters are well known, and very charming also are the Mignon Asters, which are useful to cut for the house, and the flowers appear over a lengthy season, whilst the colours are rich and varied, the white forms being especially beautiful. The Comet variety is now well known, but we may make note of it, as it is a very fine bedding kind, the flowers distinct in colour, pink, striped with white, and effective either in pots or massed together in the garden. The Aster is not grown so much in large places, we think, as in former years, but we hope that such a brilliant flower, diversified in colouring and habit, will always enjoy popularity. Nothing in its season creates richer masses of colour.

NOTES ON HARDY PLANTS.

Lathyrus latifolius Turneri.—By comparison with the type this has less foliage and more flowers; the latter are also bigger both individually and in the clusters. But the two chief points of superiority are their distinctly brighter character and greater duration. The succession, too, is remarkable, for now in the last days of September a plant five years old is simply grand, so that this is not a case of abnormal late flowering either because of the plant being young or recently transplanted.

Platycodon grandiflorum Mariesi.—When good things become duly appreciated, we shall no doubt meet with more of this in gardens where hardy perennials are cultivated. The big balloon-shaped flowers of such a rich light blue colour, sturdily held above handsome glaucous foliage by short-jointed stems from 9 inches to 15 inches high, are both freely produced and lasting, especially if the plants are grown in a little side shade, as I think should be the case. This kind comes pretty true from seed, and it may be profitably propagated by root division, for when the plants get old, say four years or more, the thick fleshy roots are apt to canker in the heart. To split and clean them gives them new life and vigour.

Ourisia coccinea.—Quite one of the brightest things is this at the present time. It certainly is a shy bloomer, but it can be managed, and to get its lovely scarlet tubular flowers on short scapes is worth a little trouble. The plant likes clay, absolute clay, but not clay in a dry baking situation, but in such a place and form as that quality of soil naturally indicates—clay in clayey surroundings and with moisture.

Silene acaulis alba.—I know many fail to make the typical rosy-flowered kind bloom, though, naturally, as a wilding it is exceedingly free. It may therefore be useful to bring to notice the white-flowered variety, which is more amenable to cultivation. It not only blooms well at the usual season, but affords us pleasure in the autumn by a fair sprinkling of its snowy flowers resting on its green cushions.

Ostrowskia magnifica.—This takes a long period of rest. It normally dies down in early

summer, but, as is common with such plants, it pushes growth early. Succulent as the roots are, I believe they can endure a fair degree of frost, but the new growth and late frosts are the puzzle. I find I get better results from newly-divided and newly-planted specimens than from established ones, simply because, as I take it, the later planted roots are later in growth, and so escape much, if not all, the March frost.

Gentiana Andrewsii.—If the flowers of this species are closed so that we cannot see the finer shades of blue of the inner part of the tubes, they are otherwise beautiful. They are of good size, well inflated and of a rich deep blue; they also appear in massive clusters compared with the size of the plant. There are also two other commendable features about this Gentian. It is one that will grow in most gardens, having no requirements of a very special nature, and the flowers appear in the autumn when fresh flowers are prized almost as much as those of the earliest spring. The plant grows from 9 inches to 1 foot high. It may be described as a glorified *G. pneumonanthe* and is one of the American species. J. WOOD.

Woodville, Kirkstall.

HOLLYHOCKS.

It seems to have been amongst the odd products of the season that there should have been in spite of the great heat and drought much less of the Hollyhock fungus than usual. I invariably found in previous years that drought assisted to develop the fungus rapidly, and leaves and stems would under its operation be quickly eaten up. Perhaps the force of this fungus is abating. In any case we have seen Hollyhocks in greater beauty during the past season than for a long time previously. Some of the best I have seen for many years were growing on a long side border at Hampton Court, extra strong plants, blooming at great height, and having some two and three stout main stems. So good were they that they evoked the warm admiration of a leading Scotch grower, pretty conclusive evidence as to their merits. Out of some fifty or so of fine plants only one had indifferent flowers, whilst most of them had blooms that would have satisfied any florist. The colours were varied, and all very effective. I learned that the plants, all from seed, had been raised and planted out during last year, but too late to bloom. The result was very fine growth and a splendid bloom this season. The hint thus given is worth adoption if really striking effects are desired, as with two or three stout stems rising up from a strong plant so much more effect is obtained. It is very interesting to learn that the plants were all from seed, because the result did but serve to show, once quality is obtained, that it may be very easily continued through seedling plants. A peculiarity of the double Hollyhock also is its tendency to reproduce the parent colour of the flowers. This rather leads to the impression that insects have little to do with fertilisation. I have always found good doubles to reproduce their own colour almost exclusively, even when all have been growing somewhat close to each other. That fact may to some extent serve to minimise variation, but after all we do not want many diverse hues; white, yellow, buff, pink, rose, red, crimson, purple and maroon present very good variety, but some will perhaps have edged or tinted flowers. The singles would be regarded as exceedingly pretty had we no fine doubles, as the flowers have a very bright and pleasing appearance, but the taste certainly now is in favour of the fine doubles. It may seem strange that it should be advised to sow Hollyhock seed now, but it is very easy to do so in a pan or shallow box, standing it in a gentle warmth and near the light; that will cause the seed to germinate freely. So soon as rough leaves are shown a cooler temperature will do, and later the plants should be potted up singly into 3-inch pots, and when partially rooted they

may be stood on the shelf of a cold house or in a frame, where they will harden. Such plants will be ready to put out about the end of April, strong and well rooted. They will make rapid growth, and every one will bloom during the ensuing summer or autumn; that is more than can be said for plants raised from a sowing made in heat in the early spring. All the same, it is preferable to sow seed in the open ground in the month of June and thus secure very strong plants to put out in the late autumn. A. D.

Fuchsia gracilis variegata.—A few plants of this pretty variegated Fuchsia planted on the margin of a bed that is otherwise filled with the dwarf Dunrobin Bedder at Chiswick merit attention by those who want a neat and effective silver-edged plant for bedding purposes. The variety makes such moderate growth, that the present plants hardly exceed 9 inches in height. The wood is very wiry and tough, and would bear pegging well, and also pinching. Flowers are hardly produced at all, and they would be somewhat out of character. It ought to make a pretty front row plant for boxes in windows. It would look very pleasing also if used to form a groundwork for strong thinly-planted Begonias. The bedding variety from Dunrobin is now blooming again very freely. It makes so poor growth, however, that plants must be grown on for a year at least in pots before they are strong enough for bedding. It also needs rich soil and plenty of water to keep it in constant bloom.—A. D.

Giant Sunflowers.—A wonderful growth was made by common annual Sunflowers this season, and mention is made of some plants that reached a height of 11 feet, the stems of the plants measuring 7 inches in circumference. That these plants produced enormous flowers there can be no doubt, and it is said the seed disc of one measured 3 feet 5 inches in circumference. These giant Sunflowers are noble objects when in bloom, and to preserve their decorative value as long as possible it is well to cut away the flowers as soon as the florets wither. The double varieties are magnificent. At the late summer exhibition of the Bath Floral Fête committee, Mr. B. R. Cator exhibited some heads of the fine double orange that were simply marvellous from their size and symmetry—masses of fine deep golden thread-like florets. It was astonishing that a common Sunflower could be produced with so much beauty. But to secure these heads, good culture is necessary, for nothing of high quality can be secured without the use of something more than ordinary means.—R. D.

Arum Lilies and drought.—From my experience of this Lily, when planted out during the summer it will stand more drought than many suppose. The practice of some is to plant in trenches like Celery and give the roots an abundance of water; but where the soil is inclined to be heavy, this treatment is quite unnecessary. Our stock of this Calla was planted on a west border last May, most of the roots having been divided. In addition to being watered at that time, they have received but one soaking since, in spite of the drought. The plants never were in better condition than at the present time, being strong, with short, stocky leaf-stalks and promising abundant flower-spikes later on.—E. M.

Calceolaria amplexicaulis.—When planted out during the summer, this species is, at a time that the others are nearly exhausted, just at its best, and for late flowering there are none to equal it. A quarter of a century ago this Calceolaria was far more common than it is now-a-days, being very generally employed for bedding purposes. Being rather a tall grower led, I suppose, to its neglect, but now that the formally arranged flower beds are less popular than formerly, and in many places are to a great extent superseded by a mixed arrangement, it will be found very useful, and in late summer and early autumn the sulphur-yellow blossoms are very bright and cheerful. It is a free, vigorous grower, hardier than some of the garden

varieties, and a desirable feature is that it does not die off suddenly when at its best, as some of them are liable to do. This Calceolaria is a native of Peru, from whence it was introduced in 1845. Some of the other species of Calceolaria are well worth a place in gardens, one of them, *C. fuchsifolia*, or *deflexa* as it is sometimes called, being thought a good deal of about a dozen years ago, but it is now seldom seen. It is a shrubby species that produces its pale yellow blossoms throughout the winter months, but is in many places a difficult plant to cultivate. *C. Pavoni* is a distinct, but coarse-growing species, and is chiefly noteworthy as being one of the parents of the hybrid *C. Burbridgei*; *C. fuchsifolia* is the other. This hybrid is a valuable autumn and winter-flowering plant, and in a light warm greenhouse it will maintain a succession of bloom for a long time.—H. P.

Pyrethrum uliginosum.—It seems difficult to name a white-flowered hardy perennial which can compare with this for cutting at this season of the year. It is so accommodating, that it will flourish almost anywhere, but deserves good treatment. A single white Chrysanthemum appears almost out of place in comparison with the usefulness of the Pyrethrum in supplying blooms at this season of the year. Owing to the dry season it has not grown to its usual height, and it has bloomed earlier for the same reason, but it is always successional. If the flowers be cut when about half expanded, they remain fresh in a cut state for a long time, and it is better for indoor decoration than Chrysanthemums and much more lasting than the Japanese Anemone.—R. D.

THE WHITE EVERLASTING PEA.

WITH great pleasure I endorse all that "J. C. B." so well says in praise of this beautiful and useful hardy plant, *Lathyrus platyphyllus* or *L. latifolius*. There are several other species well worth growing, but these have made little headway against this Everlasting Pea in its white and rose-coloured form. The latter may also be met with at times in various shades of colour, as the Everlasting Pea may be raised from seeds as well as by stem cuttings and division of the roots. It is, however, so fully and long occupied with flowering in succession in such profusion throughout the growing season, that the plant seeds but sparingly on an average of seasons, and when it does seed, the rose-coloured variety mostly reproduces itself with tolerable constancy as to colour.

The Everlasting Peas are in fact very stable in their character, and, looking at the endless variations of another species, *L. odoratus*, or Sweet Pea, it is somewhat surprising that so little has been done to alter or improve the Everlasting Peas. Those who know their supreme value for cutting in succession, as "J. C. B." and others, will probably wish that the Everlasting Peas may be left severely alone in their present state of usefulness and glory. The white especially can hardly be made more useful than it is unless it were made more fragrant. A real scarlet Everlasting Pea, to which I have seen some approximation, would also prove an acquisition; but the substance, size and staying powers of the blooms could scarcely be improved, while no plant, unless it were Nettles or Conch Grass, could excel the Everlasting Peas in their facile powers of multiplication. The whole root-runs become converted into nests of root suckers, each of which has a power of running into a fresh plant and forming a new colony. Partly, perhaps, from this marvellous capacity for increase and power of growth, the Everlasting Peas are seldom found under the highest cultivation. These Peas will live and bloom everywhere, anyhow, and yet no plant pays better for liberal culture and deep cultivation, as pointed out by "J. C. B." (page 301). During the summer now closing a deluging of house sewage once a week did not prove excessive for these fast-growing, free-blooming Peas, though in deep soils in ordinary seasons few plants, I had almost written, no plants,

will yield such a full harvest of beauty without any help of any sort from the cultivator. Let the plants have a free head and cut and come again for their blooms in basketfuls, and the more we cut the faster and more freely they come on in succession. Such is the simple law of the supply of Everlasting Peas, one or a dozen of which should be found in every garden. D. T. F.

NOTES ON TUFTED PANSIES.

In many gardens Pansies and the tufted kinds have had a bad time of it, due to the dry state of the ground and the great heat. I have seen beds that were top-dressed and watered and had every attention that went down before the fierce heat of the summer, the foliage of the plants turning brown and appearing as if burnt by fire. The Pansy and tufted kinds, especially in southern localities, require moisture and coolness, and these two having been only sparingly bestowed in the past summer, the plants suffered. Many plants have died outright, but some have escaped the trial, and it is to these the attention of the grower should be turned. The change in the weather and the grateful coolness which came as a result of the change, caused the plants which remained alive to commence a growth from the stems close to the root. To encourage these growths, all the decayed shoots should be cut away, the soil about the plants stirred, and a good root watering given to make sure the soil about them is thoroughly moist. This done, there should then be given a good surface dressing of fine rich soil, including sand and leaf mould, pressing it down somewhat firmly about the roots. A new growth will be rapidly put forth, and in November the plants may be pulled to pieces if the growth is sufficiently advanced, or they may remain until February and the divided pieces planted out in nursery beds. Cuttings have also had an unsatisfactory time, and those rooted from spring cuttings have failed when transplanted, whilst seedlings from spring-sown seeds have done little better, unless they have had a shady position and been well looked after in the matter of watering and dressing, or else kept in the boxes under the shade of trees until rain came. As one never can determine what the autumn may be like, it is always a matter of precaution to sow some seeds in July to have plants to flower the following spring. Some of these will be certain to bloom in autumn, which is a decided advantage, because it enables the grower to separate the floral wheat from the tares and secure for spring blooming varieties of good quality. R. D.

Sorghum halepense.—"H. H." sends specimens of this fine Grass as packing material for Orchid flowers, but I find that Cattleyas and other large things are best packed without anything to accompany them. This is a magnificent Grass, and it makes a very attractive plant when it does well. Of course it is not such a fine plant as *Arundo conspicua* or the Pampas Grass (*Gynerium argenteum*), but its large panicles of flowers, which are of a purplish hue, render it very effective. The plant grows from 3 feet to 4 feet in height when planted in good rich loam, and makes an abundance of large, broad, flat, dark green leaves and numerous large and dense panicles of bloom, which have a very elegant and graceful effect.—W. H. G.

Funkia grandiflora.—One of the strongest points in favour of growing this as a pot plant is that by this means it can be had in much better condition than when grown in the open ground. It is a beautiful plant in flower, the gem of the family; but as an open-air plant, except for its foliage, it is very uncertain indeed; and usually, unless some expedient is adopted to induce early blooming, the autumn rains or early frosts entirely spoil the flowering prospects. As a pot plant it can be perfectly controlled, and its blooming becomes almost a matter of certainty. When kept entirely under glass its foliage is of a much deeper green than that of open-air plants. Fine plants in

large pots, when in flower, might be stood about in the garden with good results, as the blooming season is fairly prolonged, the flowers opening in slow succession. They are long, tubular, pure white, and sweetly scented.—A. H.

Nicotiana colossea.—This is a most valuable addition to our ornamental plants for open-air decoration during the summer months. It grows to a height of from 5 feet to 6 feet, and puts forth magnificent leaves of a dark olive-green colour with midribs of rosy brown; the leaves are stout and very large when fully grown. Some plants of it grown as single specimens in a border are finely developed, and it is one of the best sub-tropical plants introduced in recent years. Being of a stout and erect growth, it appears able to withstand high winds and storms. It can be raised from seeds in the same way as other varieties of this genus.—R. D.

TUBEROUS BEGONIAS AT SWANLEY.

