[THE GARDEN.

AN  
ILLUSTRATED WEEKLY JOURNAL

OF

HORTICULTURE IN ALL ITS BRANCHES.

FOUNDED BY

*W. Robinson, Author of the "English Flower Garden."*

"You see, sweet maid, we marry  
A gentler scion to the wildest stock ;  
And make conceive a bark of baser kind  
By bud of nobler race : This is an art  
Which does mend Nature,—change it rather : but  
The art itself is nature."

*Shakespeare.*

INDEX TO VOLUME LII.

(Illustrations in Italics.)

A.

Abbotsbury, Dorset, notes from, 251  
*Achillea rupestris*, 171  
*Abutilon* *Boule de Neige*, Golden Fleece, 171; *megapotamicum*, 231  
*Abutilons* in winter, 9  
*Acacia armata*, 473; *cyonophylla* in bloom at *La Mortola*, 99; *ureophylla*, 490  
*Acacia microphylla*, 192; *ovalifolia* at *Abbotsbury*, 46  
*Acantholimon acerosum*, 389; *androsaceum*, 389; *armenium*, 389; *cephalotes*, 389; *glumaceum*, 389; *Kotschyi*, 389; *laxid rum*, 389; *limboticum*, 389; *Pinardi*, 389; *venustum*, 32, 389  
*Acantholimon*, 289  
*Acanthus hispanicus*, 240; *longifolius*, 240; *mollis*, 240; *mollis*, 239; *m. latifolius*, 240; *spicosus*, 240; *spinosissimus*, 240  
*Acanthus*, the, 239, 279  
*Acers* in flower garden, 208  
*Achillea*, 421; *egyptiaca*, 421; *ageratifolia*, 421; *Ageratum*, 421; *ergentea*, 421; *asplenifolia*, 421; *aurea*, 421; *Clavenna*, 421; *Clavenna*, 421; *Eupatorium*, 421; *hippendula*, 421; *Herba rota*, 422; *microphylla*, 422; *macrophylla*, 421; *Milefolium rosea*, 422; *mongolica*, 422; *moschata*, 422; *nana*, 422; *nobilis*, 422; *obovata*, 422; *ptarmica fl.-pl.*, 422; *ptarmica fl.-pl.*, 421; *rosa*, 421; *rupestris*, 422; *serotina plen.*, 422; *tomentosa*, 422; *timutosa*, 421; *transylvanica*, 422; *Trautmannii*, 373, 422; *umbellata*, 422; *vallesiaca*, 422  
*Achimenes*, 197; at *Sandhurst*; *Lodge*, 110  
*Acidothera bicolor*, 195  
*Acrodon*, 482; *anthora*, 482; *cammarum*, 483; *Fischeri*, 483; *Fortunii*, 483; *heterophyllum*, 483; *japonicum*, 251, 483; *Kunzei*, 483; *lycottonum*, 483; *Napellus*, 483; *orientale*, 11, 483; *pendulatum*, 483; *pyrenaicum*, 483; *uncinatum*, 483; *variegatum*, 483  
*Adiantum pedatum*, 386  
*Adiantums*, some new, 116  
*Adonis*, the, 6; *amurensis*, 7; *pyrenaica*, 7; *vernalis*, 7; *volgensis*, 7  
*Aerides affoe*, 114; *crispum*, 2; *Houllettianum*, 3  
*Aeschynanthus*, 270  
*Agapanthus umbellatus*, 19; *umbellatus*, 19; *u. albus*, 151  
*Agatheae celestis*, 251, 473  
*Agave dasylirioides*, 453; *vivipara* var. *nova*, 230  
*Agaves*, *Aloe*, as *1 Yucca* at *La Mortola*, 108  
*Ageratum*, a good dwarf blue, 303  
*Almondsbury*, notes from, 217

*Alstomeria suranti* et, 60  
*Amaryllis B. laetoura*, 231; *B. at Kew*, 279  
*American note*, 376, 452  
*Amorpha caucensis*, 112  
*Amorpha* and *Ivies*, 177  
*Arctostaphylos andrus*, 25  
*Anchusa italica*, 88  
*Anemone arborea*, 195  
*Androsace laingiana*, 111, 257, 277, 363; *A. l. at Tolly Hall, Sheffield*, 257; *macrantha*, 434  
*Anemone rotundifolia*, 22  
*Anemone japonica*, 91; *A. japonica alba*, 303; *A. j. Bridhaui*, 196; *A. j. Whirlwind*, 239, 277  
*Angelonia grandiflora alba*, 461; *A. g. a.*, 461  
*Angli*, East, Apples in, 185  
*Angraecum ardatum*, 134; *bilobum*, 376; *citratum*, 410; *falcatum*, 151; *fastuosum*, 330  
*Annuals*, some useful, 58  
*Anthemis*, 485; *Aizoon*, 485; *Biebersteini*, 485; *maculosa*, 485; *A. maculosa*, 484; *montana*, 485; *tinctoria*, 485; *A. tinctoria*, 485  
*Anthericum granum folium*, 111  
*Antirrhinum paniculata*, 503  
*Anthurium Andreanum* at *rop. pureum*, 393  
*Anthonus*, 267  
*Aotirrhinum Hendersani*, 313  
*Aotirrhinum and rabbits*, 440  
*Apeirura dinacea*, 249, 300  
*Apple Adams' Pearmain*, 248; *Alfen's Everlasting* at *Brigton*, 397; *Allington Pippin*, 349; *Autumn Pearmain*, 349; *Bleheim Orange* as a bush, 477; *Cobbett's Fall*, 248; *Cockle Pippin*, 469; *Court Ponde Plant*, 496; *Cox's Orange*, 376, 470, 497; *Devonshire Quarrenden*, 185; *Duck's Hill*, 273; *Eve*, 308; *Fearn's Pippin*, 14; *Golden Russe*, 261; *Graham*, 489; *Gravenstein*, 349; *Jas. Grieve*, 312, 316, 355, 397; *Keutish Fillbasket*, 229; *King of the Pippins*, 356; *Lady Palmouth*, 433; *Lane's Prince Alber*, 450; *Lemon Pippin*, 317, 318, 470; *Lemon Pippin*, 348; *Lord Derby*, 290; *Lo d Derby*, 290; *Mabbot's Pearmain*, 297; *Manington Pearmain*, 493; *Mère de Menage*, 35; *Newtown Pippin*, 376; *Pippin Russet*, 34; *Pott's Seedling*, 184; *Red Hawtherden*, 349; *Ricotte du Canada*, 450; *Ribston Pippin*, 357; *Ribston Pippin on a wall facing west*, 483; *Ritston Pippin on wall*, 488; *Ross Nonpareil*, 391; *Seaton House*, 470; *Striped Beaumain*, 489; *Sturmer Pippin*, 390; *Tower of Glamis*, 356; *Tyler's Kernel*, 248; *Waltham Abbey Seedling*, 261; *Wheeler's*

*Russet*, 397; *White Juneting*, 229; *White Nonpareil*, 341; *Worcester Pearmain*, 248; *Wormsley Grange Pippin*, 397; *Yorkshire Beauty*, 35  
*Apple blossom*, late, 51; crop, the, 74, 95; trees in woods, 290  
*Apples* at *Pisa* for experimental situations, 95; *crisp*, 142, 181; *early*, flavour in, 181; *highly coloured*, 396, 450; in East Anglia, 185; *on iron sile*, 349; *rich*, but tender, 141; *see* at the *Crystal Palace*, 355  
*Appointment*, Royal, 112  
*Apricot borders*, *Peas* on, 74; *tree*, sad end of a *giant*, 229; *trees*, 218; *trees* in hot weather, 139; *trees*, lifting roots of, 347  
*Apricots* and *Nectarines*, 194  
*Arctostaphylos*, 417  
*Arabis Sieboldi* in flower in Ireland, 435; in N. Wales, 513  
*Araucaria grandiflora*, 273  
*Arbutus Unedo*, 429  
*Argemone hispida*, 72  
*Arstocchia braziliensis*, 59; *gigas*, 110  
*Archiebia chio'de*, 353  
*Arphocytum gaurianum*, 477  
*Artemisia Abrotanum* in bloom, 273; *arborescens*, 277  
*Artichoke White Jerusalem*, 406, 452, 512  
*Artichoke*, *Globe*, in winter, 371; *Jerusalem*, 512; *White Jerusalem*, diseased, 494  
*Arundinaria Simoni*, 71  
*Asclepias incarnata pulchra*, 230; *tuberosa*, 91, 151, 256  
*Asparagus* *erectus*, 4; at *Ganton*, 235; *beds* in winter, 371; *manuring*, 45, 156; *watering*, 176  
*Asplenium Adianthum-nigrum*, 426; *alternifolium*, 426; *septentrionale*, 426; *Trichomanes* 426; *vide*, 423  
*Asplenium*, 219  
*Aster scris*, 236; *Amellus*, 230; *A. Riversii*, 313; *Ariadne*, 331; *dipl. tephoiodes*, 374; *ercolides*, 313; *graniflorus*, 374, 453; *linearifolius*, 273; *Linosyris*, 273; *Mrs. W. Peters*, 196, 210; *Novae Angliae pulchellus*, 251; *Novi Belgii densus*, 277; *punctatus grandiflorus*, 313; *sericeus*, 385; *spectabilis*, 253; *St. Bridg*, 303; *trichellus*, 312; *viminalis*, 303  
*Aster trials* at *Mortlake*, 302  
*Asters*, annual, 238  
*Astilbe Lemounei Gerbe d'Argent*, 91; *Thunbergii*, 115  
*Athyrium filix-femina*, 423  
*Atrypae alpina*, 474; *americana*, 402  
*August* in South Devon, 249  
*Autumn*, the, 480  
*Autumn tints*, 385, 408, 464

*Azalea calyciflora*, 490; *Dautsch's Palis*, 494; *Freya*, 507; *indica*, 174; *Ribera*, 507; *Ternstroemia*, 137  
*Azaleas* grafted on *Rhododendrons*, 336; *greenhouse*, 137, 173  
*Azolla filiculoides*, 192

B.

*Baden-Baden*, notes from, 32, 252, 342  
*Bamboos*, two new, 151  
*Banana* growing for the markets, 149

## JOHN GILBERT BAKER.

JOHN GILBERT BAKER was born at Guisborough, in Yorkshire, in 1834, and early in life devoted himself to the study of British wild flowers. In 1866 he was appointed curator of the herbarium of the Royal Gardens, Kew, having, by his publications, previously placed himself in the front rank of the authorities on British plants. His "North Yorkshire," without being a bulky book, is a model of what a local flora should be, and doubtless gained him his position at Kew, where he commenced a career of activity in botanical work which he has maintained up to the present time. Although he has done an immense amount of purely botanical work, he has been a continuous and copious contributor to what may be termed garden botany during the whole period he has been at Kew. Indeed, there is no botanist living to whom gardeners are more indebted than John Gilbert Baker, though he has persistently refrained from the discrimination and nomenclature of varieties, a task he properly left to the florist. His first work at Kew was the completion of the "Synopsis Filicum," designed and commenced by Sir William Hooker, whose sudden death happened when he had written only two or three sheets of the book that has so long been the only one in the English language containing descriptions of all the species of Ferns then known from all parts of the world. A second edition appeared in 1874, and another, containing the numerous novelties discovered since then, would be warmly welcomed now. This is not the place for a bibliography, but of his numerous popular monographs of the cultivated species of genera previously very imperfectly known we may refer to those on Agave, Aquilegia, Amaryllis, Crocus, Helleborus, Iris, Lilium, Narcissus, Pæonia, Rosa, Selaginella, Sempervivum and Yucca. This, however, is merely a tithe of the work accomplished by Mr. Baker. Among his more recent separate publications that specially appeal to the gardener are: "A Handbook of the Fern Allies," "A Hand-book of the Amaryllideæ," and "A Hand-book of the Bromeliaceæ."

But it is not only as a writer that Mr. Baker has furthered the cause of gardeners and gardening. A long generation of medical students, gardeners, and others owe the foundation of their botanical knowledge to his vigorous and sympathetic teaching. A man may be a very good gardener, it is true, without knowing anything of botany, and practical knowledge is of far more importance; yet botanical knowledge, like artistic knowledge, is capable of adding greatly to the enjoyment of gardening, and we have no hesitation in saying that the courses of lectures at Kew, in which Mr. Baker has taken a prominent part, have afforded willing men opportunities which have resulted in mental and material advantages not easily obtained elsewhere.

Among Mr. Baker's writings less known to the gardening world are a "Flora of Mauritius and Seychelles," a "Flora of the English Lake District," "A New Flora of Northumberland and Durham," and "Elementary Lessons in Botanical Geography." In addition to these he has contributed to the "Flora of British India," to the "Flora of Tropical Africa," to the monumental "Flora Brasiliensis," and other publications too numerous to mention. Amidst all this research and investigation Mr. Baker has ungrudgingly, indeed we may say amiably, devoted much time to assisting those less fortunately situated with regard to literature and type specimens, and it is only those engaged in the same or similar vocations who know how often and thoughtlessly this kind of disinterestedness is abused.

On the retirement of Professor D. Oliver in 1890, Mr. Baker was promoted to the post of keeper of the herbarium and library, a branch of the Kew establishment which is little known to the public, and which involves an amount of responsibility that surprises a casual visitor. Honours, as we all know, do not fall thickly on those engaged in scientific pursuits, and it is perhaps as well so. Mr. Baker was elected a Fellow of the Royal Society of London in 1878, and has served on the council of that body. He was also among the sixty selected to receive the Victoria medal distributed by the Royal Horticultural Society.

## ORCHIDS.

### CATCLEYA GIGAS.

ALTHOUGH the varied forms of this superb Cattleya are given many varietal names, it must be conceded that, taken as a species, it is much less variable than any other of the labiata group. Plants in two or three varieties purchased from different nurserymen are almost, if not quite, identical in the colour and markings of the blossoms, the only perceptible difference being a slight one in the size. There is not a finer species in the genus when properly managed; the immense flowers with the fine showy lip, although not quite so rich in colour as some others, are among the best for a choice display. *C. gigas* is best grown in a good light, as here the growths get well ripened, are less likely to start out of season, and are usually the forerunners of a bountiful bloom. They occur upon the forming growths, the sheath that precedes the bloom showing almost as soon as the leaf begins to open, and about five or six are produced on each spike. The aim of the cultivator should be to get the young growths on the move early in the spring, as with the increased light and temperature in early summer most of these produce spikes; whereas in winter, when light, and to a certain extent heat, have to be withheld, many of them will not do so. But even of more importance than the time of starting is getting the bulbs well ripened by a fairly high temperature when finishing, and abundance of air and light. This class of growth usually goes naturally to rest as the sun loses its power and the heat declines in autumn; the plants keep dormant with little or no trouble through the winter, and come away with a rush into flower just about now. Some may say it is easy enough to give this advice, but not so easy to follow it, and not without reason; but the more this advice is followed the greater will be the success. Then if growths do start out of season—as they sometimes will, the best of care notwithstanding—do not attempt to check

them, but encourage them by the lightest and best position in the house and careful attention to watering. Frequent disturbance at the root is unnecessary and harmful, but the plants cannot thrive in a close compost or one that is waterlogged and sour. If the young pseudo-bulbs commence to root before the flowers form they should be repotted or rebasketed then, but if they can be left until after flowering, so much the better. The roots are large and fleshy, requiring a good open description of compost and a fairly wide root-run. In small pots it is difficult to keep them at home, as they grow out over the rims every season. Where the pots are large, only a very thin compost is needed, except for large specimens, which are, unfortunately, not often seen. Baskets are very suitable for this Cattleya, as they are lighter than pots for suspending, and the freedom with which air and light play about the roots is a great advantage. Which-ever is used, keep the base of the pseudo-bulbs well up, so that they just rest on the surface of the compost, and allow a fair rise to the centre of each plant. Newly-imported plants of *C. gigas* usually arrive in fair condition, and some are so plump and fresh when received as to suggest potting up at once in peat and Moss. As a rule they are better for a few weeks' plumping up in a warm, moist house, placing in their pots before any young roots that may form are likely to be damaged in the operation. These often flower freely upon the first-formed bulbs. *C. gigas* is said to have been collected as far back as 1849 by the Polish collector, Warszewicz, to whom it was dedicated by Reichenbach, but as the above name was given to the species by Linden at a time when more plants of it were brought into cultivation, it is now the better known and generally used.

**Oncidium crispum.**—This is an old and common enough species, but the flowers are as handsome and useful as any just now. The habit is of the well-known kind in the genus, flattened, erect pseudo-bulbs occurring on a creep-

ing rhizome, the spikes appearing at the base of the last formed of these between the leaf and bulb. The number of blossoms depends upon the strength of the plant; they are individually large and showy, a pleasing combination of brown and golden yellow. *O. crispum* is not difficult to grow, yet requires careful culture, a light, almost unshaded position and plenty of water while growing.

**Oncidium Croesus.**—This hardly differs from *O. longipes*, but is rather more highly coloured, while *O. janeiriense* is another very similar kind. *O. Croesus* is now flowering with me, several spikes having as many as six or eight blossoms. The sepals and petals are reddish brown, the lip yellow with a very dark purple, almost black, disc. The flowers though small last well in good condition, are very freely produced, and when as many flowers as noted occur on the spikes the species makes a nice show. It is not a fastidious plant as to temperature, but likes more heat than the *Odontoglossum* house usually affords.—R.

**Cattleya bicolor.**—The stately habit and freedom with which this plant blooms, to say nothing of its distinctness, should ensure it a place in collections, though it must be owned it is not by any means so showy as many of the labiata and other sections now flowering. The spikes occur at the apex of growth just as the pseudo-bulbs are thickening out, and bear upwards of a dozen flowers. These are olive-brown, the centre of the lip crimson-purple, some varieties, as *C. b. Measuresiana*, having a white margin. The side lobes of the lip are small and do not enclose the column, as is usual in the genus. It is a native of Minas Geraes, a province in Brazil, and was introduced in 1837.

**Cattleya Mossiae.**—I have a plant of this species now carrying over thirty of its fine rosy-tinted blooms, each being over 8 inches across and making a fine show. The plant has not been repotted for four seasons, but every year a little of the old material is taken from the surface and replaced by new peat and Moss, taking care that plenty of charcoal or crocks is placed with it to make up for the extra thickness. It is an important point in the culture of *C. Mossiae* that the plants are kept warm and well treated after blooming, as the season is late and

it has to make up its bulbs for next year, in this way differing from *C. Gaskelliana* and other summer-flowering kinds.—R.

**Odontoglossum Lindenii.**—This species is seldom seen in flower, but when it does bloom it attracts a good deal of attention by its distinctness and fine colour. It has large pseudo-bulbs, from which springs a tall, sometimes branching spike of lemon-yellow blossoms. *O. Lindenii* is a native of New Grenada, where it was discovered many years ago, but probably again lost to cultivation, as it does not appear to have flowered in this country until much more recently. It delights in a cool, moist house and plenty of moisture all the year round.

**Cypripedium Lawrenceanum.**—This fine plant is still in bloom, and only last week I noted a fine batch just throwing up, so that the flowering season extends over three months. Not only are the blossoms large and handsome, but the foliage is more finely variegated and showy than in almost any other known kind. It is a variable kind, a handsome form with very large dorsal sepal being known as *C. L. expansum*. It is not an old species by any means, having been discovered in Borneo as recently as 1878, but has already become very popular.—H.

**Miltonia spectabilis striata.**—A pretty form of this variable species I noted in flower this week had sepals and petals of a delicate rosy white, with a suffusion of lilac-purple. The lip was lighter in ground colour, almost pure white in fact, with heavy radiating lines of deep rosy purple. All the forms of this old species are useful and interesting Orchids, lasting a long time in good condition, and when well grown flowering profusely. They thrive best in a light position shaded only from bright sunshine, with a thin surfacing of compost and a liberal supply of water while growing.—R.

**Cattleya Forbesi.**—The blossoms of this species are perhaps not large or showy enough to appeal to present-day growers, yet they have a distinct appearance that is lacking in some more showy kinds. It belongs to the same section as *C. intermedia* and grows about a foot high, producing a four or five-flowered raceme from the apex of the stem. The segments are all of a greenish yellow tint, the lip being marked in front with reddish purple. It is very free blooming, often flowering twice in a year. It is named after its discoverer—Forbes, a collector for the London Horticultural Society, who sent it home in 1823.

#### ONCIDIUM CONCOLOR.

The pretty self-coloured yellow blossoms of this *Oncidium* are among the most ornamental in the genus, notwithstanding it only grows a few inches high. On the strongest plants the bulbs seldom exceed 2 inches in height, yet from these a spike springs over a foot in length densely packed with large flowers. Though not a difficult plant to grow, it is one that when received in good condition every endeavour should be made to keep it so. Once get the pseudo-bulbs badly shrivelled from over-flowering or lack of moisture, and it will not be an easy matter to bring it back to luxuriance, but when well situated and thoroughly healthy, it is the cultivator's own fault if he does not keep it in health and increase its size. Though a native of Brazil, it is found naturally at considerable elevations upon the Organ Mountains; consequently cool and moist conditions all the year round suit it best. One thing that all these cool *Oncidiums* detest is a dry or draughty house. Air they delight in—must have, but the currents or air must be regular and tempered by moisture. Perhaps the best of all positions is one not far from a ventilator in the roof, where the air currents rustle the foliage as if moved by the touch, and in a house that never rises much above 70° in summer or falls below 50° in winter. The roots are of medium strength, but are not ambitious in leaving their pot or basket, preferring rather to coil around the lumps of charcoal and corks that

are mixed with the peat and Moss given as compost. A little only of this is required, from an inch in thickness for the smaller plants, to 1½ inches or so for the larger ones. But let the material be the best at command, as it does not like disturbance. Once in two years is often enough to repot or rebasket, but if the surface seems at all sour in the intervening season, let a little of it be removed and replaced with new. Care is needed in doing this, especially around the new pseudo-bulbs, for if the young roots are damaged or broken much more harm will be done to the plants than the top-dressing does good. After disturbance, keep the roots well on the dry side for a time, but load the atmosphere with moisture. Keep this up all the year round, and when new roots have formed and the plants are again established, water may again be freely applied. Healthy plants are not, as a rule, troubled much by insects, as they grow under conditions ungenial to the latter. Should white scale put in an appearance, lose no time in effecting a clearance of them by carefully sponging the plants time after time until all the insects are destroyed.

**Bollea cœlestis.**—This bright and pretty Orchid I recently noted in good condition. It usually bears single-flowered spikes, these being frequently over a foot in height, each blossom about 3½ inches across. The colour is a pretty light blue on the petals and sepals, shaded with mauve and white, the lip deep purple and violet. It is as good a grower perhaps as any in the genus, and if once established on a large raft or in a basket with a thin, but substantial compost will usually be satisfactory. A broken light is necessary for it, and having no pseudo-bulbs, dry rest must not be attempted. The *Cattleya* house is suitable to its needs as regards temperature, but shade must never be overlooked. *B. cœlestis* is a native of Colombia, and was introduced in 1878.—H.

**Aerides crispum.**—A good variety of this *Aerides* is a really charming Orchid and one worthy of all care. It is a tall grower, producing long branching spikes from the upper portion of the stems, and these last a long time in full beauty. The individual blooms are large and sweetly scented, the sepals and petals nearly pure white, the lip having a deep purple blotch in front that gives the species its distinct character. It requires plenty of heat to do it well, a moist atmosphere and clear light, without being scorched. Baskets or pots of *Sphagnum* and charcoal suit it well, these being very well drained and clear, as a liberal supply of water is needed when growth is active. The roots must be kept within bounds as far as possible to obtain the best results. The appearance of the roots is a good guide as to the amount of water required; when the points are fresh and green it is plain they are in search of moisture, but when they cloud over their resting season is not far off. *A. crispum* is a native of South and West India, and first flowered in England in 1841.

**Læliopsis domingensis.**—This pretty plant is seldom seen under cultivation, and more than once plants have been sold under the name that are simply one of the Mexican species of *Lælia*. Such a case was brought to my notice very recently, when a flower of *L. albidia* was sent as the kind named above. *L. domingensis* grows about 6 inches high, the pseudo-bulbs roundish and rarely exceeding 2 inches in height. The flowers are crowded upon the raceme, about half a dozen being the usual number, and they seldom expand fully, or, according to my experience, last long in good condition. It is, I believe, seldom imported by the trade or through the usual channels, but some years since I had the charge of a nice little batch of it that had been collected privately. These were fastened to small charred blocks at first, and afterwards placed entire into baskets. They were grown with *Dendrobiums* and other heat-loving species in a house little shaded, and were well watered while making their growth, but not syringed much overhead. The pseudo-bulbs complete, they were turned out to ripen with the

*Dendrobies* at first in a warm, sunny house, afterwards in the open air, and they flowered well. The sepals, petals, and lip are of a pretty soft rose, the last having a deeper-tinted blotch in front and a pale brownish-yellow throat.—H. R.

**Cattleya Warneri.**—This pretty species is in flower this week in variety, one of the most attractive forms having small, but very delicately tinted flowers. The crimson blotch on the lip is extremely rich and well defined, showing up the lighter sepals and petals. Each flower measures just over 6 inches across. It is a very near relation of *C. labiata autumnalis*, the lip markings resembling those of this more than any other of the *labiata* section. It pushes into growth early in the season, and the flower-spike appears in the centre and at once comes to perfection, in this way differing from *C. Mossiae* or *C. Mendeli*. I usually leave the plants until after flowering before repotting, as by this means the young roots that are annually emitted from the rhizome at once enter the new compost. But plants differ a little in the time of this root-production, especially those that flower late in the season, and it becomes necessary in such cases to repot about April, otherwise the plants have barely time to re-establish themselves before winter. Temperature and compost as usually recommended for this group are suitable to *C. Warneri*, a plant I always like to keep up to the light as much as possible. If unduly shaded or kept in too high a temperature after blooming, so as to cause it to break again into growth, it will not flower freely.

#### NOTES ON ORCHIDS.

GROWTH is now very active in all Orchids, and the bright sunshine lately experienced is just what was wanted for the deciduous *Dendrobies*, *Calanthes*, *Thunias*, and other occupants of the warmest or East India house. Any of these *Dendrobies* that start away into growth while in flower should be attended to at the roots after the blossoms fade, for if left too long a check is given to the growth owing to the young roots being disturbed. Small plants of *D. crassinode* or any in this class may have a little top-dressing, but it is not, as a rule, so beneficial to them as to deeper-rooting subjects. The growths on *Thunia Marshalliana* are already about 18 inches in length. The plants are standing quite in the full sun where atmospheric moisture and heat are abundant. This rapid growth, of course, makes considerable demands upon the roots, which have nearly filled the pots, and must be kept very moist. *Cypripediums* need hardly less heat, but more shade, and the colour of the young foliage is almost as attractive as that of the blossoms on many species. Plants of *Oncidium Kramerianum* that had all the old bloom-spikes removed last season are just pushing the flower-buds from new spikes formed during the present spring; consequently they make a nice succession to the earlier blooms upon plants that had not this attention. Roots and growths of these are active now, and the Moss about them must be kept moist, and if kept growing, all the better. *O. Jonesianum*, too, is on the move, though the roots are not yet starting from the young growths. A very light position only just screened from the brightest sunshine suits this best. The right temperature of this house may now range from 60° to 65° by night; the latter figure need not be exceeded all through the summer. Let the plants have the advantage of heat and moisture by day, but let the temperature be as restful as possible by night. In the *Cattleya* house there is now a fine display, *C. Mossiae* being a host, besides *C. Mendeli*, a few early plants of *C. gigas*, and one or two of the upright-flowered section. All arrears of potting among *C. Trianae*, *C. Gaskelliana*, *C. Percivaliana*, and others should be brought up, but *C. Mossiae* and *C. Warneri* may now with advantage be left until the blooms are past and the young growths advancing. In *C. Lawrenceana* we have a lovely early summer-flowering *Cattleya* that dislikes much disturbance; consequently if the roots are in fairly

good order they may be left alone, but if repotting is necessary it must be very carefully gone about. Anguloas are strong-growing, gross-feeding Orchids, requiring considerable care. I find that the best time to repot is, in most cases, as soon as the flowers are past, but no time must be lost, or the roots will be too far advanced to allow of its being done without injury. There are many other plants that may be seen to now, including Brassias of sorts, and Oncidiums having long erect spikes, as *O. sphacelatum*, *O. altissimum*, *O. incurvum*, and others. In fact, at this time of year one might almost be tempted to say, "When in doubt, repot," for disturbance of any epiphytal warm house or intermediate Orchids is fraught with less danger now than at any other season, and for reasons which are obvious. The night temperature for the Cattleya house may be kept as near as possible to 55°, running up by day with ordinary sun-heat to about 80°.

The earlier potted Pleiones are growing and rooting freely in the cool house, and when it is seen that the roots are enveloping the compost, see that they are not allowed to suffer from want of water. Even the latest kinds are by now well advanced, and there is but little danger of the roots decaying unless very carelessly watered. Odontoglossums are becoming daily more active, some of the *O. Halli* section being already in full growth and rooting freely from this year's shoots. Such plants take a good deal of water, but care is even yet needed with *O. triumphans* and the late-flowering plants of *O. luteo-purpureum*, *O. Pescatorei*, and others. *Oncidium concolor*, *Sophranitis grandiflora*, *Odontoglossum Cervantesi*, and various other small-growing kinds suspended from the roof must be carefully watched, as from the greater freedom with which the air plays about them they dry up more quickly than plants on the stage. *Sobralia macrantha* is, I should imagine, about the most thirsty subject in the family, plants that have not been potted for a couple of years taking large quantities of water daily. The great fleshy roots seem to delight at this time of year in being surrounded by moisture, and they may easily be seen foraging for it by their green hard tips. It will be more difficult now to keep the temperature of the cool house down, but endeavour as far as possible to keep it below 70° on the hottest days. This will always feel pleasantly cool, and is the best one can do. The night temperature may still stand at about 50°, this allowing of a little air being left on top as well as the usual chink on the lower ventilator. R.

#### DENDROBIUM SUPERBIENS.

In its best form this is one of the finest of the Australian Dendrobies, its long-lasting and free-flowering qualities being remarkable. The flowers occur in fine arching racemes, and are either terminal or lateral on the new pseudo-bulbs, and often the older, hard bulbs push out a few spikes. Each flower is upwards of 2 inches across, rich crimson-purple in the better forms, with a pale or pure white margin to the lip. The strongest plants are over 2 feet in height, and when this vigorous growth can be kept up under cultivation immense spikes are the result. *D. superbiens*, like *D. Phalenopsis* and others of this set, is an erratic plant to grow. Sometimes it does well in collections where apparently little trouble is taken in its culture; at others, no matter how carefully it is done, weak growths and few flowers are the rule. I am convinced that one reason for this unsatisfactory state of affairs is repotting or basketing at the wrong time—i.e., when the plants are at rest. Before I repot I like to see the young shoots several inches in length and taking on that rounded shape at the base that is precursory to root-formation. Then the plants have the advantage of the undisturbed old roots until just as they are sending out these foragers on their own account, and with a little close, warm treatment afterwards hardly any check will be observed. Regarding position and receptacles, I believe there is nothing better than

medium-sized or small pans hanging from the roof in a light and very moist house. The growth may in fact be almost wholly exposed to the sun, and if moisture in abundance is kept about them no injury to foliage or bulbs will accrue. A lot of heat, of course, is thereby generated, and it is just this kind of heat that the plant delights in. When repotting drain the pans thoroughly, placing over the crocks a little rough Sphagnum; firm the material well about the roots, this consisting of peat and Moss, with crocks and charcoal finely broken. Clip off all neatly, or it will be difficult to see whether or not the plants are dry at the roots. While growing freely abundance of water is needed, letting the roots get a little on the dry side occasionally. It is not often that the plants rest entirely during winter, but if they do, keep them dry and fairly warm. The flowers are produced at various times during the year, plants often being in bloom for six months at a time. It is a native of the islands about the Torres Straits and the adjacent mainland, and was introduced by Messrs. Veitch in 1876. H.

**Cypripedium caudatum Wallisi.**—This is a very delicate and pretty variety of *C. caudatum*, quite distinct from the typical plant. The petals are not usually so long as those of the latter, the sepals white, with pale rose and green veins, the lip white, suffused with yellow and spotted with reddish purple. *C. c. Wallisi* is a native of Ecuador, of more recent introduction than the type, having been sent home in 1872. It delights in a very open, well-drained compost, plenty of water all the year round, and the temperature of the Cattleya house is high enough for it. It was recently in good condition at Messrs. Veitch and Sons' nursery.

**Saccolabium ampullaceum.**—This bright and effective little plant is in flower at Mr. Bull's, the bright rosy magenta spikes showing up well against the deep green foliage. The plant is dwarf in habit, very free blooming when healthy, and not difficult to grow. It is a widely distributed plant in the tropical parts of India and Burmah, whence it was introduced to cultivation about the year 1837. It remained rare until nearly thirty years after, when Messrs. Hugh Low and Co. imported a quantity of plants. It thrives well in a warm, moist house, with plenty of light and abundance of water during the growing season. It does best in pans or baskets of limited size.

**Cypripedium Exul.**—This pretty species is still in bloom, but, unfortunately, does not throw so many flowers as one would like to see, though they last long in beauty. Its affinity to *C. insigne* is obvious at a glance, but of course it is quite distinct. The dorsal sepal is yellow below, pure white at the apex, and there is a number of irregular purple blotches principally about the base. The petals are narrow and light brownish yellow, the lip much clearer yellow, with one or two spots about the throat. It is as large as a medium *C. insigne*, and the plant resembles this old species in growth. A warm greenhouse temperature suits it well if given a fairly shady position and moisture in abundance in the atmosphere. The roots are strong and vigorous, delighting when healthy in a free and open, yet substantial, root-run of the class usually recommended for the genus. It is a native of Siam and was introduced to this country in 1892.

**Lycaste aromatica.**—As the specific name implies, this pretty species is sweetly scented, and this added to its bright golden tint of colour makes it welcome, though the flowers are small individually. They occur in single-flowered scapes, which are produced in abundance from the base of the last formed pseudo-bulb, and last well in good condition. Sepals, petals, and lip are all golden yellow, the last of singular form, almost cylindrical. It is of the easiest culture, and may be established with hardly any trouble. I have frequently potted up the plants just as received in light loam, peat, and Sphagnum Moss,

and by the end of the second season it is difficult to see that they are not old-established specimens. It is one of the easiest to propagate by division, and may be pulled into almost as many pieces as there are pseudo-bulbs, and each one will eventually make a plant. Each leaf is certain to grow, and these small bits have a very quaint appearance when in flower, a plant consisting of a couple of bulbs only producing perhaps a score of flowers. It does well in any cool, moist structure during summer, commences to grow soon after the flowers begin to push at the base, and may be wintered in a house kept above 45°. It is a native of Mexico, and a very old inhabitant of our Orchid houses. H.

**Aerides Houlletianum.**—The flowers of this species are extremely pretty, and it is a pity it does not attain a larger size under cultivation. That it is rather difficult to grow must be conceded, as, although in some cases it goes on and flowers year after year, it is seldom seen showing much vigour after it has been cultivated a few seasons. The habit is not unlike that of a broad-leaved form of *A. odoratum*, but the blossoms are quite distinct. These are large and more expanded than usual, the sepals and petals being greenish when first open, but changing to a beautiful nankeen-yellow. They are tipped with rosy magenta, and the fimbriated lip is similar in colour. Small plants should be grown in suspended pans or baskets not far from the roof glass in a warm, moist house. During the time growth is most active plenty of water must be given, but when at rest considerably less suffices. The compost may consist principally of Sphagnum and charcoal. *A. Houlletianum* is sometimes classed as a variety of *A. falcatum*. It is a native of Cochin China, and has been known since 1868, when it flowered with a French Orchid grower, and was named by Reichenbach after M. Houllet, of the Jardin des Plantes. It was not introduced to England until several years later, and has never become a common plant.

## KITCHEN GARDEN.

### SAVING VEGETABLE SEEDS.

SAVING seed of choice vegetables is a matter requiring great care, as the best strains are easily spoiled by cross fertilisation. It is, of course, useless trying to seed two things of the same family in the same garden, although this is sometimes attempted. Some time ago I knew of a case of spoliation that occurred in the eastern counties. A nurseryman possessed a very superior Cabbage and had seeded it successfully for several years. At length, however, a large plot was set apart for seed, the owner being ignorant that a few fields away another plot of one of the Brassicas was being seeded by another party. The result was that cross-fertilisation was effected by insects, and the grand stock of Cabbage which had been saved by a gardener for many years previous to its passing into the hands of the seedsman was completely spoiled. Anyone possessing an extra good strain of any vegetable will do well to save seed, if only a very small patch, himself, as nurserymen cannot afford to what is termed "rogue" the plants that do not correspond exactly with the type too rigidly. A gardener of my acquaintance who possesses some remarkably fine strains of vegetables always made a rule of getting several of the lodge-keepers living at the outskirts of the large deer park to set apart a small plot in their garden for, say, Cabbage, Cauliflower or Broccoli, paying them for their trouble by a supply of plants of the various sorts of winter greens. The same gardener possessed a fine strain of Brussels Sprouts, and each season, previous to commencing picking, the plot was

gone through, and a certain number of the most perfect marked by having a stake thrust into the ground. These were in due time transplanted into a spare plot and saved for seed. Beet, where lifted in autumn, was sorted over, and a few dozen of the medium-sized, best-shaped roots selected, these being clamped separately and planted out in March. The seed sower is often at much trouble to keep at bay the feathered tribe, as the finches are partial to all the Brassica tribe, also to Beet, Turnip and Endive. The gun, of course, makes them shy, but covering with fish netting is the only sure way of saving the seed. The seasons also have much to do with the good or bad quality of vegetable seeds, so that, altogether, seed saving, although a pleasant, is by no means a certain undertaking. C. C. H.

**Late Broccoli.**—Several notes have appeared in THE GARDEN recommending Late Queen as the best late Broccoli grown, but I cannot recommend it as being the best late, as it generally turns in about the end of April or early in May. Champion is one of the best Broccoli to cut in June. A good companion for it will be found in Universal, which I consider to be far in advance of Late Queen as a good late Broccoli. It has withstood 28° of frost, all the Late Queen being killed. Out of ten varieties grown three years ago only two survived, namely, Champion and Universal.—T. COCKERILL, *Gatehouse Gardens, Wirksworth.*

**Asparagus after cutting.**—I quite agree with all Mr. Parker says (p. 429), especially as to its not being good to use much salt in beds where the soil is heavy. I have a piece of heavy soil under my charge, and some six years ago a portion was sown with Asparagus, with a view to get roots for forcing. When the plants were two years old I applied a dressing of salt during the growing season. This had a bad effect, and these plants have never grown so strongly as some adjoining that had no salt applied to them. In the kitchen garden I can use salt advantageously in small quantities. I apply one or more dressings of guano during the growing season in stormy weather. I have adopted the method recommended by Mr. Parker, namely, staking the growth with Pea stakes for many years with the best results.—J. CROOK.

**Pea Springtide.**—At p. 447 Mr. Tallack praises this new early Pea, and I fully agree with his remarks. I sowed it at the end of February, and the Peas were ready for gathering the third week in June, which I consider quick work in this district after an unfavourable spring. It came in exactly at the same time as Chelsea Gem that was sown in small pots at Christmas and transplanted in March. Given good soil and liberal treatment, I am sure Springtide will please all who need extra early Peas. Sown at the beginning of February in south gardens, this Pea would be ready for use by the end of May. Like Mr. Tallack, I have not a very high opinion of Exonian; at least it did badly on my light soil, and after one year's trial I discarded it. I consider William I. a much better Pea both in regard to cropping and colour.—J. C., *Notts.*

**Pea Gradus.**—Has "A. D." got the true Gradus? as he writes at page 433, "it is tender, long-jointed, and has curled foliage." The last may be seen in the true stock, but not to a great extent and not at all to its disparagement. I have no knowledge of its behaviour, given field culture; but as an early garden Pea I place much value upon it. I am also quite sure "A. D." will not class it with such kinds as Stratagem and others of similar character, as these later kinds, I admit, are superior in habit, stouter and stronger, but later. I note "A. D." does not give us any information as to the newer Excelsior, an excellent early Marrow Pea, and earlier this season than Gradus, and dwarfier. Of course, with so short a haul it cannot be expected to bear so heavy a crop, but with me it is bearing quite close to the soil. I

fear Gradus is given a bad name, and deservedly so in many places on account of the plants being far from true. I have had three distinct types, and, as "A. D." well knows, it is an easy matter for Peas to get much mixed if not well attended to. The true stock I had of Gradus was not tender, but I fear this good Pea will not keep true.—G. W.

**Smythe's hybrid Beans.**—I refer to these dropping the prefix "French," for the use of which in relation to the dwarf section of Kidney Beans there seems to be no warrant. The term "dwarf Beans" conveys all needful information. The hybrids referred to are the product of crossing the dwarf Ne Plus Ultra with the climbing Scarlet Bean, and the result so far has not been at all satisfactory. Many seedlings are but reproductions of the dwarf parent with shorter pods. Many others are dwarfs with scarlet flowers, the pods being of an intermediate form of the dwarf type, yet rougher in flesh. No one feature has been fixed. Generally the seeds are reddish, and of the ordinary dwarf size. The great defect of the strain—which is undoubtedly of genuine hybrid character—is that no best form has been fixed. When at Basing Park last autumn I saw considerable breadths of the strain growing and fruiting. I selected one plant having scarlet flowers, carried in long racemes, yet of dwarf bushy habit, as the best. This was a great cropper, the pods long, green, handsome, and of fleshy texture. That was the best of all, and I strongly advised Mr. Smythe to make that one plant the starting point of the strain, hard roguing everything else that was not true to character. Of course, in putting a mixed hybrid strain into the market it was open to anyone who grew plants to make a selection of the same nature for himself. Naturally hybrid products take a good deal of fixing, and, even with the greatest care in selecting, several years may elapse ere that fixing is complete.—A. D.

**Onions.**—These from spring sowings are so good that there should be unusually fine crops of bulbs in the autumn. Something, whether previous season's drought or the exceeding abundant rains of the past winter, seems to have settled the maggot entirely, for I have not heard one single complaint even where two years since breadths were almost decimated. The same may indeed be said of Carrots. Recent heavy rains generally all over the kingdom have not only given to the soil that firmness which Onions so much like, but the moisture has accelerated growth unusually well. In too many directions sowing has been, as is so customary, too thick, and proper thinning left too long. It is, however, a very good plan to leave one or two rows rather thick to furnish, if wanted, small pickling bulbs; a few rows may be left half-thinned, and the rest properly thinned to ensure the production of plenty of large bulbs for ordinary use. The season should produce some wonderfully fine bulbs from plants sown under glass in mid-winter and planted out thinly in April, as growth is, with them, so rapid. There may be some danger, if artificial manure dressings are too liberally given, that stem growth may be too great and soft and ungainly bulbs produced. Keeping, in Onions, is so much a product of complete ripening that it is better to check undue growth rather than encourage it. Where the rains have been general, as in the London district for instance, Onions, now so deeply rooted, should do well without additional moisture for several weeks. Autumn-sown Onions should have the stems pinched or tied tightly round, so as to check leaf growth and promote bulb formation.—A. D.

**Early Peas.**—Peas are a fortnight later this year than they have been for the last four years. I sowed the following varieties on February 23: Lightning, Springtide, Blue Express, Chelsea Gem, Wm. Hurst, and William I. on a south border. Lightning was the first ready; three days later came Springtide and Blue Express; Chelsea Gem and Wm. Hurst will be a good ten days later; William I. is only just showing flower. I have tried most of the early Peas that have been recommended in THE GARDEN, but

Lightning has been the first ready for use during the last four years.—THOS. COCKERILL, *Gatehouse Gardens, Wirksworth.*

#### POTATO SHARPE'S VICTOR.

I CAN quite understand Mr. Crawford (p. 433) failing to get as good a return from Sharpe's Victor as he would like, as I have this season failed in the same manner and have been considering whether it is advisable to grow this kind so largely if it fails to crop as it has done this year. I think the difficulty is that we have not got the true stock of Victor which was sent out and the spurious kind often grown as Sharpe's Victor is totally distinct from the original. The stock may have become inferior, and in gardening phraseology worked out. Some kinds do this much sooner than others, and it may be so here. I am sure the stock I have at the present moment is so inferior that unless I can get it true it will be given up. For some years I saved my own seed, needing a lot for forcing, and all went well, as I had the true kind. Last season I was obliged to purchase, my own seed having been grown so long that I was under the impression it had deteriorated. Last year the crop was not good. Has Victor deteriorated, as the new seed is much inferior to the stock I discarded? Some readers of THE GARDEN may possibly be able to help us in this matter. The culture may be at fault. My soil, like Mr. Crawford's, is very light. How does it behave on heavier soil? I feed freely and the same culture has not produced such results with older varieties. For instance, I have had a stock of Alma, one of Victor's parents, for nearly twenty years, and it crops freely, but the tubers are small. This I have retained on account of its dwarf top. I got my last seed of Victor from a good source. There was no question as to price, and I am disappointed and feel it is only right to give these particulars to confirm Mr. Crawford's note. I much regret having to do so, as for years I have stood by Sharpe's Victor. With regard to Ringleader, I agree with all Mr. Crawford says in its favour. It improves as it is more largely grown, and next year it will have more space allotted to it. I have several early kinds on trial in the open. A I promises well, but Ninetyfold will, I think, be the heaviest cropper. I hope to send a note on a few of the earliest, and will then describe the best as regards crop as well as earliness. The weather up to a fortnight ago was most unfavourable for early Potatoes, but I notice Ringleader is, so far, ahead of the Ashleaves.—S. H.

— I am sorry to hear Mr. Crawford (p. 433) giving such a poor account of this old favourite. I force it in pots, and it has always done well. Outside it does very well. I have grown Ringleader two seasons, and am giving it another trial, but if no better than the last two years I shall discard it. The soil is very light, in some parts only 18 inches from the rock. I never manure for Potatoes.—T. COCKERILL, *Gatehouse Gardens, Wirksworth.*

#### SHORT NOTES.—KITCHEN.

**Pea Chelsea Gem.**—This valuable early dwarf Pea was ready for gathering with me on the last of May. The seed was sown at the end of January at the foot of a south wall on the top of the roots of Apricot trees. I have adopted this method now for six years with every success. The small round kinds do not find favour here.—J. CROOK, *Forde Abbey, Chard.*

**Sutton's Late Queen Broccoli.** It is a very important question to gardeners without the accommodation for raising early vegetables what to fill in the gap with before early Cauliflowers are ready. I see notes in THE GARDEN at various times respecting late Broccoli, but no mention of this variety, which has never failed me here in June and onwards for, I should say, twenty years. I sow about the middle of May and plant on solid ground, using no manure at the time of planting. It is a dwarf variety.—GEORGE BOLAS, *Hopton Gardens, Wirksworth.*

TREES AND SHRUBS.

THE JUDAS TREE.

(*CERCIS SILIQUASTRUM*.)

WHEN the leafless branches of the Judas tree are studded in May with a profusion of rosy coloured blooms, a good specimen, as in the illustration we give to-day, is a very beautiful object, and quite distinct from all other trees and shrubs that are then in bloom. Before the flowers fade the leaves begin to appear, the distinct shape and peculiar hue of these rendering

sauginea—to which, under the name of *E. langleyensis*, an award of merit was recently given by the Royal Horticultural Society—promises to be a valuable flowering shrub, while it should also serve to direct attention to the desirable qualities possessed by *E. Phillipiana* itself. This last, which is a native of Valdivia, had for a long time the reputation of being tender, but the last few years have proved its thorough hardiness, at least in most parts of England. It is totally unlike the other species of *Escallonia* that we have in our gardens, the leaves being very small, while the same may be said of the individual blooms. They are, however, borne in such profusion that the

among stones. It is a conifer that will thrive where most others fail, and its habit imparts that softened effect which we appreciate for toning down the harshness of an artificial rock garden. In winter its sombre green adds life and variety, besides being a capital foil for spring or winter flowering bulbs. In early summer the new growths further enhance the effectiveness of this true creeper by its pale blue-green tips. When we have quite focussed our studies of our good old things with a view to the best ways of employing them, this shrub, for its neatness, beauty and steady growth, will surely commend itself for extensive use.—J. W.

The Judas Tree at Mortimer, Berks. From a photograph by Miss Willmott, Warley.

the tree a notable object. Later in the season the large, flat seed-pods are very conspicuous, for the foliage at no time is very dense. The Judas tree is well suited for planting as a single specimen on a lawn, an old tree of it being generally a picturesque object. In common with many Leguminosae, the Judas tree will thrive fairly well in a dry spot. In such a position there is a fine old tree at Gunnersbury House which when in bloom is very picturesque. A good account of the Judas tree and its allies will be found in THE GARDEN of May 22 (p. 375) of the present year.

**Escallonia Phillipiana.**—The hybrid *Escallonia* raised between this species and *E. macrantha*

long, arching shoots are completely wreathed with them. This *Escallonia* is seen to advantage when forming a mass or clump on the grass, as the slender shoots dispose themselves in a very graceful manner, the lowermost ones sweeping the turf, while strong examples will reach a height of 6 feet or so, which under favourable conditions will probably be exceeded. The value of this *Escallonia* is enhanced by the fact that its masses of white blossoms are not produced till the majority of our flowering shrubs are over; that is to say, about midsummer or later. It is now met with in the various tree and shrub nurseries, but although moderate in price, it is rarely planted.

—T.  
**Juniperus prostrata.**—Beyond all doubt this is one of the best shrubs we have for planting

EMBOTHRIUM COCCINEUM

THE propagation of this gorgeous-flowered South American Protead is referred to on page 458, where it is said to be a difficult subject to strike from cuttings. This is quite correct unless special means are resorted to. I have often tried to strike the cuttings taken from large plants in the open ground, but in this way met with little success. Being, however, particularly anxious to strike a number of cuttings, and having a couple of plants 4 feet or 5 feet high in pots, I resolved to try the experiment of what is technically called drawing out the cuttings, that is to say, the plants were kept warmer and closer than they had hitherto been, with the result that the shoots produced under such conditions were much more attenuated than if they had grown out of doors or in a cool greenhouse temperature. When partially ripened, that is, just as these shoots had lost their extreme succulent character and become slightly firm, they were taken off at a length of about 4 inches, the cut being cleanly made just below a joint, and the bottom leaf or leaves having been removed, they were dibbled firmly into pots of very sandy peat. Pots 4 inches in diameter are particularly suitable for the purpose, as four or five cuttings can be inserted around the edge of the pot, in which position they strike root more readily than if they are put in the centre. In preparing the pots for the *Embothrium* cuttings, they should be well drained to about one-third of their depth with broken crocks. From their liability to flag, no time should be lost in inserting the cuttings after they are separated from the parent plant. The cuttings that I was so successful with were placed in a close propagating case in an intermediate house temperature, and subjected to exactly the same treatment as those of Javanese *Rhododendrons*, with which they were associated. In this way nearly every cutting rooted, when they were hardened off and potted singly into small pots, using principally sandy peat with a dash of good yellow loam. This process of drawing out cuttings in the manner detailed above may be advantageously employed in the case of many plants which are difficult to root. Where only large specimens in the open ground exist, layering is, as stated on page 458, the best means of increase. The entire order to which this *Embothrium* belongs (*Proteaceae*) is, with few exceptions, a difficult class to strike root from cuttings. Some of the *Grevilleas* are not particularly difficult, while I have also struck various kinds of *Hakea*, *Lomatia*, and *Protea*, but these cannot be depended upon, and all attempts with *Banksias* and *Dryandras* ended in failure. H. P.

**Ostrowskia magnifica alba.**—Hitherto I had seen this plant only in its ordinary colour—rather

a dull lilac—and, in common with many others, I considered it much over-rated. This year I have in my garden one which is pure white, of great beauty, and as much superior to the lilac as is the white *Abutilon vitifolium* to that of the ordinary colour; nevertheless, both these are well worthy of a place, whether in the open or near a wall. A white variety of another plant—*Geranium sanguineum*—has been rather recently introduced by Mr. Amos Perry, and it is most valuable as a companion to the brilliant crimson plant with which we all are so familiar. Where this has been found—whether in England or abroad I do not know—but on the sand-dunes or “links,” as they are called on the Northumberland coast, where the type is very abundant, I have sought for it over hundreds of acres, and sought in vain.—T. H. ARCHER-HIND, *South Devon*.

### A BEAUTIFUL ROCK GARDEN.

IN my notes on “April in South Devon” (p. 367, vol. xlix.) I alluded, shortly, to the charming rock garden of Mr. G. Soltan-Symons at Chaddlewood, near Plympton. This year, on June 1, I had a second opportunity of inspecting it. The garden, which is situated in a sheltered position at the foot of a steep slope, is particularly interesting from the fact that it is the expression of one mind—the owner’s. Every stone was placed in position, if not by himself, under his personal supervision; every denizen of the garden was planted by his own hands, while every weed or subject intentionally exterminated owed its destruction to the same nemesis.

The rockwork is throughout natural in appearance, some of the masses that hold a conspicuous position being of exceptionally fine form, while it affords sites to suit the tastes of the most fastidious rock plants, perpendicular crannies and level soil-patches, shady nooks, and full exposure to the sunlight. Since the formation of the garden many changes and improvements have been thought out and carried into effect, and a further addition is contemplated in the near future which should still further increase its attractions. Beautiful as a whole when viewed from some distance, a closer inspection reveals many exquisite vignettes of flower, Fern and rock; some—complete pictures—but a foot or so in size, but none the less delightful on that account. It may be at once premised that the rock garden of which I write, though containing a large amount of alpine plants, is not an exclusively alpine garden, subjects that commend themselves for beauty of form or colour being utilised as discretion suggests, independently of the section to which they belong.

Thus at the time of my visit *Phacelia campanulata* made breaks of vivid blue; flame-coloured Azaleas on the higher levels were just out of flower, while here and there Japanese Maples spread their deeply-cut bronzed foliage from coigns of vantage. Of alpine plants, the Edelweiss (*Gnaphalium leontopodium*) was in fine bloom. An excellent engraving, from a photograph by Mr. Soltan-Symons, appeared on p. 225, vol. xlii., over the title “The Edelweiss in a Devonshire garden,” and shows to what perfection the culture of this beautiful alpine is here brought. *Achillea rupestris* and *tomentosa* were both in bloom, as was the golden *Alyssum saxatile*. Four *Androsaces* were blooming, a splendid mass of *A. lanuginosa* covering a height of many feet of rough rockwork with its matted foliage and softly-tinted flowers, the other varieties being the white *A. lanuginosa* Leichtlini, *A. foliosa*, and *A. sarmentosa*. *Ethionema coridifolium* was bright with its rosy purple flowers, and the blue stars of *Aster*

*alpinus* stood out well against the grey rock, whilst alpine *Phloxes*, *Armerias* in variety, the white *Arenaria montana*, alpine Wallflowers (*Cheiranthus alpinus*) and *Aubrietias* were all in bloom, as was *Andromeda Catesbaei*. Candy-tuft Little Gem quite deserved its appellation, and dwarf *Campanulas* were in profuse bloom, while of the Rock Roses, *Cistus florentinus*, *C. formosus* and a pink variety were in flower, but *Cypripedium Calceolus* had gone out of bloom. Amongst the Pinks, *Dianthus alpinus*, *D. sylvestris*, and the well-known brilliant crimson Napoleon III. were noticeable, while the yellow-flowered *Draba bruniæfolia*, purple *Edraianthus* (*Wahlenbergia*) *serpyllifolius*, and the rose-coloured *Epilobium obovatum* were adding each their varied tint to the display, and the Mexican Daisy (*Erigeron mucronatus*) was thus early in the season a mass of flower. *Gentiana verna* was still in bloom, and the white *Erodium Reichardi*, from the Balearic Isles, seemed quite at home. In the bright morning sunlight the *Helianthemums*, white, yellow and red, held wide-spread the petals of every blossom. *Fabiana imbricata* was a pyramid of Heath-like bloom, and the dull red *Geum minimum* showed its flowers. Of *Genistas*, the handsome golden and chestnut *G. Andraena*, a white Broom, and *G. sagittalis* were in bloom, and the scarlet flower-spikes of *Heuchera sanguinea* showed prominently. The cool lavender-white *Iberis gibraltarica* and two of the *Lychnis* family, *L. Lagascea* and *L. viscaria splendens*, were in flower, while a plant of *Lotus peliorrhynchus*, a native of Tenerife, was producing its orange-scarlet blossoms freely from a rock-pocket. The Sand Myrtle (*Leiophyllum* (*Ledum*) *buxifolium*), with its white blooms, and the dark blue *Lithospermum prostratum* were both flowering well, while the Welsh Poppy (*Meconopsis cambrica*) is here, as in many places in Devonshire, a veritable weed. Curiously enough, seed collected and sown during the spring in pans often fails to germinate, but self-sown seedlings spring up everywhere among the rocks, in the paths, and in the neighbouring beds. Its tall drooping flower-heads of bright gold and its deeply-cut foliage make it one of the most attractive of the Poppies where it is kept under due restraint. Another yellow flower in bloom was the Sardinian *Morisia hypogaea*, while *Onosma tauricum* provided a lighter tint of the same colour. One of the most beautiful blues imaginable was that of the Rock Forget-me-not (*Myosotis rupicola*), and the Evening Primroses were represented by two varieties in bloom, *Oenothera cardiophylla* and *O. pumila*. The lovely *O. marginata* grows very strongly here, but had not commenced to bloom at the time of my visit. Two gems of the rock garden were *Oxalis alba* and *O. rosea*, with lowly flowers clustering closely to the trefoiled leaves. The violet *Phyteuma orbiculare* and the crimson *Polygonum sphaerostachyum* were both in flower, and the Rose des Alpes (*Rhododendron ferrugineum*) was studied with its crimson-pink blooms, while one of the prettiest sights of the rock garden was provided by a colony of the delicately tinted *Ranonda pyrenaica* blossoming delightfully under the shadow of a perpendicular rock. Of *Saxifrages* twenty-four varieties are grown, amongst which the handsome *Cotyledon*, with its long curving spikes of bloom, was in splendid flower, as were *S. cochlearis*, *S. sarmentosa*, *S. umbrosa*, and *S. Wallacei*, which last is strikingly handsome. In the grass under some deciduous trees the double Meadow Saxifrage (*S. granulata* fl.-pl.) must have been a beautiful sight a few weeks earlier, the sparse remaining bloom-spikes giving an idea of the picture presented, when from the

short green grass beneath the springtide canopy of the Elms the white flowers clustered thickly around the dark boles. *Sedum spatulatum*, *Sisyrinchium bermudianum*, and *Veronica prostrata* were blooming, as well as a small white *Veronica*, while the white Thyme made bevelled mats of flower and foliage between the rocks.

Many rare Ferns grow in this rock garden, the beautiful Oak Fern (*Polypodium Dryopteris*) seeding itself everywhere, while fine masses of *Adiantum pedatum* grow here and there. *Oncoclea sensibilis* also does well. In the ground surrounding the rock garden were some splendid specimens of *Abutilon vitifolium*, many feet in height, and covered with large lavender-white flowers which were very effective. Of *Acers* there were many varieties both amongst and around the rocks, perhaps the most striking being *A. polymorphum dissectum* and *A. p. palmatum*. Large bushes of *Diplopappus* and *Choisya ternata* grew among the *Rhododendrons* and Azaleas that crowned the slope, while slender Bamboos, Yuccas, and Palms, two specimens of *Chamaerops* showing flower, gave their grace of form and delicacy of outline to the picture. Hard by a *Benthamia fragifera* was in flower, and a plant of the lovely Californian Poppy (*Romneya Coulteri*) was looking well for summer bloom; a layer that had been taken off and planted near looked every whit as healthy as the parent, and evidently had not resented root-disturbance after the disastrous manner so common with this subject.

*Tropaeolum speciosum* seems thoroughly established at Chaddlewood, and is growing strongly amidst other climbers on wall and arbour. It has also been planted near some Yews so that it may wreath its scarlet trails through the glossy darkness of the evergreen. Of the fine herbaceous garden, with its Rose arches and its rare and beautiful occupants, I have now no space to speak. Possibly later in the year I may be privileged to refresh my memory by a further introduction to its occupants. S. W. F.

## GARDEN FLORA.

### PLATE 1125.

ADONIS.

(WITH A COLOURED PLATE OF *A. AMURENSIS*.)

IN those gardens where the vernal Adonis is a success it would be difficult to name any plant capable of yielding so great a profusion of blossoms. Generally speaking, the species resent close proximity to large smoky towns, and likewise to being planted in a cold, stiff clay soil. In a pure country air and a soil that is light, deep, and well drained, these plants succeed admirably. Where this is the case it is surprising what may be accomplished by exercising a little extra care with them at planting time. The most plentiful kind is *A. vernalis*, and of this alone large importations are received each year by the hardy plant specialists and offered at a cheap rate. The most unfortunate thing in connection with this plant is that these collected plants are so ruthlessly torn up prior to being sent to this country, that only the stumps of their roots, often not more than 2 inches in length, remain. Needless to say that such mutilated fragments rarely survive when planted. It is possible, however, even with such poor plants at the start to obtain a fair measure of success where a little care is given as soon as

\* Drawn for THE GARDEN by H. G. Moon in the Royal Gardens, Kew. Lithographed and printed by J. L. Goffart.

AE NI AN ASPH

the plants are received. Coming to hand in the autumn of each year, these collected plants are distributed during the ensuing months, and when planted at once in heavy soils the old root stumps that are attached quickly decay, and the plants are lost. A large number of these, however, could be saved provided the plants were simply laid in a box of cocoa-nut fibre without soil of any kind. Give a good watering and place them in the open on a bed of ashes. So long as the plants are made rather firm and kept moist, no other attention will be needed till the spring ensuing, by which time it will be found that large numbers of fibrous roots will have issued from the old stumps sufficiently to warrant their being at once planted. Where the soil is cold and stiff it must be lightened by grit and leaf-soil if the *Adonis* is to be grown with success. In very light soils, particularly such as quickly become dust-dry in summer, I have employed large quantities of well-decayed cow manure with much success. In the district of Hampton I have been singularly successful with this *Adonis*, and in a couple of years, by the simple means quoted above, have raised the finest examples I have ever seen from the quite small scraps of imported plants. After two years' growth in the heavily-manured soil here a group of plants about 20 feet long by 5½ feet wide attained to fully 18 inches high, flowering in the greatest profusion and bearing quantities of glistening golden blossoms, each nearly 5 inches across. Grown in this way this *Adonis* is one of the finest of our hardy alpine in early spring, growing and flowering and seeding with the greatest possible freedom. It will, moreover, send its roots down fully 2 feet where the soil is good and permits, and for this reason it should not be planted in the rock garden where but a very thin bed of soil exists. Too frequently, however, because this or that plant is an alpine, a mistaken notion of its requirements appears to gain ground, and many plants are set out where the soil is of the scantiest description. And though this may be true of these very plants in their native habitats, it may be equally true that their roots descend where drought is unknown. Under these circumstances a merely superficial knowledge of the surroundings of many good alpine may not unfrequently tend to mislead. On the other hand, a close scrutiny of the natural habits, combined with past knowledge and experience in our lowland gardens, should greatly assist the grower of hardy plants. All the species of *Adonis* may be raised from seed, and where good plants exist these produce flowers and seeds quite freely. The plants may also be increased by division, preferably late in summer, as soon as the seeds are ripe and gathered. Care will be needed in this, and only the point of a knife should be inserted in the woody portion of the rootstock, and having made an incision, gently wrench the stool asunder. Both seeds and collected plants of *A. vernalis* and *A. pyrenaica* are so cheap, that I would hesitate before cutting up any large clumps, as these are by no means plentiful, preferring to obtain some collected plants in the autumn if established home-grown clumps were not obtainable. Of the perennial kinds—

*ADONIS VERNALIS* is the best. Well grown, its handsome golden blossoms, that appear in March and April in the open, are often each 4 inches or 5 inches across, the plants reaching 1½ feet high. It is perhaps unfortunate that so good a plant when exhibited in spring is rarely more than 4 inches or 6 inches high, and the blossoms, small in proportion, usually fail to give a good idea of its beauty or worth. It is a very old plant, having been grown for more than a couple of centuries.

A variety of *A. vernalis*, viz., *A. v. sibirica*, differs only in its larger flowers, the handsome tufts of finely-cut leaves being much the same as in the type.

*A. PYRENAICA* is a closely allied plant from the Eastern Pyrenees, flowering somewhat later and with rather smaller yellow blossoms and more obtuse petals than in the European kind. It is in all respects a first-class border or rock plant, and where at least a foot deep of good rich light soil can be given, it will soon become established.

*A. VOLGENSIS* is a distinct species from Russia, with leaf characters intermediate between *vernalis* and *pyrenaica*, while the flowers are distinct from those of both in that the sepals of this species are pubescent externally instead of smooth, as in the better-known kinds. The flowers are yellow, each nearly 3 inches across, and appear in April or May. The earliest of all to flower is

*A. AMURENSIS*, the beautiful kind in the accompanying plate. For the past two seasons this species has flowered well at Kew in the rock garden and in the open beds. It was in its best form in the former position, as though approving of a certain amount of shelter so early in the year. This year its blossoms began to open in the first week of February, and though somewhat later the plants were laid level with the earth by snow and frost, they received no injury therefrom. Such an addition to early hardy flowers will be most welcome, and even when the flowers are past there is a considerable lasting beauty in the Davallia-like, finely-cut leaves, the latter quite distinct from those of the other species named. So far as the general character of the flowers is concerned, the plate will speak for itself; while in size they are 3 inches or so across when fully open. Judging by the plants at Kew, the progress of which I have watched with interest, this beautiful plant is of quite easy culture, and in all probability will prove as vigorous and free both in growth and flower as the Vernal *Adonis*, only flowering some weeks before this species. *A. amurensis* is a native of Manchuria, in Northern China, and coming into bloom in this country with the early species of *Crocus*, the Snowdrop, and the Snow Glory should render it conspicuous among choice early flowers in the future.

There are some annual species, though these are much inferior to the perennial sorts. Of the former, *A. aestivalis* and *A. autumnalis* are best known, both kinds having deeply coloured flowers. E. J.

## BOOKS.

### FARM AND GARDEN INSECTS.\*

THERE have been several books published lately on insects which are injurious to our crops; the latest is by Mr. W. Somerville on "Farm and Garden Insects." It is a small duodecimo volume of only 127 pages. Its *raison d'être* is not very obvious, as it does not contain anything new or which cannot be found in other works. It certainly is much smaller than the others, but then it does not include the numerous insects which attack fruit and forest trees. There are, however, many to whom this little book will be useful, notwithstanding the following adverse criticisms, as it contains in a condensed form a large amount of valuable information. It is illustrated with forty-six woodcuts, or, to be strictly correct, with forty-five, and one process block. These are mostly very poor and coarse, that of the Cabbage moth on p. 83 being quite unrecognisable. The frequent use of scientific terms in a book of this description is a great mistake, particularly when, as in this case, there is no glossary. On one page taken at random, the expressions "geniculate clubbed antennæ" "with a six-jointed funiculus," and the term "imagines" are used. What can an ordinary gardener or farmer be expected to understand from the above quotations? Again, such terms as "pergamen-

\* "Farm and Garden Insects." By William Somerville. Macmillan and Co., Limited.

tous," "dorsal surface of the meso-thorax," "caudal appendages," "parthenogenetically and viviparously" are out of a place in a book of this description. The first eighteen pages are devoted to descriptions of the anatomy of insects, their transformations, methods of reproduction, classification, &c. It is not correct, however, when speaking of the grubs of flies to say that they are "generally headless and footless." Many, but not all, have not well-defined heads, but the heads are there; nor do "certain clear-winged moths so closely resemble hornets or wasps as almost to defy recognition." The resemblance is very considerable, but no one with any knowledge of insects could mistake one for the other. In speaking of the Crustacea, the author is evidently under the impression that there is only one kind of wood louse. This is quite wrong, as there are several, and instead of "their being practically of no economic importance," they are most injurious and troublesome pests in gardens. Again, in the appendix when speaking of the *Julidæ*, or snake millipedes, the author says, "Instances of material damage having been done to plants by millipedes are very rare." This is most ridiculous, as the amount of damage which they do the roots of many plants is enormous, and they often attack ripe Strawberries. Among the "preventive and remedial measures" in the case of wireworms, powdered rape-cake is said to be distasteful to them. This is only partly true, for they are very fond of the English rape-cake, and it is used at times to attract the wireworms from the crop; but the Indian, or Karachi cake, which is made from mustard, is distasteful to them. In mentioning the Rose chafer (*Cetonia aurata*) no mention is made of the grubs which very much resemble those of the cockchafer, and are equally destructive to the roots of plants. At the end of the description of each insect, under a separate heading the appropriate "preventive and remedial" measures are given, but nothing is said to show which are preventive and which are remedial.

### AMERICAN WOODS.\*

Mr. Hough sends us part 1 of this unique publication, in which the woods of America are shown in all their beauty of colour and texture by actual specimens instead of by pictures, the ordinary method of illustration. For the practical training of the architect, builder, wood-carver, joiner, cabinet-maker, &c., nothing could be better than to have sections of the actual woods to study from, and the work will probably commend itself to the notice of the heads of technical schools in Britain, as it has already commended itself to the educational authorities in America. The products of the American forests are inexhaustible and in beauty unsurpassed. Mr. Hough has brought them to the notice of the interested public in a way which makes it impossible they can be ignored by giving us, we might almost say, living pictures of them at a price which cannot be called an adequate compensation to him. We wish the publication all the success it is certain to achieve, as it certainly deserves it.

### HOW TO GROW BEGONIAS.†

TEN years ago the lovers of the tuberous *Begonia* were wont to describe it as "the flower of the future." Whatever may have been the aspirations of those who bestowed this prophetic name upon their favourite, there is no doubt that some important advance has been made in its cultivation and popularity, and that the transformation of the tuberous *Begonia* has been very largely brought about by such eminent growers as Messrs. Laing, Cannell, Jones and others in this country, while on the Continent, M. Crousse, of Nancy, has materially contributed to its improvement.

\* Hough's "American Woods." Part 1. By Romeyn B. Hough, Lowville, New York.

† "How to Grow Begonias." By G. A. Farini. (Sampson Low, Marston and Co.)

When a flower begins to attain to more than ordinary popularity its literature is sure to increase, and the tuberous Begonia is no exception to this rule. In style and get up generally, M. Farini's treatise will compare very favourably with any of its predecessors, for it is well printed on good paper and typographically leaves little or nothing to be desired. There are also several illustrations explanatory of the text. The work is divided into three main divisions, to which are added an appendix containing lists of the varieties grown by the leading specialists. Part 1 is mainly introductory, and the construction of a cheap greenhouse and heating apparatus forms an important feature of it. Part 2 deals with hybridisation, seed sowing, storing, starting the tubers, propagating, diseases, &c. Part 3 explains how to grow fine specimens for exhibition, and gives the names of various sorts described and recommended.

## FLOWER GARDEN.

### BRUGMANSIAS IN THE FLOWER GARDEN.

It is surprising that Brugmansias should not have become more popular as sub-tropical plants. The only possible reason why their culture has not been extended in this direction is from want of more room to store them away during the winter. The old-fashioned lofty greenhouse used to be well suited to this purpose, but it does not follow that no other place is suited to keep them during the resting period. The plants can be well kept in fairly dry cellars, being lifted from the open ground when first nipped by the autumn frosts. No large ball is required so long as a fair amount of roots is preserved, these and the base being protected by plenty of fairly dry soil. When stored in such a place, all the foliage may be removed. Where Brugmansias can be grown in large tubs and stood outside during the summer, taking them indoors when danger from frost is apprehended, it is possible to always turn them to good account when put into a slightly heated house. We remember to have seen some years ago some young plants which during the summer had made rapid growth in the open ground. So much was this the case, that they did not show for flower till the autumn frosts came. These were lifted, potted carefully and placed in ainery closed for early forcing. Here they soon became established and flowered most satisfactorily, the blooms coming in very useful for cutting at a dull season. When grown in tubs the plants can remain undisturbed for several years, firm potting in good loamy soil being observed.

In selecting a spot for planting Brugmansias outdoors some amount of shelter should be given, so as to protect the plants from high winds. A well-proportioned plant will make a good central object in a large flower bed, a ground-work being formed of some dwarfier plant, as in the illustration. The plant illustrated was raised from a cutting in Lady Thompson's garden at Guiseley, Yorks. It was planted out in June, 1895, and flowered twice, the beautiful white blossoms lasting till the first frost in October. P. T.

**Tufted Pansy Lucy Franklin.**—This is a very pretty rayless flower and of large size, while the plant is also free flowering. The colour is creamy white, the lower petal being suffused with yellow, thus making a pleasing contrast in each flower. Some masses in Mr. Sydenham's garden were exceedingly interesting recently, and intensified the fact of its usefulness when grouped in a large bed by itself. The constitution is good, and those on the look out for a pleasing

novelty would find in this one a pretty change.—C.

**Tufted Pansy Sir Robert Peel.**—In this the blossoms are of medium size and produced on long erect footstalks. The colour is best described as a deep primrose self, with orange eye, a shade of colour somewhat new. The habit is all that one could wish for, the growth spreading out along the ground something after the manner peculiar to Duchess of Fife and its sports. The flowers are freely produced and they are also rayless. Being a fixed colour, too, should be a distinct point in its favour.—D. B. C.

**Tufted Pansy Isa Ferguson.**—This is one of the darkest of the fancy type of the Tufted Pansies, and created a deal of interest in Mr. Septimus Pye's stand last year at the exhibition of the National Viola Society. The lower petals are almost velvety black, with a light blotch of blue on each petal, the upper ones being a pretty glossy blue. As an exhibition sort it is very useful, and may also be welcomed in the flower garden where blooms of this type are required. It is a free-growing sort and carries its

substance, and its colour is a fixed pale yellow. Those who know the variety Lemon Queen will appreciate this variety when it is stated to be of a similar shade of colour, perhaps a trifle darker, and the rays at certain seasons are heavier in character. The habit of this variety will prevent its use with those of a more tufted and less vigorous growth, but massed in a bed by itself it is very effective.

**Late-planted Spanish Irises.**—Last autumn I proposed planting a batch of Spanish Irises late in the season in the hope of prolonging the season of blooming. I also asked whether any reader had tried the experiment and with what result. "E. J." replied, stating that he once tried the experiment, but that it was practically a failure, as growth instead of being normal was weak and stunted, and that those which grew flowered simultaneously with those planted in November. This is exactly my experience; indeed, not only am I now cutting blooms from both batches, but those on the late lot are far inferior to the others. The only way of prolonging the season is by planting in different aspects,

*Brugmansia in the flower garden at Park Gate, Guiseley, Yorks.*

flowers on long footstalks. The habit, too, is somewhat better than is generally the case in these kinds.—H. N.

**Tufted Pansy Pembroke.**—So far as one is able to judge after growing a large number of new yellow sorts alongside of the older ones, this variety appears to stand out distinctly from many others as a sort that has come to stay. The flowers are of large size, rich clear yellow, fragrant and freely borne. Most important of all, its constitution is robust, and although the habit is not so dwarf and compact as one expects in the newer introductions, yet its many good points stamp the variety as one of the very best rayless yellow sorts of the last two or three years. This was raised at Tamworth last season, and already many thousands have found their way into gardens all over the country.—C.

**Tufted Pansy Lord Salisbury.**—This is probably one of the most vigorous growing sorts of recent introduction, but, although so very strong in its growth, it does not get so ungainly as many others. Its chief points of merit are large, circular, bold-looking blossoms of much

those on a north border in a deep, moist soil coming in ten days later than where the sun reached them. Canary Bird, yellow, and Lady Blanche, white with yellow throat, are excellent.—J. C.

**Iris hexagona var. La Mance.**—This remarkable variety is now in flower in my garden, and it is, I think, the finest Iris among the known North American species. The falls, which are considerably over 2 inches in length, are of a rich purple-blue, shading to white, with a slight marking of yellow down the claw. The styles are light green, and the green colour of the centre of the flower is a noticeable feature, adding to its beauty as well as distinctness. Both standards and falls are of spreading habit. I am indebted for my plant to the great kindness of Mr. J. N. Gerard, of Elizabeth, New Jersey, by whom it was named, and by whom it is described in some notes which will be found in THE GARDEN, vol. XLVIII., p. 245. Mr. Gerard tells me he finds it hardy with him. This I have not proved, though I think it likely that it would prove the same in the majority of gardens in the south of England,

but it is quite evident that this variety possesses what Mr. Gerard claims for it, viz., a propensity to bloom freely, a quality which is somewhat conspicuous for its absence in the typical *L. hexagona*—a plant, by the way, which, partly perhaps from this fault and partly from its doubtful hardiness, is seldom met with in English gardens.—J. C. L., Maidstone.

## STOVE AND GREENHOUSE.

### CLERODENDRON FALLAX.

PERHAPS this is the best of all the shrubby species of *Clerodendron*, and if only its culture were taken up with the vigour its merits entitle it to, it would run the climbing kinds hard for a place in popularity. It is not difficult to grow, and one of the most effective of stove plants. The present is the flowering season, later plants carrying the display into August or September. The panicles of flower are bright scarlet. To keep the plants in flower as long as possible, place them in a cool, partially shaded house. The conservatory in some places is very unsuitable to stove plants even while resting, and in such this *Clerodendron* should not find a place while in bloom; it would, nevertheless, be wrong to say it is unsuitable for conservatory decoration. While in flower the plants must not be too much dried, but the fact must not be lost sight of that the apex of the season's growth has been reached, and when once the blossoms are over, the sooner in reason the plants are cut over for the season the better. This allows of the stems being made into cuttings, while the old plant must be kept on the dry side afterwards. During the winter the house in which this *Clerodendron* is grown should be kept warm, as being a native of Java too little heat is dangerous. As long as it is kept dry it will take no harm in a minimum temperature of 60°, but far below this it is not safe to go. The plants should not be repotted until they have made a little growth, just an inch or so to show that the roots are moving; then they may be repotted, single-stemmed plants flowering finely in 7-inch pots and larger ones in a size or two larger. Drain the pots well, and prepare a mixture of sound fibrous loam and peat with a plentiful addition of well-dried cow manure, for these plants have a lot to do in a few months and are gross feeders. It would be wrong to say pot loosely, yet the material must not be too tightly rammed, and where the loam is of a nature prone to run close, add a plentiful sprinkling of the best coarse silver sand. The plants may be then taken to a house with a brisk moist temperature, grown on rapidly until the flowering season, and if they can have the assistance of a little bottom-heat at starting such as is afforded by plunging in tan or similar material, it puts them rapidly out of harm's way in the matter of the drying off of the young shoots. This they will do sometimes after disturbance, and it is necessary to be very careful with the watering at first. Soot water well diluted is an excellent stimulant to this plant when the pots are filled with roots, and the same material sprinkled about under the stages and used for damping floors is of material benefit owing to the ammonia which it generates in the atmosphere. Insects dislike this kind of moisture, especially scale and its near relative mealy bug. Considerable trouble will be found with plants infested with the latter, but if taken in hand when only a few insects are present these may be easily destroyed. I once cleared a nice lot of this plant by dipping a very fine-

pointed brush pencil in methylated spirit and touching the insects with this. Heavy syringing is not advisable, but light dews in the earlier stages can do no harm. As mentioned above, this plant may be propagated by cuttings, these consisting of lengths of the stems when cut down. Any bit with about three or four joints will strike if placed in pots of sandy soil, thoroughly soaked with water and plunged in a propagating pit. R.

**Evergreen Begonias.**—Since the introduction of the many beautiful forms of summer-flowering *Begonias* the winter-flowering or evergreen section seems to have fallen into the background. Some of the varieties, however, such as *fuchsoides* and *weltoniensis*, are amongst the most useful subjects for general decoration at a time when flowering plants are none too plentiful. They are most accommodating, as if the main batch of plants is brought on in a comparatively cool temperature and a few introduced into more heat at intervals, an almost continual succession of bloom can be maintained. A mixture of good fibrous loam three parts and one part peat, leaf-mould, and silver sand suits them well. Some successful growers give a small quantity of thoroughly decomposed cow manure. The best way after flowering is to keep the roots slightly drier for a short time and then cut back, shake out, reduce the balls, and repot, giving them a genial moist temperature. *Begonias* will do well for as long a time in small pots as most things, but if large bushes are desired, liberal shifts must be given. *Weltoniensis* looks exceedingly well grown in baskets and suspended from the roof of a warm conservatory, and some of the others are equally good for this purpose.—GROWER.

**Euphorbias.**—For brilliancy of colour and usefulness in drawing-room and dinner-table decoration there are few things blooming in the dead of winter that pay for attention better than *Euphorbias*. *Jacquiniaeflora* is no doubt the most valuable, as its habit of growth allows of its being grown in the ordinary way in pots. Splendens, on account of its spiny nature, requires really to be grown so that its growths can be trained over a wall or trellis. Either in a pot or planted out and liberally treated, *E. jacquiniaeflora* will soon cover a good space and supply innumerable bracts, which are invaluable for bouquets or button-holes. Both varieties may be increased by cuttings, but some care is necessary. After detaching them from the parent plant, allow the milky matter which oozes from the cuttings to dry up. Young rooted plants need growing on in a strong, moist heat, giving them a mixture of loam, peat, a little leaf-mould, and sufficient silver sand to keep the whole open. If bushy plants are required for ordinary plant stove decoration, pinching once or twice must be practised; but the finest bracts of *Jacquiniaeflora* are produced on unstopped shoots, which will sometimes reach a length of several feet. Old or one-year-old plants should have a rest after flowering and be kept dry at the roots, being pruned back about May, and when started, shaken out and repotted in good fresh compost, afterwards treating them to a brisk, moist heat and a light position near the roof glass, shading a little during bright sunshine. A number of yearling plants should always be kept in case the cuttings should not strike satisfactorily.—J. C.

**Abutilons in winter.**—There are now many very beautiful varieties of *Abutilons*, and plants when well grown are most useful for winter decoration, the blooms being also well adapted for arranging in small glasses. For the production of good bushy plants for late autumn and winter work, cuttings should be taken in February. A few old plants may be cut back and placed in a gentle moist heat, and when the new growths are an inch or so long, they strike pretty readily if placed under a bell-glass or handlight in a gentle bottom heat. As soon as growth has started, a little air must be admitted, this being

gradually increased until the glass is entirely removed. When 1 inch or 2 inches of growth has been made the cuttings should be potted off into small pots, placed near the glass in an intermediate house and carefully watered till well established. The next shift may be into a 4½-inch pot, still keeping them in the same quarters and syringing the plants on fine sunny afternoons. Towards the end of May a warm pit or frame will be the best position for them, and if gradually inured to the air they may be fully exposed on calm, warm days in June. Some growers stand the plants out in the open during summer, and if this is a dry, sunny one they do very well; but *Abutilons* are very impatient of water at the roots, and any excess of this soon produces a yellow, unhealthy condition of the foliage. If the young plants are pinched when say 6 inches high, good stocky plants will be formed. Manure water may be given in a weak form when the plants are in full growth, and if they are wanted to flower as late as possible or right through the winter, any early-formed blooms should be removed. In October a light airy house, with a night temperature of 50°, suits them best.—GROWER.

## SOCIETIES AND EXHIBITIONS.

### ROYAL HORTICULTURAL SOCIETY.

JUNE 29.

A TRULY wonderful display has to be recorded on the above date. A finer exhibition as a whole has never been seen in the Drill Hall. It is to be hoped that some at least of the many visitors now in the metropolis took the advantage of inspecting it; at any rate there was a good attendance of Fellows and others interested in gardening. Hardy flowers were strongly in evidence, notably *Roses* and hardy border flowers. Of *Roses* there was a great diversity, and it was a welcome sight to see that "garden" *Roses* were well represented as contrasted with "exhibition" varieties. The competition in the *Rose* classes was, on the whole, very good, whilst the quality was excellent. *Orchids* were not so conspicuous, but a grand group was sent by Messrs. Veitch and Sons. There were a few excellent examples of fruits, notably of *Peaches*, *Plums*, and *Cherries*. Two of the most notable groups on this occasion were the grand display of conifers, rich in the golden and glaucous forms, and the superbly flowered specimen plants of *Malmaison Carnations*, the former from Messrs. J. Veitch and Sons, and the latter from Mr. J. P. Morgan, Dover House, Roehampton (gardener, Mr. McLeod).

### Orchid Committee.

A first-class certificate was awarded to

**LELLO-CATTLEYA EUDORA SUPERBA** (C. Mendeli crossed with *L. purpurata*).—The sepals and petals are delicate rose veined with a darker shade of colour, the lip rich crimson-purple in front, the side lobes white shading to yellow at the base, where it is lined with purple to the base. The plant is intermediate in character between the two species both in the shape of the flower and habit of growth. From Messrs. J. Veitch and Sons.

An award of merit was given to

**CYPRIPEDIUM MRS. E. V. LOW**, in which the dorsal sepal is white, shading to green at the base, and thickly spotted with dark brown spots. The petals are white slightly suffused and veined with purple, lip pale greenish-white spotted with purple. The plant carried two flowers. There is no doubt *C. niveum* has been used in its production. From Messrs. Hugh Low and Co.

Messrs. J. Veitch and Sons were awarded a silver *Flora* medal for a large group, prominent amongst which was a large specimen *Cypridium superbiens* (Veitchi) with upwards of twenty flowers. *C. Parishii* was represented by a huge specimen with four spikes of flower. Several grand forms of *C. Curtisi*, *Dendrobium Phalen-*

opsis Schröderæ, *Dendrobium glomeratum* with extra large, finely coloured flowers and *D. porphyrogastrum* (D. Huttoni crossed with *D. Dalhousianum*), sepals and petals pale lilac, lip flat and open, the front of the same shade of colour as the petals, were also shown. *D. illustre*, a hybrid between *D. chrysotoxum* and *D. Dalhousianum*, sepals and petals bright yellow, highly polished, the lip about 1 inch in width, the front half yellow, margined and thickly covered with hairs, was also noteworthy. Amongst the hybrid *Cattleyas* were *Lælio-Cattleya eximia* (L. purpurata × C. Warneri), sepals and petals deep rose, lip rich crimson-purple, margined with rose in front, the base deep yellow, lined with brown; several forms of L.-C. *Cambamiana* and L.-C. *Ascania*, the sepals pale yellow, shaded with rose, the petals cream, the lip purple in front, shading to orange-yellow at the base. *Sobralia Veitchi*, S. *Wilsoni*, and S. *macrantha* were also very fine. *Disa Veitchi* was represented by numerous finely-flowered plants. *Phalanopsis Vesta*, a hybrid between P. *Aphrodite* and P. *rosea leucaspis*, the sepals and petals white, slightly suffused with rose, the front lobe rose, shaded with yellow and spotted with brown at the base; the side lobes rose, shading to white at the base, where it is spotted with bright brown; P. *Ladde-vioacea*, a hybrid between P. *Ladde-vioacea* and P. *violacea*, intermediate in character between the two species used in its production; finely flowered *Epidendrums* and *Oncidiums* in variety made up an interesting display. Messrs. H. Low and Co. sent a small group consisting of finely-flowered *Cattleya Mossie* in variety, the best being a good form of C. M. *Reineckiana*, the lip finely marked and beautifully margined with white. *Cattleya gigas*, *Oncidium macranthum*, and *Odontoglossum crispum* were also well represented. A silver Banksian medal was awarded. Messrs. F. Sander and Co. had arranged amongst their stove and fine-foliaged plants *Sobralia Veitchi*, S. *Amesæ*, good varieties of *Odontoglossum Harryanum*, a hybrid *Cattleya* of the C. *Normani* section, *Oncidium Batemannianum*, a delicate form of *Miltonia vexillaria*, *Cypripedium bellatulum Albani*, and *Lycaste leucantha*.

Mr. F. Hardy sent a small, but interesting group, which contained good forms of C. *Mossie*, the most distinct being C. M. *Hardyæ*, with pure white sepals and petals, lip white, with rose veinings in the centre and yellow at the base, C. *Wagneri* with two flowers, a dark form of L.-C. *Arnoldiana* with three flowers, L.-C. *Hippolyta*, with two of its distinct orange and purple flowers, some remarkably well-bloomed plants of *Miltonia vexillaria superba* with rose-coloured flowers, having a dark crimson-purple disc in the centre, margined with white, and good forms of *Lælia tenebrosa*. Mr. T. B. Haywood sent two spikes of the lovely *Miltonia Daisy Haywood*, with seven and nine flowers respectively. In this the flowers are pure white, with the exception of the yellow disc in the centre. Mr. N. Blandford sent *Cattleya Warszewiczii* (Blandford's var.), a form in which the usual disc in the front of the throat had disappeared. Mr. R. I. Measures sent *Cypripedium leucochilum grandiflorum*, a wonderfully fine-shaped variety, larger and far superior in the markings to the typical form previously certificated; and C. *Salus* (concolor × *Dayanum*), intermediate in character between the two species indicated in its production. The Rev. F. Paynter sent a cross between *Phaius Humbloti* and *bicolor*, in the way of P. *Cooksoni*, but with smaller flowers. Mr. H. A. Tracey, Twickenham, sent cut flowers of *Cattleya Mendeli*, one having a rich crimson-purple lip, finely fringed in front. Another variety had the petals splashed, as in C. *Triane Bakhousiana*.

#### Floral Committee.

A first-class certificate was given to—

**THUJA GIGANTEA AUREA.**—A distinctly marked golden form of this well-known conifer, the golden tint pervading the young growth in a profuse fashion. Messrs. J. Veitch and Sons, Chelsea.

Awards of merit were given to—

**CALOCHORTUS CLAVATUS.**—A bright canary-yellow, very distinct and showy, blooms large, the petals broad, growth robust and sturdy. From Messrs. Wallace and Co., Colchester, and M. Van Tubergen, Haarlem.