ONE of the chief flowers grown at Swanley is the tuberous Begonia, and the plants in the open at Eynsford, where Mr. Cannell has many acres devoted to Asters, annuals and other things, are very fine. Upwards of 10 acres are planted in the open, the beds of great length, and each filled with distinct kinds. The colours vary from deep crimson to shades of orange. One gets now in the tuberous Begonia a remarkable wealth of colouring, and if the more showy colours are not cared for, there are a host of soft tints which may be obtained, such as delicate shades of rose, pink, yellow, and primrose, whilst the pure white variety is delightful in the open quite as much as in pots. Some kinds have flowers with white centres, but the outer portions touched with soft red and pink. Such popular flowers as the tuberous Begonia are ever changing, so to speak, and the change has been great since the time the plants were not only of a straggling habit, but bore flowers of poor colour, and very different to the broad, well-set-up blooms of more recent times. The difference in habit is most marked, the plants now being very dwarf. We noticed several good varieties of striped Begonias, and although we are much against striped flowers as a rule, these are very distinct and effective. The reason why striped flowers are too often failures in gardens is that they do not tell sufficiently, the striping, so to say, being weak and far less striking than the bold self colours. The striped Begonias are, however, welcome, and in time will become an important section. The visitor to Swanley or Eynsford in search of tuberous Begonias will be well rewarded, as besides the plants in the open, no less than five houses, each 100 feet long, are planted out with seedling Begonias, producing immense flowers of a great variety of colours. Two very striking kinds we noted were Prince of Orange, a splendid type of the single Begonia, the plant of excellent habit, erect in growth, the flowers of fine shape, orange-scarlet in colour, and produced in profusion, and Fashion, of distinct and handsome character. As we have had occasion to remark previously, this has not been the most satisfactory season for Begonias in the open, but the plants are behaving well in this nursery, although on the broad slopes at Eynsford the heat has been intense. Their fine aspect, however, under present conditions is due to the excellent culture given; the soil is thoroughly prepared, dug early in the spring, and well, but not too deeply manured.

We hope that, because the tuberous Begonias have not fulfilled expectations in all gardens this year, they will not be in any way grown less in the future. Every flower has its particular season, and in rather wet years, when the zonal Pelargoniums have run to leaf, the Begonias have been magnificent. As so much interest is being taken now in the Begonias of the semperflorens type, it is interesting to note that, although they have not done so well this year as usual, owing to the drought, they are certainly amongst the best of flowering bedding plants. One of the most effective is *B. s. atropurpurea* or Vernon's variety,

which has dark green bronzy leafage and rich crimson flowers, whilst there are also other varieties, as *alba*, *rosea* and *rubra*, each useful for creating variety in the flower garden.

CHRYSANTHEMUMS.

CULTURAL NOTES.

THE manner in which the plants are arranged when placed inside the house must depend upon circumstances, such as the means at command of the cultivator and personal taste. Where practicable an effective way of grouping them is much the best, as considerable pleasure is derived in examining them and comparing varieties. Some growers place them carelessly on the floor, but this is slovenly. Peach houses and vineries, after the fruit has been gathered, suit them admirably. The leaves from the fruit named will be falling by the time the Chrysanthemums are housed, thus admitting sufficient light. No harm is caused by shortening back the shoots of the Vines as well as cutting away all lateral growths to give the Chrysanthemums all the light possible. The plants should be arranged in a long sloping bank, as this is the best position both for observation and convenience of attending to them. If the house is wide enough to admit of their being arranged sloping towards the back of the house, and thus looking northward, much time will be saved in shading the blooms, as the plants naturally shade one another.

If exhibiting is a point to consider, it is wise to place the Japanese varieties in a house by themselves, so that more fire heat can be given them during the time the blooms are developing, as this fine section develops the florets easier and finer also under the influence of a little artificial heat. Nowhere, however, are the Japanese varieties more effective than in a large conservatory where Palms are the chief inmates, but it often happens that these structures are too moist to suit the developing blossoms. In all cases place the plants as near to the glass as possible so that they may have the full benefit of the light. The colours of each are by this means brought out in truer character than they can be where the light is diffused. The flower-stems also do not become drawn up weakly as when the plants are far from the glass. If the peduncles are weak it is an indication that the flowers will not be so good, except of course where the variety is characteristic in this respect.

As much space should be allowed between the plants as possible. When arranged in a solid bank the bottom leaves of the inside examples will quickly turn yellow and fall, but I do not know that so much harm can happen to them in consequence, because by the time that occurs the bottom leaves will have carried out their functions and the flowers will be three parts developed. We have high back walls to the vineries and Peach houses, these being excellent for training the taller specimens to. Many varieties unfortunately run up 10 feet high, and to the exhibitor these, even so tall, cannot be dispensed with. To provide places for these extra tall sorts where high houses are not available many schemes have to be resorted to, even to training them up the wires of the vineries between the Vines, allowing the flowers to hang downwards. In the case of incurved varieties this is a good plan, the petals being more inclined to incurve correctly towards the centre of the bloom than when they are erect, especially in the case of members of the Queen

family, which is an important section to the exhibitor, who cannot afford to be without some kinds of this group. E. MOLYNEUX.

Chrysanthemum Madame Greard.—This variety I am particularly pleased with, it being, I consider, an improvement on the well-known Madame Desgrange—that is when treated as a freely grown bush without any disbudding. It is a remarkably strong grower and very free flowering, the buds pushing well up above the foliage. The fault with Madame Desgrange, except in a favourable climate, is its weakly habit and also its liability to mildew. I can never succeed with it as I used to do when living in a more favourable district.—A. YOUNG.

ORCHIDS.

MILTONIAS.

I AM induced to say a few words about these plants from having received a fine flower from H. Roberts of a very good variety of the old and well-known species, *M. spectabilis*. He complains that although this species flowers well every season, it turns of such an ochreous yellow, that the effect of its flowers is killed, and he asks for advice to prevent this. The finest variety I ever remember to have seen was in the Botanic Gardens of Glasgow many years ago during the time these gardens were under the superintendence of Mr. Clarke. It was a large specimen, with very fine flowers measuring nearly 4 inches across, and these were of an exceptionally bright vinous purple. The effect produced by them was much reduced by the yellow colour of the pseudo-bulbs and leaves, which gave it the appearance of a plant flowering itself to death. Much of this may be greatly obviated by shading lightly from the sun during the hottest part of the day; indeed, I am of opinion that all plants grown under glass structures require a thin shading material put over them for an hour or two during the middle of the day. Another plan which I used to adopt when I had a large quantity of Miltonias under my charge was to water them carefully with clear soot water after the flowers began to show, which had the effect of making both pseudo-bulbs and leaves greener, and I think, too, it heightened the colour of the flowers, for I used to have some splendid dark coloured forms. This soot water, if properly prepared, and not applied too strong, would be found, I think, of great assistance to those Orchids in particular that appear to suffer from the effects of sunlight. Plants so grown succeed better than when constantly shaded, and from which I obtained good growths, but very few blooms. The Brazilian Miltonias require considerable warmth and a large amount of sun and light, accompanied by an abundant supply of water during the growing season. During the winter—that is, the resting time—they should have just sufficient moisture to maintain the bulbs in a plump condition. They require to be well drained, and do not like a great amount of soil about their roots, this consisting of good brown peat fibre mixed with an equal quantity of chopped Sphagnum Moss. The creeping kinds, such as *M. spectabilis* and its varieties, require to have their rhizomes pegged down on the surface, but the tufted kinds require potting in the usual way.

M. spectabilis appears to have been introduced about sixty years ago, and, like so many of the new Orchids of that time, was first flowered by the Messrs. Loddiges in their famous nursery at

Hackney. It is a surface-rooting plant, and its pseudo-bulbs and leaves do not exceed more than 9 inches or 10 inches in length. These are of a bright green colour when grown in the shade, but become more or less of an ochreous-yellow by exposure to the sun. The scape is one-flowered and about 10 inches in length, bearing a large flat flower, which in the one now before me measures nearly 3 inches across. I have seen them 4 inches across, this being an exceptionally fine variety; the sepals and petals ivory white, whilst the lip is large, and of a rich bright vinous purple with a few bold streaks of a darker hue. It is very handsome, and lasts a fair time in perfection.

M. spectabilis Moreliana.—This is a variety of the above-named species, differing from it in colour and in the larger size of its lip, whilst it flowers about the same time, and, therefore, is valuable to grow with it. The sepals and petals are of a rich deep purple, and the lip is of a deep rose with darker shade. It is a very desirable variety, the flowers contrasting well with those of the typical plant. The variety known as *M. atropurpurea* is very fine, being larger and richer in colour, but it is scarce. I saw it a few years ago in fine condition with Mr. Shuttleworth in his nursery in the Clapham Park Road.

M. spectabilis Radicans is a beautiful variety, figured in the "Orchid Album," pl. 164, the flowers being of a creamy white throughout, having several radiating streaks of rich purple at the base. Good varieties of *M. spectabilis* are *virginialis*, *rosea*, *lineata*, *bicolor*, and some others, which all have a close resemblance to the typical plant.

M. cuneata.—This species is of tufted growth and is very free flowering. It was always rare until Mr. Gotto, of Highgate, made it more plentiful some years ago by bringing some specimens home from Rio. It grows nearly a foot high, and bears an erect scape with about six or more flowers, which are produced in the early spring months; the sepals and petals are chestnut-brown, the apex of a pale yellow, lip large and pure white.

M. Regnelli I brought from M. Schiller's collection to England in 1862, and the next season it flowered with me. I do not know if this Miltonia already existed in English collections. It is a very beautiful species and grows to about the same height as the last-named, producing an erect scape longer than the leaves, and bearing a raceme of five or more flowers, which are waxy-white in the sepals and petals, the lip being pale rose, streaked with a deeper shade, and with a white marginal border. The very finest variety I know is called Rucker's variety, but it was afterwards figured by the name of *M. Regnelli purpurea*. It has larger flowers than the typical form, the sepals and petals of a light rosy pink, lip rich purplish-crimson with paler margins. It is a superb form, but somewhat rare.

M. Peetersi.—This has the habit of the last-named plant, and its flowers, too, are about the same size and shape; the sepals and petals deep purple, lip large, rich violet-purple, paler towards the margin. I have only seen this once in cultivation in English gardens, and this was with Mr. Shuttleworth at Clapham.

M. candida.—This is not a flat-lipped species but has spreading chestnut-brown sepals and petals, the latter slightly broader and tipped with yellow, having several transverse markings of the same colour running through them. The lip is rolled over the column, white, with some violet blotches towards the base, the variety *grandiflora* being the best, and it is amongst the most beautiful plants that can be grown for autumn flowering.

M. Clowesi.—With this species I shall conclude the enumeration of the Brazilian Miltonias, not because there are no others, but the above are amongst the best of the kinds that have been introduced in a living state. Although this species is by no means the least, it is of robust growth, some 18 inches in height, and the leaves are of a deep green colour. The peduncle is about 2 feet in height, erect, and bearing a raceme of from six to nine flowers or more, each flower being from 2 inches to 3 inches across. The sepals and petals are spreading, deep

yellow, transversely banded with chestnut; the lip is pure white, the base part deep violet. Beautiful though this plant is, a variety which I saw some few years ago called *Lamarckiana* is far better. It differs in having broader sepals and petals which are more conspicuously marked with brighter chestnut, and in the wider lip, which is not contracted in the middle. WM. HUGH GOWER.

Dendrobium Lceanum.—This is a beautiful species of which I received flowers from Mr. Sander, of St. Albans, by whom it was imported with the variety of *D. Phalenopsis* that bears Baron Schröder's name. It resembles that kind in growth, the blooms, however, being different, the sepals white at the base, where they form into a short obtuse spur, bright rosy purple at their tips. The petals are narrower than the sepals, spirally twisted, and rich rosy crimson throughout. The lip is three-lobed, side lobes large, erect, standing up beside the column, but not covering it. These are of a bright rosy-crimson, front lobe of the same tone, and having on the disc five raised and fringed lamellæ, behind which the throat is white.—W. H. G.

Dendrobium Phalenopsis Schröderiana.—One of the finest flowers I have seen of this magnificent variety comes to hand from Mr. Kerlake, who has charge of the Rev. Handley's collection at Bath. The flower is of a rich rosy-purple colour, the petals very broad, the lip large, deeply blotched in the throat with blackish maroon, and it measures considerably over 3 inches across.—W. H. G.

GARDEN FLORA.

PLATE 931.

ARUMS.

(WITH A COLOURED PLATE OF *A. SANCTUM*.*)

MANY of the hardy or half-hardy species of Arum must be regarded more in the light of curiosities than of great ornamental value, but an exception may be made in the case of a few, notably that illustrated in the coloured plate.

Of Arums proper besides that here illustrated, *A. sanctum*, we have many others, notably the

DRAGON FLOWER (*Arum Draunculus*).—A very striking plant, with a long peculiarly marked brown spathe. This forms a stout growing specimen a yard high, with ornamental divided leaves over-topped by the flowers. The blooms, however, exhale such a disagreeable odour, that they can be scarcely tolerated except in out-of-the-way places.

A. SYRIACUM blooms while still leafless. The spathe reaches a height of about 6 inches, and is inside of a deep blackish red, while the exterior is lighter coloured.

A. TRIPHYLLUM, a North American species, with the outside of the spathe striped with white, and the apex elongated in such a manner as to fall over the mouth of the flower, is well shown among other North American wild flowers in a coloured plate in *THE GARDEN*, Vol. XXIV.

A. DIOSCORIDE, with brownish green spathes spotted with purple, is very singular, and so, in fact, are most of the species. As a fine-foliaged plant,

A. ITALICUM, or at all events some forms of it, is very beautiful, for the hastate leaves are of a deep green and broadly veined with creamy white. In a sheltered spot out of doors the freshly expanded leaves form a pleasing spring feature. The common British *Lords and Ladies*,

A. MACULATUM, is also very pleasing, the bright green leaves being spotted with deep purple.

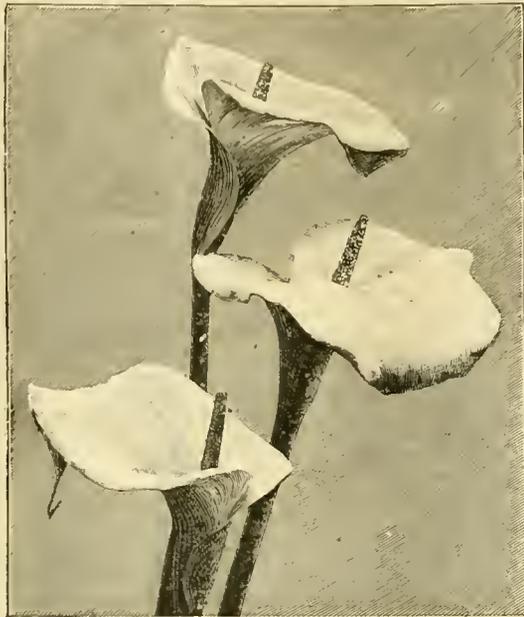

* DRAWN FOR *THE GARDEN* by Gertrude Hamilton from flowers sent by Messrs. R. Veitch and Son, Exeter. Lithographed and printed by Ben George, Hatton Garden, London.

ARISAEMA SPECIOSUM

Besides the above there are several other species and various allied plants, which, though by our botanical authorities included in the genera *Richardia*, *Arisaema*, *Amorphophallus*, *Helicodiceros*, and *Sauromatum* are by many still regarded as *Arums*.