**CARNATION HAMPDEN.**—A rich dark terra-cotta, petals incurved, non-splitting, deficient in fragrance. The colour being distinct, it is a desirable novelty, the flowers being of fine form. Mr. Martin Smith, Hayes, Kent.

**ROSE (H.T.) MARQUISE LITTA.**—A deep rose-coloured variety, somewhat loose, having large petals; a profuse-flowering variety of vigorous growth and with fine foliage. Messrs. W. Paul and Son, Waltham Cross.

**ROSE (H. TEA) SOUVENIR DE PRESIDENT CARNOT.**—White, with deep flesh centre in the bud stage, of fine form. A decidedly distinct and desirable novelty, not unlike *Souvenir de la Malmaison* in colour. Messrs. Paul and Son, Cheshunt.

**ROSE (H. TEA) MME. A. CHATENAY.**—A very bright and attractive Rose, in the way of *Grace Darling* save in its colour, a soft pink, with salmon-pink centre. A fine garden variety and quite distinct. Messrs. Paul and Son.

**ROSE (H. TEA) KAISERIN AUGUSTA VICTORIA.**—Pale creamy white, with slight tint of palest green in centre; form good, stout foot-stalks. A fine Rose for any purpose. Messrs. Paul and Son.

**BEGONIA (TUBEROUS) LADY PEARSON.**—A bright orange-scarlet double of immense size and very full, flower-trusses erect and sturdy, the foliage relatively small. Messrs. J. Laing and Sons.

A botanical certificate was given to *Encephalartos gracilis*, a distinct and novel plant with fronds 4 feet to 5 feet in length, the mid-rib profusely covered with a dense tomentose down, the pinnae rounded and small, being needle-like in form; a fine plant. Messrs. Sander and Co., St. Albans.

A very fine collection of cut hardy flowers, staged by Messrs. Barr and Sons, Covent Garden, contained some especially interesting lots of Iris, notably a collection of the *Kämpferi* varieties. Other good things were *Coreopsis grandiflora*, large and very richly coloured flowers; *Thalictrum angustifolium*, *Hemerocallis aurantiaca major*, H. *Thunbergi*, the pretty lemon-yellow variety; H. *fulva*, a dull orange-red, and a number of remarkably fine *Delphiniums* (silver Banksian medal). A similar collection of hardy flowers came from Mr. T. S. Ware, Hale Farm Nurseries, Tottenham, and was very effectively arranged with a high bank in the centre. Among the flowers shown were *Liliums*, *Iris*s, *Poppies*, many kinds of *Dianthus*es and *Pinks*, *Campanula punila*, C. *Hosti alba* and C. *cordata*, with long flowering spikes very much like a Foxglove, the whole forming a very striking blaze of colour (silver Flora medal). Messrs. Kelway, of Langport, Somerset, had a fine collection of *Delphiniums*, *Gaillardias*, *Iris Kämpferi*, and miscellaneous hardy flowers. Among these last were *Salvia dealbata*, a very remarkable looking plant with mauve-coloured bracts and lilac blooms, *Morina longifolia*, very pretty, with an abundance of cherry-pink blooms, and *Centaurea ruthenica*. The *Delphiniums* included some really superb kinds, of marvellous strength and substance and splendid colour. A few of the most striking varieties were Albert Edward, purple and dark blue; Amyas Leigh, azure-blue and lilac; Sara, a very rich sky-blue; Etoile, a dull purple double, very symmetrical in form; and The Czar, a bright royal blue. The varieties of *Iris Kämpferi* were very fine, the most striking being Beauty, Bride Elect, pure white, and Via Lactea. A few very good *Cannas* were also included in this collection (silver Banksian medal). Another group of miscellaneous hardy flowers came from Mr. M. Prichard, Christchurch, Hants, and contained some beautiful forms of *Iris Kämpferi*, *Pyrethrum Hamlet*, a very lovely rose-pink flower; *Aconitum pyramidale*, a bunch of the charming *Catananche cerulea*, and some strong *Eryngiums* (silver Banksian medal). Messrs. Wallace and Co., Colchester, again had a fine collection of their beautiful hardy

flowers, chiefly *Calochorti* and *Liliums*, with a few *Iris*es. *Calochortus citrinus*, a beautiful pure yellow, very handsomely marked in the cup; C. *Gunisoni*, a lovely pure white, with green at the base of the petals; and a number of forms of *venustus* and *Eldorado* were striking, the latter strain showing an immense range of colour (silver Flora medal). Messrs. Cheal and Sons, of Crawley, also staged a large collection of hardy flowers and shrubs, including some charming garden *Roses*, *Bardou Job*, York and Lancaster, *Cecile Brunner*, and *Gloire de Polyantha*, a number of beautiful fancy *Pansies* and bedding *Violas*. Among the shrubs, *Fraxinus aucubifolia*, *Prunus Pissardi*, *Ulmus Dampieri aurea*, *Acer Platanus purpurea*, and *Sambucus foliis luteis* were noteworthy (silver Banksian).

A beautiful group of Sweet Peas, very prettily staged, was shown by Messrs. Veitch and Sons, Chelsea, and included some new American varieties. Some of the best shown were *Blanche Terry*, which should take the place of *Painted Lady*; *Maid of Honour*, a very pretty pale lilac and white; *Dorothy Tennant*, rich mauve; *Stanley*, one of the best of the dark blues; *New Countess*, a very charming pale blue; *Orange Prince*, a bright orange-pink; and *Red Riding Hood*, a curiously-formed flower. Sweet Peas were again charmingly shown by Mr. F. G. Foster, Brockhampton Nurseries, Havant, Hants. Some of the most pleasing bunches were composed of *Creole*, a very pretty pinkish lilac, delicately shaded; *Lady Beaconsfield*, in soft shades of cream and blush; *Mrs. Eckford*, rich cream colour; *Royal Rose*, *Crown Jewel*, pink and white; *Celestial*, a very soft shade of light blue; and *Meteor*, a fiery-pink (silver Banksian medal). Messrs. Dobbie and Co., Rothsay, also staged a good collection of Sweet Peas, among them *Juanita*, a soft shade of mauve; *Triumph*, shades of bright pink; *Coquette*, creamy white, tinged with blush; *Countess of Shrewsbury*, delicate rose and white; *Lovely*, a fine variety of exquisite rose-pink colour; and *Brilliant*, a very bright and showy red. From the same firm came a very extensive collection of *Violas* and *Pansies*, the latter being huge blooms, very fine in form and colour (silver Flora medal). From Messrs. Cannell and Sons, Swanley, came a group of magnificent tuberous *Begonias*, all splendidly grown plants with very beautiful foliage, and bearing quantities of large and handsome blooms. A few of the best were Mr. Pack, a large bright pink; *Mrs. Newman*, deep rose; W. *Marshall*, a beautiful orange single; *Miss Agnes Stewart*, a large lemon-yellow single; *Lady Mary Wood*, a very delicate salmon-pink double; *Lady Salmon*, a similar flower in light yellow; and *Lord Sherbourne*, a large and very elegant flower of fiery-crimson colour (silver Banksian medal).

A fine feature of the show was a splendid group of *Malmaison Carnations* staged by Messrs. Cutbush and Son, Highgate. The plants were dwarf and wonderfully strong, the wood perfectly clean and healthy, and the flowers very full, of great size and fine substance. *Princess of Wales*, *Blush*, *Nell Gwynne* and *Rose* were the chief kinds shown (silver Flora medal). The finest *Carnations* in the show came from Mr. J. P. Morgan, Dover House, Roehampton (gardener, Mr. McLeod). These consisted of about fifty magnificent plants, enormous in size, and each one a model of good culture, both foliage and flowers being superb (silver-gilt Flora medal). Another exhibit of very great interest was a group of plants staged by Messrs. F. Sander and Co., St. Albans, and containing many rare and beautiful specimens. Very conspicuous was a batch of plants of *Watsonia iridifolia O'Brieni*, bearing spikes of beautiful white flowers. *Caladium albanense* was well shown, also a great number of varieties of *Anthuriums*, *Streptocarpus* and *Orchids* (silver-gilt Banksian). Messrs. Veitch and Sons, Chelsea, showed a box of their beautiful javanico-jasminiflorum hybrid *Rhododendrons*, including the following lovely varieties: *Souvenir de J. S. Mangles*, a vivid orange-pink; *Anabile*, a very soft rose; *Diadem*, bright orange; *Conqueror*, scarlet; *Primrose*, a

delicate pale yellow; Princess Beatrice, blush-white; President, orange-yellow; Maiden's Blush, Ceres, clear golden yellow, and Virgil, soft clear buff colour. From the same firm came baskets of the following shrubs: Escallonia Phillipiana, Indigofera decora alba, Cytisus nigricans, and a very delightful lot of Robinia hispida. Mr. H. B. May, Dyson's Lane Nurseries, Upper Edmonton, sent a large group of Adiantums, comprising a wonderfully large range of varieties, and forming a welcome relief after the blaze of colour afforded by the floral exhibits. A few particularly interesting things were A. capillus-Veneris imbricatum, A. caudatum, A. setulosum, A. cultratum, A. reniforme asarifolium, A. Hemsleyanum, A. macrophyllum, A. culpodas, A. Veitchii, A. hispidulum and A. fulvum (silver-gilt Banksian medal). A fine group of conifers was shown by Messrs. Veitch and Sons, Chelsea, and was awarded a gold medal. A few of the most striking things were Retinospora pisifera sulphurea, R. plumosa aurea, R. filifera, R. pisifera squarrosa, R. obtusa aurea, R. plumosa, R. obtusa gracilis, R. plumosa argentea, Cupressus nutkaensis, C. thuyoides leptoclada, C. Lawsoniana lutea, C. Lawsoniana albo-variegata, C. Lawsoniana Allumi, Abies excelsa inverta, A. Douglasii glauca, A. Veitchii, A. nobilis glauca, A. orientalis aurea, A. Sieboldii, and Thuja gigantea aurea.

A group of Roses of exceptional interest came from Messrs. Wm. Paul and Son, Waltham Cross, and included a selection of varieties introduced by the exhibitors during the Victorian Era. Among them were Spenser, Sylph, Pride of Waltham, Star of Waltham, Duke of York, Clio, and Enchantress. The pot plants included Merveille de Lyon, Spenser, Capt. Hayward, and White Lady (silver Banksian medal).

#### Fruit Committee.

Some very fine Plums and Cherries came from Gunnersbury House. Peaches also were fine, and Messrs. Laxton's new varieties of Strawberries most interesting. Melons, which were shown in quantity, were in most cases poor.

An award of merit was given to—

**STRAWBERRY MENTMORE.**—A dark glossy red conical fruit, not unlike La Grosse Suerée in colour. It is of good quality and a valuable main-crop variety. It is a cross between Noble and British Queen, flesh firm and crimson right through. From Messrs. Laxton, Bedford.

Messrs. Laxton also sent several other new seedlings of great merit, but some over-ripe. Commodore was most promising. This is the result of crossing Royal Sovereign and Latest of All, and was thought an excellent addition to the mid-season varieties. Alma, which has for its parents James Veitch and Sir C. Napier, is a large fruit, but somewhat tender. Profit, a cross between James Veitch and Sir J. Paxton, is a nice fruit, and promises to be a valuable one for market. These new varieties were requested to be sent to Chiswick for trial to test fruiting qualities. Some fine baskets of Monarch and Leader were staged by the same exhibitors. Mr. Hudson, Gunnersbury House, Acton, sent some very fine Plums from pot trees. Reine Claude de Comte Athlens was very fine; Jefferson's, Kirke's and Early Transparent Gage were also good. These, with Bigarreau Napoleon and Black Circassian Cherries, deserved a better award than the cultural commendation given. Mr. G. Kelk, South Villa, Regent's Park, sent three boxes of Peaches, receiving a cultural award. Dymond was very fine, Royal George and Dr. Hogg being highly coloured. Mr. Wythes, Syon House, sent the Loquat in fruit, several fruits being borne on a stem. They are not unlike Apricots in colour. The plants had been grown in a cool conservatory. The same exhibitor sent a seedling Melon. Melons were shown in quantity by Mr. Burrell, Westley Hall, Bury St. Edmunds; Mr. Martin, East Cowes, Isle of Wight; and Mr. Davies, Nidd Hall Gardens, Yorks. Mr. Beckett, Aldenham House, Elstree, sent a very fine dish of Early Morn Peas, a valuable addition to the early Marrows. It was asked to be sent to Chiswick

for trial. Messrs. Laxton also sent a new Pea, Thomas Laxton, a promising variety, a seedling from Gradus and Earliest of All. Messrs. Kelway, Langport, sent fine Gradus Peas and Bunyard's Exhibition Broad Beans.

#### ROSE SHOW.

In the competitive classes there was a fair number of exhibitors. For twenty-four single trusses the first prize went to Mr. T. B. Haywood, Woodhatch Lodge, Reigate (gardener, Mr. C. J. Salter), for a very beautiful lot of blooms, perfectly clean throughout, and of fine form and size. The best blooms were S. Marie Rodocanachi, Caroline Testout, A. K. Williams, Francois Michelon, Comte Raimband, Capt. Hayward, Mrs. J. Laing, Jeannie Dickson, La France, Horace Vernet, and Pride of Waltham. Mr. C. J. Grahame, Wrydelands, Leatherhead, gained the second prize for a very good exhibit, having fine blooms of White Lady, Viscountess Folkestone, Victor Hugo, Mrs. John Laing, Chas. Lefebvre, and Prince Arthur. In the class for twelve single trusses, distinct, Mr. O. G. Orpen, of Hillside, West Bergholt, won the first prize with good shapely blooms, Mrs. W. J. Cant, Fisher Holmes, S. M. Rodocanachi, and Mme. Luize being the best. The second prize went to Rev. A. Foster-Melliard, Sproughton Rectory, Ipswich, who had good blooms of Maréchal Niel, Lord Macaulay, Mrs. Sharman Crawford, and Gustave Piganeau. For six single trusses, distinct, Mr. G. W. Cook, Torrington Park, N. Finchley, was first with Medea, La France, Mrs. John Laing, Ulrich Brunner, Caroline Testout, and Capt. Hayward. Rev. F. Page-Roberts, Seole, Norfolk, was a good second. For nine single trusses of one variety, Mr. C. J. Grahame was first with pretty blooms of Kaiserin Augusta Victoria, and the second prize was won by Mr. T. B. Haywood, who showed Mrs. John Laing. For six singles, the first prize went to Mr. O. G. Orpen for exceedingly fine blooms of K. A. Victoria, and the second to Mr. R. H. Langton for La France. Mr. O. G. Orpen was again successful for twenty-four single trusses of Teas, having a very beautiful exhibit, containing lovely blooms of Souvenir d'Elise Vardon, Anna Ollivier, Ernest Metz, The Bride, Sylph, Catherine Mermet, and Princess of Wales. Mr. Grahame was a good second, having fine blooms of Mme. de Watteville, Cleopatra, Medea, and Innocente Pirola. For twelve singles, Rev. Hugh A. Berners, Harkstead Rectory, Ipswich, gained the first prize, having nice flowers of Ernest Metz, Catherine Mermet, Jean Ducher, Cleopatra, and Edith Gifford. Rev. A. Foster-Melliard was a very close second with Maréchal Niel, Innocente Pirola, Caroline Kuster, Ethel Brownlow, and Comtesse de Nadaillae. For six singles, the first prize went to Rev. F. Page-Roberts for a very good exhibit, containing C. de Nadaillae, The Bride, Maman Cochet, and Innocente Pirola. Mr. R. H. Langton was second. For nine singles of one variety, Mr. C. J. Grahame was first with neat and well-coloured blooms of Mme. Cusin. Mr. O. G. Orpen was a good second, showing Anna Ollivier. For six singles of one variety, Mr. R. H. Langton was first with Edith Gifford, and Rev. Foster-Melliard second with Souvenir d'Elise Vardon.

A pretty group of garden Roses was shown by Lord Penzance.

**The weather in West Herts.**—A warm week, particularly at night. On Midsummer Day the highest reading in shade was 82°, which is warmer than any reading previously registered here this year, and on three nights the exposed thermometer did not fall lower than 55°. The soil at 2 feet deep is now 3° warmer, and at 1 foot deep 4° warmer than is seasonable. Rain fell during the week to the total depth of rather more than an inch, and on the 24th, during a thunderstorm in the evening, it was falling for 3 minutes at the rate of 1½ inches an hour. On the morning of this day the heat was very great in the sun, the black bulb solar radiation thermometer rising

to 140°, or higher than in any June for ten years. June, although so changeable in temperature, was, taken as a whole, a decidedly warm month. Rain fell on twelve days to the aggregate depth of 2¾ inches, or about half an inch in excess of the June average. The sun shone on an average for 5½ hours a day, which is rather a small record for the month.—E. M., *Berkhamsted*.

## NOTES OF THE WEEK.

**Aconitum orientale** differs from the majority of its kind by its more dwarf habit, its distinctly cut foliage, and the nearly pure white blossoms that appear in early June on stems little more than 18 inches high.

**Iris Kœmpferi.**—The Drill Hall meeting on the 29th ult. brought together quite a host of these beautiful flowers, many of the large spreading blossoms being from 6 inches to 8 inches across and remarkably varied in colour.

**Clematis Fairy Queen.**—This is a fine variety for pillars or for rambling amidst the larger forms of Ivy on walls. In such positions the handsome white blossoms, which are also large, are of the showiest description and very telling at a distance.

**Wahlenbergia tenuifolia** is a neat species for the rock garden in midsummer, with narrow leaves and tufts of blue flowers on short, hairy stems. It is quite a compact-growing species, and not difficult of culture in gritty loam in sunny chinks of rockwork.

**Incarvillea Delavayi in Scotland.**—Scotland is not behind in flowering Incarvillea Delavayi. For the last three weeks it has been in great beauty here. The seed was sown two years ago, and the plants have stood the last two winters in a climate not very suitable for tender things.—W. H. M., *Manches, Dalbeattie*.

**Pratia angulata.**—As a carpet plant in moist spots, in the bog garden, or indeed any position where moisture may be secured, this is invariably a success, and equally so when grown in shallow pans, for in this way the latter may be utilised in the cool greenhouse. Just now the plant is freely covered with its pure white blossoms.

**Chrysanthemums in June.**—When the really good hardy border flowers—to say nothing of Lilies, Roses, Carnations and other things—are in their fullest beauty, Chrysanthemums are not wanted. Yet a few miserable examples were to be seen at the Drill Hall this week, and, as usual with such out-of-season exhibits, poor and altogether out of character.

**Dianthus Napoleon III.**—When well grown this is perhaps the most richly coloured of all the mule Pinks, and at times flowering so abundantly as to endanger the stock. For this reason a portion should be set aside for propagating, which is easily effected when cuttings can be secured in September. In the border in groups the rich crimson flowers of this plant are very telling.

**Iris Monnieri.**—This grand border plant was included in one or two collections at the meeting of the Royal Horticultural Society on Tuesday last, and very fine it is at this season of the year; indeed, this species, as well as other of the late kinds, appears to have been well suited this season, that is, so far as the established clumps are concerned. In the latter condition the stout stems will reach to nearly or quite 4 feet high.

**Gillenia trifoliata.**—This is one of the most charming hardy plants of the week. Although curiously light and elegant, it yet has a certain stability about it that is wanting in such things as the Gypsophila and similar plants. Like the herbaceous Spireas, G. trifoliata is a capital subject for planting on the margins of streams or any moist, half-shaded position, and if the soil is light and porous the growth is very free.

**Calochortus clavatus** is perhaps the largest flowered of this pretty group of bulbous plants,

the blooms each measuring some 4 inches across and of a clear rich yellow. The variety possesses a distinct branching habit and flowers abundantly. This handsome form received the award of merit on Tuesday last from the Royal Horticultural Society, before whom it was exhibited by Messrs. Wallace and Co., as also C. G. Van Tubergen, Holland.

**Campanula Hosti alba.**—This is a very useful and beautiful kind, with very pure white flowers on slender stems of about 18 inches high, and a kind that is not very abundant in gardens, too frequently an inferior form of *rotundifolia* having to do duty for it. The true plant has larger blossoms, that are rather more open and less drooping. The very long leaves are also a distinguishing character of the plant, which is worth a place in every garden.

**Garden Roses at Colchester.**—Single and semi-double Roses were very well shown at Colchester last week, and proved a very interesting portion of a somewhat poor show. The Austrian Briers in variety, Lord Penzance's Sweet Briers and one or two of the *R. moschata* type were very handsome. In one stand was a charming bunch of the lovely little *Ma Capucine*, one of the most suitable of all Teas for growing in a loose, natural way. All the exhibits in this class were arranged with ample foliage—the most artistic way of showing Roses.

**Lathyrus rotundifolius.**—This is probably the earliest flowering of the everlasting or perennial Peas, and for this reason valuable. The reddish pink blossoms begin to appear quite late in May or early in June, and continue for some considerable time. For its earliness alone the plant is worthy of more attention both from gardener and florist, as it is quite possible to improve by careful selection both the colour and size of the original species. Good culture alone, however, is capable of much in this direction, and when well grown it will reach 5 feet or 6 feet high.

**Gladiolus The Bride.**—Now and again when some good clumps of this useful plant appear in the hardy plant garden, we gather some idea of its usefulness, though we cannot but regret that so chaste a flower is not largely grown in private gardens generally. In the cut state its pretty spikes of snow-white blossoms will compare with the choicest of flowers, which is certainly saying a good deal. Cut in the earlier stages of development, almost every flower to the tip of the spike will expand in water, while the slender, graceful stems on which the flowers are borne are especially well suited for vases. Planted 6 inches deep it is quite hardy in many gardens.

**Polygonum baldschuanicum** is a recent addition to the list of hardy climbing plants, and should prove of value when better known. In many respects this plant is distinct from the other species of this genus, possessing a good climbing habit and woody stems of much the same substance as the Virginian Creeper, and deciduous like this latter. The plant appears quite hardy, breaks away freely from the old stems, and when in full leafage and producing its white and pink panicles of blossoms is very pleasing. This species is now flowering in the herbaceous ground at Kew, where may be seen a fine plant perhaps 10 feet or more high. Native of East Bucharra.

**Tufted Pansies from Chirside.**—Dr. Stuart sends us from his garden at Chirside a gathering of these seasonable and sweet-scented flowers. Among those sent are *Florizel* and *Rosea pallida*, which seem to us too much alike. *Border Witch* is very pretty, but it seems to vary in its shades of colour. The best one sent is *Bedding Blue*, a very rich dark blue, with a yellow eye. This is by far the finest blue we have yet seen, and if the plant flowers freely it will be a great acquisition. We should like to know something of the habit of this, as if it partakes of that of *Blue Gown* it will become popular, the colour being so telling in the mass. Quite the *Fashion* is a larger flower and of a paler blue. Dolly

Varden is distinct, but we much prefer the self colours.

**Hemerocallis aurantiaca major.**—Among the hardy cut flowers at the Drill Hall this week, the handsome spikes of this plant were conspicuous. We have no hardy perennial to compare with it. As a cut flower it is very fine, but in the open garden in a group it is the finest of all hardy plants at the present time. Happily, too, it belongs to a group of the very hardiest of garden flowers, a fact that must assist in rendering so valuable a plant doubly welcome. The blossoms are freely borne on stout stems, each head containing eight or ten of its buds to open in succession. Messrs. Wallace had a fine bowl of this with a dozen giant flowers expanded, the Messrs. Barr also exhibiting cut blooms.

**Severe hailstorms.**—On Thursday, June 24, hailstorms of terrible violence occurred throughout Essex, Middlesex and parts of Hertfordshire, doing severe damage to glasshouses on over sixty nurseries at Chelmsford and district, Ponder's End, Enfield, Enfield Highway, Waltham Cross and Harrow. Twenty-one-ounce glass of all sizes was completely riddled and considerable damage was done to the Grapes, Cucumbers, Tomatoes and all kinds of plants and Ferns. We are glad to hear that thirty nurserymen who suffered loss were insured with the Nurserymen, Market Gardeners' and General Hailstorm Insurance Corporation, of 2, King Street, Covent Garden, who immediately assessed the damage done and paid the claims six days after. One nurseryman lost 70,884 square feet of 21-ounce glass, and his claim at 3d. per square foot amounted to £886 1s.

**Campanula pulla.**—This, now fully in flower, is among the neatest as also the most free flowering of the dwarf Hairbells. The plant is a native of the mountain pastures of the Austrian Alps, and doubtless one of the best of summer alpine. In some districts, I believe, difficulty is experienced in its cultivation, but it usually grows and flowers freely in most gardens if let alone. Though among the very dwarf kinds that, as a rule, submit to almost annual transplanting and division, this one at least in this respect must be excepted. It appreciates a rich, light, free soil, and a fairly moist position when growing, and if not kept to the rock garden its whereabouts should be well marked, as scarcely any evidence of the plant is left during winter. In the border it is often lost in winter by the somewhat dangerous practice to such things of mulching and the subsequent "pricking over" with the fork.—E. J.

**Phyteuma comosum.**—Of truly summer alpine, this is still among such as are too rarely seen, and, indeed, when met with only in solitary plants usually. So interesting a plant flowering in midsummer is worth greater attention. The rather long tubular corolla, much inflated at the base, are seen in clusters of a dozen or so on very short foot-stalks, that give the appearance of nestling in the coarsely-toothed leaves of the plant, the whole not more than 4 inches or 6 inches high. The species is best suited for the rock garden in crevices, where its roots may descend into rich loam 1 foot or more in depth. It frequently succeeds when wedged between a pair of stones, the only care being to keep the plants free of slugs during winter and early spring, when the fresh young Holly-like leaves appear. The plant may be increased by division when large enough, though its very slow growth does not often permit this. Early spring is the best time for this work, potting the plants firmly in grit and loam. Whenever fresh seeds can be obtained, these should be sown at once, preferably on cocoanut fibre or Sphagnum Moss in pans, scattering the seed on the surface and always supplying moisture from below.

**Lychnis Haageana.**—It is unfortunate that this plant is not happy in all soils, and in particular is this true of very cold and heavy clay soils. Generally in light and warmer soils the plant is more easily managed, provided the small slugs

will let it alone. These pests appear to eat the crown eyes or buds away in winter, and where the plants are small there is little hope of ever seeing such again. Some years since I quite accidentally obtained a piece of valuable information regarding the likes of this plant, by planting a tuft in a very dry and hot position in a small garden. The position was nearly due south, and being immediately in front of the bay window of a small villa, and close to the wall, the soil was usually very dry and hot. Yet, notwithstanding, this plant in two seasons developed into one of the finest single specimens I have seen, the stems about 2½ feet high, bearing large heads of brilliant scarlet-crimson flowers. From seed, so large a number of fine colours may be obtained, and so strikingly brilliant are they in midsummer that the plant is worth some extra care. In those gardens where the plant succeeds with ordinary care much may be made of it by grouping it as freely as circumstances permit. The plant is just now in full beauty, and contains many striking shades of orange, scarlet, vermilion, crimson and white.—J.

**Diplacus tomentosus and Gazania hybrida latifolia.**—These both came to me from the well-known French garden of M. Victor Lemoine, of Nancy, and being now in full bloom with me must, I think, both be considered as decided acquisitions, the former to the cool greenhouse or conservatory, the second to our summer outdoor garden. The *Diplacus* comes from California and seems to be a very free-flowering variety, the pretty pale yellow blooms, which are of good size, being produced in pairs at the axils of the leaves on the tops of all the shoots. M. Lemoine describes the colour as Naples-yellow, but I should call it light canary, with two spots of golden yellow at the throat of the flower, and bright yellow stamens. Another new *Diplacus* also sent me from Nancy a year or two ago under the name of *D. grandiflorus* has larger flowers of a paler shade, and is also well worth growing. With the old *D. glutinosus*, commonly known as the shrubby Mimulus, and the deep carmine-coloured *D. puniceus*, figured in vol. 65 of the *Botanical Magazine*, on plate 3655, these two new forms would be ornamental additions to any greenhouse. The new *Gazania* is a beautiful hybrid raised by M. Lemoine by crossing *G. nivea*, the comparatively new white-flowered variety from Natal (so well figured in THE GARDEN for April 27, 1895, on plate 1011), with the larger-flowered yellow species so well known in our gardens under the name of *G. splendens*. The new hybrid has fine large pure white flowers, with a violet band on the under petal and a bright yellow centre.—W. E. GUMBLETON.

**Welbeck Abbey.**—The Duke of Portland has appointed Mr. J. Roberts—formerly gardener to the late Baron L. de Rothschild, Gunnersbury Park—head gardener at Welbeck, as Mr. Horton is retiring.

**Names of plants.**—*J. C. L.*—1, *Astragalus narbonensis*; 2, *Orchis foliosa maculata*.—*S. H. B.*—1, *Lilium chalcidonicum*; 2, poor form of *Lilium creceum*.—*Miss Palmer.*—Your Lilies are affected with the disease which has proved so disastrous of late years to the Madonna Lily, and for which no remedy has yet been found.—*Constant Subscriber.*—1, *Asplenium viviparum*; 2, *Stachys lanata*; 3, *Dactylis glomerata variegata*; 4, too shrivelled to identify; 5, *Ophiopogon Jaburan variegatum*; 6, *Pteris longifolia*; 8, send better specimen; 9 and 10, send fertile fronds; 11, *Santolira incana*; 12, *Enonymus japonicus aureo-marginatus*; 12, *Kleinia repens*. We can only undertake to name four specimens in any one week.—*C. B. B.*—The Golden Drop (*Onosma tauricum*).—*B.*—*Scilla peruviana*.—*L. T. Davis.*—*Coronilla iberica*.—*C. L.*—1, *Saxifraga Cotyledon*; 2, *Cotyledon umbilicus*; 3, *Wood Sanicle (Sanicula europæa)*.—*R. Lake.*—*Thymus alba*.—*C. Edwards.*—1, *Limnanthes Douglasi*; 2, *Spiraea aruncus*; 3, *Althæa Liliago*; 4, *Alstromeria aurea*; 5, *Funkia ovata*; 6, send better specimen.—*J. Bennet.*—a, yellow, *Pblemis frutescens*; b, blue, *Salvia pratensis*.—*Syringhill.*—Specimens too shrivelled to identify.

## ORCHARD AND FRUIT GARDEN.

### SUMMER PRUNING.

I CONSIDER summer pruning to be of the highest importance in fruit-tree culture if carried out in an intelligent manner. It would be well, perhaps, to compare the present condition of the trees with that of the same period last year. Last season, as we all have good reason to remember, was one of heat and drought, and the trees made early, but medium growth, which became fully developed, and the trees were ready for their summer pruning by the middle of June. The subsequent growth made was of little importance, which plainly showed what an effect the heat, drought, and the crops of fruit they carried had on the trees by restraining them from making any further, or, at the most, but weakly growth, and there was no stopping back to do at the latter end of August. This year, owing to the depredations of caterpillars and grubs, combined with cold weather, the trees were a much longer time than usual in starting into growth, and it looked at one time as if the insects were about to gain the upper hand. With the advent of warmer weather and the subsequent heavy and welcome rains which penetrated to the sub-soil, they soon made up for lost time, and are now pictures of health and cleanliness. Growth is very much more luxuriant than last year, in fact, more so than for many years past. The trees are not carrying such crops of fruit as they did last year, although many are heavily laden. This fact and the thorough moistening which the ground has received, have enabled them to grow away freely, and the wood has only now become sufficiently firm at the base to allow of summer pruning being performed in the case of Apples and Pears in the open quarters. To have pruned earlier would have had an injurious effect on the base buds of the young wood, as the latter being then in a soft, succulent condition, the majority would have broken and have produced a perfect forest of

growths. By exercising patience and waiting until the wood has become firm, the base buds will remain dormant and the two topmost ones only will grow out, thus ensuring the eventual production of fruit buds below or at the base, which is really one of the main reasons for performing summer pruning.

The other chief point to be gained in pruning or stopping these summer shoots is to allow sunlight and air to penetrate to all parts of the tree, which besides proving of immense benefit in increasing the size of each individual fruit, also tends to ensure a more perfect maturation of fruit buds. Each branch, when the pruning is completed, should present the appearance of a cordon tree, and if the branches are situated at good distances apart, light and air will have free play and exercise a good effect on both crops and trees.

Summer pruning is a simple operation, and consists in stopping or cutting back all growths issuing from spurs situated on the main branches to from four to five buds. The young shoot or leader growing out at the extreme end of each branch should be left any length ranging from 7 inches to 8 inches to two-thirds, according to the age and size of the trees and whether there is room or not for further extension. The leaders proper, or the central shoots on pyramidal trained trees should be merely tipped if young, and enough young shoots left to form main branches. These remarks are applicable to garden trees only, and the operation may be performed on Apple, Pear, Plum and sweet Cherry trees, and also on young orchard trees which are but as yet improperly formed.

Orchard trees, I am sorry to say, are now only commencing to recover from the caterpillar attack, and in some cases this has been so bad that it resulted in only too many instances in almost total defoliation. It will, as a matter of course, take the remainder of the season for these trees to recover, and the same may be said of garden trees where spraying has been neglected. These, and also trees which were lifted last autumn, as well as those in a weak

condition, should be exempted from summer pruning, as growth in all these cases is not likely to become at all gross. Allowing these trees to grow away unchecked will lead to increased activity at the roots, and this in turn will result in their becoming the more quickly re-established. A. W.

**Pear Olivier de Serres.**—"Midland Grower" does well in drawing attention to the merits of this excellent late keeping Pear, which I place next to Bergamote Espere in point of flavour and general good qualities. I find it is a better grower on the Pear stock than on the Quince, but on the latter it is far more prolific, and, like many other Pears which make but medium growth, it would if left alone soon crop itself to death. It is a Pear that will do with almost any amount of high feeding either in the shape of liquid or artificial manure, and will then produce very large fruits, which, as "Midland Grower" remarks, are very russety in appearance, and of first-rate flavour.—A. W.

**Fig White Marseilles.**—In answer to "J. C.'s" query, this Fig succeeds remarkably well grown in heat, and produces heavy crops of luscious fruit. It is a variety which requires severe entailment at the roots, as it is inclined to cast the first crop if allowed too much liberty in this respect. I had a large tree at one time planted in a brick pit which behaved in this way, but after root-pruning it and reducing the amount of rooting space quite two-thirds it gave no further trouble. I have since then done away with the tree and planted one of Negro Largo in its place, owing to the fruits of the latter being preferred. As a pot tree for early work it is first-rate, the pot furnishing the necessary entailment to the roots, and very large fruits are as a rule produced on trees grown in this way.—A. W.

**Strawberries as biennials.**—In very few gardens does the system of treating Strawberry plants as biennials prevail. Now is the time for any who have not so practised to put it to the test. Strawberry plants are making plenty of runners, and the plan may well be tried with Royal Sovereign, Auguste Nicaise, Noble or other early varieties. Mr. Herrin at Dropmore uses

every year a warm south border for the purpose, planting one half with Strawberry runners of the stoutest that can be obtained, 12 inches apart each way, and sowing the other half of the border with early Peas. Thus the crops are alternated yearly. Early varieties of Strawberries being planted, they fruit early, and may be cleared off quickly, some other crop, such as Coleworts, following, these being cleared off in time for sowing Peas in January. The produce of plants so obtained is always remarkably fine and abundant.—A. D.

**Black Currants.**—Both because of the general abundant rains and the absence of a fruit crop, the present season offers special inducement for the making of strong sucker growths, by which means these Currants when they become old are rejuvenated. It is well, therefore, in the case of old bushes to use the knife rather liberally in clearing out old and generally useless wood, and thus not only encourage strong root shoots to develop, but also to enable them to thoroughly mature. Whilst top trees are so much in danger of making too luxuriant wood growth, that trouble rarely affects bushes unless made very late and failing to mature. Some good may be done by gently stirring the soil about the roots with a fork, and then giving a moderate mulching of manure, so as to help retain moisture in the soil. Good wood growths now being made have till the end of September to ripen. Some such attention now may lead to the production of heavy and fine crops of Currants next year.—D.

**Apple Fearn's Pippin.**—I am glad to see a note about this Apple, and quite agree with all that Mr. Crawford has to say in its favour. I have two large bushes of it, and find it a free grower as well as an excellent cropper. Mr. Crawford does not recommend it for orchard culture, as too much time is required before the trees arrive at a profitable size. This is a good example of the influence of soils on fruit trees, as I know of a tree not far from here which grew away quickly, soon became established, and bore one of the heaviest crops of this Apple that I have ever seen anywhere. I have also been told that it succeeds well as a standard in some parts of Surrey. With me the fruits grow to a large size, and are, generally speaking, most brilliantly coloured, and the flavour is also very good. Mr. Crawford has done good service in calling attention to the fact that the fruits keep well if not gathered too soon, as I know of no other Apple more susceptible to shrivelling if gathered too early than this one.—A. W.

**Early Melons and canker.**—At p. 422 Mr. J. Crawford gives some most useful information on early Melons, especially regarding the unwise practice of not providing sufficient heating accommodation to structures for early crops. Mr. Crawford alludes to canker in early crops, attributing this sometimes to the use of water insufficiently warm. This may be so. This disease more frequently arises from other causes than using water insufficiently heated. Undoubtedly it is caused by injudicious treatment, such as allowing the plants to make a large amount of leafage and get crowded, and then cutting in the growth too severely at one time. Growing them in too close and stuffy an atmosphere will also cause it. For years I have considered keeping the collars dry an important item in Melon culture, but I never had this lesson so strongly brought to my notice as when looking over Mr. May's market nursery at the end of May. Melons were planted on a bed of soil in the centre of the house and on the sides of the two paths, from 2 feet to 3 feet apart, and trained up stakes from 4 feet to 6 feet high. When these were planted they were turned out of 5-inch pots; the balls stood on the soil, with a small casing of loam put round each. This had raised them several inches above the body of soil. When first planted they were kept moist till rooted into the lower soil. I noticed the balls had shrunk away from the soil round them. Nothing could be more satisfactory, as no canker or disease could be seen. At the time of my visit (end of May) he had begun cut-

ting. From two to three fruits to a plant were taken. No doubt the large airy houses and the high planting had much to do with this fine crop.—J. CROOK.

**Strawberries shrivelling.**—Can you tell me, from an inspection of the enclosed Strawberries, what is ruining the whole crop of fruit, and what should be done either now or to prevent a recurrence of the disaster?—F. G.

\*\* Unfortunately, you give us no idea as to the soil and treatment. The shrivelling of the fruit may have been caused by drought, by insect attacks at the root, by late planting and other causes, such as watering the plants overhead with strong sewage. From the fruits sent there appears to have been proper development, and the shrivelling is caused by some agency we have no knowledge of. Had it been excessive drought, all the fruits would not have gone; a few would have finished, though small. It may be wireworm which has devoured the roots, and, of course, the plants have collapsed. If it is so—and without roots we are unable to judge—you will need to make your land proof against this pest, and you are powerless now. The work of preparation should be done before planting. We advise a free use of gaslime and thorough exposure of soil before planting. Old garden land is more liable to attacks than others; on the other hand, recently turned-up soil, such as grass land, teems with the pest, and you will need patience to get rid of it. If you will kindly send us a few more particulars we may be the better able to help you.—ED.

#### STRAWBERRIES AND WIREWORM.

In light soils wireworm is one of the worst pests the Strawberry grower has to contend with. In my soil—one not at all adapted for the fruit—it is necessary to guard against this pest. I find the best remedy is to grow the plants one season and to change the crop the next. Some time before Strawberries were recommended to be grown as annuals I adopted this plan to get a healthy plant, and seeing what good returns such plants gave when planted early, I have devoted more space to these fruits and been less troubled with wireworm in the soil. Last season I saw some acres of plants which had been planted in land recently an old turf pasture. Heavy crops were expected in the maiden soil, but the old turf which had been turned in was a perfect nest of wireworm. The plants died off wholesale. This shows one cannot altogether rely upon new quarters unless some means are taken to rid the land of the pest. I have tried various means to effect a clearance, and find gaslime the best; and as in many places it may be procured for the carting, it is of great value to the fruit and vegetable grower. Most persons plant their Strawberries in the late summer, and where grown as yearlings the earlier the better, so as to give a long season of growth. To get the soil into condition, it is necessary to dress the land a little time before planting. In my case Strawberries follow a green crop or early Potatoes, and the land is allowed to rest as long as possible; indeed, a much longer rest would be beneficial if it could be given. The lime is placed on the surface and the lumps broken finely. This exposure pulverises the lime, and when dug in it is well mixed with the soil. Mine is a shallow soil. I am unable to turn the top spit to bottom, as the lower one rests on gravel in many parts of the garden. I have never seen any injury from gaslime used thus; in fact, when ground has been occupied I have lined just before planting, but in this case the roots must not rest on the fresh lime, and deeper digging is needed. I have seen evil results when a load of lime has been placed in

heaps and not evenly distributed over the surface when digging. Ground treated thus will be free of wireworm for two years or more, and the land will be in excellent condition for Brassicas after the Strawberries are over. There will be an absence of clubbing, so troublesome in old garden soils, and in many cases I feel sure gaslime or even common lime would be more beneficial than annual doses of manure. The best time to apply gaslime is in the late autumn or during the winter, but in many gardens one is obliged to crop the land when cleared, and Strawberries planted in the spring, which is an excellent practice if the runners are small, or taken from plants which have fruited, wintering the plants in rows and not allowing them to fruit the first season after planting, give a splendid crop the next year, and the ground can be done thoroughly at the same time, giving a rest during the winter. With winter or autumn dressings more lime may be used, and for a crop that is to stand for two or three years, it is best to specially prepare the ground during the winter in the way advised. By planting a quarter every year one can always rely upon fruits of good quality and in quantity. G. WYTHES.

#### PEACH STONES SPLITTING.

World you kindly tell me the cause of the stones of Peaches splitting?—CONSTANT SUBSCRIBER.

—Will you kindly give the reason of my Peaches cracking just before ripening? I enclose one as a sample. The roots are partly inside and allowed to go outside, and the fruits appear healthy until at the stage of the one enclosed. It is an old tree, and carrying a good crop.—J. J.

\*\* Some few varieties are addicted to this, in others it occurs casually. The worst offender in this respect is Early Rivers, and it is solely due to the fault of stone splitting that this fine variety is going, or has nearly gone out of cultivation. With me Grosse Mignonne has frequently developed a similar weakness, but nothing like so badly as Early Rivers. Although all the fruits with split stones do not ripen or drop off prematurely, it detracts considerably from their value, and ought to be prevented accordingly. Neither of the correspondents who complain of "stone decay" and splitting state whether or not they have had the same difficulty to contend with in previous seasons, and only one, "J. J.," mentions anything about the age of the trees affected. The largest fruit sent resembles a highly-coloured, perfectly ripened example of Grosse Mignonne, and not till it was handled could anything wrong be detected. There is no remedy for stone splitting as far as this crop is concerned—at least not when the fruits are as forward as those sent, and I have my doubts about its prevention in the case of later crops. Imperfect fertilisation of the flowers, over-rich borders, and an excessively moist and close atmosphere are given as either causes, or accelerating influences, of this malady, but none of these errors in culture could have been laid to my charge either in this or previous seasons, and yet I have had a few fruits with cracked stones each summer. No notice is taken of a few fruits going wrong, but if much splitting of stones took place on any trees other than of Early Rivers, then remedial measures would be quickly adopted.

If, therefore, the cases under notice are what may be termed bad ones, then I would advise correcting what outward influences are at work in the borders. Early in the autumn, or while yet the leaves are green and cling tightly to the wood, partial lifting of the roots should take place. Commence by opening a wide, deep trench 4 feet or so from the stems, and then gradually and carefully undermine and bare the roots to within 2 feet of the stems. If they are found planted too deeply, and many trees sink considerably after planting, the collars, or point of union

f topmost roots with the stems, being several inches below, instead of slightly above the level of the border, wholly lift and replant higher. In either case well undermine the reserved ball of soil, so as to be able to shorten any deep running roots there may be. The preserved roots—after having been overhauled and pruned, cutting away all broken ends and damaged portions—should be quickly relaid in fresh compost. It is here where would-be renovators must use their own discretion. If the soil was previously too light and poor, correct this fault by mixing loam of a more clayey nature with the ordinary loamy soil of the district, with a view to making it stronger and more retentive than formerly. Also, if the growth of the trees hitherto has not been quite so free as desirable, mix a little half-rotten farmyard manure and a sprinkling of bonemeal with the loam. Where, however, the soil of the border is naturally heavy and retentive—too much so, in fact—this may be remedied by the addition of sand, mortar rubbish and burnbake (soft ballast) in sufficient quantities to keep it more open and porous. The roots should be kept moist while exposed, and carefully spread out in the new compost as this is somewhat firmly added to the trench, keeping them up nearer the surface than formerly. Those who are afraid to adopt such drastic measures may meet the case by doing one side of the tree this season and the other half of the border next year. Personally, I should not hesitate about wholly lifting quite large trees in the autumn, but then the work would be done well and at the right time. When the roots have access to both inside and outside borders, one border may be renewed this season and the other next year. This process of lifting the roots and relaying in fresh compost is desirable in many cases, even if there is no trouble with the fruit, as it serves to sustain the trees in a healthy, free-bearing condition. The most successful growers practise it and are well compensated for their pains.

In the autumn, before the leaves have ceased to perform their functions, is, as was previously noted, the best time to partially or wholly lift Peach and Nectarine trees, for the very sufficient reason that root action is, or ought to be, most brisk then, and the pruned roots have time to heal and form numerous fibres before the resting period arrives. The next best time to do this important work is when the trees are bursting into growth in the spring. If the roots are much interfered with in the autumn, the leaves may flag badly for a few days, but this can be largely prevented by giving water liberally to the roots in the old soil, by affording temporary shade, by keeping the house close for about ten days, and frequently and freely syringing the trees overhead, not allowing the leaves to become really dry on sunny days. Trees treated in this way, and kept well supplied with water at the roots the following season, will usually produce full crops of excellent fruit, little or no splitting of stones being apparent.—W. I.

**Cherry Black Tartarian.**—This noble, highly-flavoured Cherry is generally described in fruit catalogues as of tender constitution, and while it will not stand orchard exposure in any but the warmest climates, it thrives on walls in the midland counties better than many of the so-called hardier varieties. Another good trait in its character is that it hangs for several weeks in good condition if protected from flies and wasps. This Cherry is also known by the name of Black Circassian. The fruit on healthy trees grows to a large size.—C. C. H.

**Cherry Florence.**—This is a large handsome variety and well worthy of a good position on a wall, but it requires a good climate to induce it to yield well. Like many of the best dessert Cherries, it does very indifferently in the Midlands, although I have a tree on a wall which now and then has a fair sprinkling of luscious fruit. It belongs to the late section, and will hang for a long time if protected from birds. It should not have a rich larder, being inclined to make very

strong growth, which does not ripen properly, gumming following. To show how climate affects Cherries as well as other fruits, I may state that Florence—which in Kent is known under the name of Wellington—is grown extensively in that county for market in standard form, the large red and yellow fruit realising high prices.—J. C.

**Beetles eating Strawberries.**—I have forwarded to you some beetles which are doing great damage to the Strawberry crop. They bury themselves in the soil during the day and come out and feed on the fruit at night. I have found as many as a dozen round one Strawberry plant, some of them 4 inches deep in the soil. I should be glad if you could give me some hint as to getting clear of them.—W. M.

\* \* \* Your Strawberries are, as you think, attacked by one of the Carabide, or ground beetles (*Harpalus ruficornis*). These beetles are, as a rule, carnivorous, and are of much use in gardens, as they and their grubs destroy other grubs and small insects, but when the Strawberry season comes round they seem to leave their natural food and live on Strawberries. It is no easy matter to destroy them; they are so smooth, hard, and active that I do not think any insecticide could be made to harm them. Raising the fruit from the ground on wire supports would probably prevent the beetles from reaching them. No straw, lawn mowings, or anything that could afford the insects any shelter should be placed near the plants. Pieces of raw meat laid about will attract large numbers of them, and a piece of coarse sacking should be laid over the meat so as to afford the beetles a shelter.—G. S. S.

## FLOWER GARDEN.

### LATHYRUS PUBESCENS.

The perennial Peas are favourites with almost every one, and either as cut flowers or for decoration are of the greatest value. Clambering over a hedge, a trellis or a rustic fence, the old-fashioned, yet ever admired, *Lathyrus latifolius* in its several shades of colour is pleasing to all, while *L. grandiflorus*, which has, perhaps, the finest single blooms of the species in cultivation, is equally charming. While these and other species less known can be had to give colour and beauty, it may seem strange that a new "Everlasting" Pea is sought after by lovers of hardy flowers. Yet this is the case, and the publication of the descriptions of some new Californian *Lathyrus* a few years ago led to a desire to add these and others to collections of hardy flowers. Some two or three of these Californian species still survive here, but one fears that their usefulness in our climate is but small. They may still flower, but though June is now fast drawing to a close, the prospect of their blooming this year seems very small. Not so, however, with the Uruguayan species, *L. pubescens*, which came into bloom here early in the month, and which one would fain hope may prove hardy in this garden by the Solway-side. Last winter was not the most severe on record, but it was among the wettest seasons we have had for long. It was thus particularly trying to plants from drier climates, and as the late spring frosts, so destructive to many flowers, did not harm this Pea, one is hopeful that in mild districts it may prove hardy enough on a wall or sheltered fence. It is distinct enough in its way to make it welcome to the many who take a pleasure in these flowers. The colour is a pleasant variety in itself. It is a bright, yet soft lavender, deeper on the standards than on the keel. It might, with a little play of fancy, serve for "Lord Anson's Blue Pea," which so many of us have tried in vain to obtain. The flowers are in neat racemes, which vary considerably in the number of blooms they produce, some showing only

five, but many nine flowers, and a few eleven. The individual blooms are comparatively small when compared with those of *L. latifolius*. The leaves and other parts of the plant are quite pubescent, so that no one can question the appropriateness of the specific name. I regret, however, that I am not aware to whom the name is due. The plant itself appears to be of a semi-shrubby nature, as the young growths on my plant were produced from the old stems which did not die down to the base. It is of a climbing habit, attaching itself readily by its tendrils to suitable supports. It has only attained a height of some 4 feet or so this season, but when it becomes better established will probably exceed this. The plant I have was very kindly given me by Mr. W. E. Cumbleton, of Belgrove, Queens-town, who raised it from seed sent him from Uruguay, but who unfortunately has not been able to preserve his plants. The native country of *L. pubescens* is apt to make one strongly sceptical of its hardiness, so in planting it out in the spring of 1896 it was placed against a trellis on the gable of an out-house with a south-west exposure. The narrow border in which it grows is a dry one, and, while this may have checked its growth, may also have contributed to the well-being of the plant in winter. It is as yet too soon to tell if this Pea will produce and ripen seed in our climate. Its distinct colouring and appearance make it not improbable that hybridisers might turn it to good account in helping to give to the perennial Peas the wide range of colour shown in the exquisite Sweet Peas so deservedly popular at the present time. S. ARNOTT.

*Cursethorn, by Dumfries, N.B.*

### NOTES ON HARDY PLANTS.

**Saponaria Boissieri.**—"Charming" is the word often applied to a well-established plant now in flower. It has some resemblance to *ocymoides* in the best forms of that well-known kind. The flowers are bigger, but the chief feature is the true, clear rose colour of the flowers, which have also a sheeny effect.

**Melittis melissophyllum.**—There are two distinct varieties of this without, so far as I know, a varietal name to distinguish them by. By this post I send a flowering stem of each. Both are beautiful when well grown and flowered, and are fit for borders where a long succession of bloom is wished for.

**Delphinium trolliifolium.**—Much the earliest of Larkspurs, this has besides a lofty and conspicuous habit. The flowers are large and of a deep blue shade, though lax on the spike. The point of this note, however, is to direct attention to an effective plant when employed in semi-shade and backed by shrubs, as suggested by a group of plants between some tall green Hollies with a west aspect. Nothing could be richer and more beautiful even without the aid of any other flowers.

**Saxifraga balcana.**—Here we have quite a new and pleasing departure. It belongs to the Aizoon section; it is also encrusted or silvery, features common enough, but not of the flowers, which are heavily and evenly spotted with red, so much so, that at a short distance the panicles of bloom have the effect of being pink. No other Saxifrage of its section in any way compares with it, except, perhaps, in a measure *Macnabiana*. Even this comparison conveys but an indifferent idea of what this dwarf kind is like. For its perfume alone it is well worth a place among the choicest alpine, and its slowness of growth, but withal sturdy habit, fits it for association with rare and slow-growing kinds.

**Dianthus Michael Foster.**—Seen in dry weather this is truly a fine single Pink—a hybrid

alpine species of the neglectus type. It is free, vigorous, effective, and not liable to disease.

**Eryngium glaciale.**—No more charming alpine plant could be mentioned for the present month. The stature is 3 inches, the whole plant silvery with exquisite green shading. All its features are on the pigmy scale, the bracts, however, large for so small a plant, supporting a dense cluster of pale blue flowers; stems, leaves, and bracts are all rigid and spiny. Though small, the plant is full of character, and capable of enlisting more than ordinary interest. Rotten stone and sand form its chief rooting medium, and as it has done so well it is reasonable to assume that at least this mode of culture will do for it.

**Edraianthus Kitaibeli.**—This distinct kind is most remarkable for its fine erect, almost tubular flowers of a rich purple (even for an *Edraianthus*) and the large bronzy red, star-like calyces. The general description of the plant may be said to place it near or between *E. dalmaticus* and *E. serpyllifolius*, and yet it is markedly distinct from either.

**Aciphylla squarrosa.**—A five-year-old specimen which flowered freely last summer is making a beautiful head of its singular foliage now. It is not always the case that old plants do so, but often die. I merely mention this fact to show that neither rule is absolute, as was thought not long ago.

**Incarvillea Delavayi.**—A few plants of this glorious new species grouped together and now in flower are very striking, and have been referred to several times in these columns. The practical point I would like to refer to is that I put half a dozen strong plants under hardy conditions and—at least so far as the winter of 1896-7 applies—all the plants came through scathless.

Woodville, Kirkstall.

J. WOOD.

#### LILIUM ELEGANS.

This Lily is a native of Japan. In Holland, too, it is largely grown, and in this country it succeeds as a border Lily better than many other species. All the forms of this Lily, and indeed nearly all the different species belonging to the upright-flowered, cup-shaped section, can be depended upon to bloom well the first season after planting, which is more than can be said of all Lilies. The different forms of this species are seen to the best advantage when planted in groups in the open border, though by some they are employed for flowering in pots. In this latter case several bulbs should be put into one pot, as in this way they form neat little masses of flower. In purchasing bulbs of any of the numerous varieties of *L. elegans*, it should be borne in mind that they are a good deal smaller than those of most species of *Lilium*. Their nearest relatives—*L. croceum* and *L. umbellatum* or *davuricum*—have bulbs a good deal larger than those of *L. elegans*. The differences that exist among the numerous varieties are not limited to the colour of the blossoms, but there is also a good deal of variation in height and in season of blooming. The dwarfiest of all are the little buff-coloured *alutaceum* met with occasionally under other names, that of aureum being often used, and *Prince of Orange*, much in the same way, but with rather more pointed leaves and somewhat deeper-coloured flowers than those of *alutaceum*. The two kinds are less than a foot in height, while the pretty and distinct *pictum* is but little more. This last (*pictum*) has widely expanded blooms of a rich yellow, splashed and flaked with red. One of the earliest of all is *marmoratum aureum* or *robustum*, whose bright reddish orange-coloured flowers are freely spotted with brown. This is also one of the tallest of the group, as it reaches a height of 2 feet or so, while another of about the same stature is *brevifolium*, with very short, exceedingly dark green leaves and flowers of a distinct reddish salmon colour without any spots. Bright coloured forms are numerous, and their nomenclature is by no means uniform, so that one may often get the same variety under two or more names. A

very richly coloured flower which I have had from Holland as *Van Houttei*, and from Japan as *fulgens*, is the best of the rich crimsons, but distinct from all are the extreme blackish blood-red flowers of *Horsmani*, known also as *haematochrom*. One of the varieties grown in considerable numbers by the Dutch is *lateritium* or *biligulatum*, whose bulbs are larger than those of most forms of *L. elegans*. The flowers of this are a kind of brownish red tint, bright and pretty when at their best, but they quickly lose their freshness and become dull; indeed, the flowers of this variety and the showy *pictum* are over in less time than those of any of the others. There is a double-flowered form of this Lily which is not nearly so pretty as the single kinds, unless in the eyes of the few who regard single blossoms of all kinds as inferior to the double ones. The doubling of this Lily is caused by the centre being partially filled with enlarged petaloid segments, thus differing altogether from the double *Tiger Lily*, in which the petals are numerous and overlap each other, forming in this way a double blossom. T.

#### PRIMULA TRAILLI.

As one of the members of the floral committee of the Royal Horticultural Society who took exception to the plant exhibited by Mr. Geo. F. Wilson on April 27 being regarded as a distinct species until fuller information was forthcoming, I may be allowed to state that there does not appear to be in the herbarium at Kew any specimen of *P. Trailli* to which it can be referred for identification, and *P. Trailli* does not find a place among the species given by Mr. George Nicholson in his "Dictionary of Gardening." It is a curious fact that one of the reasons put forward by Mr. H. Selve-Leonard for accepting it as distinct from *P. involucreta* was the fact that it had drooping flowers. Now I learn from Mr. G. F. Wilson's communication on p. 465 that this characteristic was owing to dryness at the roots of the plant and the heat of the room. At the subsequent meeting of the committee I produced a flowering plant of *P. involucreta*, with which I hold the *P. Trailli* to be identical. To show the similarity of the two, and on the strength of this, the committee came to the conclusion that it was desirable *P. Trailli* be referred to Kew for identification. It was pointed out that Mr. Wilson's specimen was much larger in all its parts than that of *P. involucreta* I produced, but that was readily enough explained, as Mr. Wilson's plant was simply a single individual which had been well cared for, while mine was an aggregation of individuals—a portion of a clump growing on rockwork in the open air. I think I am correct in stating that the so-called *P. Muuroi*, which is but a variety of *P. involucreta* and probably not markedly distinct from the type, was obtained from seed sent home by Captain Munro from the Himalayas some half a century ago, and now we have *P. Trailli* originating in the same way. I think, therefore, there is abundant reason to hesitate before Mr. Wilson's plant is accepted as a distinct species, and I regret that the committee were so precipitate in passing it as such. Mr. Nicholson was, unfortunately, absent when the award of merit was made to Mr. Wilson's plant; had he been present, the probabilities are the plant would then have been referred to Kew to certify as to its distinctness. What astonished me was the large number of votes cast for its recognition as a distinct species, and I wondered how many of those who so voted had ever seen *P. involucreta*. If *P. Trailli* as shown by Mr. Wilson can be established as a distinct species, I shall be delighted to be one of the first to congratulate him on his acquisition. *P. involucreta* promises to yield a pod of seed. Should it mature, I will carefully sow it and endeavour to furnish another proof of its identity, or otherwise, with *P. Trailli*. R. DEAN.

Eding, W.

**Digitalis lutea.**—This Foxglove is distinct in colour and growth, and is worth a place in the wild garden. Some three years ago seed of this was sown. I removed the plants to the wild garden, and since

then these have borne seed, and now early in June I have strong plants full of bloom.—DORSET.

**Tufted Pansy Mrs. H. Bellamy.**—A bed of this useful variety, containing some 500 or 600 plants of good size, was in fine condition at the Bolehall Pansy grounds recently. The plants were flowering freely, the individual blossoms being beautifully smooth and the colour also good. The upper petals are pale lavender, the lower ones being rich purple. Although the flowers of this variety are not so large as those of *Craig* or *Stophill Gem*—both of which resemble this variety in form and in colour—yet it is a matter for doubt whether these two sorts are as good for the flower garden as the one under notice. The habit of *Stophill Gem* appears to be a slight improvement upon this older variety.

**Tufted Pansy Magnificent.**—This is a seedling from the well-known tufted sort *Blue Gown*, and while it would perhaps be impossible to find a better habit than in the parent variety, and which is transmitted to the variety under notice, the flowers of this are larger, and, consequently, more effective. The blossoms are deeply veined in the centre, and the eye is perfectly free from rays. At the present time pieces which were propagated early in the spring are nice plants, each carrying quite a number of charming blossoms on footstalks of a useful length. Like many of the very compact and tufted sorts, this variety is rather later than many others in coming into flower.—C.

#### RAYLESS TUFTED PANSIES.

IN THE GARDEN of JUNE 12 some observations are recorded regarding a want of constitution in *Tufted Pansy Waterloo*. As the raiser of that flower, I was at one time of a similar opinion, but now, with a row of two-year-old plants, I have some reason to think otherwise. When we remember how seedling plants are treated in their infancy (pulled to pieces for propagation), no wonder that they are weaklings the first or second year of their growth. Let them be grown as perennials, allowed to remain for a year or two in one place, and it will be seen that they gain vigour for at least four years, and reward a little care in keeping the soil between the rows open and mulched in warm weather. A five-year-old row of *Blue Gown* treated in this fashion is at the present time as close as turf, and so smothered in flowers as to hide the foliage. *Waterloo* has rather more substance in the flower than *Blue Gown*, and the colour is also rather better, with a fine dwarf habit of growth; but no existing variety rivals *Blue Gown* in that respect. *Florizel* has come out in grand form this season from being allowed to remain where planted. When I parted with it as a seedling only one vigorous plant was in the bed, which was divided into two, and the gentleman who sent it out got one half, the produce of which seems to have flourished with him as everyone seems now to grow that variety. With these rayless forms a proper understanding should be arrived at as to what is wanted. Bedders and show varieties should be grown separately. Take *Border Witch*, for example, as a type for show in a spray. That flower is *Sylvia* crossed with a *Peacock Pansy*. Out of a large batch of seedlings, *Border Witch* was the only rayless flower in the whole lot. Some of the newest and most beautiful of the show varieties are its progeny, and these seedlings come wonderfully free from rays, but want more substance to stand heat. As bedders, *Cleg Kelly*, *Rosea pallida*, *Gold Crest*, *Waterloo*, *Blue Gown*, and *Bedding Rose*, all good and close to the ground, flower freely and will flourish in any dampish, partially shaded situation.

Hillside, Chirnside, N.B. CHARLES STUART.

## STREAMSIDE VEGETATION.

RUNNING water in the garden opens up an endless vista of possibilities in the grouping of flower and leafage along its verge; dwarf little creeping plants to fringe with lowly blossom the edges of the tinkling rill; tall spires of bloom and noble curve of leaf to border the statelier stream that moves sedately on its course; great Ferns to oversweep the trembling lip of the cascade ere its waters plunge in silver to the pool below. Sometimes, as in the accompanying illustration, the garden boundary is formed by running water; a mill-stream that waxes and wanes, is vocal or silent as the mill-wheel moves or rests. Here, on the farther bank, to which the rough rustic bridge gives access, Nature has been unrestricted, and has spread above the water a rampart of living green; facing this wild growth on the garden side, the bank above the flowering Grasses is crowned with an irregular line of white Michaelmas Daisies, holding in their widespread stars and in the un-

especially *I. pallida* and the variegated Water Flag, and lastly the beautiful *I. stylosa*, blooming at the coming of winter. *Libertia grandiflora* is another subject that flowers well by the water, and *Spiraeas* should be freely used, the tall *S. Lindleyana*, *S. ariaefolia* and *S. flagelliformis*, while of the herbaceous section there are *S. Aruncus*, *S. palmata*, *S. venusta*, *S. japonica*, and *S. filipendula*. Many of the Lilies do well in the neighbourhood of a stream, especially *L. pardalinum*, *L. canadense*, *L. superbum*, and *L. Humboldtii*, while herbaceous Phloxes, *Pyrethrum uliginosum*, Starworts, Day Lilies, Arundos, and Bamboos all have beauty of colour or of form to recommend them, and thrive best near water, and there the tall Campanulas hold their bells in perfection longer.—S. W. F.

The following has been sent us by Mr. W. G. Holland, Glan Alyn, Gresford, who kindly forwarded the photograph from which the illustration has been prepared:—

and finally giving the pit itself a thorough fumigation with sulphur. The new growth that the plants are making is likely to prove a deception, and I certainly would not trust to any such stock for a future supply. Marie Louise has been particularly subject to this disease in some parts of the United States, and many growers have been compelled to discard this lovely old variety in favour of Lady Hume Campbell, though the latter variety has not the same rich colour that is so much appreciated in a healthy and well-grown Marie Louise. Various fungicides have been tried by our Violet growers, and it has been claimed that Bordeaux mixture proves effective as a preventive, and even as a cure in light cases.—W. H. TAPLIN, *Philadelphia, Penn.*

**Silene Otites** (Spanish Catchfly).—There is quite a large colony of this plant growing on the top of the old walls of Colchester Castle, where the caretaker has his time almost occupied in preventing the visitors destroying it by picking every flower and so preventing it seeding. The plant is interesting in that it grows in company with one or two others, as Stonecrops and Wall-

Michaelmas Daisies and other plants by the side of a mill stream running through Glan Alyn Gardens, Gresford, N. Wales. From a photograph sent by Mr. W. G. Holland.

restrained freedom with which their further flower-sprays stretch athwart the stream, throwing their blossoms into strong relief against the dark background, a suggestion of unconventionality in keeping with the surroundings. Further back, looking over the white ranks of this advance guard of cultivation, stand in the tilled ground the tall Sunflowers. Only hardy flowers should be grouped by running water, and the grouping of these should be as far as possible natural, so that from earliest spring to the commencement of winter, where the contour of the banks admits, the streamside shall form a fair setting for fair flowers. Snowdrops, Scillas and Narcissi, Snowflakes and Stars of Bethlehem begin the year, followed by Irises, the Japanese *I. Kämpferi*, *I. sibirica*, the bulbous English and Spanish (*I. Xiphion* and *xiphoides*), the tall *I. orientalis* or *ochroleuca*, *I. aurea*, and *I. Monnieri*, all three similar in manner of growth and often attaining a height of nearly 6 feet, and very valuable in colonies by a streamside, the German Flags,

The illustration shows a border of white Michaelmas Daisies alongside the tail of the Gresford mill stream running through this garden. The plants have been undisturbed for some years. A rustic bridge crosses the stream at one end of the border; the other end is terminated by a summer-house built on a stone bridge over same.

**Failure of Marie Louise Violets.**—The experience of "J. R."—as related in THE GARDEN of May 1, page 310—is, unfortunately, not an uncommon one among American Violet growers, and similar failures have been the cause of great anxiety, and also severe pecuniary loss, to many growers during the past fifteen years. From the description given by "J. R.," it seems evident that his Violets have had a severe attack of Violet fungus, or, as it is generally known here, the Violet disease or spot. This disease is caused by minute fungi, most likely by *Puccinia* or *Cercospora*, and is extremely difficult to eradicate. My advice to "J. R." would be to burn every affected plant, both root and leaf, removing the soil from the pit in which the disease appeared,

flower, without an inch of soil in the crevices of the old masonry. The leaves are about 2 inches in length, the habit closely tufted, and the flower-spikes about 15 inches or 18 inches in height, bearing corymbs of greenish white blossoms. The sticky exudation common to the genus is very marked in the flower-spikes, and these appear to turn much darker with age. The Viper's Bugloss, too, is growing well and flowering in almost inaccessible parts of the walls.—R.

**Brompton Stocks.**—When "C. C. H." writes of Brompton Stocks that their great merit is their hardiness, he indicates something in them I have failed to find. Practically when growing these for several years always on the warmest and most sheltered positions I could find, I found them destroyed wholesale by frosts, and had as a last resource to put a number into pots and winter them in a greenhouse to save them. It need hardly be said that such plants seldom gave those fine spikes that strong plants unharmed outdoors would give. But even where plants did escape frost, the coll to which they were subjected seemed to have a deteriorating effect, as good double strains of both Giant White and Scarlet

presently became single, and under no conditions could they be induced to revert to the double form. How much I should like to secure seed of both these forms of a fine fairly double strain now. I look everywhere for them in gardens in vain. They seem to have quite disappeared. What are now seen appear to be the Giant Cape or Emperor Stocks, but the good old Bromptons are not. Some years since the beautiful branching Queen Stocks, scarlet, purple, and white, were grown in great quantities in the Middlesex orchards to furnish cut flowers, but these gradually became injured by frosts, dwindled away, and are now seldom seen. Yet these Stocks were amongst the most beautiful grown in gardens. Certainly the past two winters have been very merciful to biennial Stocks, but they are none the more plentiful. No doubt their culture has largely fallen into abeyance because of their comparative tenderness when severe weather prevails. Yet there can be no doubt but that few plants in gardens give more real pleasure when found in good form.—A. D.

#### DOUBLE POET'S NARCISSUS.

MR. E. JENKINS has done good service in again referring to the question of the failure of this to open in some gardens. It is one to which I have often directed some thought, from the fact that my experience with this exquisite flower in a poor and dry soil is quite contrary to that of many. When we find, however, that such authorities as Rev. G. H. Engleheart and others attribute the blindness of the buds to poverty and dryness of soil, one is apt to be rather diffident in the expression of one's views, founded though they are on some experience. The note by Mr. Jenkins, who has had so many opportunities of observing the behaviour of this double Narcissus, emboldens me, however, to give the result of my own experience with it here. When I bought this house some fourteen years ago there was a good-sized clump or two of the double Poet's Narcissus in the garden. These were growing among the roots of Gooseberry bushes in a very dry part of the garden, where about 2 feet from the surface pure sea sand underlay the soil. They had either been deeply planted originally or had been frequently covered with soil, as they were much deeper than I should care to plant them. They were also very close together, and this with the deep planting had caused them to elongate themselves until they had become quite shapeless-looking objects. I removed them after flowering that season, and in all these years I have never had a bud go blind. They have flowered regularly and satisfactorily, although several times disturbed to take off off-sets for planting in other parts of the garden. I am satisfied that dryness or poverty of soil at the flowering or any other time will not cause failure with this Narcissus in every garden, and that we must seek elsewhere for the cause. It must be mentioned that some of my clumps have had no manure in any form and are in poor and dry positions. What makes the matter more singular is that some of the single varieties flower in a less satisfactory manner than the double one. This year, for instance, a good clump of *N. poeticus recurvus* within 2 feet of one of the double Poet's Narcissus did not give me a single bloom, while the latter had a full yield of flowers. Quite close to both the small-flowered *N. poeticus*, called "*poeticus* of Linneus," flowered very freely. Why these things happen is a puzzle not easily solved.

One is glad to see the stress laid by Mr. Jenkins on early removal for the poeticus varieties. It is remarkable how soon they begin to make new roots, and if lifted after these begin to grow, it is almost impossible to avoid

injuring them to the detriment of the bulb itself. It is unfortunate that the purchase of *N. poeticus* is generally left until the bulbs of the other Narcissi are offered, and that, even if ordered early, it is not delivered before them. Personally, I would rather have *N. poeticus* removed when in flower than a fortnight after its leaves had begun to yellow. There would, I feel satisfied, be fewer losses to regret. A remark was made by Rev. G. H. Engleheart about bulbs collected in their native habitats. Unfortunately, I regret to say my losses with these make me agree with him. They seem more difficult to establish, and even their flowering the first season after planting is no guarantee that they will appear the next. Not all of us have the opportunity of searching their native habitats for exceptionally good flowers, and we are tempted to buy imported bulbs in hope of obtaining some varieties such as may be found among those from the Italian mountains. In the same connection Mr. Engleheart refers to some varieties found by our good friend Mr. James Allen. I have had the pleasure of growing six of these for a few years, but until this year have never had the satisfaction of seeing all in bloom together. They appear to be gradually overcoming their weakness, and have made stronger growth than before. They vary considerably in size, form, purity of colour, and time of flowering.

*Carsethorn, Dumfries, N.B.* S. ARNOTT.

#### TUFTED PANSIES AT TAMWORTH.

THE Tufted Pansies in Mr. William Sydenham's grounds at Tamworth are always worth seeing, and this year in particular. They are grown on a very extensive scale, over 1,000,000 plants having been ready for distribution early in the spring of the present year. By a very careful selection of varieties—many of the older and less meritorious sorts having been discarded—the collection now contains many exceedingly beautiful forms of this useful flower. One important rule observed here is the constant weeding out of sorts which do not come up to a proper standard of habit, so that those now catalogued are typical of what a Tufted Pansy should be. The newer varieties are mostly of compact, dwarf habit, or else possess that peculiar form of growth in which the shoots crawl over the soil, so that little is seen of that unwieldy and elongated growth which was often characteristic of many of the older sorts.

The grounds are situated on a slope with a western aspect and fully exposed, no shelter from the hot sun by trees being obtainable. Viewed from any point, the display of colour is a very remarkable one, and proves the value of the Tufted Pansy as an effective plant for massing in large beds and borders. The plants are arranged in a long series of beds, each about 4 feet wide, with paths arranged all round them. By these means the beds are easily examined and the plants kept in a healthy and vigorous condition. The kinds are arranged in alphabetical order, thus making it an easy matter for a visitor to find any one particular variety. The immense array of shallow frames and their accompanying lights tell their own tale of the wholesale way in which propagation is here carried out. This has already commenced with varieties where the demand is likely to be a large one, the plants being pulled to pieces repeatedly until many thousands are secured for autumn or spring planting, as the case may be. Most of the plants were flowering profusely, some varieties standing out distinctly as improvements on those already in commerce. Conspicuous among others was Lucy Franklin, with large, oval, rayless flowers of good substance and freely produced. The colour is creamy white, the bottom floret being a rich yellow. Councillor W. Waters is one of the best dark sorts, the colour being best described as bluish purple and quite distinct. This variety flowers freely and

the habit is excellent, while the constitution is all that is wanted. A variety of great promise and very striking is Devonshire Cream. This is oval in shape, rich cream in colour, with a clear orange centre. It is exceptionally free, the habit dwarf and compact. Another capital variety is M. D. Cheshire, the habit being beautifully dwarf and the plant free-flowering. The lower floret is yellow, the upper florets being a very pale shade of the same colour. A new kind named Britannia has flowers of quite a new shade of blue, and is best defined as rich metallic-blue. The blossoms stand out very prettily from a capital tufted growth, and are of good size, neat form, and with plenty of substance. Crème de la Crème is another pure cream self with a neat orange eye, while the habit is also good. Of rayless yellow varieties there were many of exceptional merit, and these should be in demand where varieties possessing good fixed colours are wanted. The premier position should be given to a seedling raised by Mr. Sydenham last year and named by him Pembroke. This variety has large, rich yellow flowers, the colouring on the lower floret being deeper and richer. The flowers are almost circular, the form good, and the flowering qualities excellent. The habit is fairly dwarf, and its constitution could not very well be better. Two or three large beds of this variety were the most conspicuous of the whole display. This variety is also fragrant. Another good rayless variety is Renown, with large oval flowers of bright yellow with a deeper colour on the lower floret. A variety with smaller flowers, also rayless, and of a pure rich yellow colour, is Fanny Emmeline, of good habit and free. A good breadth of the old variety Lord Elcho was in evidence, and while it may still be considered useful for the flower garden will not compare with many of the more beautiful rayless yellow sorts. Kitty Hay is another striking rayless yellow, with neat flowers, free, and with a nice habit. Golden Bee is a large yellow with dark rays, something after the style of Lord Elcho, but better. A variety which promises to eclipse all yellow flowers with rays is a seedling named Stephen. This is a large circular flower of the richest yellow, and is of much substance. When comparing this flower with those of other well-known varieties, its superiority was very pronounced. One very effective flower was seen in Sir Robt. Peel, the colour being an exceedingly deep rich primrose self with an orange eye. The contrast is a pleasing one, and as the habit is one of the dwarfiest known, this is an ideal one for bedding. A variety which calls for special recognition is one named Robin. The flowers are rather small, but they are produced in such numbers and so persistently, that from the commencement of the flowering season and until the late autumn there is one mass of blossom studding the capital compact growth peculiar to the variety. The flowers are on short stems and are of the palest shade of bluish-white. A large bed of The Mearns, with its large flowers of a rich plum colour, the upper florets edged white, formed a pleasing contrast to the selfs in other beds. This old variety is worthy of a place in most gardens. Formidable was flowering in a very free manner, its soft lavender blossoms, with white centre and yellow eye, being very restful and pleasing. Sweet Lavender is a variety with flowers of bluish lavender. The habit of this sort is good, and its free flowering is generally recognised. Blue Gown has often been described as one of the best bedding sorts, and, judging from a bed or two of this variety seen here, there is no doubt about it. The flowers are blue, faintly tinted mauve; the habit is dwarf and compact, and the plants one mass of blossoms of medium size. A French-white flower is Niphotos; the blossoms are large with a neat yellow eye. The habit is nice and free. President is an immense cream-coloured flower with an orange eye, and is highly thought of. A good breadth of the popular rayless creamy white Sylvia was in evidence, its dwarf habit and its freedom of flowering being very noticeable. A charming little French-white flower is Sweet Mary. This has a neat yellow

eye and it also possesses a good tufted habit. The beauty of Lemon Queen was strikingly apparent; its large circular flowers of pale primrose-yellow and its tufted, yet vigorous growth should ensure for this variety more extended culture. Jessie Alexander is an exquisite flower of large size and of good form. The colour is rosy pink, deepening to the centre; strong constitution. A seedling to be sent out next season is named Henry IV. The flower is very large, rayless, creamy white, with a yellow eye. A variety with large flowers, upper florets white, lower florets rich yellow, was named Mrs. M. S. Wales. There were several other sorts somewhat similar in colour and form, but this struck me as one of the best.

Ardwell Gem, Duchess of Fife, Goldfinch, and White Duchess were each represented in large numbers, this section proving their value as bedding sorts of the highest order. There were also many other promising novelties which space does

less. The flowers are of good size and even form, with a neat and well-defined yellow eye. The habit is compact and dwarf, and it may be considered a welcome addition to the white sorts for bedding. This variety has had several first-class certificates awarded.—D. B. C.

**White border Pink Albino.**—This was distributed a year or so ago by Mr. T. Gifford, of Tottenham, and it promises to take the lead among the pure white varieties. The plants are of compact, yet free growth, free of bloom, sending up strong footstalks crowned with good-sized white flowers, full of handsome shell-shaped petals. Then it is early to flower, which is an additional recommendation. Compared with other white Pinks I am growing, it is decidedly one of the best, and, further, it misses nothing in the way of fragrance, and is by no means such a bad pod-burster as some others. The value of the Pink for cutting early in June can scarcely be over-estimated. It follows the Daffodil and pre-

flower newly purchased pieces of it, but never a second time, as I have done with Lorteti. Iris persica, if lifted and baked on a greenhouse shelf, does fairly well. I am trying Mr. Ewbank's plan with it also this year.—GREENWOOD PIM, *Dublin*.

## STOVE AND GREENHOUSE.

### AGAPANTHUS UMBELLATUS.

THIS is a most effective subject for setting out in the garden during the summer months when grown in large pots and tubs, the blue umbels of the flower-heads, rising on their tall shafts above the curving green leaves, being admirable in both colour and form.

This Agapanthus is a native of the Cape of Good Hope, where the commonest colour is the blue usually seen in English grown specimens; from this shade, however, in its native habitat it ranges through lighter tints of blue and lavender to white, though pure white is of rare occurrence. In the south-west of England, especially where the soil is not too clayey and retentive of moisture, the Agapanthus flower, well when planted in the open, and requires little or no protection during the winter. In low-lying, damp ground where the soil is heavy the plants start late, make gross summer growth, which gets ladly cut by the first frost, and produce few flowers. In such situations, even in the south-west, pot culture is preferable to planting out, as by the former system abundance of bloom is almost assured. When the pots are crammed with roots flowers are produced in the greatest abundance, but in this condition the Agapanthus is an inveterate pot-breaker, and it is, therefore, well to avoid this by planting in 40-gallon oil casks, sawn across and well burnt out. When painted green or covered with virgin cork these will not prove unsightly. When the plants have filled the receptacle with roots, manure water should be given frequently. The Agapanthus is a moisture-loving plant, and the soil in which it is growing should never be allowed to become absolutely dry if the best results are to be obtained. S. W. F.

**Daphne indica rubra.**—This is seldom met with in the best condition, and the fact that the bloom trusses are such favourites for cutting induces a too free use of the knife on young plants, which consequently frequently do not reach a profitable size. With care good bushes may be grown in pots if plenty of drainage is provided and the foliage is kept free from aphid. The best results are, however, obtained by planting out in narrow borders of loam and peat in a position near the glass, yet shaded from bright sunshine. If the growth is secured to a trellis here and there the majority of it may be allowed to hang down loosely, and after flowering, a slight pruning of the shoots may take place instead of allowing the breaks at the extremities to come away. This keeps the plants better furnished. No plant suffers sooner from over-watering, the leaves turning yellow and sickly.—GROWER.

**Poinsettias planted out.**—As a rule the most serviceable method of growing Poinsettias in pots, as the plants can then be easily removed to where they are of most service. Still, planting out has its advantages where extra large bracts are desired for decoration in November or December. If the plants are put out in a small border at the end of a stove, the flowers make a brave show if left on the plants. At Hillside, Newark, I recently saw some wonderfully fine growths from plants growing in a shallow bed at the end of a warm, moist house. They have been there for several years, and in spring they are cut back to within three or four eyes of the base, eventually producing stout, healthy shoots.

*Agapanthus umbellatus.* From a photograph sent by Mr. S. W. Fitzherbert, Torquay.

not permit one to write about, but which may be heard of before the season is over. Seedlings are raised at Tamworth in immense numbers, the process of selection being a very difficult one. This must be carefully done, or varieties get duplicated, and of course anything of this kind must be avoided. Several unique seedlings were flowering, and these promise in the near future to supersede many sorts which at present find favour. Before concluding this note, special mention should be made of the beautiful effect created on the right of the pretty carriage-drive to Bolehall by the planting of some 50,000 plants in about a dozen varieties of the Tufted Pansy. At the time of this visit, although only comparatively recently planted, the display was quite unique; thousands of charming little blossoms in many different shades of colour made an impression that will always pleasantly be remembered. C.

**Tufted Pansy White Empress.**—In this variety we have a very refined white self and ray-

cedes the Rose, while it associates well with the double and single Pyrethrums. In addition, a good clump can be grown in a comparatively small space, and the flowers last well in a cut state.—R. D.

**Iris Lorteti.**—With reference to Mr. Ewbank's remarks on Cushion Irises (p. 428) I would like to say that this lovely Iris has just flowered with me, producing what is, I believe, an exceptionally large flower. The standards were 5 inches high, and the whole 7 inches through as it grew. The plant was treated as recommended by Mr. Ewbank some time ago in these pages. It was planted on a little mound, and when the growth was withering all the soil was carefully picked out from among the roots, which were baked in the sun under a handlight for two months, after which the plant was fully exposed to moisture, &c. A second plant treated similarly also grew strongly and produced a bud, which unfortunately fell a victim to slugs. I have tried *Iris susiana* in the same way, but have not had much success. I can occasionally

which grow to a great length and are kept away from the roof-glass by bending and tying. Feeding is liberally practised, and the result is enormous bracts of great beauty.—J. C.

#### PELARGONIUMS AT LEWISHAM.

THE Rycroft Nursery, Lewisham, in its earlier days was chiefly renowned for its excellent collection of Chrysanthemums, but at the present time Begonias and Pelargoniums enter largely into competition with the famous autumn flower, and bid fair to occupy almost as prominent a position. Those who only know Rycroft in the short, dull days of the declining year can scarcely imagine how gay the large show greenhouses appear with their present display of brilliant Pelargoniums. The various types represented consist of show, regal and decorative, with an admirable admixture of single and double zonals, and also all that is newest and best in the way of Ivy-leaved varieties, many of which are invaluable for hanging baskets and vases, and have been very greatly improved in form and colouring during the past few years. Most of the Pelargoniums of the show, regal and decorative sections are housed in one of the large 100-foot greenhouses, where they form a striking and imposing array. Altogether there are about 200 varieties, mostly in  $8\frac{1}{2}$ -inch pots, and several plants of each variety for the purpose of keeping up the stock. The Pelargoniums of the three types mentioned appear to be gaining in popularity, and we are assured that the demand for them is very much greater now than was the case a few years ago. Many of them are seedlings raised at the Rycroft Nursery, but it is interesting to record that, although a few are of foreign introduction, the collection as a whole is mainly English, and is conspicuous for the large accession of novelties that exhibit more than ordinary signs of improvement. Bridgroom is a very free-flowering variety of good habit, colour blush-pink, with deep blotches on the upper petals. Queen of the Roses is new, and an improvement on Rose Queen; the pips and trusses are large and the colour soft salmon-pink. Mrs. H. J. Jones is another with very large pips and well formed trusses; the habit is good and it blooms very freely; colour bluish-white with crimson blotches. Ed. Perkins is a fairly well-known scarlet variety. Pearl is a very chaste shade of pure white, edge of the petals crimped; the pips are of good size. A very desirable addition is Mrs. Frank Walker, which has very large pips. It is very free and makes a sturdy bushy plant. Eucharis is one of the finest whites in cultivation and keeps flowering all the summer through; the pips are large and the upper petals have two faint blotches of pale pink. Mrs. Hollingsworth is in colour salmon-rose, with deep crimson blotches. St. Blaise, with medium-sized pips, is free flowering and of good habit; colour deep red, blotched dark crimson. Among other noteworthy examples in this section mention should be made of Alice M. Love, pale soft salmon, with crimson blotches; W. C. Boys, a very pretty shade of salmon-pink and having deep crimson blotches; Ladas, blush-rose, blotched dark crimson; Mrs. W. Wright, very free flowering, large pips and trusses, edges of petals crimped, colour pale blush, upper petals blotched crimson. May Queen, Lady Isabel, Princess May, Agnes Cook, W. Wright, a sport from the preceding, colour bright lilac-mauve; Mrs. G. Gordon, quite new, with large pips and truss, colour white, suffused with a faint rosy shade, to be sent out next season with Mrs. Frank Walker, previously mentioned, and several others also attracted our attention.

#### REGAL PELARGONIUMS.

These were well represented by Duke of York, which has an immense pip and corresponding truss and is very distinct. The colour is a deep rosy marking on a white ground. Lady Duff, a sport from Duke of Fife, has fringed petals, colour rosy red, narrowly edged with white, and a white throat. Prince Henry is a variety

having large pips and a good truss; the colour is a deep rosy red, feathered and blotched. President Harrison in colour somewhat resembles the preceding, but in Dr. Masters we have a flower of a very dark crimson, blotched and feathered dark maroon; the pips, however, are only of medium size, but the plant is very free. Duke of Clarence is another of the deep-coloured kinds. It has velvety dark purple petals and a lighter centre, very striking and effective. In Prince Teck the habit is good and the flowering abundant, but the pips are not so large as in some of the others; the colour is rich rosy red, faintly shaded vermilion. Capt. Raikes Improved is deeper and richer in colour than the original and has a larger pip. It is a pretty variety, as also is Bushmill Beauty, which has a feathery mottled rose petal and a pip and truss of first-rate size. Achievement belongs to the show section; the colour is deep scarlet, with the upper petals blotched deep velvety crimson, centre white. Scarlet Gem, free, good habit, white throat, feathered purple. Bluebeard is another show variety, very rich and effective; the pips are large and the habit compact; colour pale purple, the upper petals blotched with dark velvety purple.

Leaving the large show house in which the above-mentioned types were staged, we passed into another 245 feet in length with a sharply pitched roof and devoted entirely to

#### ZONAL AND IVY-LEAVED PELARGONIUMS.

A brief indication of some of the best of these must suffice. Among double zonals, double Henri Jacoby, Raspail Improved in high tones were good. Mrs. J. Surman, blush-pink; Mr. J. Phillips, salmon; Hermione, white; Joyful, deep salmon; Rainbow, mingled salmon and purple; Apple Blossom, soft rosy pink, quite new; Mrs. W. Morris, deep salmon, rather bright in colour; and Golden Gate, orange-scarlet and of a better habit than most of the yellows, were probably the best. Single zonals were best represented by Wilhelmina, rich salmon-scarlet, large truss; Volcanic, fiery shade of crimson and white eye, large pips and truss; Suvarna, orange-scarlet, large pips and truss; Duchess of York, pure white, very large pips; Bluebeard, deep purple, slightly marked scarlet; Princess Alix, one of the largest pips, colour pale delicate rose; Mrs. D'Ombrain, very large pips, colour salmon, streaked and mottled on a white ground. Others in the single class can only be mentioned by name, as Hilda, Zenobia, Miss Jane Whitelaw, Miss A. Whitelaw, Mr. W. Walters, a fine winter-flowering white variety, Mrs. L. Humphreys, Mrs. G. P. Linford, &c.

Ivy-leaved Pelargoniums have always a beauty and a gracefulness peculiarly their own, and the collection at Rycroft contains a variety of these that should please the most fastidious. Achievement is a cross between a zonal and an Ivy-leaved; it is semi-double and of a charming shade of pale rosy pink, big trusses, and of a nice compact habit. All the true Ivy-leaved varieties we noted belong to the semi-double type, and of these Mrs. Bick, a pretty and distinct variety of rosy purple and very free, was one of the most attractive. Miss Clara Walker, deep rosy pink; Rycroft Surprise, delicate shade of soft salmon-pink; Mrs. W. E. Barling, deep rosy purple, a pretty flower; Doris Farmer, deep bright rose; Rycroft Scarlet, a deep bright shade of colour, indicated by its name; Beauty of Castlehill, with large pips, soft rosy pink; Cuvier, trusses of medium size, colour pale rosy purple, and Phrosa, pale lavender, slightly tinted mauve, were all more or less conspicuous by the purity and delicacy of their colouring, which as a rule is much less varied in this type. A few other good Ivy-leaved kinds were Souvenir de C. Turner, Giroflée, Jersey Beauty, and Jeanne d'Arc.