A. SANCTUM when in flower is a very striking plant. It is in general appearance not unlike the

Flowers of Arum Lily (*Calla aethiopica*).

Calla or *Lily of the Nile*, but is shorter and more compact in growth. The inflorescence, however, so much resembles that of this last-named, that it is sometimes spoken of as the red *Calla* and the black *Calla*, in allusion to the colour of the blossoms. The leaves are large, hastate, and of a bright shining green, while the flower well overtops the foliage exactly as in the case of the common *Calla* or *Richardia*. Nothing need be said as to the general appearance of the flower, it being so well shown on the accompanying plate; but a very notable feature of the inflorescence is that, unlike many other Aroids, the flowers are pleasantly rather than disagreeably scented. Though distributed to a considerable extent of late as *Arum sanctum*, it was formerly known as *A. palestinum*, which latter name is still, I believe, regarded as the correct one. Its usual season of blooming is during the spring months, after which the growth is perfected and it becomes quite deciduous, and if potted early in the autumn commences to root directly. If treated as a pot plant and kept in a cool greenhouse during winter, it will, provided the crowns are strong enough, flower freely, and in this way I saw some good examples of it last spring with Mr. Ware at Tottenham. As an outdoor plant it needs a sandy, well-drained border in a warm situation, for it cannot be considered hardy unless under especially favourable conditions. This *Arum* is a native of Palestine, hence the specific names of *sanctum* and *palestinum*, and where growing wild and in considerable numbers, it forms, as may readily be understood, a very striking and uncommon feature. According to the "Dictionary of Gardening," it was introduced in 1864, but it was certainly very little known till within the last few years. Now, however, it can be obtained during the dormant season at a moderate price from most of our nurserymen. This *Arum* is one of the few plants to which two first-class certificates have been awarded by our Royal Horticultural Society, the first time on February 9, 1886, and again March 21, 1891. In both instances it was shown under the name of *Arum*

palestinum. As this plant so much resembles the *Callas* or *Richardias*, which are by some included in the genus *Arum*, it will be but a slight step to that popular class of plants.

RICHARDIA ETHIOPICA is by far the best known and most commonly cultivated of the genus. It is known by several popular names, as, for instance, the *Arum Lily*, *Trumpet Lily*, and *Lily of the Nile*. This last title is, however, a misnomer, for the plant in question is a native of South Africa and has nothing whatever to do with the Nile district. During the Christmas and Easter season especially the flowers of this *Trumpet Lily* are in great demand for church decoration, and where it is largely grown for market, the aim of the cultivator is to have as many as possible in bloom at these seasons. By some they are grown altogether in pots, and by others planted out during the summer, when they make rapid growth. This last-mentioned treatment is more often followed for the supply of cut bloom than for specimen plants, as the foliage is not retained so well as when they are kept altogether in pots. There are two or three, or perhaps more varieties of this *Richardia*, the most noteworthy being *Little Gem*, which was raised and sent out by Mr. F. Elliot, of Springfield Nursery, Jersey. This is quite a miniature form, reaching a height of 9 inches to 1 foot, and is very free blooming. Good flowering examples may be had in pots 4 inches or 5 inches in diameter. A noticeable feature of this variety is the profusion of suckers which spring up around the centre plant, and from this circumstance it can be readily increased. This variety was given an award of merit by the Royal Horticultural Society on October 14, 1890, and just a year later another form was similarly honoured. This is *compacta*, which is about midway

between *Little Gem* and the ordinary kind. There is a variegated leaved variety in cultivation, but it is seldom seen, and still more rarely in a satisfactory condition, for there is a great tendency to revert to the common form. The varietal names of *gigantea* and *candidissima* may be met with in some catalogues, but concerning them I can say nothing.

R. ELLIOTTIANA has attracted a very large amount of attention within the last two or three years, and this is not to be wondered at, as it was the first of the truly golden-flowered *Richardias* to be seen in bloom in this country. This distinct form has leaves thicker in texture and of a deeper green than the common kind, while though spotted with white they are not marked in this way to the same extent as in *R. albo-maculata*. The foliage, too, of *R. Elliottiana* is blunter than in any of the others, and the leaf-stalks, especially towards the lower part, are mottled with green, brown and white, after the manner of some of the *Alocasias*. The spathes are as large as those of the common kind and of a beautiful golden yellow. Unlike *R. aethiopica*, this is deciduous during the winter months, and flowers soon after it has started into growth in the spring. It was awarded a first-class certificate May 13, 1890, and has figured at the Temple show each year since then. This *Richardia* was raised by Mr. Knight, gardener to Captain Elliott, at Farnborough Park, Hants, and was named in honour of the last-mentioned gentleman. Mr. Knight, I believe, received the seeds from South Africa, and only one germinated, which turned out to be such a valuable novelty. On June 17, 1892, the entire stock of this plant was offered for sale by Messrs. Potheroe and Morris, and produced a good deal of competition. The first lot, a good flowering plant, sold for 16 guineas, and the five following, each consisting of a single plant, realised 17, 10, 9, 8 and 6 guineas respectively. Altogether the entire stock, which consisted of 213 plants, realised a little over £400. This golden-spotted form was not allowed to remain long in undisputed possession of the field,

for on June 21, 1892, a first-class certificate was awarded to

R. PENTLANDI, which was shown by Mr. R. Whyte, of Pentland House, Lee, Kent. This in general appearance more nearly resembles the common *Trumpet Lily* than the preceding. The leaves, however, are somewhat more pointed and of a deeper green, while the colour of the spathe is if anything richer than in *R. Elliottiana*. Like that species, it is quite deciduous during the winter. As shown, it is a very beautiful form, but one that in all probability will be scarce for years.

R. ALBO-MACULATA is a free growing, free-flowering species, with rather pointed leaves of a rich green plentifully spotted with white. The spathes are of a creamy white tint with a purple blotch at the base in the interior. It is not particularly showy, and though introduced as long ago as 1859, has never been grown to any great extent. These last remarks will also apply to

R. HASTATA, one of the smaller growing kinds, with dark green leaves, while the flowers, which are mostly overtopped by the foliage, are in the form of a deep cup of a dull yellow colour, with a large blotch of crimson at the base inside. From the contracted shape of the spathe this blotch is not particularly noticeable unless closely examined. This species is furnished with large hairs towards the base of the petioles. I am inclined to think that the *Richardia* sold last winter as *Pride of the Congo* is nothing but this, though described by Mr. Brown, of Kew, as a new species under the name of *R. Lutwychei*. That gentleman seemed to attach great importance to the setose petioles of *R. Lutwychei*, but on its being pointed out that growing plants of *R. hastata* at Kew showed the same peculiarity, his opinion would appear to have modified considerably, and the matter is thus left in doubt. Anyhow, if there are slight botanical differences between the two, they are as garden plants about one and the same thing.

R. MELANOLEUCA might be a spotted-leaved form of *R. hastata*, for with the exception of the

Dragon's Mouth (*Arum crinitum*).

marking of the foliage the two are very much alike. The last of these *Richardias* to mention is a hybrid put into commerce by M. Deleuil, nurseryman, of Marseilles, under the name of

R. AURATA, and announced as a hybrid between *R. albo-maculata* and *R. hastata*, which is probably its origin, as the plant bears a certain amount of resemblance to both of these species. It is of free growth, and bids fair to attain the

dimensions of the Trumpet Lily, while the foliage is spotted, but not to the same extent as in *R. albo-maculata*. The spathe is of a soft yellow tint, blotched inside at the base with blackish purple. We heard a good deal of it last winter as a yellow-flowered kind, but in this respect it cannot compare with *R. Elliottiana* and *R. Pentlandi*. *R. aurata* received an award of merit at a meeting of the Royal Horticultural Society on June 6, but the colour is not sufficiently decided for it ever to become popular. In passing it may be noted that the showy part of the inflorescence of these Aroids, though spoken of as the flower, is really a leafy bract or spathe, the flowers proper being crowded together towards the base of the spadix. This constitutes the different Richardias that we have in cultivation, though rumours have been heard of a rose-coloured one, for which at present we seem destined to wait.

H. P.

THE WEEK'S WORK.

THE KITCHEN GARDEN.

STORING ROOT CROPS.—This work must now be proceeded with so as to get an available supply throughout the winter months. Some roots left in the ground are certainly of much better quality when this plan is adopted, digging them as required for use. Many roots are annually spoiled through being stored in warm and arid sheds. They are started into growth and get very tough and flavourless. Cool sheds are the best places, that is if there is not a well-constructed root store, but in the majority of instances any makeshift place has to be adopted, even to the extent of storing in the open air like Potatoes, which is certainly better than storing in warm sheds or rooms. There is no difficulty when storing under cover of easily obtaining the daily supply whatever the state of the weather.

CARROTS.—Unless the roots are under-sized, it is much better to lift the crop at once, as severe frost promotes decay. Not only frosts, but if left in the ground the roots are very apt to split and get eaten with grubs, the latter affecting their quality considerably. A dry day should be chosen for lifting, and do the work carefully with a fork, taking care that the roots are not broken, the tops being cut off about an inch from the crown. To ensure their remaining plump, some sand must be sprinkled amongst the roots as they are stored and place them in layers. Where a quantity has to be stored, small mounds are preferable to a large heap, taking care also that the crowns point outwards. When being stored in the open air, pit them like Potatoes, no sand in this case being required. By laying the roots in carefully, the end of the pit may be opened at weekly intervals, and a supply necessary for the week being taken out, the ends are effectually closed again to keep out frost and wet.

BETROOT.—Especially care must be taken with Beet, for if in the least injured they will bleed. Beet requires extra attention in lifting as well as storing, as the roots quickly shrink in dry and warm sheds. Growth also takes place, but this must be prevented as much as possible, or until late in the season. Of the various methods recommended for preserving the roots, a perfectly cool shed is the best. Mounding over the crowns in the rows like Potatoes may not injure the roots in light and well-drained soils, and on such staple a few rows so treated will answer for very late, but not general use. Screw off the tops by the hand at a distance of 2 inches from the crown. In storing place the roots in layers, sprinkling sand or leaf soil between each layer, or even fine earth. The crowns must point outwards, and cover over with old mats or straw. The roots may also be pitted as recommended for Carrots, or built up in a mound under trees, a little sand or leaf soil being placed between each layer. The crowns must point outwards, the whole being covered with

straw, which should be combed down to throw off wet.

TURNIPS.—Turnips have generally failed except those on heavy land, mildew having attacked them very severely, so much so that in many instances the bulbs were denuded of a greater part of their foliage. Where this state of things exists the most forward roots should be taken up and stored, the smaller being left to grow unmolested, as these are not likely to get injured by frost. It is always better to leave small or medium-sized roots of Orange Jelly and Chirk Castle Black Stone in the open during the winter, severe frosts even not injuring them. But full-sized roots of Veitch's Red Globe or any other variety are best taken up and stored similarly to Carrots, or placed in a cool shed and covered over with straw, so as to keep the air from them.

SALSIFY AND SCORZONERA.—The quality of these is certainly better when they are left in the ground, digging them up as required for use. Instead of frost injuring them it improves the quality, like Parsnips and Jerusalem Artichokes. Of course, regular supplies must be anticipated in the case of severe frost occurring by taking up the roots and storing in sand in a cool shed, or cover over a portion of the surface with dry litter, this facilitating digging, otherwise the roots would become broken in the course of digging up during severe weather.

WITLOOF.—This forces better when the roots are left in the ground than when lifted and stored, at any rate during the fore part of the winter. When left in the ground they receive a thorough rest. Of course, like as recommended for Salsify and Scorzonera, a supply must be anticipated by taking up a few roots in the case of severe frost occurring and storing in sand, or the surface covered with dry litter. The little Chinese Artichoke is also better left in the ground.

A. YOUNG.

HARDY FRUITS.

ROOT-LIFTING.—When the leaves are fast changing colour and falling from the trees is the time to commence the important work of root-lifting and pruning. Those standing most in need of this attention are all that are growing more strongly than desirable, all the trees' energies being expended on the production of wood growth. In the course of a few years those only lightly pruned will naturally become more prolific, but as we cannot all afford to wait so long, the plan of checking root growth is resorted to, this being quickly followed by a corresponding check to top growth and the formation of abundance of flower-buds. Root-lifting is also desirable in the case of naturally free-bearing trees, the work being done in this instance with a view to keeping the roots active near the surface. Left alone, the tendency is to strike downwards into the cold subsoil, and when the roots are principally so much out of the reach of warmth, air, and good food, the growth is unsatisfactory, and the fruit produced by the trees is generally poor in quality. The most successful hardy fruit growers are those who very frequently, or say every second year, lift and shorten most of the wide spreading roots of the trees, the opportunity also being taken of searching out, shortening, and bringing up those that strike downwards. Fresh soil is also of the greatest assistance to the trees, and this also can be worked in when the root-lifting is done. The latter process ought not to be very severe, the plan of doing one half of the roots one autumn and the other half in the following season being the safest and best in the case of large trees generally. Trenches should be opened about 4 feet away from medium-sized to small trees, and from 5 feet to 6 feet away from the larger specimens, any roots come across being cut through. The surface roots from the stems outwards ought then to be bared, and the undermining of the rest be proceeded with to within 18 inches or rather more of the stem in the case of comparatively young trees, and to within 3 feet or so when they have been planted several years. Shorten the roots

found at different lengths with a view to have the resulting root-fibres equally distributed throughout the border, and make clean upward cuts. Seeing that the trees operated upon have a tendency already to grow too vigorously, the soil that is to be placed about the lifted roots should not be rich in character. Fresh calcareous loam or the best loam, fibrous or otherwise, obtainable—that of a heavy nature being the best for mixing with light soils—should be principally used, an addition of old mortar rubbish and "burn-bake" being also desirable. Distribute the pruned roots evenly in this, taking particular care to bring up those previously too deep much nearer the surface.

This season, owing to the dryness of the ground and soils generally, it will be necessary in most cases to loosen the surface of the ground containing the roots to be operated upon, and to give a thorough soaking of water the day previous to commencing root-lifting. Unless this is done the soil will break up badly, great lumps falling or coming away at one time. Another soaking should also be given directly after the roots are partially re-covered with soil, a surfacing of soil and a mulching of strawy manure being applied during the next day. Thus treated, the pruned roots will soon heal and form fresh fibres before the winter arrives. When this lifting has been done in previous years, it is only necessary to open a trench close up to that last cut, the long, wide-spreading roots being pruned and some good fresh loam placed within easy reach of the root-fibres that will soon be more plentiful. These fresh additions of soil serve to keep the trees in a very healthy state, the crops produced being both heavy and good in quality. Trees on dwarfing stocks, including cordons, pyramids, and bushes, properly attended to form very many more fibres close up to the stems than do those on the natural stocks, and these require to be lifted in order to place fresh soil about them. Starving these trees is a great mistake, especially if extra fine fruit is desired. What few long, naked roots are found ought to be shortened back, and a little manure should be added to the fresh compost placed about the roots. Pyramids that are annually or even only biennially lifted should be given a half turn round, this serving to keep them uniform, that side which gets the most sunshine being naturally the best matured. Most of these trees will be found quite dry at or about the stems, and ought to be well watered prior to and after being replanted, as there is no certainty about enough rain falling this autumn and winter to properly re-moisten the hard and dry soil. In each and every case the precaution should be taken of making the ground under newly-lifted trees very solid, and any with their collars below the ordinary level ought to be raised rather above the surface, those with the collars just bare very frequently making the healthiest and most productive trees.