**Ipomœa Quamoclit.**—I. Quamoclit is a slender growing annual climber with pinnate leaves, the segments of which are remarkably narrow, thus giving to a plant a very light appearance. The flowers are small, bright red or white, and are

borne in the greatest profusion. About half a dozen plants in a pot 5 inches or 6 inches in diameter, into which a few twiggy branches are stuck for the support of the slender climbing shoots, will form a very pretty object in the greenhouse during the summer months, or if the weather is cold and damp an intermediate house temperature will suit this Ipomœa best. When grown in this way the little bright coloured blossoms like scarlet stars are particularly attractive when nestling in considerable numbers among a mass of delicate Fern-like foliage. During very hot summers I have seen it do well in the open ground, but it cannot always be depended upon in this way. Seed is readily obtainable, and will come up very quickly when sown.—H. P.

**Swainsonia Osborni.**—There are several species of Swainsonia all natives of Australia, and of them one of the best known is *S. Osborni*, which for greenhouse decoration from now onwards is very useful. It is a slender-growing, somewhat rambling plant, that may be trained up the roof of a greenhouse, or if preferred secured to a few sticks and treated as a pot plant. This Swainsonia is somewhat sparingly furnished with light pinnate leaves, from the axils of which towards the end of the shoots the flowers are produced. The individual blooms are Pea-shaped, quite an inch across, and of a bright purplish-red colour, with a white spot in the centre. These flowers are borne in upright racemes, the more vigorous having about a score of flowers in each. It commences to bloom, as a rule, about midsummer, and will often continue till the end of August or even later. When grown as bush plants in pots they should be cut back rather hard before starting into growth in the spring, as such treatment will ensure a bushy habit. The genus Swainsonia is very nearly related to the *Clianthus*, and I once saw a particularly fine specimen of *Clianthus Dampieri* grafted on to a plant of Swainsonia.—H. P.

## KITCHEN GARDEN.

### SPRING CABBAGE.

ON the growing of Cabbage for spring supplies much depends upon the time of sowing, the variety sown, and the soil and locality. I think there is a great gain in making several sowings in preference to one, as by so doing should one crop fail the others may succeed; indeed, I treat Cabbage more like Lettuce, and sow every few weeks from January till July 25, not large sowings, but enough to keep going. The earliest is made in a frame, and the plants from this sowing are now fit for use. These follow the ordinary spring Cabbage. Some of my readers may think this crop following so close on the one named is not required, as the autumn plants would produce a summer crop after being cut over. I do not care for them to do so, as young, tender heads are preferred, and what is better, the ground can be utilised much sooner. I usually make a sowing for very early supplies in June. This is, I know, not the regular routine, but if it answers it is worth a trial. In cold soil or late localities I would not defer sowing after July 15. It is a good practice to sow twice, with a fortnight between the first and second sowing, for spring supplies. I am aware in certain soils the dates are early, but a sturdy plant is a necessity. I am not an advocate for planting the autumn-sown plants, as they are usually termed, in rich soil. In many gardens quantities of manure are given and the ground trenched, and when the weather is severe the plants are so soft that they are cut down or lose their leaves before new growth is made in the spring. I do not condemn trenching, but I find (in our light soil) a firm root-hold means hardiness. In heavy

clay soils this would not apply. One must in a measure study soils, locality also, as in exposed places growth is more sturdy.

Small plants do not require large masses of rank manure, as they make but little growth from October to March. Far better feed from the time new growth is active. There is plenty of quick-acting fertilisers one can use, and liquid manure can often be employed. This is of great assistance, and the young plants soon heart and are fit for use. A later sowing is made from July 20 to July 25, and unless there is any mishap, this is a small one, as the plants sown under glass in January are quite as early, given good culture. I need early supplies, and I think early Cabbages in all gardens are appreciated. The later sowing may be termed a safeguard in case the first should fail in any way. I think much depends upon the way the plants are raised. Here good land, well enriched, is needed, as a quick growth is essential. Plant the main batch at the end of July. Full early many will say, especially in our warm soil; but earliness is our aim, and it should be borne in mind we place a good plant in what may be termed a poor soil. By a good plant I mean a strong one, with a short stem and vigorous. Drills are drawn in hard land, so that moisture is readily conveyed to the roots, and growth is hard and able to withstand our variable winters. A small plant from the later sowing would not be ready to plant till mid-October, and if a wet autumn followed would not be in condition to stand a hard winter. Plants from these late sowings come in useful as a succession to the first sowing. They may be wintered in the seed-beds, or, what is better, pricked out in rows rather closely at the end of October. Often one sees the plants in such a crowded state that it is impossible for the seedlings to develop. Quite as much care is needed at the start; indeed more, as a weak, crippled plant cannot grow freely. Ample space in the seed-bed is important, and planting out as soon as the plants are large enough; indeed, better results are secured by planting before the plants get too large, as a much shorter leg or stem is obtained, and I find the plants which touch the surface with their lower leaves winter better than those with long stems, which are apt to be twisted by rough winds. Frost cripples them, and they are the first to run in the early spring. G. WYTHES.

**Sowing Coleworts.**—This most useful winter vegetable appears to be becoming better known, but mistakes are often made in its culture, one of the commonest being sowing the seed at the wrong time. Several times I have seen Coleworts in full heart during September and October, and even earlier than that. At this date autumn Cabbages are in season, which lessens the value of the Colewort. Not only so, but, like the Savoy, their quality is much improved by having a fair amount of frost on them, and their extreme hardness renders them safe to grow even in the coldest districts. I sow my seed from the 1st to July 7, and another batch about the 15th, and in the majority of seasons this brings them to perfection from the middle of November onwards, as, fortunately, they do not heart in all at once, but piecemeal, and, another thing, they remain in good condition for a long time.—J. C.

**Cucumber Frogmore Prolific.**—Of the newer types of medium-sized handsome-shaped Cucumbers, one of the very best is Frogmore Prolific. I saw it recently at Hillside bearing a wonderful crop, and Mr. Day, the gardener, considers it of excellent flavour. In my opinion it is just the Cucumber to grow for market, as the majority of buyers prefer a small well-shaped fruit to the larger varieties. Verdant Green is not unlike the above sort in shape and general

appearance, and is a very reliable variety. At Hillside the beds in the Cucumber house are rather limited in width and depth, which is doubtless an advantage, as when the roots are working in a large quantity of rich soil a gross, unfruitful growth is encouraged. Mr. Day believes in a limited root-run, in feeding by top-dressings, and liberal supplies of liquid or artificial manure when the plants are carrying a good crop.—C. C. II.

WINTER CROPS.

THERE should be no lack of all kinds of Brassica plants to select from for filling up the different quarters, as the weather has been all that could be desired to bring the plants on strongly. The great thing one has to study now is to get them into their winter quarters before they become too large, as they are growing rapidly and will soon spoil if left in the seed-beds. The recent rains have made the ground in such a good condition to receive the plants that such a favourable opportunity should not be lost if possible. The greatest difficulty will be in finding sufficient vacant space for putting them out in most gardens, but by the time these notes appear some of the early batches of Peas will have been cleared off, which, if the surface soil is simply hoed and the rubbish raked off, will provide room for some of them. Some of the early varieties of Strawberries, too, will have been gathered, and where the plantation is upwards of three years' standing these may be destroyed with advantage, and the firm ground that will then be at liberty will prove the best position in the garden for Late Queen, Model, or other favourite late varieties of Broccoli. The error that is made in planting the above on heavily manured and recently dug ground has often been pointed out in these pages. This encourages gross growth, which is not capable of withstanding a severe winter. All that is necessary after destroying the Strawberry plants and freeing the surface of weeds and rubbish is to give the ground a good hoeing, and form the holes to receive the plants with a crowbar. Under these conditions growth will be slow, but the stems will be short and hard, and the foliage small but much firmer in texture than would be the case if grown under more generous treatment. I have taken advantage of such a favourable planting season, and being rather short of available ground at the time, to lift a good portion of the early and second early Ashleaf Potatoes to make room for a good batch of Autumn Giant Cauliflower and Veitch's Autumn Protecting Broccoli. The tubers, although barely ripe, will take no harm, and will do for immediate use, but to keep them in as good a condition as possible they were lifted carefully and spread out thinly in a cool, dark cellar and covered with straw. Indeed, when we consider the moist state of the ground, together with the great heat, I am not sure but what the tubers are as well out of the soil as in it, as they are practically as large as they ever would be, and there is a danger of them starting into growth with the heat and moisture contained in the soil. Of course, this should not be attempted with late varieties, but only the earliest whose haulm has finished growth and which is showing the first sign of ripening. This is a better plan than allowing the Potatoes to remain in the ground and placing the plants between the rows, as the haulm hampers sturdy growth and the plants suffer more or less in consequence. Where it is not desirable to lift the whole of the early Potato crop, every other row might be dug up, which will allow room for a few rows of plants which require planting at once, a successional one being made later, after the whole of the ground is cleared. Even in this case the ground should be levelled and made as firm as possible before the plants are put in.

Most growers have their favourite varieties of Broccoli to form a succession, and rightly trust to those which have proved the most hardy in their different localities. The great thing, however, after having made a selection of varieties, is to plant them in proportion, especially in a private garden,

so as to maintain a regular supply throughout the winter rather than having more than is required at one time. For instance, if ground is available, say, for ten rows of plants, two rows of each of the following should be planted: Veitch's Autumn Protecting, Snow's Winter White, Dilcock's Bride, Leamington, and Model. Of course, this is only a short list of the standard varieties for early, midseason and late supplies, and may be supplemented with several others where space allows of their being planted, though it is well to bear in mind that the season of most of these named may be prolonged by sowing at different intervals. Thus, although the first is named Autumn Protecting, it forms a good succession to Autumn Giant Cauliflowers where raised and put out early, while the same may be had in good condition often as late as February, from later sowings. Of other well-tried varieties, Spring White, Cooling's Matchless and Perfection may be named for winter and early spring use, and, to succeed these, Late Queen, Latest of All, and Cattell's Eclipse will keep up the supply well into May, with Veitch's Model maintaining succession until early Cauliflowers are ready. In each case small sturdy plants should be selected in preference to large ones, as these invariably take root quicker and prove more satisfactory than those which look much stronger at the time of planting. Although perhaps Broccoli forms the principal winter crop, there are others equally as serviceable, and often prove more hardy, which must not be neglected. These comprise Savoys and the different Bore-oles. The former perhaps can hardly be termed a choice dish, but they often prove valuable, and are appreciated when other things are scarce, especially at mid-winter. These are sometimes objected to because they are coarse, but by growing the dwarf varieties, and selecting the smallest heads, they make a change, and can hardly be objected to by anyone, especially at the season named. From the want of room we have planted a double row of Tom Thumb between newly-formed plantations of Currants and Gooseberries. The bushes being planted 4 feet between the rows, there is plenty of room for a double row of Savoys, as this dwarf variety may be planted 1 foot apart each way. Provision should also be made to make a planting now, and also for successional ones, of the different Kales, as these often prove invaluable during March and onwards, when other things are cut up with searching winds. The dwarf curled varieties when sown in May generally succeed the best, and may be planted 15 inches by 12 inches apart. These, after being cut over in spring, will afford a supply of delicate sprouts until the Asparagus season arrives and spring Cabbage becomes plentiful. These, together with Broccoli, Brussels Sprouts and other winter crops, should have the surface soil frequently hoed between them as they commence to grow, which will not only stimulate growth and keep the plants free of weeds, but slugs and other vermin will be kept in check, and the plants will make steady progress and yield good returns.

R. PARKER.

**Planting green crops.**—By sowing the Brassicas at a fixed date one cannot always have the land to plant the same, and this is a difficulty many growers have to contend with. Unless means are taken to thin out the seedlings, the plants will be poor when ground is available. I am aware we often sow much too thickly, and at this season what is termed pricking out is not always attended to, so much other work needing attention. For some years I have grown large quantities of Strawberries as annuals, and this gives me much space for winter crops. The Strawberries are not left a day after the fruit has been gathered. The tops are burned, the ashes spread, drills drawn, and a good breadth of winter greens got into their permanent quarters. As the weather of late has been favourable for planting, there is little delay, and a much better result can be secured by early planting. I am in favour of a firm root-hold for winter green

crops. Broccoli planted on hard-trodden land recently cleared of Strawberries makes a sturdy growth and is less susceptible to frost. I admit there may be less bulk, but size is not everything, and it is a great gain to the grower to preserve his crop and get a good return. There are other means to obtain a good plant, and I find later sowing than is often advised one of the best. If ground is not vacant, pricking off into lines is a safeguard, and may with advantage be practised when planting out cannot be done; there is a saving of time in the end, and a much better plant is secured. It is not possible to maintain a healthy plant in a crowded seed-bed. No matter how well watered, the plants get thin, long, and lose roots; pricking off prevents this, and a small quarter of prepared plants is much sooner attended to as regards moisture than seed-beds in which each plant is struggling for existence.—G. WYTHES.

**Shallots.**—It is surprising to find how popular these savoury bulbs are with cottagers and allotment holders. No crop seems to be in such cases more common, few are better grown. The old true Shallot and the Large Red or Jersey are equally well grown. Many of the workers like them for ordinary flavouring; others like them pickled, especially the smaller true Shallot. This variety, though the bulbs are not large, comes on good ground not only of good size, but in large clusters and remarkably clean. They should when well grown wear a satiny aspect. For domestic use the true Shallot is much better worth cultivating than the Large Red, which often resembles the Potato Onion in size and taste. Planted in rows 12 inches apart on good soil in February, growth soon follows and the produce is early ripened and ready to clear off early.—A. D.

#### CUCUMBERS AND VEGETABLE MARROWS DROPPING OFF.

I SHALL be much obliged if you will give me a hint in your next number as to the prevention of the following: Cucumbers in frame and Vegetable Marrows outside, form, grow on a little, and then die off, rotting from the end. Is it from over-watering or what? Water is generally given in the middle of the day, but withheld if dull or if the frame seems to be damp enough.—DOLAN.

\* \* In all probability insufficient warmth at the roots is responsible for the failure of Cucumbers to grow. Hotbed manure soon becomes rotten, and repeated waterings keep it in a cold, saturated state, the roots perishing when they come into contact with it. Should the warm nights and hot days continue, an improvement may be effected without a change of treatment, but a lining of nearly fresh stable manure, previously well prepared, the rank heat being got rid of by fermentation, would do good, especially if the weather should happen to be duller and colder than now (July 1). Crowded haulm may be the cause of the fruit failing to develop, and it ought to be thinned out accordingly, a repetition of this occurrence being prevented and abundance of fruit forced out by stopping all young lateral growth beyond the second leaf while yet it can be done with the finger and thumb. Continue to syringe or freely sprinkle the foliage on bright days, when the frame is closed at about 4 p.m. or rather earlier, and also keep the soil fairly moist without unduly saturating the manure below. Syringing at mid-day is unusual in the case of Cucumbers in frames. A heavy permanent shading would be injurious and seriously militate against productiveness. Shade with scrim canvas or cotton blinds during the hottest part of the day, or from 9 a.m. to 4 p.m. (to be on the safe side), and admit sunshine and light during the rest of the day. Never use cold water. That warmed by exposure in tubs to the sunshine is what Cucumbers like.

Vegetable Marrows grown too luxuriantly frequently fail to set and swell their fruit satisfactorily. Those cultivated market growers' fashion, that is to say, in the open fields with only a good

layer of manure under them, are usually the least vigorous and the most productive. These do not need daily waterings—in fact, would be better without them, especially if cold water is used. Exception to a certain extent may be made in favour of any unwisely planted in a heap of loose, quickly drying material, as this needs a good soaking of water much oftener than garden soil over a shallow bed of manure. Cold nights may have had something to do with the failure, and a change for the better may be followed by abundance of Vegetable Marrows. A check to very luxuriant growth may also, and does frequently, result in the rapid production of fruit.—I.

**Saxifraga cochlearis minor.**—This free-growing and pretty kind has been flowering abundantly during the past fortnight or so, and its pretty sprays of white, pink spotted blooms are very pleasing. It is essentially a plant for the rock garden, and for positions where its prettily crusted rosettes of leaves may be seen in company with time-marked nuggets of rock against which to nestle. In soil that is fairly deep and good, quite small plants soon spread out into compact tufts, and these if pulled to pieces and carefully replanted early in spring may soon be converted into a group 1½ feet across. Solitary tufts when allowed to cluster together into cushion-like mounds do not always flower with the same freedom as do smaller pieces that are replanted periodically, an item equally applicable to the Aizoon as well as other of the tufted kinds. It is not annual attention that is necessary for this, but separated every three years would be the means of securing a better flowering generally with many free-growing kinds. Some readers of THE GARDEN may not recognise the plant referred to above by its present name, since it is only rarely we see it correctly labelled. Invariably at the Drill Hall the plant is named *S. valdensis*, which is quite a distinct plant, generally smaller and not so free in growth or so easily cultivated.

**Philadelphus microphyllus.**—Just now the various species and varieties of *Philadelphus* are—if we exclude the *Roses*—the most conspicuous and beautiful of hardy shrubs in flower. Some of them are 10 feet, 12 feet, and, in thickly planted shrubberies where they have been drawn up, as much as 15 feet high. *P. microphyllus* is, however, the smallest of the cultivated species, and does not, apparently, get more than 2 feet to 3 feet high. It thus becomes useful for positions too restricted for the taller kinds, none of which can be pruned back without affecting their freedom in flowering. *P. microphyllus* is a rounded bush of very dense habit and with slender, wire-like stems. The leaves are ovate, about half an inch long on the young growing shoots, but only half as large on the flowering ones; they are shining green and glabrous above, greyish and hairy beneath. The flowers are pure white, each three quarters of an inch in diameter, and borne at the end of the twigs that spring from the axils of last year's growth. Their fragrance is sweet and strong, and out of doors very pleasant, strongly suggesting that of a Pine-apple. It is a native of New Mexico, Colorado, &c., and is therefore (although quite hardy) from a region that has supplied English gardens with very few shrubs that are hardy. It is necessary, as might be judged from its native home, to reserve for it a sunny position.—W. J. B.

**Anemia rotundifolia.**—This is one of the class known as flowering Ferns, in which the fertile fronds that are pushed up from the centre of the plant are totally distinct from the sterile ones, and in some kinds at least they greatly resemble the inflorescence of some herbaceous subjects. One of the commonest examples of this class is our native Royal Fern (*Osmunda regalis*), but there are several others, and among them some tender kinds. Of those that require the protection of a stove, *Anemidietyon phyllitidis* is frequently met with, while the different members of the genus *Anemia*, of which half a dozen species or thereabouts are grown in this country, are all

comparatively scarce. A very pretty member of this genus was shown at a meeting of the Royal Horticultural Society in the early part of May, when it was awarded a first-class certificate. This was *Anemia rotundifolia*, a low-growing, but spreading plant, whose comparatively long arching, barren fronds are furnished with roundish pinnae of a leathery texture and deep green in colour. The midrib is prolonged at the point for some distance beyond the pinnae, and it roots at the extreme tip and produces a young plant there. A well-grown specimen is particularly attractive and distinct, the arching fronds being disposed in a very graceful manner, while they are over-topped by the plume-like fertile ones. A very distinctive and charming feature of this Fern is the beautiful reddish-bronze tint of the young fronds, which as they mature become green. It can be raised from spores, and also increased to a limited extent by means of the young plants borne on the ends of the fronds. This *Anemia* is a native of Brazil and needs stove treatment for its successful culture.—H. P.

## GARDEN FLORA.

### PLATE 1126.

#### STENOGASTRA CONCINNA.

(WITH A COLOURED PLATE.\*)

OF all Gesnerads this is one of the most charming, and certainly it is the most diminutive of all in cultivation. The accompanying plate gives a good idea of its features except that its capacity for flowering is by no means fully indicated. The flowers, in season, are at least twice as numerous. They are beautifully and faithfully depicted, but my impression is that the leaves are always rounder and never so long as some of those shown in the plate. Though little known out of botanic gardens this plant is not new, having been introduced by Messrs. J. Veitch and Sons about thirty-six years ago. It has long been grown at Kew, and for many years it has been a favourite plant at Cambridge, never failing to excite admiration and interest. It flowers over a long season, but is in greatest perfection in spring after its rest and when making new and vigorous growth. The subterranean tubers, from which the leafy and flower-bearing stems arise, are comparatively small, scarcely equalling a Hazel-nut in size, and to get a good effect, from six to a dozen may be planted in a pot or pan according to its size.

Its culture presents no difficulty, and if rightly managed its propagation is only limited by the number of stems available, since every one can be rooted and made to form its own tuber. It should have good drainage and a soil composed of about half peat and half loam, with a liberal admixture of coarse sand. In potting, the soil should not be too deep, and lumps of sandstone here and there may appear just above the surface. During growth it should never be dry nor should it, when at rest, be quite so dry as would be right for other Gesnerads. It is best not to stow the pots away—a plan by which choice plants are sometimes lost. Let the plants remain where they may benefit from the general moisture of the house and be watered if necessary. There is no better position for this plant than a shelf near the glass and below the line of sight, if possible, for purposes of careful observation. The name here adopted is the old familiar one, but strictly the generic name is now *Sinningia*, of which *Stenogastrea* forms a section. All the *Sinningias* come from Brazil, and among them the well-known *Gloxinia* of

\* Drawn for THE GARDEN in the Cambridge Botanic Garden by H. G. Moon. Lithographed and printed by J. L. Goffart.

STENOCHA. PEA. (MONTANA)

gardens, the *Biglandularias*, *Tapeinotes*, &c. The earliest and only description I am acquainted with, under the correct genus, is that by Nicholson in his Dictionary. A figure is given in the *Botanical Magazine* of 1861, t. 5253.

R. I. LYNCH.

*Botanic Gardens, Cambridge.*

## THE WEEK'S WORK.

### KITCHEN GARDEN.

**CABBAGE.**—In many gardens sowings have been made of both Little Pixie and Rosette Colewort, as it is generally recommended to do so about the middle of June. For various reasons I consider this is somewhat early, especially if a suitable piece of ground is not available for them as soon as they are large enough for putting out, as the plants become stunted if kept in the seed-beds longer than they should be, and often fail to grow freely afterwards. It is surprising how quickly both these turn in, when planted on good ground, and to have them too early in the autumn, when perhaps other vegetables are plentiful, they do not prove so serviceable as later in the season when there is less variety to select from, while if they are required for spring use, early sowing is against them keeping properly through the winter. If seed be sown of each now, good plants will be ready in about six weeks, when there will also be more vacant ground suitable for this crop, such as that now occupied with second early Potatoes, Spinach, French Beans, and other things. Small sturdy plants always prove the most satisfactory; therefore the seed should be sown thinly, and preferably in drills, as the soil can be kept free of weeds, and the seedlings receive more light and air than when sowing is done broadcast.

**BEANS.**—It is not usual to sow Broad Beans at this season, but in some establishments they are appreciated in autumn if in a young and tender condition. A few rows of either Beck's Dwarf or Early Longpod may prove very useful later on if seed is put in now. The former could succeed early Potatoes on a warm border, and being of a dwarf habit protection is easily afforded in the autumn should it be necessary to do so. Towards the middle or end of the month another sowing of Sion House or Ne Plus Ultra French Beans may be made in such a position that a frame may be placed over them in the autumn if desired. Those that are now in bearing should be looked over daily and the crop kept closely gathered, as when the pods are allowed to remain and form seed it is at the expense of future supplies from the same plants. Although it may form a pleasing sight to see a very full row of Scarlet Runners, overcrowding is a common error and should be avoided. If only one plant were allowed to each pole, and these say 9 inches or 12 inches apart, finer Beans and a more lasting supply would be obtained. A little timely attention in regulating and stopping the most forward leaders would induce a more regular growth, and they would not become top-heavy, as is often the case towards autumn, when they are allowed to grow anyhow. This crop well repays for copious supplies of manure water. Like the dwarf varieties, a large number of old pods should not be allowed to form, as they have a most weakening effect on the plants. This is generally a favourite dish with exhibitors, and to obtain fine straight dark green pods they should be carefully selected and the pods thinned.

**ENDIVE.**—Although well-blanching Endive is always appreciated in salad, it is somewhat difficult to prevent the plants running to seed from early sowings. Seed, however, put in now may result in a good return. Ground that has been cleared of Potatoes may be used for this crop, but before the seed is put in the soil should be carefully forked over and well broken to pieces. Where this is found to be hard, dry, and lumpy, water over-night and it will fall to pieces the following morning. I prefer sowing in drills where

the plants are to remain. This not only saves the time of transplanting, but there is less risk of the plants running to seed through any check being given. Sow the seed thinly and cover with fine soil. The seedlings should be thinned down to about 6 inches apart if the Green Curled variety is grown, allowing a little more room for the stronger-growing Broad-leaved Batavian. Slugs often do much damage to the young plants during showery weather, and to guard against these, a slight dressing of soot or lime should be given after the seed is put in, repeating this occasionally when the plants come through the soil. Birds, too, are very partial to the seed, and the bed should be netted where these abound.

**CELERY.**—The earliest batch, or that required for use say at the end of August and during the following month, should now be well forward and ready for the first moulding. This requires to be done carefully and the soil put round the plants in small quantities, or there is a danger of some of the mould either getting into the centre of the plants and destroying the hearts, or when too much is afforded at once and made too firm it checks the free development of the young central leaves, and these become contracted, and if not absolutely spoilt, it detracts from the appearance when ready for use. The plants should be looked over carefully, and all decayed leaves and sucker growth at the base of the plants removed. The trenches, too, should be freed of weeds and rubbish. If rains have not been abundant and the soil is only moderately moist, a thorough soaking of liquid manure should be given some hours previous to moulding up. This is most important, as the addition of soil round the plants will prevent to a great extent future rains reaching the roots, and the plants in all probability will suffer from the want of moisture, which at no time should happen with Celery, or the produce will be tough and find little favour. After seeing that the roots are made all right in this respect, break the soil down on either side of the trench as fine as possible, so that it can be easily worked round the plants with the hand. Gather all the outer leaves round the plants in such a way that the soil cannot get into the centres and only make it moderately firm, sufficient to keep the foliage in position without crowding it together too tightly. It is best to do such work piecemeal, affording more soil once a fortnight, which will allow growth to be always a little in advance, the final moulding up being done, say, a month before the Celery is required for use.

**CUCUMBERS.**—Plants growing in frames in hotbeds that have been in bearing since April will now be showing signs of giving out, especially if they have been heavily cropped, and if it is required to keep the plants in a full bearing condition as long as possible, it will be necessary to thin out a lot of the old growth, together with a good portion of the foliage, so as to allow room for new growth to form and develop properly. A portion of the plants, too, should have all the young fruit picked off as soon as it forms, together with the male blooms, for at least a fortnight, so that the plants may have a little time to recoup themselves. The surface soil should be slightly disturbed and an inch or so of light, rich, porous compost afforded, to which should be added a slight sprinkling of soot. If the soil is heavily charged with moisture through constantly syringing the foliage, withhold water for a time, but make sure that this is the condition of the soil, say a foot deep, where most of the roots abound. Although the surface may appear wet, that beneath may be just the opposite, as the fermenting material forms a drainage, and there is a danger of the plants suffering from dryness at the roots at a time when it is considered they are all right in this respect. When water is required, a thorough soaking should be given through a coarse rose can, sufficient to penetrate through the whole of the compost and at a temperature of not less than 80°. Plants which have been rather severely pruned should be kept close and shaded for a week and the foliage dewed over

morning and evening. If the roots are healthy, new growth will soon form. This must be kept pinched at about the third leaf and regulated over the surface of the bed. Should the linings have receded from the sides of the frames, a foot or so should be well shaken out and mixed with some fresh litter. This, when replaced and made firm round the frames, building it well up to the top of the woodwork, will afford a gentle warmth, assist to retain moisture in the frame, and the plants will be greatly benefited thereby. Although plants treated in this way will mostly throw off a good second crop, it is hardly safe to trust to them to supply a large demand towards autumn. To meet this, another batch of plants should be raised now, either from seed or cuttings, and grown on ready to succeed the early batch. Another frame or house of course must be available to receive the plants, or a break in the supply for a few weeks must result if the old plants have to be cleared out to make room for them. At the time of writing we are having dull showery weather, and there is always a danger of Cucumber plants growing in light houses suffering by a sudden burst of sunshine. To guard against the foliage being scalded, a little whitening should be in readiness for syringing over the roof-glass, which would prove more beneficial to the plants than suddenly throwing the ventilators open with a view of reducing the temperature: the evil of such a practice cannot be too freely condemned. Heat, moisture and a certain amount of shade are very necessary to keep the plants in active growth, free of red spider and other insect pests.

R. PARKER.

### FRUIT HOUSES.

**PEACHES AND NECTARINES.**—Early-forced trees having been relieved of their crops, surplus shoots and the now useless bearing wood must be kept cool to enable them to retain their foliage as long as possible. To keep the leaves free from red spider and the ends of the shoots clear of aphides, the syringe or garden engine must be brought into play each day, particularly in modern houses having fixed roofs. Stop all lateral growths while it can be done with the finger and thumb, and above all things see that the borders do not get over-dry. By paying particular attention to these details, and also giving the roots the benefit of a soaking of liquid manure or a chemical stimulant in cases where the trees lack vigour, the trees will be the better prepared for the ordeal of early forcing another season. As the crops are gathered from the trees in successional houses, look them over, thin the wood if too thick, cut away that which has recently borne fruit, and in other particulars treat as advised above.

**LATER HOUSES.**—Trees on which fruits are ripening will need every encouragement as regards heat, moisture, and stimulating food, which should be applied when the borders require water. Well-drained Peach borders require a great deal of water, and this the trees must have right up to the time the fruits ripen, but feeding must cease once the pulp in the fruits is on the point of softening. Overhead syringing must also be discontinued once this stage is reached, but damping of floors and borders may go on until the fruits are ripening generally. Less advanced crops of fruit should have all leaves turned on one side and tied out of the way when shaded wholly or in part by them, and fruits inclined to droop downwards should be elevated towards the sun on strips of lath to ensure high colour. Keep all young shoots thin and carefully tied down to the trellis, and pinch lateral growths at the first leaf. Air liberally on fine days, syringe freely, and keep borders well supplied with moisture. Thin the fruits on the latest trees if not already done, pay every attention to border watering and syringing, keep the young wood thin and neatly tied down, and as soon as the fruits begin to swell freely stop all growths beyond them as an inducement for them to swell the more quickly. Well water borders if in good order, and feed according to the age and vigour of the

trees and their capabilities of assimilating the same. The ventilators of late houses may be left open continuously when warm weather prevails, but they are best closed when a sudden change to cold takes place such as occurred on June 14 and four succeeding nights, on account of the liability of an attack of mildew.

**FIGS.**—The fruit on pot trees carrying heavy second crops should be thinned before they get too far advanced. It is better to do this than distress the trees and run the risk of losing a first crop next season. These fruits will not attain to so large a size as those of the previous crop, but they are none the less useful when ripe. Figs are in almost constant demand. When the first crop has been gathered from second early trees, well wash the foliage, close the house, and start feeding the trees again to induce the second crop to swell quickly. If the mulch or top-dressing is worn out through repeated applications of water, remove as much of it as possible and apply fresh materials. Fruits on trees in succession houses will be fast approaching the ripening stage and in some cases will be ripe, when former cultural details as to the diminution of moisture and keeping up a circulation of dry warm air, together with ample ventilation by day and a lower amount at night, should be observed. In later houses such matters as the thinning and tying down of young shoots must have regular attention. It is highly necessary that the wood should be kept thin in these trees, so that it becomes thoroughly ripened by the end of the season. It is astonishing the number of fruits that well-ripened pieces of wood will produce, especially when trained directly under the roof. As mentioned in a previous calendar, young growths on all of these later trees must not be stopped, but laid in full length for future fruiting. Old trees are sometimes apt to throw up a good many suckers. These are best pulled out, as they seldom become sufficiently ripened to produce fruit. The Fig being a gross feeder, all these late trees should have free supplies of liquid food, particularly when the fruits start swelling after flowering, and this may be continued up to the time the first fruit ripens. Due attention must also be given to the mulching of borders and the daily syringing of foliage to keep off red spider.

**CAPE GOOSEBERRY.**—Established plants carrying good crops of fruit will need plenty of water and an occasional stimulant. Guano used in sufficient quantity to tinge the water is most beneficial, and at this strength may be applied again and again without fear as to results. Young plants raised from seed during the spring should be shifted into 12-inch and 14-inch pots, and as soon as the roots become active in the new compost, pinch the shoots repeatedly, or until good bushy heads are formed; they may then be allowed to bear, and the fruits will come in useful during the autumn months, when a full and varied dessert has to be forthcoming. A warm greenhouse or an orchard house answers well for the Cape Gooseberry, or it may be trained on the back wall of a Peach house. Grown in this way but little fruit would be produced the first season, as, unless planted early in the year, the energies of the plant would be principally expended in producing growth.

**HARDY FRUITS.**—Well wash early Cherry trees from which the crop has been gathered and fasten back to the walls any young shoots which had to be neglected through the trees being netted. Successional varieties on walls and trees in the open quarters should also receive a final cleansing and be netted over, otherwise birds will soon take the lot. Unless the nets are sufficiently wide to rest on the ground, they should be strained and pegged down, for if only one gap be left large enough for birds to enter they will quickly discover it and avail themselves of it.

**BUSH PLUMS.**—Owing to the light crops that the generality of these are carrying growth is very luxuriant, and had better be stopped at once. All shoots on the spurs on the main branches should, therefore, be stopped at the fourth leaf, counting from the base, while the

leaders at the ends of the branches may be left either half or two-thirds their length according to the size and age of the trees. If the trees are trained pyramidal shape, the leader may be left nearly full length in the case of young trees, but if established, cut them back about half way. Any trees which have failed to bear for the past few seasons and which make rampant growth should be marked for lifting during next autumn.

**LATE STRAWBERRIES.**—These should be kept hand-weeded, and if the fruits do not swell freely, through a weak condition of the plants, give them the benefit of a soaking of liquid manure. This must, however, be quite clear, otherwise there is a possibility of a deposit being left on some of the berries. As soon as the fruits begin to colour net them over. Get forced plants set out as soon as a piece of ground of due proportions is at liberty, and prepare ground in due course for planting with early layered runners after a sufficient number has been procured for pot work. A. W.

## ORCHIDS.

### VANDA DENISONIANA.

The blossoms of this delightful species are totally different from those of any other Vanda in that they are of the purest white, no tint of colour appearing either on the sepals, petals, or lip. In habit the plant is like a dwarf *V. suavis*, the leaves deeply channelled and much decurved, the flower-spikes appearing at the base of these when about a year old. Each flower of a good form would measure 2½ inches to 3 inches across, the sepals and petals being narrowed at the base, spreading higher up, and the lip three-lobed, somewhat fancifully described by Reichenbach as like the tail of a black cock. Six or eight of these flowers are produced upon a spike, and the present is its flowering season. The plants may be grown either in pots upon the stage or in baskets and pans suspended from the roof glass, the latter way being perhaps the more suitable owing to the freedom with which both air and light play about them. When newly imported, considerable care has been found necessary to prevent the foliage becoming loose at the axils and dropping, this being so troublesome in some cases that the plants have been entirely lost. Doubtless in a measure this is due to the time the plants are collected, and in many cases can only be partially prevented, but if more care were taken to keep water away from them when first introduced to heat there would be less trouble from this damping of the foliage. I have found such plants do well suspended upside down from the roof in a shady part of the East India house until they begin to plump up, when each plant may be separately placed in as small pots as convenient, using clean, finely broken crocks in lieu of compost. Thus after their long drying they are brought by degrees to more moisture, and their power of absorbing it becomes gradually stronger.

*Vanda Denisoniana* is not quite so strong rooting as some nearly-related kinds; consequently even for well-established plants the receptacles need not be large. If pots are used, drain them well and repot when the roots are commencing to push in spring. The cleanest and best Sphagnum obtainable mixed with charcoal and potsherds is all that is needed for compost, and this may be somewhat firmly placed over the drainage. Cut the ends off tidily and place the plants with as little delay as possible into the growing quarters, the East India house suiting it best. The plants must not be allowed to want for water, but no more than is absolutely necessary should be given.

Plants not over-supplied with roots may be left to get well on the dry side before giving a fresh supply of moisture, even while growing, and during the winter months a nominal quantity suffices. The foliage must be kept free of insects and especially scale, to which it is subject, or good results must not be looked for. *V. Denisoniana* is a native of the higher mountainous parts of Burmah, and was first discovered by General Benson growing on tall trees at an altitude of about 3000 feet above sea level. This was in 1868, and about a year afterwards it flowered for the first time in England with Messrs. Veitch. There is a variety called *hebraica*, owing to a supposed likeness in its lip markings to Hebrew characters. The sepals and petals in this case are pale sulphur-yellow. This plant was imported and sent out by Messrs. B. S. Williams and Son, who received it among an importation of the typical form about 1885.

***Dendrochilum Cobbianum.***—This is a pretty plant just commencing to flower. It is distinct from the better-known *D. glumaceum* in having longer and thinner pseudo-bulbs, the flowers occurring on long racemes, and a pretty pale yellow in colour, with an orange lip. It requires plenty of heat and a moist atmosphere while growing, the water supply being in accordance with the state of growth. It is a native of the Philippine Islands, and was introduced in 1880 by Messrs. Hugh Low and Co.

***Odontoglossum cordatum.***—Few *Odontoglossum* plants vary more than this in the quality of their blooms, though but few named forms are described. A good variety is now in flower with me, the sepals orange-yellow, heavily blotched with brown, the heart-shaped lip pure white excepting just the tip, which is reddish brown. It is a native of Guatemala, and does well with *O. grande* and similar kinds here in a cool fernery. It was first introduced about sixty years ago, but was afterwards lost to cultivation.—II.

***Stanhopea insignis.***—This is a handsome plant now in bloom, the scapes containing from three to five flowers, each about 5 inches across. They are straw-yellow on the sepals and petals, spotted with purple, the lip white, with a deep purple blotch in the cavity in the centre. *S. insignis* is the type on which the genus was founded and the first to bloom in this country, which it did as far back as 1829. It requires ample warmth and a very moist atmosphere to do it well, and should be cultivated in baskets with fairly open bottoms, so as to allow the descending flower-spikes plenty of room. The plants should be re-basketed when they begin to grow.

***Trichopilia tortilis.***—This is a free-blooming and interesting plant, the blossoms not so large as in some other members of the genus. The sepals and petals are singularly twisted, bright brown, with a yellow margin, the lip white, with a crimson throat and many spots of the same tint in front. It is best grown at the cool end of the Cattleya house, and when the roots have obtained a good hold of the compost it likes plenty of water all the year round. It has a nice appearance grown in baskets suspended from the roof, but may also be planted in medium-sized pots if more convenient. It comes from Mexico and was introduced in 1835.

***Masdevallia racemosa.***—A nice plant of this species I noted this week is bearing three spikes, one of these having seven flowers. It is quite distinct from most other *Masdevallias*, the flowers a bright orange-erimson, with an overlying tint of scarlet. The habit is not so tufted as in the *Harryana* and similar sections, the stems occurring at a slight distance apart upon a creeping rhizome. For this reason a rather larger receptacle should be given, but it has the same dislike to a heavy, close compost as the other members of the genus. It is not a common plant under cultivation, though it has long been known

to botanists. It is known also as *M. Crossii*, but *M. racemosa*, as given by Lindley, is the correct name. Though discovered by Hartweg over half a century ago, it was only introduced to cultivation by Mr. Corder in 1883.—H. R.

**Cattleya Mendeli.**—This is one of the most refined-looking of the labiate Cattleyas, and it has a longer blooming season than many. The earliest plants are in flower in April, and a few plants here are just opening, so that it extends over three months. The sepals and petals are usually nearly pure white, the elegantly frilled lip having also a good deal of white about the side lobes. The centre is crimson, lined with purple, and an orange-yellow throat. The pure white form is one of the rarest and most beautiful of the albinos in this section, and it is named, in compliment to its discoverer, C. M. Blunt.

**Habenaria bifolia.**—Very beautiful and fragrant in the woods around here is this pretty Butterfly Orchid. It is seen at its best under the shade of Hazel and other coppices, the spikes being longer and the blossoms a purer white than when growing in more open positions. The spikes grow about 18 inches high, the upper portion covered with flowers each 1 inch across. It is a useful plant for naturalising in a fairly moist position shaded from the brightest sunshine. Any good loamy soil suits it, and it will thrive better for the addition of plenty of leaf-mould when planting and an annual mulch of the same material.—SUFFOLK.

**Odontoglossum Harryanum.**—A nice spike of a good form of this favourite plant comes from a correspondent, and I have also noted it in many collections recently. Some of the varieties have the bad habit of only half opening their flowers, but this is, I think, partly caused by weakness. *O. Harryanum* is an easily enough grown plant when once in good order, but once it gets into bad condition it is by no means an easy task to bring it back to health. The pseudo-bulbs are longer and more flowers are produced upon the spike when a little more heat than that of the coolest house is allowed. It is a native of Colombia, and was first imported by the late Mr. F. Horsman, of Mark's Tey.—R.

**Oncidium luridum.**—This is a useful and handsome member of the bulbous section of the genus, of which better-known examples are *O. Lanceanum* and *O. Cavendishianum*. The leaves are pale green, and from their base a flower-spike rises often to the height of 4 feet or 5 feet, clothed with flowers over a good portion of their length. The sepals, petals, and lip are all greenish yellow, the first almost covered with light brown blotches. There is also a form of it with prettily spotted flowers. It is a native of Jamaica and other parts of America, and does well in a light position at the warmest end of the Cattleya house. It does not take kindly to disturbance, and often fails to bloom after being repotted. This need not, however, be the case if the work is carefully done. Pick out the old material and replace with new, without taking the plants out of their pots until they have outgrown them, when a shift must be given. Plenty of water is needed while growing, much less sufficing while at rest.

**Dendrobium Farmeri.**—This is one of the latest to flower of the evergreen section, and a favourite plant among Orchid growers. Strong plants have pseudo-bulbs 18 inches and upwards in height, the rather loose racemes proceeding from the upper portion of these in the usual way. It makes a fine display in the flowering house if placed there just before the blooms open, and it lasts about a fortnight in good condition. In the typical form the sepals and petals are a pale yellow, the lip deeper in colour, with an orange disc; but there are many forms of it under cultivation, some having the outer segments tinted with rose, others a deeper yellow than the type, while others again are pure white. It does well with rather less heat than the deciduous section generally requires, and may, in fact, be grown in the Cattleya house all the year round. The plant begins to grow soon after the

flowers are past, when they may be repotted if this is necessary, using a compost of peat fibre and Sphagnum Moss in equal proportions. The pots may be a little larger than usual, owing to the roots being more fleshy and pushing farther from the centre of growth. It has a wide geographical distribution in India and Moulmein, and was introduced to this country in 1847.

**Nanodes Medusæ.**—This very singular and weird-looking plant was recently in bloom with Mr. Bull. The blossoms occur at the end of the pendent, ungainly-looking growths, and are chiefly remarkable for their long-lasting qualities and the purple, deeply-fringed lip. Botanically, this plant differs little from the *Epidendrums*, but its distinct growth and general appearance will always keep it separate as a garden plant. Its culture is by no means difficult, yet it is an extraordinary fact that in many cases plants treated for years under precisely similar conditions will be found to differ greatly in health and the amount of growth made. The usual mode of culture is to plant it in pans or baskets of rough peat and Moss, suspending these from the roof. If Tree Fern stems can be procured, they make a capital holding for it. Nearly all the year round plenty of water must be given, for it seldom rests long, one set of growths being little more than half grown sometimes when another one is produced. A light position not far from the roof-glass suits it well, and as it comes from Ecuador, not much heat is necessary. It was originally introduced by Messrs. Backhouse, of York, in 1837, and it flowered for the first time in England soon after in the collection of the late Mr. John Day.

#### CATTELEYA CRISPA.

ALTHOUGH this plant is strictly a *Lælia*, it is much better known as a *Cattleya*. The plants are just now commencing to bloom, each spike carrying about half a dozen large showy flowers, rather narrow in the segments, but very bright and effective. The growth is not so tall as that of *Lælia purpurata* and rather stouter, the flower-spikes appearing on the young bulbs as they attain maturity. It is a vigorous rooting plant, and delights in a rough make-up of material consisting of about equal parts of good fibrous peat broken into lumps as large as a hen's egg, and clean freshly gathered Sphagnum. Add to this a good sprinkling of rough lumps of pottery ballast or crocks and a little rough charcoal. The growth of large plants is rather straggling and untidy, and a good deal of care is required to make a nice shapely specimen of some of the newly-imported pieces that arrive in this country. It is quite impossible to avoid burying some of the bases of the older pseudo-bulbs, but this is of little consequence if plenty of new leads can be arranged on the surface. Keep these as near the centre as convenient, as the roots then stay in the compost, and by means of stout stakes and ties draw the stems into the required position or as near as possible. The best time to repot established plants is when the growths are getting well away in spring, as the roots that are at this time emitted from the rhizome give them a good hold of the new material. Without disturbing the plants more than can be helped take away all dead roots and decaying rhizomes, also any of the older peat that has become sour. Give a good shift and fix the new compost firmly and carefully with the dibber. The plants need not be elevated much, just enough to allow superfluous water to escape and the pots must be efficiently drained. Avoid checking the young shoots by taking the plants to a cold or draughty shed, and get them back to their growing quarters with as little delay as possible. This will be the warmest and lightest part of the Cattleya house. Rather more shade than usual may be allowed after repotting, as just at this time both old and young foliage is apt to suffer. Grow on strongly in a full Cattleya temperature and plenty of atmospheric moisture, taking care that no water is allowed to lodge in the sheath formed by the growing leaf. After blooming keep

the plants a little on the dry side, give all the air possible and keep them dormant until the spring. *C. crispata* is an old species in cultivation and was sent by Sir H. Chamberlain from Rio de Janeiro in 1826. It has a wide geographical distribution in Southern Brazil, this doubtless accounting for the variable character of the flower.

**Cypripedium callosum Sanderæ.**—In Baron Schröder's group at the Temple show was a very fine plant of this *Cypripedium* bearing two splendid flowers. The dorsal sepal has no tinge of purple, but is white with heavy veining of deep green, the petals similar in ground colour and the lip pale greenish with very fine venations. The foliage is lighter than that of the type, the whole plant in fact being a lovely combination of white and various greens.

**Anæctochilus Sanderianus.**—Judging by the healthy appearance of several plants of this species exhibited by Messrs. Sander and Co., it should be more free-growing than the majority of this section. The leaves are large, oblong, deep green in the centre, becoming a purplish tint towards the outer wavy margin, the whole delightfully reticulated with golden, green and silver veins, with the usual glossy surface. If as strong growing as it looks, it should be a decided acquisition.

**Lælio-Cattleya Hippolyte.**—Several plants of this pretty hybrid were recently in bloom at Messrs. Veitch's Chelsea nursery, where it was raised and first flowered some seven or eight years since. It is a distinct and pretty plant, the blossoms occurring from the top of the bulb and in shape like those of a small *Cattleya Mossiæ*. The sepals and petals are bright orange, with a slight suffusion of rose. The lip is yellow at the base, the front lobe reddish purple and slightly fringed.

**Lælia grandis tenebrosa.**—This was exhibited by several nursery firms at the Temple, but, taken as a whole, the varieties shown were not particularly good, judging by last season's form. The plant is too well known to need description, and probably we shall see it in better form as the season becomes more advanced. *L. grandis tenebrosa* is a strong-growing, easily-cultivated species that thrives well in the warmest part of the Cattleya house. It should be potted in very rough open material on account of the size of the roots, and requires abundance of water.

**Odontoglossum crispum Starlight.**—A good deal of interest was apparent at the Temple show in this unique form of *O. crispum*, which was exhibited by Mr. R. Brooman White, of Ardaraoch. The flowers are large, of excellent shape, the petals broad and crisped, of a rosy white, suffused with a deeper tint and very profusely spotted, the spots small and reddish brown. The lip does not differ materially from that of the ordinary forms, but the plant is perfectly distinct from any other known kind and bore a strong, many-flowered spike.

**Lælio-Cattleya Digbyana-Mossiæ.** There is not a more beautiful hybrid than this in cultivation, and though by now it is no novelty, its characteristic and striking appearance calls forth many encomiums wherever exhibited. Baron Schröder, of The Dell, had a fine plant in his group at the Temple recently, superbly grown and carrying a magnificent flower. The sepals and petals are a delicate rosy lilac, the lip rather deeper in ground colour. The throat has a yellow blotch in the centre, with streaks of crimson, a deeper streak occurring in front and leading to the prettily fringed rosy pink margin.

**Oncidium phymatochilum.**—Not only are the individual blossoms of this species very interesting and quaint-looking, but in the aggregate they make a very handsome show. This may now be seen at Mr. Bull's, several large spikes being in full beauty and others advancing for flower. It is a Brazilian plant, and may be grown in an intermediate or Cattleya house temperature. The pseudo-bulbs are each about 5 inches high, each bearing a large leaf, and the spikes rise to the

height of about 18 inches. The sepals are greenish yellow, lightly spotted, the front lobe of the lip white, the sides greenish, with spots of orange and brown.

**Oncidium olivaceum Lawrenceanum.**—In habit, shape and disposition of the blossoms this somewhat resembles *O. cucullatum*, but it is far superior as a garden plant. The spikes are longer and bear a large number of flowers, each about 1 inch across. The sepals and petals are very deep chocolate-brown, slightly incurving, the dorsal sepal hooded. The column is crimson-purple, the lip deep rose, heavily spotted with brown. It thrives well in the cool house, and may be potted in peat and moss. Several nice plants were recently in flower at Mr. Bull's.

**Oncidium pulchellum.**—This is one of the prettiest of the smaller-flowered *Oncidiums*, and I lately noted some very nice spikes at Mr. Bull's. These are about a foot long and very closely studded with flowers. The sepals and petals and the broad-spreading lip are all white, the latter with a rosy suffusion and a few pink spots about the bright yellow crest. *O. pulchellum* belongs to a section of the genus too little cared for, and including such as *O. elegans*, *O. tetrapetalum*, and others. It is a native of Jamaica, and should be grown in the Cattleya house in a light and fairly sunny position. The plant itself is only a few inches in height and consists of small leaves without any pseudo-bulbs.—R.

**Lælia purpurata Ashworthiæ.**—This is one of the most distinct *Lælias* ever exhibited. The sepals and lip were of the ordinary class and colour, but the petals were marked almost in the same manner as the lip, the colour being a deep crimson-purple that commences in radiating lines at the base of each, spreading until it almost covers the segments. It was remarked that the thing was a freak and would not occur again, but as it is not its first time of flowering this is hardly likely. Nor was there anything of a monstrosity about it, for the shape of the segments was perfectly normal, the colour only distinguishing it from an ordinary *L. purpurata*. The plant bore five pseudo-bulbs.

## CHRYSANTHEMUMS.

### A TABLE OF CHRYSANTHEMUMS.

HAPPILY now for the blooms of a high standard of excellence other uses than merely placing them upon an exhibition table are being found. This is a matter for congratulation, for while most growers value smaller blossoms cut from plants grown in a free manner, the majority of them would readily acknowledge the superiority of the large flowers for all kinds of bold and striking decoration. Such a fact cannot fail to give an impetus to the cultivation of high-class flowers.

As in all floral decorations, colour is one of the most important essentials. The more general use of large flowers for tables, sideboards, vases, &c., would result in many dowdy-looking and badly-coloured flowers being discarded in favour of others somewhat smaller, yet decidedly brighter in colour. There is one important fact to be remembered when arranging large *Chrysanthemums*, and that is unless the stems be almost entirely denuded of their foliage, the blossoms collapse in a comparatively short time. While blooms which have been treated in this way have kept in a fresh condition for some days, others not subjected to this treatment have succumbed in a few hours, especially in a hot and ill-ventilated room. This disadvantage in the loss of their own foliage may be overcome by the use of small fine-leaved plants in association with them. Plants such as *Cocos Weddelliana*, *Crotons*, *Eulalia japonica variegata*, small Ferns, *Pterises*, with an edging of *Isoplepis gracilis* and *Panicum variegatum* are

each exceedingly useful when arranged with a proper regard for colour effect. Then there are so many *Chrysanthemums* grown on single stems from late propagated cuttings and flowered in 5-inch and 6-inch pots. These are often used for the decoration of sideboards and other equally important positions, and as the foliage in this case has not to be interfered with, very little else is needed.

For table decoration, or for individual vases for the drawing-room or hall, the large flowers of the *Chrysanthemum* are seen to immense advantage. Fine bold-looking arrangements are generally appreciated, and are a welcome change from those in which smaller flowers have been in general use. Vases confined to one colour, or, if the selection be a limited one, those of such colours as will harmonise should be chosen, and in association with them quite a wealth of foliage with rich autumnal tints lends itself ad-

### CULTURAL NOTES.

To grow *Chrysanthemums* well they require plenty of room. Crowding is often a cause of indifferent blooms, a large number of plants being allowed to stand almost close together even when more space is available. I have noted such look well in the bulk; that is, the leaves become large and very green, but they are wanting in texture and the stems produced are likewise soft. Wood like this is not the kind to produce solid well-formed flowers. It must be firm and well ripened; then if it be not over-large, good results will follow. *Chrysanthemum* plants in single rows around the sides of walks are usually in a suitable spot, especially if this be not shaded unduly by trees, and if they are stood about a foot apart; all other things being attended to, we should expect satisfactory growth. Crowding, however, is most noticeable when a plot of ground is given up to their

A table of *Chrysanthemums* and foliage. From a photograph sent by Miss H. Vernon, Auchans House, Kilmarnock.

mirably to these arrangements. More particularly is this noticeable in the richly coloured flowers of yellow, orange, and crimson, the pink and white blossoms being seen to greater advantage with silvery-tinted foliage, and a few pieces of deeper and richer coloured copper shades.

Ideas in regard to floral arrangements are becoming changed, and there is good reason to believe that the handsome blooms of the *Chrysanthemum*, which at one time were rarely used in the house, will in the future be largely in demand for this purpose, thanks to the efforts of the leading exhibitors in their endeavours to prove the usefulness of large flowers for all kinds of decoration. One good result of the popularity of this system will be the retention in the lists of the *Chrysanthemum* specialists of a large number of varieties of good colour and most desirable form which for ordinary exhibition purposes are a trifle undersized.

D. B. CRANE.

summer culture. I would here insist upon the space of 5 feet to 6 feet between each row and quite 18 inches from pot to pot in the rows. There is then ample room not only to get among the plants for the necessary work, but air and light may pass freely about the leaves, and the growth becomes firm as it advances. The pots may be stood on boards. This is usually done to prevent the roots from wandering in the earth through the drainage hole, and thus causing a check when removed. One need not go to this trouble if the pots be turned occasionally throughout the summer, and a bottom of ashes is cooler—an item worth noting. It is not an easy matter to prevent the roots getting scorched at the sunny sides of the pots in very hot weather. I have known cultivators who have allowed the weeds to grow around them to provide a little shade, with some effect, although the presence of these is not taking to the eye.

Tie the central stems of the plants to sticks before they get long. The need of this has been apparent lately when rough winds have been so frequent. A large number of the lower leaves of my plants are blown off. This gives them a naked look for a time, but it is astonishing how quickly they recover when the elements are more favourable. I must say I do not view with apprehension the loss of a few of the lower leaves. Their work will have been finished long before the end of the season, and they are as well thinned out to allow a thorough ripening of the stem.

Tall-grown plants are still, I fear, one of the drawbacks of growing large blooms of Chrysanthemums, and no system of topping generally will make them more dwarf only at the expense of the blossom. I have more than once noted improvement in this direction, but some of the newer varieties are as ungainly in growth as the older sorts, discarded, perhaps, because of this habit. *Australie*, for instance, seems likely to have stems 9 feet high before the season is over, and *Mme. Carnot* is not a nice grower. *Pride of Madford*, *Phœbus*, *M. Chénon de Léché*, *Australian Gold*, and *Oceana* are among newer sorts with a taking habit of growth, and ample foliage of a dark green colour. Watering plants in pots requires more care than many appear to think and a great number of Chrysanthemums suffer in this respect. I feel certain giving too much moisture at the roots rather than not enough is often the cause of unhealthy plants. This over-watering is very likely to occur at the present time, just after the plants are placed in the flowering pots. I am a firm believer in keeping the soil on the dry side, at least until the same is completely filled with roots. In the case of the subject of these notes that is not likely to be yet, so that it is wise to be very cautious in the supply of water. I know watering Chrysanthemums is considered quite a daily item. That is to say, a supply is given almost regardless of the weather. Now, it occurs to me that during dull, sunless days, unless the wind is drying, there is enough moisture in the atmosphere to prevent the leaves from flagging; and at such times the roots are more likely to be moving in partially dry earth than in that in a sodden state. I would rather sprinkle the leaves than pour water on the roots during sunless weather. I should then expect to find roots coming to the surface for moisture. During bright sunshine the danger of over-watering exists in a far less degree and flagging of the leaves is then avoided. But not even then is it wise to water every plant at the same time. Go over the collection in the morning and deal with those quite dry at the roots. Then again at mid-day and in the evening take another round among the plants. The well-known practice of tapping the pots is a good one. A ringing sound usually indicates dryness at the root. But if a doubt exists, lift a pot, and its comparative weight will provide a very good sign of the condition of the earth. A cultural error to be avoided is not giving enough water at a time to thoroughly soak the whole ball of earth. Mere top moisture will not do; the bottom must be soaked as well. Then the mistake of applying manures too early is not uncommon. Stimulants are not necessary at the time roots have ample fresh earth to run in. To give fertilisers then is a sure means of either unhealthy or soft growth. When stimulants may be given depends upon the time the plants are potted and the size of the pots used. If the plants are growing freely and the foliage healthy in tone, we may be sure proper food is being supplied in abundance. When the pots are well filled with roots the leaves quickly put on a starved

look, and then is the time to begin feeding. Towards the end of July is usually a very good time. H. S.

### THE LANDSCAPE GARDENER AND HIS WORK.

HAVING been frequently exasperated by the use in American writings of the term *landscape architect* and *landscape engineer*, we see with much pleasure a protest against the use of these terms by Mr. O. C. Simonds, of Chicago, in an article which in other respects is interesting and true. Even our old friend Meehan, of Philadelphia, has described himself somewhere as a "landscape engineer" as a word a curious hybrid and in idea horrible.

The term "landscape gardener," instead of "landscape engineer" or "landscape architect," is used here because it is believed by the writer to be the most suitable to convey the meaning intended. When one considers engineering in connection with landscapes, instead of thinking of any artistic result, he is more apt to think of the road scars along mountain sides, of the destruction of beautiful scenery along river banks, of the changing of watercourses into sewers, of railway embankments, canals and dams. The term "architect" brings to mind a man who aims to design structures. His materials are stone, brick, the various metals, wood, glass, paint, &c. On the other hand, the term landscape gardener has first, "landscape," which as defined by Hamerton must necessarily be an artistic portion of the earth's surface, and then "gardener," which indicates that the materials used will be those found in a garden or in Nature.

What are the attainments of a skilful landscape gardener? His art applies to any outdoor scenery which can be affected by the hand of man. It is of the first importance, therefore, that he know how to arrange the ground surface, the trees, shrubs, and other plants, the ponds and streams, the points of view and the open spaces or vistas, so that the general effect will be beautiful. No matter how great his knowledge of soils, of drainage, of road construction and of the structure and characteristics of the various species of plants may be, if he fails to make an artistic arrangement he is not a landscape gardener.

Next in importance to a knowledge of arrangement comes the ability to produce a result which, with a reasonable amount of attention, will continue to improve with added years of growth. This ability will rest in part on an acquaintance with the habits and life history of the plants used and of the situations to which they are adapted. The points of view will require a study of the relations of buildings, drives and walks to the landscapes. Where the landscape is an important feature the landscape gardener should work with the architect in the preparation of the preliminary sketches. Unfortunately, architects frequently design residences and other buildings without any regard to the site and the characteristic features which may have attracted the owner. Cases are not unknown where houses have been so designed and placed that the kitchen and servants' rooms shut off the very best views from the family living rooms. A landscape gardener should place his drives where they will command good views while not interfering with the landscape, and he should know how to place them so they will be convenient, have easy grades and proper drainage and how to construct them in a durable manner with a satisfactory wearing surface. He should know how to economise in regard to space and cost of the work coming under his direction. While he should have no pecuniary interest in any work that is carried on—that is, should have no interest in any nursery or nursery stock, or act as agent for any firm—he should usually purchase the material furnished by nurserymen on account of his knowledge of what is required, of the prices that should be paid, and the standing of the various

nursery firms. He will often be able to save an owner several times the amount of his fees by his knowledge of the value of plants.

His work should commence with a study of the value of a given piece of ground for the purpose intended, especially when that purpose is the making of a park, a botanic or public garden, home grounds or airy roadway. The ground in question may have features which would be of great importance in the design to be worked out, such as an important view of a large body of water, a valley or a distant stretch of country, a grove of our native trees or woodland, a rocky ledge, a steep bluff or a ravine, or it may lack beauty which could be secured by the selection of another piece of ground. When the site is finally selected a thorough study should be made of its characteristic features and of all the surroundings, and after such study the landscape gardener should have a clear conception of the effect he means to produce, of its appearance when the first planting shall have been done when years have elapsed. Not only that, but he should have in his mind the various effects of spring, summer, fall and winter.

Having made his design and perhaps sketched it on paper ("perhaps," because a sketch is not always necessary, and there are cases in which the best result will be produced by working directly on the ground), he proceeds to execute it just as his brother artist proceeds to paint a picture. He has 10,000 servants to help him. If he wishes a dark green carried up from a given place on the ground he chooses a Maple, or if the green is to continue through the water he chooses a Pine as his servant to gather the materials already found or placed in the ground. If he wishes a red in winter he chooses a Dogwood, which will put this colour in its bark, or if he wishes a red in summer he chooses a Rose. To be sure the servant must breathe the surrounding air while doing the work required. By choosing the right number and kind of such helpers a great mass of colour may be carried high into the air or spread out on the ground like a carpet. The colours may be varied from time to time, or bits of one colour may be scattered upon another. Choosing the right servants is not always an easy task, but each one performs with marvellous skill the work he or she is able to do. Whether the living picture, as a whole, will be satisfactory or not will, however, depend upon the choice made by the landscape gardener, provided his supervision is continued for a long enough time. The continued supervision is required because it takes time—in some cases years—for the servants mentioned, the various trees, shrubs, vines and herbaceous plants, to do their part in making the picture. Few of the members of the profession, to say nothing of the clients, appreciate the importance of an oversight extending through a series of years. The architect's work is finished with the completion of a building; the painter's when he puts his last touches on a canvas, but what a landscape gardener must have in mind is not a single picture, but a series of pictures having more or less resemblance to each other, changing more rapidly with the first than with the later growth, and needing from time to time the inspection and criticism of a trained eye. This inspection may be made by visiting a place once a year, once a month, or even more frequently, as may be agreed on with the client, but it should not be omitted.

What compensation will a landscape gardener receive for his work? In the first place, he will enjoy the beauty of Nature far more than most men. He will also get much pleasure from his work. He will have a chance to get the pure, clear air of the country, to take walks through the woods and over fields. These are important considerations, but he must also receive money and have a basis for his charges. It takes as much natural ability and as much time spent in study to become proficient in his profession as it does to become a good lawyer, a good physician, a good engineer, or a good architect, and his pay should equal theirs. Moreover, he must travel and see what others have done in other cities and

countries, and he should give special attention to what Nature has done. This requires both time and money. The percentage charge made by architects is not applicable to landscape work. A fee determined by an estimate of the time required in making a design is usually most satisfactory, or an arrangement may be made to charge a certain amount by the day, the month or the year. The subsequent supervision should be a separate matter from the original design and execution of the work. If an agreement for a given amount per year is made for supervision, the landscape gardener will feel more free to inspect the work as often as he may deem advisable than if he charges for each visit. His income should increase with his skill and experience, just as that of a lawyer increases when his ability is demonstrated by his practice, or the charges of a painter increase when the critics recognise the merit of his productions.

In conclusion, it may be well to state that the best result will only be attained when the client has an intelligent appreciation of what is aimed at by the landscape gardener, and is in full sympathy with him.—*Park and Cemetery.*

## TREES AND SHRUBS.

### SPIRÆA FLAGELLIFORMIS.

THE subject of the accompanying illustration is one of the most distinct of the Spiræa family, the form of its long slender shoots, studded with thickly-set rosettes of white blossom, being well depicted in the illustration. Some of these curving shoots are a yard in length, whilst others branching thickly show palmate surfaces of blossom. Though growing more rapidly when planted in the neighbourhood of water, moisture is not so indispensable for this Spiræa as for others of the family, proof of which is afforded by the specimen here illustrated, which is evidently in rude health, though situated in a position that would at first sight appear to be particularly ill-adapted to the wants of a Spiræa, for it is planted in light, shaly soil on the steeply-sloping bank of the river Dart, hard by its entrance to the sea, fully exposed to the south, though sheltered from the north and east. In the same garden are many rarities that are at home in the shelter afforded by the lie of the land and in the warmth engendered by the proximity of the sea, the nature of the soil and the southern sunshine. Here *Acacia dealbata* grows and flowers well. *Embothrium coccineum*, *Eucalyptus globulus*, *Dracenas*, *Palms* and other sub-tropical subjects find the conditions suited to their requirements, but that *Spiræa flagelliformis* should have appreciated like conditions would scarcely be credited did not the photograph taken during the arid summer of last year give evidence of its luxuriance and prove that this Spiræa may be grown successfully in many positions that would be quite unsuited to others of the shrubby section, such as *S. arifolia* and *S. Lindleyana*. In the present year this specimen promises to excel its display of the preceding summer, showing that it has not suffered materially from the long-existing drought of 1896. *Spiræa flagelliformis* has many synonyms, of which the most common is *S. canescens*. S. W. F.

**Escallonia Phillipiana.**—The bulk of the Escallonias only succeed really well when they are grown on a wall or in those parts of the country like Devon and Cornwall where many things that are only half hardy near London flourish in full

exposure. The great value of *E. Phillipiana* consists in its being hardier than any other species, thriving perfectly, as it does, in the open in the London district. It is, moreover, very distinct, and both in its flower and mode of growth quite different from the others. Its leaves are quite small—half an inch to three-quarters of an inch long—almost without stalks, quite smooth and faintly toothed at the edges. The flowers also are small (from one-third of an inch to half an inch in diameter), pure white, but borne in the greatest profusion. The whole plant has a curious resemblance to the Australian myrtaceous shrub *Leptospermum scoparium* both in its leaf and flower. Many of the main branches are long, slender, and more or less pendulous. At the present they are cylindrical masses of white blossom, and the shrub, indeed, is one of the most beautiful of those that flower in late June and July. It is a native of Valdivia, and was originally sent home about a quarter of a century ago by Pearce, who was then collecting for

3. *L. palustre* (syns., *L. angustifolium*, *L. longifolium*, *L. odoratum*). North Europe, North Asia, and North America.

The "Kew Index" includes a fourth specific name—*L. californicum*—the original description of which appears in the "Proceedings of the Californian Academy" for the year 1863, and is by Dr. Kellogg. Judging from it (but in the absence of specimens or further information) it is most likely a form of *L. glandulosum*, which is a native of California. *L. latifolium* and *L. palustre* have been in cultivation for more than 130 years, but the other, *L. glandulosum*, is quite a new introduction to this country, and the fact of its having flowered at Kew for the first time a few weeks ago may be made the opportunity of passing it and its two fellow species in review. They belong to the Heath family, and, like many of their allies, are notable for their rounded, compact habit and

*Spiræa flagelliformis.* From a photograph sent by Mr. S. W. Fitzherbert, Lonscombe House, Torquay.

Messrs. Veitch. It can be propagated from cuttings put in during August.—W. J. B.

### LEDUMS.

JUDGING by the number of names that have been given to the Ledums, one might conclude that the genus was quite an extensive one. There are, however, but three species in cultivation, and these, so far as I can ascertain, make the total number of species known and discovered. They are, at any rate, the only ones represented in the herbarium at Kew. Their names and commonest synonyms are as follows:—

1. *L. glandulosum*. West North America.
2. *L. latifolium* (syns., *L. canadense*, *L. groenlandicum*). North America and Greenland.

the freedom with which they flower. They are evergreen, and the flowers are white; whilst always of low stature, they are sometimes even prostrate. They inhabit the swamps and marshes of the cool temperate and arctic regions of the three northern continents, and under cultivation should be given a peaty soil deep enough to be permanently cool and moist. They ripen seeds freely in this country, and these afford a plentiful though not very quick means of increase. Propagation can, however, be also effected by layers.

**L. GLANDULOSUM.**—It is curious that a shrub like this, which is evidently as handsome as any of the Ledums, should so long have remained unknown to English gardeners. It was described over fifty years ago by Nuttall, the American scientist, and has several times been collected for

herbaria since then, but it was not until 1894, when Professor Sargent sent seeds of it to Kew, that the species was introduced to this country. These young plants have this year flowered very prettily and the species promises to have all the beauty of the two older species. It is a Western North American shrub, being found in California, British Columbia, &c., but not on the eastern side of the continent. From the other two species this is quite distinct, chiefly by reason of the foliage. The leaves are ovate, each from three-quarters of an inch to nearly 2 inches in length, glossy green above, and the slightly glaucous under surface is dotted with small, flat glands to which the specific name refers. Of the soft rusty coloured wool which is so prominent a feature beneath the leaves of the other two species there is no trace in this, and, except for a few hairs when quite young, they are glabrous. Neither have they the revolute margins seen in the others. The flowers are each three-quarters of an inch in diameter, pure white and each has ten stamens; they appear in terminal clusters 2 inches to 3 inches across. Wild specimens are described as growing from 2 feet to 6 feet high, and the species is therefore considerably taller-growing than either of its fellows. Already the small plants at Kew give indications of a quicker growth and more open habit. As a new addition to the peat-loving American plants, this is certainly one that merits notice from those interested in that beautiful class of shrubs.

**L. LATIFOLIUM.**—From *L. palustre*—to which it is nearly allied—this species can be distinguished by its broader leaves and by each flower having five to seven instead of ten stamens. The seed vessels are also slightly different in shape. It has not such an extended distribution, being found chiefly in North America, where it reaches from Newfoundland southwards to Oregon. It exists, however, in Greenland also. The leaves are narrow oblong, usually from 1 inch to 2 inches long, sometimes as much as 2½ inches long by three-quarters of an inch wide; the margins are curled under as in *L. palustre*, and the lower surface is covered with the same rusty-coloured wool. The flowers are each half an inch to three-quarters of an inch across, white, and produced during May in dense corymbose clusters at the ends of the shoots. As a garden plant it is preferable to *L. palustre*, the larger foliage improving its appearance. In spite of the differences mentioned above, this species and *L. palustre* come so near each other that more than one authority has made them forms of the one species. *L. latifolium* globosum is a variety with exceptionally large and globular flower-trusses.

**L. PALUSTRE.**—This is by far the most widely spread in a state of nature of any *Ledum*, encircling the entire globe at high latitudes and penetrating within the Arctic Circle. It is equally common in North Europe, Siberia and Japan, and it spreads from east to west of the northern parts of North America. It has been found wild in Perthshire. It is a densely leafy bush from 1 foot to 2 feet high, the leaves being the narrowest of the *Ledums*, and varying from half an inch to 1½ inches in length. In the far northern latitudes the leaves are sometimes no more than one-sixteenth of an inch wide. The margins are always curled under, and the lower surface is covered with a reddish soft wool. The flowers appear during May, closely set in terminal clusters, each flower about half an inch in diameter. The stamens are ten in number, and this is the chief character that distinguishes the species from the nearly allied and very similar *L. latifolium*. A common name for this species is Labrador Tea, on account of its leaves being infused and used as a substitute for tea. *L. latifolium* is employed for the same purpose, but this is preferable.

**L. P. VAR. DILATATUM** is a Japanese form distinguished by its leaves being oblong-oval, and thus larger and broader than those of the ordinary *L. palustre*, and more like those of *L. latifolium*.

**L. P. VAR. DECUMBENS** is a prostrate form with very small, narrow leaves, and comes from the

most northerly regions reached by the species, but there is every gradation between it and the ordinary form.

W. J. BEAN.

## SOCIETIES AND EXHIBITIONS.

### CRYSTAL PALACE ROSE SHOW.

JULY 2.

A LARGE and beautiful show was brought together on this occasion, certainly larger and better than has been seen for the past two or three years. Competition was in most classes tolerably keen, and the average merit of the exhibits decidedly good.

#### NURSERYMEN.

In division A the first prize in the class for seventy-two single trusses was won by Messrs. Harkness and Sons, Hitchin, for a magnificent collection of blooms, fine in form and condition, the best being Comte de Raimbaud, Marie Baumann, Mme. Eugène Verdier, Earl of Dufferin, Prince Arthur, Kaiserin Augusta Victoria, Comte de Ludre, Marie Rady, Mme. Delville, Victor Hugo, Crown Prince, The Bride, Duke of Edinburgh, Marie Verdier, Camille Bernardin, Xavier Olibo, Cath. Mermet, S. M. Rodocanachi, Marquise de Castellane, Thomas Mills, Helen Keller, A. K. Williams, Chas. Lefebvre, Francois Michelin, Dupuy Jamain, Duc d'Orleans, Mme. Montel, Gustave Piganeau, Horace Vernet, Mrs. John Laing, Mrs. Paul, Dr. Andry, Capt. Hayward, and Fisher Holmes. Mr. B. R. Cant was a good second, showing fine blooms of Horace Vernet, Duchesse de Morny, Camille Bernardin, Countess of Oxford, Dupuy Jamain, Marie Verdier, Comte de Ludre, Alfred Colomb, Mme. Hoste, Victor Hugo, Princess of Wales, S. M. Rodocanachi, Duke of Wellington, Lady Helen Stuart, Beauty of Waltham, Ulrich Brunner, General Jacqueminot, Mme. Cusin, Prince Arthur, Mme. Eugène Verdier, Gustave Piganeau, A. K. Williams, Xavier Olibo, Jean Souperet, and Annie Laxton. For forty varieties distinct, three trusses of each, the first went to Mr. B. R. Cant, of Colchester, for an exhibit of very high merit, wonderfully even in quality throughout, many of the blooms being quite perfect in form and condition. The best were A. K. Williams, Marquise Litta, Ulrich Brunner, Mme. Cusin, three superb blooms, Helen Keller, Marchioness of Dufferin, S. M. Rodocanachi, Mme. Gabriel Luizet, Gustave Piganeau, Horace Vernet, three perfect flowers, and Mrs. Sharman Crawford. Messrs. Harkness and Sons, Hitchin, won the second prize with a remarkably good collection, but not so uniform as the preceding. The best varieties were Ulrich Brunner, superb blooms; Francois Michelin, Helen Keller, Earl of Dufferin, Camille Bernardin, Gustave Piganeau, Marquise de Litta, Horace Vernet, Comte de Raimbaud, Caroline Testout and Mrs. W. J. Grant. For forty-eight singles, the first prize went to Messrs. J. Townsend and Sons, Worcester, for a beautifully clean lot of blooms, the best being Catherine Mermet, Gustave Piganeau, Prince Arthur, La Duchesse de Morny, Marquise Litta, Comte de Raimbaud, Duke of Edinburgh, Marie Verdier, Camille Bernardin and Dupuy Jamain. Messrs. J. Burrell and Co., Howe House, Cambridge, won the second prize with an almost equally good exhibit, containing fine blooms of Innocente Pirola, La France, Duke of Wellington, Ethel Brownlow, Xavier Olibo, Mrs. W. J. Grant, A. K. Williams, The Bride, S. M. Rodocanachi, Earl of Dufferin and Mrs. John Laing. Mr. C. Turner, Slough, was an easy first for twenty-four singles, showing a very fine set of blooms, among which Victor Hugo, Mrs. J. Laing, Marie Baumann, Pride of Waltham, Ulrich Brunner, Mons. E. Y. Teas, Fisher Holmes, Ernest Metz and A. K. Williams were strikingly good. The second went to Mr. John Mattock, New Headington, Oxford, for another very good box containing Horace Vernet, Ulrich Brunner, Duke of Wellington, Victor

Hugo, Duke of Connaught and Marie Baumann. For twenty-four distinct, three trusses of each, the first prize went to Messrs. D. Prior and Son, Colchester, for an exhibit of high merit, the blooms being large, well formed and of splendid substance. The finest kinds were Horace Vernet, Ulrich Brunner, Caroline Testout, Marie Finger, Gustave Piganeau, Mrs. John Laing, Abel Carrière, A. K. Williams, Mrs. Sharman Crawford and La Rosière. The second prize was awarded to Mr. G. Mount, of Canterbury, who had lovely blooms of Fisher Holmes, Ulrich Brunner and Mrs. John Laing. The next class was for twelve distinct singles of varieties sent out by Messrs. A. Dickson and Sons, Co. Down, Ireland, and the first prize was won by Messrs. Harkness and Sons, whose box contained beautiful blooms of Mrs. W. J. Grant, Earl of Dufferin, Helen Keller, Jeannie Dickson and Ethel Brownlow. Mr. B. R. Cant, of Colchester, was a good second with Mrs. Sharman Crawford, Ethel Brownlow, Jeannie Dickson, Margaret Dickson and Marjorie.

#### AMATEURS.

For thirty-six single trusses, Mr. E. B. Lindsell, Bearton, Hitchin, was first with a remarkably good and even exhibit, with hardly a poor bloom. The best were Ulrich Brunner, Marchioness of Dufferin, Gustave Piganeau, Catherine Mermet, Mme. Hausman, Mme. Cusin, Alf. Colomb, Mme. de Watteville, Mme. Hoste, Muriel Grahame, Innocente Pirola, Horace Vernet, Mrs. Grant, Duc d'Orleans, and Mrs. John Laing. Mr. C. J. Grahame, Wrydelands, Leatherhead, was a good second, having fine blooms of White Lady, Chas. Lefebvre, A. K. Williams, Prince Arthur, Horace Vernet, Victor Hugo, Mrs. W. J. Grant, and Duke of Wellington. In the class for thirty-six distinct, single trusses, Mr. E. B. Lindsell was again first, showing good flowers of Capt. Hayward, Horace Vernet, Gustave Piganeau, Prince Arthur, Ulrich Brunner, Dr. Andry, Mme. de Watteville, and Louis van Houtte. Mr. Thos. Hobbs, Easton, Bristol, was a close second, S. M. Rodocanachi, La France, Her Majesty, Le Havre, Mrs. John Laing, and Star of Waltham being the best. Mr. E. B. Lindsell was first also for eight distinct trebles, his best kinds being Mrs. Grant, Ulrich Brunner, Mrs. J. Laing, A. K. Williams, and Horace Vernet. The second was awarded to Rev. J. H. Pemberton for good blooms of A. K. Williams, Horace Vernet, Mrs. J. Laing, Francois Michelin, and Comte Raimbaud. For twelve singles of any Rose, except Tea or Noisette, the first went to Mr. H. V. Machin, Worksop, for Gustave Piganeau, and the second to Mr. J. Gurney-Fowler for Caroline Testout. The first prize for twenty-four distinct singles went to Mr. S. S. Berger, Stevenage, for a charmingly coloured and shapely set of blooms, including Prince Arthur, Mme. Gabriel Luizet, Belle Siebrecht, Comte Raimbaud, Duke of Edinburgh, and Duke of Wellington. Mr. Edward Mawley, Rosebank, Berkhamsted, was an excellent second with beautiful flowers of Duke of Fife, Ulrich Brunner, Dupuy Jamain, Alf. Colomb, and Marie Finger. Mr. O. G. Orpen, Colchester, was easily first for nine singles of any Rose except Tea or Noisette, showing a box of very lovely blooms of K. A. Victoria. Mr. E. M. Bethune, Ilorham, was a close second with a very uniform box of Marie Baumann. For six trebles, distinct, Mr. E. Mawley, Rosebank, Berkhamsted, was first with a splendid collection, showing Marie Finger, Dupuy Jamain, Ulrich Brunner, Mme. Gabriel Luizet, Horace Vernet, and Mrs. John Laing. The second went to Mr. P. Burnand, Hill Grange, Reigate, his exhibit including good examples of Innocente Pirola, Mme. Cusin, and Duke of Edinburgh. For nine distinct singles, Mr. G. Moules, Hitchin, gained the first prize with very fine blooms of C. Raimbaud, Souvenir d'Elise, Beauty of Waltham, Her Majesty, Catherine Mermet, Ulrich Brunner, Francois Michelin, Earl Dufferin, and Caroline Testout. Mr. M. W. Little, Leicester, was second, having good specimens of S. M. Rodocanachi, Mme. Hoste, and Mrs. J. Laing. Mr. G. W. Cook, North Finchley, was successful for

six trebles, having Capt. Hayward, Mrs. John Laing, and La France in fine condition. Mr. R. H. Langton, Hendon Hill, won the second prize. For six singles, distinct, Mr. R. Foley Hobbs, Worcester, was first, his exhibit containing fine specimens of Ulrich Brunner, S. M. Rodocanachi, and Ernest Metz. Mr. R. W. Bowyer, Hertford, was a very close second, having Caroline Testout, Marie Baumann, and K. A. Victoria. In another class for six distinct singles, Mr. A. Munt, Slough, was first with very beautiful flowers of The Bride, Ernest Metz, K. A. Victoria, and Innocente Pirola. Mr. E. R. Smith, Muswell Hill, being second. Mr. H. P. Landon, Brentwood, was placed first for four distinct trebles, showing Victor Hugo, La France. Mrs. John Laing, and Caroline Testout; Mr. J. Parker, Old Headington, was second. For twelve distinct singles, the first went to Mr. W. Kingston, Bedford, who had good blooms of A. K. Williams, Ulrich Brunner, Camille Bernardin, and Alf. Colomb. Rev. A. Cecil Johnson, Ipswich, was a very good second. For six single trusses of any Rose except Tea or Noisette, Mr. G. W. Cook, North Finchley, was first with a beautiful box of Mrs. John Laing, Mr. J. Cobden Trueman being second with Her Majesty. Mr. E. B. Lindsell was first for six distinct singles of varieties sent out by Messrs. A. Dickson and Sons, showing Mrs. Crawford, Earl Dufferin, Muriel Grahame, and Helen Keller in good form. Rev. J. H. Pemberton was a close second. In another class for six distinct singles, Rev. A. Cecil Johnson was first and Mr. J. Cobden Trueman second, both lots being good. Mr. S. S. Berger gained the first prize in yet another class for six singles, while Miss Jebb, of Rotherham, was second. Mr. G. W. Cook was a splendid first for six singles grown within eight miles of Charing Cross, showing Duke of Wellington, Caroline Testout, Capt. Hayward, Mrs. John Laing and La France in good style, Mr. Jno. Bateman, Archway Road, was given the second award. For six distinct single trusses of new Roses, Rev. J. H. Pemberton was successful, showing good blooms of Capt. Hayward and Marquise de Litta. Mr. O. G. Orpen was second. The latter exhibitor was first for eighteen distinct Teas and Noisettes—a very beautiful collection, every bloom faultless. The best were Catherine Mermet, Medea, Maman Cochet, Cleopatra, Mme. Cusin, Ernest Metz, Maréchal Niel and The Bride. Mr. C. J. Grahame was second also with a very fine exhibit, his best blooms being Ethel Brownlow, Catherine Mermet and Mme. Cusin. For twelve distinct singles in the same division, Mr. E. M. Bethune, Horsham, was a splendid first, showing Catherine Mermet, Bridesmaid, The Bride, Caroline Kuster, Mme. Cusin, Marie Van Houtte, Ethel Brownlow and Maman Cochet among the best blooms. Rev. Hugh Berners was a good second. Mr. C. J. Grahame was successful for eight distinct trebles, having a clear and uniform exhibit, including Catherine Mermet, Innocente Pirola, Mme. Cusin, Maman Cochet, The Bride and Francaise Kruger. The second went to Mr. S. P. Budd, of Bath. For nine singles of any one variety, Mr. E. M. Bethune was first with a nice box of Catherine Mermet, and Mr. C. J. Grahame second with Mme. Cusin. For twelve distinct singles, Mr. J. Parker gained the highest award, his box containing excellent blooms of Anna Ollivier, Princess of Wales, Mme. Cusin and Mme. Hoste. Rev. J. H. Pemberton was second. Miss Baker, of Reigate, was successful for nine distinct singles, her best blooms being Jean Ducher, Maman Cochet, Ernest Metz and Etoile de Lyon. Mr. P. Burnand was an excellent second. Rev. A. Cecil Johnson, of Ipswich, was first in the next class for nine singles, with fine flowers of Cleopatra, Mme. Cusin and The Bride. The second went to Mr. G. Moules. Rev. F. R. Burnside gained the first for six distinct singles. For four distinct trebles, Mr. J. Parker was a capital first, showing Marie Van Houtte, Catherine Mermet, The Bride and Mme. Cusin. Mr. R. Foley Hobbs gained the first for six singles of one variety with a good box of Catherine Mermet.

A very lovely exhibit was that of Mr. O. G. Orpen, who won the first for six bunches with seven trusses to a bunch. Every variety was remarkably good, but the best were Anna Ollivier, Marie Van Houtte, Mme. Hoste, and Mme. Cusin. For eighteen bunches of garden Roses, distinct, Mr. W. V. Machin was first with fine bunches of Perle d'Or, Laurette Messimy, Mignonne, Macrantha, Crimson Rambler, Marquis of Salisbury, Cecile Brunner, Homère, and Bardou Job. Mr. A. Tate, Leatherhead, was a very excellent second, his best bunches being Laurette Messimy, Gloire Lyonnaise, Rosa Mundi, Bardou Job, Gustave Regis, Perle d'Or, L'Idéal, and W. A. Richardson. The bunching and arrangement were far superior to those of the former exhibit. Mrs. A. E. Perkins was first for six bunches of garden Roses, distinct, and had a very splendid exhibit, comprising Marquis of Salisbury, Mme. Pernet-Ducher, and Mme. C. Guinoiseau.

#### OPEN CLASSES.

For twelve bunches, distinct, of any variety, Mr. John Mattock was first, his best bunches being Marie Van Houtte and Innocente Pirola. For twelve single trusses of any yellow Rose, Mr. George Prince was successful, showing a very beautiful box of Comtesse de Nadailac, very fine in form and rich in colour. Messrs. D. Prior & Son were given the first for twelve Hybrid Teas, having a grand lot of blooms, including K. A. Victoria, White Lady, and C. Testout. Messrs. Harkness and Sons were first for twelve singles of any dark crimson, showing a fine set of Horace Vernet. Messrs. A. Dickson and Son were first for twelve single trusses of any new Rose, showing a magnificent lot of Mrs. W. J. Grant. For twelve singles of any crimson Rose, Messrs. Dickson were again successful, having a fine box of A. K. Williams. Mr. B. R. Cant gained the first for twelve singles of any Tea or Noisette with a charming box of Mme. Cusin. Messrs. Townsend and Sons were first for twelve singles of any light Rose, sending a box of splendid blooms of Mrs. J. Laing. For twelve single trusses of new Roses, distinct, Messrs. Dickson, Co. Down, were first with Mrs. Mawley, Ulster, Lady Clannorris, Tom Wood, Countess of Caledon, Killarney, Eileen, Mrs. W. J. Grant, Alex. Dickson, Bessie Brown, and Mrs. Grahame. For three single trusses of any new seedling Rose or distinct sport, a gold medal was awarded to Messrs. A. Dickson and Sons for a finely shaped pink Rose called Ulster. For thirty-six bunches of garden Roses, distinct, the first prize was won by Messrs. Paul and Son, Cheshunt, their best bunches being Mme. Falcot, Perle d'Or, Gallica, Georges Pernet, White Pet. Alistair Stella Grey, Bardou Job, Moss Blanche Moreau, Gloire des Polyanthas, Mme. P. Ducher, Marquis of Salisbury, Ma Capucine, and W. A. Richardson. For eighteen bunches of garden Roses, Mr. Chas. Turner, Slough, was first with good bunches of Bardou Job, Laurette Messimy, Hebe's Lip, Mme. P. Ducher, Crimson Rambler, and Gloria Mundi. For nine bunches of single-flowered Roses, Messrs. Cooling, of Bath, were a good first. For twelve distinct trebles (nurserymen), Mr. G. Prince was first, his best varieties being Ethel Brownlow, Mme. Cusin, Maman Cochet, Alba rosea, Ernest Metz, Anna Ollivier and Catherine Mermet. In the same division Messrs. J. Burrell and Co. were first for eighteen distinct singles, the best being Mme. de Watteville, Ernest Metz, Catherine Mermet, Jean Ducher, Bridesmaid and Mme. Cusin. For twenty-four distinct singles, Mr. Frank Cant was first with a very fine exhibit, including Maman Cochet, Ethel Brownlow, Ernest Metz, Jean Ducher and Medea. The silver medal for the best bloom of any Rose other than Tea or Noisette, exhibited by a nurseryman, was won by Messrs. Harkness for a bloom of Horace Vernet. The similar award for the best bloom of any Tea or Noisette was gained by Mr. B. R. Cant for a flower of Mme. Cusin. A like award for amateurs was given to Mr. E. B. Lindsell for a bloom of Muriel Grahame. The silver medal for the best bloom other than Tea or Noisette,

grown by an amateur, went to Mr. O. G. Orpen for K. A. Victoria.