TRANSPLANTING FRUIT BUSHES.—Now is a good time to commence the rearrangement of fruit bushes. Quite large Gooseberry and Currants would transplant safely and well during this month, and many of them would well repay for the trouble taken with them. For instance, if it is decided to permanently cover a quarter or border with galvanised wire netting, a strong wooden structure being erected to support this, the start ought to be made with fairly large bushes. If against a cool wall this may be covered with Plum trees, and the border in front be planted with Gooseberry and Currant bushes moved from other parts of the garden. Let them have the benefit of a deeply-dug, well-worked root-run, a little manure being also forked into both spits when large bushes are to occupy the ground. Gooseberries and Currants thrive best in a rather retentive soil, and very light ground would be better fitted for their reception by having clayey loam or marl freely mixed with it. Select strong bushes in good health, avoiding if possible those that have been much weakened by either caterpillar or red spider attacks, move with a good ball of soil about the roots, and replant firmly. A distance of 4 feet apart each way is none too much. Gooseberry bushes already under net-covered structures,

and which were badly weakened by insect attacks, will not produce much fruit next season, and, where possible, they may with advantage be shifted out and their places taken by healthier bushes. Some of the best sorts for these places are Early Sulphur, Whitesmith, Whinham's Industry, Green Champagne and Warrington, the latter being by far the most extensively planted owing to its being much the best keeper. A stock of young bushes ought always to be kept in readiness for making good any blanks.

W. IGGULDEN.

PLANT HOUSES.

GREENHOUSE PLANTS.—Although up to the time of writing this week's calendar no frost has occurred (in this locality) to do any material harm to even such tender subjects as Heliotropes, yet it is not safe to defer any longer the final housing of all the plants. Oftentimes when a rather sharp frost does not towards the end of September give us a friendly warning of the approach of real autumnal weather, one is led to defer the completion of indoor arrangements somewhat too long. The last plants to be taken under cover are usually those that are employed for effect in the flower garden or pleasure grounds. These, it is true, are most of them of comparatively hardy constitution, but if they do take any harm it is of a more permanent character. This should be borne in mind, and no risk be run just to save the breaking up of the arrangements for a few days only. These plants, consisting as they do of fine foliage subjects in the main, will in all probability have made good progress during such a favourable summer as the past.

Where, therefore, there is any need of repotting I would advise that it be done at once, otherwise in attempting to carry the plants through the winter as they are there will be the further risk of weakening them materially. Take Palms and Cordylines, for instance, as cases in point. The former if excessively pot-bound will force their way upwards out of the pots, leaving the soil oftentimes level with the rims; this allows of no room for watering, and the plants consequently suffer from drought. The latter if plunged will have made surface roots into the outer soil; to lose these is a pity if by giving an additional shift this loss can be avoided. Too often these classes of plants are considered as being capable of any endurance, and the postponement of that attention which is given to others taken as a matter of course.

Such succulent plants as Agaves will, it is true, continue to thrive well in the same pots for years, but these long-suffering subjects will in time rebel against such treatment. If any Agaves, Yuccas, or other succulents are seen to be in an unsatisfactory condition at the roots when taken indoors, I would prefer to repot them at once rather than run the risk of their going from bad to worse before the spring, which otherwise will be the better season for potting them. Dwarf succulents used in bedding, but plunged in pots, as the tenderer Echeverias, the Pachyphytums, and Cotyledons, can be safely kept in a pit near the glass, where, by the aid of a little warmth from hot-water pipes, a dry atmosphere with a temperature not less than 5° above freezing can be maintained through the winter. In lifting these plants our plan is to stow them away as they are fairly close together, and repot in the spring where needful. To divide any of these for purposes of propagation thus late in the autumn is not advisable.

Grevillea robusta, *Ficus elastica*, and other similar plants with fine roots will in most instances be quite safe in the pots they are now in, seeing to it that the drainage is free when they are lifted. Oranges and Lemons in pots or tubs should not be left out any longer. If it is not possible to house them at once, the better way will be to stand them under the friendly shelter of some trees or in out-houses just to save them from the frost. It will be just possible that some scale or other insects will be infesting these plants; if this be so, do not

let it escape notice. Of all permanent pot plants of the greenhouse or conservatory, there are none which will stand outside so long in the late autumn as the Camellias. These may be left out with a little protection until the Chrysanthemums are in a measure over, when more room will be at disposal for them. Meanwhile, if any sharp frosts occur, and that continuously, some protection should be afforded to the roots by wrapping mats or sacking around the larger pots, and by plunging the smaller ones up to the rims. Although outside, do not let the Camellias in any sense suffer for want of water; this they may do even yet before one is almost aware of the fact.

Cinerarias and herbaceous Calceolarias will still be perfectly safe in cold pits or even frames; to bring these comparatively hardy plants into the houses yet is a mistake. They will continue to thrive well for weeks to come on a cool bottom, ventilation being carefully attended to on all occasions, only being kept close in the case of actual frost. Mildew may make a start upon the larger Cineraria leaves, but if this be closely looked after no harm will be done by lightly dusting the plants with sulphur; in both cases it is possible that slugs will give some trouble, but the prevention of injury from this source is only a matter of ordinary everyday attention. Mats should be used to cover the glass when frosts occur, not that a degree or two will injure either the one or the other, but it is just as well not to drop below 32°. Chinese Primulas, both single and double, should, on the other hand, be housed as soon as possible in light airy houses or pits.

JAMES HUDSON.

ORCHIDS.

THERE are some plants which greatly puzzle the best Orchid growers to grow well for many years in succession, amongst them some of the distinct and beautiful *Oncidiums*, such as *O. Forbesi*, *O. crispum*, *O. varicosum*, and the pretty little *O. concolor*. After they have been imported a year or two the splendid spikes are exceedingly beautiful; but it is not long before it is seen that they have passed the zenith of their beauty, and in time the bulbs are not vigorous enough to bloom. The question arises here whether it would not be better if the plants were not allowed to flower for the first year or two until they became well established, when they might be allowed to produce their spikes after the roots had thoroughly established themselves in the fibrous peat and Sphagnum. Another beautiful Orchid, but one not easy to establish, is the *Cœlogyne barbata*. I well remember the first time it was sold in the auction rooms as imported. The plants were as fresh and sound as it was possible for them to be after a long sea voyage. I bought half a dozen specimens, thinking that the plant would be easy to establish, but it was a great disappointment. Only two of them flowered, and that only once. How different from *C. cristata*, the bulbs of which soon lose their plumpness, even when merely separated for increase of stock, but speedily recover and flower well again. *C. barbata* should bloom now, and it requires frequent supplies of water, also to be placed in a light position near the roof glass, but not exposed to bright sunshine. See that all the plants that are usually removed from the cool house to the Cattleya house are now in their winter quarters. I have already advised this, and had given orders to have it done in our own collection, but I found *Masdevallia tovarensis* had not been removed. This has now been done, and nearly all the Orchids are in the position in which they will remain for the winter. The operations required in the various departments consist first of all in cleanliness. The shadings have all been taken down, and the next thing to do is to thoroughly clean the wood and glass-work both inside and outside the house, and as the plants have to be removed as the work proceeds, it affords an excellent opportunity to get at them, so that they can be thoroughly cleaned and surface dressed. See also that they are not overcrowded. It is a great mistake to allow Orchids in any

of the divisions to be arranged too closely together, especially in winter. We have not had anything like so much bother with woodlice since green frogs have been introduced to the houses. These active little creatures seem to thrive best in the Cattleya house, and soon get outside both the cool and warm houses. It is vexing to hear them croaking in the bushes hundreds of yards from the houses, and one may spend hours looking for them, although by the noise they make they are within a few yards. I certainly advise establishing them in all the Orchid houses if possible. They are quite at home in our Cattleya house, and some of them have grown quite plump on the good fare they are able to find. Slugs and woodlice must be got rid of in some way, and this seems to be the best plan I have yet tried. Green-fly and thrips may be destroyed by fumigating at this season of the year in the Cattleya house, and I can say from experience that some of the patent fumigating material now sold is safer to use than the tobacco paper or rag of which one does not exactly know the strength. I have tried two or three of them and have pretty well given up the use of tobacco paper, which is not safe to use in Orchid houses, especially in the warmest and cool houses. In the East India house the *Saccolabium* show by the green healthy tips to the roots that they have not yet ceased active growth, and as much may be said of the *Vandas* and some of the *Aerides* in the Cattleya house. Keep the Sphagnum Moss in a growing condition on the surface. It is well not to have too great a depth of this, as it is sure to decay an inch or so underneath the surface, and very damp decayed Sphagnum Moss is the death of most of the roots that come in contact with it, but they revel in the moist, live surface Moss, or thrive well outside of it altogether. As long as the tips of the roots of the above Orchids remain green and in good growing condition, they must have enough water to keep the Moss thriving on the surface. When a film of a greyish tint closes over the tips of the roots this is a sign that they have arrived at the resting period, and will not need much water until it is seen they are ready to start into growth again. When writing of *Vandas* of the *V. suavis* and *V. tricolor* type, mention must be made of a totally different species, *V. Cathcarti*. It is altogether distinct in its growth, and although now more plentiful than it used to be, is still a scarce plant and not often seen in flower. The blossom takes a long time to develop, but this does not matter, as it is very interesting to watch the development of the flowers from the bud state to full development. The fleshy sepals and petals, the singular form of the labellum, and above all the beautiful markings of the sepals and petals cannot fail to please. It will now be in flower or getting into that stage. Each plant may produce two spikes, with from two to four flowers upon each. It requires much the same treatment as the rest of the *Vandas*. The *Dendrobiums* now at rest want looking over occasionally to see that none of them are being too much rested, especially the slender growing species, of which *D. Falconeri* may be considered as the type. This species may remain without water for weeks at a time, and dryness is essential to its flowering next year. I have had good plants of this beautiful *Dendrobium* get into bad condition owing to allowing the roots to shrivel up in the effort to provide a good resting period for it, in order that abundant bloom may be produced the following season. When they are likely to suffer from over-dryness I give them some water at the roots. They may go through the winter without any water, and flower abundantly the following season, but the loss of vigour may be such that the plants would take long to recover from the exhaustion.

J. DOUGLAS.

Old Apple trees.—I quite agree with what your correspondent "A. D." says in regard to the value, in the average of years, of old well-cared-for Apple trees. The season of 1893, so strongly characterised by heat and drought, has with me at any rate very forcibly determined the value of

many of them far less affected by circumstances that caused young trees in cultivated ground to lose much of their fruit. The deep and far-reaching roots of the venerable occupants of some of my orchards have enabled them to carry marvellous crops, which have all the merit of high colour and quality, though not of size, that will compete with recent acquisitions grown on young highly-fed trees. I was curious to have the produce of our tree of that excellent Apple Lincoln Holland Pippin measured, and the result was 20 bushels of good fruit from it. Other old trees, the fruit of which has not yet been gathered, promise to afford equally good results, amongst which may be named Elenheim Orange, Betty Geeson, the Eve Apple, the Belvoir variety of Herefordshire Pearmain, and Normanton Wonder.—W. INGRAM, *Belvoir*.

THE PAST SUMMER.

THE past season will be long remembered, especially by the poor, who have their own method of remembering times and seasons by remarkable events which have taken place in them. This neighbourhood has been particularly unfortunate in not getting the heavy showers which we have seen pass up the Severn Sea, or hanging over the Cotswold Hills, while we have not had a drop of refreshing rain from the "hot and copper sky." Our farmers have been sadly tantalised in this way. Over and over again the glass went down and great massive clouds rose up, and still no rain for them, though their neighbours a few miles off got drenching showers. For one thing, our retentive soil can stand such drought better than many districts. The Somerset fields and hillsides were fearfully burnt up early in the year, while we were still fairly green in this part of the world. Gardeners have, of course, depended on the supply of water from tanks, reservoirs, and pumps. One thing we ought to learn from 1893, to be more careful not to lose or waste water at any time. It is too precious a thing to waste even when it seems over-abundant. Now that petroleum barrels can be had at such a cheap rate there is less excuse for allowing water from the roofs to be lost. A capital tank can be made by joining together, where they touch when placed side by side, five or six barrels. It is easy to make a water-tight connection between them, and then, of course, they fill from one another until, if six petroleum barrels be thus united, the quantity stored away will be about 250 gallons. Such a tank is inexpensive and durable. The only objection to it is the room which the barrels occupy. But very often they can be placed against a wall where they are not in the way, and where the shoot from the roof above can be easily guided into one of them. I must say the present aspect of my kitchen garden is simply astonishing. I never saw it at this time of the year flourishing so well. The various green crops for the winter are looking extremely luxuriant. The heads on Veitch's Autumn Giant Cauliflower, though growing on a dry bank, are a large average. London Coleworts have delicious looking round Cabbage heads. Celery is remarkably fine, and Brussels Sprouts, if anything, too gigantic. Endive promises to be better than ever, and Tomatoes, which have been ripening since June, are still producing a fair crop of their delicious fruits. I might go on and enumerate other vegetables in the same way, and when we raise our eyes from the ground to the walls the size and abundance of Pears still hanging are simply wonderful. Easter Beurré, Thompson's, Beurré Diel, Beurré Hardy, Winter Nelis, and Marie Louise have been pleasant to the eye, and at the present time are delightful for dessert or keeping for a later date. A tall tree of Louise Bonne of Jersey, too tall to be got at by any ladder, has broken down in its topmost branches from the weight of fruit, which was of immense size. Thus from fruits and vegetables which have depended on the season only and have had no artificial assistance in watering we have evidence that a dry, hot summer is after all the best. Of course,

many things have suffered, and others have entailed a large amount of unusual labour with the water-can. Chrysanthemums, though watered twice a day, drooped occasionally on a hot afternoon, which is not good for them, but, nevertheless, they have not lost their leaves, which clothe the stems right down to the ground, and the buds look promising. Violets have shown signs of red spider, but they are recovering now that they are put into their winter quarters and can be more effectively watered. My plants of Ricinus, which sometimes do not produce any seed at all, have this year huge bunches of their round oily-looking fruit covered all over with stout, soft hairs. I have occasionally, but rarely saved my own seed from this plant; this year any quantity of seed could be obtained from it.

What will be the result of this year on the ensuing summer of 1894? Those who live to see another year should carefully note the results. Fruit trees can hardly bear such a heavy crop as this year a second time. I have a beautiful Siberian Crab tree which has been the admiration of visitors to the garden all the year, first in the flowers, latterly in the extraordinary crop of its lovely fruit. One large bough gave way before I could relieve it in any way of its heavy burden, and I shall be very glad if the tree itself survives the great strain which has been put upon it. This tree will undoubtedly suffer. What will other trees do? I see on forward trees the promise of a large quantity of blossom next season. If ripening the wood by summer sun has anything to do with it, next season should be as prolific as this. But could the trees bear it? I shall try to fortify them with an extra quantity of manure. I see a shrub of Chimonanthus fragrans is showing a large quantity of buds this year. It is one of those flowering shrubs which depends largely, I think, on the ripening of the wood. I must say it is pleasant in the last days of December or early in January to gather the sweet-scented flowers from this shrub. Their curious colour and aromatic scent make them very acceptable in the midst of the darkest part of winter. What will bulbs do? My flowers of *Crocus speciosus* are just fading. They were lovely as ever, but had not increased so much as I expected. But *Zephyranthes candida* has given me a nice lot of its beautiful white flowers. I want to see the effect of such a hot dry time on the various Lilies and on such plants as *Iris reticulata* and *I. persica*. I suppose they ought to benefit from having experienced a season more like that to which they are accustomed in their native haunts. The usual soft green grass of the lawn recovered once its usual condition under the influence of a short period of rain, but at the present time it is again brown and hard and slippery.