#### MISCELLANEOUS.

Exhibits under this section were also very numerous and good. Messrs. Wallace, of Colchester, again had a beautiful group of hardy flowers, chiefly Lilliums and Calochorti, arranged with excellent effect. Among the Lilliums the following were conspicuous: L. Hansoni, L. Parryi, L. dalmaticum and L. canadense. The collection of Calochorti included the usual varieties which have been lately shown, C. venustus citrinus being again very beautiful, also the lighter-coloured forms of the same strain. Other notable things were Hemerocallis aurantiaca major, with remarkably large blooms, and Iris aurea. Sweet Peas were again beautifully shown by Mr. F. G. Foster, Brockhampton Nurseries, Havant, Hants, such varieties as Royal Rose, Mrs. Gladstone, Daybreak, Brilliant, Countess of Radnor and many others equally good being shown in fine form. A very pretty group of hardy flowers was staged by Messrs. A. W. Young and Co., Stevenage, Herts, and contained a great variety of beautiful Campanulas, a good collection of Digitalis, the old-fashioned, but charming Sweet Williams and Shirley Poppies. Mr. M. Pritchard, Christchurch, Hants, had a small, but very good group of hardy flowers, among which were some fine blooms of Iris Kämpferi, a bunch of large flowers of Chrysanthemum maximum, and a number of very lovely Potentillas. Yet another attractive collection of hardy flowers and shrubs shown by Messrs. Cheal and Sons, Crawley, included some good Roses and some charming Tufted Pansies. A very extensive and handsome exhibit was arranged by Messrs. J. Laing and Sons, Forest Hill. It consisted of a superb collection of tuberous Begonias, backed with choice Palms and flanked on each side with a group of splendidly grown and coloured Caladiums, and extended in one direction with a very representative collection of hardy flowers. The arrangement was throughout very effective. A few good plants of Malmaison Carnations were noticeable.

A large group of Roses, very rich and varied in effect, was arranged by Messrs. Wm. Paul and Son, Waltham Cross, and comprised fine examples of cut blooms, standard trees, and dwarf bushes. Among the best varieties were White Lady, Belle Siebrecht, Mme. Hoste, Spenser, Gloire Lyonnaise, Roberta, and Grand Duc de Luxembourg, all these being effectively massed in baskets. There were also good blooms of Empress Alexandra of Russia, Queen Mab, and Xavier Olibo, and a good collection of Briers and garden Roses. Another nice collection of cut Roses came from Messrs. Geo. Jackman and Son, Woking, Surrey, and in it button-hole Roses were particularly attractive, such varieties as W. A. Richardson, Rêve d'Or, Mme. Falcot, Mme. Lacharme, l'Idéal, and Perle d'Or being very lovely. Messrs. Geo. Bunyard and Co., Maidstone, sent five boxes of twenty-four blooms each, with some excellent flowers among them. The following were the best: Capt. Hayward, Caroline Testout, Mme. G. Luizet, Gustave Piganeau, Jean Ducher, Augustine Guinoiseau, Innocente Pirola, Her Majesty, and La France. The same exhibit included some beautiful bunches of garden and button-hole Roses, among which the common Moss Rose and the Polyantha varieties were notable. Messrs. John Laing and Sons also had an admirable and representative collection of cut Roses.

A full prize list will be found in our advertisement columns.

— If the exhibition of the National Rose Society at Portsmouth was the smallest the society has yet held, that which took place at the Crystal Palace on the 2nd inst. proved, on the other hand, the most extensive on record. The number of exhibition Roses staged in competition on that occasion amounted in all to 7200, or 1450 more than the average for the five previous metropolitan shows of the society, and 100 blooms more than at the largest of these exhibitions—that of 1892,

There were over 100 exhibitors, whose exhibits, arranged according to the number contributed by each county, were as follows: Essex heads the list with 71 exhibits, Surrey comes next with 51, then Middlesex with 35, Herts 34, Kent 32, Oxford 29, Notts 26, Somerset 20, Sussex 20, Worcester 19, Gloucester 15, Suffolk 15, Berks 12, Leicester 10, Wilts 8, Bucks 7, Devon 6, Hants (including Isle of Wight) 6, Derby 5, Northampton 5, Yorks 3, Bedford 2, Cambridge 2, Shropshire 2, Dorset 1, Stafford 1, and Warwick 1. In addition to the English contributions, seven exhibits came from Wales and eleven from Ireland, but, unlike last year, there were no Scotch-grown Roses. Seldom, if ever, has the society held a more enjoyable exhibition. The day, although dull, proved fine and cool, thus allowing the blooms to continue fresh and bright during the whole day. The general quality of the flowers was remarkably good, and particularly was this the case in the exhibits from many of the smaller growers. Moreover, there was at no time any overcrowding, so that the blooms could be inspected with comfort by both members and visitors.—E. M., *Berkhamsstead*.

NATIONAL AMATEUR GARDENERS' ASSOCIATION.

JULY 3.

The exhibition of this association in conjunction with the garden party held at the Royal Botanic Gardens, Regent's Park, W., on Saturday last was not a very extensive one, but being so ably supplemented by several very excellent trade exhibits, the display was very interesting.

Flowers, fruits, and vegetables were each represented. Roses were shown in good form. Mr. G. W. Cook, The Briars, North Finchley, showing a fine lot of Teas in a competitive class. Hon. Edith Gifford, Innocente Pirola, Mme. de Watteville, Mme. Hoste, and Princess of Wales being the best in his stand. H.P.'s were best in the exhibit of Mr. Geo. Moules, who had a small box in which the blooms showed high culture. They were of much substance and very fresh. Tufted Pansies were well shown, Mr. R. M. Dougall, Walthamstow, winning the "Pye" trophy. The most notable flowers were Mrs. C. E. Gordon, Cottage Maid, Magic, A. J. Rowberry, Lord Salisbury, Florizel, Norah May, and Stophill Gem. Hardy flowers were seen in excellent condition, and there were some very fine individual exhibits. Vegetables were not very numerous, but they were of a high order of merit in each instance. Fruit was almost exclusively confined to bush fruit and Strawberries, and the exhibits proved that even among amateurs most excellent results have been achieved this season. Except in the case of a vase and hand-basket, the decorative exhibits were very poor, and the exhibitors have much yet to learn.

The trade exhibits were very much appreciated. Tuberos-rooted Begonias in splendid condition came from Mr. H. J. Jones, Ryecroft Nursery, Lewisham. Messrs. H. Cannell and Sons, Swanley, showed an interesting group of Cannas, Queen Charlotte, Pavonia, and Duchess of York standing out prominently from the others. Mr. Baxter, Woking, staged a number of sprays of Tufted Pansies, which were much admired. Mr. W. Rumsey had a fine display of cut Roses. Messrs. W. Cutbush and Sons, Highgate, had a superb group of Malmaison Carnations, the pink and flesh-coloured varieties being nicely balanced. Hardy flowers were sent by Messrs. J. Laing and Sons, Messrs. Barr and Sons, and Mr. T. S. Ware, each firm making a splendid display. Messrs. Dobbie and Co. made a very beautiful display of Sweet Peas.

**Royal Horticultural Society.**—The next fruit and floral meeting of the Royal Horticultural Society will be held on Tuesday, July 13, in the Drill Hall, James Street, Westminster, 1 to 5 p.m. A lecture on "Mutual Accommodation between Plant Organs" will be given by the Rev. Prof. Geo. Henslow, M.A., F.L.S., at 3 o'clock.

NOTES OF THE WEEK.

**Gaillardia Vivian Grey** is perhaps the most distinct variety yet raised, the flowers being of a clear uniform light yellow throughout, and of rather a pleasing shade in the border.

**Pentstemon diffusus.**—A very pretty kind of dwarf habit, with numerous spikes of flowers of a rose-purple tint externally, and internally of an azure-blue shade. The plant is well worth growing for its early flowering.

**Rose Captain Christie.**—We recently saw this handsome Rose in excellent form in a garden near Hampton Court. The plants were dwarf and sturdy, and being freely employed made a fine display of large and handsome flowers.

**Phloxes.**—Some of the very earliest of herbaceous Phloxes are *Le Soleil* and *Belair*, the former with bright rose-pink blossoms, the latter bearing rose-purple flowers in large panicles. As early kinds in this group these are worth noting.

**Carnation Miss Ellen Terry.**—So far as size and purity of blossom are concerned, this variety is quite a success, while of fragrance it has none; a misfortune in a variety that otherwise possesses considerable merit. It is rare that any flower is so devoid of scent as this.

**Callas in the open air.**—From Mr. Sangwin, The Gardens, Trellissick, Truro, come some handsome flowers and leaves of these, showing how well they do in the open air in Cornwall. The flowers are large, of fine substance and on strong foot-stalks, the leaves large and leathery.

**Ornithogalum pyramidale** produces, as the name implies, a large pyramid of pure white blossoms on stems 18 inches or so high that have a good effect in rather cool spots in the border. Where a mixed collection of hardy bulbs is grown this Spanish kind should always be found.

**Madonna Lilies** are now very beautiful in many gardens, and where the plants are free from disease the effect is very fine. In some districts we have seen but little of the disease this year, while in one cottage garden that contained quite a large number of spikes, one was very badly affected, while the rest were fresh and healthy looking.

**Codonopsis ovata.**—This curious little member of the Campanulaceae was included last week in Mr. Prichard's group of hardy flowers at the Drill Hall. The bluish-purple blossoms which are paler inside, are very curiously marked. When given a good position on a warm border this does well, and for a long time is covered with its drooping blossoms.

**Photinia japonica** (Loquat).—Considerable interest centred around some fruiting branches of this plant at the Drill Hall a week ago when Mr. Geo. Wythes exhibited several fully ripe fruits from Syon House. It is known as the Japanese Medlar or Quince, and the fruit rarely ripens in this country. Both the seed and pulp are very distinct in appearance.

**Morina longifolia.**—This is doubtless among the most striking of border perennials now in bloom. The spiny leaves are each about 18 inches long, and when developed very distinct and effective. From these in summer a flower-spike issues, containing crowded whorls of blossoms that change from white to pink and ultimately to a rich crimson hue that renders it a very conspicuous object.

**Oenothera speciosa** is now very showy, producing large white, rose-tinted blossoms in great profusion. Internally the handsome blossoms are nearly pure white, these presently changing colour with age. In this way various shades are seen when the plant is used freely. In good soil the plant grows and flowers freely. For flowering from June onwards for weeks in succession it is of considerable value.

**Pink Albino.**—I forward you a few blooms of my new Pink Albino. It received an award of

merit at the Royal Horticultural Society, June 15. It is a good grower and free bloomer, and also forces well.—J. LAMB, *Burton Joyce, Notts.*

\* \* This is a pure white smooth-edged variety of the border Pink, the flowers large and of fine form. In the blooms sent there are no signs of bursting. The fragrance, too, is very pronounced. Ed.

**Cytisus nigricans** is a neat and pretty kind with erect spikes of yellow blossoms on rather long peduncles. The leaves are trifoliate and stalked, and pubescent on the under surface. It is quite distinct among the later flowering kinds and worthy of attention. *C. n. longi-pedunculata* appears to differ only in the longer stems to the sprays of blossom. Both kinds were exhibited at the last meeting of the Royal Horticultural Society.

**Hemerocallis Thunbergi.** This beautiful form is not so freely grown as it deserves; indeed, many gardens are without it altogether. Yet notwithstanding, it is of equal value with *H. flava*, that comes earlier into flower, while the above, which is somewhat dwarfer and produces larger blossoms of a paler shade of yellow, makes a capital succession. As a border plant it is all that could be wished for, being hardy, vigorous and free flowering.

**Galega officinalis** is now a very pretty as well as useful plant either for the border or for cutting. Neat in habit and free and continuous in flowering, it should be grown freely where large supplies of cut bloom are needed. Its pretty pea-shaped blossoms of blue-lilac are produced in somewhat pyramidal clusters for a long time. There is also a pure white form of this plant that should be grown by all who have to furnish useful flowers in quantity. Both are of the easiest culture, and may be readily increased.

**Magnolia macrophylla.**—Messrs. Veitch send us from their nursery at Coombe Wood a flower of this distinct Magnolia. The flower out in the bud is priceless as to its beauty, and no Lily could equal it in form. The leaves are nearly 18 inches long, the under sides of a delicate silver hue. It is a native of North Carolina and has been introduced into England many years. There is at Claremont a remarkably fine specimen of this some 40 feet high. Mr. Burrell showed some blooms from this tree at one of the meetings of the Royal Horticultural Society last year.

**Senecio japonica.**—This handsome plant should always be borne in mind when hardy fine-foliaged plants, particularly such as are of a moisture-loving disposition, are being arranged in groups or masses. Planted in deep loamy soil where the roots may readily reach moisture, this fine plant will give but little trouble. Well grown, its handsome divided leaves attain to large size, and in summer a bold head of flowers several feet high is produced, the ray florets being of a rich deep orange. This handsome plant was included in Messrs. Barr's group at the Drill Hall last week.

**Tropæolum polyphyllum.**—When soplanted in the rock garden that the rather succulent growths can trail at will, this is a beautiful and interesting plant long before a flower is seen. This is the outcome of its silvery grey leaves. With about 2 feet of growth the blossoms appear, and furnish the stems for some time. The species is not only perfectly hardy, but it will force its way through the hardest of soil, frequently appearing in the gravel walk a yard away from the spot where the original tuber was placed. Occasionally the plant is trained upwards, though as we think only to hide its best side.

**Geranium sanguineum album** is certainly an acquisition, but from the difference between it and the type I am inclined to think it is hardly a variation only. The flowers do not open (in my specimen) flat and with overlapping petals, as in the type, but are distinctly stellate and at the same time cup-shaped. The growth, too, seems more straggling as yet and the flower pedicels longer. I note a difference, too, in the shape of

the leaves. They are more regularly palmate and lobed than in *G. sanguineum*. It would be interesting to know its origin, although it will make no difference to its value in the garden.—T. J. W., *Crouch End*.

**Acantholimon venustum** is a lovely summer alpine, as choice and beautiful as it is rare. The largest single specimen I have grown or seen, produced some thirty of its prettily formed sprays of pink blossom, one and sometimes two sprays issuing from its spiny-pointed rosettes. The foliage is quite rigid, and its almost invisible needle-like spines very sharp. This species is not nearly so free as the better known kind, *A. glumaceum*, often used as an edging, and in this way growing freely. This latter cannot compare with the above, which is of much slower growth and seeds only rarely. It is now one of the most charming plants flowering in the rock garden, and worthy of increase by every known means. Gritty loam and a sunny position suit it well.—J.

**Iris Kämpferi**.—I send you herewith a few blooms of my first crop of Japanese *Iris Kämpferi*. I think them extremely beautiful, and these Irises might with advantage be largely grown in our English gardens. I got these over direct from Japan, and they came in very good condition and have since bloomed well in the gardens at Fairawn. Those which were planted on a comparatively dry site and well exposed to the sun always come up first, but they do not carry the finest blooms. A batch which I planted round the edges of the pond and not in a sunny situation flower later, but the blooms are always larger and more beautifully coloured. I will send you a few of the later blooms soon. They are very free flowering, and they bloom almost equally well in ordinary flower beds and when planted in the grass in a damp situation, but I think it is under the latter conditions that they attain their greatest beauty. Some of the blooms measure 6 inches across, and the tints vary—purple, violet, striped varieties of these tints with white striping, and some of them are pure white without any admixture of colour. I have not as yet tried growing them from seed.—ERNEST HART, *Fairlawn, Totteridge, Herts.*

**Philadelphus Lemoinei**.—Each succeeding June confirms the good opinion formed of this hybrid at the time it was sent out by its raiser, Mons. Lemoine, of Nancy. The distinctness of *P. microphyllus* from all the rest of the Mock Oranges made it a very promising subject for the hybridiser, and by crossing it with the old and well-known *P. coronarius*, M. Lemoine has added to our collections a shrub that is not only a beautiful one, but one more distinct from the rest of the *Philadelphuses* than most of the so-called species in that genus are from each other. The influence of *P. coronarius* has given the hybrid a much stronger and more vigorous growth than that of *P. microphyllus*, but the latter species has bequeathed the purer whiteness of its flowers, together with their sweeter, lighter perfume. *P. Lemoinei* grows 4 feet to 5 feet high (it may be more eventually), of somewhat erect habit, with thin ovate leaves each 2 inches long, that have a few scattered teeth on the margin. The flowers are each 1 inch to 1½ inches across, and produced from the short axillary shoots of last year's branches in such abundance as to transform them into columnar masses of pure white blossom. M. Lemoine has sent out several other hybrids originating from the same parents; among them are *Lemoinei erectus* (scarcely different from the above), *Boule d'Argent* (double) and *candelabra*.—W. J. B.

**The Calochorti** are now among the most charming of flowers in the open, and where due attention has been given to the soil in which they are growing, a good display of flowers is almost sure to result. Particularly good and showy in their varied colours is the section of these known as the *Eldorado* strain. The almost endless variety of colour in this group is very remarkable, and varies from purple and reddish purple to rich red-pink, and even salmon shades, the many inter-

mediate hues defying description. The lovely golden yellow, known as *venustus citrinus*, is a beautiful flower, the beauty of which is enhanced by pencillings and blotches of a reddish hue. As a cut flower for small vases this is quite unique, and quite equal to many of the choicest Orchids in point of beauty, while the bulbs are cheap. A very handsome form, with yellow blossoms each 4 inches or 5 inches across, is *C. clavatus*, which hitherto has been unknown to cultivators of this beautiful class, though botanists have for years known of its existence. Another really beautiful kind, perhaps the most chaste of all, is *C. Guni-soni*, with pure white flowers, having a zone of a yellowish green shade in the centre. These lovely things may be grown in pots, though they flower much more freely in prepared soil in the open ground.

**Notes from Baden-Baden**.—*Richardia Ad-kumi* is now flowering in an open border. It is distinct from *R. Nelsoni* in its glaucous green, more sagittate leaves and the somewhat larger flowers, which also are creamy white, with a shade of sulphur, and have the violet-black blotch extended up to two-thirds of the spathe. Both species are likely to become popular. Several plants from a batch of seedlings of *R. Rehmanni* are now blooming, and it is singular how different they are in the pink shading; some are pink, others are white with a pinkish shade. A pleasing contrast to these is produced by a small group of a superior form of *Sandersonia aurantiaca*. The plants are 4 feet high, having each six to ten flowers the size of a Walnut; these orange bells, backed by the fresh green, healthy leaves, look very striking. In the rock garden *Campanula mirabilis* is now in full flower, and it well deserves its name. It is a low pyramid about 2 feet through, forming a much-divided, branching bush, covered with hundreds of its pale blue flowers, which are nearly the size of those of *C. Medium*. For the introduction of this very beautiful plant horticulture is indebted to the munificence of M. Wm. Barbey and to the unwearied exertions of the botanist, M. N. Alboff, who found the plant as a single specimen—no second found—in a rocky part of the Caucasus. Here it has proved perfectly hardy.—MAX LEICHTLIN, *Baden-Baden*.

## PUBLIC GARDENS.

**Open space for Clerkenwell**.—Yesterday afternoon Captain F. T. Penton opened the churchyard in connection with the old church of St. James, Pentonville, which has been laid out by the Metropolitan Public Gardens Association as a recreation ground. The ground, which is within the parish of Clerkenwell, will be maintained by the vestry. This is the fifth open space which the Metropolitan Public Gardens Association has provided in the parish. The Earl of Meath said that the whole of the money for laying out the ground—£600—had been provided by the City of London Parochial Foundation, and Captain Penton had promised to provide a fountain at a cost of £100.

**Battersea Park**.—A proposal will shortly come before the London County Council for the construction of a suitable embankment along the whole river frontage of Battersea Park. The existing river wall is of a very slight nature, and a large proportion of it is in an extremely bad condition. The Parks and Open Spaces Committee of the Council, who are making the proposal, state that the present wall may be described as a mere skin of concrete blocks, generally 9 inches in thickness and in some cases less. For some years past it has been the practice to patch the worst places from time to time at an annual outlay of some £400 or £500. The result, however, has not been satisfactory, and the deterioration which has arisen in past years has not been overtaken, so that the wall is steadily growing worse. The Council's engineer reported in 1895 that the cost of putting the wall into a proper state of

repair, if undertaken at that time, would be about £6000, and that even then there would be a subsequent annual charge of about £200 for its maintenance. Under these circumstances the committee are firmly of opinion that the best and most economical course would be to reconstruct the wall in a substantial manner. The length of the river front of the park is about 1300 yards, or about three-quarters of a mile, and the engineer is of opinion that a granite-faced wall with a granite parapet can be constructed there for the sum of £43,500. In view of the large recurring charge for maintaining the existing wall and of the economy that would ultimately be effected by the substitution for it of a permanent granite embankment, and also taking into account the enhancement of the appearance of the park, the committee strongly recommend the Council to adopt their scheme. It is proposed that the cost of the improvement shall be charged to capital account, the repayment being spread over the full term of the stock, out of the proceeds of the issue of which the cost would be defrayed.

## THE VICTORIA MEDAL OF HONOUR IN HORTICULTURE.

THE following is the official list of those who have been selected by the Royal Horticultural Society as the recipients of the medal in honour of the Queen's Diamond Jubilee:—

Baker, J. G., F.R.S.	Moore, F. W.
Balfour, Prof. Isaac	Morris, Dr. D.
Barr, Peter	McIndoe, James
Barron, A. F.	Milner, H. E.
Beale, E. J.	Molyneux, E.
Bull, Wm.	Monro, G.
Bunyard, Geo.	Maries, Chas.
Burbridge, F. W.	Nicholson, G.
Crump, W.	O'Brien, Jas.
Dunn, Malcolm	Paul, Geo.
D'Ombraïn, Rev. H. H.	Paul, William
Druery, C. T.	Rivers, T. F.
Dean, R.	Rothschild, Hon. Walter
Dickson, Geo. (Chester)	Schröder, Baron
Elwes, H. J.	Sander, F.
Ellacombe, Rev. Canon	Seden, J.
Foster, Prof. M.	Smith, J. (Mentmore)
Fraser, John (S. Woodford)	Smith, Martin R.
Gordon, Geo.	Speed, R.
Hooker, Sir Jos. D.	Sutton, A. W.
Henslow, Rev. Geo.	Sherwood, N. N.
Hole, Very Rev. Dean	Thomas, Owen
Hudson, J.	Thomson, David
Heal, J.	Thompson, W.
Horne, Rev. F. D.	Turner, H.
Herbst, H.	Willmott, Miss
Jekyll, Miss G.	Wolley-Dod, Rev. C.
Kay, Peter	Wright, J.
Laing, John	Wythes, Geo.
	Wilson, G. F.

**The weather in West Herts**.—A week of changeable, but, on the whole, moderately warm weather. On the 2nd inst. the reading in shade rose only to 62°, but on two other occasions it exceeded 70°. The nights were, as a rule, warm. Since the beginning of the month the temperature of the ground at 1 foot deep has fallen 3°, but is still slightly above the mean for this depth. Rain fell on only one day, and then the amount deposited proved insignificant. The winds have been mostly high, and the record of bright sunshine rather below the average for the time of year.—E. M., *Berkhamsted*.

## BOOKS RECEIVED.

"Paying Pleasures of Country Life." By various authors. G. Routledge and Sons, Ltd.

"The New Gulliver; or, Travels in Athomia." By C. T. Druery, F.R.S. Roxburghe Press, Victoria Street, Westminster.

**Names of plants**.—*H. Osman*.—The Fern is *Adiantum concinnum*. We cannot undertake to name varieties of *Coleus*.—*George Phelly*.—2, *Heuchera Richardsoni*; others next week.—*C. P.*—Please send specimens.—*N. P.*—*Phalæopsis amabilis*.

# THE GARDEN.

No. 1339—Vol. LII.]

[JULY 17, 1897

## INDEX.

(Illustrations in Italics.)

<b>Orchard and Fruit:—</b>	Dendromecon rigidum .. .. 39	Rose Comtesse de Murinais 40	<b>Kitchen:—</b>	Echinops ruthenicus .. .. 52
Apple Mere de Ménage .. 35	Dictamnus Fraxinella .. .. 38	Rose Jean Chérpin .. .. 42	Asparagus, manuring .. .. 45	Gaillardias .. .. 51
Apple Pine-apple Russet .. 34	<i>Gonista peacor</i> on a carpet of .. .. 38	Rose Kaiserin Augusta Victoria .. .. 40	Carrots, young, for winter .. 45	Hollyhocks, single .. .. 51
Apple Yorkshire Beauty .. 35	<i>Aubrietia Leichtlini</i> at .. .. 38	Rose Magdeleine de Châtellier .. .. 42	Lettuce, good autumn .. .. 44	Indigofera floribunda .. .. 51
Cucumber Veitch's Challenger .. 33	<i>Abbotsbury</i> .. .. 48	Rose Medea .. .. 42	Pea Early Morn .. .. 45	Iris Kämpferi .. .. 51
Currant La Versailles .. .. 35	Gladiolus The Bride, hardiness of .. .. 36	Rose notes .. .. 40	Pea Gradus .. .. 45	Lilium Browni .. .. 51
Currants, Red, pruning .. 35	Malva moschata alba .. .. 39	Rose Robusta .. .. 42	Peas, new .. .. 45	Lilium japonicum Kramerii .. 51
Eugenia Ugni .. .. 34	Pansies, Tufted, at Chiswick .. 33	Rose S. M. Rodocanachi .. 41	Peas, very dwarf .. .. 45	Lycchnis vespertina plena .. 52
Grape Duke of Buccleuch .. 35	<i>Penstemon Scutleri</i> in rock garden at <i>Abbotsbury</i> .. 42	Rose Thomas Mills .. .. 42	Potato Sharpe's Victor .. .. 45	Nymphaea Maribacca alba .. 51
Melon Eastnor Castle .. .. 33	Plants, notes on hardy .. .. 36	Rose W. A. Richardson, colour in .. .. 41		Pelargonium Beauty of Golden Hill .. .. 51
Melon Royal Favourite .. .. 33	Poppies, Oriental .. .. 39	Roses at Portsmouth .. .. 40	<b>Stove and Greenhouse:—</b>	Phlox Coquelicot .. .. 52
Nectarine Early Rivers .. .. 33	Primula Trailli .. .. 36	Roses Hebe's Lip and Reine Blanche .. .. 42	Carnation Mrs. Everard .. 46	Rose Empress Alexandra of Russia .. .. 51
Nectarine Victoria .. .. 33	Rock garden, the, at <i>Abbotsbury</i> , Newton Abbot .. 37	Roses Marquise de Salisbury and Camoens as standards .. 42	Carnations, Malmaison, at Culford .. .. 46	Scolymus grandiflorus .. .. 51
Peach Alexander .. .. 34	<i>Saxifraga longifolia</i> and <i>Edwardsii</i> , colony of, at <i>Abbotsbury</i> .. .. 37	Roses, new, at the Crystal Palace .. .. 41	Eupatorium odoratum .. .. 47	Sidalcea malvedora Listeri .. 51
Peach blister .. .. 33	Silene maritima plena .. .. 36	Roses, seedling .. .. 42	Freesias all the year round .. 46	Watsonia iridifolia O'Brieni .. 52
Peach Crimson Galande .. 35	Spring, the English, an appreciation of .. .. 39	Roses with coloured foliage .. 41	Poinsettias, growing .. .. 46	
Peach Prince of Wales .. .. 35	<i>Stipa</i> , rocky portion of, at <i>Abbotsbury</i> .. .. 39	Roses, yellow .. .. 41		<b>Public Gardens:—</b>
Peach Stirling Castle .. .. 34	<b>Roses:—</b>			Open spaces .. .. 52
Raspberries, yellow .. .. 33	Rosa alpina and its var. <i>R. a. pyrenaica</i> .. .. 41	<b>Garden Flora:—</b>		Waudsworth, open space for .. 52
Strawberry Monarch .. .. 35	Rosa laevigata .. .. 41	Cinerarias, hybrid .. .. 43	<b>Societies:—</b>	
Strawberry season, a short .. 34	Rose Abel Carrière .. .. 42	<i>Senecio multiflorus</i> × <i>guardia Civarata</i> .. .. 43	Royal Horticultural .. .. 49	
Strawberry season, prolonging the .. .. 35	Rose Baroness Rothschild .. 41	<b>Week's Work:—</b>		
Strawberry Stevens' Wonder .. 35	Rose Blanchefleur .. .. 40	Fruit garden, the hardy .. .. 43	<b>Notes of the Week:—</b>

Carnation Lord Rendlesham .. 39			Campandula G. F. Wilson .. 51	Balimodendron argenteum .. 42
Delphinium spikes, exhibiting .. .. 39			Carnation Jim Smyth .. .. 51	Haw, a singular .. .. 52

## ORCHARD AND FRUIT GARDEN.

### PEACH BLISTER.

The abnormal prevalence of blister on outdoor Peach trees, which seems general throughout the country this year, may be of some service by adding to one's knowledge of the influence of aspect. In this district the visitation has been very severe, and I notice that trees on south walls are looking far worse than those facing west; indeed, they are reduced in many instances to the merest scarecrows. The season will be gone before all signs of the scourge have been eliminated, and the trees will have to strain all their resources in order to become furnished with good bearing wood for another year. All hopes of a good crop have been shattered for this season, for though plenty of the fruits set, those on the worst branches failed to swell. This is very unfortunate, as many gardeners who had almost given up Peaches in the open have lately been planting again and were looking forward to a good harvest. The comparative well-being of trees facing west holds out hope that a remedy is to be found in choice of site, and that we may, by providing complete shelter, either temporary or permanent, from east winds, cope with the difficulty. It may be objected to my suggestion as to planting on west walls that Peach trees require all the sunshine they can get in order to ripen the wood properly, and this would probably be a safe objection with very late varieties, which are also late in losing their leaves, but it has no weight when mid-season and second early varieties—the only ones which come really to perfection on outside walls far north of London—are grown. For the shooting season and for market very late Peaches are only a little less valuable than early forced fruit, and those which pay least well are the midseason varieties which have been grown in cool houses, and which all ripen together and make a glut. The same varieties on a west wall ripen well, but later, and they then pay for growing. I believe that too much stress is

often laid on the advice to thoroughly ripen the wood of Peach trees. Most growers have seen plenty of instances in which comparatively green shoots have set and carried through fruits not to be beaten by those on their more favoured fellows, and, provided they have been given plenty of room, have perfected good foliage and are of good size without being gross. These conditions may be attained as well on a west as on a south wall; better, in fact, if the tendency to blister is reduced. It would be interesting to learn how Peaches in other districts have fared, and especially if aspect has had any influence, beneficial or otherwise, on the trees.

Livermere Park.

J. C. TALLACK.

**Nectarine Victoria.**—As is well known, this fine Nectarine is apt to crack badly, but looking through the houses at Culford recently I found a splendid crop of fine fruit and not one cracked. This is the result of cropping heavily, combined probably with something that the variety likes in the soil and careful treatment. Humboldt, too, was fruiting grandly, and of Peaches Grosse Mignonne, Lady Palmerston, a good Peach with deep coloured flesh, and Royal George, were all carrying heavy crops of fine fruit.

**Melon Royal Favourite.**—This Melon appears to be well adapted for early forcing. Some time since I saw a nice crop hanging in the early house at Hillside, and Mr. Day, the gardener, thinks very highly of it. Last year at the same place it was grown in a later house, the crop, size of fruit, and quality being all that could be desired. Royal Favourite is sure to be largely grown, as few varieties have so fine an appearance, the colour of well-finished fruit being a beautiful lemon. It is also particularly well netted.—J. C.

**Cucumber Veitch's Challenger.**—I have given this Cucumber a trial this season, and the results are very satisfactory, as it is not only a heavy and continuous cropper, but the majority of the fruits grow very straight and they have but little shank. They vary in length from 18 inches to 20 inches; the colour is also good, being a nice deep green, and they carry a heavy

bloom. It is a white-spined variety, but the fruits are but sparsely clothed with spines, and the colour of the flesh and flavour are all one wish for in a Cucumber. I have neither seen nor grown a Cucumber for a long time past which has given me greater satisfaction than Challenger, and have accordingly marked it for extended cultivation.—A. W.

**Yellow Raspberries.**—It is somewhat surprising that the yellow and white varieties of Raspberries are not more commonly grown—at least in private gardens—as they are so useful for dessert and make quite an attractive dish. The old White Antwerp is well worth growing, as although not so free as the red variety of that name, it bears profitable crops in good soil and the flavour is delicious. White Magnum Bonum, of larger size than Antwerp and early ripening, is a grand Raspberry, and, where only one summer white variety is grown, is perhaps the best, all points considered. For bearing in autumn, the canes being cut down in February, Yellow Quatre Saisons should be grown. This is a good bearer and the fruit is of fine flavour and valuable for mixing with the red Belle de Fontenay for dessert at a season when outdoor fruit is becoming scarce.—C. C. H.

**Melon Eastnor Castle.**—An old favourite and still one of the best of Melons among the dark green-fleshed section. It is seldom met with in cultivation now, owing, I believe, to the difficulty in obtaining seed of the true strain. I grew it this year for supplying the first crop, having been disappointed in obtaining seed of my favourite kind for that purpose—Davenham Early. The seed of Eastnor Castle proved to be true, the plants producing a good crop of even-sized fruits, all of which bore unmistakable signs of its parentage, Eastnor Castle being, as is well known, the product of a cross between Victory of Bath and Beechwood. The parents were two most excellent kinds in themselves, and it is doubtful whether the progeny—the variety under consideration—has ever been surpassed in point of flavour. A large fruit grower, when looking round these gardens a few weeks ago, made the remark that he grows none but Eastnor Castle Melon for his own eating, and has done so for many years past, as he considers the flavour to

be perfection. It is a capital grower and very prolific, being suitable for growing either on the restrictive or extension principle, and the individual fruits attain a large size under good cultivation. A great boon would be conferred on gardeners if someone possessing a true stock of this excellent Melon would increase it by saving and eventually distributing the seed, as I feel sure that many would be glad to obtain it once again.—A. W.

#### A SHORT STRAWBERRY SEASON.

LAST year the supply of Strawberries failed very quickly, but this season it was even worse in many districts. Rain fell opportunely, or otherwise the crop would have been a complete failure. As far as market growers are concerned, the reason for the shortness of the supply is not far to seek. All the early flowers either expanded or scarcely showing colour were blackened by frosts, and as a consequence fully a week was lost, and the crop was also much lighter than usual, or considerably below the average. Then came the spell of exceptionally hot weather in June, and this rushed in the later varieties. During the week ending July 3 Strawberries were spoiling in the shops in large quantities. Less than a week later the season was practically over.

Protecting rows or beds of Strawberry plants in flower from frost may seem a rather heavy undertaking, but I have never found it so, and in two seasons out of three found that the outlay of a few shillings saved fruit worth nearly as many pounds. In the first place the rows of plants ought always to be worth the trouble of attending to. It is strong, young, or comparatively young plants that give the best results. Any upwards of three years old cannot be depended upon to do well in the majority of gardens. They are the first to suffer from the effects of severe winter frosts, they are invariably later in producing ripe fruit than strong young plants; the fruit, if plentiful, is usually undersized and indifferent in point of flavour, and these old plants are the first to feel the effects of drought. A good succession of young Strawberry plants ought, then, to be constantly provided. There should be no waiting for the old plants to show signs of failing before planting more, but each season rows or beds, according to circumstances, should be planted and an equal number of old ones destroyed. By old plants I mean any that have produced three good crops of fruit. Hundreds of readers can doubtless point to older and, in their estimation, very profitable beds, but after many years' experience the conclusion I have arrived at is that younger plants give much the best results, that is if we take into consideration the quality as well as quantity of fruit supplied, and also the duration of the supply.

Market growers who plant by the acre have almost, perforce, to be content to dibble out runners late in the season and to prevent these from fruiting the following summer, in order that they may attain a serviceable size for fruiting one year later. Not so the private gardener. He can layer his runners early into either ridges of fresh soil or pots, well-rooted plants being ready for their fruiting quarters by the end of July. It is then when they ought to be replanted, delaying this important work till late in August, owing, it may be, to the site for them not being ready earlier proving a great mistake. Strawberries should have a freely-manured, deeply-dug site, and if trenching is practised—a desirable proceeding—this ought to be done in the winter previous, in order that the ground may have time to settle and to become well mellowed for the Strawberry

plants. Crop this trenched ground with early maturing Potatoes, and these can be cleared off, leaving the soil in admirable condition in time to plant Strawberries. By planting the latter early and firmly, and subsequently keeping them well watered, also free of weeds and runners, grand plants capable of producing a full crop of fine fruit can be grown before the winter stops further progress for a time.

Strawberries in many cases are planted too thickly. Instead of the plants being disposed 18 inches asunder in rows 2 feet or rather more apart, the more satisfactory distances would, in the end, be found 2 feet and 3 feet respectively. When grown closely together they smother and rob each other; whereas when more room is allowed, the individual plants produce heavier crops, which seldom fail to ripen properly, for the simple reason they are not smothered by leaves. One reason why the Strawberries grown in the open fields are often superior in point of flavour to those produced by plants of the same variety in private gardens is because they get more light, sunshine, and air. The plants, owing to rooting in solid ground, form short, stout foliage, and they also have abundance of room. During the height of the season the ripening fruit can be seen between the rows of plants in long bands of colour; whereas the luxuriant foliage on garden-grown plants not infrequently hides the fruit and spoils the quality. For an extra early supply of Strawberries, plant Noble, Royal Sovereign, John Ruskin, or other favourite early-ripening variety more thickly, or from 15 inches to 18 inches apart each way, on a warm sloping border where they can and ought to be protected when in flower. Only crop them once, the plants, after having also yielded abundance of early runners, paying well for the trouble taken with them. Young plants invariably give the earliest ripe fruit. Late Strawberries are quite as much appreciated, if not more so than early ones, and in order to prolong the season, plant either Loxford Hall Seedling or Latest of All on a cool border. I have found both of these varieties succeed remarkably well on a wide wall border facing north-east. Other varieties have been tried in a similar position, but they never equalled the two named either for lateness, weight of crop, size of individual fruit, or quality. Curiously enough, the plants fail after giving two crops. The one-year-old plants produce the finest fruit, and the two-year-old the latest and heaviest crop. Loxford Hall Seedling is not a strong grower, and may be planted about 18 inches apart each way.

W. IGGULDEN.

**Apple Pine-apple Russet.**—A medium-sized, but highly-flavoured dessert Apple, coming into use about Christmas-time, when it is much appreciated. The fruits are roundish ovate, with a pale yellow skin, sometimes coated all over with russet and in some instances merely strewn with irregular patches of dark brown russet. As its name denotes, it has a pine-apple flavour, which is very pronounced, and the flesh, which is yellowish white, is very juicy. The tree is healthy, hardy, grows well, and makes a fine bush or pyramid.—S. E. P.

**Peach Alexander.**—In my opinion this is one of the earliest and hardest varieties of the Peach yet produced for outdoor culture, and this opinion is not given after one or two years' trial only, as I have grown it for the past twelve years. It is a most vigorous grower, making plenty of foliage, while it is a very free cropper, and it is but seldom that it misses bearing. The fruits, which grow to a fair size, are brightly coloured and the flavour is very good for such an early variety. On a west wall the fruit generally ripens from July

10 to the 15th, but this season it is a little later than usual. It should be freely planted for the earliest supply where Peaches succeed outdoors.—S. E. P.

**Peach Stirling Castle.**—This is still one of the best second earlies we have for general excellence, whether grown indoors or out. A little later than Royal George, it forms a good succession to that variety, and its large, handsome and highly-coloured fruits leave nothing to be desired in the way of flavour. It is a hardy, vigorous grower and an excellent forcer, and, unlike its companion Royal George, it is quite free from attacks of mildew. A few years ago on a west wall I lost a fine old tree of Stirling Castle which would be more than thirty years old, and this tree invariably bore heavy crops of large highly-coloured fruits. Intending planters of Peach trees should certainly make a note of Stirling Castle as being a first-rate second early kind, and one that possesses a vigorous constitution.—W.

**Eugenia Ugni.**—This is an evergreen fruiting shrub belonging to the Myrtle family the fruits of which are edible. It is a native of Southern Chili, and must therefore be accorded the protection of an orchard house or greenhouse, as it is not hardy. Under glass this Eugenia fruits freely, and the individual fruits, though small, or about the size of an ordinary Red Currant, are of a pinkish colour, while the flavour is very agreeable, somewhat resembling that of a Strawberry. It succeeds best grown as a bush in a pot or tub, and for compost, two-thirds loam and one of peat with a liberal addition of sand seem to suit it well. Those in search of a novelty may do worse than purchase one or more plants for filling an odd corner in either of the structures mentioned, and the fruit ripening as it does in the autumn would then be very acceptable.—A. W.

#### STRAWBERRIES.

As the fruit committee of the Royal Horticultural Society at a recent examination of the numerous varieties of Strawberries being grown at Chiswick made only one award, and that but an award of merit, to Wonderful, a mid-season variety that carries heavy crops of fruit of medium size, longish form, and excellent flavour, it may be assumed that so far no very special merit has this season been displayed. It is undoubtedly most advantageous as well as right that all new sorts should be grown at Chiswick before awards are made, as the true habit and cropping quality of each one are then so admirably seen. A marked feature of the numerous varieties at Chiswick, both old and new, is the comparative absence of that high quality which is so generally termed flavour. A few have it in good form, but so many have it not. The best flavoured this season were Royal Sovereign, President, Edouard Lefort, Auguste Boisselot, and Latest of All, not really very late here, whilst of newer varieties but not yet fruiting their best because young plants, Admiral and G. Wythes give good promise. Wonderful, as mentioned above, is also of nice flavour. There seems to be so much labour expended in securing varieties that carry heavy crops of large fruit, that only very rarely does real flavour crop up. Nothing in new Strawberries last year excelled, or indeed came near to, Veitch's Perfection. That is, however, a distinctly late variety, as might be expected from the progeny of British Queen and Waterloo, and so far that has not been tested this year. Its habit is excellent, as the leaf growth is moderate and compact, and the flower-stems stand up prominently and very erect. But whilst moderate leafage may be good for pot culture, outdoors stronger leafage is no evil, as it shades the ground and the fruit. If anyone wishes to have a variety that is an enormous cropper, he can hardly do

better than grow Acquisition. The fruits are large, but soft and flavourless. Those who like an immense fruiter also, but producing rather smaller and firmer fruits well suited for preserving, will do well to grow Newton Seedling. It is really a sight to see the crop of fruit, and not bad fruit either, which two-year plants of this variety produce. In the direction of cropping we may well be satisfied, and as to size of fruits, more than satisfied. In new varieties we need flavour, which is so rarely found. Some seem to think flavour is found in sweetness, others in acidity, which they term briskness; but real flavour is an indescribable quantity, delicious to the palate, and more resembles perfume in a flower than colour or beauty. The fruits of the variety Wonderful are ideal ones for the dessert because they are not large and can be eaten at once. Another desirable feature in Strawberries is solidity. So many are soft-fleshed and, to use a current phrase, will not travel. How many of the varieties growing at Chiswick have soft, pulpy fruits and full of water. We want much more of flesh and less water. A. D.

**Currant La Versailles.**—It is somewhat surprising that this Red Currant is not more generally known and cultivated. I have heard it said that it is a shy bearer, but with me it crops better than any other sort, and that on a light soil which does not hold moisture very well. Others condemn it on account of its ungainly growth, the lower branches often being crooked and growing in a downward direction; but I cannot see that this is a sufficient reason for discarding it where profit is the chief consideration. Were I planting Currant bushes with a view to growing for market I certainly should go in for La Versailles. I thin out the trees well, so as to admit plenty of light and sunshine, and the noble bunches of fruit colour up beautifully. The fruit will hang a long time in good condition if protected from birds, and is unsurpassed for wines and jellies.—C. C. H.

**Strawberry Stevens' Wonder.**—I do not remember to have seen a note on this Strawberry other than as a forcing variety. I was induced to plant it for first crop in the open, but with disastrous results, as it is not early and not at all a heavy cropper. In the open it makes a lot of top growth, just the reverse of what one might expect, and it cannot be termed early. My first fruits—these badly shaped and of poor quality—came in with President, a mid-season variety. Stevens' Wonder is useless for general cropping. Had it been as early in the open as under glass it would have been a valuable introduction. Before penning these lines I waited to see how it did in soil of a different character from mine in another locality, and though there is less leafage there was no advantage as regards earliness. It would be well if others who have given it a trial for early fruiting in the open would give their experience. My soil may not have suited it, and other readers may have had better results.—S. M.

**Grape Duke of Buccleuch.**—This, although a grand Grape when in perfect condition, is seldom seen in anything but a ragged form, the berries more often than not being badly spotted. Attempting to grow the Duke on its own roots generally ends in failure, the wood being rank and sappy and many of the laterals barren. Some contend that the way out of the difficulty is to work it on to the Black Hamburgh, but I have seen it fail in a good many instances so worked. Golden Queen seems to suit this capricious Grape well, as, indeed, it does other uncertain varieties, such as Alwick Seedling. A few years ago I put a bottle graft of the Duke on to Golden Queen, and it has done well, improving each year and exhibiting very little trace of the well-known spot, which often disfigures the berries and renders them useless. Almost every lateral bears a bunch, and the berries swell to a large size. As soon as softening commences a rather drier, bracing atmosphere

is necessary, giving atmospheric moisture when air is on.—C.

**Apple Yorkshire Beauty.**—This Apple is synonymous with Red Hawthornden, but I think the appellation Yorkshire Beauty has the prior claim as far as nomenclature is concerned. It is rightly named, for it has a beautiful wax-like appearance, with a handsome rosy blush on the exposed side of the fruit when fully ripe. Orchard-grown fruits are generally more highly coloured than are those produced on bushes and pyramids. It is an excellent market kind; the fruits grow from medium to large in size, some being round and somewhat flattened, while others are inclined to be conical. The flesh is tender, white and juicy. It is an excellent cropper grown in any form of tree, and should be largely planted for market. Trees worked on the Paradise stock require rather careful pruning, as large numbers of fruit buds are produced at the tips of the young wood. These should therefore be left until the crop has been gathered, when they may be spurred back. This Apple is not a long keeper, and is at its best during October and November; after this it is apt to go woolly.—A. W.

**Apple Mere de Menage.**—Next to Norfolk and Herefordshire Beauties, this is the deepest coloured Apple grown among table fruits. We have darker-coloured fruits among the cider Apples. An old kind, named Red German or German, runs it very close for colour, but it is neither so large nor so handsome an Apple, and it does not keep so well as Mere de Menage, which comes into use in December. In a properly constructed Apple room the fruits will keep in good condition until March. In some seasons the fruits grow to an extraordinary size. Such was the case last year, and in average seasons they attain to good dimensions. The fruits are very firm and heavy, the flesh crisp and juicy, and it is an excellent cooker. Young trees are inclined to make rampant growth, but in the case of pyramids and bushes lifting soon rectifies this, and once they commence to bear they give no further trouble.—S. E.

PROLONGING THE STRAWBERRY SEASON.

THOSE who require Strawberries for a long period may have them of excellent quality for five or six weeks. Such kinds as the well-known and still valuable President, La Grosse Sucrée, Gunton Park, and Sir C. Napier may be relied upon for main-crop supplies. Strawberries, with special culture, may be had as late as September and October by planting forced plants to fruit a second time. Very few growers have the means to grow so late a crop. All do not force to have the plants at command, and it is to Strawberries grown in the ordinary way I would refer. For late crops, the Queen family in certain localities does well on a north border if the soil is heavy and good cultivation can be given. The fruits obtained from such a border are superior in quality to those in a more open quarter. I have grown British Queen on a cool border when it failed in the open in a drier soil. Frogmore Late Pine is a specially good late Strawberry, and with me it succeeds in light soil without special culture. I do not allow the plants to bear more than two crops. This variety is not a large grower, makes but few runners, and is a superb fruit as regards flavour; indeed, I have seen it preferred by some to a British Queen. It is one of the highest-flavoured Strawberries grown. I do not give it much room—2 feet by 18 inches between the plants—and grown on an east or north border it is a fortnight later than the mid-season varieties. Another excellent variety of the Pine family is Elton Pine, a larger fruit than Frogmore Late Pine, more acid, and on this account much liked for preserving. This is earlier than the Frogmore Late Pine, a heavier cropper, of a rich red colour, and does well in any soil. The Filbert Pine is not so well known as its merits deserve. This grows where others of the Pine section fail. It has more foliage and the

fruits are of a dull orange-red. It grows well in light soil and will be found suitable to follow the mid-season varieties.

A variety named Georges Lesnir, a continental variety, has proved a good late fruiter. It cannot be classed as a Pine variety, but it has a rich Pine flavour, is of large size, and liked by many. It is a continuous bearer, a valuable late fruiter, and admirably adapted for north borders. This will provide dishes for a fortnight or three weeks in good soils. My best late kind, if quantity, size, and quality are considered, is Laxton's Latest of All. The name is not a happy one, as it is now (July 7) ripe on a north border. We have others of the Pine family later, also Oxonian. Latest of All is a very fine fruit of true Queen flavour, and good colour. It is a small grower, needs planting close, and does best from young plants. This under a north wall will give ripe fruit for three weeks, and its good quality should commend it to all growers who require late fruit. With me it gains favour yearly, and though like the Queen it does not always ripen quite to the point of the fruit, it is far ahead of others in most respects, and if I were restricted to one late variety I would give Latest of All the preference. Oxonian is later, larger, and of good colour, but it lacks quality. It is a robust grower, and fruits freely from young plants. M. W.

**Strawberry Monarch.**—After the good accounts I had heard of this Strawberry, I confess I am rather disappointed in it. It is a splendid grower, and the fruit is absolutely faultless in appearance, very large and highly coloured, but, like Royal Sovereign, it lacks the rich vinous flavour one looks for in a first-rate Strawberry. Many people will consider it good enough for general use, and as a market fruit it may do very well, for it is a very heavy bearer; but where flavour is required we must look beyond Monarch.—W.

—This new Strawberry does well on the light soil of my garden, growing vigorously and producing fruit of large size and highly coloured. I obtained the plants in small pots last autumn, and so small and indifferently rooted were they that I did not expect much from them this season. They have, however, made wonderfully fine plants, the foliage being large, and apparently a good resister of spider. I am informed that on good Strawberry soil Monarch grows to an enormous size, and that it is certain to become a popular variety.—C. C. H.

**Pruning Red Currants.**—Would you through the columns of THE GARDEN tell me when is the right time to prune Red Currants?—PERPLEXED.

\* \* Red Currants may be pruned at any time from November to March during absence of sharp frost. Bushes growing in strong retentive soil, and which consequently ripen their wood later than those in a lighter, warmer compost, had better be left till say January, this giving them all the longer a rest. Young trees also that have made very vigorous growth may be left till the same date. In large gardens pruning has to be pushed on all through the winter whenever the weather is open. As a rule there is no advantage in deferring the pruning of bush fruit of all kinds after the foliage has fallen and the sap has ceased to flow.—ED.

SHORT NOTES.—FRUIT.

**Nectarine Early Rivers.**—The other day I saw a tree of this variety, and was much struck with the handsome appearance of the fruits, which were fast approaching maturity. It certainly is a great advance on Lord Napier as far as colour is concerned, and if the flavour is only as good as its outward appearance betoken, it is indeed a most valuable addition to the race of early Nectarines. I intend giving it a trial next season.—W. S. E.

**Peach Prince of Wales.**—This is a most excellent Peach for outdoor wall culture, coming into use at the latter end of September when given a western aspect. It is a heavy bearer and the tree is hardy and makes vigorous growth. This season is no

exception to the rule as far as its cropping is concerned, as it is again bearing well. The fruits when ripe are highly coloured, attain a large size, and are richly flavoured.—S. E. P.

**Peach Crimson Galande.**—Last year I sent a note in praise of this fine Peach. I now wish to draw attention to its free-cropping qualities in order that intending planters and those unacquainted with it may learn what a reliable Peach it is. I have grown it for several years past outdoors and have never known it to miss a crop, the present season proving no exception to the rule, and this when one hears so many complaints of a scarcity of outdoor Peaches. The tree is also very hardy and makes plenty of healthy growth, and with me is not so liable to insect attacks as are many other varieties, while size, colour, and flavour are all one can wish for.—A. W.

## FLOWER GARDEN.

### PRIMULA TRAILLI.

I was much interested in Mr. Richard Dean's remarks concerning the plant above-named as exhibited in April last before the Royal Horticultural Society, and while I cannot fully agree with Mr. Dean that the plant exhibited by Mr. G. F. Wilson is "identical" with *P. involucrata*, I go a long way when I say the differences between the two are very small and quite insufficient to entitle it to specific rank. My first impression of the plant was that it was *involucrata*, but, remembering the creamy blossoms of this plant, I could not longer regard it "identical" with the typical species, and concluded at once that it was a well-marked variety of this well-known plant. Mr. Wilson's plant is undoubtedly related to *P. involucrata*, though it certainly possesses minor differences, e.g., some slight colour in the flowers, and, as shown, slight differences of foliage also. These latter, however, in so far as it refers to the aspect of the leaves, may in a measure have been accounted for owing to the dry state of the plant, which I subsequently found was drooping from lack of moisture. Had the plant been immersed in a pail of water a few minutes and placed before the committee an hour later, the horizontally-disposed leaves may have assumed a more erect form, and thus brought it even more closely in touch with the type to which it undoubtedly belongs—viz., *P. involucrata*. The fact should not be lost sight of that this is a decidedly moisture-loving species, and to exhibit such a plant lacking moisture is to deprive it for the moment of some, at least, of its essential characteristics. I am surprised that the so-called *P. Trailli* obtained a large number of votes for specific rank, which only shows the need for such plants being placed before a sub-committee of hardy plant experts, whose decision shall be final. *P. Trailli* is not mentioned in the synonymic list that obtained at the *Primula* conference of April, 1886.—E. JENKINS, *Hampton Hill*.

—With reference to several notices about *Primula Trailli* in recent numbers of *THE GARDEN*, I think it may be of interest to mention that I received about two years ago a large packet of seed from Dr. Watt himself so labelled. The seedlings flowered well last year, but I could see no difference botanically between them and the species I have long had under cultivation as *P. involucrata*, Wallich (Munroi, Lindl.). Dr. Watt was in England last year, so I showed him his seedlings in flower. He at once said that they had nothing in common with his *P. Trailli*, which was a much larger and handsomer species, and that his collector must have gathered the seed from *P. involucrata* by mistake. These same plants (I have eight pots full) came up much stronger this spring, flowering abundantly and ripening seed; some even are still throwing up flowering spikes. The

flowers differ considerably in colour, varying from pure white to more or less pronounced lilac, also in size, some of my flowers being larger than those on the plant exhibited at the Royal Horticultural meeting by Mr. G. F. Wilson.—R. H. B.

—I have only a few remarks to make on the note on *Primula Trailli* at page 16. I told the committee in a note to the chairman all I knew about the *Primrose*. The seed came to me from a friend, a first-class Indian botanist, who must have been well acquainted with *P. Munroi* or *involucrata*. He asked that I should be careful with it, as the *Primrose* had not been bloomed in this country. I have grown *P. Munroi* or *P. involucrata* for many years. There is an especial interest attached to it from the fact that it was in full retreat in Afghanistan that Lieutenant Munroe (afterwards General Munroe, a great authority on grasses) saw the plant and secured it in spite of danger. The more I see of *P. Trailli* the more I am convinced that it is a real acquisition. I am an old man, so must not look forward too much, but hope next season to show the *Primrose* before the committee in such form that the great majority of the members will not only be glad that they gave an award of merit, but will consider the plant worthy of a first-class certificate as being a valuable new plant.—GEORGE F. WILSON.

**Sweet Pea Aurora.**—This is a new American variety sent out this season with a great reputation, but, as far as my own experience of it by growing it goes, and also what I have seen of it elsewhere, I hold it to be disappointing. It has a fault common to many of our newer varieties of Sweet Peas—that of the standards not being erect and displaying themselves to the best advantage, but curling down over the wings and hiding them from view. What is absolutely necessary is stout, erect, smooth, well-formed standards standing up, so that the colour of the wings can be distinctly seen. Queen of England, white, is a good model to follow, and no new variety can be accepted as first-rate which has curled incurving standards. *Aurora* is white, distinctly striped with bright pinkish rose, or, as the Americans give it, orange-salmon. The woodcut of this given in catalogues shows the standards of this variety to be perfectly erect, broad, smooth, and so displayed to the very best advantage. But we get used to woodcuts of novelties; they are devised to provoke a sale; the blossoms are large in size, but the defect mentioned above does not enable them to be seen to the best advantage.—R. D.

**Silene maritima plena.**—It is very curious to note the behaviour of this plant and its shy flowering, as referred to by Mr. Wood at page 466. Having invariably succeeded with it, and in gardens and soils very opposite in many ways, I had regarded it as among those alpine plants that could be depended upon to flower abundantly and regularly year after year. Indeed, this is after many years' experience of it, for the plant has grown so freely in some instances that I have pruned back the whole, or, at any rate, the bulk of the current season's growth, quite close upon several occasions, and if the subsequent growth is any guarantee of the wisdom of the experiment, I can only say that it was so successful that it was often repeated in subsequent years. In my experience this plant has not only grown freely, but flowered abundantly. It will repay a liberal treatment, and in the raised positions of the rock garden I have mixed manure freely with the soil with excellent results. Chalk I have never added in any instance, but in very heavy soils leaf-mould and cocoa-nut fibre to lighten the soil. In light sandy soils patches 2 feet or more across, that produce hundreds of handsome flowers in a season, have resulted in two years. Cuttings inserted in September in sandy soil soon root, and if planted in good light soil early in March, will give some flowers before the plants are a year old.—E. J.

**Hardiness of Gladiolus The Bride.**—This cannot be too largely grown in any garden,

public or private. For cutting it has few or no equals. It is invaluable in pots and delightful in lines or groups in the open air. Even in gardens where the hardiness of *The Bride* may be doubtful it is more worthy of being lifted and stored in safe quarters during the winter months than so many other *Gladioli* that are mostly subjected to this treatment. Before the present magnificent garden hybrids were raised, the older species, such as *byzantinus*, *cardinalis*, *gandavensis*, &c., were generally subjected to this treatment with the best results. *The Bride* is even more worthy of this extra labour where there is the slightest reason to doubt its perfect hardiness. Independent even of this consideration it is possible that the annual lifting and re-planting of *The Bride* may add to its vigour, health, and beauty. It may stand considerable cold in earth and air with impunity or without positive injury. It is certain, from the enormous quantities forced and bloomed under glass, that it thrives under genial conditions. Nor must the safe proviso of at least 6-inch deep protection of earth over the corms of *The Bride* be forgotten. If an inch or two of cocoa fibre be added to that the corms will be all the safer.—D. T. F.

### NOTES ON HARDY PLANTS.

**Ranunculus crenatus.**—There is a special way of propagating this slow-growing, but free-flowering species, and all the group to which it is most nearly allied. The idea is to take advantage of its free flowering otherwise than from seed, which happens, as in this case, to be rarely fertile. The early spring or winter flowers have a short and stout scape, with a sort of node or bract joint about midway up. When the flower is half expanded, pick it off; the result is that a foliar development sets in at the joint, and by June it becomes a nice rosetted tuft of leaves, only needing to be pulled off the parent plant with original flower-stem and set at once as an offset, though there may be no roots. Contact with the soil causes roots to be emitted in two or three days in June, and the young plants are assured. Of course it is only worth while to adopt such special means of propagation where offsets and seed largely fail, and it need not be said that but few plants lend themselves to this mode of increase, and certainly all species of the genus *Ranunculus* do not.

**Trautvetteria palmata** is a free-flowering plant of 2 feet to 3 feet stature, and delightful for a half-shaded position. The corymbs of bloom remind one of the white fluffy *Thalictrums*; but not only are they more symmetrical, but far more durable. It is decidedly showy, but, what is perhaps more, it is unique and most interesting.

**Geranium lancastriense album.**—This new variety in all except the colour of its flowers more resembles var. *sanguineum* than the type, i.e., its branches are more ascending, longer and longer jointed. The big white flowers are, of course, its main feature and the only one to note, and these are certainly striking.

**Dianthus Lindsayi.**—This is a curious and pleasing cross between *D. alpinus* and *D. barbatus*, with all the variations of colour common in the *Sweet William*. There is a strong suggestion of alpinus in the large flat flowers, which do not come out all at once in big corymbs, as with *barbatus*. Stature 9 inches to 1 foot.

**Cytisus schipkaensis** is now beautifully in flower, and by far one of the best dwarf and spreading white-flowered things now out. This is saying a deal when so many of the dwarf shrubby *Veronicas* and *Leiophyllums* are out too. One formed a good opinion of this with its clusters of large white flowers at the first sight, but my old specimen of three or four years has improved year after year as it has become more established, and in no respect more than the size and purity of its flowers. A deep root-run of stony soil with full exposure to sunshine seems to suit it well. J. Wood.

*Woodville, Kirkstall.*

### THE ROCK GARDEN AT ABBOTSBURY, NEWTON ABBOT, DEVON.

IN previous numbers of THE GARDEN I have given a long series of articles dealing with the construction of rock gardens. As, however, these essays were necessarily more or less theoretical, I propose giving a practical example of a rock garden actually constructed at Abbotsbury, the residence of the late Mr. E. Fisher. Having arranged this rock garden, I can speak of the various combinations and effects from practical experience. It cannot be said that the site was a very suitable one, inasmuch as it consisted of an ordinary pasture field about an acre in extent, bordered on one side by the town of Newton Abbot and on the other by a row of huge Elm trees adjoining the pleasure grounds. As irregularity is one of the most important conditions for a picturesque arrange-

the surface of the stones plastered with cement or any other substance (as is so often done to the detriment of the plants). The formation of the pond, waterfall, and cave would, of course, have been impossible without cement, but even here it was used only in places entirely hidden from view, so that in the whole of this rock garden not a particle of cement work or masonry of any kind can be seen.

In arranging the rocks, I followed the principle so often advocated in these columns, *i.e.*, the rocks were disposed in groups of all sizes, with grassy slopes full of flowers, and banks of miniature rock shrubs here and there to give the necessary repose; and though each individual group would distinctly show the stratified character of real rock, the whole of the groups combined represent a most irregular and broken-up appearance. A considerable portion of the field was given up to plantations for

description, but I hope to best serve the interest of the readers of THE GARDEN by giving a short review of such arrangements of plants, &c., as have given the most satisfactory results. Throughout this work I have tried to avoid an aimless scattering of plants, but rather to mass the various kinds of shrubs, as well as rock plants, into effective groups.

Entering the rock garden from the drive, the visitor meets with groups of all kinds of flowering shrubs, such as *Coryopteris mastacanthus*, *Choisya ternata*, *Magnolias*, *Rhododendrons*, *Heaths*, *Cydonia*, &c. All are fringed with hardy perennials. The largest, and in spring perhaps the most effective, of these groups consists exclusively of a large collection of *Berberis*, containing, among others, *B. Thunbergi*, *B. aristata*, *B. japonica*, *B. buxifolia*, *B. Fremonti*, *B. Darwini*, *B. stenophylla*, *B. asperma*, *B. vulgaris atro-purpurea*, *B. nepalensis*, *B. ilicifolia*, &c. Traversing a grass path between groups of Bamboos and various *Cistuses* of the larger kinds, such as *C. ladaniferus*, *C. crispus*, *C. florentinus* and others, the

#### ROCK GARDEN PROPER

opens into view, and its beginning is indicated by scattered blocks of rock protruding here and there from the sward, or from a mass of *Saxifragas* and other plants. A bold mass of rock forms a pleasing recess, with seats commanding a view of the waterfall and other features. The plants furnishing this recess are, like the rocks, of the larger and bolder type, such as Australian Tree Lupines, *Dracocephalum grandiflorum*, masses of *Heuchera sanguinea*, *Pentstemon ovatus*, carpets of *Gaultheria procumbens*, *G. nummulariifolia*, &c., and closer to the eye the golden yellow *Morisia hypogea* and other plants of the smaller type. Most effective is a fine specimen of *Pentstemon Scouleri*, with its large bright purple flowers (see illustration p. 42). The plant here illustrated is growing in a mixture of loam and stones on an elevated position, and it measures considerably more than a yard across, being only 15 inches in height. *Romneya Coulteri*, the great Californian Tree Poppy, is doing well at the foot of a grassy slope, divided by a path from a bog garden extending to the margin of the pond. One of the handsomest plants in this part is the great Japanese Groundsel (*Senecio japonica*), with its huge lacinated leaves and enormous yellow flowers on stems over a yard high. In a shady recess are *Cypripedium spectabile*, the yellow-flowering *Saxifraga Hirculus grandiflora*, *Primula Poissoni* and many others, while the sunny part of the bog garden contains among others a mass of *Dodecatheon*, *Houstonia cerulea*, *Primula farinosa*, *P. rosea*, *Saxifraga aizoides*, several *Pinguiculas* and a host of others. *Dryas octopetala* has spread out into a large carpet, increasing faster than its yellow companion, *Dryas Drummondii*. A group of rocks about 3 feet high is devoted almost entirely to *Dianthus*es of various kinds, including *D. neglectus*, *D. alpinus*, *D. caesius*, *D. glaucus*, *D. alpestris*, *D. cinnabarinus*, *D. sylvestris*, &c. *Gentians* in about a dozen varieties were planted in rocky beds on a lower level. *Gentiana bavarica* has unfortunately made very slow progress, but is doing better since it was shaded. Besides *G. acaulis*, which forms a large mass by itself, *G. septemfida*, *G. cruciata* and *G. verna* have flourished best. Above the *Gentians* are various *Anemones* and *Saxifragas*. *Anemone Pulsatilla* is luxuriating in a flat space at the foot of an almost perpendicular group of large rocks. *Opuntias* of various kinds crown the top of this rock, but the almost vertical fissures at the sides have become the home of many ch ice Rockfoils, such as *Saxifraga Frederici Augusti*

Colony of *Saxifraga longifolia* and Edelweiss in rock garden at Abbotsbury. From a photograph sent by Messrs. R. Veitch and Son, Exeter.

ment, considerable excavations were made, and the soil thus gained was used for forming banks and planted with suitable trees and shrubs to form a screen. The Elm trees were made "harmless" by a deep concrete wall completely under ground, which effectually prevents the intrusion of tree roots into the rock garden proper. The object of the rock garden was to provide a home for as many mountain flowers as possible, and to furnish a picturesque adjunct to the gardens where apparently natural rocks should be scattered in profusion and adorned with plants so selected as to form a source of interest practically all the year round. The rocks were built with limestone of a light brown colour, which shows the plants to great advantage. In imitating the strata of natural rock no cement was used, the crevices being filled with suitable plants instead. Neither was

shelter, with broad, irregular fringes for all kinds of hardy plants of the bolder type, arranged for the most part in large, irregular masses. The central portion, forming the rock garden proper, is from 60 yards to 80 yards in length and about 35 yards in width. There are bold features, such as a waterfall 15 feet or more in height, a shady Fern-lined cave with seats, a streamlet fringed with water-loving plants, a pond aglow with *Marliac's* Water Lilies, a bog garden, and rock steps of natural appearance facilitating access to every portion of the work. There are also introduced several stepping-stone bridges and smaller groups of scattered rocks devoted exclusively to the smallest and choicest gems of the mountain flora. Inasmuch as close on 2000 species of plants were used for the embellishment of this rock garden, I cannot here enter into a detailed

(true), *S. luteo-viridis*, *S. apiculata*, *S. Burseriana* major, and, above all, that silvery queen of Rockfoils, *Saxifraga longifolia*, a group of which intermixed with *Edelweiss* is shown in illustration, p. 37. Some of these handsome rosettes have already attained a considerable size, and grouped together their effect is decidedly striking. Rocky steps lead from this point over a steep slope about 12 feet high and fully exposed to the mid-day sun. Here masses of *Helianthemum* have spread out into a large group of brilliant colours a dozen yards or more in extent, and their somewhat rapid progress is checked by a stepping-stone path carpeted entirely with the bright blue *Veronica alpina*. Another part of this sunny slope is devoted entirely to different kinds of *Sedum*, *Sempervivum*, and a mass of the handsome hardy *Mesembryanthemum uncinatum*. A sheltered nook also exposed to the full sun contains a collection of plants recently introduced by Messrs. Veitch from Colorado. Of these, *Townsendia Wilcoxiana* and several species of *Erigeron*, *Trimorphaea*, and *Erysimum purpureum* have done exceedingly well, but I failed with *Polemonium confertum melitum* and *Phacelia sericea*. The steps leading over this slope are very convenient, but they resemble an accidental pass formed by Nature rather than a staircase. Every crevice is filled with carpeting plants, from which the stepping stones protrude naturally. Among other plants I used *Thymus lanuginosus*, *Arenaria balearica*, *Herniaria glabra*, *Arenaria cæspitosa*, *Veronica repens*, *Sedum dasyphyllum*, &c.

At the bottom of the afore-mentioned sunny slope is a small group of rocks reserved for small alpine which either hate limestone or do not require it. Though the outside part of this rock bed is bounded by the same kind of limestone rocks as the rest of the work, the interior of all the crevices is filled with granite and sandstone chippings mixed with the soil. In this part flourish, among others, *Lewisia rediviva*, *Ranunculus parnassifolius*, *Saxifraga calyciflora* with its handsome red flowers, *Androsace carnea*, *Linum maritimum*, *Linum Lewisii*, *Achillea umbellata*, *Dianthus glacialis*, and many others. *Androsace glacialis* did well for a time, but died the second year.

#### THE CAVE,

which is close by the last-named group, is, of course, formed by the largest and boldest rocks. The entrance is marked by almost perpendicular "cliffs," furnished in every crevice with suitable plants. On the north side are masses of *Ranonda pyrenaica*, including the pure white variety, whilst from a shady nook at the foot of the rock spring *Primula sikkimensis*, *Primula japonica*, *Polypodium canbriicum*, and such carpet plants as *Mitchella repens* and *Linnaea borealis*. Facing south is a bold prominence planted with the variegated New Zealand Flax, and the larger ledges of the rocks above are devoted to groups of such plants as *Achillea tomentosa*, *Campanula glomerata dahurica*, *Erigeron aurantiacus*, *Cheiranthus alpinus*, *Polemonium reptans*, *Polemonium humile*, &c. The lower parts nearer the eye are adorned with dwarfier kinds of plants, noteworthy *Lithospermum prostratum*, falling in a large blue sheet over the stone, *Erinus alpinus* and its white variety, *Hypericum repens* and others. The interior of the cave is partly lined with *Selaginella helvetica*, *Cystopteris fragilis*, *Cyrtomium falcatum*, *Scolopendrium fissum*, *Scolopendrium crispum*, *Erpeton reniforme* and other good things. Above the cave, and partly hanging over the large boulders forming the roof, are *Mullenbeckia complexa*, *Polygonum vacciniifolium* and *Arbutus*

*Uva-ursi* entwined with *Smilax aspera* and the long-flowering shoots of *Tropæolum tuberosum*. Here also are shrubs among the rocks. Very graceful in appearance is the New Zealand Broom (*Notospartium Carmichaeliæ*) with its arching branches covered with pink flowers. *Citrus trifoliatus*, Pomegranate, and *Desmodium penduliflorum* are also conspicuous. The last-named is intended chiefly for autumn display, when the long arches of rosy purple flowers are very telling. Masses of *Waldsteinia fragarioides* and the beautiful blue *Camassia esculenta* are most cheering in spring. But, perhaps, one of the most effective groups of spring flowers is that showing a large plant of *Genista præcox* with its elegant pale sulphur-coloured flowers on a carpet of the rosy purple *Aubrieta Leichtlini* (see illustration, p. 48). Though the engraving portrays the shape, it can give no idea of the charming contrast of colour. In order to give some amount of probability to the idea of the cave being a production of Nature, it was necessary to keep its immediate surroundings more bold and massive in character than other parts; the rocky ledges were, therefore, kept rather wide and were planted with groups as large as the space would allow. One ledge is devoted entirely to the golden yellow *Onosma tauricum*, another to the "Alpen Rose," *Rhododendron ferrugineum*, and *Rhododendron hirsutum*, while still others are adorned with *Centaurea macrocephala*, *Centaurea montana* and its varieties, *Carpenteria californica* with its large white flowers, *Pinus Pumilio*, *Anthericum liliastrum*, and a whole host of others too numerous to mention. A portion of the rocky steps leading from the top of the cave down to the waterfall is seen in illustration, p. 39. Except where the foot falls, these steps are carpeted entirely with various suitable plants; the sides of the steps are bordered at times by almost perpendicular rocks, and in such cases plants are chosen that look most graceful when their flowering branches fall down over the rocks. *Vittadenia triloba* (syn., *Erigeron mucronatus*), for instance, forms long festoons hanging down at great length, and very graceful, too, are *Tunica Saxifraga*, *Arenaria montana*, *Arenaria grandiflora*, *Campanula isophylla* and its white variety, *Glossocoma clematidea*, with its bell-shaped flowers of peculiar marking, *Umbilicus chrysanthus*, and many more.

The rocks at this point are traversed by an apparently natural gully, and the scene is enlivened by a waterfall a little over 15 feet high and from 5 feet to 8 feet in width tumbling over the rocks and wetting with its spray the numerous plants which here have found a home. One of the happiest of these is *Acena ovalifolia* (see illustration, p. 46), which hitherto I had often used with good effect for covering dry stony banks, but never before have I seen it flourish as in this position where its foliage is wetted occasionally by the spray of the waterfall. The illustration shows only a portion of the plant, which has spread out into a curtain quite 10 feet long and 5 feet wide, forming with its deep green foliage an excellent background to the bright alpine flowers arranged in front of it. I would strongly recommend this plant for a similar position. Above the waterfall *Rubus deliciosus* spreads its arching branches covered with white flowers over a prominent rock, which later in the season is almost hidden from view by the brilliant blue flowers of *Plumbago Lar-pente*. The streamlet which forms the waterfall is traversed by a stepping-stone bridge. A mass of rocks close by is covered in spring by a large group of *Edraianthus* (*Wahlenbergia*), succeeded in autumn by a brilliant display of

*Zauschneria californica splendens*. On the sides of the streamlet are such water-loving plants as *Spirea palmata*, *Astilbe rivularis*, *Iris* in variety, and *Spirea astilloides*. The source of the streamlet is lost to view in a Fern-lined cleft of a rock, covered in spring by masses of *Plox* of the setacea type, succeeded by late-flowering alpine in many sorts.

A walk around the rocks near the waterfall leads again to a lower level. In a large shady recess are many varieties of hardy *Cyclamen* of both autumn and spring-flowering kinds. Some of the dwarfest kinds of Japanese Maples of the *Acer polymorphum dissectum* type are planted between the *Cyclamens*, and give them the shade they love so well. Separated from the main rocks by a grass path is a group devoted on the shady side to the Fire Pink (*Silene virginica*), the bright purple *Saxifraga pyrenaica superba* and a few others, but the chief adornment of this group is formed by *Hairbells* and *Poppies*, a combination, by the way, which has given very satisfactory results. The collection of *Campanulas* includes, among others, *Campanula G. F. Wilson*, *C. Waldsteiniana*, *C. garganica hirsuta*, *C. Elatines*, *C. Raineri*, *C. Zoysi*, *C. Hosti*, *C. Erinus*, &c. The *Poppies* are confined mostly to the neatest and smallest kinds of the *Papaver alpinum* section in its various shades of red, pink, yellow and white. A low, almost flat portion of the ground near the pond is planted with *Primula Sieboldi* and *Spirea filipendula*, the latter flowering when the season of the *Primula* is over. Close by are also numerous other *Primulas* of the alpine type, such as *P. Auricula*, *P. Clusiana*, *P. marginata* and others.

#### THE POND,

which is fed by the water coming from the waterfall, is, of course, as irregular as possible. Of cement and other substances used in its construction no trace is visible. The sides consist only partly of rocks. Here and there intervene grassy banks covered with *Iris*es, or with such things as *Osmunda regalis*, *Saxifraga peltata* and the gigantic *Spirea kamtschatica*. On a water-soaked promontory and surrounded by smaller plants *Gunnera manicata* is in a fair way of feeling at home. That the pond itself is furnished with aquatics goes without saying. Special places were prepared for them below the surface of the water. *Marliac's* lovely *Nymphaeas* have given the most satisfactory results. Of the larger kinds, *N. Marliacea carnea*, *N. M. Chromatella* and *N. M. rosea* were introduced, and of the smaller kinds, the varieties planted were *N. Laydekeri rosea*, *N. pygmæa alba* and *N. pygmæa helvola*. On the east side of the pond the water again emerges as a streamlet, which is crossed by stepping-stones, and finally the water is lost to view beneath a rock. On the south side of the pond are a Heath bed and also a specially constructed rocky bed reserved for very choice alpine of the smallest kinds, such as *Androsaces*, *Soldanellas*, *Silene acaulis*, *Silene exscapa*, *Draba bruniefolia*, *Aretia vitellina*, *Cyananthus lobatus*, *Cerastium lanatum villosum*, *Umbilicus spinosus*, *Morisia hypogæa*, *Senecio incanus* and other gems which one likes to have close to the eye, where they can be watched more effectively than when scattered in places where they are likely to be overrun by plants of coarse growth. The whole of the work, including the planting, was carried out by Messrs. R. Veitch and Son, of Exeter.

*Elmside, Eceter.*

F. W. MEYER.

**Dictamnus Fraxinella.**—The rosy purple form of this is now very attractive. The spikes are each about 18 inches in height, bearing a loose raceme of widely opened flowers that show up well

on the green foliage. To get large plants of this species they should be planted in good soil, not too moist, and left alone, these having a much better effect than small clumps. There is also a white form of this plant, but it is not pure, and, taken all round, the purple form is the better.

**Exhibiting Delphinium spikes.**—How much better would these flowers look if set up in large vases in quantity, such as seven or eight spikes of any one variety, and spread out, some leafage being added. But those who exhibit these things seem to want to show as many varieties as possible rather than endeavour to attract attention by setting up a bold exhibit of fine bunches in large vases. How noble large *Chrysanthemums* and *Paonies* look set up in this fashion; so also would *Roses* if we could get them on sufficiently long stems always. Mr. G. Mount shows *Roses* sometimes in this fashion, and singularly beautiful they are. Some day perhaps we may hope to see *Cactus Dahlias* so shown rather than having them tied hard into triangular-shaped clusters by the aid of wire frames. If those enterprising nurserymen who exhibit hardy flowers so largely and so generously at the Drill Hall meetings would but select the best only—not more than some two dozen—and set them up in good clumps artistically spread out and stood in large vases, what a gain it would be all round. I hope some day that at least *Delphinium* spikes may be so exhibited.—A. D.

**Oriental Poppies.**—“R. D.” in an interesting note on page 467 refers to these showy plants. They are still quite gay here—that is to say, the typical form and the darker crimson kinds. The variety *Silver Queen* I consider not worth growing, as it is neither white nor rose, but a very undecided and unattractive tint of light purple. These washed-out-looking colours, so far from being specially named, ought never to be grown in any quantity. *Salmon Queen* as I have it here is quite a different thing, and very pretty if not grown in company with the deeper and brighter coloured forms. Each colour should be kept separate, with a considerable distance between them, if the best results are looked for. Nothing is worse than planting these *Poppies*, as I saw them recently, close to double red *Paonies*. Both flower about the same time and both are noble hardy plants, but the effect of one kills the other, so to speak. In the bracteatum section the large dazzling scarlet *Beauty of Livermere* is one of the best, but, as “R. D.” points out, many fine and varied forms can be raised if the seed is obtained from a reliable source.—R., *Suffolk*.

**Carnation Lord Rendlesham.**—This excellent variety should be included in all collections, its distinct shade of colour—buff ground, suffused with rose—giving it a most attractive appearance. It is, moreover, a very robust grower, making abundance of grass and opening its first flowers early in the season. Its continuous habit of flowering, and the fact that it grows and flowers well in light shallow soil, enhance its value. *Carnations* of this colour are none too plentiful, and several of the varieties have weak constitutions and often die out if the soil is not of the very best description. Those who have not yet obtained it

should do so during the coming autumn.—*Grower*.

**Malva moschata alba.**—Here is a hardy perennial which is delightful in the border at this season of the year, but too seldom met with. It is easily enough grown, one of those plants which takes good care of itself and is not easily killed. I find that it does best in an open sunny position, care being of course taken that it does not suffer from want of water when the weather is hot and dry. I have plants which have formed pyramids of shoots, and they have a fine effect when in full bloom. The plant is readily raised from seed.—R. D.

THE ENGLISH SPRING—AN APPRECIATION.

As in bright mid-May, after a three-months' absence from England, one journeys swiftly Devonwards, past fields golden with *Buttercups*, orchards

and as belonging by right to English skies alone, possibly because in childhood conditions were chiefly favourable for prolonged study of the heavens, from beneath the shadows of the Elms or from the top of the newly-stacked hayrick, at what time such white fleecy clouds slowly traversed the blue vault. Doubtless in those careless days we took but little heed of the beauties of Nature, but wiser Memory focussed them on her retina against the time when the stress of life brought ability to understand and appreciate. Now and again the scent of a *Bean* field recalls the refrain of the “*Bee Song*,” “I all day long have filled my sack Among *Bean* blossoms white and black.” Anon, sweeping out of a deep cutting, we fly by “cottage chimney smoking from the woods and cottage gardens smelling everywhere, confused with smell of orchards.”

At length, driving up the narrow tree-embowered valley in the sunset, we see the swallows hawking along the stream, the swifts wheeling on tense pinions far overhead in the clear sky, and note that the martins have renewed their nests beneath the eaves. The cuckoo calls a welcome from the copse; the pink *Thorn* and *Laburnum*, though past their best, still show their colours over the winding village road, and the garden is odorous with *Lilac*, while in the house great bowls of early *Tea Roses* fill the rooms with fragrance. That the goddess of spring is coy and uncertain must be allowed, but to be so is an attribute of the “eternal feminine” that serves but to render her smiles the more fascinating. Surely on such a day no one, least of all the wanderer, is inclined to cavil at the English spring! S. W. F.

**Dendromecon rigidum.**—I shall be glad of any information as to the outdoor culture of this. Should it be in the full sun? My plant faces west.—H. B.

\*\* This member of the *Poppy* family should be well suited in a westerly or south-westerly position, though one of the largest plants we have seen was in a position nearly due south at the foot of a wall and growing freely. We have our doubts, however, as to the perfect hardiness of this Californian plant, and unless your plant is strong and well established, we would suggest either lifting and potting it in September or October, or giving it the protection of some dry bracken about the branches, and say 3 inches of coal-ashes or cocoa-fibre refuse at the roots. The plant will doubtless prove most hardy in a raised position in the rock garden, where a not over-luxuriant growth will be formed, and where if planted at the base of a bold piece of rock the plant would receive protection. In the more favoured parts of these islands it should prove a very charming as well as useful subject. Very firm planting in loam and sandy peat without manure suits it well.—Ed.

**Tufted Pansies at Chiswick.**—The trial of these hardy plants at Chiswick is this season not a success, growers having but poorly responded to the council's request for plants. The site selected for the purpose is without doubt a first-rate one, and has the advantage of shade on the south side and but one face. Of pale-lued varieties, most certainly the prettiest is *Bridegroom*. The flowers, of good form, flat, and borne in great profusion, are of a soft pale lilac hue. They open nearly white and deepen in colour with age. The habit is excellent. *Bluestone* has the very best dwarf habit, and the flowers are flat, round, and bold; colour slate-blue. It is a capital variety to work upon to secure quality and good habit. *Pencaitland* is very pleasing, but the yellowish tint of the lower petal detracts somewhat from the whiteness of the upper ones. Still, at Chiswick it is very pretty. *Trentham Purple* seems to be the best of its section, and *W. Niel* the best of the reddish-lued varieties. We have but to see a collection of the numerous varieties in commerce set up in spray form at exhibitions, if not to be seen growing, to be able to distinguish the worthy from the worthless. So many that help to make up these displays and are thought to be pretty are soon found to be

Portion of rocky steps at Abbotsbury. From a photograph sent by Messrs. R. Veitch and Son, Exeter. (See p. 33.)

here and there still pink with *Apple* bloom, and hedges white with blossoming *Hawthorn*, it is with feelings akin to penitence that one returns to the old allegiance, and is inclined to recant all that one has thought and said in praise of the beauties of foreign climes, so infinitely more precious appear the well-remembered charms of an English spring. There is a restfulness in the gentle sweep of the landscape to be found in no other lands—truly, “God's finger touched, but did not press in making England”—an ineffable peace in the emerald pastures where the red cattle browse; in the cool coombes where the evening sunlight slants athwart the transparent green of the young *Beech* leaves—one of the most beautiful sights in Nature. “Such nooks of valleys lined with *Orchises*, fed full of noises by invisible streams.” The very cloudlets that sail serenely across the blue sky, though cloud-shapes are much the same all the world over, seem familiar

useless for outdoor or garden decoration. It seems a pity that some classification cannot be made of those Pansies, those that are really useful for massing or bedding, or growing in large tufts in borders to give good effects, being divided from those numerous worthless varieties that give no pleasing effects whatever.—A. D.

## ROSE GARDEN.

### ROSE NOTES.

Now that our Roses are in full growth and beauty, they will be much benefited by a free use of stimulants. Too often these are given to a weakly plant and withheld from one carrying a lot of bloom and growth. A weakly plant cannot use additional food to the same advantage as one in full vigour and activity. Either cultivate the surface-soil frequently with the hoe or mulch with some well-decayed manure. Where Roses are grown for decoration in the garden, I would not use a mulch, but give a dressing of some artificial manure and stir or hoe this in at once. Natural manures are more beneficial and lasting, but they are all more or less unpleasant in the Rose garden. The production of exhibition blooms is another matter. A most important item at this season is the budding of stocks. July is an excellent time for this operation, and all stocks of the hedge Brier intended for standards should be budded this month. Select buds from a strong-growing plant of each variety, and also give a little consideration to the matter of quality and freedom with which the plant flowers. Much of the so-called deterioration of Roses can be traced to injudicious selection of buds. We are careful with seed-saving and in the propagation of many plants by cuttings, and yet often take a Rose-bud without any attention to selection as regards the healthy, vigorous and free-flowering properties of the parent plant. In the issue for June 26 "A. D." writes of Briers as hedgerow plants. I do not think any plant will make a better, more impenetrable or sweeter-scented hedge than the hybrid sweet Briers. I am sure no animal would face my own plants, now some 4 feet to 6 feet through and 10 feet to 12 feet high. It would be easy to tie these into a narrower space, but I have left them to grow at will, and they have been a delightful feature ever since early in May. The trusses of deep scarlet upon Anne of Gierstein and Meg Merrilies, also the deep metallic salmon and copper of Lady Penzance have been very showy. Jeannie Deans produces the finest trusses with me, many carrying from one to two dozen buds and blooms. This is a semi-double, a more lasting flower, and with rather sweeter foliage than the others. Grand as these Briers are in every form, I like them best when worked as tall standards. The long rods of blossoms droop over very gracefully, and are of a decidedly deeper colour than when worked upon the Manetti stock. I am trying them as stocks for Roses, and they certainly root more freely than the ordinary hedge Brier. To prune these is a mistake, but they grow so strongly that one may well have to use the knife or bill-hook to keep them within bounds in many instances.

Referring to colour in W. Allen Richardson, remarked upon by "S. W. F.," my own observations all point to cold and changeable weather as the main cause of pale coloured flowers. Apart from this, W. Allen Richardson is naturally a most changeable blossom. It is not difficult to cut a flower that would pass for Lamarque, one even paler yellow, one a deep yolk of egg and orange, and more than one combination of these colours from the same

truss, especially early in the season. Under glass I have seldom had pale blossoms, while a cold season outside almost invariably gives the dingy white and pale lemon colour that has so often disappointed the grower and caused many unjustified complaints, suggesting that the nurseryman had supplied a duplicate, or at least an inferior example of this popular variety. We find this diversity of colour in many Roses, notably Mme. Lambard, with its deep crimson, very pale salmon, and intermediate shades. Even Maréchal Niel sometimes gives us a very pale lemon, quite as much so as many specimens of the so-called White Maréchal Niel which I have seen this spring. The same plant will often throw good blooms of a deep golden yellow, and also of a pure and clear yellow shade, Jean Ducher, Rainbow, Marie Van Houtte, Anna Ollivier, Pride of Reigate, and others also vary very much. "Philomel's" notes upon Rose sports are most interesting, and his timely warning to amateurs as regards the watching and testing of any apparent departure before deciding it is really new is very opportune. Recently I have had a comparatively large number of sports. I have cut several from La France, C. Mernet, Souvenir d'un Ami, and a grand acquisition from Sunset which I am sure will become one of our most popular Roses. This season I cut a bloom of Letty Coles that quite eclipses any other specimen I have hitherto seen of this sport from Mme. Willermoz.

A note in the same issue upon Rosa rugosa Belle Poitevine I can fully confirm. M. Bruant kindly sent me a ground plant of this and his other new rugosa, calocarpa, before they were sent out. Both are beautiful at the time of writing, and have been for several weeks. R. calocarpa is my favourite of the two—a better grower than Belle Poitevine, flowering in immense trusses, a perfect bush of scarlet berries late in the summer. Both last year and 1895-6 this was a grand sight with its deep golden, pale yellow, and crimson-shaded foliage. I was able to cut large sprays long after the majority of our deciduous shrubs were quite bare, and they retained their leaves well when cut. We must feed climbers upon walls, and cut away the bulk of last season's wood that has now gone out of flower. A little judicious use of the knife at this season saves loss of much growth later on. It is healthy rods that flower best later on, and by thinning out the wood now, we ensure good growths with less risk of their forming upon old and badly-placed wood.

RIDGEWOOD.

**Rose Comtesse de Murinais** is a vigorous growing Moss Rose that would make a fine pillar variety. I think these strong growing Mosses should be more often trained in this form, for not only would they give variety to the walks, drives, and wild gardens where these pillar Roses are usually employed, but the style of training is decidedly favourable to a freer production of blossoms. This Rose has fine trusses of white flowers, and the lovely mossy buds are tipped with rosy pink, which form a pretty contrast to the white expanded flowers.—E.