A GLOUCESTERSHIRE PARSON.

ORCHARD AND FRUIT GARDEN.

APRICOT TREES FRUITING.

IN this and adjoining counties Apricots never were earlier, at least I have no record of their being so, and they were also plentiful. Of course, we lost size, but even medium sized Apricots are appreciated. In penning this note my object is to point out the value of securing a crop yearly by growing those kinds which thrive best. Success is best secured by keeping the roots on the surface, and this can only be done by lifting, and there is no better time than the end of September or beginning of October for this. To get good fruit it is necessary to top-dress liberally. This top-dressing in time buries the large roots, and it is these that go wrong; hence the necessity of lifting. I am aware many object to root-pruning or lifting. I do not advise harsh measures either in lifting or pruning, as severe mutilation of roots is not suggested. Of course, with old fruitless trees it is impossible to lift without sacrificing some of the roots. With these I advise a middle course. As is often the case, one learns a lesson when least expected. I

required an east wall for other fruits occupied by both old and young Apricot trees, as these were very unsatisfactory as regards cropping and cankered badly. The young trees we lifted the first week in October and cut a trench completely round the large old trees with large boles as thick as one's leg. These trenches were cut at a yard from the wall, filled in with lighter compost just where the old roots were cut and carefully lifted the next October just as the leaves began to colour. From these old trees a very heavy crop has been obtained every season. I must admit we did not spare moisture after lifting, the leaves did not shrivel and the roots were kept moist, the trees being syringed several times a day and shaded with thick canvas. The younger trees gave little trouble, though every care was taken to preserve the foliage till the last. In lifting we got a good ball of earth to both old and young trees. I attribute much of our success to early lifting and to raising and keeping the roots on the surface. By lifting before the leaves turn colour, the trees have time to make fresh roots, and Apricots being the earliest fruit trees we have in bloom, there is only a short season of rest, so that early removal is essential to success. Of course, in removal from an east to a west or south-west aspect the position was greatly improved. In many instances it is not necessary to remove, but only to lift and replant, so that the work is much simplified, and I do not hesitate to affirm the trees in a majority of cases would well repay time and cost of renewal. In lifting old trees I advise previous preparation, and to lift early in the autumn. It is also equally necessary to use some fresh rooting material for exhausted trees, and there is no better material than good sound loam with a liberal quantity of old mortar rubble in soils deficient of lime. Manure of any kind I do not advise mixed with the loam, preferring to use it twice or thrice a year as a mulch, and applying copious supplies of liquid during the growing season. The want of moisture enters largely into the cause of failure. I do not mean moisture when at rest so much as when the trees are growing vigorously. Moisture, of course, is more necessary in light soils, as I am inclined to think the trees frequently suffer from this cause. Even now we give our trees a thorough soaking weekly. Good hardy varieties to plant are the Large Red and Large Early. Breda, also Kaisha will often succeed where others fail. Hemskirk will often grow where Moorpark fails, this latter being so subject to canker. Of course, when young trees have to be sent from a distance it is impossible to plant thus early. My note refers to lifting trees at home. G. WYTHES.

Jaffa Oranges.—The British Consul at Jerusalem has recently sent to the Foreign Office a translation of a report by an engineer of the Turkish Government on a scheme for irrigating the plains and Orange gardens of Jaffa, in which, incidentally, some interesting information is given in regard to the famous Jaffa Oranges. The town, it is said, owes its importance to its climate, which is extremely favourable for Orange growing. In consequence the port is surrounded on the land side by Orange groves, covering an area of about 1780 acres. Jaffa Oranges, on account of their excellent flavour, have of late years acquired a world-wide reputation, and while some eighteen years ago they were known only at Beyrout, Alexandria and Constantinople, enormous quantities are now exported to Europe, America, and even to India, and their cultivation has consequently increased to a very considerable extent. A special feature of Jaffa Oranges is that they will keep from thirty to forty days, and, if properly packed, for two and even three months. New Orange groves are continually being laid out, and the total number is now 400, against 200 fifteen years ago. This, again, has affected the population of Jaffa, which now contains 42,000 inhabitants, against 15,000 inhabitants twelve years ago. The exports for the last few years have averaged 36,000 boxes per annum, and owing chiefly to this trade Jaffa ranks next to Beyrout in importance among Syrian

coast towns. Orange growing in Syria is conducted exclusively by natives. Each Orange garden contains about 2000 square feet of planted area, equal to about 1300 trees to 2½ acres. The trees begin to bear the fourth year after planting, but it is estimated that it takes seven and sometimes eight years before an Orange orchard yields a remunerative crop. During all this time, and even afterwards, the orchards have to be watered continually, and this irrigation is the most difficult and laborious part of the work, inasmuch as the water has to be drawn by means of primitive water-wheels from wells dug in the gardens 90 feet and even 100 feet deep. Pumping by horse-power has been tried and in some rare cases steam, but both have failed to give satisfaction.

BROWN TURKEY FIG.

THERE are one or more very popular varieties of most kinds of fruit cultivated either under glass or in the open, but in only one instance can it be said that these more than hold their own against all comers. The one notable exception to the rule will be found in the Brown Turkey Fig. It may be some of the varieties of recent introduction will prove superior to it, but at present there are none in general cultivation that possess so many good qualities, and, if the truth must be told, I very much question if it will ever be largely superseded. Presumably, the Brown Turkey was brought to us from the country from which it takes its name, but by whom and when it was introduced I have no means of ascertaining. By all accounts White Marseilles was the variety first cultivated in this country, this being introduced from the south of Europe by Cardinal Pole about the year 1525. All that I can further ascertain is the fact of Brown Turkey being grown in this country at the beginning of the present century under the synonyms of Large Blue, Brown Italian, Brown Naples and Murray or Murray's Purple. McIntosh does not speak very highly of it under either of those names, but has nothing but praise for Lee's Perpetual, this proving that there was some confusion in nomenclature even in his days, as it is now very generally recognised that Lee's Perpetual and Brown Turkey are one and the same thing. That there are some who consider them distinct cannot be denied. For instance, I once saw a remarkably good crop of Figs in a forcing house at Beaham Court, near Newbury, the trees being named Lee's Perpetual, but at other places I have since seen trees of Brown Turkey equally good. Seeing also that the individual fruit cannot well be separated, the only conclusion that can be arrived at is that either Lee's Perpetual has completely ousted out the true Brown Turkey, or else that the different degrees of productiveness are more or less the result of varying soils, sites and other conditions.

For open air culture the Brown Turkey is simply invaluable. Naturally it is very much more productive during a hot and dry season than it is during our average summers, and the season of 1893 will long be remembered as being one of the best for Figs within the memory of the present generation of gardeners. It is not often that Figs from open-air trees are both so plentiful and good as they were by the middle of August this year. Not only did the fruit ripen to perfection, but there is every likelihood of good crops forming next season owing to the young wood being shorter-jointed and firmer than usual. As far as inland places generally are concerned, it is useless attempting to cultivate the Brown Turkey or any other variety of Figs other than against the hottest

walls, those facing south-east apparently being the best sites, but along the south coast, and Kent, Sussex, and the Isle of Wight in particular, it is possible to grow Figs very successfully in the form of low standards. There are many fine old trees existing in those favoured localities, and it has been repeatedly my lot to gather some remarkably good fruit from some of them. Doubtless the climate has much to do with this success, but unless the soil also is suitable the growth will not be hard and short-jointed enough to either withstand severe frost or to produce fruit very freely. It is astonishing what grand trees sometimes form in the poorest soil. Evidently the trees derive a considerable amount of food from the salt-laden atmosphere, or how else are we to account for the magnificent specimens one comes across with their roots in a soil largely composed of chalk? I have previously had occasion to allude to some very large old trees of Brown Turkey that were at one time growing against the high wall of a viaduct connecting railway tunnels under or near to the Shakespeare Cliff, Dover. All the soil these trees had to grow in was brought down

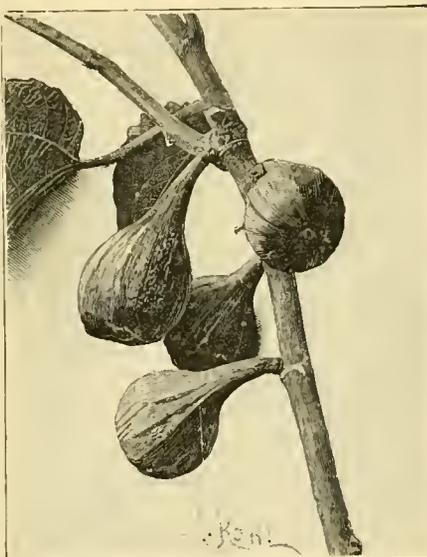

Fig Brown Turkey.

from the aforesaid cliff in baskets and consisted largely of chalk. Being unable to find the notes I took of these trees somewhere about eighteen years ago, I am unable to give their dimensions, and can only say their equal I have never met with. The young wood was near the stoutness of a man's second finger, very short-jointed, and extremely productive. So fine were the fruit, that it sold readily in Dover at an average of 4s. per dozen. At times the sea water, or rather the spray, dashed over these trees, this happening more especially in the spring and autumn, till at last one exceptionally high tide, and which did much damage along the sea coast, washed every particle of soil from the roots and killed the trees. Pears tried in the same position were a miserable failure. The stem of another extra fine tree of Brown Turkey growing about two miles from the seashore in Sussex was at one time actually used as a walking-stick. Being left standing on the moist floor of a back kitchen, it budded after the fashion of Aaron's Rod, was duly planted, and, I believe, is still in existence. In less genial positions the trees have to be protected during severe winters, or either the young or fruiting wood is crippled or the trees killed down to the

ground. A gross habit of growth must also be prevented as much as possible. A free admixture of chalk to either poor virgin loam or ordinary garden soil and a firm root-run are the best preventives of grossness. Failing chalk, substitute mortar rubbish, a thick layer of this being placed 18 inches below the tree where the subsoil is of a clayey nature. Curtailing or checking the root-run by means of a hard gravel path answers well in some cases, but after the trees have attained a great size, the wood being somewhat stunted, a surfacing of manure or an occasional soaking of liquid manure may be given with advantage. At least, that is my experience gained, let me add, in a district where Figs are both extensively and well grown.

Allusion has already been made to the great value of the Brown Turkey for house culture, but I shall venture to again return to that part of my subject. The variety under notice succeeds well either in pots, much confined borders or in a fairly extended root-run, the two former conditions being most desirable when the head-room also is limited. Naturally, confining the roots to either pots or narrow walled-in borders is a sure antidote to rank growth, but it is possible to reach the other extreme and starve the trees unduly. Figs are among the most hungry trees in cultivation, and unless the great mass of roots they invariably form are kept well supplied with moisture and liquid manure after once the soil has been robbed of its fertility, light crops of small fruit are inevitable. Partial lifting and relaying the freely-shortened roots in fresh soil, as well as rich top-dressings, are also most beneficial to trees that are in small borders; while large old trees in pots should be allowed to root out into a border of some kind. Unless so treated, it will be scarcely possible to recognise that the fruit is that of Brown Turkey. Bush trees are all very well in their way, but for producing fine fruit in quantity, give me trees trained all over the roof and not far from the glass. Planting against a back wall and training the trees from this down the roof effectually checks grossness, but very good results attend the practice of putting out a tree or trees with clean stems, training the branches in all directions and not too thickly. In this case the root-run should not be much limited, and may, in fact, extend over the greater part of the house. A rich soil ought not to be given at the outset in any case, as being conducive to rank growth. The old formula, this being quite fresh turfy loam chopped up roughly, with mortar rubbish or chalk freely intermixed, answers well. If the trees are to have a rather extended root-run, it is well to form the border piecemeal. Pot trees of Brown Turkey can be made to give three crops in one season, but the wise cultivator is content with two, the same number being taken from trees planted out and forced gently. The second-crop fruits are always the most delicious in flavour, and it is these, I believe, that are principally dried, pressed into boxes and sent to us from the south of Europe. Many of them also find their way into Covent Garden Market in a fresh state. W. I.

Vine Trahurier.—Under this name there is growing on a west wall at Chiswick a Vine that has very deep claret or crimson leafage, and has a very attractive appearance. It seems to indicate that it would prove a most valuable addition to our decorative climbers not only in the autumn, but all the summer. The one shoot made this season hardly exceeds 3 feet in length, but it may be all the same, robust when it once gets a good start. Of course, it is not possible to say how far it may prove suffi-

ciently robust for the purpose indicated, but experience will soon show. If not too strong on its own roots, it may do well worked upon some other free growing variety. In any case its beauty even in its present comparatively small state is undoubted. Some readers may know of it elsewhere, and if so, will perhaps give their experience of the variety, which is so worthy of attention.—D.

Apple Hambledon Deux Ans.—Eight miles from where this Apple originated and from which it takes its name, there are plenty of gardens which, unfortunately, have no other kind growing in but this one, and they are in all cases old trees, and in a district where Apples are much grown I do not know where there is a single tree less than twenty years old. This, I am pleased to find, is because the quality of this fruit is inferior. As a market Apple it fetches less than any other—a good test of its quality. Any amount of picked fruits have been sold at 1s. 3d. per bushel, which cannot be regarded as remunerative. Far better plant Devonshire Quarrenden and obtain 7s. per bushel.—E. M.

Apple Ecklinville.—In this district a market cannot be found for this Apple on account of the soft skin and flesh. No Apple that I know is so quickly “pitted,” as it were, by handling. Certainly it has stood the effects of the drought worse than any other sort here this season. The skin suddenly became spotted, and everyone knows that this means early decay. As an Apple for cooking and for early and free cropping quality it is not to be excelled, but for market purpose it is not first-rate. I am not giving my opinion based upon a single tree or two in the garden, but from hundreds in the orchard.—E. M.

PEACHES IN THE OPEN AIR.

As was to have been expected, this semi-tropical summer has given a powerful stimulus to Peach culture in the open air. Not a few growers had begun to despair of them, when this arid summer has turned the tide once more towards Peaches. Not that those who knew the art of their culture in the open best ever despaired of a fair amount of success—and reaped it too—on an average of seasons. Of course there were summers when Peaches, as well as other crops, went to the wall, and never returned from it in luscious form. But on the other hand Peaches have yielded quite as good average as Pears, while as for quality, outdoor varieties have more than held their own against those under glass. And now once more we shall have a fast and furious run on Peaches in the open. It is hardly needful to add here that Peaches in this wide sense include Nectarines, and it may also be added that unless the fever becomes too furious, the more growers of Peaches in the open the better. The race in Peach growing in the open is won by skill rather than climate, and if so, then most who run that race can win. The field is wide, covering all our south and west walls, notwithstanding one of our correspondents' failure on the latter (p. 302). But then he can afford such failures on west walls, as he claims that east walls would be better, as a greater length of sunshine obtains on the east wall than on the west. This will come on most Peach growers as a surprise. But if it be absolutely true without the addition of other points in the cardinals and other sheltering influences, the fact may have an important bearing on the future of Peach culture in the open air. An east wall for Peaches has been looked on as the certain route to failure, less, however, probably from the dearth of sunshine than the freezing force of the east wind in the spring. But the genial west and the warm south furnish a wide area for Peach growing in the open air without encroaching on the east for Plums and Cherries or hardy Pears.

On reading the two excellent letters of your correspondents W. Strugnell and “Y. A. H.” one gets a glimpse of the two extremes of pruning, or the lack of it, on which Peach growing in the open has so often been wrecked. The first recommends

cutting away the old bearing wood directly the crop is gathered, and fixing the wood remaining thinly over the wall for the sun and air to act perfectly on them to mature and strengthen the dormant buds.

“Y. A. H.” points out that another cause of failure in the cultivation of Peaches in the open air is in not allowing the trees to carry sufficient foliage. Thin training is all very well, but this can be carried too far. As long as each shoot has sufficient space so as to be well exposed to direct light, this is quite sufficient without having them 10 inches or a foot apart, as some people think the better distance. As “Y. A. H.” truly observes, the two extremes of overcrowding and over-pruning must be avoided, and the happy mean of wood and leaves established as the bases of durability and fertility in Peach growing in the open air. Were all the secrets of hot walls revealed, probably it might be found that quite as many Peach trees have been burned as frozen to death in our so-called sunless climate. Sunless, indeed! Those of us who have spent many hours on the face of a Peach or Apricot wall this summer will ever after declare that their one fear was that they, as well as the trees, might melt with fervent heat, especially on the bald and bare places that some declare to be essential to successful Peach growing in the open air in England. D. T. F.

APPLES AND PEARS ON HEAVY SOILS.

THE crops of these this season have been exceptionally good. Not only is there an abundance of fruit, but the samples are also better than I have ever seen them in this part of the country. Some of the old trees that have not borne a crop of fruit for years are so thickly laden, that the boughs are weighed down with them, and those on young trees are particularly fine. An old tree of Williams' Bon Chrétien growing in a cottage garden near here had ten bushels of fruit gathered from it; the sample was better than I had ever seen before. In another cottage garden a tree of Warner's King Apple produced some remarkably fine fruit, some of the best samples weighing 22 ozs. Peasgood's Nonsuch from bush trees in some cases weighed 20 ozs. Other large growing kinds were likewise good, as some fruit of Stirling Castle weighed over 16 ozs., Pott's Seedling and Ecklinville Seedling being also very fine. King of the Pippins again is more like Blenheim Orange, and some samples of Cox's Orange Pippin are unusually fine. The late kinds, too, have grown above the average size this season, especially Norfolk Beaufin and Easter Pippin.

Pears, as a rule, especially the more delicate kinds, are apt to crack on this cold, stiff clay, but this season they have grown to an extraordinary size even on old trees, and are free from all the blemishes one is accustomed to see in a wet season. Some fruit of Beurré Diel weighed 23 ozs. each, Glou Morceau 20 ozs., and Van Mons Leon Leclerc 20 ozs. Some of the coarser kinds have grown to an enormous size. What a pity it is that at all the shows size is the chief point taken into consideration by the judges. How is it that such fine flavoured varieties as White Doyenné, Gansel's Bergamot, Seckel, Thompson's, Hacon's Incomparable, Winter Nelis, Passe Colmar, and Jean de Witte are passed over and preference given to such coarse kinds as Beurré Diel, Triomphe de Jodoigne, Pitmaston Duchess, Conseiller de la Cour, Vicar of Winkfield, Beurré de l'Assomption, and the like? Surely it is high time that these monstrosities were discouraged. Flavour should always stand first in all fruits that are shown for dessert; size should be a secondary consideration. The present season should teach those that have to contend with a cold clay a good lesson or two. First, then, if the soil can be deprived of the superfluous moisture, there will be no cracking of the fruit; and secondly, that if this be done, the fruit will grow larger by the soil being raised to a higher temperature. It is not difficult to drain land in most places, but soil such as I have to contend with in this neigh-

bourhood holds the water to such an extent if not worked very carefully that there would be much difficulty in getting the water to pass into the drains; however, if plenty of rubble were used round the trees, this would have a tendency to keep the soil porous so that the roots would be able to penetrate it more readily. Sap flows more quickly in hot weather we all know, but if the roots are not able to take up sufficient nourishment to cause it to flow freely, there will be a check to the tree's growth, and the crops will likewise suffer. We see trees that are planted on land having a gravelly subsoil, or those grown on the limestone or chalk, producing the best crops in moist seasons, while those planted in clayey ground do not make satisfactory progress; the reason is, the latter soil is too cold to cause a free circulation of sap, while the former kind is rendered more fertile by the falling showers, and does not get dried up, as has been the case this year. Let those, then, that have stiff soil to contend with try to make it so that the moisture may pass through it more freely. H. C. PRINSEP.

FERNS.

SPEAR-FRONDED FERNS.

(DORYOPTERIS.)

In this family of Ferns we have some exceedingly handsome species. The fronds are all firm in texture and of a deep green colour. One species, *D. nobilis*, has a broad band of white running through the centre of its young frond, and the mature form, which is large and palmate, has all the primary divisions similarly banded. This fine plant was introduced by the Messrs. Veitch, of Chelsea. *Doryopteris* are mostly natives of Tropical America, but *D. ludens*, which was introduced by Mr. W. Bull, is a native of India and the Philippine Islands. It is very interesting and well worth growing.

There are many forms of this genus, and many of the kinds are grouped together under one name, but which as garden plants are very distinct. My correspondent “C. H.” appears to be very anxious to fill a stove fernery with new and distinct species. The fronds sent are (1) *D. Alcyonis*, which I have not seen for a very long time, and I think came from M. Linden under this name. I have observed that it very readily breaks into the palmate form, which I have never observed in *D. sagittifolia*. It never attains the size of the last-named, but yet it is a name which I do not find recognised by any authority. Another very elegant little species which I have received upon one or two occasions from the Organ Mountain district of Brazil is (2) *D. lonchophora*, but which has never yet been introduced in a living state. There are several others that have not yet been introduced into Europe in a living state, whilst of those we have there appears to be a great confusion in the names. I suppose this arises from the study of herbarium specimens alone, but the different kinds if obtained true will retain their distinctiveness, and prove well worthy of cultivation. They are nearly related to the genus *Pteris*, but they differ in having the internal veins beautifully reticulated, whilst in *Pteris* they are free. They are easily grown into good specimens. The pots should not be too large, and they require to be well drained, using for soil equal parts of loam and sandy peat. The majority of the kinds will succeed well in a cool stove, but they like a warmer position for the winter months.

The following kinds are worthy of the attention of all Fern growers:—

D. ALCYONIS.—This grows some 6 inches or 8 inches high. It makes simple sagittate fronds, of

which the lower points are lengthened out. It soon begins to make palmate fronds, but yet the simple ones appear to be mature, for they are provided with a bold continuous line of brown sori round the margin; the stem is black, and the frond deep green on the upper side, paler beneath. It comes from Brazil.

D. COLLINA is a small species, having palmate fronds some 6 inches or 8 inches high and 3 inches broad. These are palmate, with from three to five lobes, the bottom pair only being lobed or toothed on the lower edge. The colour is bright green above, paler beneath, the stem and the principal branches being jet black. This plant, if got true, I have never found to develop into any other form, but it maintains its character. It is one of the prettiest Ferns to adorn a lady's fernery and is a native of Brazil.

D. LUDENS.—This species is found in the hills of Chittagong, seldom exceeding 1000 feet elevation, and it also occurs in the Philippine Islands. It appears to differ from all the other kinds in growth, the fronds rising from a creeping rhizome, whilst all the others are tufted. The simple fronds have rounded lobes, the fertile ones being taller, often reaching a foot high and palmate, the lobes not again divided.

D. NOBILIS.—This is a grand species, making fronds which are palmate and much lobed, some 8 inches in height and a foot wide. The colour is bright shining green, having a broad band of white along the principal segments. In the young state, however, they are simple and sagittate, the lobes much developed, some 8 inches or 9 inches long and upwards of 2 inches in breadth, dark shining green, with a broad band of white down the centre. It comes from Brazil.

D. PALMATA is a beautiful type, having fronds 9 inches to 1 foot high and about 5 inches in breadth, palmately divided, the lower segments drooping. It is also prolific at the base of the frond, colour bright green with jet black stripes. It is a native of Brazil and Venezuela.

D. PEDATA is perhaps the most beautiful of the smaller set of the Doryopteris. Its fronds are about 9 inches high and 5 inches wide when well grown, the frond being more lobed than in *D. palmata*, especially at the base, but it is not prolific like that species. Colour bright shining green. It is from the West Indies and Brazil.

D. SAGITTIFOLIA is a pretty simple-fronded species, which character it retains. It grows to upwards of 1 foot high, about half of which is usually naked stem. The fronds are bright green in colour and coriaceous in texture.

W. HUGH GOWER.

THE FRUIT CROPS.

SCOTLAND.

Castlemilk, Dumfriesshire.—Fruit crops abundant, Apples being heavy and of good size. Pears good. Plums heavy, especially the usual free-bearing varieties, and Cherries, both sweet and Morello, good. Strawberries good crop, but soon over. All other small fruits most abundant, Gooseberries especially so, and likewise the caterpillars, which have been destructive all round this season.

In the kitchen garden the crops, on the whole, are and have been good. Peas, as might be expected, have not borne the usual crop and their season has been short, later sowings of second early varieties doing well. Broad and French Beans extra good, Golden Waxpod and Mont d'Or especially fine. These two varieties with us require an exceptional season. Potatoes have done well, Sutton's Supreme and Windsor Castle being well worth special mention. The early Cauliflowers and Carrots were badly attacked with grub, and wasps were both numerous and aggressive.—**WILLIAM KING.**

Wemyss Castle, Fifeshire.—This has been the best spring and summer that I can remember,

and in consequence we have had a most excellent crop of all fruits, with the exception of Pears, which are almost *nil*. All trees bloomed profusely, and in the absence of east winds, to which we are much exposed, the fruit set over-abundantly, and with the great heat came rapidly to maturity. We gathered our first fruit twenty-seven days earlier than last year.

All vegetables have done well except late planted Broccoli, which suffered from the severe heat and drought, but which the showers of last month are rapidly making up.—**J. CLARK.**

Drumlanrig.—The spring and summer here have been exceptionally warm, and all flowering plants and crops of fruits and vegetables are quite three weeks earlier than usual. It has been much drier than ordinary, but there have been rains at intervals, and the consequence is that everything looks unusually well. Small fruits were abundant, Apples as large at this date as they usually are a month later.

The Potato crop is healthy and abundant. We are now having frequent and heavy thunder showers, and everything is making rapid progress. Turnips and Potatoes in the fields are remarkably fine.—**D. THOMSON.**

Fyvie Castle, Aberdeen.—All sorts of small fruits in this locality are most prolific, and for wall fruit, Plums in particular are the best crop that I have ever seen. Apricots are only a fair crop, as they do not succeed well in this cold climate. We have a good crop of Apples and Pears, and the Cherries did fairly well. Both fruits and vegetables seem to be quite a month earlier than last year.

Vegetables suffered in June for the want of rain, especially Peas, which are not up to what they were last year. Potatoes are a good crop and of first-class quality. We have suffered more than usual with maggot on Onions, Cauliflower, Cabbage, &c., and many lost their crop. The month of June was exceptionally dry and hot. We registered 92° in the shade on June 18. We are now getting abundance of rain, and things are doing well.—**SIMON CAMPBELL.**

Cullen House, Cullen, N.B.—The fruit crops in this district are a fair average. The small bush fruits are most abundant, with the exception of Strawberries, which lasted for a very short time, owing, no doubt, to the long-continued drought. The crop on walls and standards is not what it at one time promised to be. Peaches and Nectarines are thin outside, but very early. I pulled the first ripe Peach of the Early Alexander variety on July 11. Figs on the open wall are very promising. Plums are an average. Pears fair in some cases; in others very good. Cherries good, but Apples are very scarce, although the blossom was abundant and apparently set. The fruits have dropped of late very much, no doubt owing to the drought.

The vegetable crop has suffered greatly, owing to the excessive drought. Early Potatoes were small, but very early. Later varieties gave promise of a fair crop, yet Onions and Carrots were almost completely destroyed by the canker. Peas and the Cabbages suffered very much by the drought, as also did Cauliflowers, buttoning very badly, more especially the second planting. Crops since the rain have again picked up, and with a good autumn might finish a fair season yet.—**J. FRASER SMITH.**

Broxmouth Park, Dunbar.—With the wood of our fruit trees and bushes being well ripened in autumn and the milder weather than usual in spring, there was an abundant set of all crops. Apples are a heavy crop on such as Keswick Codlin, Lord Suffield, Warner's King, Stirling Castle, Tower of Glamis, Ecklinville, Duchess of Oldenburg, Worcester Pearmain, King of Pippins and Grange's Pearmain. Pears, though, are not so regular, but good crops are being borne on Beurré Diel, Louise Bonne of Jersey, Beurré Gifford, Jargonelle, Beurré Rance and Beurré de l'Assomption. Apricots are a splendid crop, also Plums, and have had to be well thinned. Early Peaches are good. Waterloo and Hale's Early began to ripen at the end of July, and with the warmer weather this

summer they are of finer quality. Strawberries, Gooseberries and Currants have been above the average, which told upon the size and quality, partly caused by the want of rain at the proper time to assist them to swell. Raspberries have seldom been so fine, and I find Superlative for size and quality is a great acquisition.

Potatoes and all sorts of vegetables are doing well this season, and field Potatoes never looked better.—**WM. MCKELVIE.**

Aboyne Castle.—Taking the fruit crops generally, with the exception of Pears, which are very light, we have a fair average crop. Strawberries, which are very largely grown in this district, were generally three weeks earlier, fruit small as a rule, but fine in flavour, the principal sorts grown being Rivers' Eliza, President and Elton Pine, with Myatt's for late work. Captain, Noble, Competitor and several others of the newer Strawberries find no favour owing to want of flavour and colour. Apples are a fine crop, trees very healthy and fruit fine. Plums for our light soils a good crop all round on the walls. Early Prolific was ready to gather on July 13. Gooseberries, Raspberries and Black Currants have been a heavy crop.

As regards vegetables they are generally abundant and of fine quality, excepting Cauliflowers, which have been small due to the check received in the early summer. Owing to the absence of frost, French Beans, Marrows, Celery, &c., are very fine, better than for years.—**W. BACK.**

Dalkeith, Midlothian.—The fruit crop in this district on the whole is exceptionally good, and most kinds are bearing very fine fruit. In early spring the weather was very favourable for the flowering and the setting of the fruit, but the long-continued drought thinned the crop of Apples and Pears, that left, however, swelling to a large size, and will be very much better than the average. Apricots, Plums and Cherries are bearing the finest crops they have carried for many years. Strawberries, after they got the first rain on June 22, did remarkably well. On our light rich soil James Veitch and some others of the large varieties of Strawberries bore very large and fine crops. John Ruskin also proved an early and abundant bearer, and continued bearing longer than any of the other early varieties grown here. Raspberries were a fine crop, Superlative being the best red, and Magnum Bonum the best white. Currants of all kinds were abundant and fine. Gooseberries were also a very large crop where they escaped the ravages of aphides and red spider.