**Rose Kaiserin Augusta Victoria.**—This comparatively new Hybrid Tea is certainly among the best introductions of late years either as a garden Rose or as a show flower. It is also likely to be much prized by growers for market, as it has most of the characteristics required as a sale bloom. It is white, faintly tinted cream colour, and perfect in shape. The flowers are borne on stiff foot-stalks in profusion, and the growth of the plant is excellent; the leaves fine and not so liable to mildew as those of many kinds. I saw a fine lot of plants in pots of this a few days ago, and have at various times noted

it growing well out of doors. All interested may safely add this fine variety to their collections.—H.

**Rose Blanche fleur** (Hybrid Gallica).—It is rather surprising that these white summer-flowering Roses are not more in request. Their earliness commends them to all who have large demands for white flowers, for they come with the Pinks and the Pæonies, and are always welcome. Perhaps one cannot say the above Rose is pure white, there being a distinct shade of flesh colour in the flowers, but for all ordinary purposes it may be used as a white Rose. This variety flowered with me this year quite a week earlier than Mme. Plantier and Mme. Hardy grown under the same conditions.—E.

**Rose Rosomane Alix Huguier.**—At present this novelty has attracted little attention, but I think it deserves notice. It is evidently a seedling from Lady Mary Fitzwilliam, and by many rosarians it might be considered too much like that variety; but let anyone compare the two together, and he will quickly discern a decided difference. The flowers of the Rose under notice have a distinct buff shading, and they are much higher in the centre than those of Lady Mary Fitzwilliam, the reflexed edges of the petals seen in Lady Mary Fitzwilliam giving place to a perfectly pointed, globular-shaped centre in Rosomane A. Huguier. The flowers are of enormous size and have a peculiar appearance upon such a dwarf plant, for, unfortunately, it has inherited its very moderate growth from its parent. I am hopeful this defective habit of growth will be quickly remedied, as we already have instances of improved vigour by hybridisation in the offspring of Lady Mary Fitzwilliam, as evidenced in those superb varieties Souvenir du President Carnot and Antoine Rivière.—W. E.

### ROSES AT PORTSMOUTH.

THE extra early date of the first National Rose Society's exhibition for 1897 had a bad effect upon the number of exhibits at Portsmouth on June 18. In several classes there were no competitors, and in others only one or two. It was the smallest show yet held by this society, and only containing 1660 blooms from some three dozen or so exhibitors. But we saw some good quality both among the Hybrid Perpetuals and Teas. As a proof of the scarcity of good Roses at this early date, such prominent growers as Messrs. Harkness and Sons, E. B. Lindsell, O. G. Orpen, H. Machin, the Rev. Foster-Melliard, and others were absent. Colchester, Oxford, and Torquay provided the best exhibition flowers among trade classes, and there were excellent garden Roses from Bath, Colchester, Cheshunt, Oxford, and Leatherhead.

The medal blooms were Mrs. John Laing and Lady Mary Fitzwilliam among Hybrid Perpetuals and Hybrid Teas, Mme. de Watteville and Comtesse de Nadaillac winning in the Tea and Noisette sections. The chief amateur prize, also the two silver medals, were awarded to Mr. Mease, gardener to Mr. Tate, Leatherhead, for a box of twelve, consisting of Mme. de Watteville, Rubens, Caroline Kuster, Mme. Cusin, Catherine Mernet, Comtesse de Nadaillac, and Souvenir de S. A. Prince (Teas), with Mrs. John Laing, Hippolyte Barreau, La France, and Jeannie Dickson among the H. P.'s and H. Teas.

Some reference must be made to newer varieties. Tom Wood is a grandly formed H. P., of a clear cherry red, and one that retains its freshness and shape for a long time. Mrs. R. G. Sharman-Crawford was staged in splendid form. A pretty pink and salmon sport from S. Marie Rodocanachi was staged in Mr. F. Cant's box of forty-eight varieties. It is a very promising and distinct Rose, but it was the unfortunate cause of Mr. Cant's disqualification, new Roses not being eligible until either properly named or in commerce under a recognised cognomen. A box of Laurence Allen from Messrs. Cooling and Sons, also their new pillar Rose, Purity, were much admired. The former I have described quite

recently, but Purity is newer. This is a pure white when fully opened, of fair size, grand shape, borne in large trusses, and evidently a very free bloomer. H. P. Rev. Allan Cheales, from Messrs. Paul and Son, Cheshunt, is quite distinct in colour, a pretty rosy purple, clear, and well built up, but rather thin in petal as here shown.

By far the best show was made by garden Roses. These were really good, both trade and amateur stands being in grand condition. Among the very best I noticed Ma Capucine, Janet's Pride, Austrian Copper, Maiden's Blush, Polyantha simplex, Rainbow, Lucida plena, Grandiflora, Hebe's Lip, Royal Scarlet, Harrisoni, Crested Cabbage, and Moss Cristata. R.

**Yellow Roses.**—To make yellow Roses deeper in their tint of colour I recently noted a plan new to me. The variety was Perle des Jardins, a Tea-scented kind in great demand in the cut state, the blooms of which were almost white in colour through the heat of the sun under glass. The flowers were cut in the bud state during early morning, placed thickly in bunches in water and put into a dark cellar. By the following evening the change was surprising; and twenty-four hours after they were cut I saw the same blooms in the market quite a deep yellow in tint. They were readily purchased, being considered highly coloured. Whether it would affect all yellow Roses I do not know, Perle des Jardins being exceptional in many ways. It has flowers of rare substance and will put up with sprinkling with impunity. Water will spoil the petals of many Roses with light tints. It appears to be the yellow for market, no other kind seeming to provide such an abundant crop of nicely-formed blooms.—H. S.

**Rosa levigata.**—I notice that on p. 384 the large single white Rose, blooms of which I sent up from Kingswear, has been provided with a name—Rosa levigata. I find in the "Gardener's Dictionary" that Rosa levigata is synonymous with Rosa sinica, which hails from China, and has the date 1759 against it; both seem to have an American name—the Cherokee Rose—applied to them, though why this should be if they have a Chinese origin it is difficult to imagine. R. sinica grows freely on the shores of the Mediterranean, but is, I fancy, from specimens I have seen, smaller both in flower and leaf than the South Devon specimen now under notice. Perhaps, however, those who have a greater experience of R. sinica have seen flowers of that variety 5 inches in diameter. I hope next year to be able to compare a R. sinica brought from Mentone and now growing at Torquay with the Kingswear R. levigata, which was sent to England from Abbotabad, in N.W. India. On further examination of the foliage of R. gigantea, I detect a difference to that of R. levigata.—S. W. F., Torquay.

**Roses with coloured foliage.**—Not the least of the many charms of the Tea-scented, China and kindred classes, especially of modern varieties, is centred in their matchless ruby and bronze foliage. One could truly say that the young growths of all Roses are beautiful, but the classes named excel all others in this quality. Even among the Teas and allied classes some varieties are more richly coloured than others, and their effectiveness might be serviceably employed to produce during the summer, in conspicuous positions, a mass of rich foliage in addition to their beautiful flowers. The following varieties are more or less conspicuous for their grand foliage: *Chinas*: Cramoisi Supérieur, Fabvier, Queen Mab, Mme. L. Messimy, Mme. Eugène Resal. *Teas*: Sunset, Perle des Jardins, Devoniensis, Perle de Fen, Beauté Inconstante, Duchesse d'Auerstadt, Mme. Berard, Waltham Climber No. 3, Sylph, Bouquet d'Or, Souvenir de Mme. Sablayrolles, Souvenir de Catherine Guillot. *Hybrid Teas*: Captain Christy, Bardou Job, Grace Darling, Belle Siebrecht, Cheshunt Hybrid, Mme. Jos. Combet, La Fraicheur, Gloire Lyonnaise. *Noisettes*: Fellenberg, Mme. Pierre Cochet, Réve d'Or. *Hybrid Perpetuals*: General Baron Berge,

Lord Bacon, Grand Mogul, Empereur de Maroc. *Hybrid Chinese*: Blairi No. 2. *Scampervirens*: Flora. *Hybrid Ayrshire*: Mme. Vivand Morel. *Microphylla*: Ma Surprise. *Boursault*: Gracilis. *Bourbon*: M. A. Maillé, Souvenir de Lieutenant Bujon, Gloire des Rosomanes, Sir Jos. Paxton, Rosa Brunoni, R. rubrifolia.

**Colour in Rose William Allan Richardson.**—Much has been written of late concerning the varying colour of this favourite Rose. When first sent out many had the impression that it was delicate and required a wall. This, however, was a delusion, as it thrives in many cold and exposed situations. What it likes is a free and unrestricted growth, resenting severe pruning; and my experience is that trees on walls that are annually spurred back somewhat rigidly, in order to keep them within bounds, produce not only the fewest, but the most inferior coloured blooms. Grown on its own roots, planted where it has an opportunity of rambling, and no further pruning done than the unripe tips of the growths shortened and weak shoots removed, together with what old wood can be spared, is the way to get the best results, the long one-year-old arched growths being literally covered with good-sized blooms of the deepest orange. It seems to enjoy a good holding loam.—GROWER.

—I have read "S. W. F.'s" note in THE GARDEN (June 26) on "Lack of Colour in W. A. Richardson Rose," and beg to say that one of my neighbours has this Rose in full bloom, all the flowers in beautiful colour, except those about to drop. The flowers remind me of those of a Rose I saw in the south of the United States; the grower did not know the name, but because of its rich colour it was called the Brown Rose. The flowers differed from those of W. A. Richardson in being very dark on the outside, brown, tinged slightly with red, and lighter inside. I sent cuttings of it to my garden (we then lived at Newport, Rhode Island, U.S.A.). The flowers were beautiful for a year or two, and then lost their colour.—M. CROFT, South Park, Wadhurst, Sussex.

#### NEW ROSES AT THE CRYSTAL PALACE.

THE number and quality of the new Roses at this meeting of the National Rose Society were so marked, that a note on a few of the best, for the benefit of those unable to attend, may be valuable. Limiting myself to twelve—the six best already in commerce and the six which had the most promising appearance among those shown for the first time—I must commence with

**MURIEL GRAHAME**, a grand sport from Catherine Mermet, which has already given us The Bride, Waban, and Bridesmaid. Muriel Grahame won one of the silver medals, that for the best Tea or Noisette throughout the whole show in amateurs' classes. It would have done the same even if the many trade collections had been included. In every way it is a grand example of a creamy blush form of Catherine Mermet. At first it did not come sufficiently full with many to be of great promise, but no one could find any fault with the magnificent flower staged in Mr. E. B. Lindsell's champion trophy stand.

**MAMAN COCHET** is another Tea, and I believe, the only seedling from Catherine Mermet. It is of grand size and form, a capital grower and free bloomer, quite unique in its deep salmon and coppery-peach shadings.

**MRS. W. J. GRANT** has often been described, but now that much of the weakness from excessive propagation has departed, we are seeing it in that beautiful form possessed by one bloom at Chester in 1892. A freer bloomer we do not possess, while every bud is useful from the very earliest stages. The colour is a deep pink, buds long, and blooms well formed.

**MRS. RUMSEY** is one of our best late pink Roses. It is absolutely mildew-proof so far as I have grown and seen it. The presence of deep green foliage free from this disfiguring disease is a great desideratum towards the end of the sea-

son, and it is then that this Rose is in much better form than when staged at the Crystal Palace.

**TOM WOOD** is perfect in shape, size, and habit of growth. The flower lasts a long time and retains its deep cherry-red colour well.

**HELEN KELLER** is a thoroughly reliable exhibition Rose, and is also a grand variety in the garden. It is a clear rosy cerise.

Of Roses not yet in commerce, a Hybrid Perpetual named

**ULSTER** won the much-coveted gold medal. This is a vigorous grower, with smooth wood, and evidently a very prolific bloomer. There is much of the deep salmony-pink found in a bright Caroline Testout, with a distinct edging of silvery pink. Substance and form are really excellent, and if it will open well we have a grand addition to salmon-pinks.

**KILLARNEY** appears to be a Hybrid Tea. To my mind it was better, more distinct and taking than Ulster, but it was not staged for the medal, and no ground plant was exhibited. I understood Mr. Dickson, Jun., to say it was a promising Rose, of good habit and free-blooming. It is certainly a most fascinating shade of salmony-peach, with clear silvery edges, of grand form, good size and substance.

**BESSIE BROWN** is a pale salmon and cream, a most promising Rose in every way.

**MRS. GRAHAME** also promises well. It is a flower with much the same form and shades of colour as might be imagined from a combination of Mme. Bravy and K. A. Victoria. These four came from Messrs. Dickson, Newtownards, who are evidently likely to outdo all other growers in the matter of new introductions.

**MRS. F. CANT** is a very pale coloured form of Gabriel Luizet. It seems distinct, and was well shown among new Roses and as twelve of any one variety. The growth is shorter than in G. Luizet and rather more robust.

**R. B. CATER**, from Messrs. Cooling and Sons, Bath, has much of the rosy-cerise found in Helen Keller, is of more cupped form, distinct in growth, and a very promising new Rose.

If I mention Golden Gate, Mrs. Mawley, Rev. Allan Cheales, Countess of Caledon, Lady Clanmorris, Daisy, Sylph, Eileen, First Cross, Antoine Rivoire, Laurence Allen, Bladud, Captain Hayward (good), Clio, Mrs. W. C. Whitney, Comtesse Dusy, and T. B. Hayward, I think the pick of new Roses as seen at the Crystal Palace are included. RIDGEWOOD.

**Rose Baroness Rothschild.**—This delicately coloured pink Rose still remains a great favourite amongst all classes, and no wonder. In symmetry it far outstrips the well-known La France, which must be caught in the half-expanded bud stage to be presentable, especially if the blooms are wanted for exhibition. The Baroness is of sturdy growth and soon makes large bushes if mulched and liberally fed. La France stands an exposed situation as well as any Rose I know, and this fact is a strong recommendation. I have it in an eastern flower garden fully exposed to every gale, and in vigour of growth and the way in which it survives severe winters it surpasses the generality of Hybrid Perpetuals growing in the same position.—GROWER.

**Rose S. M. Rodocanachi.**—This splendid Rose should be in every collection, being a hardy, robust, and exceedingly free bloomer. The trusses—for it rarely throws solitary flowers—are borne on extra stout growths, five or six grand half-expanded buds being often obtainable on one shoot. I can confidently recommend this Rose for planting in light shallow soils on account of its vigorous habit of growth, which withstands drought well. On account of its clustering habit of flowering it may not be so useful for cutting or exhibition, as the use of the knife means a sacrifice of numerous smaller buds; but for making a brave show in bed or border few can beat it.—GROWER.

—This is a superb variety, and the exhibitor should take care that a goodly number of plants

is grown, as it is a good reliable kind. It was well exhibited last week at the Drill Hall, and also at the Crystal Palace. Both the fine globular form with the showy guard petals and the charming and lively rose colour are very attractive. I cannot altogether recommend it for garden decoration. It has the fault of Marie Baumann in hanging its head and thus hiding its beauty from view.—P.

**Rosa alpina and its variety R. a. pyrenaica** both form pretty masses of colour in the rock garden, where they may be used as a sort of background. Smaller and younger plants may be used in the fissures of the rock, where they may rest their heads on a projecting ledge of stone. By confining the plants to pots it is possible to keep them quite dwarf for some years, and even in this way they are pretty, with their solitary blossoms of rosy pink.

**Rose Robusta** (Bourbon).—One often bears expressions of regret that Crinon Rambler is not autumn flowering. The above Rose supplies the long-felt want of a grand vivid crimson autumnal variety. It is exceptionally vigorous and will make enormous shoots 7 feet to 8 feet long each season. The colour is as rich and velvety as in Duke of Edinburgh, and the flowers, if not so large, are nevertheless most abundantly produced. The reddish wood and leaf-stalks are also very beautiful. I can highly recommend it as a pillar or climbing Rose.—P.

**Roses Hebe's Lip and Reine Blanche.**—These two Roses appear to be identical. I believe the latter was sent out as an improvement on the former, but I have them almost close to each other and I can discern no difference whatever in the two kinds. Hebe's Lip is a delightful Rose, and is evidently closely allied to the Damasks. It is single, or perhaps one should call it semi-double, as there are two rows of petals. These petals are ivory white, but the great attraction is the beautiful carmine edging which is seen upon the outer and sometimes upon the inner row. It is a strong growing variety, with dull green foliage and very prickly wood. The flowers are produced in clusters of five and six.—P.

**Seedling Roses.**—It was the general opinion of those who saw at the Drill Hall the collection of seedling Roses from Lord Penzance that he was making very slow progress towards enriching our collections with good permanent varieties. Although some of the kinds put up were very pleasing in colour, the only conclusion I could come to was that he was only reproducing varieties and forms which have appeared and been discarded long ago. I am confident that if Lord Penzance would work upon these seedlings with their hybrid nature, in two or three generations some good enduring varieties would be the result, instead of our already extensive collections being burdened with worthless kinds, such as some of those which have already appeared.—P.

**Rose Medea.**—This grand Tea Rose has been seen very fine this season, and it is gradually taking its place among the leading exhibition Teas. Both at the Drill Hall and also at the Crystal Palace last week Mr. Orpen, of Colchester, put up some fine specimens that recalled in the beautiful colour and substantial flower that almost forgotten Rose (loth of Gold. The growth of Medea is not climbing, but it is very vigorous, after the style of Marie Van Houtte, and as it is such a very full flower, doubtless a low wall would be the best position in which to grow it. At the Temple show the raisers—Messrs. W. Paul and Son, of Waltham Cross—exhibited some very fine flowers growing on standards, proving it to be a valuable kind for greenhouse culture.—P.

#### SHORT NOTES—ROSES.

**Rose Jean Cherpin.**—Purple Roses are generally disliked, and perhaps when dying off the blossoms are not very beautiful, but I think that no one would object to the lovely buds of this Rose which are so freely produced. It is a splendid variety to

grow to furnish large supplies of eut flowers, and when judiciously intermingled with pinks, whites, and crimsons, the colour is not at all objectionable.—P.

**Rose Abel Carriere.**—This is one of the most reliable of the very dark Roses. It is certainly far superior to such kinds as Jean Liabaud and Baron de Bonstettin, which yield a good flower very rarely. The splendid colour of Abel Carriere is always welcome in a collection, the rich velvety maroon contrasting well with paler tints. It is a good grower and the form of flower excellent; in fact, I consider it the best all-round dark Rose we possess.—E.

**Roses Marquise de Salisbury and Camoens** as standards.—Probably one could not select two more effective Roses to grow in standard or half-standard form than the kinds named above. They appear to vie with the Monthly Roses for continuous blooming. A grand display would be ensured if these two varieties were extensively planted either in conjunction or separately. The vivid crimson of Marquise de Salisbury would at all times serve to enhance the lovely pink of Camoens.

**Rose Thomas Mills** is a brilliant crimson, vigorous growing Rose. Its form is perfect, and

the Drill Hall, is a near ally of the Weigelas; indeed, by our botanical authorities the genus Weigela is now absorbed into that of Diervilla. The Weigelas, however, as represented by the old-world species and the innumerable hybrids raised therefrom, will in most cases retain the name that they have so long been known by, and under which they have attained the great popularity that they bear at the present day. The plants to which the name of Diervilla has always been applied are *D. canadensis* and *D. sessilifolia*, both natives of North America. The older of the two, *D. canadensis*—which is also known by the specific name of *trifida*—was introduced as long ago as 1739. It forms a somewhat spreading bush a yard or more high, with Weigela-like foliage and small yellow blossoms, which are borne during June and July. *D. sessilifolia*, which is a native of Carolina and Tennessee, is decidedly more ornamental than the other, the leaves being larger and more pointed, and when first expanded they are yellowish, but when mature become somewhat flushed with red when in full sunshine.

*Pentstemon Scouleri* in the rock garden at Abbotsbury. From a photograph sent by Messrs. R. Veitch and Son, Exeter. (See p. 38.)

although it is generally deficient in fulness, it may nevertheless often be found in exhibition boxes. This variety is by no means a shy bloomer, but I would recommend that at pruning time the growths should be left fairly long. It would be a fine kind for a pillar Rose or as a standard.—E.

**Rose Magdeleine de Chatellier** is a fine addition to the popular Polyantha class. It is quite distinct from Perle d'Or and Etoile d'Or. The colour is saffron-yellow, shaded with rosy buff, and the charming little buds expand to beautiful imbricated flowers that are highly attractive. Provided the colours are distinct and their Lilliputian character is retained, one cannot well have too many of these pretty little Roses, so useful are they.—E.

**Diervilla sessilifolia.**—This interesting but uncommon shrub, which was recently shown at

The flowers are yellow, and borne for some time during the summer months. Not only is this shrub well worth growing for its own sake, but in conjunction with the garden varieties of Weigela it may in the hybridist's hands give us some distinct forms.—T.

**Halimodendron argenteum.**—By July a great many of our flowering shrubs are past, but among those still in bloom the above-mentioned Halimodendron, known also as the Siberian Salt Tree, merits recognition, for it is decidedly ornamental, and quite distinct from anything else in flower. It forms a freely-branched bush, 6 feet or so in height, whose slender shoots are clothed with silvery-grey leaves, which impart to it quite an uncommon appearance. The pea-shaped blossoms, which are of a rosy-purple colour, are borne for some distance along the slender arching shoots, and a succession is kept up for some time. This Halimodendron is perfectly hardy, will hold

its own better than many other shrubs in hot sandy soils, while it vies with the Tamarisk in its ability to withstand the salt spray in the immediate vicinity of the sea. It is an old inhabitant of our gardens, but one rarely seen, though far more worthy of a place than many subjects which are generally planted. The silvery character of its foliage is more pronounced when exposed to full sunshine than if the plant is in a partially shaded position.

GARDEN FLORA.

PLATE 1127.

HYBRID CINERARIAS.

(WITH A COLOURED PLATE.\*)

THE accompanying plate represents three of the colour forms obtained in the Botanic Gardens, Cambridge, by crossing *Senecio multiflorus* (female) with the well-known florist's *Cineraria*. They were selected by the artist as the most beautiful from about half a dozen, all of which fairly repeat the colour of the pollen parent used in each particular case. The colours of the *Cineraria* have been so transmitted that white centres are perfectly pure and not in the least affected by the rosy-lilac of the female parent, while the selfs of blue, purple and maroon are bright and clear, though with brilliancy toned down to some extent. It appears, indeed, that the *Cineraria* always carries a strong influence in colour and size whatever the other parent may be, and whether used as male or female. The plants of this cross reversed were also very beautiful, but the habit was not so good and the general result less satisfactory from a decorative point of view. To the artistic eye, and in the opinion of all who are not enamoured of the florist's ideal, the hybrids depicted in this plate are far more beautiful than the garden *Cineraria*, having a lightness and grace of habit which do not belong to the latter, while possessing at the same time an equal beauty of colour. The graceful sprays are very suitable for cutting and look extremely well in water. They have conveniently long stems, and are elegant because all the flower-heads have sufficient space to be seen properly, which in the dense head of an ordinary *Cineraria* is hardly the case. In these hybrids the advantage is gained of a greatly extended flowering season. The plants may be cut back or the first branches of the inflorescence may naturally exhaust themselves, when below new growths appear and produce a fresh crop of flowers. Although the garden *Cineraria* does this to some extent, the habit is much stronger in *Senecio multiflorus*, and from this species it has been transmitted to the hybrids. In general habit the plants are very nearly intermediate, but much depends on culture, for small useful plants may be obtained in 6-inch pots, or they may be grown to be quite 3 feet high. All grow very freely, and, though quite as liable to greenfly as the *Cineraria*, may be regarded as less exacting in general treatment. They appear to have gained by the constitution of the female parent. In comparison with many plants these hybrids are shy seeders, but there will be no difficulty in the hands of those who seed the *Cineraria*. A selection of these hybrids was exhibited at the Drill Hall in January, and though all were much admired, the rosy form (most fully represented in the plate) was generally considered the best. The plants commenced to bloom some time before Christmas,

and some of the same batch are still in flower at the end of June. For purposes of identification it may be said that these hybrids are called *Cineraria Lynchei* by Mr. Watson in the *Garden and Forest* of February last.

Other species besides *S. multiflorus* with which the *Cineraria* has been hybridised in the Cambridge Botanic Gardens are *Senecio Heritieri* (female) and *S. eruentus* (male). A plant of the first has been exceedingly charming, producing on many stems with small leaves a number of large pure white flowers. Of the second cross were many beautiful plants, and one in particular, quite different from all the others, made a magnificent object. Below was a conical mass of large densely-set leaves, and above a

*Senecio multiflorus* x Garden *Cineraria*. Height of plant above pot, 2 feet 6 inches. From a photograph sent by Mr. R. I. Lynch, Botanic Gardens, Cambridge.

panicle of large maroon-coloured flowers about 2½ feet across, the entire plant being not quite 3 feet high.

R. IRWIN LYNCH.

Botanic Gardens, Cambridge.

**Veronica lycopodioides.**—This minute shrub of 3 inches to 4 inches is flowering fairly well this summer on the older and more exposed specimens. The form and pose of the flowers are pretty but common in the better-known dwarf shrubby species, but the peculiar foliage as implied by the specific name lends itself as a foil to the flowers in such a manner that the specimens are distinctly attractive. As a rock garden subject this is decidedly first-rate.—J. W.

THE WEEK'S WORK.

HARDY FRUIT GARDEN.

**PEACHES AND NECTARINES.** Since last writing about these, the trees have made excellent growth, and they are also keeping clean. As it is important in outdoor Peach culture to have the wood well ripened, the young shoots must be kept well fastened back to the walls. While this is being performed, attention should be directed to the stopping of lateral shoots, also to see that none of the fruits are likely to be injured through being in too close proximity to wall nails or wires, cutting away any ties which are already beginning to encircle branches too tightly. The crop, where necessary, should be finally thinned, and

wash the trees as often as circumstances will allow to keep the foliage clear of red spider. The latter pest is more to be dreaded than aphid after this time of the year, and once it gains a good hold on a tree it is almost impossible to eradicate it; hence the wisdom of giving the trees a daily wash, for they cannot endure cold water. Border waterings will entirely depend on the amount of rainfall and the nature of the soil in each locality. When needed, give sufficient to soak the border throughout, and assist all well-cropped trees with a stimulant either in the form of liquid or an artificial manure. Barren trees should not have too much moisture supplied to the roots, and so long as they keep clean and free from spider withhold the water-pot or hose as the case may be. Give young trees every attention in the way of pinching back the strong shoots to equalise growth, and train and tack in the remainder. If any of these are newly planted, see that they do not want for water at the roots.

**APRICOTS.**—These, like the foregoing, are making free growth and stand in need of another look over, as the breastwood and laterals will soon run away with the nourishment needed for the support of the fruits, which are now taking their final swelling. The tree should therefore be closely stopped, and the young wood

previously laid in must have further support in the shape of nails and shreds to prevent it from hanging loose and presenting an untidy appearance. Now that the fruits are swelling fast see that the trees do not want for moisture at the roots, as if the borders are well drained it is almost impossible to overwater Apricots. It is this deficiency of root moisture which causes so many fruits to be mealy or, at any rate, deficient of juice when ripe. When once the final swelling commences water is needed in ample quantities, unless the rainfall should prove sufficient—which is seldom the case with me—to enable the trees to lay on plenty of pulp. Follow up the daily washing of the trees, if only to keep woodlice from effecting a lodgment in old walls, as these soon spoil the best fruits and

\* Drawn for THE GARDEN by H. G. Moon in the Botanic Gardens, Cambridge. Lithographed and printed by J. L. Goffart.

those nestling close to the wall if left unmolested. Some growers move the leaves on one side to expose the fruits when they commence to ripen, but it is a practice I cannot recommend, as it leads to the portion of the fruit facing outwards becoming ripe in advance of the base. I always find that the fruits ripen more regularly and thoroughly when slightly shaded by the foliage, and have discontinued exposing them to the sun for some years past. Renew the mulch on the border if necessary, as we may yet have more hot, parching weather to contend with. Young trees in full growth and devoid of fruit must not be given stimulants, which older trees require, and, if growth is inclined to be rank, give no more water at the roots than is necessary to keep them in a healthy condition.

**WALL PEARS.**—Where the stopping of these has been delayed no time should be lost in getting it done, and if the trees have made an excessive amount of growth, and disbudbing has been neglected, twist or pull out the surplus shoots at the base. This enables weak and watery shoots being got rid of, to the benefit of those retained. These latter, with the exception of leaders at the ends of branches in fan and diagonally-trained trees, should be stopped back to four buds. In the case of cordons the same amount of stopping is required, leaving the leaders full length if the trees are young and have not filled their allotted space. The majority of the trees are carrying good crops here. It is surprising how quickly Pears develop and to what a size they attain when fed with superphosphate of lime and muriate of potash, and there are no other manures that I am acquainted with which have such a marked effect when judiciously applied. Heavily-laden trees should be thinned, although if there are any doubts in the matter it would be better to wait another week or so; but, generally speaking, the best and most healthy-looking fruits can be quickly discovered after the month of June is past. Should hot, dry weather set in, renew the mulch, and keep the roots of the trees moist by watering when necessary.

**PLUMS ON WALLS.**—In many places the crops, it is to be feared, will be short, and in some instances *nil*. Where this is the case the trees must be judiciously handled, otherwise they will make rank growth, which, if continued late in the season, will lead to the trees being unfruitful another season in consequence of the wood being unripened. Stimulants should, therefore, be withheld, and no water given at the roots unless absolutely necessary. The trees themselves must, however, be kept clean, and after stopping the spur wood and tacking or tying in that required for furnishing, give them a thorough washing, and follow it up as often as time will permit. Trees which are bearing must be well fed to enable them to carry as heavy a crop as possible, but if the fruits are too close together a little thinning will be beneficial. Look well after young cordon trees and stop all side growths. This is an excellent way of growing the choice dessert varieties, and it is also a quick method of covering walls and any odd corner on wall buttresses. Nearly all varieties succeed grown in this way, the only exception, so far as I know, being Victoria, which gives but poor returns.

**BUSH MORELOS.**—These are, as usual, carrying heavy crops of fruit, and the trees have made good growth. The points of the shoots should now be pinched out, and where there is an excess of these, a slight thinning may be done. This will obviate the necessity for any winter-pruning. That other fine cooking Cherry, Kentish Red, should also be treated in like manner.

**APPLES AND PEARS.**—These, whether grown as bushes or pyramids, should be summer-pruned. It is many years since the trees made so much growth as they have done this season, and it is healthy and clean. The stopping in this case amounts to the cutting back of the young shoots on the spurs on the main branches to from four to five leaves, and in leaving the leading shoots at the extremities one-third, one-half, or two-thirds

their length, according to the age or the amount of space the trees have to fill. This will allow light and air to penetrate all parts of the trees and aid in the ripening of wood and buds for another season. Heavy crops of Apples will be the exception more than the rule, but still there should be no hesitation about thinning in the case of trees which are heavily laden.

**CORDON GOOSEBERRIES.**—Young trees planted last winter should have the leading shoot tied to the wires, or be fastened back to the wall, and stop in the side growths to two or three buds. Established trees should also be stopped in, only in their case leave from four to five buds.

A. W.

#### KITCHEN GARDEN.

**CABBAGE.**—We have arrived at the time when the first sowing of spring Cabbage should be made. It is a mistake to suppose that one sowing, and at a fixed date, is always going to prove satisfactory, as the plants are apt to suffer from a variety of causes, while, owing to the seasons varying, the plants may be too forward in one instance to withstand a severe winter, and in another so backward that they do not become thoroughly established before bad weather sets in. There is also a risk of losing many of the plants through the attacks of slugs and other pests. To ensure a good supply of first-class heads at a season when they are most appreciated, viz., from early spring until Asparagus and other choice vegetables become plentiful, three sowings at least should be made at intervals of about ten days or a fortnight. Allow plenty of space in forming the beds, so that the seed may be sown thinly, which will enable the seedlings to make sturdy growth, so that they can be planted direct into their permanent quarters without the extra trouble of pricking them off into nursery beds. No crop repays better for generous treatment in the way of well-cultivated soil than this, and to ensure vigorous plants from the first, the seed-bed should be selected in an open position, and if the ground be poor or exhausted by a previous crop, a dressing of thoroughly decayed manure, or, what is preferable, a dressing from a spent Mushroom bed, should be afforded and forked in rather deeply. After the ground has settled, the first sowing should be made broadcast, well covering the seed with fine soil from the frame-yard; the next sowing may be made in a similar way, but I prefer to raise the last batch of plants in drills, as many of these will remain undisturbed through the winter and prove valuable for planting out in the spring. As these seeds have to be sown when the ground is generally in a parched condition, frequent watering is not only necessary to assist the seed to germinate quickly, but also to sustain the young plants until they become well established. Net the beds over to prevent birds doing any damage, and thus save loss of time and plants. A slight dusting of slaked lime will ward off slugs and other vermin. As regards varieties, most growers rely on those which have proved suitable to their climate, but there are few gardens now where Ellam's Early does not find a place. At least three varieties should be sown, which will not only allow of a good selection being made, but there is the advantage of a succession of young tender heads being maintained, which is a great point to study with this crop, as they soon lose flavour when they become large and coarse.

**CELERY.**—More trenches should be made as soon as ground becomes available, so that the late batch of plants can be got in before they become too large. The weather of late has been favourable for those that have been recently planted, as well as causing the earliest plants to make rapid growth. Continue to draw a little fresh soil round the plants as they require it, which is better than banking them up with a great quantity at one time. After the desired number of plants has been put out, those that remain in the nursery beds should be watered and in other ways encouraged to grow freely, as these

will prove valuable for the kitchen and save digging from the trenches.

**SALADS.**—Continue to sow Lettuce seed about every ten days. With the exception of the earliest lot of plants, I have not transplanted any of these this season, as by sowing the seed broadcast and thinly, this extra labour is dispensed with, the plants receive no check from transplanting, and they turn in quicker. The site selected should be one where the plants do not receive the full force of the sun at mid-day, and they will last longer in a serviceable condition. Radishes, Endive and Mustard and Cress should also be sown at short intervals, as these are always more appreciated when used in a fresh young state.

**MISCELLANEOUS.**—Many of the early crops, such as Peas, &c., will now be over, and all remains of these and other things should be cleared off the ground as soon as possible, thus preserving a tidy appearance in the garden and the land from unnecessary impoverishment. Take the earliest opportunity also to manure, and get the same in a suitable condition to receive succeeding crops.

R. PARKER.

#### KITCHEN GARDEN.

##### GOOD AUTUMN LETTUCE.

FOR many years I relied upon All the Year Round for autumn sowing, but it is not always reliable, and few varieties will compare with the Hammersmith Hardy Green for August sowing to stand over the winter and furnish an early spring supply. I am aware even the Hammersmith is not hardy in our erratic climate. I have lost quite as many plants from continual rains, but the severe east wind after frost withers up the tender leaves, and the plants collapse. Few things are more appreciated in March and April than early Lettuce, and to obtain these one must not be niggardly in sowing in the early autumn. I am aware there are other kinds equally as hardy as the one named. A favourite Lettuce of late years with me has been Lee's Immense Hardy Green; I think the term "Immense" may be left out. It is an excellent variety, as hardy as the Hammersmith Hardy Green, growing freely in well-drained soil, turning in quickly in the spring, and of good quality. Another very fine type of autumn Lettuce is Stanstead Park. This is quite distinct from those named above, and excellent for autumn sowing. It is very hardy and a rapid grower in the early spring—indeed, earlier than Lee's Hardy Green—of compact habit and a beautiful light-green colour. Of Cos varieties the Hardy Bath or Brown Sugar-loaf is difficult to beat, and one of the best for winter and spring supplies of Lettuce. It follows the Cabbage varieties, and may be sown in August, as large plants do not winter well. A new variety I tried last season proved an excellent winter and spring Lettuce. This is a small kind—Sutton's Intermediate, a cross between a Cabbage and Cos, more upright in growth than the Cabbage, but hardier and earlier than the true Cos. The plants have scarcely any leg or stem, being close to the soil. It resembles in colour the old Bath Cos, but is quite distinct, being much smaller. Winter Green is also good, hardy, and distinct. I have less liking for Cos Lettuce for spring use than Cabbage Lettuce, as earliness is essential. An Early Cabbage Lettuce sown in February is nearly as early as the autumn-sown Cos; on the other hand many prefer Cos. It is useless to sow for spring supplies in places where slugs or snails abound, as these pests soon clear a quarter, and I prefer an open bed to that on a south or warm border, as the plants are more hardy and less

njured by cold. A well-drained soil is a necessity for the plants, and thin sowing is needed to give the seedlings room to grow. I find raised beds in an open exposed quarter give the best plants for early spring planting. I am aware the plants are much earlier when planted out in autumn, but owing to losses I do not advise planting largely. I have obtained early produce by sowing thinly in rows on a south border and not transplanting. I prefer to sow broadcast in beds when quantities are needed in spring, transplanting at the end of February or early in March to warm borders.  
G.W.S.

**Gradus Pea.**—I trust I made it clear in referring to Gradus Pea that my experience of it was in a very exposed place, out in a large field and under field culture. At Richmond, where the soil and situation both are warmer, it has done better, but still in neither case is it so good a cropper as Ameer, which is at the most but two days later. As an early warm border Pea there can be no doubt that Gradus is a valuable requisition. Even for that purpose, however, I should like it better were it shorter-jointed. At Richmond still under field culture I have found Bountiful, A 1, and Empress of India to be all capital first earlys, about 3 feet in height, and good croppers; indeed, it is now absurd to sow labourless round earlys.—A. D.

**Very dwarf Peas.**—How very popular American Wonder still is with many persons for first early sowing in rows at 20 inches apart. It necessitates no expenditure of money and labour in staking, gives really good gatherings of pods, and can be if needed intercropped ere finally cleared off. William Hurst and Chelsea Gem sown in rows 2 feet apart are even better and more productive. Then also at 2 feet come Daisy and Dwarf Defiance, both really first-rate dwarf Peas, cropping wonderfully. English Wonder has smaller pods, and may be sown even rather closer, but the crop and quality are first-rate. I find this Pea also in commerce as Witham Wonder. A fine podding Pea of this section is Early Dwarf Marrowfat, and there is no better late dwarf than Omega. Those who grow these short varieties will find they get as fine Pea quality from them as from the tallest.—A. D.

**Young Carrots for winter.**—There is no difficulty in having a good supply of Carrots in winter, but my note refers to young roots. Now is the time to sow for winter supplies, and the best varieties are the stump-rooted kinds, those one usually sows in the early spring, such as Early Nantes, Early Gem, or a Short Horn. These should be sown thinly in well-manured soil, and should the weather be dry it is well to water to assist the seed to germinate freely. With winter Carrots one must guard against slugs, wireworm, and other pests. The wireworm is one of the worst, and it is well to dress the land before digging with lime and soot, and in soils with a tendency to wireworm gas-lime should be employed. Wood ashes is a splendid fertiliser if this can be used in quantity, and in heavy clay soils the addition of road scrapings, old mortar rubble, or spent manure is of great value. There need be no fear of the crop failing. Carrots are quite hardy, and they are much sweeter when drawn fresh.—G. WYTHES.

**Pea Early Morn.**—I have this season given the above new Pea a trial forced under glass, and as a first early in the open, and consider it a very superior variety, a grand cropper, with splendid flavour. I am obliged to grow early Peas in quantity, and I note "J. C.'s" remarks at p. 4, and would ask him to give this a trial. I feel sure he will place it equal with the one he notes. I find it superior, having a larger pod and being a very heavy cropper. The pod is much larger than that of Springtide, in fact it more resembles the Stratagem type than any I know. Though it is large it is very early. The true Stratagem is not early, in fact more a mid-season variety, and not

adapted for early sowing in cold heavy soils, whereas Early Morn with me germinated freely sown early in February, and was fit to gather the second week in June. These remarks apply to the open-ground crop; those raised in pots were planted out in March, the Peas being fit for use the last week in May. Early Morn grows 2½ feet high. The pods had eight to ten Peas in a pod and of splendid flavour.—G. WYTHES.

**New Peas.**—The fruit and vegetable committee of the Royal Horticultural Society did well at the conclusion of their Pea inspection last year to request that such standard varieties as Chelsea Gem, Duke of Albany, Sharpe's Queen, William I., Autocrat, and No Plus Ultra be grown this year to furnish fair objects of comparison with new varieties. Hence when a meeting of that body was held at Chiswick on the 1st inst., out of some fifty varieties examined the lowest award was given to three varieties, Saccharine, a 4-foot Pea having a fair crop of long green pods; Harbinger, 4 feet, good crop of short pods, an early variety; and to Parchment, one of the French sugar Peas for cooking whole. Something of a really remarkable character is now needed in Peas to command any high award. In what direction it is to be looked for it is difficult to say; crops seem to be now all that are possible, flavour is relatively good too in the best, though not all that can be desired generally. Colour, too, is good, whilst we have all heights. Anyone familiar with Peas knows that average excellence being so good it is very hard indeed to beat it. It is a question whether those who have secured a score or so of the very best varieties now in commerce will not render horticulture more service by constant hard selection of the best forms in each case for seeding, and thus practically improve existing stocks, rather than to waste effort over the raising by intercrossing of new varieties, nine-tenths of which are no better, and many are worse than existing best sorts.—A. D.

#### MANURING ASPARAGUS.

From the end of June till the end of August is, I find, the best time to give manures to Asparagus beds. I have great faith in liquid manure from stables or cowsheds. This given freely is invaluable whilst the crowns are being formed for next season's crop. I am aware many growers prefer fertilisers, but, unless copious supplies of water are given at the same time, it is useless to give dry food which the roots cannot get hold of. Another point deserving of attention is to feed when growth is most active. I am not adverse to manures earlier, say from the beginning of May, if not given to excess; indeed, in light soils there is no better time to apply salt than May and June, if given in showery weather, but it is most injurious given in the late autumn, as I fail to see what good it can do when top growth has ceased and in a measure the plants are at rest. Many good roots in heavy clay soils have been killed by salt dressings in the autumn, also by heavy coatings of manure. If beds could be regularly irrigated from now to the end of August, especially when there are wide alleys between the plants, and the soil gravel, such irrigation would do so much good that manures at other times would be little needed. The best Asparagus I ever grew was on beds on the flat. These I flooded with liquid manure; during growth, no food of any kind was needed. By this system I could cut Asparagus much later; indeed, a few beds were cut well into August, and there was no lack of grass as long as I irrigated freely. I am aware at certain seasons one has a difficulty in finding labour to give all things the proper attention. Fertilisers are so soon applied that they have become fashionable, but I have more faith in abundance of liquid food if it can be obtained and labour found to apply it. There is no better food for Asparagus, and given at the right moment it is soon absorbed and builds up strong crowns, with a strong top growth. It must not be thought I do not value artificial manures. These are most valuable used

as I advise above when the plant is in full growth. Many cannot obtain liquid manure, and the fertilisers are of great value. One I have found excellent is fish manure and soot well watered in. Near dwellings fish manure is objectionable when left on the surface, but when mixed with soot and watered in the strong smell is soon lost. Sulphate of potash mixed in equal quantity with guano is an excellent food. Nitrate of potash given in a soluble state is a quick acting fertiliser, and given as a top-dressing is best applied in showery weather.  
G. WYTHES.

**Potato Sharpe's Victor.**—The discussion on early Potatoes, and Sharpe's Victor in particular, proves that this variety is falling into disfavour. Opinions as to its merits have been divided from the first, and I may say that with me it never was worthy of a place, though I grew a limited quantity of it for some years, but eventually discarded it entirely. The soil on which it was grown is light and sandy, and usually produces Potatoes of high quality, but Victor never would pass as a good variety, either in texture, flavour or colour. The stock was certainly true, so the failure could not be attributed to the reason suggested by "S. H." (p. 4). Some of the newer early Potatoes are proving so good and so productive with me that it seems probable that the older Ashleaf varieties will follow Victor on the discarded list. My first and best early this year was Duke of York, a little-known variety that was first distributed, I believe, by a Norwich firm. This has been in all respects excellent and the crop was enormous. It is a most precocious variety in the way of making shoots in the store room, and it seems difficult to keep it back by any ordinary means. So the coolest storage should be given, or the sprouts will be in great danger of being damaged when planting. Following closely on Duke of York and good at all points with me is Ringleader. This has now had several years' trial, and it has always been good and far ahead of the older Ashleaf varieties as a cropper. The tubers, too, are bigger, and I think that all other early varieties will be discarded here in favour of the two mentioned, unless in the meanwhile some other crops up better than either, which is not probable. While writing of Potatoes, I take the opportunity of referring again to the merits of Snowdrop, which is always first-class here. It is a second early, but should be planted in plenty in preference to too many early varieties, as it has wonderful recuperative powers after having been cut down by frost, a merit which most if not all of the early ones lack.—J. C. TALLACK.

—That there are two or more varieties of Sharpe's Victor no experienced cultivator will deny, the white fleshed being decidedly inferior to the yellow. I am inclined to think there are other spurious Victors in the field. I have seen Sharpe's Victor in an infinite variety of soils and positions, and do not remember a case of failure in the genuine Victor. It is not generally a heavy cropper nor a large Potato, but it is a sure cropper, of high quality, and one of the earliest in cultivation; and then it is so short topped that it may be planted close enough together to yield a fair average crop without overcrowding. Possibly "S. H." overfed his Potatoes, as he confesses that he feeds freely. Immediately under "S. H.'s" note appears that of Mr. Cockerill, with whom Victor does well in pots and outside, who says his soil is very light, in some parts 28 inches from the rock, and that he never manures for Potatoes. The striking contrast on the same page should give "S. H." cause for thought, though he hastened to add, the same culture has not produced such results on older varieties. The same two writers form equally opposite estimates as to Ringleader. "S. H." says it is growing into higher favour and is furnished with more room every year, Mr. Cockerill saying he has grown Ringleader two seasons and is giving it another trial, but if no better than the last two years he shall discard it. Does "S. H." carefully green his seed Potatoes

of Victor and other sorts, and was the fresh seed bought in greened? Last year I heard a complaint of Victor. Inquiring about the seed for planting, I was told that it was all in the heap before me, a small hillock on the floor of tubers almost hidden under green tops. Further inquiry brought out the fact that the stock had been picked over for all the finer tubers to be eaten in the early autumn or winter, the small left for seed, found towards planting time in the state described. Perhaps no Potato benefits more from early and thorough greening of the sets and cool storage in the light in single file than Sharpe's Victor.—D. T. F.

## STOVE AND GREENHOUSE.

### FREESIAS ALL THE YEAR ROUND.

A CORRESPONDENT, "L. P.," inquires as to the treatment and cultivation of these beautiful plants to ensure, if possible, having them in flower "all the year round." We are afraid we cannot hold out much hope of success in this respect, when the most successful growers both in Guernsey and England have to be content with something less than six months as a maximum wherein good flowers may be secured with any degree of certainty. Freesias, in common with all other bulbous or tuberous-rooted plants, have in their native habitat, *i.e.*, the Cape of Good Hope, a fixed season of flowering, that in these islands is merely accelerated or extended according to the means and methods adopted. The largest growers of these plants secure their supplies as early as possible in the summer months, and commence potting or boxing in July and August. Boxing is that mostly in vogue by the market men who cultivate these flowers by the thousand, the Guernsey growers, by their altered circumstances, being enabled to start cutting in November under glass, and from this time onwards till late in spring. Want of sun prevents the English growers obtaining the same results at this season, while later on their produce is highly creditable. The best advice we are able to give "L. P." for prolonging the season to its utmost limit is contained in the following: Plant in successive batches from the end of July to end of October in pots 5 inches in diameter, or boxes 15 inches long, 10 inches wide, and 4 inches deep inside, permitting an opening, say half an inch wide, in the bottom for free drainage. Such boxes will accommodate four dozen large tubers, which when planted should be covered with not more than half an inch of soil. The pots named will each accommodate half a dozen tubers. A good mixture to grow them in consists of fibrous loam one half, to which add peat and well-decayed leaf soil and sharp sandy grit. Well-decayed and rather finely sifted cow manure may be added at the rate of one-fifth part. When planted, the batches may be first well watered, placed on a bed of ashes, and then covered with 2 inches of cocoa-nut fibre. Later planted lots should be treated similarly in all respects, though as the colder nights appear they will be safer for the protection of a frame to keep off excessive wet. It will be well if the whole of what is intended for early work under glass be planted at much the same time, thus encouraging an early and abundant rooting before placing in the greenhouse. With the advent of the latter a light airy position and as near the glass as possible should be chosen, and with increasing growth water must be given without stint. Anything approaching dryness at the root generally ends in failure. A fatal error is often the outcome of stagnant root moisture, due to the placing of the pots in saucers that are rarely dry, for while with a free drainage the water supplies may be abundant, the other extreme will quickly make its own mark. By early potting and subsequent forcing these fragrant flowers may be had for at least six months in succession without scarcely any break. And after this the season may be

perhaps somewhat further prolonged by placing the bulbs in dry sand in a frost-proof shed or cellar for planting in a sunny frame about the middle of February. Such a frame, however, will need some preparation, raising the soil a foot above the surroundings. This could be done on the principle of a shallow manure frame, planting the bulbs in a bed of soil 6 inches deep on the top. Loam, leaf-soil and rotten manure, with plenty of grit, should be the soil used. Make the bed rather firm and plant the tubers nearly an inch deep. It will be better that the soil be sufficiently moist to dispense with any watering at planting time, and afterwards as needed. In case of hard weather, such a frame will need covering. When all signs of frost are past the lights may be removed. A frame 6 feet by 4 feet will take 200 or 300 bulbs, and in this way, provided the prolonged

plants. Five hundred were arranged in one house all in flower, and when it is said that some of the specimens are carrying as many as fifteen fine large blooms, the effect may be imagined. In reply to inquiries, Mr. R. Davidson kindly gave me a short account of his mode of treatment. The layers are secured as early as possible, the first batch now being ready for potting, others coming on in succession. Being thus well established before the winter they are kept well on the dry side in pits and span-roofed houses with as much air as possible kept on and the pipes well heated. The difference in plants that were for a time kept in a rather deep pit and others grown in a light span house is very marked, the latter of course being much more satisfactory. The potting compost is made up of good sound loam, peat fibre and a rather liberal allowance of sharp silver sand.

*Aconononifolia*, forming a curtain 10 feet by 5 feet, in the rock garden at Abbotsbury.  
From a photograph sent by Messrs. R. Veitch and Son, Exeter. (See p. 38.)

season of rest is not injurious to the tubers, you may get some late flowers. We think it well to say from our own experience, under not very favourable conditions, however, that a full measure of success in frame culture is not usually ensured in England, though, treated in the way suggested and similarly to *Ixia* and such things, with due care the prolonged flowering would amply repay the labour entailed. We know of no publication dealing fully with the culture of these plants.—Ed.

**Malmaison Carnations at Culford.**—In few places are these beautiful plants more successfully grown than here, and although the season is getting over, I noted this week a splendid lot of

A little of a good concentrated fertiliser is also allowed, and the pots well drained. The centre of the compost is kept a little higher to throw off superfluous water from the stems and the plants are very firmly potted. The final potting takes place about the middle of January, the pots used being apparently the 10-inch size for two-year-old plants. They are not kept after the second season, and, judging by the appearance of a large batch of last season just gone out of flower, they will be quite large enough. About 2000 plants in all are grown, but this number will probably have to be increased in order to fill a fine new house being erected for their reception.

**Carnation Mrs. Everard Hambro.**—When the first batch of new Malmaison Carnations was

sent out, many were doubtful whether the constitution would be as robust and the plants as free flowering as in the original flesh-coloured form. Experience, however, proves that in this respect they are all that can be desired, while some of the varieties are of the richest and most delicate colours. To my mind one of the showiest and best is Mrs. Everard Hambro. The flowers are of extra large size, massive in form, and of a deep carmine-rose colour, which contrasts most pleasingly with the lighter flowers of the old flesh-coloured form. It makes abundance of grass, so that even from a single stock plant a good number of plants may be secured by layering as soon as flowering is over. The sooner after this the better. Another very vigorous and reliable variety is Sir Evelyn Wood. The flowers are large and massive, having a ground colour of salmon-pink striped with rose. The flowers of the Malmaisons are a little too massive for some people, but they cannot be dispensed with, preventing as they do a blank between the last of the Tree Carnations under glass and the earliest flowering border varieties. A fairly long succession of bloom may be secured from them if a portion of the plants is placed in a comfortable house facing south and the remainder in one having a north outlook. This is a great gain where the blooms are required for indoor decoration. From the time the young plants are potted up in autumn, a cool atmosphere, free from excessive damp in winter, perfect freedom from aphids by occasional fumigations and a good turfy loam, with sufficient grit to keep it porous at each potting, are the main points in their culture.—J. C.

**Eupatorium odoratum.**—There are several varieties of this autumn and winter-blooming plant, the most useful, perhaps, being odoratum. Cuttings are easily struck in a gentle bottom-heat beneath a bell-glass as soon as a few inches of new growth have been made after cutting back old plants in spring. Several may be grown on in one pot, larger bushes being thereby secured in one season with one or two stoppings. A good holding loam, with plenty of open material in the shape of coarse sand or road grit, grows them well; some add a little leaf-mould or even decomposed cow or horse manure, but I think the former compost is best, as assistance can be given when the pots are filled with roots, and unripened growth often fails to produce flowers satisfactorily. Fine bushes may be grown in two seasons in 10-inch or 12-inch pots. Old plants cut closely back in February or March and all weakly one-year shoots removed soon break freely if kept on the dry side and afterwards treated to a comfortable moist house and syringed daily. When the shoots are an inch long, repotting, if necessary, should be done, but good-sized plants will, if well top-dressed and assisted throughout the summer with liquid manure, flower freely for several seasons. In June, after duly hardening off in a frame, the plants do best stood on coal ashes in a sheltered corner, removing under glass again at the close of October. Green fly is sometimes troublesome, in which case remove under glass and fumigate with tobacco paper, or syringe with tobacco water as they stand in the open, laying the plants on their sides during the operation.—GROWER.

#### GROWING POINSETTIAS.

WHAT is the best treatment to procure large heads of Poinsettia? I keep mine through the summer in a cool vinery. I grow two-year-old plants; they always fail with me after taking them into heat. As a rule, the foliage turns yellow and falls off until only the bract is left.—PERPLEXED.

\* \* \* There are several methods of culture by which large bracts are produced. Some successful growers, who propagate annually and bloom the plants in from 4½-inch to 6-inch pots, strike their cuttings say in April. Propagating too early is an evil, as it is then difficult to keep the plants dwarf, as having to keep them in heat and

moisture so long in the spring induces a leggy growth in the first stages. By striking in April the plants get nicely established and ready for a 4½-inch pot in June, when if a pit having a gentle warmth from hot-water pipes is at hand, no better place can be had, giving them a position near the glass and standing the pots on coal ashes. Should the weather prove unusually hot, the pipe heat can be dispensed with, a liberal supply of air being given on fine sunny days. Towards the end of July a shift into a 6-inch pot may be given, using good turfy loam, leaf-mould and a little coarse sand. Towards autumn, as the pots become filled with roots, feeding with weak farm-yard liquid, say three times a week, will be beneficial. Where no pipe-heat exists, the most must be made of sun-heat, and great care used in airing on dull, sunless days, or a check soon occurs. Extra fine bracts are also produced by planting out in a pit or deep frame in June, giving each plant plenty of room and a good larder for the roots, closing early on sunny afternoons and syringing overhead. About the middle of September lift the plants carefully and pot, returning afterwards to the same frame and keeping close and moist for ten days till established. If care is used very few of the lower leaves will fall, and in October removal to a moist house, having a night temperature of 60°, must take place, still keeping them near the roof glass. Defoliation often occurs from defective drainage or too much water, especially liquid manure.—Ed.

#### JUNE IN SOUTH DEVON.

ALTERNATIONS of rain and sunshine have kept the garden flowers growing freely, though some of the taller subjects have been rather battered by the heavier falls. The double white Achillea ptarmica The Pearl has come into fine bloom, and in the wild garden the tall Monkshood (Aconitum Napellus) has reared its blue flower-heads. The hybrid Aquilegias have been beautiful as ever, with their sweeping spurs and faint colour gradations, and a mass of the yellow A. chrysantha has had a pretty effect. The hybrid Alstroemerias came into full bloom at the latter part of the month, and division of the clumps, last autumn, seems to have rendered them even stronger than usual. Their colours, ranging from crimson to faintest cream, create a delicious harmony when the flowers are arranged in large bowls or vases. Alstroemeria aurea is also now in bloom, but its vivid orange blossoms have not the charm of hue possessed by the hybrid section. The delicate Antherium liliastrium (St. Bruno's Lily) and its larger form, A. l. majus, have, with St. Bernard's Lily (A. liliago), commenced their blooming period. The bright blue Anchusa italica, though straggling in growth, is effective when massed, and as it is not particular as to soil or position, can be planted advantageously in out-of-the-way corners. The white Antirrhinum is already in full flower, and is very effective for massing. This strain is always raised from cuttings, being of a singularly pure white and of good habit. Its seed rarely produces white-flowered specimens, and the seedlings are almost invariably coarser in growth than the parent plants. In a neighbouring pond Apogon distachyon has spread its Hawthorn-scented blooms in profusion, while in the rock garden two of the Armerias, A. speciosa and A. bracteata rosea, are in flower, the latter particularly handsome at the present time. The quaint Astrantia maxima is also in bloom, and in shady spots Aubrietia violacea is still blossoming. The beautiful Calceolarias or Mariposa Lilies, planted last autumn, came through the winter with no protection, and commenced to bloom in the middle of the month. The varieties of C. venustus are of exceeding beauty, and it seems almost an impossibility for such small bulbs to produce flowers in such number and of such size. No flower-lover can look at these beautiful blossoms without admiration, and I shall certainly increase my stock next autumn. The blooms are so exquisitely pencilled with pink, purple, and maroon, so strikingly splashed with bold blotches of chestnut

and black, each set in a halo of sulphur or orange, with outward-curving petals of such transparent purity, that one can scarcely credit the fact that these are flowers of the open English air. June is the month when the Campanulas are at their best, C. glomerata being in bloom before its commencement, and C. carpatia being also common to May. The tall Campanula grandis and its white variety have been, as usual, very telling in the wild garden, where the still stronger-growing C. latifolia, both purple and white, throws up its spires of pendent blooms to a height of over 4 feet. Unfortunately, handsome as they are, neither of these Campanulas is particularly satisfactory for providing cut bloom, though, if cut and placed in water at once, they will last for a few hours; for travelling, however, they are absolutely useless. C. persicifolia alba, its larger variety major, and the double white form C. p. alba plena, last well when cut, especially the latter. The Canterbury Bells (C. Medium) have been very ornamental, and when the flowers are picked off as they fade, will perfect a second pyramid of bloom. Centaurea rubra was in flower early in the month, and before its close the great C. macrocephala lifted its golden brushes of bloom from the back of the border, while the blue Cornflower (Centaurea cyaneus) appeared but to be temporarily extinguished by the Jubilee celebrations, cornflower-blue being the exact tint required for the tricolour bouquets and button-holes. Cerastium tomentosum is too common to be allowed valuable space, but hanging, a glaucous white-starred sheet, from an old wall, it has a distinctly beautiful effect. The bright golden Coreopsis grandiflora is in full glory, many of the individual flowers being over 4 inches in breadth; these with their long stalks are excellent for indoor arrangements and are produced in profusion till late autumn. The tall Delphiniums have been very ornamental, especially those with Cambridge-blue flowers, this tint, a good deal lighter than that of Myosotis dissitiflora, being rare in the garden. Delphinium nudicaule seems a plant of rather weak constitution, but its scarlet flower-heads are pretty. The Burning Bush (Dictamnus Fraxinella) and its white variety have been in bloom, the type generally preceding the variation by some days. One of the brightest spots in the garden has been a bed of Dianthus Napoleon III., a glow of vivid crimson. Doronicum plantagineum excelsum Harpur-Crewe, though its regular season of bloom closed early in May, still produces a few great golden stars, while Erigeron speciosus (Stenactis speciosa), with its lavender-tinted yellow-centred blooms, is in the zenith of its beauty, which, however, is a lasting one, this plant having been in bloom for nearly six months during the previous year. The colour of the blossoms especially adapts them for association with white flowers, and many beautiful combinations are possible in this direction.

The Mexican Daisy (Erigeron mucronatus) has been in bloom for two months, and will doubtless continue to produce its simple flowers for another four or five. This plant is quite a weed in some gardens and seeds itself in the walls, from which little plants grown in the crevices between the bricks flower abundantly. The Caucasian Sea Holly (Eryngium Oliverianum) is at present one of the handsomest subjects in the garden, its great flower-heads having assumed the metallic, steely lustre that renders it so striking at the time of its flower ng. E. amethystinum is another handsome species, its iridescence being, as the name implies, more amethystine than blue. The white Foxgloves have reared their tall spires against the evergreens in the wild garden where the Funkias are coming into bloom, F. Sieboldi, with its large cordate leaves, being exceptionally handsome. About the middle of the month Galega officinalis commenced to flower, but its handsomer white variety was a full ten days later in opening its Pea-shaped blossoms. The latter is by far the more valuable of the two, and, associated with the scarlet Lychnis chalcidonica, creates a pleasing contrast. Early Gladioli have been very gay, but there is no doubt that these succeed better in

light soil than in heavy. Some very strong clumps which I lately saw growing in shaly ground had in two years increased in size and vigour wonderfully, while in the heavy soil of my own garden they diminish. Amongst the best are *G. Colvillei* The Bride, *ardens*, *insignis*, *delicatis-sim's* Blushing Bride, Prince Albert and Salmon Queen. Where they succeed and increase they should be grown in quantity, as they are very decorative in the garden and cannot be surpassed for cut bloom. *Gaillardia grandiflora* has been handsome with its rich crimson and yellow, while *Geum coccineum*, though less brilliant than in May, gives a bright note of colour, and *G. montanum* is studded alike with its yellow blooms and quaint fluffy seed-vessels. Against an Ivy-covered wall the delicate *Geranium striatum* is blooming, and *G. armenum* is also flowering freely. Of Day Lilies, *Hemerocallis flava* was in flower at the commencement of the month, its fragrant yellow blossoms being almost past before the first flower of *H. fulva* expanded. Planted by Madonna Lilies the tint of the latter shows to advantage. *H. Kwanso* fol. var. had not commenced to bloom at the month's end. The Sun Roses (*Helianthemum*) were beautiful in the rock garden during the intervals of sunshine, but a rather unwelcome reminder of autumn has shown itself in the form of a premature crop of bloom on *Helianthus multiflorus* Soleil d'Or. *Heuchera sanguinea* has produced its delicate coral-red bloom-sprays, which are in request for indoor decoration, in abundance. *Hypericum Moserianum* is in full flower, while the common St. John's Wort (*H. calycinum*) has clothed an almost perpendicular bank with its growth for many yards, and is now studded with its wide-spread golden blooms. *Inula glandulosa* has produced its large many-rayed flowers in profusion, but their season of beauty is not a lasting one. The coarse *I. Helenium* has also been blooming in a little-visited corner. It was sold to me some years since as *Telekia speciosa*, a plant which it somewhat resembles.

The Iris family began their display in May and ended it with the last day of June. *I. sibirica* by the streamside has been very fine, but some of the German Flags have bloomed poorly, notably the beautiful Princess of Wales, the best white, which did not open a single blossom. My two favourites—*I. pallida* (pale lavender) and *I. flavescens* (light sulphur)—however, did well, and the suave effect produced by their flowers interspersed with the apricot-tinted *Papaver pilosum*, which grows amongst the Iris clumps, would have been well worthy of the brush of that painter of beautiful colour schemes, the late Henry Moore. English and Spanish Irises have both been good, but both demand good drainage in heavy soils. The finest clump of the former that I know consisted four years ago of one or two bulbs; this year there were fifteen splendid flowers of a lovely soft, French-grey tint. The clump in question is situated at the extreme edge of a flat bed, where it is retained by about 3 feet of stonework. The soil is heavy, but the drainage is naturally ample, and the bulbs have never been touched since their first planting. In both English and Spanish Irises the self-coloured flowers are to be preferred to those splashed or flaked, and the best effect is produced by massing the colours separately. *I. Kämpferi* has flowered, but I have had the misfortune to lose a fine clump through the devastations of water rats. *I. orientalis* (syn., *ochroleuca*), *I. aurea* and *I. Monnieri*, all precisely similar in habit, have been fine, some having grown over 5 feet high and many having flowered. The variegated Water Flag has also been a striking object, but its variegation passes with its flowers, and its sword leaves are now purely green. I saw the other day at Kingswear, on the banks of the Dart, a colony of *Jaborosa integrifolia* growing with the greatest vigour. It had spread over a large portion of the sheltered bed where it was planted, and had even invaded the gravel path; in fact, it gave the appearance of being as rampant in growth as Horse Radish. It was bearing its white fragrant flowers in pro-

fusion. The soil in which it is growing is very light and on a steep slope. Of the Lilies, *L. pyrenaicum* was the first, being almost over by June 1. Then came *davuricum*, *Thunbergianum* and the beautiful little *L. elegans*, then *L. Martagon* and *Martagon album*, followed by *L. croceum*, *L. candidum* and *L. pardalinum*. *L. candidum* seems to be doing remarkably well this season, and, though we have had heavy rains, has shown no trace of the disease, of which I have as yet seen no signs in this neighbourhood. *L. pardalinum* is especially fine, several stems being nearly 6 feet in height and bearing from thirty to fifty flowers and buds. This Lily seems to have a much stronger constitution than the other so-called swamp Lilies, *L. superbum* and *L. canadense*, which grow in the same bed, but never show a like vigour. *Lavatera trimestris* (white, pink and crimson) is already in bloom, and *Linum flavum* is a patch of light gold on the edge of the rock garden, while *Linum narbonense* is also flowering. *Libertia grandiflora* is well worth

year, however, at Kingswear I was charmed to see plants from some of my cuttings a blaze of scarlet, and I hear from the Isles of Scilly, where I also sent it, that it is a wonderful sight at the present time. It has been sent from there to Kew, and has, I am told, been assigned the name of *M. amenum*. I saw it a few weeks since in full bloom on a balcony in the Spanish frontier town of Tuy. By the water the *Mimulus* is a wealth of gold and chestnut, where, in the shade, *Myosotis palustris* and *M. dissitiflora* spread their different shades of azure, and the white flowers of *Saxifraga Wallacei* droop from the overhanging stones. On the Bergamot the large crimson flower-heads are fully expanded, contrasting well with the golden yellow of *Oenothera fruticosa*. *O. Youngi* and the charming *O. marginata* are also in flower, and the giant Evening Primrose (*O. Lamarckiana*) is also coming into bloom. In the early days of June the Arabian Star of Bethlehem (*Ornithogalum arabicum*) was in fine flower, and *Onosma tauricum* is now thickly set with yellow

*Genista præcox* on a carpet of *Aubrietia Leichtlini* at Abbotsbury. From a photograph sent by Messrs. R. Veitch and Son, Exeter. (See p. 38.)

growing, as it blooms with exceeding freedom, increases rapidly, and is also not to be despised for cutting. The Lupines, white and blue, were handsome while they lasted, and the yellow tree Lupine has just commenced to flower. The scarlet blooms of *Lychmis chalcidonica* strike a high note of colour in the garden, and *L. viscaria splendens* fl. pl. is little behind it in brightness. *L. vespertina alba plena* has also been in bloom, but its flowers are not so effective as those of the two first-named. The white Musk Mallow (*Malva moschata alba*) is in flower, and in some gardens the *Mesembryanthemum* are a sight of marvellous brilliance. The soil of my garden is too damp and heavy for them, and I have had to give up their culture. About ten years ago I brought from the Cape a plant of an exceedingly bright vermilion *Mesembryanthemum* which I was never able to flower. This

The soil of my garden is too damp and heavy for them, and I have had to give up their culture. About ten years ago I brought from the Cape a plant of an exceedingly bright vermilion *Mesembryanthemum* which I was never able to flower. This

Coulteri expanded its first delicate blossom, but established plants will probably not commence their blooming season for a few weeks, as they are at present growing strongly. The double white Rockets with the moister weather experienced this June have been more fragrant than during the past three years. These, like the Madonna Lilies, seem to thrive best in cottage gardens. Fair Maids of France (*Ranunculus acutifolius* fl.-pl.) and *R. acris* fl.-pl. have both been blossoming, while the Roses have been looking better than for years past, the plants being particularly clean and healthy and the flowers symmetrical. The Austrian Brier hedge with its bright gold and copper was a brilliant spectacle when at its best, and Paul's Carmine Pillar Rose has been much admired, as was Lady Penzance of the hybrid Sweet Briers. A very beautiful new Rose, something after the manner of Ideal, is Irene Watts, an indescribable mixture of subdued tints ranging from a suspicion of scarlet, through orange and apricot to shell-pink and faintest saffron. The Sweet Peas have come out in force this year, but the differences between some of the varieties are so slight as to be imperceptible. Perhaps the best combination for arrangement in bowls is Countess of Radnor, lavender, Venus, very pale blush, and Primrose or Mrs. Eckford, both white, with a trace of yellow. *Scabiosa caucasica* has opened its first light blue flowers, and *Sedum album* and the pink-flowered *Semprevivum arvense* are, as usual at midsummer, murmurous with the honey-bees. The delicate little *Silene alpestris* is starred with its tiny white blossoms, while *S. maritima* fl.-pl. has studded its glaucous leaves with close-set blossoms. Many of the Spiræas have been in bloom through the month. Of the herbaecous section, *S. Aruncus*, *S. filipendula*, *S. japonica*, *S. palmata* and *S. venusta*, while of the shrubby Spiræas, *S. flagelliformis* has commenced to flower. *Thalictrum aquilegifolium* and *T. adiantifolium* have both been in bloom, though that of the latter Meadow Rue is of no decorative value, its sole beauty consisting in the Maiden-hair-like foliage. The handsome purple-flowered *Tradescantia virginica* has almost gone out of cultivation, but may occasionally be seen in cottage gardens, in some of which it is now blooming in company with the old-fashioned Jacob's Ladder (*Polemonium coeruleum*) and its white variety, Sweet Williams and Pansies. *Verbascum phoeniceum*, both purple and white, are now in flower, as is the blue *Veronica spicata*. Violas are also very charming, Border Witch and Countess of Kintore being especially pleasing. Of climbers, *Clematis Miss Bateman* has been remarkably fine on a Laurel archway, while *C. Jackmani* has spread its purple veil over bank, porch and ivied wall, and the fragrant Jasmine has starred a pergola with its white flower-clusters. *J. revolutum* is also in bloom. *Solanum jasminoides*, unharmed by the winter, has commenced to flower close under the eaves; by the end of the autumn the house will be clad in bridal attire with its blossoming. *Tropeolum speciosum*, in a spot where its roots are shaded, has painted a space of wall with its vivid vermilion, and at last seems thoroughly at home.

*Benthamia fragifera*, which suffered so much in the severe weather three winters ago, is covered with bloom, and no longer shows any effects of the visitation. The *Deutzias* are in wonderful flower, even better than in 1895, simply masses of white. *Dracenas* have been in bloom in many cases, one specimen not 6 feet high bearing a huge flower-spike 3 feet through, about which all the bees in the valley seemed to congregate. Other shrubs in bloom have been the *Syringas*, *Ceanothus azureus*, *Cistus ladaniferus*, *Fabiana imbricata*, *Kalmia*, *Ozothamnus thyrsoides*, *Veronicas* and *Weigelas*. The first flower was cut from the standard *Magnolia grandiflora* on June 22, exactly one week later than in 1896.

S. W. F.

**Calochortus Plummeræ aureus.**—Among Calochorti this is perhaps the most vigorous, as it

is also the most remarkable for its handsome flowers. At the last meeting of the Royal Horticultural Society Messrs. Wallace had a fine exhibit of this kind for which an award of merit was obtained. When under the best conditions the plant will attain to nearly 3 feet high, producing its giant blossoms over a long season. This variety has blossoms each nearly 4 inches across and of a clear golden yellow, with a faint ring of reddish-mahogany in the upper part of the flower, while inside it is densely bearded.

## SOCIETIES AND EXHIBITIONS.

### ROYAL HORTICULTURAL SOCIETY.

JULY 13.

As regards extent, there was a perceptible falling off at this meeting, yet there was quite sufficient to well repay a visit. The predominating feature was the hardy border and other flowers, which were fully represented from various sources. Hardy Lilies, Calochorti, &c., came from Colchester, these, as at previous meetings, being of remarkably good quality. Carnations from Chelsea showed what can be done within the London radius with this popular border flower. Sweet Peas in most lovely tints and of good quality came from Wem, with hardy flowers from Tottenham, Tunbridge Wells, Southampton, and elsewhere. All made a most brilliant display, whilst of garden Roses there was a fine show from Colechester, which district might fairly be termed the "home of the Rose." Of pot plants, the best exhibits by far were the beautifully grown lot of Aspleniums from the Dyson's Lane Nurseries, which had the stamp of hardiness upon them, and a good display of tuberous Begonias from Yeovil. Note should also be made of the exhibit of the new hybrid Water Lilies from the extensive collection at Gunnersbury House, the individual flowers being of good quality.

Orchids were singularly few, a few choice hybrids being the almost only exhibit. Fruit was grandly represented by the superb collection of pot-grown Cherries from Sawbridgeworth, the varieties being of the finest quality and the fruits of immense size. Of Gooseberries there was a fine selection in pots from Langley. The premier exhibit, however, remains to be noted, viz., the grand collection of vegetables shown from the gardens at Aldenham House, Elstree, whence Mr. Beckett had brought as representative a collection as could be possibly desired, and that of fine table quality without any undue coarseness.

### Orchid Committee.

Awards of merit were given to—

**LALIO-CATTLEYA CANHAMIANA VAR. ALBIDA** (*L. purpurata* crossed with *Cattleya Mossie*).—A lovely form with white sepals and petals. The petals have a slight tinge of rose. The lip is crimson-purple margined with white, the side lobes rich crimson-purple, shading to yellow, and lined with brown at the base.

**PHAIUS ASHWORTHIANUS** (*P. Manni* × *P. maculatus*).—This is a lovely form, the sepals and petals rich yellow, the lip deep brown, lined with bright yellow. The upper lobes of the lip are rich yellow on the outside, lined on the inside similarly to the front lobe. It is one of the most distinct we have seen. The flower-scape was about 3 feet long, and carried ten flowers and buds. From Messrs. F. Sander and Co.

**EPIDENDRUM NEMORALE.**—A well-known species which had never been previously certificated. The sepals and petals, each about 2½ inches in length, are of a delicate rose colour, the large front lobe of the lip nearly white, tinted with rose towards the centre, where it has numerous purple veinings. The side lobes are deep rose, lined with purple at the base. A finely developed cut spike was exhibited. From Frau Ida Brandt, Zurich, Switzerland.

Messrs. J. Veitch and Sons, Ltd., sent a small collection of choice hybrids. In addition to the

plants certificated, there were two slightly different forms of *Lalio-Cattleya Canhamiana albida*, a grand plant with three flowers of *L. C. Zephyra* (*C. Mendeli* × *L. xanthina*), the sepals rich golden yellow, the petals lighter than the sepals; the lip has a purple blotch in front, margined with white, the side lobes creamy white, shading to yellow, and lined with purple through the base. This hybrid certainly improves on acquaintance. *L. C. Eunoma* (*L. pumila* × *C. Gaskelliana*) is one of the finest of the *L. pumila* crosses. The sepals, about 3 inches in length, are deep rose in colour; the petals, longer than the sepals, 2½ inches in breadth, are similar in colour to the sepals; the lip rich crimson-purple in front, shading to a deep orange-yellow in the throat. Two plants of *Disa Veitchi* were also included. Messrs. F. Sander and Co. sent *Cypripedium orphanum*, *C. Euryale*, *C. Svend Bruun*, and *C. Malus*, which closely resembled *C. T. W. Bond*. It is said to be a hybrid between *C. lirsutissimum* and *C. Lawrenceanum*. Mr. E. Ashworth, Harefield Hall, Cheshire, sent good forms of *C. Warszewiczii* (*C. gigas*), the white *C. Eldorado Wallisi*, and a grand form of *C. Mossie*, lip very similar to that of *C. M. Richard Curnow*. Two flowers of *C. superba alba*, the sepals and petals white, slightly tinted with rose, the lip white, with a few lines of purple in the centre in front of the small yellow disc, and *Lalio-Cattleya Mendeli*, now rarely met with, were also sent. A cut flower of the new *Dendrobium Victoria Regia*, recently imported, was also shown. In this the sepals and petals are blue at the top, veined with a darker shade, the base being wholly greenish white, the lip violet in front, where it has numerous purple lines; the column ivory white. It is very distinct in colour, but is scarcely worthy of the high opinion given it. Frau Ida Brandt sent a spotted form of *Odontoglossum* in the way of *O. Willekeanum*, a grand spike of *Phaius Humbloti*, and cut spikes of *Epidendrum cochleatum*, *E. atropurpureum*, *E. Brassavola*, and *Phalanopsis violacea*.

### Floral Committee.

First-class certificates were on this occasion voted to the following:—

**NYMPHEA MARILICEA ALBIDA**, which is beyond any question the finest white Water Lily in cultivation, fully-developed flowers being quite 2 inches in diameter, the white being purer than in the well-known *N. alba*. The vigour of this newer form is also remarkable in the immense size of the leaves, whilst each flower is supported upon remarkably stout footstalks. Being quite hardy and a free-flowering plant, this variety should be noted by growers. From the collection of Mr. Leopold de Rothschild, Gunnersbury House, Acton (gardener, Mr. J. Hudson).

**PLATANUS OCCIDENTALIS ARGENTEO-VARIEGATA.**—A thoroughly well-marked form of this Plane, the younger leaves almost entirely of a creamy white shade, the older ones possessing more green in them. This is a very showy variegated plant, and its future career will be watched with interest. From Mr. John Russell, The Nurseries, Richmond, Surrey.

Awards of merit were voted to—

**ROSE (TEA-SCENTED) SYLPHI**, a decided acquisition, being so very distinct in colour, a soft, pale creamy blush pervading the flowers, with deeper blush tints in the bud stage; a lovely Rose and of fine form. From Messrs. W. Paul and Son, Waltham Cross.

**LOBELIA TENUIOR GRANDIFLORA.**—A very distinct *Lobelia* of slender yet erect growth which branches at the base; each flower is fully 1 inch across, the colour a bright blue with a variation in one instance to nearly white. From Mr. B. Ladham, Shirley Nurseries, Southampton.

**CALOCHORTUS PLUMMERÆ AUREUS.**—A remarkably fine form with large flowers, the petals of which are of extra breadth, whilst the colour is a deep golden yellow, the hairs at the base being very profuse. A distinct acquisition to the race. From Messrs. Wallace and Co., Colchester.

**SALVIA BICOLOR.**—A North African species from Morocco, and at the same time hardy in this country. The growth is exceedingly vigorous, the flowering shoots being branching and clothed with flowers from base to top, the colours being pale lavender, blue and white. From Sir Trevor Lawrence, Burford Lodge, Dorking (gardener, Mr. Bain).

**NYMPHÆA ELLISIANA.**—One of the more recent hybrids raised by M. Latour-Marliac and a decidedly distinct novelty. The growth is moderate with leaves of medium size, the colour a brilliant carmine suffused with purple. M. Latour-Marliac considers this Lily to be one of the best in cultivation. When well established it will no doubt be finer. Mr. J. Hudson.

**BEGONIA MISS GRIFFITHS.**—A large double-flowered tuberous variety, very full, the petals distinctly undulated at the margins, the colour a pale blush-white. Mr. Davis, Yeovil.

A botanical certificate was given to

**ARISTOLOCHIA BRAZILIENSIS.**—A variety with flowers above the average size, the venations and groundwork of the colouring being much darker than usual. Mr. H. Wallace, Amoy, China.

Messrs. R. Wallace and Co., Colchester, again staged an extensive group of Lilliums and Calochorti, the former including a beautiful batch of *L. umbellatum* Cloth of Gold, *L. Henryi*, *L. Krameri*, one of the most attractive of the pink-coloured Lillies, and *L. speciosum album novum*. The Calochorti were as usual of fine form and well grown, the Eldorado forms especially showing remarkable variations in colour (silver Flora medal). Messrs. Veitch and Sons, Chelsea, also had a large and fine collection of hardy flowers, arranged with admirable judgment. Among the notable things were *Achillea Eupatorium*, *Campanula carpatia alba*, *Helenium pumilum*, particularly fine in colour and size; *Acanthus latifolius*, *Cimicifuga racemosa*, *Prunella Webbiana*, and *Linum flavum*. There were also a collection of very fine *Iris Kampferi* seedlings and a group of Carnations, including many beautiful and delicate varieties. A few of the most striking were George Cruikshank, a richly-coloured flower, salmon and scarlet, and very full; Sweet Brier, a lovely cardinal, of good form and substance; Eldorado, a charming yellow and pink fancy; Golden Eagle, Voltaire, and Cardinal Wolsey (silver-gilt Banksian). Another good group of hardy flowers came from Mr. B. Ladhams, The Shirley Nurseries, Southampton, and included *Verbascum phoeniceum*, *Physostegia virginiana alba*, *Eriogonum missouriensis*, a number of varieties of *Campanula*, a beautiful form of *Scabiosa caucasica*, and some good varieties of *Echinops* and *Eryngium* (silver Flora medal). Hardy flowers were again well shown by Messrs. Barr and Sons, Covent Garden, the group being admirably arranged and full of interest. Sweet Peas were particularly good, also *Chrysanthemum maximum*, a number of well-grown Pentstemons, varieties of *Iris Kampferi*, and *Coreopsis grandiflora* (silver Banksian medal). A small group of hardy flowers was shown by Messrs. Young and Co., Stevenage, Herts, and in it were *Aconitum Napellus* and some good *Gaillardias* and Sweet Williams.

A particularly delightful exhibit was a collection of Sweet Peas, shown by Mr. Henry Eckford, Wem, Shropshire. Every variety was finely grown, the size, form and colour of the blooms being excellent. Among the finest varieties were *Blanche Burpee*, unrivalled among the pure whites; *Lovely*, very delicate pink, large blooms; *Mrs. Eckford*, very handsome primrose-yellow self; *Shahzada*, very dark maroon, the wing petals purple; *Lottie Eckford*, pure white, suffused with lilac; *Duchess of York*, *Venus*, *Mars*, the largest and finest bright red; *Mrs. Gladstone*, *Dorothy Tennant*, a fine deep mauve; *Stanley*, very deep maroon, with shades of purple; and *Salopian*, a rich dark red (silver Flora medal). Mr. J. Charlton, Tunbridge Wells, also exhibited hardy flowers, among them being a good bunch of *Agrostemma coronaria*, *Salvia argentea*, a good collection of *Alstroemerias*, *Platyodon Mariesi* and

*Scolymus grandiflorus* (silver Banksian medal). Another group of hardy flowers came from Mr. T. S. Ware, Tottenham, *Veronicas* and *Alstroemerias* being good (silver Banksian medal). Cut *Begonias* were well shown by Mr. B. R. Davis, Yeovil. All were in admirable condition, with full and well formed petals, the colours throughout very beautiful (silver Banksian medal). Another interesting exhibit was a group of seedling *Begonias* from seed sown five months ago, sent by Messrs. Cannell and Sons, Swanley. They were an admirable batch of plants, dwarf and strong in growth. A strain of rich crimson flowers was particularly fine (bronze Banksian medal). Mr. James Douglas, Great Bookham, Surrey, had a collection of cut Carnations, very good material, containing a number of new varieties, among which were *Lancer*, a shapely crimson and yellow fancy; *Bedminster*, similar in colour, but larger; *Ibis*, a pale blush self; *Mrs. James Douglas*, a handsome bright red self, and *Endymion*, a very lovely pink self of splendid form. A good group of *Roses* came from Messrs. William Paul and Son, Waltham Cross. Some of the best were *Empress Alexandra of Russia*, a new Tea Rose of excellent quality, with a good hard centre. The colour is charming, being a beautifully shaded rose, tinged with apricot. The foliage is good. It appears to be a very free bloomer, and should prove a great acquisition. Other good things were *White Lady*; *Sylph*, a new Tea of very lovely form, pale pink in colour; *Enchantress*, and *Waltham Standard*, a new H.P. Messrs. Frank Cant and Co., Colchester, also exhibited cut *Roses*, the best in their group being a dozen superb blooms of *A. K. Williams*. The *Bride*, *Mme. de Watteville*, *Mme. Cusin*, *Innocente Pirola*, *Cath. Mermie*, and *Mme. Lambard* were also good (silver Flora medal). From Messrs. F. Sander and Co. came a group of *Watsonia iridifolia* O'Brien, handsome plants, bearing fine spikes of pure white blooms. A grand group of *Aspleniums* was staged by Mr. H. B. May, Dyson's Lane Nurseries, Upper Edmonton, and included *Asplenium nidus phyllitidis*, *A. Mayi*, *A. contiguum*, *A. cucumatum*, *A. Herbsti*, *A. nobile*, *A. erectum*, *A. cultriforme*, and *A. lucidum* (silver-gilt Flora medal).

For twelve bunches of hardy flowers, Mr. C. Herrin, Dropmore, Maidenhead, was awarded first prize, showing fine bunches of *Helianthus multiflorus*, a seedling *Delphinium*, *Achillea* The Pearl, *Yucca gloriosa*, *Aconitum bicolor*, *Rose Crimson Rambler*, *Spirea arifolia*, *Galega officinalis*, *Lilium candidum*, *Lysimachia thyrsoiflora*, *Lathyrus grandiflorus*, and *Alstroemeria aurantiaca*. Foreign bunches of hardy flowers, Miss Debenham, St. Albans, was first, her best bunches being *Erigeron speciosus superbus*, *Alstroemeria aurantiaca*, *Eryngium Oliverianum*, *Lilium candidum*, and *Hedysarum obscurum*.

#### Fruit Committee.

The exhibits before this committee took up quite half the hall. The vegetables from Aldenham were superb, and Messrs. Veitch's and Messrs. Rivers' fruit very fine.

Awards of merit were given to—

**MELON SYON PERFECTION.**—This is a seedling from Syon House and Beauty of Syon. It is a medium-sized fruit, nicely netted, with a greenish rind, but bright scarlet flesh of rich flavour, and great depth. It is one of the best flavoured Melons of the year. From Mr. G. Wythes, gardener to Earl Percy, Syon House, Brentford.

**THE LOGAN BERRY, or Strawberry Raspberry.**—An American fruit, with foliage not unlike our Raspberries, but of dwarf and bushy growth. The fruits, long and freely produced, are of a dull red colour and a brisk acid flavour. It is a decided acquisition for cooking or preserves, and is stated to crop freely. From Messrs. Bunyard and Co., Maidstone.

Messrs. Veitch, Ltd., Royal Exotic Nursery, Chelsea, staged a very fine lot of Gooseberries which had been grown in pots at their Langley nurseries. This was a remarkable exhibit, as Gooseberries grown thus are so subject to red spider. The trees were perfect specimens of

culture and laden with fruit. Forty varieties were staged. The best varieties were *Industry*, *Red Champagne*, *Whitesmith*, *Coiner*, *Highlander*, *Forester*, *Wellington*, *Leader*, *Golden Drop*, *Railway*, and *High Sheriff*. A very large tray of the new Strawberry Veitch's Perfection was also staged. The committee thought it excellent, and confirmed the award given last year (silver-gilt Knightian medal). Messrs. Rivers and Son, Sawbridgeworth, Herts, sent twenty varieties of Cherries, remarkable for their size and colour. The fruits of *Monstreuse de Mezel* were of enormous size, also those of *Bigarreau de Schreken* and *Noir de Guben*. Rivers' Early Black was equally fine, and was noticeable for its small stone with so much flesh. Several others of the *Bigarreau* type were very fine (silver-gilt Knightian medal). Mr. Allan, Gunton Park Gardens, Norwich, staged a new Strawberry, *Lady Suffield*, a dark red fruit, firm and good. This the committee thought too much like *Lord Suffield*.

The finest exhibit was the superb lot of vegetables from Aldenham, thirty-two varieties being set up in large quantities, the produce just the kind for table. Cauliflowers were very fine, and were represented by *Webb's Mammoth*, *Veitch's Autumn Giant*, and *Walcheren*. Onions were equally good, the varieties being *Red Italian* and *White Leviathan*. There were excellent Cucumbers *Beckett's Victory*, with very fine *Sutton's Perfection* and *Polegate Tomatoes*. Peas were shown in three varieties, the best being *Early Morn* and *Ne Plus Ultra*, *Duke of Albany* the other. *Sutton's Snowball Turnip* and *Globe Beetroot*, with perfect *Vegetable Marrows*, *Pen-y-hyd* and *Moore's Cream* were also shown. Carrots were perfect, the varieties being *Sutton's Gem* and *James' Intermediate*. Potatoes, in two varieties, included first-rate *Rivers' Ashleaf* with *Sharpe's Victor*, and a nice compact Cabbage, *Carter's Model*, with *Broad Beans* in variety (gold medal). From Mr. Beckett, Aldenham House, Elstree, Herts.