All vegetable crops have done well throughout the season. The early kinds came into use fully three weeks earlier than usual, and were of excellent quality. The showers of rain during the end of June and throughout July have produced great luxuriance of growth in crops of autumn and winter vegetables, and for the latter a dry autumn would be beneficial, or they will suffer if a severe winter sets in. Potatoes are a splendid crop, and scarcely a sign of disease among them. Early Potatoes are lifting well and of the finest quality.—**M. DUNN.**

Auchin Castle, Moffat.—Situated as we are in the extreme north of Upper Annandale among the hills at an altitude of 700 feet above sea level, the finer class of fruit is not much grown. The soil is generally very poor. This season has been most favourable to the growth of most things, and quite a month earlier than last year. Strawberries, more particularly on young plantations, have been heavy and good in quality. Gooseberries very heavy. Black and Red Currants good crops. Raspberries good. Apples thin on some trees, but clean and swelling well. Plums and Cherries a good average crop and better in quality than last year.

Vegetables have been finer than for years. Peas have filled well. Potatoes remarkably good. We have not had French Beans for three years, but this year they are very plentiful. All other crops proportionately good, showing that a dry season suits this locality best.—**W. MCADAM.**

Dalmeny Park, Midlothian.—Fruit here will be a good average crop, the exception being early Strawberries, which were only half a crop.

Late kinds had a heavy crop. Early Apples and Pears are good, but late ones short; also Morello Cherries. All fruit trees when in flower promised an abundant crop, and I hoped to realise the promise, as no frosts occurred to blight the fruit buds, a most unusual thing here in the spring months.

Vegetables of all kinds have done well, but since July 1 Peas have made very little headway. Potatoes look well, and they are of good quality this season, being two weeks earlier than I have ever seen them here before.—J. MOYES.

Tynninghame, East Lothian.—This has been a delightful year. Among the fruit crops there is no out-standing failure, and in the case of Pears alone is there an appearance of a deficient crop, and it is only the very aged trees that have not borne. Young healthy trees are carrying good crops of fine fruit. Our earliest gathering of these was on August 1. Strawberries in some localities had been much damaged by the intense frost during winter, the remaining plants suffering again from the drought; but the crop was fairly good, though quickly past. The Apple crop is a good one, numbers of the trees so heavily laden that they had to be lightened by thinning. The fruit, moreover, is large and clean, the early varieties turning in quickly. Apricots and Plums each set fruit in strings on the branches, and, of course, both had to be severely thinned. Plums especially are large and fine. In July, Rivers' Early Prolific, The Czar and a green unnamed Plum ripened. Apricots also were ripe in July, and a few Peaches (Alexander) August 1. All small fruits were most abundant. The first ripe Fig was gathered on July 15, its weight 6 ozs., and up to August 1 over forty fruits, averaging three to the lb., have been gathered off the one tree. This is, so far as I can gather, quite unprecedented. I have seen ripe fruit about the third week in August and fruit as large, but I have never heard of Figs grown entirely out of doors ripening so early in Scotland.

With regard to vegetables, Onions, Carrots and early Cauliflowers have succumbed to attacks of maggots. In cottage gardens all kinds of Brassica have been destroyed. However, since the break-up of the drought the vegetable quarters have become furnished with crops of all kinds earlier than usual and of superior quality. Early Potatoes were somewhat small, but of excellent quality. Later crops leave nothing to be desired, and all winter crops are making rapid progress. One lesson taught very emphatically by the heat and drought is the benefit of deep cultivation combined with a high state of fertility in the soil. Where these have been wanting, it is noticeable how all crops have suffered. Where present the heat was, almost without exception, decidedly beneficial.—R. P. BROTHERSTON.

Galloway House Gardens, Wigtownshire.—The present season will be long remembered in this district for the general abundance and good quality of the fruit crop, also for the very hot weather and the plague of wasps. Strawberries ripened a month earlier than usual, and the early and midseason kinds produced good crops of fruit; late ones suffered from the drought, which prevented the fruit from swelling as it ought. Raspberries were a small crop and soon over. Currants and Gooseberries were heavy crops; the latter in places were badly attacked by caterpillars. Apricots were an excellent crop, the best we have had for some years. Peaches and Nectarines very good, the fruit somewhat smaller than usual, but richly coloured and of good quality. Plums are abundant, all kinds bearing well, both on walls and standards; Coe's Golden Drop is particularly fine and heavily cropped. Damsons very good, but not much grown in this part except in private gardens. Cherries were a good average crop, May Duke being extra good; Morellos about an average. Apples are a good even crop, young trees generally heavily laden, and older ones carrying a fair crop, which for size, colour, and soundness are superior to former years. Pears must be considered the crop of the season; all the best and most generally grown varieties are bearing heavily, and the fruits are above an average in size and quality, specimens

of Marie Louise and Pitmaston Duchess weighing 12 ozs. and 24 ozs. respectively. The rainfall in this part to the end of August was but 2 inches below the average, a fair proportion of which fell since midsummer; this has proved very beneficial to the fruit crops, also to the fruit buds for next year, as I never saw them more promising.—J. DAY.

SUPPLEMENTARY.

Penrose, Helston, Cornwall.—Apples here are an exceptionally heavy crop, fully a month earlier than usual, fruit clean, of good size and grand colour, particularly such fine sorts as Adams' Pearmain, Blenheim Orange, Cox's Orange, and Ribston Pippin. Lord Suffield, Warner's King, and many other good kinds in orchards are a most profuse crop, tons of which will be converted into cider during the week. Sturmer Pippin, Cornish Gilliflower, and other late kinds are suffering badly from attacks of tomtits, blackbirds, &c., which one can scarcely understand in such a season as this. Plums were a heavy crop and of good quality. Peaches and Nectarines both good. Currants and Gooseberries were fine crops, the latter requiring two good applications of hellebore powder to keep down caterpillar. Strawberries (thanks to a plentiful supply of water running through the garden) were fine indeed, though probably somewhat short-lived.

First and second early Peas did very well; later sorts but indifferent. Potatoes variable; early sorts, such as Sharpe's Victor and Veitch's Ash-leaf, did well; Champions quite a failure; Magnums are an immense crop. No disease as yet. Celery very good; also Carrots and Parsnips. Earliest hatches of Cauliflowers were all destroyed by maggot. Tall field Broccoli are looking well. Wasps have been only too plentiful, but by closely following up nests with cyanide of potassium and one or two applications of Scott's wasp destroyer on the walls and in vinerias have kept them fairly under.—PHILIP MURTON.

Bardney Manor, Lincoln.—We are not able to give a very good account of the fruit crop in Lincolnshire. In the spring we thought the year would prove a good one, but as we had no rain from February 27 until June 19, all sorts of Apples are very small and are still falling off; the crop will be about average. Plums are under average, and the trees in most gardens are badly blighted. Cherries on walls and bushes are a good crop, as also Apricots. Strawberries were much under the average, especially on light sandy land. Raspberries, Gooseberries, Currants (Black, Red, and White) were fairly good.—J. ROWLANDS.

Coolhurst Gardens, Horsham, Sussex.—Strawberries were a good crop all through, Vicomtesse and Garibaldi being almost equal in productiveness, and it matters little whether either or both are grown, they are so close in all respects. No garden should be without them, as they seem to thrive in any soil or situation. President comes next in productiveness, if not one of the most productive of all Strawberries. Severe winters are hard on its foliage. Sir Joseph Paxton, James Veitch, and Empress Eugénie are specially fine for dessert; these being grown on highly cultivated land with heavy mulchings in autumn and spring will give excellent returns provided they are grown 2 feet between the plants in the rows. To have fine well developed fruit of good flavour that room is needed. We have tried many of the newer varieties, and have given them an equal chance with the older sorts, and although many of them possess good points, yet they fail to equal in all respects those above named, and consequently not grown. Notwithstanding the severe drought of four months length, we had an excellent crop of fine fruit, the plants all being healthy and free from insects. Deeply cultivated land in good heart has shown in a high degree through the past drought that that is the lines on which all land should be cultivated, and then there would be an almost certainty in any season of a crop whether in the garden or in the field. Raspberries have been fairly good, grown on deep land and well mulched. Black Currants

much the same, Red and White plentiful and good. Plums a heavy crop all through, and thinning needed to lighten the trees. Pears plentiful, too, and swelling since the rain. All wall trees had to be washed with the engine to clean the foliage of insects, which were abundant. Apples here are not plentiful, only some trees bearing well, others thin and small; but Apples on Grass will be smaller than usual owing to the dry state of the ground; the rain soaking in more freely where the trees are on open ground will likely promote the best fruit.

Vegetables of all kinds have suffered severely from drought and insects together. Potatoes a good crop with little disease.—A. KEMP.

Hardwick Gardens, Sedgefield, Ferryhill.—Apples, Black Currants and Plums good. Gooseberries enormous crop. Peaches and Pears medium. Raspberries poor. Strawberries a failure, the land being very light. Apricots exceptionally good. Red Currants large crop, but the fruit small.

Vegetables are all good with the exception of Carrots and Onions. Other crops in the neighbourhood on the whole are excellent.—J. W. TURNER.

Bickley Park, Chislehurst.—There is a plentiful crop of Apples about this part, the trees in many cases being too much loaded. With us Blenheim Orange is an exception. Last year we had a good crop. Lane's Prince Albert bears every year. The soil is sand and gravel, very poor for Pears, some sorts scarcely living, but we have some pyramid trees, such as Thompson's, Burrell Clairgeau, Durondeau, Beurrié, Diel, Gratioli of Jersey, Fondante d'Automne bearing very heavy crops. We have a heavy crop of Plums, the trees on the walls wanting much thinning. Cherries a good crop, both of Morello and dessert kinds, though they have suffered a little from black fly. We have excellent crops of Peaches and Nectarines, also Apricots, though these last run rather small. Currants and Gooseberries a heavy crop and good; we had to water them, also the Raspberries, which would have been very poor without watering; as it was, we had a good quantity, Semper Fidelis being the best. I have only a few canes of Superlative and Norwich Giant, both good bearers. Strawberries were very poor; undoubtedly they would have been better had they been watered, but as many of the plants had failed I did not trouble about them. All the vines were very fruitful. Our Figs outside at one time showed well for a good crop.

Our first two crops of Peas did well, but the later sorts badly; this was also the case with Broad Beans. Potatoes are good in quality, but a light crop, the tubers being small, but so far very free from disease.—JAMES NEIGHBOUR.

Croft Castle, Eardisland.—We have had a very exceptional season, dry, and particularly so up till July 15, but most things have done well, both vegetables and fruit. Strawberries have been plentiful and good, and also Gooseberries. Currants have not been good, getting blighted. Apricots have set well and Peaches. Plums have been rather blighted, but yet in many places were well loaded with fruit. Apples and Pears in most places are a plentiful crop.

Potatoes are plentiful, the early ones not a heavy crop owing to the drought. I have not seen any disease at present, but some black spots have appeared on the foliage in places.—W. BYTHEWAY.

Astley Hall, Stourport.—In reply to your inquiries respecting the fruit and vegetable crops in this district, I am sorry to say we have suffered very much from the exceptionally dry season. With regard to fruit, the small bush fruit has been plentiful, but wanting in flavour. Apples and Pears are a failure except in a few favoured places. The crop of Plums on wall trees is good, but standard trees are very thin. Damsons are a failure. They are largely grown in this neighbourhood, and are readily bought up for making dye. They are looked upon by cottagers as the rye-payers; therefore, it is a great loss to them. These notes only apply to this neighbourhood. I should think by the supply coming into the markets they have been more fortunate in other

districts. We are on the banks of the Severn, and the spring frosts affect the bloom.

It has been hard work to keep up a supply of vegetables, everything having to be watered to keep it alive. Peas growing in gardens have only yielded about half a crop, but those in the fields have yielded in most cases a good crop. Cabbages have suffered very much from the caterpillar. The Onion fly has been very busy; many beds in this neighbourhood are entirely destroyed by them. Potatoes are fairly good, but not a full crop. There is a prospect of a good crop of later kinds, the rain coming just in time to save them. Vegetation has greatly improved since the rain has come, and winter vegetables promise well.—F. BOORER.

SOCIETIES AND EXHIBITIONS.

ROYAL HORTICULTURAL SOCIETY.

A REMARKABLY fine show was that in the Drill Hall on Tuesday last.

Floral Committee.

The following each received a first class certificate:—

NERINE ELEGANS ALBA.—A somewhat inconspicuous variety, as the entire plant in bloom was hardly 8 inches in height, bearing a small spike of white flowers that resembled those of a very large single white Hyacinth. From T. S. Ware, Tottenham.

HEMANTHUS LINDENI.—A form carrying three heads or trusses of an unusually large size and of a salmon-carmine hue. From M. Linden, Brussels.

ANTHURIUM WEMBECKIANUM.—The spathe of medium size, thick and glossy, and almost pure white. From Messrs. Linden, Brussels.

QUERCUS AMERICANA SPLENDENS.—An intensely deep red-leaved Oak, a bunch of branches of which was shown, the leafage of bold size, deeply cut and splendidly coloured. It must be a glorious thing in the autumn sunlight. Mr. A. Waterer, Knap Hill.

An award of merit went to each of the following Dahlias:—

PURPLE PRINCE.—A true Cactus form, of a deep rich crimson, flushed with violet. From Messrs. Perkins and Son, Coventry. Old Gold.—One of the decorative section, of a rich golden buff colour. From Messrs. Cannell and Sons, Swanley. Miss Arnold.—A decorative kind, the colour soft puce, very free. From Mr. J. Arnold, Devonport. Emily Hopper.—Bright yellow, a pleasing, though hardly novel pompon, and to single Dahlia Ethel Swan, colour old gold, with a ring of rich red round the eye; very novel. Both from Mr. T. S. Ware.

CARNATION Mlle. THERESA FRANCO.—A dwarf, very free grower, evidently of the perpetual type; flowers large, full, and of a very pleasing rosy carmine colour. From Messrs. Jas. Veitch and Sons. Also to

CARNATIONS REGINALD GODFREY, bright salmon, and Mary Godfrey, pure white, both richly perfumed. From Mr. J. Godfrey, Exmouth.

CHRYSANTHEMUM MRS. P. BLAIR—A very fine broad, flattish Japanese incurved with very stout petals, upper side white, much flushed and veined with deep red. Shown by Mr. R. Owen, Maidenhead.

A silver-gilt Flora medal was awarded to a very large group of Adiantums from Mr. H. B. May, of Edmonton. Probably many who saw this collection had previously little knowledge of the remarkable variety of kinds. A silver medal was deservedly awarded to the large collection of fibrous-rooted Begonias sent up in big clumps in broad shallow baskets by Mr. Sanders, gardener to Mr.

Alfred de Rothschild, Halton, Tring. These were all of the semperflorens type, and illustrated in a very effective way the great value of these Begonias for summer bedding. Bronze Banksian medals were awarded to Mr. T. Mortimer, Swiss Nursery, Farnham, for a very clean, bright lot of show and fancy Dahlias, including many of the best sorts. Also three large boxes full of blooms of *Stephanotis floribunda*, the effect of which was somewhat depreciated by the white paper lining of the boxes. To Mr. G. Bunyard, Maidstone, for a collection of branches of ornamental hardy trees and shrubs, including rich coloured Maples, Oaks, Sumach, Poplars, the Tulip Tree, &c.; and to Messrs. H. Cannell and Sons for a collection of decorative and Cactus Dahlias, Chrysanthemums, Pelargoniums, &c.

There was a small competition in a class for twelve bunches of hardy perennials, the exhibitors being Mr. G. Sage, of Ham House Gardens, and Miss Debenham, St. Albans. The former, placed first, had fine bunches of various things. Messrs. J. Veitch and Sons showed a basket of the blue Sage, *Caryopteris mastacantha*, *Streptocarpus* in variety, many showing deep and rich colouring; hybrid *Rhododendrons* of the javanicum type; also *Amasonia punicea* var. *calycina*, carrying long spike-like bracts of red leafage with projecting tube-shaped flowers of pure white colour; with this was the pretty *Pteris Victoriae*, forming a pleasing base. Mr. H. J. Jones, of Ryecroft Nursery, Lewisbam, had a pompon Dahlia of a bright red colour, the plant some 25 inches in height, and blooming freely. Messrs. Pitcher and Manda, Hextable, Kent, showed some good blooms of new Chrysanthemums, chiefly Japanese. Mr. T. S. Ware had, in addition to things mentioned, a big clump of *Aster grandiflora*, flowers large and of a pleasing lavender-lilac; Cactus Dahlia Mrs. A. Peart, white; Iris alata, mauve-blue, very dwarf; some Cactus and single Dahlias. Mr. W. Wells, Earlswood, had a big collection of cut Chrysanthemums, including Coronet, yellow, broad incurved petals; Elaine, Mons. E. Pynaert van Geert, rich orange-buff; Duchess of York, old gold colour, and various seedlings. Mr. Rickwood, gardener to the Dowager Lady Freae, Fulwell House, Twickenham, set up a group of cut flowers of double and single Begonias in very pleasing form and variety (vote of thanks). Mr. De B. Crawshaw, Sevenoaks, had some tipped and shaded single Dahlias rather oddly marked. Mr. Landsett, Leicester, showed Dahlia Beauty of Barkley, semi-Cactus form, the petals fluted, white edged scarlet. Messrs. R. Veitch and Son, Exeter, staged Pink Ernest Ladhams, now so well known. Mr. Anthony Waterer again exhibited flowers of his new shrubby *Spiraea* Anthony Waterer as evidence of its late-blooming properties. Mrs. J. Phippen, Reading, had Cactus Dahlia G. Phippen, heavy maroon. Messrs. Perkins and Son Cactus Dahlia Matchless, black-maroon. Mr. G. A. Farini, Forest Hill, showed double Begonias. Mr. R. Owen had several new Chrysanthemums. From Mr. Earp, gardener to the Rt. Hon. Joseph Chamberlain, M.P., Highbury, came three spathes of Anthuriums, two white and not so good as Mons. Linden's, and one of a salmon-carmine, with very long, erect spadix that is striking. Messrs. Hugh Low and Co., Clapton, had some excellent Lilliums—*L. nepalense* and *L. Wallichianum*. The Royal Gardens, Kew, sent a group of interesting plants and flowers, five of which were awarded first class certificates. These were *Disa Premier*, described elsewhere; *Bomarea patacoensis*, also known as *B. conferta*, a beautiful greenhouse climber with stems about 20 feet long, each bearing a bunch of about thirty flowers as large as those of *Phileas*, and of a rich scarlet colour; *Solanum Wendlandi*, a noble stove climber, which has been an annual attraction for several years at Kew, where it is now magnificent in the succulent house, and of which a plate was published in THE GARDEN, 1890, Vol. XXXVII., p. 104; *Ptychoraphis angusta*, an elegant pinnate-leaved Palm from the Nicobar Islands, which promises to rival, if not surpass, *Cocos Weddelliana*; *Tecoma Smithi*, a hybrid between *T. capensis* and *T. velutina*, the

latter being merely a variety of the well-known *T. stans*. This hybrid is certain to become a popular greenhouse plant, as it grows rapidly, flowers freely, and bears terminal bunches of bright yellow tubular flowers. It first flowered at Kew three years ago, having been raised from seeds sent thither by the director of the Melbourne Botanic Garden. Other plants shown were *Clematis Stanleyi*, the tall white-flowered *Kniphofia modesta*, *Melianthus trimenianus*, and a collection of new seedling *Streptocarpus*. There were also examples of the Inca or yellow Peruvian Potato, which were grown at Kew from seeds presented by the Rev. W. H. Sewell, of Yaxley Vicarage, remarkable for their yellow flesh and for the length of their haulms, which was stated to be 6 feet.

Orchid Committee.

A first-class certificate went to—

DISA PREMIER, a new hybrid obtained by crossing the hybrid *D. Veitchi* with *D. tripetaloides*. It has the leaves and habit of *D. grandiflora*, and a spike 2 feet high bearing six open flowers besides buds; they are 1½ inches across and coloured bright rose red. From the Royal Gardens, Kew.

Sir Trevor Lawrence, Bart., exhibited a basketful of the very beautiful *Habenaria militaris*. There were about two dozen plants, and some of them bore twenty flowers in a head. We congratulate Mr. White on his success in the cultivation of this plant. It was awarded a silver Flora medal. The same exhibitor sent the Burford Lodge hybrid *Cypripedium* named *cooco-Lawre*, bearing a remarkable fasciated inflorescence, two flowers having united and formed a "twin" arrangement of sepals and petals with two distinct pouches. C. Lawrebel and *Dendrobium d'Albertisi* (shown as *D. Mirbellianum*) were also shown in flower. Mr. A. J. Hollington (gardener Mr. Ayling), sent a seedling *Cypripedium* in the way of C. Lawrenceanum, and named C. Richardsoni, and a hybrid *Cattleya* named Davisi, and said to be the result of crossing C. elegans and C. Gaskelliana, but it is so similar to C. Loddigesi in the form and colour of its flowers, that we suspect this species to be one of the parents rather than C. elegans. It is a beautiful plant whatever its parentage. Major-General Berkeley, of Southampton, sent *Odontoglossum Uro-Skinneri* album, bearing a six-flowered scape and differing from the type in having small greenish sepals and petals and a pure white labellum. It received an award of merit. Mr. J. Forster Alcock, of Northchurch, Berkhamsted, sent a richly coloured variety of *Cattleya labiata*, *Cattleya bicolor* bearing a stout scape with five flowers, and *Odontoglossum grande*. Mr. S. G. Lutwyche sent a small group of popular Orchids, including *Lycaste Skinneri* alba, *Cypripedium Crossianum*, and *Zygopetalum Mackayi* with five flower-spikes.

The trade exhibits were unusually interesting. Messrs. J. Veitch and Sons sent *Cypripedium Arthurianum pulchellum*, which differs from the type (also exhibited) from the fact that one of its parents is the Chantini variety of C. insigne, from which it inherits the reddish spots and larger area of white on the dorsal sepal. Messrs. F. Sander and Co. were awarded a silver Banksian medal for a group of Orchids, which comprised some good and distinct varieties of *Cattleya labiata*, *Phalaenopsis Lowi*, *Batemannia Burti*, *Pescatorea Klambochorum*, *Miltonia vexillaria*, *Oncidium incrvum* and an unnamed species which we should call a form of *O. Cebolleta*. *Cypripedium Cecilia* (C. tonsum × C. Spicerianum) and C. Coppenianum, in the way of C. Schroederi, were also shown. A new hybrid *Cattleya* named *Kranzlini*, said to be raised from C. elegans prasiata and C. Wageneri, looked closely related to C. Davisi shown by Mr. Hollington, but differed in the width of its segments and the markings on the labellum. Messrs. H. Low and Co. had a mixed group of Orchids and *Lilium nepalense*, for which a silver Banksian medal was awarded. *Cattleya Alexandra*, *Stanhopea Amesi-ana*, the sensitive-lipped *Masdevallia muscosa* some good plants of *Vanda Kimballiana*—a super Orchid when properly grown, producing spikes nearly 2 feet long; *Dendrobium Lowi* and *Cypri-*

pedium radiosum superbum were the most notable plants in this group. Messrs. B. S. Williams and Son were awarded a silver Banksian medal for a group which included *Dendrobium superbiens* and its variety *Goldiei*, *D. Phalenopsis* in variety, *Lycaste lanipes* with six large greenish white flowers, *Miltonia Roezli* alba and some of the rarer hybrid *Cypripediums*, viz., *C. Arthurianum*, *C. oenanthum superbum*, *C. Adonis*, *C. tonsum* and *C. Pitcherianum Wellsianum*, a variety with large dark-coloured flowers. A small plant, bearing two flowers, of the rare *Pachystoma Thomsonianum* was also included in this group.

Messrs. Lewis and Co., of Southgate, were awarded a botanical certificate for their little *Habenaria cinnabarina*, shown with four spikes of flowers.

The Horticulture Internationale, Brussels (M. Linden), sent a group of interesting Orchids, to which a silver Flora medal was awarded. It comprised some good varieties of *Cattleya labiata* (*Warocqueana*) to one of which, named *fascinator*, an award of merit was given. It was remarkable for its large flowers, their deep mauve colour and the deep maroon front lobe of the large crisped white marginal labellum. *Cattleya elegans* was also represented by several good-named varieties, and one of them, viz., *Luciani*, received an award of merit. It is not unlike a very good *C. bicolor*, but the labellum is coloured deep rich maroon. A four-flowered spike of *C. Alexandrae*, two varieties of *C. Aclandiae*, two of *C. Eldorado*, one of them named *Oweni* receiving an award of merit on account of the whiteness of its segments and the rich yellow and crimson of its labellum; a very fine variety of *C. gigas* named *giganteum*; and an exceptionally richly marked variety of *C. maxima* named *Leopoldi* were other notable *Cattleyas* shown. *Cochlidia vulcanica* var. *grandiflora* with large flowers on long scapes is the best form we have seen of this plant. There were also a good example of *Cypripedium Rothschildianum* bearing four flowers on one scape, and a hybrid named *Spicero-Lowianum*, which received an award of merit. It has a dorsal sepal somewhat like that of *C. Spicerianum*, and petals 3 inches long, slightly twisted and coloured green, with brown spots, the upper portion tinged with red; the labellum is dark green, with a few indistinct lines of brown. An exceptionally interesting Orchid in this group was *Warszewiczella Lindenii*, first exhibited at the Drill Hall by Messrs. Linden in June, 1892, when it was awarded a certificate. Its flowers are 3 inches across and of the purest snow-white, save only a few purple lines on the disc of the labellum. The lateral sepals are curved and horn-like, giving the flowers a very striking form.

Fruit Committee.

There was a very fine show of fruit, the centre of the hall being filled with large collections. Several certificates were given to both fruit and vegetables; the latter having been given previously at Chiswick were now confirmed. In this matter there is room for considerable improvement, as the committee at Chiswick are enabled to see the things when growing and often in a cooked state, and thus base their awards; whereas at Westminster only a single dish is seen, and in some cases the award of the Chiswick committee is overruled.

The following each received a first-class certificate:—

BEURRE FOUQUERAY PEAR.—A first-class dessert fruit of large size and splendid flavour, having a firm, brisk flesh. It resembles somewhat in shape *Duchesse d'Angoulême* and *Marie Louise d'Uccle*. It has been previously described in THE GARDEN.

APPLE HAMBLING'S SEEDLING.—A new variety sent by Major Hambling, Dunstable. This is a very large dessert or cooking fruit, being somewhat like *Reinette du Canada* in appearance. The flesh is firm, sweet, and the flavour brisk. This will prove a valuable keeping variety, and one of the best of the numerous additions to this class of fruit.

POTATOES.—These had been before the committee at Chiswick recently. Jeannie Deans.—A white flesh pebble-shaped variety of first-rate quality when cooked. It is a heavy cropper and disease-proof. From Messrs. Carter and Co., Holborn. **Early Regent.**—A roundish tuber of good shape, yellow flesh and russet skin. It is a heavy cropper and of good quality, much after the old Regent, but earlier. One of the best known for quality, but not so liable to disease as the old form. From Messrs. Veitch, Chelsea. **Nellie Langtry.**—This is a pebble shaped variety of great merit, and excellent when cooked, being of high quality. It has rather deep eyes and rough skin. Shown by Mr. H. Fletcher, Anerley. **Major Neve.**—A long pebble-shaped tuber, yellow flesh, shallow eyes, of first-rate quality, a heavy cropper, disease-proof, and good flavour. From Mr. H. Pincham, Cranbrook, Kent. **Radcliffe Kidney.**—A medium-sized tuber, russet skin, and very few and shallow eyes. It is of excellent flavour and a heavy cropper. Shown by Mr. Selby. **Success.**—A kidney variety, with white flesh and very few eyes. It is of first-rate flavour when cooked and a heavy cropper. From Mr. Apin, Hasfield Court, Gloucester. **Conference.**—A round potato of great merit, having deep pink eyes, and of first-rate quality. When cooked it is very dry and floury. This has been in commerce some time. It was tried at Chiswick and gave great satisfaction. From Mr. R. Dean, Ealing.

Awards of merit went to the following:—

ONION SOUTHPORT YELLOW GLOBE.—A variety with yellow skin and of flattish globe shape, very solid, and an excellent keeper. **Southport Red Globe.**—This has a bright red skin and of globular shape. It is of a fine strain and an even cropper. **Cocoa-nut** is a very large type, resembling a Cocoa-nut in shape, the skin pale straw colour, with white flesh. The above came from Mr. Deverill, Banbury. **Prizetaker.**—A very fine type, somewhat after the Southport. It is a globe-shaped bulb, flattened at base, very firm and first-rate quality. From Messrs. Henderson, New York. **Globe Madeira.**—A large red-skin Onion of the autumn section, and one of the best out of a large number at Chiswick. **Italian Tripoli** is another of the autumn section, and of great merit. The bulb is large and solid, not a good keeper, but excellent for early use. Both these were from Messrs. Vilmorin, of Paris.

A very fine collection of fruit was staged by Messrs. Veitch, Chelsea, comprising 180 dishes of Apples, twelve large flat baskets and twenty-five dishes of Pears. Among the Apples there were grand dishes of *Cox's Orange*, *Scarlet Russet*, *Margil*, *American Mother*, *Court Pendu Plat*, *Rosemary Russet*, *Melon*, *Baxter's Pearmain*, *Northern Spy*, *Scarlet Nonpareil*, *St. Edmund's Pippin* (a fine dish), *Golden Pippin*, *Royal Russet*, *Ribston* and *Adams' Pearmain*. The best cooking kinds were *Lane's Prince Albert*, *Seaton House*, *Bi-marek*, *Hawthornden*, *Mère de Méoage*, *Peasgood's Non-such* (grand), *Alfriston*, *The Queen*, *Lord Derby*, *Cellini*, and *Northern Greening*. There were also fine fruits of *Beurré Bachelier*, *Glou Morceau*, the new *Beurré Fonqueray*, *Beurré Clairgeau*, *Marie Louise*, *Grosse Calebasse*, *Ne Plus Meuris*, and *Winter Nelis* Pears. A beautiful dish of *Superlative Raspberry*, *Crabs*, and other fruits. A gold medal awarded. Messrs. Bunyard and Co., Maidstone, also staged a grand collection, noteworthy for choice dessert varieties, no less than 120 distinct dessert kinds being staged, and forty dishes of Pears. The Apples were staged in a novel way. The fruits were classed, the Pearmain, Pippins, Nonpareils, Russet and American kinds being kept distinct. Such varieties as *Oker*, *Jefferson*, *Lady Sudeley*, *Margil*, those of the *Calville* type, *Scarlet Nonpareil*, *Ashmead's Kernel*, *Mother* and *Melon* Apple, *Washington*, *Cellini*, *King of Pippins* (very fine), *Cox's Orange* and *Fearn's Pippin*; these very fine. There was some fine dishes of *Calebasse* and other stewing Pears, *Doyenné du Comice*, *Van Mons* *Leon Leclerc*, *Marie Louise*, *Marie Louise d'Uccle*, and *Princess*. A gold medal was awarded. Mr. J. Watkins, Pomona Farm, Hereford, staged eighteen very fine dishes of Pears. There were