Messrs. Carter, High Holborn, sent a very fine collection of Lettuce and a few Turnips, the quality good for so dry a season. The most noticeable were *New York*, *Carter's Longstander*, *Sugarloaf*, *Continuity*, an excellent Cabbage variety with purple leaves, *Ne Plus Ultra*, *Victoria*, and *Buttercup*. Among the ten varieties of Turnips, *Purple Top Strapleaf* was very good (silver Banksian medal). Messrs. W. W. Johnson and Son, Boston, Lincolnshire, staged forty varieties of Peas, mostly excellent samples. *Boston Unrivalled* was very fine, and such kinds as *Windsor Castle*, *Gradus*, *Duke of York*, *The Queen*, *Peerless*, *Stratagem*, *Sutton's Seedling*, *Marrowfat*, *Ambassador*, and *Alderman* were also good (silver Banksian medal). Mr. Eckford, Wem, Salop, sent half a dozen varieties of Peas of great merit. These the committee desired to be sent to Chiswick for trial to test cropping. Messrs. R. Veitch and Son, Exeter, sent Peas *Veitch's Perfection* and *Goldfinder*, and their *Broad Bean Exhibition Longpod*.

The awards given at Chiswick on the 1st inst. were now confirmed, awards of merit being given to—

**STRAWBERRY WONDERFUL.**—A variety having long scarlet fruits produced in great profusion. Flesh firm and of excellent flavour. From Messrs. Bunyard and Co., Maidstone.

**BROAD BEAN CHAMPION.**—A very large pod, long and handsome. It is a very free cropper. From Messrs. Dobbie and Co., Rothesay, N.B.

The award to the other Broad Bean (*Exhibition Longpod*), given three marks, was not confirmed. Messrs. R. Veitch and Son, Exeter, sent up a nice dish, but it was decided to grow this variety again at Chiswick with others for comparison. This also applies to *Harrison's Robin Hood*.

#### MEETING AT CHISWICK.

This committee met at the society's gardens and inspected the Peas, several of which were not ready at the last meeting.

Awards of merit were given to—

**PEA VEITCH'S PERFECTION.**—An old and well-known variety of sterling merit. This variety originated at Exeter many years ago, and was now grown from seed sent by Messrs. R. Veitch and Son, Exeter.

**PEA MAJESTIC.**—A very fine marrow variety, producing in each pod seven to nine Peas of large size, excellent quality and a good green colour. It is not unlike *Ne Plus Ultra*, and grows 3 feet high. From Messrs. Watkins and Simpson, Strand, W.C.

**PEA CAPTAIN CUTLER.**—A very fine Pea, with large pod and of branching habit, after the *Autocrat* type. It grows 4 feet high and is of first-class quality. From Messrs. Hurst and Son, Houndsditch, E.C.

Pea Goldfinder was thought to be an excellent variety, and will doubtless be seen again at an earlier stage of its growth. Mr. Hudson, Gunnersbury House, Acton, sent Strawberry Louis Gauthier, a French variety with a white berry, a heavy cropper, and useful on account of its bearing a second crop in the autumn. The fruits sent were over-ripe, and the committee requested that it be sent again, when fruiting in the autumn.

On this occasion all the committees met and sat down to an excellent luncheon, the president (Sir Trevor Lawrence, Bt.) in the chair. The chairman said the council were greatly indebted to the committee for the time they gave the society and the interest they took in its affairs, and introduced Dr. Masters, who opened a discussion on how to better utilise Chiswick Gardens. He stated that, as regarded past results, no horticultural society could compare with the Royal Horticultural, but his remarks more concerned the future and how to keep up the society. In these days Kew did what the society formerly did, and nurserymen were ever on the alert to get good things. What they had to consider was how to make the gardens more useful. He thought they should make the gardens more educational. He would leave the practical part of the subject to those who understood it, and he would suggest they should have a model garden, and have types of vegetables, fruits and flowers, or type collections, not mere varieties. They would do well to have lectures on pruning and other subjects, trials of manures and the best means to cope with disease. As regards the educational part, he would like to see the students drafted to Kew in the evenings to hear the lectures there, and the Kew students could with advantage come to Chiswick and get a knowledge of fruit culture. In America there was a much better educational system, and the State supplied the means. He knew it was useless to apply to the State in this case, but the county councils had means and could supply them. In America there was a better knowledge of disease, and spraying of trees was well understood. Dr. Masters read extracts from eminent botanists in America, who thought the society could well undertake the above work. He advised more study, and to use the gardens for that purpose.

Sir Joseph Hooker complimented Dr. Masters on his able speech, and alluded to the good work done at Chiswick in the past. He agreed with what had been said as to the value of education. There were great difficulties in the way of State aid. He recounted the troubles they experienced at Kew. He would have been pleased to help them in the project of utilising Kew had it been in his power, and he sympathised with them in the good work suggested. Mr. Harry Veitch expected they would find difficulties in doing all at Chiswick as suggested. They must remember the place was now more confined and the results could not be so satisfactory as further afield with better soil and purer air, and Chiswick would yearly be less valuable as an experimental centre. He would gladly assist in any way possible. Dr. Plowright spoke as to the American system; he would like to see it given a trial at Chiswick. M. H. Vilmorin wrote from Paris regretting his being unable to attend. He placed high value on the

good work done at Chiswick in the past. He valued the trials, and he strongly advised continuing the same. Mr. M. Dunn wrote from Dalkeith Gardens, and noted the value of Chiswick Gardens as trial grounds. He would like to see this work extended and the commercial part of the gardens done away with, thus giving more time and scope to the testing and growth of all new things. The chairman, in proposing a hearty vote of thanks to Dr. Masters for his able address, alluded to these two valuable opinions from practical men, far apart and with a good knowledge of the subject, and trusted the discussion might lead to useful results.

## NOTES OF THE WEEK.

**Gaillardias** are among the gayest flowers of the week. A seasonable reminder is that a few seeds, if sown at once, will make nice plants for putting out in October in permanent places, and as such make the best flowering plants a year hence, no time should be lost in securing seed.

**Carnation Jim Smyth** is, perhaps, one of the very finest of border Carnations so far as size of flowers and the clear rich scarlet colour are concerned. The variety possesses a certain amount of freedom also, judging by a handful of blossoms and buds at the Drill Hall this week.

**Sidalcea malviflora Listeri.**—Some pretty spikes of this charming kind were exhibited at the Drill Hall on Tuesday last. It is a pale pink variety, and if free flowering would make a most welcome feature in the garden. The blossoms are each nearly  $\frac{1}{2}$  inches across, prettily fringed at the edge.

**Lilium japonicum Kramerii.**—Some very deeply coloured blossoms, as shown by Messrs. Barr at the Drill Hall this week, showed the variety of colour even in this plant in its wild state. The blossoms were also shorter in the trumpet, and could it be but well grown generally it would make a lovely plant for our gardens.

**Clematis Jackmani** is now particularly fine in many districts. It is one of many plants raised during the present century that has found favour with the large majority of those possessing a garden. The free-growing character of the plant and the rich profusion of flowers help to make it the most useful of a valuable race of plants.

**Late Apple blossom.**—An Apple tree here, on which the fruit is about the size of a small hen's egg, is now displaying a few clusters of bloom, one of which I enclose. The bloom of this and another tree in May last was very seriously damaged by frost, and that of some other trees here was entirely destroyed at the same time.—W. M., *Wexford*.

**Campanula G. F. Wilson.**—This very showy plant is now blooming freely, and in some instances quite attractive from the large masses of its flowers. As a rock plant it is very desirable, succeeding best, however, where a good depth of soil exists. It is a hybrid or more than ordinary value, and more of such good and distinct plants would be welcome in our gardens in the height of summer.

**Indigofera floribunda.**—A large example of this about 10 feet across is now flowering freely in the nurseries of Messrs. Veitch at Chelsea. The flowering has only just begun, so to speak, since the plant during many weeks in succession produces its lilac-purple blossoms, and loosely trained to a wall is pleasing also in its habit of growth. The example in question has occupied its present position for years and is still fresh and vigorous.

**Carnation Nell Gwynne.**—This handsome variety is the first pure white kind belonging to the Malmaison type of Carnations, and in its foliage, even more so than in the large, handsome snow-white blossoms, it is unmistakably of this set. In the bud and form of calyx, however, there is evidence of another type, which recalls the large flowers of *Ellen Terry*, perhaps the

largest white of the border section. The above will no doubt be speedily followed by others of equal merit.

**Scolymus grandiflorus** is one of the large growing Thistle-like composites that is worth more attention in gardens. Not that the plant is worth the best positions, yet it has a decorative value of its own when seen in groups of a dozen in the higher parts of the rock garden. Such a position would be in keeping with the rugged or picturesque character of the plant generally, and when crowned with its deep golden flower heads it is very effective.

**Rose Empress Alexandra of Russia.**—This lovely new Rose was exhibited by Messrs. Wm. Paul and Son at the Drill Hall this week, and possesses the merit of an entirely new shade of colour, while the blossoms are full and of good form. The predominant shade is a salmony bronze, with a shading on the tips of the petals of cherry-rose—a really charming combination. A large basket of its flowers and buds displayed it to considerable advantage.

**Brodiaea grandiflora.**—For the rock garden or the border this is perhaps not only the showiest, but also the brightest of its race. Indeed, the clear rich blue of its flowers is very remarkable, if not unique, especially so when planted freely, so that a good idea may be formed of its value. In loamy soil it is of easy culture, and worth growing freely from the fact that blue flowers of this class are not abundant at midsummer. Such plants cannot be too widely known.

**Single Hollyhocks** in almost every shade of colour and in some cases 9 feet and 10 feet high now produce a distinct effect in the garden. The rose, pink, and white flowers are especially pleasing from a colour point of view, and not less so by the light and airy character as compared with the double forms. Of no small value is the fact that the majority of single kinds, while growing much more freely generally, enjoy almost perfect immunity from disease.

**Iris Kämpferi.**—The large collection of flowers that the Messrs. Veitch brought to the Drill Hall on Tuesday last would appear to do away with the need for obtaining named varieties of these plants. The group, which was labelled "seedlings," showed not only very large and good flowers, but considerable variety also, sufficient for almost any purpose. Indeed, it is surprising what beautiful forms could have been selected from the large array of blossoms shown.

**Pelargonium Beauty of Castle Hill.**—This Ivy-leaved *Pelargonium* is the most free-flowering of all the double varieties of this useful group, and, together with its compact habit and vigorous growth, may safely be regarded as one of the very finest ever raised. The brighter coloured variety *Souvenir de Chas. Turner* and the above constitute a pair very difficult to equal. Both kinds were raised by the late Mr. Robert Owen, of Maidenhead, and are still in the first rank of these plants.

**Crassula coccinea.**—It is only occasionally that the brilliant colour of the flowers of this plant is brought to such perfection as was the case with a group of large plants noted at Chelsea the other day. The exceeding brilliancy of the heads of blossom was conspicuous at a considerable distance. Frequently when grown under glass much of the intense scarlet hue is wanting. The plants were placed in the open in full sun, and this plan is worthy of imitation by anyone who experiences difficulty in obtaining finely coloured heads of bloom.

**Nymphæa Marliacea albida.**—The noble blossoms of this came before the Royal Horticultural Society on Tuesday last and a first-class certificate, which they justly deserved, was at once awarded. A group of this noble form when fully established will create quite a new feature in the water gardens of this country. Mr. Hudson, with commendable forethought, exhibited all the blossoms in a shallow tray of water, and accompanied by their foliage in each instance they

formed a pleasing as well as instructive exhibit. The flowers came from Messrs. de Rothschild, Gunnersbury House.

**Lychnis vespertina plena** is an old-fashioned border flower that produces for several weeks in succession almost endless quantities of pure white double flowers. As a border subject it is among the best, but it is not specially suited for cutting, owing to the peculiar nature of the stems, that do not take water so readily as many things. In some soils the plant frequently sheds many of its flower buds, a circumstance in all probability due to the absence or presence of certain food supplies. In gardens where the soil is deep and rich, and where also a certain amount of chalk is contained in the soil, the plant will attain to great size and flower in proportion.

**Echinops ruthenica**.—The globular heads of purple-blue that crown this plant at the present time provide it with a touch of picturesque beauty that is often admired in the garden or woodland. The plant is in this way just removed from the ordinary flowering subjects which are of daily occurrence; yet at the same time such things have their decorative side if only they are seen in groups of sufficient size to render them effective. Planted in deep and fairly good soil, it should be allowed to remain a year or two to become well established. Seed, division and root cuttings are the means employed to increase this, as also the allied forms.

**Campanula Balchiniana**.—A very fine batch of this distinct hybrid may be seen in Messrs. Veitch's nursery at Chelsea. The plant is variously employed, mainly, however, suspended in baskets and in small pots. It is also on trial in the open air, though as yet it is not so effective in this way; but as a margin near the grass, provided the brightness of the variegation is maintained, it should prove very effective. Under glass the variegation is exceedingly bright and effective, and the flowers, a rather dark blue, show to advantage. In size and shape the blossoms are a counterpart of those of *C. fragilis*, which is one of its parents, while the colour is somewhat darker.

**Watsonia iridifolia O'Brieni**.—A grand exhibit of this plant under the name of *Ardernei*, from Messrs. Sander, was among the finest things in the Drill Hall this week. The plants, which were arranged on the floor, were about 6 feet high, bold and vigorous, as well as abundantly flowered. The effect of the group was very fine, as may be gathered from the fact that the flowering spikes were nearly 3 feet in length and in prime condition. All the plants were grown in quite small pots. It would be difficult to name a finer subject for the cool conservatory, where it may be planted in bold groups among the finer Palms and such things, and thus produce a remarkable effect.

**Lilium Browni**.—The Messrs. Wallace brought to the Royal Horticultural show this week one of the finest displays of this Lily we have yet seen in a cut state. It is undoubtedly a noble Lily, vigorous, too, and of fairly easy culture in a deep bed of peaty soil or even peat and loam. The segments were finely coloured externally, which is one of the chief points of beauty in this noble kind. In the planting it is well to keep the bulbs some 4 inches under the surface, and by planting in groups between dwarf shrubs afford shelter for the young growth in spring. Beyond this it is not difficult to establish, though preferring a little distant shade to full sun. Once planted the bulbs are usually safe for two or three years, giving a little very rotten light manure as a mulch only each year in autumn.

**Phlox Coquelicot**.—At the present time there is a good collection of the garden varieties of Phlox in some beds near the T range at Kew, and this particular form stands out as the brightest of them all; indeed, viewed from a distance, the eye is at once arrested by its vivid colour. It may perhaps be best described as of a bright salmon-scarlet tint, with a shading of violet just in the centre. Though so superior, its merits do not ap-

pear to be very generally known, for I have looked for it in vain in two or three catalogues.

\* \* Is not this the variety which used to be grown many years ago under the name of Lothair? Lothair was in the collection of Phloxes grown in the Royal Horticultural Society's gardens twenty years ago, and its distinct shade of colour (orange-scarlet) always arrested attention.—ED.

#### SUB-TENANT HOLDING OVER.

I SHALL esteem it a favour if you can advise me under the following circumstances:—

1. I am at present occupying a small nursery of three acres in Surrey, of which for ten years I held an underlease (the latter expiring in March last) at a rental of £85 per annum.

2. Prior to the expiring of underlease I offered to renew the lease at £70 per annum. This offer, however, has not been accepted or refused, though in conversation with owner's solicitor a certain reduction of rent was regarded probable, £75 per year being mentioned.

3. As a full quarter has now elapsed since the expiration of underlease, I am anxious to know what rental in the absence of any agreement whatever can be justly demanded, and whether such would be regarded as a precedent in future.

4. In event of owner not conforming to my terms, what notice to quit (under the circumstances) am I compelled to give? I am told I occupy the position of yearly tenant and subject to six months' notice. Is this so?

5. Tenant from whom I underlease has now left; his tenancy was completed by me, and the owner I refer to above is really the owner. The land is covered with glass, in which produce for market is grown.—LEASEHOLDER.

\* \* When the tenant for a term of years holds over after the expiration of his lease, he becomes a tenant on sufferance; but when he pays, or agrees to pay, any subsequent rent at the previous rate, a new tenancy is thereby created upon the same terms and conditions as those contained in the expired lease so far as those are not inconsistent with a yearly tenancy. Although you are (or were) only a sub-tenant, your position is not really different from that of a superior tenant holding over; you are a tenant on sufferance and the landlord may at any time bring ejection against you. It was your duty to give up possession when the term of your lease expired, and you should either have quitted or have brought the negotiations for a renewal of the tenancy to a conclusion. You might have been unable to negotiate terms satisfactory to yourself, but in that event you should have quitted. Until rent is paid, or agreed to be paid, you are not a yearly tenant; you are and will remain a tenant on sufferance, and you are entitled to no notice whatever. Your landlord cannot recover any rent from you, but he can recover from you compensation for the use and occupation of the holding, and the amount recoverable is not necessarily the old rent. It will be such sum as the jury may find the occupation to be worth, and may be greater or less than the old rent. As your landlord's solicitor regarded a reduction of £10 a year as probable, it seems likely that the landlord will accept rent at that rate, as he evidently wishes you to remain as tenant, but, if he thinks proper, he may refuse to accept any sum less than he chooses to demand, and on your refusal may take his chance with a jury. You certainly cannot compel him to accept the reduction of £15 you required, and you should make the best arrangement you can with him. Such rent as you may now pay will continue to be payable, unless you enter into an express contract for some other sum.—K. C. T.

**The weather in West Herts.**—On each of the last six days the temperature in shade has risen above 70°, and on three of them exceeded 75°. On the other hand, most of the nights proved cold for midsummer, and on that preceding the 8th the exposed thermometer fell to within a degree of the freezing point, or lower than in any

July for ten years. Consequently the difference between the highest and lowest reading has on several days been unusually great. At 2 feet deep the ground is now 3°, and at 1 foot deep 5°, warmer than the average. For more than a fortnight scarcely any rain has fallen, and the soil is now becoming very dry, no measurable quantity of rain-water having come through either percolation gauge since the 10th. The atmosphere has been dry and the record of bright sunshine remarkably good, averaging for the week more than 10½ hours a day.—E. M., *Berkhamsted*.

**A singular Haw.**—I enclose a specimen of a Haw so singular in its appearance that very few, I think, would recognise it as the fruit of the White Thorn. It is, as you will see, very much swollen as compared with the others in the same bunch, and is covered all over with small woolly tufts, set in a very even and regular manner. Perhaps "G. S. S." might be able to explain what is the matter with it if he would kindly examine it.—W. M.

\* \* The Haw you sent is infested by a fungus, one of the cluster cup fungi (*Rustelia lacerata*). It is at times very common on the Hawthorn, on the leaves as well as on the fruit. If you can find another Haw which has been attacked and examine it with a magnifying glass, you will find a number of little so-called "cups" clustered together.—G. S. S.

#### PUBLIC GARDENS.

**Open space for Wandsworth.**—On Wednesday last, upon the motion of Mr. S. Creswell, it was resolved to ask the London County Council to take steps to secure the land abutting on the river Thames at Putney Bridge Road as a recreation ground for the parish of Wandsworth. The Board has already voted £10,000 towards the cost of the acquisition, which is estimated at £36,000.

**Open spaces.**—At the monthly meeting of the Metropolitan Public Gardens Association, 83, Lancaster Gate, W., the Earl of Meath, chairman, presiding, it was announced that the association had completed the laying out of St. James's Churchyard, Pentonville, by means of a grant of £600 from the City Parochial Foundation, and that the ground was opened to the public by Captain Penton, the freeholder, on the 6th inst.; that St. Matthew's Churchyard, Bethnal Green, was approaching completion, and would be opened on the 20th inst.; that the gymnastic apparatus granted by the association had been erected at St. Nicholas' playground, Deptford, and that this ground would be completed and opened in about a fortnight's time. Progress was reported with regard to the laying out of the East Street site at Walworth, and it was stated that the association had received the gift of a handsome drinking fountain for this ground from Mr. L. H. Isaacs. It was agreed to renew a previous offer to lay out Christ Church Churchyard, Blackfriars Road, and a disused burial-ground in York Road, Walworth, provided their maintenance was secured. It was agreed to support schemes for the preservation of vacant sites near the Essex Road, Islington, and in Wandsworth, Bromley, and other localities, and to offer prizes for the best designs for durable yet artistic drinking fountains, costing not more than £50 and £100 respectively.

**Names of plants.**—*J. B. Wady*.—1, *Erica tetralix*; 2, *Erica cinerea*.—*J. Bennett*.—1, *Cypripedium Rothschildianum*; 2, not recognised.—*Arthur T. Bowles*.—*Genista tinctoria*.—*Bannerman*.—1, *Rose Boursault* "Blush"; 3, *Rose Maiden* Blush, not *Celestial*.—*Sophia C. White*.—1, *Campanula urticaefolia*; 2, *Campanula persicifolia*; 3, *Veronica buxifolia*; 4, *Veronica silicifolia*; 5, *Geranium armenium*; 6, *Alonsoa myrtifolia*.—*Alpha*.—*Gladiolus byzantinus*.—*A. ## ORCHIDS.

### ODONTOGLOSSUMS.

THE flowering of *O. Schleiperianum* and its varieties leads one to the consideration of the section of the genus to which it belongs, and with these only I purpose to deal in this note. Regarding their blooming season, they are rather erratic, especially *O. Inseleyi*, which I have noted at different places flowering in almost every month during the year. But from now onwards is usually regarded as the time to see them in beauty. Their natural habitat is in Mexico, Guatemala and Costa Rica, where, although at a greater distance from the equator than that at which the crispum types are found, the climate is warmer. Their treatment indeed is rather more like that of inter-tropical kinds than the purely alpine species named above, in that they like a certain resting season distinct from their season of growth. Not that they require dry treatment at the roots, for if this is long persisted in the plants soon show by their shrivelled pseudo-bulbs that the lack of moisture is not at all to their taste. What they like is a rather drier atmosphere, with a very free circulation of warm, dry air during the time growth is inactive. This is from the time the blossoms fade until growth starts in early summer, the actual time varying a little in the different species. Soon after, root-action becomes more brisk, and the plants may, if necessary, be repotted. Frequent disturbance is harmful, but the plants must not be allowed to remain in sour compost. The roots are larger than those of most Odontoglossums, and a wider pot is therefore required. A couple of inches margin all round the pseudo-bulbs is not too much, provided the plants are healthy and well rooted, the pots well drained, and the compost kept thin, rough, and open. Good peat broken into rough lumps, a little Moss, and plenty of crocks and charcoal will be the material for it, about a couple of inches of this sufficing for medium-sized specimens. A little more warmth

is beneficial after disturbance, the roots being stimulated thereby, especially if kept rather on the dry side and the atmosphere moist. The plants are not so fastidious in their atmospheric requirements as are the crispum and similar kinds, their wants being easily met in a house kept at a night temperature of about 55° while growth is active, rising about 10° by fire-heat, and rather more in bright weather. Shade is an important point, and the blinds should be kept down at this time of the year until the sun has left the house. While at rest more light is required, but bright sunshine must even then be partially excluded. Insects of most kinds are very fond of all the plants in this section, so cultivators will do well to be on the look-out and ready with preventive measures. Perhaps the best known of all this class of plants is

*O. GRANDE*, a superb Orchid when in good cultural condition and well flowered. The spikes on the strongest plants contain from six to eight flowers, these measuring about 5 inches across, the sepals and petals bright golden yellow, heavily blotched with brown; the lip whitish in ground colour and similarly marked. The bulbs are roundish, deep green, each bearing a pair—sometimes three—of nearly oblong leaves, lightly spotted when young. It comes from Guatemala, and first bloomed in England in 1841 with the Duke of Bedford, but this was several years after its introduction.

*O. INSELEYI* is a lovely Orchid in its better forms, and bears a considerable resemblance to the last named in growth. The flowers are smaller, of varied tints of yellow in the ground colour of the segments, which are not so heavily blotched with brown as those of *O. grande*. The lip has a belt of bright red spots on a golden yellow ground colour—a bright and beautiful combination. There are many named forms, of which *O. I. splendens* is perhaps the best, a large and very highly coloured variety by no means common in cultivation. *O. Inseleyi* is a native of Oaxaca, in Mexico, and is named after the gardener of the gentleman who introduced it in 1839. It was at that time, however, very rare, and afterwards almost lost to cultivation, but about

twenty years ago and at frequent intervals since it has been imported in large quantities.

*O. SCHLEIPERIANUM* is another variable kind, not so large as *O. grande* and a little different in shape. The petals in some varieties are almost wholly yellow; in others there are blotches of orange, more or less clearly defined, on a yellow ground, but all are useful garden Orchids. It first flowered in this country about 1856, having been imported from Costa Rica among other species, and was named by Reichenbach after H. Schleiper, a German Orchid grower. The blossoms of all the species here described have a great likeness one to another, and, as noted above, the plants thrive under similar conditions. If the plants are healthy, no harm is done by leaving the flowers on until they fade, and as they last a long time in full beauty their value in keeping up a late summer and autumn display is obvious.

*Lælia Latona*.—I noticed a very fine plant of this beautiful hybrid in Messrs. Charlesworth's exhibit at the Temple show. It was bearing six flowers, the largest about 5 inches across. *L. Latona* was raised by Messrs. J. Veitch and Sons, who obtained it by crossing *L. cinnabarina* with *L. purpurata*. As may be imagined, it is a highly-coloured flower, the sepals and petals narrow, of a pretty light orange. The labellum is delicately margined with deep orange, its undulate form giving it the appearance of being fringed. The front lobe is crimson-purple, and the base is creamy white. As usual, I think with hybrids having *L. cinnabarina* as one of the parents the influence of this species is very apparent.—R.

*Lælio-Cattleya Lady Wigan*.—This is a remarkably fine hybrid, and the opinion of more than one expert Orchid grower was that it was the best exhibited at the Temple. It is the progeny of *L. purpurata* *Russelliana* and *Cattleya Mossiae* *aurea*, and combines the excellent qualities of its parents in a remarkable degree. An object-lesson as to how these strong-growing hybrids progress was afforded by the plant from Messrs. Charlesworth and Co., of Heaton, Bradford. The oldest of the four pseudo-bulbs was not a quarter the size of the one now flowering, and a young growth just pushing gave even greater promise

The contour of the blossoms rather favoured *L. purpurata*, the sepals and petals, of a rosy white shade, being well thrown back. The lip was large, of almost circular outline in front, with a frilled margin, pink in the ground colour, with veins of deep crimson-purple; the throat rich yellow and lightly spotted. The colours are soft, yet clear and well defined. It is an undoubted acquisition to this rapidly extending genus.

**Dendrobium revolutum.**—In the choice group of Orchids exhibited by Sir Trevor Lawrence at the Temple show was a plant of this species, carrying a good number of flowers upon three out of the four bulbs of which it consisted. In habit as in the manner of flowering it somewhat resembles a weak *D. Dearei*, but apparently the flowers occur singly instead of in racemes. The sepals and petals are short and of the purest white; the lip distinctly three-lobed, and very broad in comparison with the other parts of the flower. In colour it is a pale green, the centre lobe having a median line of clouded white, streaked also with brown. Although it cannot be described as a showy species it is decidedly pretty and free-blooming, and not a mere botanical curiosity.

#### LELIA PURPURATA.

This popular species might be very much better cultivated in many places were a little more thought given to minor details of management. These consist in timely attention to cleaning, repotting, and various other items that are in many cases gone about in a thoughtless manner, yet with a rule-of-thumb kind of precision. Orchid houses, as generally understood, are small stuffy places, little suited to these denizens of the forest. Inexperienced and self-satisfied cultivators say that their plants do very well in the structures provided for them, forgetting, perhaps, the fact that these were in good condition at the start, and a season or two in such places is no criterion. But take the average plants as met with in small houses and the same as seen in large collections of private persons or nurserymen, where a roomy structure is set apart for these and their new congeners, the Cattleyas. In the former case the plants have been so shaded that the growth is poor and far from free-flowering, or else burnt up by having been grown with their heads almost touching the glass when the sun has been shining upon them. Either of these cases contrasts badly with a similar lot of plants grown in a house where there are no such extremes, and where the plants can be arranged with their heads a yard or more from the roof. But while gardeners cannot alter their houses, there are many gardens where the plants may be removed to vinerias, Peach houses or similar places during the summer months with no detriment to the occupants of such structures, and a great advantage both to themselves and the other Orchids left behind. In the winter, when they are, comparatively speaking, at rest, they may be returned to the old quarters, remaining here until growth has again started. Those who have neither large Orchid houses nor any other structures where the plants have plenty of room must do the best they can with the means at disposal, and they will find early morning ventilation of great assistance, by keeping the foliage cool and obviating the necessity of shading until the sun has been shining on the plants a little while. If the sun is allowed to shine on the foliage with the night moisture still about it, the leaves scorch almost as quickly as Vine leaves similarly situated.

*Lælia purpurata* is not so constant in its habits as species like *L. superbiens* and many of the Cattleyas. Often when one is least expecting it comes a free emission of young roots;

often, indeed, when one does not want them, for in many cases they are precursory to the growths starting that would be better kept dormant during the dull winter days. Sometimes they send up a sheath in autumn, and from this push a spike of flower in early summer; at others they keep quiet after blooming, and flower upon the newly-formed pseudo-bulbs. For this reason it is not wise to set any exact season for repotting, but to do this when it is apparent that no check will be given, and that the plant will soon take to the new material. Repotting ought not to be done oftener than is really necessary, and no disturbance of the roots need take place other than what is necessary to remove old or sour material. Large old-established specimens need careful handling and judicious management afterwards, or more harm than good will result. The plants are often so well supplied with roots, that the whole of the old compost and drainage material is firmly enwrapped. Doubtless in most cases there will be a little towards the centre of this ball of roots that is not quite as it should be, but to get at this means breaking many of the outer tiers of healthy roots and thereby endangering the health of the plant. Here let well alone is the safest policy, and by allowing a fair shift and filling up with new material of good quality, the plant goes on again for several years. For compost use good peat and fresh Sphagnum, adding thereto abundance of roughly broken charcoal and crocks. Never let the plants suffer from want of water during the resting season, as this weakens them considerably. While growing they take a very free supply. After disturbance, water carefully and very lightly until new roots are starting, while no overhead sprinkling is allowable during dull or wet weather. Keep the atmosphere well charged with moisture while the growth is active, and never allow insects to obtain a hold on the plants.

There is a large number of named varieties of *L. purpurata*, all more or less distinct from the type and all capital garden Orchids. Its native home is in Santa Catherina, in Brazil, where it appears to have been discovered by a collector in the employ of M. Verschaffelt, of Ghent. This was in 1847, and since then it has been so freely imported by various firms that it is now one of the best known and useful in the family.

#### SCHOMBURGKIA TIBICINIS.

As showing how nearly related are some genera of Orchids, it is difficult to tell the difference at the first glance in the habit of this plant and a *Lælia superbiens*, while the spikes are similarly produced, the flowers also being much alike in structure. There is no difficulty in growing *S. tibicinis*, though with some growers it does not flower very freely. Sometimes this is the result of not ripening the growth thoroughly. What this species delights in during the growing season is a house kept nicely warm, yet with abundance of air left on, this consolidating the growth as it is produced and tending to hard pseudo-bulbs and plenty of flower. The pseudo-bulbs being quite finished, the plants may be stood nearly in the full sun and the water supply reduced by degrees, until in winter hardly any is needed. It would be unwise to dry off badly-ripened plants, for these would at once shrivel, but with those treated as above described it is surprising how little water they take while resting. The growth commences in early summer, and should the compost be in bad condition the plants may then be repotted. Use lumps of peat broken in various sizes, according to the size of the plant, and plenty of Sphagnum Moss, of which latter the roots seem very fond. Add roughly broken char-

coal and crocks and drain the pots thoroughly, protecting the drainage with a little rough Moss. Keep the leads as near the centre of the pot as convenient, and the line of compost may be finished a little above the rims, forming a cone, on which the base of the new bulbs should just rest. The habit of the plant is nearly erect, the stems about 18 inches high when strong, with two or three large ovate, green leaves. The long spikes of flower appear between these, and attain a height of 4 feet and upwards. The flowers are variable in size, those of a good form measuring over 3 inches across, the sepals and petals prettily undulated at the edges, of a bright rosy purple tint, becoming lighter at the base and of a brownish tint at the tips. The column is not enfolded by the lip, but stands exposed, the side lobes of the latter being yellow with streaks of deep purple, the front lobe white, with purple venations and margin. It flowers at various times through the late spring and summer, the blossoms lasting about a fortnight in good condition. It is a native of Mexico and Central America, having been first discovered by Mr. G. Ure-Skinner in Honduras. It first flowered in England in 1840 with Mr. Bateman.

**Epiphronitis Veitchi.**—This quaint yet beautiful little hybrid seems to be nearly always in flower, and we noticed several plants of it recently in Messrs. Veitch's nursery. It partakes most of the habit of its pollen parent, *Epidendrum radicans*, but the glowing tint of the flowers also shows the influence of *Sophronitis*.

**Oncidium pulvinatum.**—This is a beautiful and free-blooming *Oncidium*, the long branching, many-flowered spikes having a fine appearance, and the small branching bits are very useful for cutting. It grows with great freedom in either pots or baskets suspended from the roof, and in this way the blossoms show to great advantage. About equal parts of peat fibre and Sphagnum Moss over good drainage suit it well, and plenty of water must be given while growing.

**Peristeria cerina.**—This is by no means so frequently seen as *P. elata*. The habit is not unlike that of the last named, though not usually so vigorous; the spikes are pendent and crowded with flowers of a deep yellow, dotted about the lip with crimson-purple. During the growing season this Orchid requires the heat of the Cattleya house, and must be very freely watered at the roots. A decided rest must afterwards be allowed or the plants fail to bloom freely. The present is its flowering season.

**Epidendrum vitellinum.**—This I noted in good condition this week, a plant in a 5-inch pot having seven spikes each bearing a large number of the brightly tinted flowers. The bright scarlet and yellow of these blossoms have a fine effect against the deep green foliage, and the length of time the flowers last makes it a most desirable garden species. It is of the easiest culture, growing freely in a mixture of peat and Moss in a cool, moist temperature all the year round. It is a native of various parts of Mexico, and is usually found at a considerable elevation.—R.

**Promenæa stapelioides.**—Although not a showy plant, this little Orchid is worth a place in collections. The habit is that of a very small *Lycaste*, and the pretty blossoms occurring from the sides of the pseudo-bulbs are rather a pretty combination of yellow and purple. It is of fairly easy culture in a nicely-tempered cool and moist house where the light is fairly clear, and where very little sun can reach the rather tender foliage. The plant is very impatient of anything like a close or sour compost, and for this reason repotting is usually necessary at least once in two years.

**Epidendrum Frederici Gulielmi.**—The deep purplish-red blossoms of this species are very attractive, but the plants have rather an ungainly habit. The stems are a yard or more in height, about as thick as one's finger, bearing leaves each about 6 inches in length. The flowers

appear on terminal racemes, and are each about a couple of inches across. Its cultural requirements are a clear light in a warm, moist house where it can have plenty of head room. The roots may be confined to medium-sized pots in a well-drained compost consisting of peat and Moss, and must be kept fairly moist all the year round. It was discovered many years ago, but until recently was somewhat rare.

**Zygopetalum rostratum.**—It must be confessed that this is a difficult plant to keep in health for any length of time. The pseudo-bulbs and leaves are small and extremely apt to be checked by the least deviation from the proper atmosphere or by undue disturbance. Undoubtedly the best way to grow it is on a piece of tree Fern stem, the natural roughness of this material forming a good roothold and obviating the necessity for frequent removal. It is a pretty plant when in bloom, the flowers rosy-purple and white in a pretty and effective contrast. Coming from Demerara, plenty of heat and a very moist atmosphere all the year round suit it, and its habit will not allow of a long dry rest.

## KITCHEN GARDEN.

### SAVING SEEDS.

In your issue of July 3 (p. 3) an article on "Saving Seeds" by "C. C. H." seems to me to want a reply from some practical seedsman. While a long experience has made me familiar with the difficulties of saving choice stocks of vegetable seeds, I cannot allow that "nurserymen cannot afford to rogue their stocks too rigidly." All seedsman of any note do so most carefully, and, speaking for my firm, we find buyers perfectly willing to pay a fair price for selected stocks—i.e., dependable selections—and some of these have been in our hands for thirty or forty years, and are perfectly true to type, while we readily seize on any improvement that can be effected, and we are convinced others do the same. Then you may say, "Why are there so many inferior stocks in the country?" Simply because the competition in the seed trade, wholesale and retail, is so keen, and there are a lot of retail dealers—chemists, grocers, ironmongers, &c.—who do not "know" the business, but buy the cheapest, and retail so as to cut one another in value. The wholesale people must meet this demand, and as labour and rents are heavy in Britain, many seeds are sent abroad to be grown, and in many (not all) cases that care and attention are not given to isolate crops that those who have large holdings in Britain can give. Again, the growth of allotments makes the business more difficult, as it is not unusual to see Cales, Cabbages, Sprouts, &c., all flowering at the same time. The burden of this is, if the public will pay a fair price they can command a genuine article, and far better than any home-saved stocks as a whole.—GEORGE BUNYARD.

The notes on the saving of vegetable seeds by "C. C. H." (p. 3) were interesting as well as instructive reading, as pointing out the great uncertainties of the work unless the utmost care in preventing insect interference is given. I have only attempted seed-saving on a small scale, preferring to leave such in the hands of those having large experience and facilities for carrying it out successfully. An experience gained some few years since, which exactly coincides with the incident given by "C. C. H.," made me resolve to leave seed-saving of the Brassica family alone. What I purposed saving a seed-stock from in that case was a particularly good Broccoli, and having no other of the Cabbage family in bloom in the garden at the same time, I did not deem it needful to protect it from insects. But the mistake made was only too apparent. When the produce should have given first-class marketable Broccoli the following year, it could only be used in the same manner as Chou de Burghley. The mischief must have been done by bees carrying pollen from some distant cottage garden or allotment,

owners of which often save seeds of some favourite winter greens. Had I taken the precaution to have enclosed the plants during the flowering period in muslin or some similar insect-resisting material, all would have been well, no doubt. The lesson, however, made a lasting impression on my memory, and I would strongly advise anyone contemplating the growth of seeds in a private garden to protect the plants from being fertilised by foreign pollen, carried, it may be, long distances by bees. "C. C. H." does not say that his friend took the trouble to exclude bees, even when the lodge-keepers were entrusted with their growth, so as to isolate the several kinds under treatment, although the case of spoliation which happened with the nurseryman proves conclusively that some such course is necessary. Onions, although much frequented by bees while in flower, do not seem so easily affected as the Brassica family, for having saved my own seeds of this vegetable, and in two or three varieties, I have found them come quite true to character without any attempt at the exclusion of bees. It is not often that in purchased seeds one gets this loss of character through accidental cross-fertilisation, but it has actually happened with me this summer, the variety ordered being the invaluable late winter green, Asparagus or Buda Kale. I always sow this on the plot where it is intended to mature in the same manner as one does Turnips, as it is not so readily transplanted as other varieties, and I do not in any case put in the seeds until June. I have had to destroy almost the whole of the plants thus raised this year, there being but very few true ones to be found, the majority favouring the Couve Tronchuda in appearance more than anything else. I have sown fresh seed again, which, although late, may yet be in time to be useful in late spring next year. This seed, I should have said, was obtained locally, but was grown in the eastern counties.—W. S., *Wills*.

**Early Cabbage.**—There have been many complaints regarding the lateness and bad hearting of Cabbage, but I have not much reason to complain—no "bolting" nor losses of any kind have been sustained out of five or six sorts. Earliest of all has been the favourite; close hearting, few outside leaves, fine quality, and earliness are its properties. I believe in well-manured ground for Cabbage, with a free root run on deeply dug or trenched ground. On poor soils where the roots of Cabbage cannot work freely, running to seed is greatly encouraged. Rosette Colewort is not so much grown as it should be; it is one of the hardiest of Brassicas, and can be had (by successive planting) from autumn till late in the spring. In July and early in August planting may begin. I have a letter from a friend in Staffordshire who says this Colewort was never seen injured by frost in that district, where it has so often been grown with great success. No test as to hardiness of any plant (grown in the open during winter) can be greater than here. On cold heavy soil below the level of the river Forth, this neat little Colewort stands uninjured.—M. TEMPLE, *Carron, N.B.*

**Early and late Peas.**—After growing Chelsea Gem for several years, it holds its own against all comers as an abundant bearer of good quality, and is ready for use as early as any I have tried. Some peas of reputed earliness are too small in pod and too dumpty in form for cooks to be bothered with them. I have always favoured well-tilled ground for Peas; they are thus protected from drought, and during wet seasons they do not get water-logged. It is a good plan, where such can be afforded, to cover peas, when sown in drills, with decayed vegetable refuse, or a mixture of decayed manure and waste soil of any kind. Seldom have I seen drought or mildew attack Peas with a covering—say, 3 inches thick—of such material over them. Even in the south of England they do not often suffer. Watering often does more harm than good to the crop, as by continuous surface dribblings the soil is battered hard and the Pea roots severely checked. With

all the excellent additions to the lists of Peas, the most popular among old sorts Dr. McLean, Champion of England, Ne Plus Ultra, Sangster's No. 1, and Dickson's Favourite—are often seen among the winning lots at exhibitions.—M. TEMPLE, *Carron, N.B.*

**Lettuce running to seed.**—In few seasons have Lettuces bolted so badly as this. The Spring Cos varieties, owing to the drought, bolted badly, and since then the Cabbage varieties are worse, as, no matter what care is taken in watering in our light soil, they run wholesale. It is not a question of variety, as all are alike, and even on a cool north border transplanted plants are not reliable. Doubtless it is caused by the sudden changes of weather. I am aware there is a remedy, but it is not always convenient to sow Lettuce to stand without transplanting, and I notice this season, even with sown plants, they run worse than I have known them in previous years. I sow every three weeks, from May to the end of July. Some of your readers may have had similar failures and have found out a remedy. I have in previous seasons depended upon sown plants for mid-summer and July use, but this season they have failed, the Cabbage varieties being the worst.—S. H. B.

**Late Broccoli.**—I have been much interested in reading recent notes which have appeared in THE GARDEN on this subject, as I am rather a large grower of late Broccoli. The kinds mentioned by your correspondents have not been tried here, and I rely entirely on Maincrop, Dickson's Late May, and Model for late supply. The seed of these three kinds is sown in the second week in May each year, and the plants are generally set out on a piece of ground just cleared of a crop of second early Peas and early Cauliflowers. The ground receives no preparation beyond hoeing to free the surface of weeds, and the soil being firm, the plants make but medium growth. In the month of October the plants are all heeled over towards the north, and the percentage of losses from severe frost during the winter is but small. The three kinds named afford an unbroken supply of good heads from the commencement of May until the middle of June, by which time the earliest Cauliflowers are ready for cutting. Model is the last to come into use and, strange as it may seem, this variety is preferred to all others, Cauliflowers included, for pickling. Being but a medium and very dwarf grower, the plants of Model may be set out a trifle closer than would be admissible with the more robust-growing kinds—a great desideratum where space is limited.—A. W.

**Medium-sized Peas.**—Many people object to extra large Peas, and as the majority of the new varieties are of that type, one has to go back to older sorts. I am growing Fillbasket this season, and shall do so in future—for the dining-room, few varieties, all points considered, surpassing it. Its dark green colour and sweet flavour are strong recommendations. Further, its height is most convenient, and its cropping qualities are wonderful. Previous to the large-podded Peas being introduced I used to grow Fillbasket in a shallow trench, mulching and feeding when bearing a crop; and the handsome curved pods looked well dished up for exhibition. I wonder this old Pea has not been more generally grown for market, as I am certain it would prove most remunerative. Another, and a most excellent, medium-sized variety, and one which should be grown in every garden on account of its productiveness and general good quality, is Criterion. Its size and deep green colour remind one strongly of Ne Plus Ultra, the usual height of the haulm being from 4 feet to 5 feet. Criterion is a capital dry weather Pea, and grows well in light, porous soil. Gardeners who have tried it have made it a rule to include it afterwards in their seed list. A Pea called Nottingham Wonder, better known in the midlands than elsewhere, is another of the medium-sized varieties. The haulm is very vigorous, reminding one of that of Antocrat, some 4 feet high, and covered with pods in all

tages, the colour excellent and flavour good. More mid-season medium-sized Peas exist, but they are none too plentiful. The three above named will please all who may try them.—J. C.

#### QUALITY IN PEAS.

Of late years there has been better quality in Peas, especially in early or second early varieties, and with good quality we have got a dwarf habit with large pods. For some years past I have grown Peas largely, and have endeavoured to get those which are able to resist our variable climate. Most growers will agree with me when I state Peas are hardier than many persons think. Peas not raised in heat and always exposed have not suffered from frost when the tops are a few inches out of the soil. I am aware in cold, wet soil the seeds suffer, and this is a point we must not overlook, and with the newer types with Marrow blood means must be taken to assist rapid germination. I am not in favour of autumn sowing. A Pea—Springtide—noted in these pages last week (p. 4) is a very early variety, and far in advance of the smaller kinds. In this note I have no desire to condemn old varieties or extol new ones, but I am an advocate for progress, and with no vegetables have there been greater strides than with Peas. This is of great benefit to those who have limited space and who need to grow their crops quickly. The best quality Peas among the newer types are those which run from 2 feet to 4 feet, mostly between those heights, and as some of these are equal in size of pod to the Duke of Albany, there is a great advance. I do not look upon the Duke of Albany as a good quality Pea; had it not been for its exhibition value it would never have found the favour it did. I am not a lover of any Pea which gives its crop on the top of the haulm all at one time, and if not gathered quickly it is of poor quality. What I term a good Pea keeps up a succession of pods. The best Peas are those which yield well from the base, and as many of the newer varieties do this and may be termed continuous croppers, there is a great gain to the grower, who, if he sows thinly and feeds freely, can get a much heavier crop than from the small white or blue early Peas, or the very dwarf forms only a few inches above the soil. These latter may have been useful before these later introductions, but, like the many selected earlies of Early Sunrise type, they are out of date if quality is considered. I noted recently in these pages a well-known authority on Peas had scant praise for some of these first earlies, as they are termed, and I certainly think where quality is considered they are out of place. Much time and labour of late years have been bestowed upon garden Peas, and with size a dwarf habit is secured. There is now no need to grow 6-foot or 7-foot Peas even for midseason or late crops; the newer kinds are equally prolific, with a dwarf habit.

S. M.

**Onions in 1897.**—It was recently remarked in THE GARDEN that Onion crops sown in spring were this season exceptionally free from maggot and disease of all kinds, and promised to be heavy and good. I can corroborate this so far as my own neighbourhood is concerned, many plots on light, shallow soils, where great difficulty in securing even half a crop has usually been experienced, looking just now very healthy, with no blanks in them. The fact that there was much more moisture in the ground from autumn and winter rains, together with the unusually cool spring, is put down generally as the chief cause of this improved state of things, the general belief being that if the plants are able to grow to a certain size without molestation to the stage—in fact, when they commence to bulb—the Onion maggot will not molest them; at any rate, to any great extent. That this idea is perfectly correct is, I think, plainly proved by the fact that those gardeners who have of late years sown their seed in boxes in February, hardened the plants off in frames and planted out early, have had no trouble

in securing good all-round crops of Onions. One or two gardeners I know raise and grow the whole of their spring crop in this way, ignoring the extra labour—which, indeed, is not so great as some might imagine, as seedlings raised in a genial temperature give very little trouble, beyond a sprinkling to keep them moist, till transplanting time arrives, the ground being prepared some time previous to give it a chance to settle. A handy man will soon plant out a few thousand seedlings. Where this plan is adopted, the labour of thinning out—as is the case when seed is sown in the ordinary way—is avoided, and, all things considered, there is little difference in the long run so far as labour is concerned. On shallow, hot soils this system is undoubtedly the best.—J. CRAWFORD.

#### FLOWER GARDEN.

##### NARCISSUS MME. DE GRAAFF.

I look upon Mme. de Graaff as one of the best of new Narcissi. There may be others more distinct and striking in colour, but its perfect form, robust constitution and wonderfully free-blooming habit will keep it in the front rank of the choicest Daffodils when many of its competitors are forgotten. Besides the good qualities above mentioned, this variety increases rapidly and grows almost as strongly as Emperor or Empress. The segments of the perianth are pure white, of good form and firm texture. The trumpet is pale sulphur and has a peculiar appearance, unlike that of any other Daffodil. The brim of the trumpet is rolled back, which gives the bloom a distinct character. If the flowers are cut in a young state and opened indoors they will be almost perfectly white. When this Daffodil can be bought at a cheaper rate than at present obtains, it will no doubt be very freely planted.

J. D. PEARSON.

Chilwell Nurseries, Notts.

**Lychnis chalconica.**—It is not easy to surpass the handsome heads of brilliant scarlet flowers this plant is capable of producing when well grown in deep rich soil. It is at such times one of the most striking of hardy perennials, and one of the easiest to grow or increase by seeds.

**Campanula turbinata alba.**—A most useful variety early in July that may be planted in rock garden or border. The habit is very neat and somewhat dwarfer than in *C. carpatica* or its white variety, while it usually precedes these latter in the time of flowering. But even if they came together they are sufficiently distinct to be useful.

**Tufted Pansy Violetta.**—This excellent variety is now in fine form. Small pieces which were propagated very late last season, and which also looked very insignificant and unpromising early in the present season, are now all that one could well wish for. The growth has lately been very rapid, and they have already filled up all the space between the plants. A careful mulching early in June was much appreciated. This pretty little rayless white variety is being used very freely in the gardens at Regent's Park, and appears to lend additional charm to several long narrow borders of Fuchsias as a carpeting plant. The white is very pure, and this together with a splash of yellow on the lower petal makes the display more effective. It is also sweetly scented.

**Gladiolus The Bride planted out.**—Reference was made a few weeks ago to the value of this chaste Gladiolus in summer, the writer stating that it did well planted out in open borders. I used to think this might be done in the south of England, but was quite surprised a few days ago to see a truly magnificent lot in a Newark florist's window just cut from the open nursery beds. Thousands were planted, and nearly all of them

have grown and flowered well. The position is a sunny one and the ground somewhat sandy and well drained. It seems to dislike cold and wet, therefore the season may have suited it; artificial waterings, of course, having been given, the rainfall in this district having been small. The florist in question finds that the flower-spikes open all the way up, even though half of the blooms may only be in the bud state when cut.—J. C.

##### PRIMULA TRAILLI.

In your last issue Mr. R. Dean contributes a note on this plant, criticising those of us upon the floral committee of the Royal Horticultural Society who thought that the plant sent up by Mr. G. F. Wilson was entitled to rank as a new species, and not merely as a variety of *P. involucreta*. Allow me to point out—for the question involved is of constant recurrence and of general interest—what I regard as the fundamental fallacy of his reasoning. He evidently assumes—as I think he will admit—that the character and extent of those differences which entitle to specific as distinct from varietal rank are matters not of individual opinion merely, but of recognised scientific precision and certainty. I am under the impression that that view was long ago exploded among plant physiologists. If Mr. Dean can show me to be wrong, and can indicate a finer scientific principle, widely recognised, by which it shall be decided whether a new form is to be deemed a new species or merely a variety of an existing one, he will both surprise and oblige me. He and I see a plant differing structurally more or less from those hitherto tabulated. He and I answer the question, "species or variety?" if we answer it at all, by making up our minds whether the differences are solid enough to justify the creation of a new species. And our minds may be differently made up without either of us being able properly to claim that for any assignable reason he is right and the other wrong. The case is not altered by the fact that certain characteristics—for instance, colour of flower—are generally admitted not to entitle to specific rank. Nor is it altered by the fact that more persons agree with me than with him on any such question. What is no doubt wanted, and very badly wanted, is the recognition of some standard authority whose decisions in such matters—albeit necessarily arbitrary—shall, as matter of convenience, be accepted by all. But those most fit for the office (*e.g.*, the Kew authorities), would, I take it, be the first to insist on the necessarily arbitrary character of their decisions, in regard, that is, to new plants.—H. SELFE-LEONARD, *Guildford*.

—I read Mr. Jenkins's note at p. 36 with the greater interest knowing that he has had considerable experience with herbaceous and alpine plants. The drooping of the plant exhibited was caused only by want of water, and by the Drill Hall being more than usually hot and stuffy, as it seemed to me, though I have not been able to attend there often lately. The flowers soon held up their heads on the plant being watered when it got home. I presume *P. Trailli* was not mentioned at the *Primula* conference, from being unknown in this country. If the plants raised by "R. H. B." last year from seed sent him by Dr. Watt were no finer than those we had then from seed sent by my botanist friend (not Dr. Watt), I do not wonder that Dr. Watt, if familiar with the *Primrose* in its proper form, should have said that "they had nothing in common with his *P. Trailli*, which was a much larger and handsomer species." This last description would exactly apply to my plants of this year. My experience agrees with "R. H. B.'s," as the plants after blooming and ripening seed are flowering again, but with weaker flowering spikes. It is certainly a more free-flowering *Primrose*, and though, of course, it cannot be compared with the more showy members of its family, such as *P. japonica*, it has a quiet beauty of its own, which, combined with its very sweet scent, will, I think, make it a favourite, at least with amateurs.—GEORGE F. WILSON.

*Narcissus Mme. de Graaf.* From a photograph by Mr. J. D. Pearson, Chilwell, Notts.

## SOME USEFUL ANNUALS.

ALTHOUGH many flower gardens are now nearly filled with perennials, and things of a transitory nature are but sparingly used, there are some annuals so useful for cutting, and also some that make such a bright and, for the one season, such an enduring display, that one can hardly dispense with them. There is a tendency sometimes to think that whilst perennials must be well provided for, annuals of any description can be allowed to shift for themselves; but if we remember that the majority are vigorous both in root and foliage, and will flower under favourable conditions for nearly four months, it is reasonable to conclude that they require a very considerable amount of sustenance. *Gypsophila elegans* comes considerably earlier than the perennial form even under a north wall, and from that site I started cutting in quantity the last week in June. I like to make two sowings of this, the one in the open in the site above named, where the plants grow strongly and throw some fine heads of flower, the other about a month earlier under cover, from whence the plants are removed to well-prepared patches on the open border, and where they come early into flower if care is taken in the removal. Its chief value lies in the light and graceful panicles available for cutting early in the season. It is not a long-enduring annual, and I should not recommend its use for prominent places in the flower garden. Iceland Poppies pay for early and thin sowing under cover. They should be handled carefully in the pricking out, so as to disturb the roots as little as possible, and when the plants are ready for the open border they should have a thorough soaking and be lifted with a nice mass of roots. It is not advisable to use any members of the Poppy family in vases that are only filled bi-weekly, but they come in very useful for dinner-table work or anything of a similar nature where they are only needed for the day or evening, as the case may be. The fact that this particular variety is, from a flowering standpoint, of long duration is sufficient to lead to the conclusion that it wants a bit of good soil, not necessarily rich, but of the quality essential to produce good vegetables. Seedling Carnations are just now among the best for cutting. They are from seed that I did not obtain until rather late in 1896, and the plants consequently only threw one, or at most two flower-stems last season. They made, however, a fine lot of grass, and looked so promising that I decided to let them remain, with the result that they all came safely through the winter and are now a mass of flower, some of the varieties being very good and all as yet non-splitters, the colours out at present being scarlet, rose, and primrose selfs, and flaked in great variety. It is worth noting that while among the named varieties, over which a lot of trouble was taken in the way of layering, lifting, and replanting, there was so much loss, the seedlings should have proved perfectly hardy. It is essential when dealing with annuals to cater for the popular taste, and the three already mentioned are great favourites; so, too, are Gaillardias. Given the most careful attention and early sowing, the annual forms do not flower so early as the perennials, but when they do come there is a very gorgeous display, only rivalled, I think, by the best strains of *Salpiglossis*. They stand very well when cut.

*Linum grandiflorum* supplies at the present time the colour to be found later in masses of scarlet Begonias and Pelargoniums. Given good treatment, it is a long-enduring annual, and one of the best for filling portions of borders in outlying parts of the garden. A liberal dose of manure, deep tith, and early thinning to a foot each way are conditions essential to successful culture. Although Petunias do not come under the heading of those things useful for cutting, they rank together with Verbenas, as about the best of the *bona fide* bedding annuals, possessing the merit of being easily grown, coming quickly into flower, and lasting out well to the end of the season. Very great improvement has been effected within the last few years in Petunias both in the way of

introductions and in hybridising. I measured lately some flowers of Carter's Empress quite 5 inches across, and the colours vary from a slightly shaded white to an intense purple, with a very richly marked throat. The growth being proportionately strong, it is advisable if the plants are pegged to get them down as early as possible; if allowed to make considerable headway, it is difficult to perform the operation without snapping them at the collar. I was rather amused the other day when making a tour of inspection of cottage gardens to meet more than once with the remark that the flowering season of the Sweet Peas was very brief, coupled with the information that the growers liked to save their own seed—a fact, by the way, plainly evident from the countless numbers of seed-pods that were hanging. If this is allowed to go too far it is difficult to pull the plants round, but if the foliage is still fairly green and there are indications of growth, it may be effected by the removal of all seed-pods, a thick mulch of good manure, and a thorough soaking with water. There is no mistaking the fact that Sweet Peas amply repay a little careful attention. In the newer varieties, with an improvement in the flower come a greater vigour and length of stalk, making them of additional value for cutting. E. B. C.

**Tufted Pansy Ardwell Gem** appears to be in excellent condition just now. Small plants which were put out quite late this season are growing freely. Although given a distance between each plant of 15 inches, the dwarf creeping form of growth has already filled up the intervening space, and the plants are flowering most profusely. It is an ideal sort for the flower garden, and although somewhat old, yet compares favourably with many of the newer introductions. —H. N.

**Tufted Pansy Princess Louise** is now at its best, the cooler evenings of the last week benefitting the plants considerably. This only goes to prove that this variety is one very partial to cooler weather, and this probably accounts for the plants looking so well during the early part of August, 1896, when it was credited with a first-class certificate by the Viola conference committee. The form of growth is compact and tufted, the constitution robust, and the flowers of medium size and good form. There is no trace of rays in the flowers at the present time, and the plants are literally covered with charming blossoms. —D. B. C.

**Tufted Pansy Florizel.**—This fine variety should be grown by all who are interested in these useful plants. The flowers are of large size, very neat and pretty. The colour varies slightly under the very trying climatic conditions which prevail in the south of England. In cooler quarters and where partial shade can be given the colour may be described as a very pretty bluish-lilac. Very hot sunshine bleaches the flowers, so that the colour is less pronounced. This slight defect, however, is not sufficient to deter anyone from taking this variety in hand, as it is deserving of one of the foremost positions in every selection. The blossoms are rayless, with a neat yellow eye. The growth is beautifully tufted, and the constitution is also good. —D. B. C.

**Lilium Roezli.**—This rare Lily is just now flowering at Kew, where, in a bed at the back of the Palm house, it seems to be quite at home. It is nearly related to *L. pardalinum*, and might perhaps be regarded as a variety thereof, but in colour at least it is quite distinct from any of the forms of *L. pardalinum* that we have in our gardens. In *L. Roezli* the leaves are long and narrow, and though occasionally borne in whorls, as in many of the Martagon section to which it belongs, in most instances the whorls are broken up and the leaves scattered in an irregular manner around the stem. The flowers are about the size of those of *L. pardalinum*, with the segments much reflexed. The colour is a bright yellow, the central portion dotted more or less with small purplish brown spots. They are borne in a

somewhat pyramidal-shaped raceme, each bloom being supported on a long stalk. This Lily is a native of California, from whence it was introduced in 1871 by the collector whose name it bears, but it has always been scarce, and at times there has been a certain amount of confusion with regard to it. The bulbs of this are rhizomatous, a feature limited to those species that are natives of North America. A soil composed of at least a fair amount of vegetable matter and a moderately moist, though not water-logged, position will no doubt suit it best.—H. P.

## PLANTS FOR A BACKGROUND.

IN old-fashioned gardens where the planting is carried out as far as possible on natural lines I always think suitable backgrounds play a most important part. Doubtless in the majority of gardens many beds are so situated that there is nothing in the way of tree or shrub life near them, but if they can be placed in positions where this is available, the effect of many flowers is considerably enhanced. This is very noticeable in the case of walls forming a background to borders and that are comparatively bare of foliage. Until the clothing process is completed, one may tax his ingenuity to plant such borders effectively, but the task is easy when the wall is clothed from top to bottom with a mass of greenery. Such a wall and border about 100 yards long are close at hand, the one covered with Wistaria and the other nearly furnished with perennials of various heights. Any available spaces I always fill in with Cactus Dahlias, Cannas, annual miniature Sunflowers, and the like, with the full assurance that they will show to advantage against the leafy background. Another old wall against which were planted in bygone days many things scarcely *bona fide* wall plants, as the Judas Tree, the variegated Buckthorn, *Escallonia macrantha*, the single and double forms of *Deutzia crenata*, and others have served as a background to a small Rose garden, big old stuff of the vigorous pillar varieties being planted comparatively close up, and the different sections worked down to a group of Polyanthas immediately in front. It was not, however, a background of wall, whether clothed or otherwise, that occurred to my mind when starting these notes, but rather the utilisation, more or less, in the open of tree and shrub life as a finish to the groups of flowering plants, and the idea may be illustrated by quoting a few examples. A bed of scarlet Cannas, well grown both in the matter of flower and foliage, may look very well right out in the open, but certainly not so well as when placed in some cosy nook backed and flanked by some light-foliaged tree or shrub. Doubtless many readers of THE GARDEN may remember the interesting notes on flower garden topics penned by the late Mr. Wildsmith and his enthusiasm over his hedge of Lawson's Cypress, with Cactus Dahlias growing in front of and practically amongst it. I thought of this the other day when noting a planting of Fire King and Panthea Dahlias partly between and partly in front of a considerable number of cut-back stuff of *Ailantus glandulosa*, the latter one of the very best hardy foliaged plants we have. Take again the case of the tree-like shrub *Prunus Pissardi*; how admirably *Galtonia candicans*, the Sweet Tobacco and big plants of the white *Marguerite* show against its bright-coloured foliage, but I think even a better combination is furnished by the *Prunus* in the background faced by *Purity Starwort*, and the latter in its turn by the large-flowered form of *Amellus*. Some of the perennial Sunflowers also show well against this shrub, notably *Helenium nudiflorum*. Very few gardens possess occasional plants of *Magnolia macrophylla*. I think, however, this big-leaved tree might be planted with advantage given a sheltered nook, because where it does well it is absolutely unique as a background for tall-flowering plants combining hardiness with tropical foliage. Where flowering or fine-leaved shrubs exist at the back of borders, the planting in front of them should always be carried out with the view to secure

effective and pleasing contrasts, and this, fortunately, can be done well with the aid of hardy things without troubling with plants that have to be renewed annually. Instances of this are to be found in clumps of the large-flowered *Syringa* faced with *Delphiniums*, and later the double *Deutzia crenata* and some of the earlier *Phloxes*. As a matter of fact, however, all deciduous shrubs that are left practically free and not annually mutilated with a pair of shears act, quite apart from their flowers, as admirable backgrounds to the taller perennials, especially if the latter are so planted that the flower-stems or heads, as the case may be, show up naturally amongst the foliage of the shrubs. In the case of a background of conifers, especially if the latter are of stiff, formal habit, the selection of flowers to face them is not so easy; preference should be given to those of irregular habit, such, for instance, as *Delphiniums* or *Anchusa italica*, as opposed to dense heads that keep about the same level. The same principle applies to all hardy plant borders that are of sufficient width to allow of the planting of some three or four species across the same. The relief of a

deep line of the *Lobelias* to the 'white-leaved' *Veronica*. The flower of the latter plant, by the way, affords as pleasing a contrast to its foliage as is furnished by *Carnations* of the crimson *Clove*, *Mephisto* and *Uriah Pike* types. E. B. C.

AUTUMN CROCUSES.

IN too many gardens the *Crocus* is only known as a flower of spring; not as one which will also light up the garden when other dwarf flowers are few and far between, and taller plants dreary-looking and forlorn. This should not

autumn-flowering *Croci* from those which bloom in winter. They merge almost imperceptibly into each other, but only those are named here which usually bloom from August until the beginning of December, when what, for convenience' sake, are called the winter-flowering species come into flower. Even in these late days, though little sun appears to persuade the flowers to open, the coloured cones are pleasing.

Of the various species and varieties of these *Croci* as now offered for sale, there are four species which no one should be without. Others ought to be added, but *C. iridiflorus* of Maw (byzantinus of Baker), *C. pulchellus*, *C. speciosus*, and *C. zonatus* should not be omitted when purchasing. I have named them alphabetically; each is so beautiful that it seems invidious to arrange them any other way. They have also the merit (to some it will appear a fault) of being moderate in price, the first being slightly more expensive than the others.

*CROCUS IRIDIFLORUS*.—This name, for what appears good reasons, was given by Mr. George Maw, who follows Heuffel, although Mr. Baker prefers the prior name of *byzantinus*, used by Parkinson, in accordance with the practice of the present day. The appearance of the flower is so like that of the *Iris* that one cannot but regret that the name of *iridiflorus* has not been adopted, especially as that of *byzantinus*, Mr. Maw says, implies an error as to its geographical distribution, its habitats being the Banat and Transylvania. The outer segments are a clear rich purple, the inner being much smaller and pale lilac in colour. The stigmata are purple and longer than the orange-coloured anther, the filament being lilac. The flower of this species is very large, and a clump presents a very beautiful appearance when in flower in September and October. I observe a variety, offered as major, in some catalogues. I have not seen this, but it is said to be much larger than the type; if so, it must be fine indeed. The next of the four is

*C. PULCHELLUS*, which is an exquisite little *Crocus* differing entirely in appearance from the foregoing and charming us more by its refinement than its brilliancy. This was sent to me from the Bithynian Olympus, where it is abundant. The corms from that mountain produced flowers varying considerably in colour, size, and form. The typical colour of the flower is described as bright bluish lilac, with the outside of the outer segments self-coloured, the inner segments being marked with five narrow dark purple lines. There is also a white variety. The flowers here, as already said, vary much, ranging from almost white to the bluish lilac, which is the typical colour. *C. pulchellus* flowers very freely here from September onward, and is increasing quickly by young corms and by seeds, which are very freely produced. Besides occurring on Mount Olympus, it is said to be plentiful in the thickets bordering the Bosphorus. The third species—

*C. SPECIOSUS*—is, perhaps, the best known of the four. This *Crocus* is very distinct in appearance from the foregoing, and from its colouring and the size of its flowers is remarkably effective when grown in quantity. It is very moderate in price, and may thus be planted in considerable numbers. It is also an early bloomer, flowering with me generally early in September, but very rarely in the end of August. The flowers, which are large and open widely to the sun, are of a colour variously described as bluish violet, bluish purple and bright lilac. Possibly the second most nearly approaches the shade. The segments are prettily marked with dark purple veins. These, with the bright orange anthers and stigmata, add much to the effect and beauty of the flowers. It is widely spread in a wild state, occurring in North Persia, Georgia, the Caucasus, the Crimea, Hungary and Transylvania. Although the best known, and said by Mr. George Maw to be a common garden plant, there are thousands of gardens where it is unknown, and where it would be a cherished flower planted in the grass, the

Autumn Crocuses.

heavy group by one of light, graceful habit adds greatly to the effectiveness of the whole, and should be quite as much a matter for consideration at planting time as the judicious arrangement of different colours. In this latter matter what wonderful contrasts can be managed with *bona fide* hardy plants, quite as good, I fancy, if this be the special aim as were ever brought about by the most lavish use of tender subjects. I have noted, for instance, within the last few days Soapdragons of various heights in an endless variety of shades, from almost a pure white to an intense maroon; tufted Pansies very similar, Pentstemons running rather more on the one shade, but still very varied, and fine-foliaged plants so far as the present time is concerned, from the

be, for, given a warm and sunny spot, the autumn-flowering species will give the greatest pleasure. It is true we have not a satisfactory yellow-flowered *Crocus* for autumn, but we have blues, lilacs, purples and whites, with zones, stripes, and pencillings of various kinds to add to their beauty. More refined in every way than the *Colchicums* or *Meadow Saffrons*, so often called "Autumn Crocuses," they have charms and graces to please the most fastidious and exacting admirer of garden flowers. It is difficult to draw a line which will separate the

borders, or the rock garden. The newer *C. speciosus* Aitchisoni is an exceedingly fine variety, eclipsing in size the type. Generally speaking, there does not seem to be much variation in *C. speciosus*, but from seeds purchased I observe a tendency to variety of shade of colour. It produces seeds very seldom here. Of the last of the four—

*C. ZONATUS*—it is hardly possible to speak too highly. It is an exquisite little *Crocus*, with rosy lilac flowers, with an orange-scarlet base. It flowers early—from the middle of September in good positions—and is so cheap now that it ought to be freely planted. It comes from Cilicia, where it was discovered in 1855. This beautiful little member of the genus requires little or no care, and will give much pleasure to its owner from year to year.

A desire to speak at greater length of four fine *Crocuses* such as these must necessarily reduce the space available for the numerous species not yet mentioned. Among the white autumn *Croci* we have *Boryi*; *cancellatus*, which has a purple base, and of which there are several varieties, including some with lilac flowers; *hadriaticus*, with its variety *chrysolobonius*, which has a yellow throat; and *ochroleucus*, a creamy white flower with orange base. I find that *hadriaticus* is the most satisfactory of these here, *ochroleucus* being a little late and needing a sheltered place.

*C. ASTURICUS*, of which there are some good varieties, varying from purple to lilac, is also a good *Crocus*, but I prefer the equally moderately-priced

*C. LONGIFLORUS*, a pretty, free-blooming species from South Italy, with soft rose-lilac flowers.

*C. CLUSI* is a good *Crocus* with comparatively large flowers and quite hardy here, although it increases rather slowly with me. The rare

*C. VALLICOLA* is difficult to establish and is rather disappointing. It is thin in the segments, and the flowers are neither pure white nor a good cream colour. It has the reputation of being among the earliest to flower, but I do not find this the case. A coveted species is

*C. SCHAROJANI*, which, did it thrive, would give us the yellow species we desire among the autumnal *Crocuses*. I have had this, or what passed for it, but it was among the few failures I have had among these flowers. Coming from an altitude of 7000 feet, it should grow with us in Great Britain, but one must wait for fresh importations, as, so far as I know, it is not now in the market.

*C. NUDIFLORUS* is a fairly well-known species in some districts, and is said to be naturalised near Nottingham. It has bluish purple flowers.

*C. SALZMANNI* is a cheap *Crocus*, also with lilac flowers and dark-coloured feathering.

*C. MEDIUS* is purple-lilac, and  
*C. TOURNEFORTI* has delicately tinted rose-lilac flowers. The old Saffron *Crocus*—

*C. SATIVUS*—is fastidious in its ways, and in many gardens—this among the number—refuses to bloom after the first year. Possibly lifting annually and drying off might remedy this, but with so many other good *Crocuses* it is hardly worth while to trouble doing this. Its variety *C. s. Pallasi*, with lilac flowers, flowers annually here, but *C. s. Elwesi*, which has been in my garden for some years, never blooms. The variety *Hausknechti* is said to be free-flowering, but it has not been tried here.

There are a few other species named in Mr. George Maw's great monograph which I have not yet grown, but enough has been already said to show to some extent the variety at command. It now only remains to say a few words as to their

#### CULTIVATION.

Their great requirements in our climate are sun, shelter and a rather light soil. The two first are of primary importance for flowers coming when sunlight is becoming scarce and

when the winds of autumn are playing havoc with the flowers. Sheltered sunny places on the grass, cosy corners in the rock garden, or borders sheltered from high winds will suit them well. If the grower care to be at the trouble, he will find that a bell-glass or sheet of glass overhead some choice *Crocus* will give him the enjoyment he seeks oftentimes when without it the flower would remain closed. Plant with the crown of the corn about 2 inches deep. Another golden rule is to plant as early as the corns can be obtained. If flowers are wanted this year, this must be attended to, and by doing so there is more probability of success in the future as well. With a few clumps of such flowers as these showing among the grass or through some mossy Saxifrage or other surface-rooting plant, the shortening days need be no longer unrelieved by the brightness of dwarfier flowers than the *Asters* and their few companions of tall growth, which form the sole interest of many gardens at these times. S. ARNOTT.

*Carsethorn, by Dumfries, N.B.*

*Coreopsis grandiflora superba*.—For the flower garden this is certainly one of the neatest and most elegant of hardy plants now in bloom. The plant is worth more than passing notice, for it is rare that we find such profuse flowering in combination with so acceptable a colour. Its remarkable freedom of flowering renders it specially suitable for large beds, and well grown in such its blossoms—a beautiful shade of clear yellow—may any day be counted by the hundred. In this way a profusion of its handsome blossoms is kept up for weeks together. For vase decoration the thin, wiry stems are excellent in every way, and little wonder the plant finds such favour with the florist generally.

*Omphalodes Luciliae*.—Where this plant thrives it is one of the most exquisite of all alpine, yet one always more or less difficult to keep, and still more difficult to increase to any extent. Slugs are particularly fond of its leaves, and will quickly clear off every vestige of growth. In no garden of my acquaintance has this plant proved such a complete success as it did in that of the late Mr. Jas. Atkins, of Painswick, for here the plant not only grew freely, but it also rambled about, quite a large piece being practically clothed with the plant. No very special means were employed to bring about so very desirable a result, which was more due to local influences than anything else. Evidently the high and dry position of this garden suited the plant. Usually under cultivation the plant will succeed in a mixture of peat and loam, with an addition of finely broken brick and some sand. In the rock garden a deep crevice filled with this soil would also suit it. Where the plant exists a few seeds may be saved each year, and though the seedlings present some variation of foliage, the greyish tint at times being absent, the flowers are much the same. The plant should never be disturbed in autumn or winter, but in April or May for careful division.—J.

*Geranium sanguineum album*.—If the plant mentioned by Mr. Archer-Hind on page 6, and by "T. J. W." on p. 31, is the same as that in my garden, it originated on the Kirkcudbrightshire coast of the Solway. It was found among the typical *G. sanguineum* by Mr. W. D. Robinson-Douglas, of Orchardton, from whom I had it. From the remarks of "T. J. W.," I think it is the same as his plant. There are many thousands of *G. sanguineum* along the coast of this part of the Solway, but I have never seen any variation among them. The latter correspondent has raised an interesting question by saying that, from the difference between this plant and the type, he is inclined to think it is hardly a variation only. The points of difference of which he speaks are very apparent, and it differs as much except in lightness of colour from *G. s. lancastriense*, the Walney Island plant, which more nearly resembles

the type than *G. s. album* does. *G. pratense* is abundant on the Solway coast and occurs within a short distance of where *G. s. album* was found—between the rivers Urr and Dee. Is it possible that it may be a hybrid between it and *G. sanguineum*? Through an error in the delivery of the issue of July 3, I did not see Mr. Archer-Hind's note until that of "T. J. W." was read. If either of your correspondents would like to compare plants I shall be pleased to send them specimens.—S. ARNOTT, *Carsethorn, by Dumfries, N.B.*

*Alstroemeria aurantiaca*.—The various species of this genus are among the most useful flowers for cutting at the present time, and among them the above is a most popular kind. The variously coloured heads of bloom are produced on long stems that render them valuable for the decoration of large vases, and where large beds exist in the garden the flowering sprays are most freely produced. Planted 6 inches deep in good soil the plants are safe for years. Where variety is needed, the forms of *A. chilensis* or *A. psittacina* may be added, selecting a more sheltered position for the former and planting deeper to keep secure from frost.

*Sweet Pea Brilliant*.—This is a new American Sweet Pea, said to be a bright scarlet variety of improved form. The colour is really bright crimson-scarlet. The other day I was looking through a large and representative collection of Sweet Peas, including most of the new varieties. I gathered first a spray of Brilliant, then one of ignea, one of Cardinal, which is described as a brilliant crimson-scarlet, one of Firefly, glowing crimson-scarlet, and lastly, one of Invincible Carmine. The likeness between the five was remarkable. I thought Cardinal the best of the five, having the deepest, yet brightest colour. Here then is an illustration of the sameness in Sweet Peas of which many complain. Mr. Henry Eckford has given us many varieties and is still producing others. Now not a few American-raised sorts are being sent into the English market, and the fear is lest we get the English varieties first in the field over again. I have just counted eighty-four so-called varieties in one catalogue, and it seems incredible to think these are all distinct from each other. I have enumerated five crimson-coloured varieties in which sameness of character is unmistakably displayed. We have at least five white varieties, including the old white. So many are scarcely wanted, but they appear in lists, and each is stated to be very true. In ten years time we may have another eighty varieties at the rate they are coming over from America. A thorough trial and selection are becoming absolutely necessary. The question is, who will undertake it?—R. D.

#### TRANSPLANTING DAFFODILS.

I HAVE so frequently seen the annual lifting of Daffodils recommended in THE GARDEN and elsewhere, that I am tempted to ask what advantages are in a general way to be derived therefrom. I know that in trade establishments annual lifting is absolutely necessary, and it may be that in the case of some delicate kinds where the soil is heavy and the average rainfall high the ripening of the bulbs may to a certain extent be perfected by lifting them and laying them out in a dry, warm place for a month or so, but in soil of a fairly light character, where moisture rapidly drains away and which in late summer frequently becomes dust-dry to a depth of several inches, I fail to see in what way annual lifting can be beneficial. My own experience is against the frequent transplanting of *Narcissi*. I never by any chance obtain flowers of such good quality from bulbs that have been moved as from those that have been two or three years undisturbed. It may be urged that when the bulbs are lifted after blooming they are apt to remain rather too long out of the soil, and I am free to own that it does frequently happen that replanting is

deferred until autumn is fairly advanced. When the bulbs are not set out until October, it is easy to understand that roots are not so abundant as is the case with undisturbed bulbs. Narcissi commence to push out roots quite early in September, so that if out of the soil for some weeks after that time, there must be some loss of strength. It does, however, seem strange that this should be the case when it is a question of removal only. One would think that there could be absolutely no diminution in the blooming powers of bulbs that are simply transferred from one place to another. According to my experience, however, this is exactly just what does happen. Last autumn, for instance, I removed some established clumps of Horsfieldi, Emperor, and others. The bulbs were just beginning to show roots, and they were very carefully lifted and replanted at once. Some few bulbs were overlooked, and the difference in the quality of the blooms they produced was very striking. On the transplanted bulbs the flower-stems were much shorter, and the flowers one-sixth less in size.

In a general way I am convinced that nothing is gained by frequent transplanting, and that the best results are gained by planting the bulbs some 8 inches apart and allowing them to remain several years undisturbed. I grow such kinds as Horsfieldi, Emperor, cernuus, obvallaris, Empress, and Sir Watkin for cut bloom, and my plan has been to set the bulbs out at the above-mentioned distance in 4-foot beds, allowing them to remain about five years, and my best results are obtained after the second year from planting. Sir Watkin this spring was very fine, better than I ever had it, and the bulbs were planted four years ago. All my experience of Daffodil culture has been gained on the light Surrey loamy soil, and it may be that in the case of soil of an opposite character frequent transplanting may be beneficial, or, indeed, in the case of some kinds rarely necessary. This is a matter that every grower of these bulbous flowers can easily determine for himself, as in the course of a couple of seasons a definite result might be arrived at. Five years ago one single bulb of poeticus ornatus happened to be planted in a small border where miscellaneous things are grown. The bulb was a good one, as good in appearance as any that come from leading growers of this family. It produced a flower such as is generally brought into Covent Garden, and made a good growth. It has, however, been very interesting to note the sure, but gradual increase of this bulb. It has formed a clump that this spring bore twenty flowers. It is not only that the number of bulbs has increased, but there has been a yearly corresponding increase in vigour. This season the flower-stems were 2½ feet high, with blooms of finer quality than I ever saw on newly-purchased bulbs—finer, indeed, than I ever saw before of this Narciss. Had I planted an equal number of the best quality bulbs last autumn, I am confident that I should not have had a similar result. I never fully realised what a grand thing princeps is until I saw it in the form of established clumps at Oakwood. The flowers were one-third larger than those produced by bulbs which I obtained from a reliable source, and that were planted the previous autumn. The latter have remained undisturbed for three years, and are gradually taking on the character that distinguishes this Daffodil in its highest state of development. In the face of such facts, one may doubt the wisdom of the annual lifting that is practised by those who grow in quantity for cut bloom. The expense

of lifting and replanting an acre of Daffodils is considerable, and the advantage derived therefrom appears to me to be very doubtful. After all, the frequent disturbance is unnatural in the case of such a perfectly hardy bulbous flower. The common Lent Lily in meadow and copse and the old double naturalised in grass and woodland are object lessons which ought to guide us in this matter.

*Byfleet.*

#### CARNATIONS AT CHELSEA.

BORDER Carnations are at the present time an interesting feature in Messrs. James Veitch and Sons' nursery in the King's Road, Chelsea. They are interesting because of the number of varieties grown, and they are instructive because of the fact that visitors will see them in large numbers in the open beds and in such a way that their relative value may be determined at a glance. And it will be no disparagement in the least to state that what under many and various adverse conditions in the open is well grown by the Messrs. Veitch at Chelsea, may, under improved surroundings and purer air, be much better grown in many parts of the country. Something like a foot deep of fresh soil has been added to the beds during the past winter, the old soil not having been changed for several years. Unfortunately the fresh soil contained wireworm in sufficient quantity to make one or two small gaps in what otherwise would have been a most complete series of beds, replete with an assortment of all that is good in one of the most valued groups of hardy florists' flowers. Only a very few of the leading flowers are now at their best and still fewer in the very earliest varieties that show any sign of passing, but even of these there is yet quite a store of lateral buds that will carry on the display for a couple or three weeks longer in some instances at least.

The entire batch is growing in a series of oblong beds, each kind represented by a large block. In this way a good idea may be formed of their true worth in the garden. We will for the present direct attention to the more worthy, taking the newer kinds first. Of these, Sea Gull and Her Grace are two of the most lovely of blush-tinted flowers, both large and sufficiently full to recommend themselves to all, delicate in their beautiful shade, and both singularly free and good in habit. Exile and Miss Maud Sullivan, again, are selfs of rose and rose-scarlet hue, the former remarkable in its perfect form and fine petal, indeed a grand Carnation in every respect, while the latter is wonderfully free and pleasing. Another fine form is Winifred, this being especially noteworthy for its free, compact form and dwarf as well as perfect habit. The clear apricot-coloured flowers are faultless. W. J. Fish and Sweet Briar are scarlets of differing shades, the former intense in its brilliancy; while Princess Charles of Denmark, as a white for the open border, has much to commend it to general use in its fine form and good habit. Ellen Terry and Mrs. Eric Hambro are fine whites, the former very large, the latter perfection in its glistening purity and form of petal, though not so full as some and worthy of a stouter footstalk. Foremost among the yellow kinds are Britannia, Primrose Day, Mrs. Patrick Campbell and Miss Audrey Campbell—a set very difficult to equal from an all-round standpoint. Equally important is it that any grower may with advantage embrace the whole of these, and the well-known Germania also, without any fear of overdoing this particular shade, as they give a good succession naturally, besides possessing a pleasing variety of colour. One or two yellow-ground kinds were very fine; these are Eldorado and Golden Eagle. The former is distinctly marked with bright rosy red; the latter, deeper in its golden yellow shade in the centre, is also prettily marked red. Both are perfection in size, fulness of flowers and form. Nereus is another of these, a very handsome flower, margined with deep rose; while Mr. Nigel, the earliest blossoms of which were only then expanding, is perhaps

the handsomest of all this race. This last, by the way, possesses more of the true character of the yellow-ground type, while its heavy edge of crimson is very pronounced, and a flower which all must admire. Hayes' Scarlet is a grand self Carnation, most decided in its brilliant hue of colour, and a good doer. King Arthur, also a scarlet, is perhaps the largest flower of this shade among true border kinds. Flowers 5 inches across have been taken from plants grown in the Chelsea nursery, and in this respect quite equal to those of the Malmaison type and worthy of pot culture. Before taking leave of the best of recent introductions, special mention must be made of Mephisto, a dark crimson self. This is not only a highly finished flower, but its pronounced erect habit in the buds, as in the expanded flowers, will render it valuable for the flower garden. More than this, it should make one of two parents possessing this very desirable character, viz., a footstalk sufficiently strong to hold the best flowers well up. At the present time many kinds have such weakly stems and peduncles to the blossoms that at flowering time, unless tied to near the bud, they droop in the most helpless fashion; and now that the flowers themselves have attained to such perfection the florist may do worse than devote attention to this particular defect in many kinds.

In the general collection we noted many fine sorts, which for convenience here we will refer to in their shades of colour. In scarlet, Joe Willet, Cantab, with strong clove scent, and Napoleon III. strike one as very good, the two first especially good and free in growth also, while the latter is a very neat and compact kind. Among the rose and rose-pink self varieties Eudoxia is very fine and most desirable, while Celia, Lothair, Rose Celestial, Ketton Rose, and Duchess of York appeal to one as the indispensables of this set. It is worthy of note, too, how specially beautiful these kinds are when protected in a shady, cold house, a course of treatment which appears to bring refinement of a very charming type. For this same reason these self-colours of this shade should not be planted in fully exposed places; when in rather reverse positions their beauty is much longer retained. Of pure whites, Mrs. Frank Watts and Snowdon are very fine, the former free and dwarf also, while the latter is very desirable in size as in other qualities. To the crimson already mentioned, and apart from others too well known to be repeated, Uncle Tom must be added for its size, freedom, and good petal. In yellow and buff, Duc d'Orleans, with Florence and Coruna, are all worthy sorts, while The Dey, Mrs. Seymour-Banocrie, Elsie, and George Cruickshank are conspicuous among such as are included in the fancy varieties.

These, then, are a few of the most noticeable at the time of our visit; others as good are appearing daily, and beyond these a beautiful array may be seen in perfection in pots in one of the adjacent houses, where with only ordinary care in quite small pots they give abundantly, and in the best of health, of their varied, beautiful, and in many instances delightfully fragrant flowers.

**Begonia Worthiana.**—The aim of the cultivator in the raising of new Begonias has been principally directed towards the production of large round flowers, which hold themselves in a partially erect manner, and are thus seen to the best advantage. Under glass no exception can be taken to this section, but when employed in the flower garden the large blooms are easily injured by wind and rain, whereas the smaller and drooping blossoms will not suffer in the least. For this reason *B. Worthiana* is popular as a bedding variety, for the flowers, though numerous, are not large, and stand the weather well. They are of an orange scarlet colour; indeed, it is a type of *Begonia* of which we had many forms twenty years or more ago, but now-a-days they are rarely seen.—H.P.

**Lathyrus rotundifolius.**—In a recent issue of THE GARDEN this is stated to be the earliest

blooming of the Everlasting Peas. The writer, however, is not quite correct, for *L. Sibthorpi* precedes it by about three weeks. This latter is not often seen in good condition, being of slower growth and taking some years to grow into a good-sized specimen. My plant is about seven years old and is only just beginning to be effective. It apparently likes a rather light, well-drained soil, with plenty of food in the form of an annual top-dressing of good manure applied in the winter months. As an early-blooming Pea this is worth a place where a succession of hardy flowers is required all the season through, but it is certainly inferior from a decorative point of view to its near relative *latifolius*, which if not of easy culture would probably be held in much higher estimation by hardy flower growers generally. It would be difficult to find anything finer than the masses of this Pea that one sees in cottage gardens.—J. C. B.

#### THE CALOCHORTI.

THE various species of *Calochortus* have been coming into flower since early June, and now, at the end of the month, are in their best form. These native plants seem to be much neglected, though they are among the most distinctly and beautifully flowered of bulbs. It is probable that many who have ventured to grow them have been disappointed in results, for the cultural directions of catalogues are usually hazy or else incorrect. They also often recommend cultivation in frames, or other conditions which deter most growers from attempting their cultivation. My experience with all the species is that they are neither tender nor at all difficult to flower in this latitude in an ordinary garden border. I have tested them for several years and sacrificed my first collection to satisfy myself as to whether they would or would not survive. One should hesitate in offering any hard and fast rule for the cultivation of plants, for they can often be grown under widely differing conditions. *Calochorti* grow naturally in regions rainless in summer, and where dormant plants waken into growth in the fall under the influence of moisture, but not necessarily of a high temperature. They are hardy here without protection, but must be classed with those bulbous plants whose foliage will not always endure the rigours of our winters. The successful growth of such bulbs requires that, after being thoroughly ripened in the early summer, they shall be kept perfectly dormant so late in the year that no foliage can appear above ground until early in the ensuing spring. The simplest and safest procedure is to lift the bulbs after the ripening foliage indicates rest and store them in dry earth in a warm dry place, planting out when the ground has lost its warmth, which in New Jersey is in November. Under such treatment they grow and flower well here, even in soil too hard to work in dry weather, and with no other attention than that already suggested. Of course, one does not plant bulbs in manured soil or in soil rich in humus, which will hold water and ferment to their injury. In the state of nature many bulbs seek the depths evidently to escape detrimental surface humus. *Calochortus* bulbs, if left in the ground here, may or may not survive the summer if the soil is not too wet, but the safe practice is to lift them.

There are more than a score of species. From a garden point of view they may be divided into two sections—the Star Tulips and the Mariposa, or Butterfly Tulips. The former are free-growing plants, many-stemmed, and bear a profusion of small flowers, with petals closed into irregular globes. *Calochortus pulchellus* (yellow), *C. albus* and the red form, *C. amoenus*, are the best trio. The Butterfly Tulips are entirely different in habit and form, and find their most distinct expression in the white and roseate flowered kinds, as these are spotted and lined with the butterfly markings, from which they receive the popular name. The markings are quaintly beautiful in dull reds, browns, yellows and green, sometimes in eye-like forms, at others in a few bold lines sketched, as it

were, on some part of the broad petals, mostly on the base, but sometimes in the centre. Markings of similar character are also found on the very narrow green sepals. The flowers are three-petaled, and about 3 inches in diameter, borne about 12 inches high on thin stems. The foliage is narrow and scanty. A good selection of these would be *C. venustus enlatus*, *C. pictus*, *C. venustus roseus* and *C. Eldorado* (rose).

Of the yellow self-flowered kinds, perhaps the best is *Calochortus luteus* var. *concolor*, a deep golden flower and a vigorous species. There are also many purple forms, mostly self-coloured or slightly shaded, which do not appeal to me as favourably as the others, though there are spotted kinds. The best is probably *C. splendens*, a lilac-coloured form, which has finely-dentated petals, and the base of the cup filled with hair-like growths. Many of the *Calochorti* have these growths, but none, I think, in such profusion. Probably the specific name of this species refers rather to some one's botanical enthusiasm than the gratification of his colour sense. *C. Catalinae* is a distinct kind, the white petals being flushed with purple on the outside. *Calochorti* seem to be attractive to a number of different insects, and they bear seeds freely. *C. Plummera* seems to be a late-flowering species.—J. N. GERARD, in *Garden and Forest*.

**Dahlias.**—These now require frequent attention, the extra dry atmosphere which has prevailed of late being against them. Mulching thickly with well-decomposed manure and giving occasional copious waterings must likewise be practised if robust plants and normal well-coloured blooms are expected. Earwigs must now be watched for; although there are as yet no flower-buds of any importance to injure, the pests feed on the foliage and may soon cripple the plants. Some growers use small flower-pots elevated on a stout stick, a small quantity of hay or Moss being put into each pot and these examined daily. I have, however, killed most by placing in the plants 9-inch lengths of Broad Bean stalks, tapping these every morning on the edge of a pail containing boiling water to destroy them.—C. C. H.

**Gladioli.**—Gladioli will now be making rapid growth, and, provided they get sufficient moisture at the roots, they enjoy a maximum amount of sunshine. Gladioli always pay for an addition of sweet, fresh loamy soil and leaf-mould to the bed or border when planted out in spring, and this can best be done by drawing drills, planting the bulbs, and afterwards filling in with the new compost. Mulching is very beneficial—in fact, imperative—where the plants occupy a warm, sunny position, which they always should do, and, being planted in rows, staking, as a safeguard against rough winds, is best done by fixing a stout stake at each end of the row where they are short ones, and carrying a horizontal rod across from one to the other, afterwards tying each plant to it. Liquid manure the colour of pale ale improves both the size and colour of the spikes, and, where required to remain in good condition for as long a period as possible, a temporary shade may well be erected over them. For church and, indeed, general decoration nothing beats *G. breuchleyensis*.—J. C.

**Coreopsis lanceolata.**—For cutting I know of nothing more useful than this during the early summer months, its long and slender stems making it suitable alike for large or small vases. As a biennial it is very fine and easily raised from seed. In good soil it grows quite 2 feet in height. In a mass it has a very bright and telling effect, and supplies material for house decoration in almost unlimited quantity. The blooms, too, last well in water, which cannot be said of many better-known and more popular flowers. Arranged with light foliage, such as *Asparagus*, or kept alone, the flowers are very pleasing, because so very light and brightly coloured. My plants were raised last year in May, temporarily transplanted when large enough, and finally

planted in the autumn. They bear removal well in the autumn or winter, as they make large balls of fibrous roots.—W. S., *Wills*.

#### SHORT NOTES.—FLOWER.

**Tufted Pansy Pencaitland** is essentially a plant for garden decoration. It seems to succeed better during cooler weather. The flowers are of medium size, pure white, with a slight suffusion of yellow on the lower petal. It is of free and dwarf habit and flowers very freely.—H. N.

**Tufted Pansy Mrs. C. F. Gordon.**—This may be described as an improved Countess of Kintore, and for its dwarf, compact form of growth should be more often used. The flowers are large, circular, of neat form, and borne on long foot-stalks. The colour may be described as bluish purple, shading to pale lavender on the outer edge. The habit of growth, too, is very good.—C.

**Tufted Pansy Devonshire Cream.**—Of the later introductions, this variety is deserving of special notice. In my own garden a few plants are flowering very freely. The flower is of good size, rich cream, with an orange centre, and rayless. It is of a dwarf, compact habit. A few thousand plants of this variety massed together in a large bed will long be remembered.—C. A. H.

**Verbascum phœniceum and varieties.**—These are very beautiful at the present time in the wild garden growing amongst the grass and in mixed beds. The plants are self-sown. The slender spikes in masses waving amongst the somewhat long grass produce a charming effect. One of their great recommendations is they are not particular as to soil. I have some plants growing on a thin stony soil.—DORSET.

**Tufted Pansy Endymion.**—This is a very striking new variety, colour light yellow and the bloom of remarkable substance. In size it surpasses any sort known. It will, therefore, be invaluable to exhibitors. The habit, again, is excellent and the growth free; it will consequently be not less useful for bedding. A large bed of this variety at the nursery of Mr. Baxter, Woking, now forms a mass of colour most distinct and beautiful.—S.

### GARDEN FLORA.

#### PLATE 1128.

##### ROSE AUGUSTINE GUINOISSEAU.

(WITH A COLOURED PLATE.\*)

GENERALLY speaking, Roses were never more lovely than they have been this year, and the garden varieties have seldom been seen in greater perfection. The above Rose is a sport from *La France*. I readily admit that it lacks the fulness of its parent, but with this exception and in its colour it is in every way equal to *La France*; indeed, in my opinion it excels that variety in effectiveness. It is a Rose that requires liberal treatment, such as weak doses of liquid manure and a sprinkling of good guano now and then.

Although it is a fine variety to grow as a standard, the best effect is produced when a dozen to a hundred plants are massed together on the grass. It is rather a misnomer to term this Rose the *White La France*, for in reality its flowers are of the delicate pink shade seen in sea Anemones. However, viewed from a distance, a mass of this Rose has the same effect as if it were pure white. I think it is even more deliciously fragrant than *La France*—if that were possible. It grows freely upon its own roots. Now that the budding season is upon us it would be interesting to bud two or more of the *La France* tribe upon one standard stock. For instance, *Augustine Guinoisseau* and *Belle Siebrecht* would harmonise well together, or the former and *La France* or *Caroline Testout* would make another good combination. One

\* Drawn for THE GARDEN by H. G. Moon at Gravelye Manor, Sussex. Lithographed and printed by J. L. Goffart.

THE ROSE

could readily gather from remarks overheard at the Crystal Palace show recently that these delightful garden Roses are becoming increasingly popular. Surely nothing can surpass in beauty masses or hedges of the Rose under notice and others of the same tribe already mentioned, and in addition I might mention others such as Marquise Litta, Viscountess Folkestone, Grand Duc de Luxembourg, Marquise de Salisbury, Mme. Pernet-Ducher, Enehantress, Clio, Mme. Laurette Messimy, Mme. Lambert, Marie Van Houtte, Hon. Edith Gifford, White Lady, Gloire des Polyantha, and many others.

## PHILOMEL.

## THE WEEK'S WORK.

## KITCHEN GARDEN.

**WINTER TOMATOES.**—The chief reason these do not yield full crops during the early winter months is more often than not owing to not starting the plants soon enough in the summer. Unless strong plants, 3 feet at least in height, are well set with fruit by the end of September, at which time they are taken indoors and placed in their winter quarters, it is hardly worth troubling with them, as they would not repay for the room and attention they require. Sturdy plants should now be ready for placing into fruiting pots. Nothing is gained by overpotting the plants, neither should they have very rich soil, or growth will be too free. Nine-inch pots and only three parts filled with soil will meet the requirements of the plants at first, as they can be top-dressed later on. Pot firmly, as this further tends to promote a sturdy growth. The plants should be stood in a sunny position, but not exposed to wind. A piece of slate should be placed beneath each pot to prevent the roots taking to the ashes or other material on which they are standing, as well as to prevent the ingress of worms. Although the plants are all the better for full exposure to the sun so long as they are copiously supplied with water, it is well to shield the pots from its full force, or many of the roots may suffer. It is easily done if the plants are stood in line about a foot apart by laying a 9-inch board against them, which is better than plunging the pots in ashes. It is better to keep the plants to a single stem, affording a stout stake to each, so that growth can be secured against wind as it develops. If the plants have become rather tall before they are potted, it would be wise to twist the stems round the pots, the object being to induce them to form fruit clusters from base to summit. Although it is considered neither necessary nor desirable to syringe Tomato plants at any time, a slight dewing say twice a week after a very hot day tends to keep the plants healthy without the risk of encouraging disease. Manure water will not be required until the plants are well furnished with fruit and this has commenced to swell.

**SUMMER FRUITERS.**—Of late the weather has been very favourable for these, being both hot and dry, which has assisted the flowers to set freely. Feeding should commence directly a few pounds of fruit are swelling, and the plants should be relieved of these when they are about three parts coloured, especially if they have to be packed and sent any distance. The plants are often allowed to grow at will until a quantity of fruit has formed, when they are suddenly stripped of the main foliage and side shoots so as to expose the fruit to the sun. Apart from this being very rough treatment to the plants there is also a danger of the fruit being scalded by sudden exposure, causing many of the finest to become useless. Let the sun act on the fruit by all means, but avoid stripping the plants suddenly of a quantity of foliage. Most of the plants, whether growing against a wall or trained to stakes in the open, will be all the better for a mulching of some description, which will assist to promote active surface roots and also to swell off the fruit.

**POTATOES.**—All the early ones and many of the second earlies, such as Beauty of Hebron, have ripened up quickly, and it would be advisable to lift and store them in a cool cellar before we get any rain. This, together with the heat that is in the ground, would undoubtedly cause the tubers to start into growth again, which would greatly impair their quality; therefore no time should be lost after the skins have become firm in making sure of them by lifting at once.

**SHALLOTS.**—These, too, have ripened quickly, and in many gardens will be ready for lifting. It is neither necessary nor desirable that the chumps should be broken to pieces and the bulbs singled out, it being better to leave them whole for a week or so until they are thoroughly matured, when they may be divided, sorted, and stored away in a dry, airy place.

**HERBS.**—A good store of dry herbs during the winter is invaluable, and steps should be taken to collect and preserve a quantity of each kind before the season becomes too far advanced, as both Mint and Marjoram will lose substance in their leaves if not cut at once. To dry these properly, they should be made up in small bundles and suspended in a dry, airy shed. When laid in the sun to dry they wither too quickly and there is much waste. RICHARD PARKER.

## FRUIT HOUSES.

**EARLY ORCHARD HOUSE.**—The crops of fruit having been gathered, the trees should be moved outdoors, as advised in a previous calendar. If arranged in one block where they can get full sunshine all day long, with plenty of old hotbed or some other non-conducting material packed amongst the pots and tubs to keep the roots cool, and such matters as syringing and watering strictly attended to, the wood will soon ripen and the trees be ready for re-tubbing or potting shortly. In the meantime, pots, tubs and compost should be prepared. The clearance of this house will enable a rearrangement of the occupants of later houses being made, when the most forward can be grouped by themselves in it and pushed forward if desired. In any case the trees will appreciate an extension of room, especially if at all crowded, while the attendants will be the better able to get about amongst them.

**LATER HOUSES.**—Most, if not all the fruits on the trees will now be taking their last swelling. If necessary to hurry them, advantage should be taken of solar heat to push them forward, and close the house in the afternoon early enough to run the temperature up to 85° or 90°. If time is of no consequence, the ventilators may be kept fully open, when, with due attention to routine matters in the way of watering, with the administering of stimulants in safe quantities, together with ample syringings during fine weather and damping of paths, floors and beds, the fruits will attain their fullest size and eventually ripen to perfection.

**CHERRIES.**—The earliest forced trees in pots and tubs will have been moved outdoors ere this, and must be treated in the same way as recommended for other orchard-house trees with regard to mulching, &c. Permanently planted trees must have all the air it is possible to afford them, and the foliage should receive a daily wash of cold water to check red spider and keep the soil about the roots in a proper state of moisture. Old trees may have the assistance of liquid manure, which will greatly benefit them and cause the fruit to swell up to full size. Later houses, in which ripe fruits of the Bigarrean and Royal Duke section are ripe, must have an abundance of air during the daytime. A thin shading of white-wash on the roof will help to prolong the supply if the crop is wanted to last as long as possible. Stretch netting over the ventilators and doorways to keep out birds, and to prevent the atmosphere of the house becoming too dry, damp the floors about mid-day when the ventilators are fully open. Give clear water to pot trees as often as they require it, but guard against an excess, and maintain an ample mulch not only on the surface of the pots, but on borders also

where the trees are planted out. When the crop is gathered take steps to give the trees a cleansing and treat as above.

**PLUM HOUSE.**—Trees from which the fruit has been gathered should be turned outdoors if in pots, and assisted with liquid manure if in a weak or stunted condition. Permanently planted trees also appreciate the same amount of attention, and will then give all the better account of themselves another season. These trees must now have an abundance of air, and the garden engine or hose should be brought to play on the foliage daily. Less forward trees laden with fruit must be kept well fed and top-dressings and mulchings renewed as often as required. Attend to the pinching in of side growths on the main branches to allow sunlight and air free play, and stop leading shoots on young trees by pinching out the tips if they have reached their limits. Continue syringing the trees until the fruits show signs of ripening, when it must cease, especially if the water of the district contains lime in solution, as this will spot and disfigure them. When syringing has to be discontinued, the floors and beds may be more freely damped on fine days, which will compensate in some measure for the loss of moisture occasioned by the abandonment of syringing. When the Plums ripen, less atmospheric moisture will be required, and when fully ripe the house must be kept cool and dry, giving just enough water at the roots to prevent the fruit from shrivelling and the foliage from flagging. Such varieties as Jefferson's, Golden Drop, and some of the Gages will hang for a long time in good condition, and even if they do shrivel a little it will add to their value, as they are then the more richly flavoured.

**PEARS.**—If all the malformed and surplus fruits have been removed and the trees liberally treated at the roots, the early varieties of Pears will be making great headway. Continue to give them ample root waterings, supplemented with a stimulant of some description, until the fruits show signs of ripening, after which give nothing but clear water. These early Pears may be placed outdoors to ripen if they are not required at any particular date, and this will give the later varieties more space when a rearrangement takes place. If moved outdoors, the pots should either be plunged in a border or have a mulch of half-decayed manure placed round them, or the difficulty may be got over by sinking them in tubs and filling in the intervening space with short manure. I have practised this with excellent results, and prefer it to plunging. Watering, too, must be well looked after, and a daily wash with the syringe each evening will have a wonderful effect in reviving the flagging energies of the trees after hot, scorching days. Trees of later varieties must have every attention, and if still too heavily laden, give them a further thinning. It is better to do this than run the risk of over-cropping them, however much the well-laden branches may tempt the tyro to do so, as the aggregate weight of fruit will far exceed that produced by the trees if left unthinned. To overcrop is a fatal mistake, as not only does it lead to the production of inferior fruit, but the energies of the trees become so overtaxed, that they require a whole season in which to recuperate. It is often necessary with such large-fruited varieties as Doyenné du Comice, Duchesse d'Angoulême, &c., to afford them support when the fruits become heavy, and this is best done by means of stakes, to which the branches should be securely tied. With regard to watering and other such routine matters, Pears require the same treatment as that accorded to Plums. Attend to the pinching back of young growths on established cordons and bushes, also young trees, but in their case merely tip the leading shoots. If aphides take possession of the points of the shoots, as they are sometimes apt to do, dip them in a strong solution of some approved insecticide and well wash with clear water afterwards.

**POT VINES.**—Those intended for early forcing should now be ripening up, and as the canes become brown, more air must be admitted and less atmospheric moisture kept up. Stimulating root-

waterings must, however, be given until they are turned outdoors to finish, and as it is highly necessary to keep the foliage clean and intact, syringing should not be abandoned until they are removed. When ready for removal, stand them at the foot of a hedge or a wall having a south or western aspect, and fasten the canes securely with shreds and nails, or tie them to the hedge, as the case may be. Until the foliage drops, watering must be strictly attended to.

**STRAWBERRIES.**—Where these are forced, the potting of the earliest varieties will now be engaging attention. When once the pots are well filled with roots, the runners should at once be separated from the parent plants and stood for a few days in a shady place and contiguous to the potting shed if possible, after which the sooner they are potted the better. When potted, stand each plant level on a firm, open, gravelled space, or on boards by the sides of walks, and in addition to seeing that they get all the water they require, syringe them daily also in fine weather.

A. W.

## ORCHARD AND FRUIT GARDEN.

### NEW STRAWBERRY BEDS.

**DURING** the next week or so Strawberry growers will be busy layering young runners, both for growing on in pots for forcing and also for forming permanent beds. In a few gardens of extra large dimensions a quarter is annually devoted to young plants for the production of runners alone, all bloom-trusses being removed as soon as they appear, in order to strengthen the runners. Many, however, cannot afford this, and have to be contented with runners from the bearing plot. Some gardeners still adhere to the old-fashioned plan of planting stock plants by the sides of the kitchen garden walks in front of espaliers, and I use all such available space myself for the purpose. I plant biennially, placing small sticks between the old plants previous to chopping them up as a guide, so as to change the ground each year. A few spits of the old border are then taken out, this being replaced with good maiden loam, rammed firmly, and planting in the centre a good strong plant. In this position the pots can be plunged or half plunged with ease, and daily watering and general attention become an easy matter. The great drawback attending runners on bearing beds is the danger of trampling them with the feet, which to some extent the most careful cannot avoid, and if, as they need to be in order to preserve them, they are laid between the plants in the rows before picking or even netting commences, they get unduly shaded by the foliage. Good results, however, follow this system, especially if plenty of space is allowed both between the plants and rows, 2 feet being none too much. Early preparation of the ground is important, as loose, unsettled soil is against the plants in more ways than one. Where digging or trenching immediately precedes planting, extra treading and, in the case of light soils, the use of the garden roller become a necessity. That Strawberries prefer a firm root-run I have had proof over and over again. Mr. Allan, of Gunton, who, as is well known, excels in Strawberry culture, always selected a suitable plot of ground in spring, digging it one spit and the crumbs, and placing the manure in the bottom. On this was sown his main crop of Onions in rows 3 feet apart. The frequent trampling during summer to attend to the crop rendered the ground firm, and here in due time his Strawberries were planted. The plants went away rapidly, did not suffer from drought in a hot autumn, as where the ground was newly turned and comparatively loose, and the growth

was of such a character that with a fair amount of sunshine in September and October maturity was certain. A cube of maiden loam rammed firmly round each ball, watered home, and a slight mulch of leafy material to act as a conservator of moisture, give the plants all the better chance. If growth is normal and the autumn sunny, several waterings with liquid manure may safely be given, but in dull, sunless seasons water pure and simple had better be adhered to. In the majority of seasons and under the best management red spider will appear, but in any case the young plants in pots, both for forcing and planting out, had better be laid on their side as soon as detached from the parent, and vigorously syringed with sulphur water. This will clear them of the pest and ensure a clean and healthy growth, as it often happens that some time elapses between severing the young plants and planting or potting them. The best place in the interval is behind a north wall. Early planting, however, is very important. A change of runners every few years always pays.

J. CRAWFORD.

**Strawberry Empress of India.**—As a mid-season variety I should say this would be hard to beat. It is of medium growth, but very free-bearing, the berries not large, but of a bright, deep scarlet colour and rich flavour. The fruits, being firm, travel well, and grown here alongside most of the newer varieties that have been much advertised and sought after, Empress of India beats them all except for size of fruit.—C.

**Strawberry Latest of All.**—Out of a dozen plants of this variety I have not succeeded in getting a perfect fruit, though they bore freely. All the fruit as soon as they began to show signs of colouring were attacked by a kind of fungus, which caused the flesh to become hard and worthless. I shall be glad to know if this is the general experience of this variety. My plants are growing in a fairly strong loam. Royal Sovereign, growing by the side of it, has done well and given me some excellent fruit.—R. D.

**Melon Knowsley Favourite.**—This Melon, the result of a cross between Knowsley Green and William Tillery, still holds its own among the numerous varieties which have been introduced within recent years. I grew it the first year it was sent out, and the high opinion then formed of it has been confirmed by subsequent trials. This season the fruits have been all one could wish, and so thoroughly have they ripened and so exquisitely flavoured is the deep pale green flesh, that every particle is fit for consumption close up to the rind. The fruits, rather inclined to be oval in shape, prettily netted, and golden yellow in colour, vary in weight from 3 lbs. to 5 lbs. The only drawback in this excellent Melon is the fact of its being a strong grower, which precludes it from being classed as a good kind for growing as a cordon. Where ample room can be afforded the plants they give first-class results in the shape of heavy crops of handsome and deliciously flavoured fruits.—A. W.

**Thinning hardy fruits.**—It is of great advantage to thin Apples and Pears, and to do the thinning before the fruits get too far advanced. My note more concerns late varieties of Apples. These when given more room to develop come much finer, keep better, and have more colour. In the case of certain varieties of dessert kinds the fruits are none too large, and some crop very freely. I have found thinning at this season of great advantage, as by so doing size is obtained and keeping improved. It may be asked why leave the thinning till July when it could have been done a month earlier? The reason is that one cannot be sure of the fruit not dropping till July is well advanced, and in the case of late Apples and Pears there is a period of three months before the fruit is stored. A few varieties of late Pears crop so freely on bush and pyramid trees that they would not be worth storage unless well

thinned. It is surprising the progress the fruits make after they have been thinned.—B. M.

**Strawberry Royal Sovereign.**—I have been disappointed with the above Strawberry this year. I have had an excellent crop of fruit, but the flavour is very poor. It is a splendid Strawberry to look at. I have let several people taste it, but all complain about the flavour. The soil here is very light and naturally poor, from 18 inches to 2 feet of soil resting on the natural rock. The ground was trenched, plenty of manure worked in, and allowed to settle for a fortnight, then well trod before being planted. The plants were well mulched with rotten manure soon after planting, and well mulched again this spring with stable litter. Noble, on the contrary, is very fine in flavour, the best all-round Strawberry to grow. Latest of All was the first to ripen with me this season. On this soil it does very badly, making very little growth, and the foliage is very yellow. I shall not grow it another season. I have tried Auguste Nicaise for the first time this year, and have been very pleased with it; it is a finely flavoured variety. I notice that some of the plants have round fruit, very much like Noble, while others are cockscomb-shaped. Would some reader of THE GARDEN kindly give me the names of two good Strawberries for preserving suitable for light soil?—THOMAS COCKERILL, *The Gatehouse, Wirksworth, Derby.*

### THE ORIGINAL LOGANBERRY BUSH.

The following notes by Judge Logan, of Santa Cruz, California, in Bulletin No. 45 of the Agricultural Experiment Station of the Rhode Island College of Agriculture and Mechanic Arts, will, we hope, prove interesting to our readers, seeing that this new fruit has just been certificated by the fruit committee of the Royal Horticultural Society:—

Prior to 1880, taking great interest in small fruits, particularly the Blackberry and Raspberry, I had tried in my garden every variety of those berries that I could obtain. Among them were the Texas Early, a high bush, *Rubus villosus*, the Aughinbaugh, a pistillate Dewberry, and an old variety of red Raspberry which had been cultivated here for many years, name unknown, but resembling the Red Antwerp. The Texas Early is sometimes called Crandall's Early, because brought to this State by Dr. Crandall, of Auburn. I was not satisfied with any of these fruits as a table berry. The wild *Rubus ursinus*, of which the Aughinbaugh was the best variety obtainable, bore a fruit that was all that could be desired in flavour, but all of the *Rubus ursinus* type are weak growers and poor bearers, so much so that they are unprofitable for general cultivation. The Aughinbaugh being pistillate or uni-sexual, I deemed it possible to grow a cross between it and some other early Blackberry, such as the Texas. I did not then think it possible to cross the *Rubus ursinus* with the Lawton, Kittatinny, or any other *Rubus villosus*, for the reason that the latter flower after the *ursinus*, and repeated trials of such a cross since that time have been failures with me. I had by the merest accident planted the Texas on one side of the Aughinbaugh and the red Raspberry heretofore spoken of on the other. The canes of all three intermingled and flowered and fruited together. For the purpose of securing an intermediate form between the Aughinbaugh and the Texas, I gathered and planted the seed of the former in August, 1881, expecting a cross between those two Blackberries. A cross between the Blackberry and Raspberry was not then intended or even deemed possible by me. I raised about fifty of these seedling plants. During the next season, 1882, I saw from the growth of the canes that the cross had produced something heretofore unknown. The canes of all except one were unlike anything I had ever seen before that time. The exception was a plant very similar in every respect to the Aughinbaugh

parent, but very much larger and of stronger growth. This was the Loganberry. In the spring of 1883 I set the gardener to cultivate these plants. In doing so, by an unfortunate accident, the Loganberry plant barely escaped extinction. When he got through with it there were but two or three buds left to fruit that year. The last of May, 1883, the fruit ripened, and then for the first time the extent of the creation was noticed. It has been repeatedly stated in public prints that I entertained the idea when I planted those seeds of a cross between the Raspberry and Blackberry. I am sorry to disturb one of the supposed truths of history, but candour compels me to say that such is not the case. I did not then deem such a cross possible, and did not know what I had done until May, 1883, when the plant first fruited. Subsequent observations of the Loganberry have confirmed me in the belief that it is entirely unique and distinct as a fruit. It is as much a new and individual creation of the Rubus family as the Blackberry or Raspberry. Repeated plantings of the seed since that time have confirmed this individuality. Out of thousands grown from seeds not one has to my knowledge ever shown any of the distinct characteristics of either parent; not one has gone back to the original type of either the red Raspberry or the Auginbaugh Blackberry. Most of the seedlings, to be sure, are inferior to the original; perhaps one in 100 only has any merit whatever, but they are all, like the Loganberry, essentially a red Blackberry, but similar in form of cane, leaf, time of ripening and sex of flowers to the original Loganberry. All my efforts, too, in the direction of crossing the Loganberry with either of its parents, or with the other seedling crosses between the Auginbaugh and the Texas have so far been failures.

The characteristics of the Loganberry as to shape and conformation of fruit, and the canes and roots, are essentially those of the Auginbaugh. Unlike the Raspberry parent, they have no adventitious root-buds, being propagated entirely by growth from the tips of the canes, like the Blackcap Raspberry. The fruiting canes are replenished each year by shoots from the crowns, which fruit and die yearly like all others of the Rubus family. The core remains with the fruit like the Blackberry. Its principal similarity with the Raspberry is in the colour and the flavour, although the Blackberry dominates in flavour as well as in all other characteristics except colour. As to the fact of the plant being a hybrid between the Blackberry and the Raspberry, of course there is no absolute proof. The colour, with the distinct Raspberry flavour of the fruit, and the circumstances under which it originated, I think render the fact of such a cross almost certain. Since then, too, the possibility of a cross between the Raspberry and Blackberry has been demonstrated beyond a doubt. At the same time as the origination of the Loganberry, and from the seeds planted with the seed that produced that fruit, another creation was produced in the Rubus family of very great interest. I have stated that from the seeds planted in 1881, about fifty plants came, of which the Loganberry was only one. These plants were crosses between the High Bush Texas and the Auginbaugh Dewberry, and are in the Blackberry family just as unique as the Loganberry. Most of the characteristics of this new Blackberry are from the mother, the Auginbaugh. Like the Loganberry, it has no adventitious root-buds, but is propagated from the tips only, the same as the Auginbaugh and the Logan. The berry is very long; specimens have been found 2½ inches, shining black, with the flavour of the Rubus ursinus. The canes are peculiar. They are covered with small spines, thickly interspersed and not very strong. The canes are sometimes 1½ inches in diameter, and start up in the spring like the High Bush, but when they get 4 feet or 5 feet high they start off with a trailing habit and sometimes grow over 30 feet long, and towards autumn the tips seek the ground and root. One of the great characteristics of all these fruits is the fact that they ripen very early, generally beginning in this climate in the

middle of May, six or eight weeks earlier than the earliest of the High Bush varieties. As to the adaptability of these berries to the different climates, I am not able definitely to say. The University of California has experiment stations in all altitudes in this State—high, low, hot, dry, and moist. At all of these stations they have the Loganberry, and the reports from all are that the berry is doing well. As I have before stated, the Loganberry is reproduced from seed, and while such seedlings are essentially Loganberries, not one in a thousand is equal to the original. Such seedlings are rank frauds when sent out as the Loganberry, and unprincipled nurserymen in this State, having in view only a little temporary advantage, have been flooding the East with such seedlings, and wherever sent the result has been condemnation of the Loganberry. The bulk of the fruiting of this plant is in May, June and July. However, the autumn crop is often of considerable importance.

#### CHERRIES FOR AMATEURS.

AMATEURS are often at a loss to know what varieties of Cherries to plant, and their too often limited wall space necessitates a wise selection, as many of the choice dessert Cherries are such strong growers and shy bearers, and are not brought into a profitable state, except by the most skilful treatment. Others there are, however, that with ordinary attention usually give a good return, always provided the climate is tolerably good, as few of the Bigarreau and finer sorts do satisfactorily as a rule in midland and northern districts. A very early, handsome black Cherry which should be in every collection, however limited, is Early Rivers. It is grown as a standard in the south and succeeds well, but on a wall the fruit grows much larger and the flavour is rich and juicy. Another fine early variety is Belle d'Orleans, of a handsome red colour, bearing very freely and paying well for wall space; the flavour is very good. Too many early fruiting kinds are not desirable in a limited collection, but where the soil is heavy and none too warm no better variety can be planted than Elton. In such a medium most sorts soon gum and canker, even if lifting when young and replanting are practised, so that Elton will suit those who have not strictly a Cherry soil. The flavour is average, and colour yellowish-red. Of the Bigarreau section, Governor Wood is one of the finest, and may be safely planted on wall in midland localities, seldom missing a crop, and in good Cherry seasons bearing enormously. Like many of this class, it is liable to gum if planted in low, dry situations. Kentish Bigarreau or Amber Heart, as it is sometimes called in Kentish gardens, is still one of the most reliable and profitable Cherries, a red and yellow fruit, growing to a very large size. This variety is cultivated extensively for market in Kent and Sussex. It is a constant bearer and sure to please those who plant it. The well-known Bigarreau Napoleon succeeds well in most gardens in good climates, bearing freely fine showy fruit of excellent flavour. It is good for mid-season supply. For keeping up the supply during August, Black Circassian, or Tartarian, a noble black Cherry and one that succeeds on a wall in cold districts better than many, is indispensable. The quality is first rate, and it will hang in good condition for several weeks if netted to protect from birds. For late supplies, Florence, a variety grown in standard form in Kent, produces enormous fruit on a wall, but must not have a rich larder, or growth will be too strong. In market gardens this is known as Wellington. As a very late variety grown on east or west walls, Late Duke, a slightly acid variety, bearing well and hanging long, is reliable in all climates and soils.

When young Cherries take to a gross growth when first planted, the best remedy is to lift in November and replant near the surface in soil to which has been added a good percentage of old mortar rubble, ramming very firmly and depriving the trees of any extra coarse roots. Planting on stations composed of slates or tiles is always advisable. C. C. II.

**Strawberries in the north.**—Royal Sovereign Strawberry has become very popular in the north by reason of its earliness, free bearing, and large fruit of good quality. It does not grow so freely on some soils as Garibaldi, Duke of Edinburgh, President and John Ruskin. The last is among the earliest I have tried and a most abundant bearer, especially the first year after being planted. For preserving it is first-rate. I prefer planting out those which have been forced in pots on rich ground, well trenched, then trodden firmly while the weather is dry. During June is a good time to plant. The ground between can be utilised for Spinach to be removed while the crop is young, Onions to be pulled green, Lettuce and young Turnips. Garibaldi as a general cropper is popular in the north.—M. TEMPLE, *Carron, N.B.*

**Fruit notes.**—I do not remember such a season of wind, rain and changeable temperature as we have experienced here for three months past. When Apples, Plums, Cherries (in fact, most other fruits) were setting, rains, cold and heavy, were continuous, and the wind was such as one would consider severe during January, and seldom remained twelve hours in the same direction. North-easterly winds were most prevalent. Though Apples, Cherries and all small fruits are very abundant, they were well thinned. It is well when planting in orchards and gardens to keep in mind that many varieties of fruits are more hardy than others. Those Apples which have set very freely are Lord Grosvenor (in clusters all over the trees), Cellini, Golden Spire, Northing (Greening, King of Pippins, Seaton House, Stirling Castle and Yorkshire Greening. These never fail, and always give a useful supply from August to May.—M. TEMPLE, *Carron, N.B.*

**Peach stones splitting.**—One very important and necessary constituent in all fruit soils is lime. This applies more particularly to stone fruit. I know some soils practically free from lime. These are useless for stone fruit unless liberal additions of good air-slaked lime are made. It would be interesting if the correspondent to whom "W. I." replied in last week's issue would kindly say whether his soil is on a limestone or chalk formation or otherwise. If the borders are renovated, as "W. I." suggests, I would strongly recommend the addition of say one part of air-slaked lime to twenty of "W. I.'s" admirable border compost, as lime enters so largely into the process of stone formation, and I believe in a great measure prevents stone-splitting. I find, as a rule, a great many persons put too much faith in old mortar rubbish. This material is of little use for supplying the necessary substance, although it is admirably suited for correcting adhesiveness in strong soils.—J. EASTER, *Nostell Priory Gardens.*

**Browallia speciosa major.**—Blue flowers are generally scarce in the greenhouse during the summer and early autumn months. This Browallia, however, is just the thing for this purpose, as it is of easy culture and will continue to bloom for a long time, while the flowers are of a beautiful shade of deep blue with a lighter centre. This refers to the blooms when they are first expanded, for with age they become paler, while, singularly enough, they also increase in size. It may be readily grown from seed, which ripens freely. Sown in the spring in a gentle heat, the young plants when large enough may be pricked off into pots or pans. They may then be potted off singly, or, what is far better, half a dozen or so can be dibbled into pots 5 inches in diameter, and in this way, if sturdy growth is encouraged,

they form neat little specimens. Good loamy soil, with an admixture of well-decayed leaf-mould and manure with a dash of sand, will suit this *Browallia* well. It is a native of the temperate regions of South America. An allied species, *B. elata*, has been cultivated in gardens for years.—H. P.

## TREES AND SHRUBS.

### THE WISTARIA.

It is a pity people do not more often plant the *Wistaria*, as the beauty of old specimens when in bloom is worth striving for. The *Wistaria* is a fast growing plant, and one has not long to wait before getting some flowers if it is planted under favourable conditions in a free, light soil. In exposed places the flowers of the *Wistaria* are sometimes injured by severe frost before they open, but in favourable years they escape, and then this fine climber is seen to the best advantage, the rich green foliage making a fine background to the flowers. It is most often seen against a wall, but it has also a picturesque appearance when its vigorous branches can ramble into the head of a neighbouring tree. If planted in this way care must be taken not to put it too close to the trunk of the tree, as then it is simply starved to death.

When growing the *Wistaria* against a house a little care in training is well repaid. A system of pruning nearly similar to that of the spur system in Grape pruning should be adopted, or rather a system combining that with the plan generally adopted for fruit trees which bear their flowers and fruit on old spurs. In the month of July all shoots that may be reserved on the main or leading stems should be pinched back to within a foot of the main stem in order to check the rampant growth. These shoots will again break into growth from the buds just behind where the shoot was stopped, and after these shoots have grown a few inches they should be again stopped. The result will be the formation of flower spurs at the foot of the shoot first shortened. Early in the following spring these shoots should be cut back to within five or six eyes of the main stem, and the young growths from these eyes are then to be treated in the same way as those of the previous year. By following this course of treatment long continuous wreaths of flower will be produced. When the leading stems have reached the length it is intended they should attain they should also be stopped, and the result will be a trim appearance of the plant, which yet will not appear stiff and formal. W. T.

**Ceanothus azureus.**—It is singular that the varieties of this pretty old plant are not more grown. It is true they are a little tender in some places, but there are many things given frame cultivation during the winter that are less deserving than these. Nor is frame cultivation necessary, for in plenty of places this proves almost perfectly hardy. In an Essex garden last week I noticed a plant trained up a potting shed wall—not the ideal place for it by any means, still it was extremely pretty. This plant has stood the last five winters in its present position, and it is now about 6 feet high and almost entirely covered with the pretty blue flowers.—C.

**Platanus occidentalis argentea variegata.**—As exhibited at the Drill Hall last week this plant promises to be of some value. The effect produced by its remarkable variegation is very good indeed, and the plants, which were some 8 feet high, were in excellent condition. Unlike many highly variegated subjects, the variegation does not appear so much in the young leaves, these being of a buff tinge, but as they get older the white variegation stands out in

marked contrast. If of permanent character, it should prove of considerable service among ornamental trees for parks and gardens.

**Spiræa japonica glabrata.**—This *Spiræa*, of which there is a large circular bed at Kew, at the present time presents an almost unbroken sheet of blossoms. There is a good deal of confusion in the nomenclature of this section of *Spiræa*, the specific name of *callosa* being far more generally used than that of *japonica*. The variety *glabrata* is certainly a very desirable form, the bushes composing the bed in question being 3 feet to 4 feet high, and each shoot is terminated by a large flattened corymb of blossoms, which when first expanded are of a bright carmine-rose tint, becom-

appearance unless the old flower-heads are picked off, as if this is done the secondary ones develop and continue the display of bloom. It is a pretty little plant for the rockwork. *S. bullata* also bears the specific name of *crispifolia*.—T.

**The white Jasmine.**—In any selection of flowering climbers this must have a place, for common though it be, it is admired by everyone, the handsome deep green foliage serving as an admirable setting to the pure white fragrant blossoms. Many a country cottage may be seen adorned with this Jasmine, and when allowed to grow at will it is really charming. The display of flowers, too, is by no means fleeting, for it blooms more or less throughout the summer. If

it is secured to any substantial support and then allowed to grow at will it assumes a dense bush-like mass, totally devoid of any stiffness or formality. Several examples of this Jasmine unfavourably situated in different parts of London, yet laden with blossom, have come under my notice of late. The stiff, vigorous-growing Himalayan *Jasminum Wallichianum* is also in many places flowering freely, but not where at all unfavourably situated.—T.

**Deutzia crenata** and varieties.—Soon after midsummer the different forms of this *Deutzia* are at their best, and the two double-flowered varieties are certainly entitled to a place among the finest of our flowering shrubs. Besides the typical kind with single white blossoms, there is a double one with white flowers, and another in which the exterior of the blooms is tinged with purple, which feature is far more pronounced in the bud state than it is after the blossoms are expanded. From a fine-foliage point of view *D. c. punctata* or *variegata* is noticeable, the leaves being freckled in a peculiar manner with green and white in about equal proportions. The bark of the young shoots is reddish, and the effect of a small bush of this variety as viewed at a distance is very like that of

A flowering branch of *Wistaria*. From a photograph sent by Mr. Mallet, Culverwell, Bath.

ing paler with age. After the principal cluster of blossoms secondary ones are pushed out, and by this means the flowering season is considerably prolonged. It is a good plan to cut off the old flower clusters as soon as they are past their best.—H. P.

**Spiræa bullata.**—This, the smallest growing of all the members of this extensive genus, forms a compact little shrub not much more than 6 inches high, every shoot of which is just now terminated by a crowded cluster of bright carmine-coloured blossoms. They do not, however, retain their freshness long and the plant soon presents a dull

*Vitis heterophylla variegata*, in which the same colours occur. *Deutzia crenata* is, compared with the popular *D. gracilis*, quite a giant, and it is a worthy associate of the Mock Oranges, all of which flower at much the same time.—T.

**Erica stricta.**—Of the taller-growing Heaths, there is none better adapted for our climate than this. Whilst such species as *arborea*, *codonodes* (properly *lusitanica*) and *mediterranea* all suffered badly in the spring of 1895, some being wholly killed, this species survived with but little injury. This summer it has flowered profusely, and even now is still pretty. Like the other species

just mentioned as less hardy, it is a native of South Europe, and has been in cultivation since 1765. Its leaves are linear, scarcely one-fourth of an inch long, dark green, and produced thickly on the stems in whorls of four. The flowers are borne in umbels terminating each twig, and are of a bright purplish rose: they are pitcher-shaped, contracted at the mouth, and are about as long as the leaves. The shrub is of rather erect habit, and grows 5 feet to 6 feet high about London, but probably more in milder localities.—W. J. B.

**Cratægus cordata.**—Although introduced as long ago as 1738, this Thorn is still quite an uncommon one in this country. It is said also to be rare in a wild state in its native home—the United States. Like most of the Thorns, it is a small tree and is not often more than 20 feet high in Britain. It differs from all the others in being the latest to bloom. The flowers commence to expand in the latter half of June, and even now (in mid-July) the trees are still white with them. They are followed by the small fruits, which are only one-third of an inch across, but bright red when ripe, and produced in sufficient quantity to render the trees ornamental at that time. The tree is distinct also, and easily recognised by its leaves, which are of a peculiarly glossy green and quite smooth; they are 2 inches to 3 inches long, the main outline triangular, but with margins cut up into several lobes, these again being irregularly notched. The branches are armed with slender spines, the largest 3 inches or so long. The neat and distinct appearance of this Thorn, as well as its late flowering, ought to obtain for it a greater amount of notice than has yet been given to it. It is commonly known as the Washington Thorn.—B.

**Spiræa discolor** (syn., *S. ariaefolia*).—This species, although it does not possess the rich colour of some of the dwarfed ones now in bloom, is still one of the most graceful and striking of Spiræas at this or any season. It is a native of North-west America, and was introduced in 1827. It reaches 8 feet to 10 feet in height, and is thus one of the tallest Spiræas we possess. Its strong shoots are erect at first, but many of them droop gracefully over at the top where the large panicles are borne. The panicles are pyramidal in outline and as much as 6 inches or 8 inches in diameter at the base. The flowers are of a dull white, and the panicle has a somewhat fluffy appearance on account of the numerous and prominent stamens each flower possesses. The species is often called by a more recent name, *ariaefolia*, which refers to the resemblance its leaves bear to those of *Pyrus Aria*: they are, however, much smaller, being 1½ inches to 3 inches long but the outline is much the same, and the lower surfaces are covered with soft hairs that give a greyish appearance. Scattered through the delightful woods at Dropmore there are numerous fine examples of this Spiræa. Many of them are in semi-shade, and, standing well above the undergrowth, the graceful flower-laden branches have a most charming effect.—W. J. B.

**Ligustrum sinense.**—There are few hardy shrubs in flower now that make so conspicuous a feature in the garden as this Chinese Privet. It is, indeed, the most effective of all the species grown for the sake of their flowers. Its habit is graceful, and if the plants are given a sufficiently sheltered place, also luxuriant. It is tenderer than some of the Privets, and is best planted with other shrubs for the sake of shelter. Although never killed outright by cold in the London district, its branches are cut back in severe weather, and the plant loses some of its natural elegance thereby. Its leaves are of a rather light green, thin in texture, with the petioles so twisted as to bring the blades into two opposite rows. The natural habit of the shrub is to form a wide-spreading, rather flat top, narrowing to the naked stems near the ground. At the present time the foliage is almost hidden by the panicles of white flowers, which form a dense canopy over the whole upper part of the shrubs. In the arboretum at Kew it has been planted in groups, and the masses of white are very striking, all the

more so now that shrubs in flower are becoming much scarcer out-of-doors. It is not evergreen, but retains its leaves and fruits (which are small and purple) almost through the winter. This Privet was introduced from China by Robert Fortune about 1861 or 1865.—W. J. B.

**The Spanish Broom** (*Spartium junceum*).—Among the comparatively few leguminous shrubs now in flower, the Spanish Broom is the most striking and beautiful. I never saw it so fine or in such abundance as it is in the shrubberies surrounding the railway station at Taplow, in Buckinghamshire. Here large rounded bushes averaging 6 feet in height and perhaps 4 feet in width are now covered with glowing masses of bright clear yellow flowers. The species is a native of the countries of South-western Europe, but it is hardy in all but exceptional winters, such as that of 1894-5, when it was cut back or killed outright in many places. The flowers are among the largest seen in the hardy Leguminosæ, measuring 2 inches in vertical diameter, and the heart-shaped standard petal being exceptionally large. The whole flower is of a bright yellow, varying, however, in depth of shade in different plants. The shrub is of erect growth and the spikes terminate the shoots; one spike will bear twenty or more flowers, about half-a-dozen of which are open at one time. The leaves, which are few, measure from 1 inch to 2 inches long and are quite narrow. The young stems are very Rush-like, being dark green, slender, and largely filled with pith. Seeds ripen in abundance and they afford the best means of increase. The habit of the shrub is improved by the shoots being frequently stopped when it is young. There used to be a double-flowered variety in cultivation, but it appears to be lost. Does any reader of THE GARDEN possess it or know where it can be obtained?—B.

BOOKS.

LAWNS AND GARDENS.\*

Judging by the many books on garden design, gardening is rapidly becoming a fashionable art. People begin to see in it something more than the rule of thumb which they might have concluded it to be from much of the flower gardening still existing both in America and England. The author of this book may be a very able practitioner, but his book bears the ugly mark of many books of our own day in heavy clayed paper and cuts done by some brutal processes, some of them the worst we have ever seen—for instance, p. 257 Chinese *Wistaria*; p. 238, *Black Haw*; p. 227, *Spiræa*. Coming to the matter of the book, one is rather stopped at the outset (page 4) by the following:—

*It is evident that nowhere in the world a wholly natural scenery exists; even in the high Alps the mountaineer builds his tiny cottages and surrounds it with degrading associations; there are hardly any primitive forests left, and if there were they would not be wholly natural.*

A statement untrue in all ways. Leaving out America and the vast regions there still untouched by man, there is scarcely even a small country in Europe which has not many thousand acres of perfectly natural forest, the very uselessness of the ground and its elevation in many cases compelling that state of things. Young or old writers who make such silly statements would be much better prepared for their work by an excursion through such forests. They would get many lessons both in form and grouping, and also learn how the rocks come out of the ground naturally, and how flowers take to them. Another very ignorant statement is at page 31 about wild gardening.

*Of late years wild gardening has been much recommended, and it has been claimed that anybody, by sowing a mixture of flower seeds in the garden, would obtain the most charming results.*

It would do the author good to see a few clouds of the bolder *Narcissi* some April day happily in

\* "Lawns and Gardens." By N. Jönsson-Rose. Putnam's, New York.

the grass in a wild garden, or in June to go along a grassy path with many wild *Roses* on each side. He would then perhaps begin to see what the wild garden meant in some ways. Though parts of the book show a good disposition and a tendency towards right effort, when one is confronted by statements of this kind it is difficult to persevere in reading whilst there are so many other sources of instruction. The illustrations of bridges and garden buildings, although the author rightly asks for simplicity, are, like all illustrations in this kind of book that we have seen, far too pretentious. In none is this more visible than in French gardens, in which far too much attention is paid to structures that ought in better design to take their place simply and quietly, as a boathouse does on a Norfolk broad or a bridge over a stream in a country district in Wales. But these things would not look so well to many in a drawing as the simpler work, and gardens, like buildings, are no doubt destined for a long time to be ruined by showy plans and designs. W. R.

WOBURN EXPERIMENTAL FRUIT FARM, FIRST REPORT.\*

WHAT in the United States of America and some few other countries is undertaken by the Government in England largely left to private individuals to carry out. As far as fruit culture is concerned, anything in the shape of well-planned experiments has not been attempted on a large scale and in a strictly disinterested manner till quite recently, and it was left to the Duke of Bedford, assisted by Mr. S. U. Pickering, F.R.S., to step into the breach. A series of ably-planned experiments with all kinds of hardy fruit were initiated in a large field at Ridgmont, Beds (adjoining the Woburn Agricultural Experimental Farm), in 1894, and already an elaborate report of nearly 200 pages is before us. In this report we are presented with full particulars of all that has been done, with much that is still in contemplation, and from it will be gathered that neither pains nor expense will be spared in making the undertaking the success it fully deserves. Much that is interesting and corroborative is placed before us in this first report. Practically nothing but what is already known to experienced fruit-growers has been brought forward, nor is there much probability of really valuable information, from a commercial point of view, being forthcoming for many years to come.

It ought not to be taken for granted that because the average farmer knows so little about fruit culture the professional fruit farmer is equally ignorant. On the contrary, many of them are shrewd, clever, and, above all things, very practical men, fully capable, too, of growing fruit successfully and profitably—in some instances under adverse circumstances. These men are not likely to be benefited by the Woburn experiments, and in all probability, if the reports were presented to them, would laugh at those puny half-acre plots, intended, presumably, to revolutionise fruit-farming for profit, and also treat all those formidable columns of figures with which the report abounds much as the authors went out of their way to suggest should be done with certain Government publications, viz., trouble themselves no further about matters which are evidently not adapted to their comprehension (see page 157). The scientist revels in his columns of figures—cannot have too many placed before him, in fact. Not so the market grower and farmer. These latter would prefer reports as presented by those in charge of the various experimental stations in America, the Cornell University in particular. In these there are numerous practical hints and conclusions, presented in a form easily comprehended.

At Woburn an almost endless series of experiments are now in full swing. Every possible

\* "Woburn Experimental Fruit Farm." First report, by the Duke of Bedford and Spencer N. Pickering, F.R.S. Eyre and Spottiswoode, London.

right and wrong way of treating fruit trees, notably Apples, will be shown, and there ought really to be something among them to prove of educational value to the majority of visitors who may inspect them during the next quarter of a century. Already the ill-effects of planting carelessly, planting in shallow soil, and not keeping the surface-soil free of grass or weeds are, according to the report, showing plainly, the photographs of neglected as compared with properly tended trees being most suggestive. It is in the matter of planting too deeply and sowing over the ground at once, instead of a few years hence, where so many farmers are at fault, though in not a few counties these blunders have been repeatedly and forcibly brought home to them by horticultural instructors and others. They also require educating in the art of pruning young trees, and in this direction, again, the Woburn report gives instructive examples of what is best to be done. Plots are also set apart for demonstrating the correct time for both summer and winter pruning, and any doubts upon these points ought to be set at rest—say in the course of ten years. Nothing very conclusive can be demonstrated much under that time. The Woburn tenantry will have good opportunities afforded for deciding which are the best kinds of hardy fruit to plant, the trials of varieties being most complete; but beyond Bedfordshire the information gained in that direction will not be very reliable. Strawberries, again, are on trial, eighty or more varieties occupying separate plots, and have nearly thirty pages in the report devoted to remarks upon them. If from among these a thoroughly reliable late variety, good for either market or for private gardens, is found, that will be well worthy of being made public, and a few other facts, plainly told, about other little-known varieties would be welcomed by innumerable Strawberry growers. We are, however, warned not to place too much reliance upon these experiments with Strawberries, for it is stated on page 190 that "Even within the limits of the farm (20 acres) the same varieties have given different results according to their situation, and there is evidence to prove that the Strawberry is very sensitive to slight variations in the conditions under which it is grown."

Hedgerow planting has not received nearly as much attention at the hands of British fruit-growers as it has on the Continent, numerous excuses, including the boy "bogey," being offered for this. At Ridgmont various hedges have been planted for "protective purposes" of fruit trees of different descriptions, and these will be scanned very closely during the next few years. In these hedgerows are comprised nine varieties of Crabs, five varieties of Plums, four of Damsons, one of Bullace, four of Nuts, two of Quinces, three of Medlars, and one species of Berberis. Some of the most profitable hedgerows in this country are to be found in Essex. In this instance the hedge is formed of Filberts, with standards of Apples and Damsons, about 12 feet apart, dotted among them. Why are there not more dividing and shelter hedges of this description to be met with? There ought to be no waiting to see the results of the Ridgmont experiments. W. I.

**Seedling Gloxinias.**—Young Gloxinias from spring-sown seed are often neglected, being left in the seed-pans or pots too long and becoming drawn and weakly. The tiny plants should be thinned out where too crowded as soon as they can be handled. A shady, but not dark position and a moist temperature of 65° or 70° suit them. February-sown batches should be first potted into very small pots, and later on into  $\frac{1}{2}$ -inch pots, the former size being sufficiently large for those sown in March and April. Thrips often attack the foliage unless the syringe is freely used, a gentle fumigation once in three weeks being a good safeguard against the pest. A compost of three parts light fibrous loam and one part leaf-mould and silver sand will grow Gloxinias well. These yearling bulbs, if care-

fully wintered in a temperature of say 50° or 55° and potted the following February, will make grand plants the second summer.—J. C.

## ROSE GARDEN.

### BANKSIAN ROSES.

THESE charming Roses are worthy of a place in every garden where a suitable position can be found for them. In northern or cold districts none of the Banksian Roses thrive satisfactorily in the open air unless it is in a sheltered posi-

tion and against a south wall. In such cases as these, therefore, it is best to give them a place under glass. The back wall of a greenhouse is a capital position for them, and so is the roof or rafters of a conservatory. In southern and warm districts, however, the Banksian Roses should be planted outdoors, for there they are undoubtedly seen to the best advantage. Few climbers produce such a pretty sight as these delightful Roses during the month of May and in early June. Near Winchester, in Hampshire, I have often seen a cottage that has its front wall literally laden with clusters of the yellow kind. The tree, which has been in its present position for more than thirty years, has

been carefully attended to, never disappointing its owner by not producing a moderate amount of bloom even in the worst seasons. Last year, when I saw it about the middle of May, it presented a most charming appearance, being one mass of yellow. This variety appears to be rather hardier than the white-flowered kind and more free-blooming. Both, however, are good and deserving of greater attention than has hitherto been paid them. There are several varieties of the type. One named Fortunei produces flowers similar to those of the old yellow, but larger, while the same may be said of alba grandiflora in regard to white

*Banksian Roses. From a photograph sent by the Rev. John A. Lloyd, The Vicarage, Mere, Wilts.*

tion and against a south wall. In such cases as these, therefore, it is best to give them a place under glass. The back wall of a greenhouse is a capital position for them, and so is the roof or rafters of a conservatory. In southern and warm districts, however, the Banksian Roses should be planted outdoors, for there they are undoubtedly seen to the best advantage. Few climbers produce such a pretty sight as these delightful Roses during the month of May and in early June. Near Winchester, in Hampshire, I have often seen a cottage that has its front wall literally laden with clusters of the yellow kind. The tree, which has been in its present position for more than thirty years, has

varieties. Jaume Serin, with yellow flowers, and odoratissima, which produces clusters of fragrant white blooms, are also useful varieties.

The culture of Banksian Roses is comparatively simple. As has been said, they require a warm south wall, and should, moreover, be planted in a kindly soil. That of a light loamy or sandy nature is most suitable for them; indeed, to plant in other than this is courting failure. If possible, a bricked-in border should be given them, especially where the soil has a tendency to be wet, and this must be well drained by placing a layer of broken bricks in the bottom. I have established plants by placing them in a tub well drained and sunk

into the ground, filling it as full as was necessary with a prepared compost of turfy loam and decayed manure. This involves a little more than ordinary trouble, but it pays. When planted in greenhouse borders, of course less care need be taken, especially when the roots will be confined to a certain space. But, whether indoors or out, it cannot be too strongly impressed upon readers that to obtain the best results, planting must of necessity be performed in a judicious and workmanlike manner. The pruning of Banksian Roses is somewhat imperfectly understood. They should be pruned immediately after flowering. Thin out the long shoots, laying in sufficient to cover the space only, and these at a good distance apart so that they may become thoroughly ripened. Those that are laid in should be shortened, say to about one-third their length in most cases, just removing the tips in others. From the points of these, new growths will be formed during the summer, and in early spring cut them back to within 2 inches or 3 inches of their base, leaving say three good eyes. From these a bountiful supply of flowers will be produced. A mulching of decayed manure placed around the stems and over the roots will help to conserve the moisture during summer and assist the tree wonderfully, while in winter it may be necessary to neatly twist a few hay or straw bands around the stem if the weather is at all severe. C.

**Sweet-scented Roses.**—It is high time the National Rose Society took up this matter of fragrance with spirit. Let every Rose lose one, two, or more points on the show table that has no odour. Let no Rose receive a medal as the best Rose at any show unless sweet-scented. I will only make one more suggestion for the present, and that is, that at every show held by the National Rose Society, and all societies affiliated with it, one or more prizes shall be offered for collections of the sweetest Roses and for the sweetest Rose in the show. The fact is, while we have been developing size, laying on colour, elaborating form to great perfection, we have done little or nothing to intensify the sweetness of our Roses.—D. T. F.

**SOCIETIES AND EXHIBITIONS.**

**NATIONAL VIOLA SOCIETY.**

**BOTANIC SOCIETY, JULY 17.**

THE second annual exhibition of this society was held at the Royal Botanic Gardens, Regent's Park, on Saturday last, and may be considered in every way a distinct success. The exhibits were arranged on either side of the corridor leading to the conservatory, and this year, owing to the free growth of *Cobaea scandens*, which is used on the roof, capital shade was obtained overhead. The south-western side being covered with green baize, the enclosure was kept in a cool condition, and the exhibition consequently rendered more successful. Only in a very few instances, even late in the day, was there to be seen any evidence of the flowers withering, the sprays of blossoms looking remarkably fresh after so long exposure. The exhibits came from all parts of the country, several well-known Scotch growers sending up interesting collections, while flowers from the west country were useful for comparison with the former and those grown in the neighbourhood of London and the south of England. The honours of the display were about equally divided, amateur growers and those of the trade occupying about half of the space allotted. There appeared to be more exhibitors than last year, thus showing that a greater interest is being evinced in the flower, more especially in the amateur section. There seemed to be a general feeling that

the display was a few weeks later than it ought to be, the climatic conditions prevailing in the south during the past fortnight being exceedingly trying, and much against the different forms of the Pansy being seen in first-rate condition. This, combined with heat of an exceptionally trying kind for two or three days previous to the show, made the display all the more meritorious when these facts are considered.

Fancy Pansies were seen in goodly numbers and in fairly good form for so late in the season, and a few trays of the show forms were also in evidence, although these seemed of interest but few. Tufted Pansies, however, were well shown, and made by far the largest display. The great variety of their colouring—in many instances of the most refined kind, combined with the chaste characteristics of many of the newer varieties—made the display of greater interest to the many visitors to the show during the afternoon and evening. The public appeared to evince a greater interest than on any similar occasion during recent years, and there is a better prospect for the flower than at one time seemed possible. Growing plants, too were shown, the free-flowering character of the Tufted Pansy perhaps being better appreciated in this way, while one class of especial interest was that in which the flowers were arranged in specimen glasses, with foliage added to give additional effect. This latter competition proved the value of the Tufted Pansy for table decoration, the blossoms keeping beautifully fresh and no stiffness being apparent in their arrangement.

**TUFTED PANSIES.**

The premier class in the open section was for forty-eight sprays of Tufted Pansies, distinct, nine blooms in each spray, and arranged with their own foliage. The leading position was occupied by Mr. W. Baxter, Woking, who had a very nice lot of flowers of good size, and representative of the different types of the flower now finding most favour. His best sprays were Mrs. C. F. Gordon, Craigie, Christiana, creamy white, with a large, rich orange eye and very dwarf; Wm. Haig, the best of the indigo-blue flowers; White Empress, a new rayless white self; Stobhill Gem, an exquisite flower; Lemon Queen, a useful pale yellow self; Cherry Park, Endymion, a rather large flower, in colour half-way between Ardwell Gem and Lemon Queen; Cottage Maid, one of the best dark fancy flowers; Ardwell Gem, Princess Louise, a medium-sized, pure rayless yellow self and a good bedding sort; Charm, Florizel, one of the very best, blush-lilac; Blush Queen, Marchioness, pure white, neat orange eye; and Yellow King, a dense yellow bloom of good size and substance. The only other exhibitor in this class was Mr. J. Forbes, Hawick, N.B., who was placed second with a nice lot of flowers, conspicuous among them being Lord Salisbury, an immense pale yellow flower of much substance; Edina, clouded and streaked blue on a grey ground, good size; The Mearns, Mrs. Daniel, citron, yellow eye; and Magie, a deep rich rose flower and very striking. For twenty-four sprays, distinct, six blooms in each spray, Mr. J. Smellie, Busby, near Glasgow, N.B., was placed in the premier position with nice fresh, clean, and large flowers. They were a beautifully even lot, his best varieties being Dorothy, a lovely pale blue self with a neat yellow eye; Liz Barron, a very large circular rosy purple; Duchess of York, white, with well-defined dark rays; A. J. Rowberry, deep rich yellow rayless self; Maud, a beautiful pale rayless flower; Sir Visto, large, striped deep blue flower on a white ground; Lizzie Paul, good yellow rayed self, large; Iona, and Dandy Dimmont, petals alternately marked purple and white. Mr. M. Campbell, Blantyre, N.B., was a good second. Sheelah, pale rose, with deep crimson centre, a very effective flower; Isa Fergusson, very dark blue-black lower petals, upper ones glossy blue; Magie, Lizzie Paul, and Border Witch, one of the prettiest of the edged flowers, being the best. There were two competitors in the class for twelve rayless kinds, Mr.

J. Forbes taking the leading position, his best flowers being Florizel, Marchioness, and Border Witch, Messrs. Isaac House and Son, Coombe Nurseries, Westbury-on-Trym, Bristol, securing second place with A. J. Rowberry, Princess Louise, White Empress, and Duchess of Albany in good form. In the class for six sprays rayless, miniature type, Mr. Forbes was first with Ophir, deep yellow; Violetta, white; Marginata, white, faintly edged blue, and Gold Crest, golden yellow. A pretty lavender-blue seedling in this stand was also much admired. Mr. J. Smellie was second. The class for three sprays yellow selfs was a very interesting one. Mr. M. Campbell was first with good sprays of A. J. Rowberry and Lizzie Paul, while Mr. J. Smellie closely followed him with A. J. Rowberry, Lizzie Paul and Mary Gilbert, altogether a very rich lot. The class for a similar number of white flowers was secured by Messrs. Isaac House and Son with Christiana, White Empress, a superb flower, and Countess of Hope-toun. Mr. M. Campbell occupied second position with Nellie, the best of the white rayless sorts; Lady Salisbury, heavily rayed; and Duchess of York. Three sprays of the Duchess of Fife family, which includes that already mentioned with Goldfinch and White Duchess, made an exceedingly pretty display. Only one competitor entered for the table decoration, and that was a poor lot, a greater inducement than a bronze medal of the Royal Botanic Society being necessary to ensure a really good display. Mr. W. Allison, Kingston-on-Thames, was the only competitor. This class might be made a very good one if liberally treated, as the flowers are so well adapted for this kind of work. A class for which a special prize was offered was for six sprays, arranged with any other than Viola foliage. The competition was keen, resulting in Mr. R. T. Dougall being placed first with a very pretty, simple and neat arrangement. His flowers were backed with bright green sprays of Asparagus, the top spray being set off with a few pieces of grass—altogether a delightful contrast. Mr. M. Campbell was second, he using Asparagus and Maiden-hair Fern, but his arrangement was too formal and heavy. Another class of special interest for which prizes were offered by the president was for six Tufted Pansies, distinct, shown as the plants grow, to be grown in the open air in any simple receptacle. The names of a few dozen varieties from which the selection was to be made were specified, and this contained many of the best of the old and newer sorts. Mr. D. B. Crane, Highgate, N., secured premier honours with six plants growing in a circular wicker basket. His selection was confined to Blue Gown, a fine plant covered with blossoms; Ardwell Gem, freely flowered; Border Witch; Princess Louise; Mrs. Scott, pure white, very free, and another creamy-white seedling. The few intervening spaces were mossed over, adding materially to the finish. Such an exhibit should be very convincing as to the value of these plants for garden decoration, and is worthy of more consideration when making up another show. Messrs. I. House and Son were second with plants growing in pots and in a nice fresh and healthy condition. Their selection was White Empress, Florizel, Sheelah, Christiana, W. Haig and A. J. Rowberry. The amateur display under this heading was very fine, Mr. R. T. Dougall winning first prize for twelve sprays, distinct, with grand blooms. His best flowers were Nellie, Dorothy, White Duchess, very chaste; Florizel, A. J. Rowberry and Stobhill Gem. Mr. J. P. Sheldon, South Woodford, was second, his best being Goldfinch, Iona, Duchess of Fife and Ardwell Gem. For six sprays, distinct, Mr. J. Maxwell, Dalton Newton, N.B., was first with Butterfly, a heavily edged flower; Lizzie Paul, J. Pretswell and Princess Beatrice. Dr. Shackleton, Sydenham, was a good second, with neat and even flowers, Pencaitland, white, flushed yellow lower petal, Blush Queen and White Duchess being very good. For six sprays rayless flowers, Mr. D. B. Crane was first with an even lot of chaste-looking blossoms, Christiana, Nellie, Florizel, A. J. Rowberry, Devonshire Cream and Border Witch being those

staged. Mr. B. G. Sinclair, Highgate Road, was second with a pretty lot. Mr. Crane was first for three sprays white, showing Nellie, Ethel Hancock, pure white, and Christiana, Mr. Leonard Brown, Brentwood, being a good second with Vestal, Ethel Hancock and Lord Fitzgerald, pure snow-white flower. Mr. Crane was again first for three sprays yellow, showing A. J. Rowberry, Ardwell Gem and Princess Louise. The Duchess of Fife family was well shown here, Mr. J. J. Sheldon being accorded leading honours with large and well coloured flowers, Mr. L. Brown securing second position with a very fine lot. A charming contrast to the formal arrangement of the flowers was a class for eighteen varieties of Tufted Pansies, six blooms of each arranged in specimen glasses with their own foliage, neither blooms nor foliage to be wired. Mr. A. J. Rowberry, South Woodford, was a good first, with large richly-coloured flowers arranged in a free and informal manner. The system of exhibiting the flower commends itself, as showing the practical uses to which the Tufted Pansy in a cut state may be placed. At future exhibitions other classes confined to different colours, forms, &c., might with advantage be added. Dr. Shackleton was second with a fresh and meritorious display, many individual specimens being very beautiful indeed. The Tufted Pansies as a whole appear to be the more popular, and such a display cannot fail to further encourage their cultivation.

#### FANCY AND SHOW PANSIES.

These were exclusively confined to the open classes, there being no competition in the amateur classes, probably owing to want of enterprise on the part of the latter. The premier class, for which a gold medal was offered as first prize, was won by Mr. M. Campbell, Blantyre, N.B., and was for forty-eight bunches or sprays, distinct, six blooms in each spray or bunch. These were a heavy lot of flowers, and showed their appreciation of the cooler climatic conditions of the north. The best sprays were Dr. Jameson, Sir J. M. Watson, Marmion, dense violet blotch, laced rosy white; J. Jackson, Annie Ross, Colonel M. R. G. Buchanan, and several excellent seedlings. Second prize was secured by Messrs. Isaac House and Son, Bristol, with a fresh and even lot of flowers, and being grown some 300 miles further south than those in the first prize stand, were a highly creditable lot. Conspicuous among them were John Connor, Earl of Beaconsfield, Bronze Prince (good colour), and Rev. J. Abernethy. For twenty-four fancy Pansies, distinct, Mr. M. Campbell was again first, with good blooms of Colonel, M. R. G. Buchanan, J. Jackson, J. Menzies, large circular flower, white ground, neat solid purple blotch; Sir J. Watson, James P. Tait, and Miss Stirling. Mr. J. Smellie was second with smaller, but fresh blooms, Mrs. R. G. Moir, Ben Doulton, C. J. Pooler, W. P. Crosbie, and Valkyrie being in good form. The last named was first for twelve fancy Pansies, and occupied a similar position for twelve show Pansies, the best flowers of the latter being William Fulton, J. McClelland, and Busby Beauty.

Messrs. Dobbie and Co., Orpington and Rothsay, staged a fine collection of Tufted Pansies, embracing all the popular sorts, and including one or two highly-coloured flowers of great promise. Half-a-dozen well-grown plants of White Empress Tufted Pansy from Messrs. I. House and Son were also much admired. The Exhibitors' Supply Stores, Kingston-on-Thames, exhibited their many useful devices for simplifying the labours of the exhibitor.

**The Norwich Rose show.**—The northern exhibition of the National Rose Society, which was held on the 15th inst. in conjunction with the Norfolk and Norwich Horticultural Society, was a most successful one. The total number of exhibition Roses staged in the joint show amounted to 3590, which is 500 more than the average for the previous five northern shows, and greater than at any similar exhibition of the society, with the exception of those held at Birmingham in 1890, at

Chester in 1892, and at Derby in 1895. There were in all exactly fifty exhibitors and 220 exhibits. Arranging the latter according to the number contributed by each county they come out as follows: Norfolk, 55 exhibits; Essex, 46; Herts, 32; Suffolk, 23; Notts, 15; Oxford, 9; Surrey, 8; Derby, 7; Worcester, 7; Cambridge, 4; Yorkshire, 4; Leicester, 3, and Middlesex, 3. Nearly 7000 persons visited the show, which is a record attendance for a summer exhibition of the local society. —E. M., *Berkhamsted*.

#### NATIONAL CARNATION SOCIETY.

BOTANIC GARDENS, REGENT'S PARK, JULY 21.

A CARNATION show in these days is very different from what it was thirty years ago, so many new types having been obtained and new classes established. The schedule of prizes of the National Carnation and Picotee Society consists of forty classes, and when they are well filled a considerable space of tabling is required. The lover of the Carnation who grows only for exhibition finds an abundance of material to his hand, and those who, caring nothing for show flowers, but valuing them for border decoration, can have an abundance of varieties suited to their purpose. Those who prefer the striking self flowers, or the almost infinite variety of the fancies with their varied markings, or they who have a warm regard for the yellow-ground varieties, can enjoy surveying the choicest representatives of these sections, while there is abundant illustration of how delightfully the Carnation lends itself to manifold decorative purposes. Eighty years ago some sixty named varieties of double Carnations were in cultivation, for the florist was already at work improving the race. From that time onwards sorts in immense numbers have been obtained, and at present the varieties are bewildering in regard to their numbers. The winter and spring-flowering types were practically unknown three-quarters of a century ago, and if it be correct to say that the Malmaison type originated in the gardens of the French Empress Josephine at Malmaison, then it is a product of the same period. The Malmaison Carnation is valuable as filling up the interval between the winter-flowering and the outdoor summer-flowering varieties, but it is now possible to have Carnations in bloom all the year round. The culture of the Carnation for market is now a great industry. One interesting fact in connection with the Carnations grown for exhibition is the lasting value of some of them. Take Sarah Payne, which to-day stands almost at the head of the pink and purple bizarres, it was sent out fifty years ago and was in fine form at this exhibition. Admiral Curzon, scarlet bizarre, is older still, for it has been in cultivation since 1845, and if leading exhibitors were called upon to-day to name the two best flowers in this section Admiral Curzon would be one of them. Its sport—Sportsman, scarlet flake—has been in cultivation forty-two years, and is still widely grown and exhibited. Many other fine varieties, Picotees as well as Carnations, have been in cultivation for many years. Many new varieties are constantly being raised, but they are by no means always improvements upon existing varieties.

A fear that the weather might prove very hot and sunny and seriously affect the flowers if arranged under the glass corridor by the side of the large tent, led to the flowers being arranged within the latter, which under the dull morning light had a dismal appearance. The place was far too large. The light improved by the afternoon and caused a brighter appearance to the display. But the dried-up turf banks made an incongruous background to the flowers, and they were so low down that stooping was necessary to read the names. These were not faults of the executive, but of the place in which the blooms were staged. Should the exhibition be held in the gardens of the Royal Botanic Society again, let us hope that a spacious tent will be erected upon the lawn where the blooms would be seen to the best advantage and with better effect. There

were not wanting on the part of the visitors protests against the old-established practice of showing the blooms on stands with paper collars beneath them. But the exhibitor holds to the old ways because they, in his opinion, enable the individual blooms to be seen at their best, and no protests will ever alter them. The white collar, always larger than the bloom above it, enables the sharp circular outline of the petals to be displayed, showing their evenness and smoothness; so the florist will go along the old paths; but then there are many other classes in which the blooms are differently shown, and so the two schools find their ideas expressed in object lessons.

#### CUT BLOOMS.

The leading class was for twenty-four blooms of bizarres and flakes in not less than twelve varieties. The scarlet bizarres, Robert Houlgrave, Admiral Curzon, and Duke of York represented the darkest and richest flowers, because maroon and scarlet are on a white ground. Crimson bizarres have crimson and deep rose markings; some of the best were Thaddeus and Rifleman. Pink bizarres have purple and pink markings; the most striking were Sarah Payne and Arline. Purple flakes were represented by Prince George of Wales, Billy Henderson, and Charles Henwood; scarlet flakes by Tom Pinley, Fred, and Sportsman, and the soft rose flakes by M. Rowan and Sybil. This collection, which was awarded the first prize, came from Mr. C. Turner, Royal Nursery, Slough, thus regaining the old position of supremacy of some seasons ago. Mr. M. Rowan, Manor Street, Clapham, which is now almost in the heart of London, was second, he had some very fine blooms. Mr. James Douglas was third. Eight collections competed in this class. With twelve blooms Mr. Charles Phillips, Brockwell, was first, his leading blooms being mainly those already named. Messrs. Thomson and Co., Sparkhill, Birmingham, were second. Then came the selfs, bold and striking as they always are, one of the brightest features in the show. There were eight collections of twenty-four blooms, and they formed attractive patches of colour. Mr. C. Blich, gardener to Mr. M. R. Smith, Hayes, was first. Of yellow selfs he had Naiad, Mrs. Prinsep, a very fine variety, Maron, Proserpine, and Boreas; of crimson shades, Solon, and The Cadi; scarlet, Mrs. McRae and Boniface; rose, Endymion, very fine, and Tredegondi; pink, Elsie; blush, Her Grace and Purity; white, Ptarmigan, Helmsman, and Mrs. Eric Hambro, a splendid lot, mainly recently raised seedlings. Mr. C. Turner was second, and here the finest were Germania, Coronna and Miss Audry Campbell, yellow; white, Iona, and Mrs. Eric Hambro; and scarlet, King of Scarlets. Mr. Jas. Douglas was third. Mr. E. Colby Sharpin had the best twelve selfs, the leading ones, Nabob, apricot in tint; Mrs. Colby Sharpin, Thomas Parkinson, Seagull, and Ruby, rich purple. Mr. C. Phillips was second, and Messrs. Thomson and Co. third. In the class for six blooms the judges appeared to have selected the largest and coarsest, which came from Mr. S. A. Wout. The finest quality was decidedly in the second prize stand from Mr. A. R. Brown; this stand contained a highly promising blush seedling.

#### FANCIES.

Under this heading came the large and increasing section of yellow grounds and anything other than a true bizarre, flake, or self. There were six stands of twenty-four blooms, and here again Mr. C. Turner was first with a magnificent lot of flowers, chief among them The Gift, Duchess of Portland, white, striped with rose, charming; May Queen, Virgo, George Cruickshank, Primrose League, and fine seedlings, largely yellow grounds. Mr. James Douglas was second, Mr. Weguelin, Teignmouth, third. Mr. C. Phillips had the best twelve fancies. Mr. G. Chaundy, Oxford, was second. With six fancies, of which there were ten collections, Mr. W. Garton, Jun., was first, and Mr. A. Greenfield Patton second.

In the single bloom classes the best s.b. was Robert Houlgrave; the best c.b.'s, Master Fred,

Phæbe, and J. S. Hedderly; p.p.b.'s, William Skirving and Ellis Crossley; p.f.'s, Gordon Lewis and Mrs. Douglas; s.f.'s, John Wormald, Guardsman, and J. P. Sharp; rose flakes, William of Wykeham, Thalia, and Mr. Rowan; white or blush selfs, Mrs. Eric Hambro and Sir Guy; rose, Loveliness; scarlet, Verena, Little John, and Hayes Scarlet; maroon, Uncle Tom and Mephisto; yellow, Lord Wantage and Germania; bull, Mrs. Colby Sharpin and The Beau; fanies, Broderick, Cecil Rhodes, and Monareh.

The premier Carnations were—bizarre, R. Houlgrave, shown by Mr. M. Rowan; flaked, Matador, from Mr. J. Douglas; self, Mrs. Prinsep, yellow, from Mr. M. R. Smith; fancy, Badminton, from Mr. M. R. Smith.

#### PICOTEES.

There were six collections of twenty-four blooms of the pretty chaste Picotee, Mr. C. Turner being again first. Of red edges he had Brunette and Mrs. Gorton; purple edges, Mary and Muriel; rose edges, which greatly preponderated, Clio, Duchess of York, Favourite, Lady Emily Van de Meyer, Little Phil and Mrs. Payne. Mr. J. Douglas, who was second, had Fortrose, a light edged rose of great purity and beauty; also Constance Heron, Athene and Mrs. Sharp, and red-edged Ganymede. Mr. M. Rowan was awarded the third prize. With twelve varieties Messrs. Thomson and Co. were placed first. Mr. G. Chaundy, Oxford, was second and Mr. C. Phillips third. Mr. A. R. Brown was placed first with six blooms and Mr. T. Anstiss second. With twelve varieties of yellow grounds Mr. M. R. Smith was first, having a very fine dozen in Badminton, Doris, Voltaire, Mohican, Golden Eagle, Borderer, Mrs. Tremayne, His Excellency, and seedlings. Mr. J. Douglas came second and Mr. C. Phillips was third. With six yellow grounds Mr. Fred Hooper, Bath, came first, having May Queen, Mrs. Gooden, Florrie Henwood, Ladas, Mrs. R. Sydenham, and a seedling. Mr. C. Harden came second, he having Harlequin, and Mrs. Douglas. In the classes for single blooms of Picotees the best heavy red edges were Ganymede, Brunette, and Heart's Delight; light red edge, Mrs. Gorton and Her Majesty; heavy purple edge, Polly, Brazil and Muriel; light purple edge, Summertide, Esther, and Harry Kenyon; heavy rose edge, Lady Laura and Little Phil; light rose edge, Mrs. Payne; heavy scarlet edge, Duchess of York and Mrs. Sharp; light scarlet edge, Favourite; yellow ground, Mrs. Douglas. The premier heavy edge Picotee was rose edge Duchess of York, from Mr. C. Turner the light edge, Fortrose, from Mr. J. Douglas.

Then followed seven classes for undressed flowers, each bloom shown with a spray of foliage. The value of these as an attractive part of the exhibition was practically nil. Given an ordinary bloom of a Carnation to which is tied a sprig of foliage, and we get at the flowers filling these classes. The teaching value of these classes is no more than can be gained from the basket of a flower seller at the Royal Exchange.

Plants in pots were shown in several classes, chief among them one for twelve specimens, three and four plants being allowed in a pot. Mr. M. R. Smith was first with a very fine group, chief among them Lady Jane Grey, a beautiful soft, rosy heliotrope-coloured flower, very distinct and of fine quality. Mr. C. Turner was second and Mr. J. Douglas third. There was also a class for a single plant. Mr. M. R. Smith had the best group, occupying a space of 50 feet—a superb group of about 100 plants of very high quality. Mr. C. Turner was second. But one group occupying 30 feet was shown—that from Mr. J. Douglas, which gained the first prize. The best vase of Carnations came from Mr. J. Douglas, very tastefully arranged. Mr. M. V. Charington was second and Mr. Munt third. The best dinner-table for twelve persons was set up by Mr. C. Blick; a large centre and two side pieces, with a number of subsidiary small vases. Mr. W. Green, Harold Wood, was second with much the same arrangement, but not so elaborately finished. There were also classes for sprays

and button-holes, all of a somewhat formal appearance. Then followed the Martin Smith prizes for Carnations for the open border; for the best border variety in a bunch of not less than twelve trusses; also for six varieties of self-coloured border Carnations, and for nine bunches of flake, bizarre or fancy varieties. A careful scrutiny of these failed to leave the impression that anything was shown among them illustrating a real advance upon what is already grown. A goodly number of bunches were staged, but it appeared to be quite unnecessary to give the names of the varieties of any of the winning bunches.

#### SEEDLINGS.

What prizes were awarded to these we were unable to learn. Some of the judging had to be deferred until after the luncheon, owing to the altogether unnecessary late hour at which the judges were able to get to work. Surely such a small show can be arranged in time for the judges to commence at 11 a.m., the hour named in the schedule. One certificate of merit was awarded to light rose edge Picotee Fortrose, a very refined variety from Mr. J. Douglas.

Miscellaneous exhibits included a table of Caladiums from Messrs. B. Peed and Son, a table of charming floral decorations from Mr. J. R. Chard, Stoke Newington, Sweet Peas from Messrs. Barr and Sons, and Carnations from Messrs. Jas. Veitch and Sons and Mr. E. F. Hepper, Hoddesden.

#### Gardeners' Royal Benevolent Institution.

—We are asked to state that the Merchant Taylors' Company and the Skinners' Company have each given the sum of £10 10s. to the funds of this institution.

**Royal Horticultural Society.**—The next meeting of the Royal Horticultural Society's committees takes place on Tuesday, July 27, in the Drill Hall, James' Street, Victoria Street, at 12 o'clock. At this meeting a silver Flora medal is offered for competition (amateurs) for best collection of cactaceous plants. At 3 p.m. Mr. W. D. Drury will give a paper on "Familiar Garden Insects, Friends and Foes."

## NOTES OF THE WEEK.

**Carnation Cinnamon** is one of the most distinct as well as decided of the salmon-apricot shades, a colour as yet not over-plentiful, though among the most desirable of these flowers. Some capital blooms were shown at the Drill Hall last week.

**Tea Roses.**—Messrs. Wm. Paul and Son send us some excellent Roses, of which Enchantress is a beauty. Sylph, Zephyr and Empress Alexandra of Russia are also sent. Enchantress we have tried, and it is a good Tea Rose for this country, in which every Rose does not open well.

**Flowers from Hassocks.**—I have forwarded per parcels post a truss of blooms of *Agapanthus umbellatus albus*, of which I have some fine plants in flower now, and which make a fine show; also a few spikes of flower of *Pentstemon Toreyi*. I do not think this is very common, as one does not see much of it.—W. RICHARDSON.

**Erodium Manescavi** is one of the prettiest of the Cranesbill family, and for a long season produces quantities of its rosy red blossoms. The plant is of the simplest culture, thriving well in ordinary garden soil, and is suited to the rock garden or border in almost any position. It is not suited for cutting, and therefore capable of a long display in the garden.

**Prunella Webbiana.**—This kind is worth a more exalted place, if only for its very distinct heads of purplish rose. Not unfrequently the plant is rather roughly treated in the garden, though as we recently noted a large group of it, we were quite favourably impressed by the very

distinct mass of colour that may be turned to good account in many gardens.

**Arundinaria Simoni.**—In April and May I took up a quantity of large clumps of the above named Bamboo, divided them and planted them in more suitable positions, with the result that all the young culms are furnished with striated leaves, showing plainly, I think, that the variety known as *Simoni striata* is merely a sport from the above-named species.—W. O., *Fota*.

**Lachenalia glaucina.**—The curiously formed blossoms of this are of a steel-blue shade, amid which a certain shade of green appears—a rather peculiar combination in a flower, and which appears variable in the different stages of development. The Messrs. Wallace had pots of this curious species at the Royal Horticultural show recently, and we noted the same plant flowering also at Kew.

**Myrtles in tubs.**—I send you a photo of one of our Myrtles, the height of which is 10 feet, width 4 feet. These plants give quite a unique appearance to their surroundings when placed out of doors. I have often wondered why Myrtles are not more grown for standing out on terraces and other places during the summer months. The Myrtle will stand several degrees of frost.—J. EASTER, *Nostell Priory Gardens*.

**Pentstemon Richardsoni** is one of the most showy of this race now in flower, producing long spikes of blossoms, nearly 3 feet in length, of light blue flowers, shaded with red on the upper surface of the corolla. It is a beautiful kind when seen growing in large clumps in the border, and certainly among the most desirable of this extensive group. This plant was very conspicuous in Mr. Ware's group at the Drill Hall recently.

**Eryngium giganteum.**—In place of the prevailing shades of blue so characteristic of the leafage and inflorescence of these plants as a rule, we have in this handsome kind a silvery sheen that in its way is equally telling. The well-established clumps of three years, whether in the border, woodland, or rock garden, of this plant cannot fail to merit approval in any of these positions, particularly the latter, where if associated with bold or rugged rocks they would have a value of their own. In deep sandy loam this plant is safe for several years in succession.

**Salvia bicolor.**—Some handsome bunches of this plant at the Drill Hall last week proved beyond doubt that it possesses a value of its own for the garden. The plant is distinct in many ways from the majority of hardy plants, and where space can be afforded would no doubt prove useful in the border or rock garden. The hardy species of this genus are somewhat vigorous in growth and desirable also. The spikes of flowers are each from 2 feet to 3 feet in length and well furnished throughout their length with blossoms of pale blue and white.

**Nymphaea pygmaea helvola.**—While in every detail of foliage and flower this is decidedly pigmy in character, it is none the less beautiful and interesting. A week ago, from Gumersbury House, Mr. J. Hudson brought several blooms of this almost unique kind to the Royal Horticultural show, and among the more lovely and imposing sorts this dwarf kind, with creamy flowers that have a deep yellow centre, was noticeable. All the blossoms, together with their own foliage, were in each instance exhibited floating in a shallow tray of water—a thoughtful as well as natural method of exhibiting aquatics.

**Campanula Tenoreana.**—This diminutive little species is somewhat scarce in cultivation, though it is one of the prettiest of the dwarf kinds for the rock garden when well grown. The species forms a spreading tuft of heart-shaped and deeply serrated leaves, from which issue the erect flower stems. In place of the usual bell-shaped blossoms, however, we have in this species flowers of about an inch long, distinctly cylindrical in outline, and of a lilac-blue externally. In rather moist loamy soil and a partially shaded position this distinct plant is usually a success, and is

worth attention. The plant is about 6 inches high and comes from Naples.

**Argemone hispida** is a curious as well as beautiful plant, curious in the glaucous, prickly, thistle-like foliage, and beautiful in the large, handsome pure white flowers that are nearly 4 inches across. The species has been called the Prickly Poppy, which name conveys a capital idea of the plant. It is a fine subject for the garden in summer-time, giving it always the warmest positions and a fairly good and deep soil. The plant in its Californian home is said to be perennial, but this is not the case in British gardens where it is best treated as a good annual to be raised early each year from seed.

**Contrasts in shrubberies.**—This may be produced either by foliage or by flowers. As an example of the former, the variegated Tree Mallow gives most distinct effects; it is well worth growing, either singly in a flower bed or combined with shrubs. The Tree Lupine when in bloom is an example of the latter kind of contrast, and is not nearly so often seen as it deserves to be. The flowers of the normal form of it are pale yellow and very abundant. The plant of which I send a photograph was 4 feet high, 8 feet in diameter, and two years old. There is a white variety of it.—W. THOMSON, *Bishops Teignton*.

**Eccremocarpos scaber.**—Here we have a really delightful climber that is not often seen; notwithstanding, it flowers long and freely during the summer months. The plant may not prove perfectly hardy in all parts of England, though in southern and western districts it grows freely and flowers year by year. The best position for it is against a wall facing south or south-west. In just this position a large plant has stood for years, and for some time past its sprays of orange-scarlet blossom have been very pretty, rambling amid the slender twigs of *Jasminum officinale*. It may be freely raised from seed early in the year and planted out in May.

**A blue Wallflower.**—Several times within the last few years I have accidentally come across a purplish-coloured Wallflower growing among batches of the common type, and produced from packets of mixed seed. Perhaps I might describe this "sport" as a purplish or bluish lilac, but it is a very distinct variety, and I should feel obliged by any of your readers telling me where it can be got true, and when and where it originated. In the "English Flower Garden" three old original types are mentioned among "the choice old double kinds," and one of these is the old double purple. Other distinct varieties are mentioned, but the colour I refer to is not common.—FANCER.

**Lilium Henryi.**—Some early spikes of this unique Lily were included in Messrs. Wallace's group at the Drill Hall a week ago. In the cut state as much as the open border a most favourable impression of its value gains ground. We have in this fine species what is so much wanted in really good Lilies for the open garden—a combined vigour of constitution with great freedom of flowering. For such Lilies as are likely to prove of permanent value for the garden there is yet abundant room, and for British gardens generally these must needs possess the vigour, freedom and general hardiness of the speciosum section, which is perhaps the most serviceable in this respect.

**Campanula Hendersoni.**—This, one of the most useful and beautiful of this genus, does not appear to be so well known as it deserves. Though not a difficult plant to establish, we believe it is only rarely that large tufts are secured even in good collections of hardy plants. Some of the largest single specimens we have seen were grown in a rather heavy loam, these being fully 18 inches across, and forming a perfect pyramidal cushion-like tuft covered with large and pleasing flowers. Too frequently this suffers through being in a position much too dry to suit its requirements; and if planted in the rock garden this should be borne in mind, while the

plant somewhat resents a too frequent disturbance at the root.

**Japanese Irises on Long Island.**—A year ago in the home nursery here I was astonished by the profuse blooming of some tufts of Japanese Irises that were growing in full sun upon an exposed gravelly knoll—conditions exactly opposite to those supposed to be essential for these Irises. Recently I saw Mr. J. L. Child's Irises at Floral Park, Long Island. There were several rows of a kind, each row about 500 feet long, the varieties mostly selfs. Two acres of ground were one solid sheet of colour, white, blue, pink, purple and intermediate shades, some individual blooms measuring 10 inches across. Here were Japanese Irises under quite the reverse of aquatic conditions. The soil of Long Island is loose, light and sandy, and all bulbous plants thrive well. Japanese Irises ought to be tried under similar conditions in England.—A. HERRINGTON, *Madison, N.J.*

**Begonia Lafayette.**—This handsome tuberous-rooted kind promises to be one of the finest acquisitions to the so-called bedding section of this family that has ever been introduced. The variety is as remarkable in its erect bushy habit as it is in its freedom of flowering, and not less so for the rich, intense bright crimson of its flowers. These latter are of medium size as compared with the huge blooms one is getting accustomed to, while in colour they bear some resemblance to those of *Davisi* fl.-pl., one of the early double sorts that is scarcely excelled in colour among the best to-day. Planted out it would probably attain from 12 inches to 15 inches high, and if associated thinly with *Dactylis elegantissima*, would make a most charming bed in a rather cool spot on the grass. Quite recently this variety was freely represented at Chelsea, where it is largely grown by the Messrs. Veitch and Sons.

**Lilium Alexandræ.**—At the last meeting of the Royal Horticultural Society Messrs. Wallace, of Colchester, had pot plants of this remarkable hybrid Lily, though, unfortunately, the blossoms were not quite expanded. The plant in question was about 2 feet high, and carried four of its giant horizontally-disposed blossoms. These are perfectly white, with a slight shading of green at the base, the segments remarkable for their great substance. The hybrid character is well depicted in both leaf and stem, the latter partaking of auratum in its formation and colour, while the leaf character partakes of auratum and speciosum, the shortened peduncle of the latter group being rather pronounced, while in their firm substance and horizontal aspect there would appear a touch of *L. longiflorum*. From one of the expanding flowers the huge brown anthers were noticeable, and fully open it is doubtless one of the most beautiful of Lilies.

**Water Lilies.**—July and August are the great Water Lily months of the season, and wherever there are well-established clumps of *Nymphaea caudicidissima*, *N. Marliacea albida*, *N. M. carnea* and *N. M. rosacea* and others, they will now be in great beauty. The little pond here has been gay with flowers since the middle of June, but the largest and most richly coloured flowers come in July. One point in Water Lily culture worthy of attention is the prompt removal of all old flowers, and the more blooms there are cut in the bud or newly-opened stages the more will follow. As cut flowers, Water Lilies of all kinds are well-nigh perfect, and as cut and packed tightly in their own damp leaves they will carry well for long distances and quickly revive and open perfectly when immersed and floated in fresh water in large and shallow bowls. Not only is our small pond a great attraction to Water Lily-loving visitors, but the cut flowers are welcome to our absent friends.—F. W. B., *Dublin*.

**The weather in West Herts.**—Between the 8th and 21st all the days were more or less unseasonably warm, and on the 18th the shade temperature rose to 80°. During the same fortnight the nights, on the other hand, were mostly rather

cold for the time of year. Consequently, the range in temperature has been considerable, and on the 15th it amounted to 33°. The temperature of the soil has fallen somewhat during the last few days, but is still about 4° above what is seasonable both at 1 foot and 2 feet deep. Until the 19th no rain worth mentioning had fallen for nearly three weeks, but since then there has been rain on two days to the depth altogether of about half an inch. The ground, however, still remains dry at a short distance below the surface, no measurable quantity of water having come through either percolation gauge for over ten days. On two days during the week the air remained unusually dry, the difference between the reading of an ordinary thermometer and one with its bulb kept constantly moist amounting to 18°. During the past six days the atmosphere has been very calm, the rate of movement averaging less than two miles an hour.—E. M., *Berkhamsted*.

## PUBLIC GARDENS.

**Open space for Bethnal Green.**—Lord Meath, on behalf of the Metropolitan Public Gardens Association, on Tuesday afternoon, opened to the public the old churchyard and burial ground, 3 acres in extent, of the parish church of St. Matthew, Bethnal Green. Lord Meath said as far back as 1883 steps were taken to acquire the ground. The population of Bethnal Green was 130,000, and altogether there were but 20 acres of public open space.

**Brockwell Park rating appeal dismissed.** The House of Lords (present the Lord Chancellor, and Lords Herschell, Macnaghten, and Morris) heard on Monday the case of the Churchwardens and Overseers of Lambeth *v.* the London County Council. It was an appeal from an order of the Court of Appeal reversing a judgment of the Queen's Bench Division in August, 1895, and it raised the question whether the County Council were rateable as occupiers of Brockwell Park, which was vested in them solely for the purpose of maintaining it for the use of the public. The respondents were assessed for poor-rates in respect of this park as beneficial owners. The property consisted of (besides the laud) a mansion house, a lodge, and a cottage. The Queen's Bench Division decided that the estate was beneficially occupied by the respondents, and they were liable to be assessed. The Court of Appeal, consisting of the Master of the Rolls and Lords Justices Smith and Rigby, reversed that decision, being of opinion that no part of the property could be a source of pecuniary profit to the respondents. Hence the present appeal. The appellants' contention was that the estate was beneficially occupied by the respondents, and that such occupation was not rendered non-beneficial by the fact that the property could not become a source of pecuniary profit to them. The respondents, on the other hand, submitted that the premises were not capable of yielding a net annual value, after the expenses of maintaining and repairing them had been paid; consequently that the park was not liable to assessment. The Lord Chancellor, in giving judgment, said he was of opinion that the park was not rateable. He did not think that there could here be a rateable occupation by anybody. "The public" was not a rateable occupier, and he thought that one sentence disposed of the case. The County Council were merely custodians or trustees for the public, and there was no beneficial occupation by them. They could not use the park for any profitable purpose, and they must allow the public the free and unrestricted use of it. The appeal must be dismissed. The other noble and learned lords agreed, and the appeal was dismissed, with costs.

**Names of plants.**—*G. E. P.*—1, *Mackaya bella*; 2, *Ipomœa Horsfalliæ*; 3, *Allamanda violacea*; 4, *Rudbeckia californica*; 5, *Anthemis nobilis*; 6; Shrivelled beyond identification.—*J. R. Droop.*—*Alostromeria aurantiaca*.

## ORCHARD AND FRUIT GARDEN.

### TREATMENT OF PEACHES WHEN STONING.

PEACH trees not unfrequently drop their fruit when stoning, this evil being much more common in early and second early houses than in later ones, when the crop comes on from start to finish under more natural conditions. Opinions vary as to the safest temperature at which to keep the house during this somewhat trying time, few caring to adopt a higher one than 65° during hours of darkness, others regarding 60° as a safer figure. I think a good deal depends on the outside temperature, a few degrees above the latter doing no harm—when frost-free, genial weather prevails—keeping as near to it as possible when the open air thermometer falls below freezing point. Early Peach houses, like early Melon houses, should be furnished with plenty of hot-water pipes, so that the desired night heat can be maintained without over-pressure, the excessive pipe heat destroying the needful atmospheric moisture, a great drawback to the trees at any time, but especially when the fruit is stoning. Many gardeners court failure by leaving far too many fruit on the trees, thinking that this is a safeguard in case of falling during stoning. Greater safety would, however, be secured by using a freer hand when the fruits were in an earlier stage, although I do not agree with those who advocate reducing the fruit to the required number previous to stoning, and I think the majority of gardeners will agree with me. If the extra thinning out of wood which the trees may require is not completed before stoning commences, I think it is best to postpone it till this is completed, as using the knife freely at that stage is apt to give a check and cause dropping. Too early closing of Peach houses on hot sunny days just at this period is injurious, the fruit being practically at a stand-

still. Defer final closing till a little later in the day, taking care that the foliage gets dry by nightfall. The bad practice of having wet foliage during hours of darkness is more dangerous still when the fruit is stoning, wet trees and a lowered temperature for several nights being quite sufficient to cause the fruit to turn yellow and drop. Some people have said that it is a bad plan to water the borders when the fruit is stoning, but this, I think, is quite imaginary, as trees growing in pots and tubs have to be watered almost daily. It is a good plan to thoroughly soak the borders just previous to the fruit stoning; they will then with a mulch go on until swelling again commences with further moisture, unless very limited in width and depth. Red spider on the leaves, caused by insufficient use of the syringe previous to stoning, is a fertile cause of dropping.

J. CRAWFORD.

**Strawberry Dr. Hogg.**—In the note on "Prolonging the Strawberry Season," "M. W." (p. 35) does not notice this variety. It has been very satisfactory here, one-year plants throwing a large quantity of fruits of excellent quality. How it would behave on a light soil I cannot say, but on heavy land it does capitally, the only fault being the unfinished points of the fruit. Latest of All, on the other hand, having much less foliage ripens better, but is not so late as the variety named above, the fruits of which are still (July 17) good in the open garden.—SUFFOLK.

**The Strawberry beetle.**—The Strawberry beetle appears to be more troublesome this summer than usual. In some parts of East Anglia, notably near Great Yarmouth, this pest has completely destroyed the entire crop. The difficulty with most people is to find a plan of extermination, as the beetles carry on the greater part of their work during the night, and treading about amongst the plants at random would soon spoil the fruit. One grower, however, seems to have hit on a plan of reducing the beetles by a very simple method. A lot of jam jars were obtained and a little lemon water put into each of them, having previously sunk them in the ground

to the rim and covered each jar with litter. Another and a still more successful remedy of the same grower consisted in placing some hens in coops with chickens near the beds. These soon cleared off the beetles and a host of other insect pests.—GROWER.

**Black Currants.**—These are almost a failure in many cottage and large gardens in this neighbourhood, but I have had a capital crop of fine fruit. In a measure I attribute this to thinning the wood at the time the fruit is being gathered. Any boughs that are in the least crowding their neighbours are cut out entire with the fruit on and taken to a shed, where the latter can be easily and more quickly gathered. This allows the sun and air to reach the shoots left, ripening them thoroughly and enabling the later foliage to grow to its full size, an important point in all fruit culture.—R., Suffolk.

**Peach Prince of Wales.**—At page 35 this Peach is mentioned as being a good one for growing on open walls. I can also recommend it for culture under glass. I have had a tree of this variety in a lean-to house for the last twelve years, and it has never missed a crop. The flower is small, but the fruit always sets thickly, much thinning generally being needed. The tree is not forced, but allowed to come on gradually, the fruit usually ripening about the middle of August. The fruit is very highly coloured where exposed to the sun and the flavour is excellent. I should say Prince of Wales is one of the most certain varieties in cultivation, the tree being in no way a strong grower, but making under ordinary care short, well-furnished growths. I believe it is largely grown for market, a pretty sure proof of its value.—J. C.

**Melon Eastnor Castle.**—"A. W." does well to draw attention to this old Melon. Some gardeners of my acquaintance think it rather capricious, and certainly it does require good cultivation, but it well repays any extra trouble. I have found it rather liable to scorch if careful airing is not practised and a little air admitted early in the morning. It certainly is a grand Melon, and no mistake can be made in growing it where first-rate flavour is a consideration. Another good old Melon, now almost discarded, is Heckfield Hybrid. A few gardeners still cling

to it, and certainly, all points considered, it takes a lot of beating. It is one of the very best of setters, and that, too, in a lower temperature than many sorts like, and a full crop may generally be relied upon. The finest crop of it I ever saw was from plants grown in pots and plunged in a bed of leaves in small lean-to houses in Kent. Many sorts that do not always set well when planted out are fertile enough when grown in pots.—C. C. H.

**The Loganberry.**—In last week's GARDEN this new fruit was noted as having received an award of merit. I am able to say something concerning it, having grown and fruited it this season. With me the fruits, which are very similar to a Raspberry in shape, have larger pips and are darker in colour, the flesh being firm, as though they would travel well, and the flavour briskly acid, there being plenty of juice. It should make a capital preserve. I received the plants last autumn, and instead of planting out at once, I potted the plants up and wintered them in a cold frame, putting them in the open garden in a sunny position in spring. A few fruits have been produced and stout canes thrown up, somewhat like those of a Raspberry, but more prickly, and by the number of fruits which the plant bore this season, the yield ought to be an abundant one in 1898. Increase is done by division of the roots, and if this is done in autumn and the pieces grown on in small pots and planted out in March, the plants stand the best chance.—J. CRAWFORD.

#### THE LONGLEAT MUSCAT GRAPES.

If the Longleat Grapes are not so much in evidence as they used to be, those who pay a visit to the famous vinery in which they are grown will find that there are no signs of any decadence in the Vines, or of any want of ability to manage them properly. On the contrary, it is doubtful if they were ever so uniformly good as they are this season. The central portion of a grand span-roofed structure is wholly devoted to the growth of Muscat of Alexandria Grape. This division measures 90 feet in length, and is 30 feet wide. The roof is completely occupied by four Vines only, and these have been planted about twenty-five years. These four Vines are planted one in each corner, and trained along the front till they meet each other. From these main stems, each of which at 2 feet from the ground measures close upon 18 inches in circumference, rods are taken up the roof at intervals of 6 feet. These have been gradually extended till they have reached the opposite side, so that the trellis is now actually covered with stout rods 3 feet apart only. An easy curve is given the rods, and nowhere are they less than 18 inches from the glass. Thanks to this arrangement and to good cultivation generally, not a burnt or scalded leaf is to be seen, and no trace of red spider could be found, but all the leaves are in perfect condition. Curiously enough, neither the leaves nor the lateral growth are ever large on these Longleat Vines. I have paid frequent visits to this vinery during the past fifteen years, and each season have been struck with the comparative smallness of both the young wood and the leaves, and the reasons for this have never been satisfactorily explained. But if the wood and foliage are small this cannot be said of either the crop or the individual bunches. There is a bunch to about every 18 inches run of rod, all are on the large side, and perfectly furnished with large berries which only require a few weeks more sunshine to finish them properly. Scores of bunches are not less than 5 lbs. each in weight, and some might be found equal to scaling 8 lbs. Altogether there cannot be far short of one ton of Grapes in that compartment, and Mr. J. Trollope, the head gardener at Longleat, has every reason to feel proud of what he has accomplished. I ought, perhaps, to add that the roots are believed to be wholly inside the house, but this cannot be vouched for owing to the roots from the Vines in an adjoining division having once forced their way through the brickwork of foundation wall and spread far and

wide before it was known they had escaped control. The soil surrounding the Longleat vinery is of a heavy clayey nature, and Vines rooting into it are prone to slanking of berries, consequently Mr. Trollope keeps the roots in the inside border as much as possible. No great amount of manure of any kind is applied to the borders, but plenty of liquid manure and water are given.

W. IGGULDEN.

#### LATE STRAWBERRIES.

NEVER have late Strawberries been more appreciated than this year, and though the season was one of the shortest owing to heat and drought, I am now gathering Latest of All and Oxonian from young plants on a north border. British Queen has also done well this year on a north border under a high wall, the plants having been put out in the spring of 1896 from pots, being too small to plant out when potted up the previous autumn. Those who value quality in Strawberries may with advantage grow the British Queen and Pine varieties in this way, as they make runners rather sparsely, and when procured from fruiting plants are not obtainable in time to plant for fruiting the first season. Grown thus, it is well to remove the weak trusses, which show soon after planting. Latest of All treated as an annual gives grand fruit as regards size, but treated as advised for the Queen it is very fine, and the fruit is produced in quantity. These remarks are equally applicable to several of the Pine family. Oxonian does so well, it is not necessary to refer at length to this variety. Unfortunately, it is of poor quality, but its lateness makes it valuable. I usually plant it early in August for the following July supplies. This year our season will have been five weeks; not a bad one when the heat and drought are taken into account, and seeing how soon the mid-season and early kinds also were over; without late fruiterers it would have been a short season indeed. This will induce me to plant more late varieties. I am aware in wet seasons, if late plants are at all thick, the fruits decay badly. I am not an advocate for planting too closely, and I think there is no need to grow old plants—in fact, even the Queen and Pine family should be cleared after the second crop. There is a great gain in early planting, as the plants, becoming established, winter so much better.

G. WYTHES.

**Strawberry Monarch.**—"W." (p. 35) states this is of poor quality in the open. I have not found it so; indeed, though it cannot be compared to a British Queen, it is superior to some of the older varieties, the flavour of which is rarely questioned. For forcing I do not recommend it. As a midseason kind in the open it is very good. I fail to see the objection to Royal Sovereign. With me it does not lack the quality I have heard several growers complain of, and I am this season adding another 1000 to the number for early work. I admit the fruit must be gathered before it gets too ripe for travelling or sale. It is my mainstay for forcing and first crop in the open, and the plant being so robust does well in our poor soil. For flavour "W." would do well to give the newer Veitch's Perfection a trial.—G. W. S.

**The Strawberry of the year.**—My remarks apply to the new Veitch's Perfection, the result of a cross between British Queen and Waterloo. This new kind was staged on a recent occasion before the fruit committee of the Royal Horticultural Society, and every member was delighted with its quality. I am not a great lover of the Waterloo type; it is too dark, and in hot, dry seasons soon suffers. Another point, it is none too free the first year. Fortunately, Perfection has not the failings of Waterloo. It is not a gross grower, is a grand fruiter the first season, and a superb fruit. Messrs. Veitch are to be congratulated on giving Strawberry lovers such a reliable variety. I do not advise it as a forever, not having given it a

trial, but in a season anything but good for Strawberries it has done well. Of course, it is early to state how it will thrive in all soils, but so far it is happy in one not the best for Strawberries.—G. WYTHES.

**Peas on Apricot borders.**—For many years I have endeavoured to give Apricot roots a free run, and on no account have I planted directly on the roots, allowing a 4-feet space from the wall. At p. 4 Mr. Crook advises sowing Peas on the top of the Apricot roots. I do not think this advisable if directly over the roots as stated. Possibly in Mr. Crook's locality Apricots do well. Mine are none too vigorous, and I could ill afford to rob them by planting or sowing vegetables directly over them. Few fruit trees root so near the surface as Apricots. Though one often sees grand fruit trees with the roots under a hard gravel walk, their well-doing is because the roots are cool and undisturbed.—M. W.

**Raspberry troubles.**—Raspberries as a rule do so well in various soils that it is somewhat unusual to see general failure. Yet at Clendon Park, the gardener, Mr. Blake, in spite of all he can do to get rid of the trouble, has to see his canes die wholesale, so that where the winter canes indicate a good product in the summer, it is found that no leaves are put forth in the spring, and three-fourths are then dead. That result is specially the case in the third and fourth years after planting. Later, were not other plantings made, the breadths would be absolutely dead. That the soil, which is of a fairly retentive nature on a deep bed of chalk, is at fault there can be no doubt, and frequent planting of young canes on fresh soil seems to be the only alleviation. Things are almost as bad at Bramley Park. Possibly some reader may be able to furnish some remedy for this trouble.—A. D.

#### THE APPLE CROP.

If my own fruit garden might be taken as a fair sample of what has happened all over the country, the Apple crop of 1897 would have to be classed as a complete failure. Fortunately, it is only in comparatively low positions where the whole of the Apple blossom was destroyed by spring frosts, and it will be found that there are better crops in many districts than thought possible at one time. It is true that much damage was done by frost to the blossom on trees situated well out of the valleys, but it was so very abundant and in some instances most robust, that enough survived to give a fairly heavy crop of fruit. In my rounds in this and adjoining counties (Somerset and Wiltshire) I have been pleased to see some orchard trees quite heavily laden with fruit; but, unfortunately, the majority of the orchards are old and situated in valleys, and as a consequence of this want of forethought the supply of fruit will not be equal to local demand even. It is worthy of note that fruit and forest trees, notably the Ash and Oak, were severely damaged by frost in the valleys, but escaped on ground not more than 50 feet higher. Surely this ought to be a lesson to those contemplating planting more fruit trees next autumn. The famous Toddington orchards are arranged some on low ground, others in quite high positions, and the remainder midway between them. If I am rightly informed, it is the intermediate sites that answer best in most years, but I cannot say how they have succeeded this season. Once more shelter trees have done good service, but it is only on the east side where this is apparent. Tall trees on the east side of an orchard shade the fruit trees in their immediate vicinity from the early morning sun, just long enough for the frost to go out of the blossoms slowly. It is the rapid thaw that does the mischief, and those who afforded a light protection to their garden trees have

good reason to be pleased with the result. The blossom on these protected trees was frozen hard, but the shade from bright morning sunshine saved much of it. It is also worthy of note that in some gardens where bush trees are bare of fruit, those horizontally trained are carrying moderately good crops.

Some varieties when in bloom stand frost better than others, but none that I am acquainted with has proved so reliable as the old Keswick Codlin. Not only in these districts, but round London and, in particular, Gammersbury way, the Keswick Codlin is carrying the best crops, and it is a fortunate circumstance that this old favourite has not been wholly superseded by Lord Sutherland, Lord Grosvenor and other large Codlins, which are the most profitable in some seasons. Ecklinville, again, is going out of favour with market-growers owing to the softness of the fruit, but garden and small orchard trees of this reliable sort are cropping so well this season that they will not be discarded in a hurry. It is one of those varieties that never quite fail, and which produce enormous crops in some seasons. Warner's King—a variety authorities agree in praising—has once more justified the encomiums bestowed upon it. Many garden trees of it are carrying good crops of large well-formed fruit, and this will be fully appreciated. Cellini Pippin is not a variety I should consider good for resisting frost when in flower, but, all the same, I know where there are garden trees of it very heavily laden with fruit, while Cox's Orange Pippin and Margil near at hand have not a single well-formed fruit on them. Garden trees of Blenheim Pippin are also failures this season, but there is a good sprinkling of fruit on many fine old standards. The trees of Bismarck that have come under my notice flowered too profusely, and not many fruits are the outcome. So also did the deservedly popular Lane's Prince Albert, yet some of the low standards are carrying half a crop of fruit. I could point to trees of this invaluable Apple that have not really failed once during the past thirteen years, and this cannot be said of any other variety in the collection. When the reports of fruit crops come to be analysed, it will be found that one or two varieties of Apples will stand out pre-eminently as being the most profitable in a bad season.

W. I.

#### MELONS AT LONGLEAT.

MELONS are grown to perfection in the gardens at Longleat, Wiltshire. Mr. J. Trollope being quite as successful with them as the two well-known gardeners who preceded him. The extension system is adopted, four plants occupying the same amount of roof space as a dozen or more do in most other gardens. Instead of the lateral shoots being stopped at the second or third leaf beyond the first fruit that shows on them, they are freely and early thinned out and trained horizontally to a distance of 4 feet, sometimes more than this, before they are topped. The bulk of the crop is produced by the sub-laterals or breaks from the laterals, and not all at once, but in succession, so that it is nothing uncommon to see fruit in all stages of growth on the same plants. According to most gardeners' views, the disadvantages attending the extension system of growing Melons more than outweigh the advantages. I am not so sure about that. No doubt a greater variety can be grown by planting thickly, but who cares for so many sorts? As a matter of fact, not more than one good green-fleshed and one scarlet-fleshed variety need be grown in any garden. The cultivator should know his variety and its requirements or treatment well, and then there would be fewer failures. Mr. Trollope laughs at the idea of losing plants from canker just when a good crop is set on them, and if what I have seen

at different times at Longleat is any criterion, canker may simply be defied. The plants are put out in a nearly solid bed of strong fibrous loam cut thickly, and a fresh wall of turf is added when the roots have taken full possession of that they were first planted in. Instead of being put together in a rounded heap, in which form the water is thrown off only too effectively, the soil immediately about the collars of the plants only is raised higher than the rest and kept constantly dry—that is after the plants are 2 feet in height—while the main portion of the loam is quite flat, absorbing most of the water applied to it accordingly. In this respect the Melons are treated similarly to and receive quite as much water as Cucumbers growing in adjoining houses. As a consequence the soil is completely over-run with a network of root fibres, the surface being quite white with them. There is no premature loss of lower leaves owing to want of light, no canker to be alarmed about, and no drying off at the roots either as a preventive of fruit cracking or because the crop is ripening. Need any surprise be expressed at the solidity or high character of the fruit produced under such conditions? It is the half-starved plants that fail to produce heavy crops of superior fruits, and it is only by high culture, somewhat on the lines I have briefly sketched out, that a succession of handsome, richly flavoured Melons can be had from a single plant.

W. I.

**Strawberry Latest of All.**—I saw this variety fruiting in an almost wonderful way in Lord Onslow's garden, Clandon Park, Surrey, just recently. Not a fruit was left on any other variety, but this one was loaded with fine fruit. It has been recommended to be grown on a cool north border, where doubtless it would be later still. In this case it was fruiting in an open quarter. Whilst no doubt the plants like a deep soil and a cool situation, it is evident the fruits need plenty of sunshine to ripen them, as they do not colour right out, but resemble greatly one of the parents—British Queen. The breadth was at its best on July 10, but there was plenty of fine fruits on July 15. The one-year-old plants had the finest fruit and the two-year-old plants the heaviest crop.—A. D.

**Standard bush fruits.**—The standard Gooseberries some 3½ feet to 4 feet in height, recently exhibited at the Drill Hall by Messrs. Veitch and Sons, were worked upon Ribes aureum stocks. These are easily obtained of a good length from cuttings. The height mentioned, however, seems needless, as from 2½ feet to 3 feet would be much better. No doubt Red Currants would bear similar treatment, and the fine La Versailles makes a capital standard on its own roots if kept hard pruned. In no case should such heads of Gooseberries or Currants be allowed to extend unduly. Kept close home and bushy they are first-rate, and produce very fine clean fruit. The heads are easily protected with nets or thin canvas. Blackbirds and thrushes usually attack fruit from below and not from above.—A. D.

**Work amongst Strawberries.**—The Strawberry season, so far as the early and midseason kinds are concerned, being at an end, the plantations should, in all cases where they are to be retained for another year, be put in order without delay. If layering was done when advised and the necessary numbers obtained, the runners will either have been severed or be ready for severance from the parent plants. When the pots are removed the way is then clear for dealing with the plants as their condition may demand. Those set out last autumn will merely require trimming up, which will simply mean the cutting away of the oldest leaves and divesting them of surplus runners. Older plants carrying more foliage will need a more severe trimming, and in all cases where the leaves have become badly infested, either with mildew, red spider or any other fungoid or insect pests, the plants, if worth retaining, had better have the whole of the foliage cut away. This should at once be removed and burnt to prevent the insects or disease from

spreading. The quickest way of dealing with plantations in such a plight is to mow the leaves off with a scythe, only care should be taken to see that the crowns do not become injured by cutting too low down. If this is done at once the plants will then make plenty of new foliage, which will become fully developed and hardened by the end of the autumn. After the plants have been trimmed up, the surplus runners cut away and the ground hoed, both to lighten the surface and to get rid of weeds, spread a mulch of well-rotted manure about 2 inches thick between the rows. This will induce the plants to make an abundance of new roots and foliage, which in turn lead to the building up and development of good sound crowns, and thus render the production of heavy crops of fruit another season all the more certain.—A. W.

## ORCHIDS.

### NOTES ON PESCATOREAS.

THESE singular and interesting Orchids are not so easy to cultivate as the usual run of species. The first point to notice is their having neither pseudo-bulbs nor large thick fleshy foliage to sustain them during the resting season. They require as much rest as a Dendrobium, though it is rest of a different kind. No attempt must be made to dry them off, or probably it will lead to their disappearance altogether, but a slight diminution in the water supply, combined with a little more air and rather lower temperature, causes a cessation of growth and a general hardening of the plants. This cool treatment should be led up to a certain extent by exposure to more light when the little tufts of leaves are complete and the flowers past. During the time the plants are in active growth the best position is a shady one in an intermediate temperature where moisture is abundant and a fair quantity of light is allowed to reach them. A bright, glaring light is wrong, as the foliage cannot stand it; a dense shade all the year round, on the other hand, produces growths so poor in texture, that the least check in winter causes them to be attacked by spot or to lose their foliage. If the Cattleya house is a large roomy structure and one not likely to part with its moisture readily, this makes an ideal place for them if the requisite shade can be afforded. But if the intermediate house is at all inclined to be draughty or dry they are far better in the closer and warmer atmosphere of the East India house. The growth will be more free and the plants in every way more satisfactory. With regard to the treatment of the roots, the most important point is cleanliness. In a mixture that runs together and forms a heavy inert mass they are never long-lived, yet they are of a strong fleshy character and want feeding. Disturbance is their bane, so when a renewal of material is required it should be carefully done and with a view to its lasting.

Pescatoreas thrive well in baskets or flat pans, and even in pots if the drainage is thorough, the layers of crocks being well protected in every case by some rough Moss. Have good fibrous brown peat prepared by shaking out all sand and earth, and clean, freshly-gathered Sphagnum Moss, plenty of clean crocks and charcoal to keep the whole open, and, if it can be obtained, a little of that nice silky loam so much looked after by gardeners. This makes a medium that, while holding abundant moisture for the need of the plants, will not become sour or water-logged. A fair margin may be left around the plants, as they make rapid progress when healthy and strong, and ought not to require another shift for three years. Before

placing in the new material be very careful that none of the old sour peat is left. It is better by far to shake them right out and to wash every particle of old material away than to leave anything likely to contaminate the new material. The plants need not be elevated much above the rims of the pots or baskets, and the new compost should be kept moderately firm about the roots, pressing it in with a blunt dibber. The likeliest time to repot is when the growths are getting well away in spring or early summer before they commence to root on their own account. Water must be judiciously applied until the roots are again active, when a rather free supply is necessary until the time mentioned above.

**Stanhopea oculata.**—This, one of the brightest of the Stanhopeas, is now in bloom. The blossoms are not so large as those of *S. grandiflora* or *tigrina*, but more showy than those of either, owing to the large spots of purplish lilac on a yellow ground. Fleeting as any in the genus, it seldom lasts over a week, but strong plants are very beautiful meanwhile. Grow it in baskets of peat, Sphagnum, and charcoal, with a little loam fibre or leaf-soil, and place some large lumps of charcoal over the bottom to allow the scapes to descend freely. Water abundantly overhead in summer and at the roots.

**Oncidium prætextum.**—A good form of this species is as nice as anything in the *O. crispum* section, the blossoms being prettily marked, freely produced, and slightly scented. Its culture is not difficult, but sometimes it has a tendency to grow out of season, which should, if possible, be checked by ripening up the growth well in autumn and endeavouring to rest it naturally. The compost for *O. prætextum* may be of an ordinary description, and a thin layer only is needed, either over good drainage in a basket or arranged on a raft. It does well in an intermediate temperature, as it is a native of Brazil, whence it was introduced in 1876.

**Cattleya Eldorado.**—This is a distinct and pretty *Cattleya*, not so large as some of the labiata section, but yet very telling. It flowers upon the young pseudo-bulb as a rule, but I have known it rest in sheath for a month or two and then send up a flower after the manner of *C. Percivaliana*. The sepals and petals are pale rose or lilac, much lighter in some forms than others, the distinctive character of the lip being a yellowish or orange area, bordered with white. The front portion is crimson-purple, and it is prettily fringed all round. *C. Eldorado*, though not so strong as *C. Mossia*, presents no particular difficulty in its culture. The growth should be gently excited in spring, and kept going until the pseudo-bulbs are well finished, and then if possible kept dormant through the winter. It is a native of the Rio Negro district, and though imported by M. Linden in 1865, was not much known until about a dozen years later.

**Cattleya Hardyana.**—The parentage of this lovely natural hybrid having been proved, it is desirable that those having the convenience should raise it artificially at every opportunity. Its parents, *C. gigas* and *C. Dowiana aurea*, do not, it is true, always bloom at exactly the same time, but they do occasionally, and even without this the pollen of *C. gigas* may be easily kept a little while and still retain its potency. Beautiful indeed is the progeny of these two splendid *Cattleyas*, and free blooming and strong growing as well. As is now well known, it first appeared in the collection of Mr. G. Hardy, of Timperley, after whom it was named, and soon after it appeared in many other places from imported batches of *C. gigas*. Its affinity to the species mentioned above led Orchid growers to think it a natural hybrid between them, and that this view was correct, Mr. Norman Cookson's artificially raised plants—exhibited last autumn—proved. The best form of *C. Hardyana* I have seen was nearly 8 inches across the sepals and petals, bright rosy

magenta, the lip, a most lovely feature, being deep crimson-purple, veined with gold. The plants thrive in the warmest and lightest part of the *Cattleya* house, and should be well grown in early summer, ripened and kept dormant after blooming.—H. R.

**Spathoglottis aureo-Vieillardii.**—This is a remarkable and somewhat variable hybrid raised by Mr. Seden. It is the result of crossing the two species from which the name is derived. The sepals are each about 1½ inches in length, pale yellow, suffused with purple, and thickly covered with rich purple spots. The petals, of about the same length as the sepals, are about 1 inch in breadth, the ground colour similar to that of the sepals, but more densely spotted with larger purple spots. The front lobe of the lip is rich crimson-purple, shading to yellow and thickly spotted with brown, the side lobes yellow, spotted with purple at the apex, white spotted with violet at the base. It is well deserving of attention from lovers of this beautiful species of Orchids. It is now in flower in Messrs. J. Veitch and Sons' nursery at Chelsea. It requires the treatment of the warm house, with a humid atmosphere and an abundance of moisture while in active growth.—STELIS.

**Saccolabium cœleste.**—This is a dwarf and very beautiful species, the pretty blue-tinted blossoms plentifully produced upon the spikes having a distinct character. It is fairly stout, and the spikes occur at this season from near the apex of growth, each flower being about 1 inch across, whitish, tipped with blue. To grow it well, a large, moist, tropical house is most desirable, the atmosphere in such structures suiting all the distichous section of Orchids better than that created by a low, narrow house, where the first upward move of [the ventilator takes out most of the moisture. It does well in open wood baskets, Sphagnum Moss and plenty of roughly broken charcoal suiting it well as a rooting medium. The safest time to rebasket the plants is about March or April, and in doing so it must be borne in mind that few plants like disturbance less. For this reason it is wise to give a basket large enough to keep it in health for several seasons, and when a new one becomes necessary take the old one to pieces as carefully as possible, syringing away the old decayed Moss and placing the pieces of wood that the roots have attached themselves to into the new basket. While growth is active and the roots are also growing freely the Moss should never be really dry, but a considerable reduction must be made in the water supply during the winter. *S. cœleste* is a native of Siam, where it is found growing in almost unshaded positions, consequently plenty of light must be allowed.

#### ONCIDIUM INCURVUM.

The colours of this charming little *Oncidium* are distinct and telling, the long arching spikes of flowers being very useful for cutting. On the plant, too, they make a pretty show. The ordeal of standing week after week in the dry, vitiated air of living rooms is too much for most Orchids, and though a little of it does not hurt *O. incurvum*, it is not wise to leave the plants indoors too long. As far as the flowers themselves go, they may, if the plant be strong and healthy, remain on until they begin to fade, always provided, of course, that water is duly supplied to the roots and the atmosphere is right. Weak, badly-rooted plants, on the other hand, should have the bloom spikes taken off soon after these come to maturity, for they are a strain on the plants for a long time while forming. The spikes appear at the base of the last-formed pseudo-bulbs and grow a yard or more in length, the flowers elegantly yet closely set upon small side branchlets. The sepals and petals are small and narrow, creamy-white with rosy-purple bands, the lip white, and the entire flower is seldom more than an inch and a half across. *O. incurvum* is a native of Mexico, and while thriving fairly well under cool treatment,

produces larger pseudo-bulbs and longer spikes in a rather higher temperature. Too much heat, on the other hand, is very injurious. It will do well in a similar temperature to that required by the Mexican section of *Lelia*, but likes more shade. The roots are not large, but are plentifully produced; consequently, a compost of medium quality may be given. The plants do well in pots, these being well drained and large enough to allow of 2 inches at least around the plant. Large old specimens do better in shallower receptacles, the pans pierced with holes around the sides suiting them well. Such plants require careful handling when renewal of the compost becomes necessary, as the best roots are often on the outer portion of the ball, and a lot of older, partly decayed ones further in. There is only one thing to be done, and that is careful hand-picking of the decayed parts, as far as these can be got at, without damage to the younger healthy ones. Its season of growth and rest is usually well defined, and, as a general rule, no special treatment is necessary, but it is an advantage during late autumn, after the flowers are past, to keep them in a light and moderately sunny position.

**Phalænopsis Ludde-violacea** is a distinct hybrid raised in Messrs. Veitch's nursery by crossing the two species indicated in the name. It is apparently of good constitution and very free-flowering. A plant with three spikes and six expanded flowers was recently noticed in bloom in the Chelsea nurseries. The sepals and petals are deep rose, marbled with white, the lip rich crimson in front, with several slightly raised hairy ridges, the side lobes rose, shading to yellow at the base.—S.

**Phalænopsis Vesta.**—This lovely hybrid is the result of crossing *P. Aphrodite* and *P. rosea leucaspis*. It is in the way of the beautiful natural hybrid *P. intermedia*. The sepals and petals are white, shaded with rose, the front lobe of the lip deep purple, shading to yellow, and spotted with brown at the base, the side lobes rose-purple at the apex, white at the base, where it is thickly spotted with rich brown. A strong plant carrying a spike of seven flowers I lately noticed.—S.

**Phalænopsis Hebe.**—This, the result of crossing *P. rosea* and *P. Sanderiana*, differs principally from *P. intermedia* and *P. Vesta* in its broader and more highly-coloured sepals and petals, which are white, heavily suffused with rose over the basal half. The lip, similar in character to that of *P. intermedia*, is purple in front, shading to yellow and spotted with reddish brown at the base. It is a free-flowering variety and of good constitution, requiring the usual *Phalænopsis* treatment and should be grown suspended from the roof.—S.

**Miltonia Bleuana virginalis.**—This distinct and lovely hybrid differs from the typical forms raised by M. Bleu, of Paris, in that it has almost completely lost the colouring usually seen on the disc of the lip and at the base of the petals. The sepals are pure white, petals white, with a very slight indication of rose at the base, the lip upwards of 2 inches across, white, with a superb purple disc. It is the result of crossing *M. Roezli* and *M. vexillaria*. A strong plant of this variety was recently in flower in the collection of Mr. E. Ashworth, Harefield Hall, Cheshire.—STELIS.

**Cattleya Aclandiae.**—Growers often make the mistake of treating this *Cattleya* the same as a strong-growing *C. labiata* or some similar kind. This is quite wrong, for though block treatment is decidedly too poor to obtain the best results, it is infinitely better than stifling the roots under several inches of peat and Moss. It is never happier than on a raft with a little compost about the roots, just enough not to prevent the air from playing freely about them. Grow it thus in an intermediate house, and let it have its own way in regard to resting or otherwise, and it is usually satisfactory.

TREES AND SHRUBS.

KALMIAS.

AMONG the dwarf evergreens there are few that rank higher in merit than the Kalmias. There are altogether seven species known, but of these only three appear to be in cultivation, all of which are valuable as garden shrubs. The genus is purely an American one, extending from the arctic regions in the north as far as Cuba in the south. The tallest growing of the three species here described—*K. latifolia*—is commonly known as the Mountain Laurel, and is one of the chief favourites among the many plants suggested for the national flower of the United States. The name *Kalmia* was

*sideratum*, and this is why deep trenching is recommended. In hot, sandy soils the ground should be removed to a depth of 2 feet and replaced at the bottom with the best of the natural soil mixed with a heavier loam, filling the upper part with a mixture of peat, leaf-soil, and loam. This may be a troublesome and perhaps costly business, but it is cheapest in the end, and saves much labour in watering during hot summer weather. All the three species here mentioned ripen seed in this country, by means of which they can be increased. Layers and cuttings may also be employed, but seeds are preferable.

Both *K. angustifolia* and *K. latifolia* may be used for forcing. The plants should be potted up at the beginning of winter, and may be brought into the forcing house at intervals to

origin, and, according to Loudon, is a native of the mountains of New Jersey. It is easily distinguished by its larger, oblong or ovate leaves, which almost suggest a small-leaved *K. latifolia* in their glossy green colour and firmness of texture. They are produced in whorls of three or four leaves at each joint, and the whole shrub is of taller, more robust growth.

*K. A. VAR. NANA* is also a distinct and very pretty plant. It is of close dwarf growth, forming a neat dense bush 1 foot or less high, and useful as an edging or for a front place in a group of the taller Kalmias.

*K. A. VAR. RUBRA* has flowers in which the purplish tinge of the ordinary form gives place to a purer red. Of the several varieties it is the richest in hue.

*K. GLAUCA*.—This species differs considerably in general aspect from the other two, and compared

*Kalmia latifolia*. From a photograph by Mr. F. Mason-Good, Winchfield, Hants.

given to these shrubs by Linnaeus in honour of Peter Kalm, a pupil of his, and afterwards a professor of botany in Sweden. He travelled in Eastern North America about the middle of the last century. The Kalmias belong to the ericaceous family, the flowers being rather flat and saucer-shaped and borne at, or near, the ends of the previous season's branches. They require the same conditions under cultivation as the great majority of their allies—the so-called "American" plants. A soil of a peaty nature is best, but in gardens consisting of pure loam they may be grown well by trenching deeply and mixing plenty of well-decayed leaf-soil and as much peat as can be afforded with the top spit. They have the same antipathy to lime at the roots, which renders the cultivation of so many ericaceous plants in chalky soils a difficult and expensive matter. A cool and continuously moist soil is an important de-

provide a succession, but slow and gentle forcing is necessary.

*K. ANGUSTIFOLIA* is a very pretty dwarf shrub growing from 1 foot to 3 feet high, which flowers during June. Its leaves are oblong and blunt and from 1 inch to 2 inches long. The name *angustifolia* (narrow-leaved) is only appropriate as distinguishing the species from the larger, broader-leaved *K. latifolia*. They are, as a rule, produced in threes at each node. The flowers are of a purplish-red (but of different shades), each a little under half an inch in diameter, the corymbs being produced in the leaf-axils near the ends of the shoots, sometimes extending several inches downwards from the tips and forming a showy cylinder-shaped mass of blossom. It is a very free-flowering plant. It was introduced in 1736 from Canada, but extends from there southwards to the hills of the Carolinas. Of the several named varieties in cultivation the most distinct is

*K. A. VAR. OVATA*. This is a form of natural

with either of them, but especially *K. latifolia*, is poor and scanty in appearance. Out of flower it is by no means so handsome a shrub. The leaves are almost sessile and about an inch long; they are ovate-oblong, but often appear narrower on account of the edges being curled under, and are mostly borne in pairs at each joint, but occasionally in threes. The revolute margins of the leaves and the glaucous white colour of the under-surface render the species easily distinguishable at any time. The flowers are reddish-lilac, each over half an inch across, and produced in terminal corymbs. The species was introduced from the United States in 1767. It is in flower, as a rule, early in April, and is thus two months or so in advance of its two fellow species.

*K. LATIFOLIA*.—This is much the largest of the Kalmias, and may frequently be seen 6 feet or 8 feet high in this country, whilst in the Southern Alleghany Mountains it is said occasionally to attain a height of 20 feet. It is a very handsome

shrub both as regards its foliage and blossom, and in places where the conditions suit it there are few evergreens of greater beauty and value. Among the many fine things that may be seen at Dropmore are large spreading bushes of this *Kalmia* in perfect health. The leaves are alternate and not produced in whorls, as in the other two species, although they are clustered towards the end of each growth: they are of a dark lustrous green and taper to a point at both ends, averaging about 3 inches in length by  $\frac{1}{2}$  inches in width. The flowers appear in June in a cluster of corymbs terminating the shoot. Each flower is about three-quarters of an inch in diameter, and is rose-coloured. The shade varies in depth in different plants, and the flowers are sometimes almost white. London says the leaves are poisonous to cattle and sheep, but not to deer.

**K. L. VAR. MYRTIFOLIA** is a distinct and very pretty plant, although not so well known as one might expect. It is of dwarfer habit, and its leaves are not much larger than those of the Myrtle, being about  $\frac{1}{2}$  inches long, from a quarter of an inch to half an inch wide, and sharply pointed. The flowers also are smaller than in the type, but the whole plant when in bloom is as pretty as it is neat and compact. I have seen it in quantity and in fine condition in the Knap Hill Nursery.

**K. L. VAR. POLYPETALA**.—Professor Sargent, of the Arnold Arboretum, sent a plant of this variety to Kew three or four years ago. Its foliage does not differ from that of the ordinary *K. latifolia*, but the corolla, instead of having the usual saucer shape, is divided into several segments, as the name implies. It flowers each year at Kew at the same time as the others, but deserves mention merely as a curious freak.

Besides these three species and their varieties there appear to have been in cultivation, formerly if not now, two other species—viz., *cuneata* and *hirsuta*, but I have seen neither of them. It would be interesting to know if any reader of THE GARDEN cultivates either of these species at the present time. W. J. BEAN.

**Lonicera japonica**.—This name includes the different forms of one species of Honeysuckle which are variously known in gardens and nurseries as *L. chinensis*, *Halleana*, *flexuosa* and *brachypoda*. It is just now one of the most charming shrubs in flower, alike for the luxuriant elegance of its growth and for the sweet, strong fragrance of its blossoms. It is a climbing plant, but by giving it the support of three stakes 6 feet or more high, arranged as a tripod, it will form a dense graceful bush, and may in this way be used to furnish the open border. It has broad ovate leaves, each from  $\frac{1}{2}$  inches to 3 inches long, of a beautiful rich green. They are opposite, and a pair of flowers is produced in the axil of each one, so that four flowers appear at every joint. At first they are creamy white, but gradually become yellow with age, the four upper parts of the corolla uniting to form a broad, oblong standard. The fragrance is like that of our native Honeysuckle, with a suggestion of Cowslip added. In mild winters like the two last this *Lonicera* is evergreen. It is a native of China and Japan.—W. J. B.

**Ledums as fly-catchers**.—As a note supplementary to Mr. Bean's admirable paper on these plants in THE GARDEN, p. 28, I should like to point out their fly-catching propensities. Early in May of this year, Mr. Smith, of Newry, sent me sprays of *Ledum palustre* or *L. glandulosum*, I am not certain which, with the remark that the flowers had a singular attraction for gnats or small flies. The flower-clusters bore out his observations, each bloom having one or more small black gnats in its centre firmly glued to the glandular and viscid ovaries. On sending some of the specimens to Dr. G. H. Carpenter, of the Dublin Natural History Museum, he kindly identified the little flies as *Empis vernalis*, Meig., and remarked that he did not previously know of the insect-trapping propensities of these Heath.

Whether the insects are caught in a merely mechanical way, as happens when flies stick on to the outside of the glutinous corollas of some Cape Ericas, or whether they are useful in securing cross-fertilisation, is not accurately known, but as the flies live for some days struggling inside the flowers, it seems probable that they may be of some aid in fertilisation.—F. W. BURBIDGE.

## BOOKS.

### POT-POURRI FROM A SURREY GARDEN.\*

GARDENING is rapidly becoming a fashionable subject for writers, some of whom, it is true, are very ill-prepared for the task, as we may see by the silly articles in one evening paper. Those illustrate a new way of writing, like the new way of drawing—that is, having no preparation for the work, but writing as a person might who had never thought of the subject at all. Only a month or two ago in a well-known magazine appeared an article on flowers, in which it was stated that it was about twenty years ago since English people began to take an interest in them! Mrs. Earle's book is not, we are glad to say, of this class. She comes of people who for a good many generations back took their highest pleasure in their gardens, and greater pleasure than we fear the present generation of women on bykes, women at golf and cricket, horsewomen and new women generally are likely to share. It is an interesting book about many things, and Mrs. Earle being a good gardener and not a mere patron of the art, there is not a little to be learnt in it, and much with which we agree, especially in her remarks about the spoiling of vegetables under the name of "improvements."

It is a great mistake, when marking the nurseryman's seed list, to order the vegetable described as "giant," "large," "perfection," &c. Unless your soil is very strong such vegetables do not grow large, and they do grow tough and tasteless. This "giant" cultivation has been brought about to win prizes at shows. Amongst the delicious vegetables that have been ruined by growing them too large are Brussels Sprouts. I consider those sold in the London shops are not worth eating, they are so coarse; but one can get the seeds of old-fashioned small kinds. These are far sweeter, nicer and prettier, either for putting into soup, for boiling and frying afterwards in butter, or for boiling quite plainly in the ordinary English way. They are also far more delicate for a purée, which is an excellent way of dressing them. If fried and put on buttered toast, they make a very nice second-course vegetable in winter.

It is curious that, notwithstanding the talk about a thing, how many years it takes the French to take up Rhubarb or the English Celeriac, about which Mrs. Earle writes—

Celeriac is an excellent vegetable, not very common in England, and, when carefully cooked, with a good brown sauce, forms a valuable contribution to the winter supply. One of the constant difficulties in the management of a house, whether large or small, where the vegetable are grown and not bought, is that the gardener brings them in, and the cook throws them away into a corner of the scullery or into the pig-tub. Only last summer a gardener from a large place in the neighbourhood said to me while walking round my small garden: "What! you grow Cardoons? I took in beautiful ones last year, but they were never used: the cook said she didn't know how to cook them." The following is a good recipe: The length of time Cardoons re-

\* "Pot-Pourri from a Surrey Garden." By Mrs. C. W. Earle. (London: Smith, Elder and Co.)

quire in cooking depends on age and size, and varies from half an hour to three or four hours. Scrape the stalks and pull off all that is thready outside. Cut them into bits about 4 inches or 5 inches long, or longer if served in a long, narrow dish with marrow on toast at each end. As you cut them throw them into a basin full of water, into which you put a little flower to keep them a good colour. When all are prepared, have ready a large crockery stew-pan with boiling water, herbs, a little salt and pepper, and a good-sized piece of raw bacon. The rind of the bacon should be cut in little bits, but not so small as to get mixed with the Cardoons. Boil the whole slowly, and prepare a brown sauce apart with well-flavoured stock. Thicken this with flower (burnt to a light coffee colour), butter and a little sherry. Let it simmer for two hours, skimming it well. Strain it half an hour before serving.

### A FINE STAR OF BETHLEHEM.

A few years ago I brought from Paris some bulbs of *Ornithogalum pyramidale*, the flower-spikes of which are sold at the end of June in the Paris flower market under the name of *L'épée de la Vierge*. I have never seen the plant grown anywhere in England as I have grown it, and yet in every way it is quite one of the most satisfactory flowers for picking that I know. If you gather it just as one flower is coming out, the whole of the long spike grows and flowers in water up to the very top, bending and curling about, and assuming the most graceful curves. No one can grow a better flower plant to send to London. It has one fault in the garden—the leaves droop and turn rather spotty and yellow before the flower comes quite to its prime; but this defect can indeed be forgiven for the sake of its many merits. I cultivate it nearly as I do the above-mentioned Lilies; only, when the bulbs are dug up I place the small ones at once in a nursery, but the large ones are well dried in the sun and not replanted till October. A mulching when they begin to show through in the spring does them good.

### GARDEN LAWNS BARE OF FLOWERS.

In the old days of bedding-out, lawns used to be cut up into beds and patterns. Now the fashion has changed, and bedding-out has become so generally condemned that most people have levelled and turfed over the rounds, stars, crescents, and oblongs that used to enliven their lawns for a short time, at any rate, every autumn. As a result of this reaction, there are now an immense number of large, dull lawns, which as a rule slope slightly away from the house, and often to the south. They are wet in rain, and dry and brown in hot weather. They have their weekly shave with the mowing machine, and lie baking in the sunshine. The poor plants, which would flower and do well in the open, are planted at the edges of the shrubberies, where—in a light soil at any rate—they are robbed and starved into ugliness and failure by their stronger neighbours.

### GROWING THE WHITE LILY.

The difficulties of growing the Madonna Lilies seem to be overcome by Mrs. Earle, and we cannot do better than let her tell her own story.

*July 8*.—I consider no trouble too great, whether the garden be large or small, to grow the beautiful stately Madonna Lily (*Lilium candidum*). It requires very different treatment from other Lilies, and flourishes in rich, heavy soils in full sun, where many Lilies would fail. Gardening books often tell you it is fatal to move these Lilies, but I think this has arisen from gardeners moving or disturbing them when they have "done" their borders in October or November, and when the Lilies have made an autumn growth; moving them then is fatal. When I used to leave them alone they made an excellent top growth in spring, but dried up and died down without flowering. What I now do when they begin to die down some time this month, whether they have flowered or not, is to dig them up carefully with a fork, remove all offsets, re-make and

manure the ground well, mixing with it some brick rubbish or chalk, and then replace the large bulbs, planting them rather deep, and not too close together. In this way every bulb flowers. A little liquid manure helps them to open well when they are in bud the following June. The small offsets are put into a nursery apart, and many of them will flower the following year in a way that does admirably for picking.

**A NEGLECTED SALAD.**

February 14.—Salads are rather a difficulty during the early spring in English gardens. In seasonless London everything is always to be bought. I wonder why Mâche (Corn Salad, or Lamb's Lettuce), so much grown in France, is so little cultivated here? People fairly well up in gardening come back from France in the winter, thinking they have discovered something new. Mâche is a little difficult to grow in very light soils, and the safest plan is to make several sowings in July and August. We find it most useful, but, without constant reminding, no English gardener thinks of it at all, though it is in all the seed catalogues. As it is an annual, without sowing you naturally do not get it, and if sown too late, it is bound to fail. In very dry weather we have to water it at first.

**ASPECT OF HOUSE.**

The next question of the aspect of a house is sensibly discussed

The longest side of the house faces west. How I love it because of this! To my mind every country house is dull that does not face west and have its principal view that way. Modern civilisation forbids us to enjoy the sunrise, but the varied effects of the sunset sky glorify everything—the most common-place gable or the ugliest chimney-stack, a Scotch Fir or an open field, which assumes a green under an evening primrose sky that it never has at any other time. The sky is like the sea for its ever-changefulness. You may watch sunsets most carefully every day in the year, and never will you see twice exactly the same effect. How we all know, and notice after midsummer, that marching south of the sun at setting-time! The old fellow in June sets right away to the north, over the common, changing group of trees and a little distant hill to purple and blue. At the autumn equinox he looks straight in at the windows as he goes down between the stems of the two tall Fir trees. Who, when forced to come in to dinner on a summer's evening, does not appreciate a west dining-room with tall panes of glass which give the power to measure the gradations of the sky, from the deep grey-blue of night's garments at the top, to the bright gold, streaked with purple and crimson, at the base—the earth growing mysteriously dark all the while, and the evening star shining brighter every minute? Architects tell you, and men say, they prefer that a house should face south-east. I do not at all agree with them; the effects of evening to me are too much to give up for any other advantage in the world, real or imaginary. It is far easier to make some other room into a breakfast-room, to catch the morning sun in winter, than to change your dining-room in the summer for the sake of the sunsets.

**THE WINDOW BLIND NUISANCE.**

There are many matters in the book of interest to the householder besides the gardening part and many good recipes. The following may be of use to the many who have suffered and suffer daily with the innumerable patents to produce that nuisance, the jack-in-the-box window blind, where no patent or mechanism of any kind is required.

They are expensive to put up, expensive to maintain, and very difficult to keep clean in London. I never have them in my own rooms, in bedrooms or servants' rooms, in the stable or gardener's cottage. What I do have is an inner curtain hung from a small rod on the window. It can be made of any variety of material, to suit

the different windows and the requirements of the room—thin silk (the effects of light through silk—orange, red, yellow or green are very pretty), chintz, muslin, or the thickest dark blue or green twill lined with calico, to keep out light in the bedrooms in the country (in London I think light blue or green twill unlined is sufficient); and the most useful of all is the common red Turkey twill, lined or unlined, which washes year after year, and always looks fresh, clean, and bright, and practically never wears out. In many modern windows these inner curtains enable you to dispense with heavy outside curtains altogether—to my mind an advantage, as drawn curtains almost always make a

means of prong or hoe. Mulching is most helpful in maintaining vigour and free-flowering. If the second spit cannot with safety be brought to the surface, let it be turned over and well broken. — M. T., *Carrou, N.B.*

**ROSE GARDEN.**

**ARRANGING TEA-SCENTED ROSES IN VASES.**

Few flowers are so highly esteemed for decoration as the Tea-scented Rose, being charming in colour and refined in appearance. Added to the foregoing characteristics there is another charm—that of fragrance. For this valuable property alone these flowers are more readily appreciated than the brighter and perhaps more striking Hybrid Perpetuals, and in the arrangement of vases, epergnes, hand-baskets and other receptacles the Tea Rose for the purpose of home decoration is more often sought after.

As already mentioned, the Tea-scented Roses give us soft and beautifully refined colours—white, blush-white, delicate rose, pale pink, flesh colour, yellow, fawn, apricot, salmon-pink, rich salmon and carmine, besides many other intermediate shades. Any reader with a taste for the pleasing association of colour should have little difficulty in fixing upon those which would give the best and prettiest effects. For associating with these Roses nothing suits them so well as their own foliage. From the time that the first lot of blossoms is ready a grand lot of Rose foliage may also be obtained. That of the Tea-scented Rose is often so highly coloured that this is often in itself quite a picture, and when in such condition there is nothing better for association with the blossoms than a free use of its sprays and

*A Vase of Tea Roses.*

room stuffy and nearly as airless as did the shutters of our forefathers. All the same, thick curtains are, of course, required in the country in winter for warmth.

**Pansy culture.**—It is often remarked that Pansies can be cultivated in Scotland in a manner which southern cultivators cannot imitate. This I dispute. I have cultivated them with comparative ease in the south and west of England. Trench the ground thoroughly two spades deep, place a good coating of decayed farmyard manure under the top spit, give plenty of room to the plants, and if watering is necessary, let a thorough soaking be given. If this cannot be done, better give none at all, and keep the surface loose by

leaves. The Tea Roses are more easily arranged in vases, &c., than the H.P.'s, and often, being less cumbersome, the simplest novice may achieve considerable success. Most Rose growers are opposed to the use of wires when decorating a stand or filling a vase. Where a number of individual blooms are arranged in one vase the necessary lightness and grace could not well be obtained without the aid of wire supports. Bouquet "stubs" are the best for the purpose, and they can be bought of any florist. The Rose should be wired in such a way that it does not become an eyesore to anyone. Hand-baskets and the base of an epergne should be filled with a nice green

Moss, and the wires fixed on the stem of the Rose should be stuck into this material, plenty of space for each flower with its sprays of leaves being allowed. In this way a dozen Roses may be sufficient to fill a pretty hand-basket or bowl for a dinner-table decoration. Adopting the same rule, vases of large size should have the opening filled with Moss, and the flowers arranged in like manner to that described for baskets, &c.

Small tubes and vases are seen to greatest advantage when filled simply with two or three small flowers and buds. Epergnes are best when filled with medium-sized flowers and buds, about three blooms being allotted to each arm of the stand. Crowding must always be avoided. Each bloom should stand out distinctly from its neighbour, and so that the foliage which was cut with the flower should also lend attractiveness to the arrangement. Noble vases of the Tea Rose may easily be arranged, and without artificial support, when the flowers are cut in sprays.

**Rose T. B. Haywood.**—This Rose undoubtedly has a future as a good reliable late-flowering Hybrid Perpetual. It has the fine form of Mme. Victor Verdier, and the colour is a rich crimson somewhat in the way of Louis Van Houtte. I consider it a worthy addition to a class that has had but few notable acquisitions during recent years.—P.

**Rose Waltham Climber No. 3.**—Fragrant varieties of Roses can never become too plentiful. I think I should not be far wrong in saying that to the majority of individuals colour and perfume take precedence over form and habit. The above Rose is very sweetly scented, and for a climbing Rose this is a great boon. The flowers are of a clear scarlet-crimson colour. It is a very double variety, and the pointed outer petals resemble in a small way those of La France. This Rose is a good vigorous grower, with reddish foliage, and is admirably adapted for a south or west wall.—E.

**Rose Josephine Marot** is a splendid showy garden variety at present very little known. It is of very vigorous habit, producing fine bunches of flowers on good stiff stems. A peculiarity of this Rose is that each panicle of blossom will be composed of Roses of three different colours. The half-open flowers are of a delicate blush shade, merging to almost pure white as they expand, whilst the pretty buds are of a deep rosy hue. As the flowers are very lasting, these three colours may be seen at one time upon one stem, thus producing a very distinct and pretty effect. It is an excellent variety for cutting.

**Rose Climbing Niphetos.**—This Rose appears to improve with age. A few years ago I planted it in a greenhouse, fixing a trellis to train it on. The plant grew vigorously enough, in fact more so than I had ever seen the ordinary Niphetos do, but for several seasons it produced very few blooms. As it became thoroughly established, however, and grew less vigorously, flowers were produced in much greater quantities. I think they are less compact than those of the old variety. After flowering is past, all old wood that can be spared should be removed and the young shoots of the current year tied evenly in. This will give the plant a much better chance than if the thinning is left till the winter.—GROWER.

**Rosa lævigata** *rel.* **R. sinica** *rel.* **R. ternata.**—Several notices have appeared lately in THE GARDEN concerning this beautiful Rose, but I have not seen one fact mentioned—viz., that the leaf of this Rose is composed of three, and only three, leaflets, and, to the best of my belief, no other Rose has this characteristic. In this country it flowers several times in the year, and when it is at its best it is really a splendid object covered with its enormous blooms, 4 inches or 5 inches in diameter, and in such profusion that at a short distance one would say a white

sheet had been spread over the plant. The leaves are as evergreen and coriaceous as those of the Camellia, whence, no doubt, in many French catalogues it is called Rose Camellia.—F., *Benifica*, *near Lisbon*.

**Rose The Garland.**—This Hybrid Musk Rose should find a place in every wild garden, or failing that it should be planted where it can clamber over stumps of trees, arbours, or in fact any position where a good free-growing Rose is wanted. Its immense panicles of fragrant tiny buff coloured buds and creamy white blossoms are lovely. The individual flowers are about 1½ inches in diameter, and it is quite common to see a shoot of this Rose bearing ten to twelve laterals, each one of these containing as many as twenty to thirty buds and blossoms. When the blossoms upon these laterals are all expanded, revealing as they do the beautiful and numerous yellow stamens, they have indeed a very pretty effect.

**Rose Souvenir de Mme. Eugene Verdier** (H.P.)—This variety must not be confounded with a very lovely Hybrid Tea of the same name. It belongs to a type of Rose that formerly was much appreciated. The flowers are very large and extremely flat, but such Roses have gone out of fashion in this country, although on the Continent they still are held in esteem. I maintain that the more diversity of form we can secure the more interesting will be our collections, and upon this ground I recommend the above variety. The colour is a pleasing shade of rosy-pink, and the very double flowers are quite 7 inches in diameter. Such enormous blossoms, borne as they are upon still Etienne Levet-like stems, have a very decorative value, and one can imagine that a fine effect would be produced by massing together a goodly number of plants of such a fine Rose.

#### PROGRESS IN HOME-RAISED ROSES.

In looking over the official list of new Roses issued to members of the National Rose Society, I am struck with the large total named as being introduced in the spring of 1894 and subsequently. No doubt very few of the Continental varieties have been missed, but no less than 343 are mentioned as appearing in English nurserymen's lists since 1894. Over fifty of these are British or Irish raised Roses, and include such grand novelties as Muriel Grahame, Tom Wood, Alister Stella Gray, Captain Hayward, Jeannie Deans, Empress Alexandra of Russia, Helen Keller, Laurence Allen, Mrs. Rumsey, Mrs. W. J. Grant, Mrs. R. G. S. Crawford, and Sylph. Home-raised Roses have been so numerous, that few really good new ones come from the Continent when compared to previous years. Among the 350 I can only find Alice Furon, Antoine Rivoire, Charlotte Gillemot, Comtesse Dusy, Germaine Trochu, Mme. A. Chataney, Hippolyte Barreau, Mme. Carnot, Mme. Jules Finger, Mme. Wagram, Comtesse de Thronpe, Princesse Alice de Monaco, Mrs. W. C. Whitney, and Yvonne Gravier as likely to be standard varieties; most of the remainder from abroad will certainly not be grown to any appreciable extent. Although it may well happen that a few are missed from the above list, it does not look promising to find little over a dozen one can really recommend out of 300 distributed in 1894 and since. Among our home-raised varieties we find very few indeed that are not still favourites in the garden. There is no need to name a long list, but taking a few which occur while I write, we find some really grand quality. Duke of Edinburgh, Beauty of Waltham, Prince Arthur, Her Majesty, Mrs. John Laing, Duke of Connaught, Duchess of Bedford, Earl of Dufferin, Ethel Brownlow, Margaret Dickson, Salamander, Lady Mary Fitzwilliam, Viscountess Folkestone, Devoniansis, Cleopatra, Mrs. Paul, Souvenir de S. A. Prince, Lady Henry Grosvenor, and Cheshant Hybrid are only a very few in addition to the grand varieties named from among the newer introductions, and this gives us a much higher percentage of good Roses than can be found in the many hundreds raised abroad.

But Continental growers have given us some of the grandest of all. A. K. Williams, Horace Vernet, Charles Lefebvre, Alfred Colomb, General Jacqueminot, Dupuy Jamain, Gabriel Luizet, Marie Baumann, Maurice Bernardin, Ulrich Brunner, and Prince C. de Rohan among the Hybrid Perpetuals; with Anna Ollivier, Catherine Mermet, Comtesse de Nadaillac, Edith Gifford, Innocente Pirola, Niphetos, Marie Van Houtte, and Maréchal Niel cannot well be beaten in their respective colours; but these are the pick of over 2000 varieties. In Mr. E. B. Lindsell's champion stand of thirty-six varieties at the recent Crystal Palace show no less than thirteen were of home origin; while in the seventy-two staged by Messrs. Harkness and Sons, and which won the champion trophy in the trade classes, there were twenty-six home-raised Roses. In each case a little more than a third of the varieties staged were raised in Great Britain or Ireland, and when we consider the enormous number sent out by Continental growers this is a very satisfactory account, especially when we also note that fifteen out of the twenty-six were of quite recent origin.

We have yet another proof of improvement in this respect. In a very strongly-contested class for twelve new Roses, and which was open for any of the 343 varieties named by the society, Messrs. Dickson and Sons, Newtownards, were a long way ahead with those of their own raising only, and no less than nine of these have yet to be put into commerce. It would be difficult to find a better dozen than the following: Mrs. John Laing and Mrs. R. G. Sharman-Crawford are two of the grandest and most distinct pinks. They are always good, no matter the season, and are grand in growth and free blooming. In Duke of Edinburgh and Prince Arthur we have two of our best dark crimsons, always of good form, quite distinct, and opening well. If we want two good whites, none can be better than Souvenir de S. A. Prince and Climbing Niphetos, both sports from varieties that have been prime favourites for more than fifty years, and retaining all their good qualities with the purest white blossoms. In Crimson Rambler and Waltham Climber No. 3 we have two of the very best deep reds for walls, arches, or pillars. Viscountess Folkestone gives us a grand salmon-shaded flesh tint and some of the sweetest scent found in Roses. Her Majesty is well known as the best large Rose with a clear satiny-pink shade, and Mrs. W. J. Grant cannot be beaten for freedom of flowering and in usefulness of its blossoms from the bud stage upwards. Our best striped Rose is found in Pride of Reigate, and it would be very easy to name a second dozen in no way inferior to the above.

RIDGEWOOD.

#### SWEET-SCENTED ROSES.

"D. T. F.'s" note (p. 69) implies that the National Rose Society, or rosarians generally, have quite lost sight of perfume in Roses. Now there are very few Roses that do not smell sweetly, certainly less than a dozen, and I note that no less than thirty-eight are mentioned in the society's catalogue as being specially fragrant. His suggestion of prizes for the sweetest Rose or Roses in a show is almost impossible to carry out. Who shall decide when there is such a difference of tastes? I know persons who even profess to find very little perfume in Socrates and La France when compared to other varieties. "D. T. F." writes that we have developed size, form, and colour, and done "little or nothing" to intensify sweetness. Baroness Rothschild is scentless, but Laurence Allen, a Rose of 1896, is more double, of better form, a little brighter in colour than the Baroness, and certainly one of the sweetest-scented Roses grown. Is not l'Idéal equally as sweet as the old Damasks? Mrs. W. J. Grant, Captain Hayward, Gustave Piganeau, Mme. de Watteville, G. Nabonnand, Luciole, Antoine Rivoire, Mrs. W. C. Whitney, Pink Rover, Viscountess Folkestone, and Mme. Alfred Carrière are only a few of those introduced recently, and which are more than usually sweet-scented, even

when compared to the very best of our old Roses. Nor do any of the raisers omit to give prominence to the quality of perfume when describing varieties, thus clearly showing that this is still considered a desirable quality in the Rose.

I maintain that, compared to the number of varieties grown, Roses are even sweeter now than was the case years ago, and if we can have more perpetual-flowering qualities, better form, and higher colours, so much more to the credit of raisers.

RIDGEWOOD.

**Rose Horace Vernet.**—This superb Rose was exhibited in grand form at the recent Crystal Palace Rose show, and doubtless it has won many more admirers. The fact, however, cannot be too widely known that such flowers are produced upon what are known as maiden plants, that is plants budded last year. Practically it is a failure as a cut-back, and unless one is prepared to bud a few each year, it will be better not to attempt its cultivation only in a very limited quantity. It is very unfortunate that such a variety should be thus handicapped, but it does not stand alone in this respect, there being several kinds, for instance, Xavier Olibo, Louis Van Houtte, Harrison Weir, &c., that are only really good as maidens.—GROWER.

**Roses with coloured foliage.**—In a note upon the above (page 41) I notice two important omissions. *Perle de Lyon*, an old Tea, sent out in 1873, has the deepest bronzy purple foliage of any Rose. Unfortunately, it does not produce very good flowers. They are uncertain in opening, but of the deepest golden yellow. *Mme. Dennis* is another old Tea, of great vigour, and producing quantities of buds and new growth throughout the season. I have several rows of this grown solely for the supply of deep bronzy-red foliage. One does not like to cut away the pretty tips of growth in many varieties and so sacrifice bloom; but *Mme. Dennis* is not of much service as a flower, and produces such quantities of young shoots that one need have no compunction in this respect.—RIDGEWOOD.

**Colour in Roses William Allen Richardson and l'Idéal.**—I have been interested in the correspondence lately appearing in THE GARDEN on this subject. Two growers this spring have asked me if I knew whether this sporting (if I may so term it) was general with the two varieties given above, neither having noticed this freak before. In both cases the majority of blooms have come white instead of their true colour. I have grown both, but have never as yet seen them do this. *l'Idéal* flowers profusely every year on a low south wall and the colour is superb. I prune my plant fairly close every spring, as the wall is only 5 feet high. I have it on its own roots as well as on the *Manetti*, but can detect no difference as regards the colour. Another good Rose I would like to advocate the claim of as a button-hole Rose is *Papa Gontier*, a beautiful bright crimson and a good doer.—J. MAYNE, *Bicton, Devon*.

**Scotch Roses at last.**—Those who have seen the Aberdeen, Dundee, and Edinburgh Roses at their best regret the abnormal lateness of the season that prevented these from taking a part in the Rose show at the Crystal Palace on July 2 this year. At a recent meeting of the Scottish Horticultural Association in Edinburgh there were some choice blooms from the Messrs. Croll, of Broughty Ferry, Dundee, and Mr. Hugh Dickson, of Belfast, also sent some beautiful Roses. Among Dundee Roses the following were superb: *Gustave Piganeau*, *White Lady*, *Comte de Raimbaud*, *Caroline Testout*, Mrs. John Laing, *Francois Michelon*, *Lord Bacon*, *La France*, *Marguerite de St. Amand*, *Senateur Vaisse*, *Victor Verdier*, *Niphotos*, *Luciole*, *Rubens*, *Jean Ducher*, and *Mme. Welch*. These and other fine Roses were fringed with choice bunches of *Common and Crested Moss*, *Wm. Allen Richardson*, *Gloire des Polyantha*, &c. Among Mr. Dickson's Irish blooms the following were among the best: *Gustave Piganeau*, *Caroline*

*d'Arden*, Mrs. John Laing, Countess of Devonshire, Countess of Sutherland, *Prosper Laugier*, *Heinrich Schultheis*, and Mrs. *Sharman Crawford*.—D. T. F.

**Rose notes.**—I do not know what may be the experience of those who have the advantage of a good Rose soil. Here, where the soil is very light, a few characteristics of the present season are a very fine display of Teas, especially on walls, a good display generally on standards and bushes, but quickly over, and very favourable notes on some of the less-known Roses and one or two that are sometimes decidedly poor. In the latter may be mentioned the white and yellow forms of *Banksian* that have flowered remarkably well. In the single or semi-double class *Bardon Job* is a great favourite, and is the only variety of this particular shade in the section. It stands very fairly in a cut state, much better than the appearance of the flower would indicate. *Macrantha* contrasts finely with it, and alternate plants of these two varieties make a very attractive bed. I have been interested this year in our small colony of the *Polyanthas*. The plants have been in their present quarters for several seasons, are consequently well established, and flower with great profusion. I think the best members of the family might be utilised more frequently in connection with standards. If alternate plants were put in we should have Rose beds fairly well covered instead of looking on a collection of walking-sticks. Unnecessary crowding can always be avoided. In a cut state the *Polyantha* family are beginning to be appreciated at their true value, and few things are better for vases than nice clusters of such varieties as *Ma Paquerette*, *Perle d'Or*, and *Red Pet*.—E. B. C.

## STOVE AND GREENHOUSE.

### ZONAL PELARGONIUMS FOR WINTER.

WHATEVER the value of these plants in the flower garden, there can be no question as to their utility for winter blooming, their bright and telling colours lighting up the greenhouse when it is most needful. Doubtless the modern style of horticultural structures has done a great deal to bring this phase of their culture into popularity, but the efforts of English raisers of new varieties have done a great deal more. In the old style of house the plants made plenty of wood during winter, but the absence of light and air prevented this blooming with any degree of freedom. In present-day houses opposite conditions obtain, and the plants thrive accordingly. I am now potting up the stock for next winter. They are potted in good loam of a fibrous character, a little dried cow manure, and plenty of leaf-mould and sand. After potting they should be stood outside in the full sun and kept well on the dry side until root action is free, when a fairly liberal allowance is necessary. So treated, the plants make a stouter growth than in frames, owing partly to the fact that more room can be allowed. They are almost sure to push flower buds at once, but these should be pinched out. The plants may stand in the open until the middle or end of August according to the weather, when protection must be given. At all times under glass a good circulation of warm dry air must be kept up about the plants, these being stood as close to the roof as possible and no shading allowed at any time. If more convenient, the plants may be brought on in batches to keep up a succession of bloom, though the same plants will go on blooming for several months. In the meantime, it is true, they are apt to grow a little unshapely, but if duly fed at the roots the quality of the flowers is as good at the end of the season as at the beginning. The plants after blooming may be

placed in a vinery or greenhouse and kept a little on the dry side until June, when they may be cut back, using the prunings for propagation if desired, and stood outside. Double-flowered varieties require rather more warmth to induce them to open freely than do single ones, but in a house kept up to 60° at night and fairly dry either will be satisfactory. The varieties are too numerous to give anything like a good selection, but, as a general rule, the English-raised varieties are far superior to the continental ones.

R.

**Heliotrope planted out.**—It is surprising how much space *Heliotrope* planted out in a border and trained over a trellis on a back wall will cover in a single season. In a garden near here the *Heliotrope* is a great favourite, and provision is made for a supply of cut bloom all the year round. At Christmas one large spreading plant on a vinery wall was covered with large trusses of fragrant bloom. Cuttings are taken in spring, and as soon as rooted are grown on in a moist intermediate temperature, being duly potted on until a 6-inch pot is well filled with roots. Planting out is then done in a good loamy soil and where a fair amount of light can reach the plant. An increased quantity of bloom in winter may be secured by pinching out the bloom-trusses in summer.—J. C.

**Streptosolen Jamesoni.**—This has been many times alluded to in THE GARDEN as a desirable plant for the greenhouse, its distinct shade of colour and freedom of blooming standing it in good stead. Besides this, too, it will bloom freely in the open ground during the summer months. In Hyde Park some large plants of it are flowering in as great profusion as the large *Heliotropes* and *Fuchsias* with which they are associated. The genus *Streptosolen* is nearly related to that of *Browallia*; indeed, by some authorities it is included in this last-named genus. In colour, however, it is totally different from the commonly-grown forms of *Browallia*, in most of which the flowers are of some shade of blue, whereas the blossoms of the *Streptosolen*, which are of a lightish yellow when they first expand, change afterwards to a bright cinnabar-red. This *Streptosolen* was introduced nearly fifty years ago, but was soon lost to cultivation. M. André, however, re-discovered it in Ecuador in 1882 and imported it into France, from whence it soon became general in cultivation.—H. P.

**Kämpferia Kirki.**—In some of the *Kämpferias* their handsome foliage is the principal claim to recognition, while in others the flowers are so ornamental that they well merit cultivation. The species above mentioned belongs to the latter class, and very pretty it is when in flower, and though the blooms are thin in texture and do not remain long in perfection, yet a succession is kept up from one scape for a considerable time. This *Kämpferia* forms a thick, fleshy root-stock, and passes the winter in a totally dormant state. Upon the return of spring, a few plantain-like leaves are pushed up from each crown, and generally during the month of June the flower-scapes make their appearance. In shape, size, and colour the flowers bear a great general resemblance to those of *Mitonia vexillaria*, but they are more flimsy and do not last so long. This *Kämpferia* is a native of the Zanzibar region, and when first flowered in this country, about sixteen years ago, it was known as *Cienkowskia Kirki*, under which name it was figured in THE GARDEN, November 19, 1881. Like most of the *Gingerworts* to which it belongs, this *Kämpferia* is of easy culture, all that is required being to keep it nearly dry during the winter, and about February the root-stock must be shaken clear of the old soil and again repotted in a compost consisting of loam, well-decayed leaf-mould, and sand. After this the soil must be kept slightly moist till the leaves begin to push above the surface, when the supply of water must be increased. It is readily propagated by

division, which is best carried out when repotting. This *Kæmpferia* is such a distinct plant that when in bloom it will attract a good deal of attention for this reason, as well as for the beauty of its blossoms. A second species, *K. rotunda*, with purple and white blossoms, was figured in THE GARDEN, August 18, 1888, while of those remarkable for the beauty of their foliage, *K. Gilberti* is one of the best. This forms a dense tuft of Funkia-like leaves of a deep green, marked with white. It grows about 6 inches high and is very useful for edging groups.—T.

— Although the flowers of this plant do not last very long, they are produced over a long season. The flowers, of a soft rosy purple tint with a yellow centre, are each about 3 inches in diameter. They occur on a slender stem from 6 inches to a foot in height. The culture of this plant is not difficult. It should be grown in a moist stove heat and potted in a mixture of peat, fibrous loam, plenty of sand and a little well-dried cow manure. The plants rest all through the winter, and may at this time be kept nearly or quite dry in a warm greenhouse temperature. They may be repotted just before growth commences, kept moist when the growth becomes active and until this shows signs of dying off in autumn. It is a native of Zanzibar, whence it was introduced in 1872.—GROWER.

#### SUMMER TREATMENT OF CALLAS.

For many years I adopted the plan of planting out my Arum Lilies in the open garden in June and lifting in autumn. No fault could be found with the growth the plants made, but the system has its drawbacks, one of the greatest being the destruction of so many of the young succulent rootlets, which cannot be avoided, however much care may be taken. Further, after potting and housing, many of the main leaves are apt to go off, rot sometimes seizing the stems. They are also so tender, that the first sharp frost cripples them if it catches them in the open garden. I do not mean to say that good results are not obtained by the planting-out system, but for the production of early blooms and, for the matter of that, quantity too, I think the pot system is the best. The plan recommended last season by "E. J." of keeping the plants through the summer in the pots and resting them, repotting them in August, has been practised by several gardeners hereabouts for years with the best results. The new roots being made after potting takes place, none of them are sacrificed, as is the case when they are lifted from the garden. Rotting of the leaf-stems is unknown, and an early and abundant lot of bloom is certain. One neighbour of mine allows his plants to remain in the same pots for two seasons, merely examining the drainage each autumn, surface dressing with rich loamy compost, and feeding with liquid manure when in full growth. The plants during summer are stood under the shade of a tall hedge and not watered at all, merely getting what reaches them from the clouds. Another grower lays the pots on their sides and allows the balls to become quite dry during the resting period, reducing the latter somewhat in autumn and repotting. No one could possibly wish for a better display of bloom, and I intend in future to treat my plants in this way—in fact, am doing so this season, feeling quite sanguine as to results.

A MIDLAND GROWER.

**Lagerstrœmia indica.**—Among the plants at one time popular in our gardens, but now rarely seen, must be included this Lagerstrœmia, or Crape Myrtle as it is sometimes called, which is one of the showiest of all our greenhouse flowering shrubs. Why it is not more generally met with is hard to say, for its cultural requirements are not at all exacting, and when in bloom it is the admiration of everyone. Though bearing the specific name of *indica*, this Lagerstrœmia is a native of China, from whence it was introduced

in 1816. It forms a freely-branched shrub, that grows from 6 feet to 10 feet high, and is clothed with deep green ovate leaves. The flowers, which are of a particularly attractive shade of rich pink, are borne in terminal panicles, and so freely are they produced that when at their best the plant is quite a mass of bloom. The petals being very much crisped, the clusters of flowers have a peculiarly loose and uncommon appearance. It may be grown in large pots or tubs, as the Orange is sometimes treated, and in this way it may be kept in health and flowered year after year with but little attention. It succeeds best in a rather warm greenhouse, and a thorough ripening of the wood is necessary in order to ensure a good display of bloom.—H. P.

**Potting Primulas.**—A good many Primulas of the single section will be potted this month into their blooming pots. The old plan of standing the plants behind north walls during summer is less common than formerly, many gardeners preferring to give them more light and sun. For some years past I have grown mine in a frame facing south, the glass being rather heavily shaded, this shading being reduced as autumn approaches. I was induced to try this plan from seeing large numbers of healthy plants in a nursery near Birmingham grown in low span-roofed houses, the roof-glass being merely shaded with whitening and the pots stood on coal ashes. Nothing could possibly have been more healthy, and I find that stouter plants and better trusses of bloom are produced on plants so grown than when brought on in semi-darkness behind north walls, especially if the season is dull and sunless. The pots should be well drained, and a compost of light fibrous loam, leaf-mould and silver sand used. Some growers add a little decomposed cow manure with good results, but feeding when the pots are getting well filled with roots can always be resorted to. Gardeners formerly used to pot Primulas with the neck or base of the plant out of the soil, steadying them with small wooden pegs, having an idea that basal rot followed lowering them well into the soil. This, however, was more imaginary than real, it being far better to make the plants quite steady and to exercise due care afterwards in watering. Under this treatment fewer plants will succumb in winter than when the crowns are left out of the soil, dry rot then often destroying many. Primulas enjoy a gentle damping over each fine afternoon, putting a little air on for the night.—J. C.

**Hibiscus Trionum.**—Last summer my gardener in my garden in Wiltshire called my attention to what looked like a weed growing between two flints, which formed part of an edging on the north-west side of my kitchen garden. It shortly afterwards presented me with a remarkable flower. I sent it to the editor of THE GARDEN for naming, and he was good enough to inform me that it was *Hibiscus Trionum*, called also *Hibiscus africanus*; and I have since found it very accurately figured in Nicholson's "Dictionary." The flower is about the size of a double florin, the petals a soft yellow, with a fine dash of purple at their base—a very lovely flower indeed. It kept on flowering from the beginning of August till the beginning of October. I was able to obtain from it a large quantity of seed and also a number of cuttings. I have made a little bed of seedlings (the seed having been sown in heat) now beginning to flower abundantly, and throwing out vigorous lateral shoots, each clothed with buds. It has but two demerits: one is that the flowers are very short-lived, but for this defect there is compensation in its freedom of flowering; and the other is that they shut up early in the afternoon. I have never seen the plant either at Kew or in any private or nursery garden, and how the seed came to deposit itself where it did is a matter for speculation. It is a curious fact that another plant of it showed itself last year at the same time in the garden of a relation of mine near Gosport.—G. R. R.

## GARDEN FLORA.

### PLATE 1129.

#### BICOLOR DAFFODIL ELLEN WILLMOTT.

(WITH A COLOURED PLATE.\*)

In any list of the largest, best, and most shapely Daffodils now known, I think growers would place this noble variety at the top of the poll. So far as can be known at present, it would appear to possess nearly, if not quite, all the requisites of a perfect garden flower. It blooms freely, and its flowers are shapely and of good substance and colour, as shown in the illustration. To say that it has received a first-class certificate does not prove much, since that honour has been showered on other and inferior varieties, but an early bloom from the original seedling bulb obtained the premier prize as the most perfect new Daffodil at the Birmingham Narcissus show two or three years ago, and it created, moreover, a good deal of interest amongst connoisseurs then present. This variety also received the silver-gilt Flora medal of the Royal Horticultural Society as the premier Narcissus of 1895. This noble Daffodil is named in compliment to Miss Ellen Willmott, of Warley Place, a most enthusiastic and successful amateur gardener. It is a seedling from John Horsfield crossed with pollen of a fine selected form of *N. variiformis*. It first flowered in 1894, and in 1895 a bloom obtained medals for the premier seedling both at the Royal Horticultural Society and at Birmingham. In 1897 it obtained a first-class certificate from the Royal Horticultural Society. The plant is somewhat dwarf, but throws up a tall, stout stem, bearing a flower of great substance and symmetry. It is early flowering, a little in advance of John Horsfield, of which it seems to possess the robust constitution.

But there are other very fine new Daffodils quite as vigorous in habit and as large in flower as is Mr. Engleheart's seedling, but as I believe even the best of them lack two at least of the essentials of a perfect bloom, viz., form and substance, not even the big and beautiful Weardale Perfection having quite the form, substance, and perfect balance between perianth and trumpet that are such features in the variety now illustrated. One of the greatest difficulties experienced by raisers of seedling Daffodils is to obtain well-balanced flowers, since the natural tendency is for either the perianth or the trumpet to preponderate in size, and more especially in form and substance. This natural tendency is remarkably well shown in the imported seedlings of the Daffodil known in gardens as *N. variiformis*, amongst which may be found the widest of variations, as implied in the name. Many forms are poor and thin, but now and then forms bloom that would compare with the plate; in fact, the best forms of *N. variiformis* yield flowers that are well-nigh as perfect as could be desired, but one can never be certain of obtaining them. A perfect bulb one year carries a perfect bloom, but the chances are that the bulb splits or divides after flowering, and yields two or three very ordinary blooms the following year. I mention the wild *N. variiformis* because its best and finest blooms so closely resemble those of Ellen Willmott in size, form and colour, although they may not be absolutely so perfect in substance or texture of perianth as is that nearly perfect and matchless flower. When I say a flower of any Daffodil is well-nigh matchless, it becomes necessary to allude to the

\* Drawn for THE GARDEN in Rev. G. H. Engleheart's garden by H. G. Moon. Lithographed and printed by J. L. Goffart.

known claimants in the select honour list of Daffodils, and those enumerated below are those of the first rank or quality as known to me: Ellen Willmott, Weardale Perfection, Mine. de Graaff (which at its best is an exquisite ivory-white flower, a glorified J. B. M. Camm), Hodsocks Pride (a common-place name for a really fine yellow flower) raised at Hodsocks Priory, Notts, by Mr. Mallendar, and once a premier bloom at the Birmingham Narcissus show. Monarch is another fine thing, and we have also Glory of Leyden and Golden Bell, all yellows. A very remarkable yellow seedling in the way of Hodsocks Pride was found some few years ago in the garden at Kells by the Marchioness of Headfort, and the first bloom was one of the most perfect flowers I ever saw. It was a chance seedling, and promises to become one of the best of all yellow Daffodils in the future. The above are the best of modern seedlings, and they will compete for place in our gardens until newer and still finer kinds surpass them. They are not, however, likely to be too plentiful for some years to come, since the price of a bulb of each variety would amount to a considerable sum. It is curious that in self-yellow Daffodils nothing so far, surpasses the wild *N. maximus* at its best. The seedling M. J. Berkeley, although good on some soils, cannot compete with the old *maximus* of gardens, nor with the *maximus* which Rev. C. W. Dod saw wild on the Landes of Dax, near Bayonne. It can never now be known how *N. maximus* found its way to the College Gardens at Dublin, whence it found its way to England and elsewhere, but that it therein attains remarkable height and size of flower has long been known. I can never grow Dutch or Lincolnshire *maximus* bulbs to anything like the same state of perfection as our own old stock, and yet the wild bulbs from Bayonne, kindly sent for comparison by the Rev. C. Wolley-Dod some years ago, are fully equal in growth and size of flower to our old stock. This must not be taken as an admission that they are identically the same, for there are notable differences—viz., the colour of the Bayonne flowers is a shade or so paler yellow, the twist in perianth is less marked, and whereas my own old stock dies down in June or July, the Bayonne bulbs retain their leaves quite green six weeks or more later in the season. We badly want pure strong yellows of the *maximus* and Santa Maria tone of colour, but of more free habit of growth and blossoming. Even a strong-growing and free-flowering strain of *N. obvallaris* would be a great gain.

Robust and free-growing white Daffodils are also desirable, and may perhaps be obtained by cross-fertilisation. So far it seems impossible to obtain colour in the trumpets of true Daffodils. It is possible to infuse orange and red into the cups of *N. incomparabilis* and *N. Bernardi*, but in crossing these highly-coloured kinds back with the true Daffodils it again becomes lost. A well-known statesman once said, "The more difficult a thing is to do, the more necessary it often becomes to get it done;" and colour in true big trumpet Daffodils is most assuredly a want long felt and a result much to be desired.

The plate is a faithful, but by no means a too flattering portrait of this variety. It shows remarkably well one essential characteristic on which all perfect perianth lobes in Daffodils absolutely depend. This is the slight overlapping along the margins of the lobes, and especially at their tips or apices. The central bundle of nerves forms a backbone, as it were, to the perianth lobes, but it is the tightening consequent on the infolding of the

perianth margins that also adds much to the rigidity of the flower. In other words, the growth along the perianth margins is slightly less than that which takes place in the centre; hence the stiffened bending forward and inwards of the perianth lobes on the principle of the open umbrella. Slight structural details, or apparently trifling differences of growth like these, often make the whole difference between a perfect flower and a loose or floppy one. These remarks also apply to bulb growth, which progresses through cycles or in a rhythmical manner; hence, in order to grow the most perfect flowers, we must study the production or growth of bulbs up to a maximum point, as do the growers of the finest Dutch Hyacinths, and as the Tulip fanciers did in the old days of exhibiting these flowers. A seedling Narcissus bulb is at its best the second or third year after first flowering, and it is only by annual division and careful replanting and cultivation that the maximum effort of the seedling bulb is ever again reached.

F. W. BUREIDGE.

## THE WEEK'S WORK.

### FRUIT HOUSES.

**LATE MELONS.**—If seed was sown as advised and the plants well looked after, they will now be ready for planting. The house selected for growing late Melons in should be well heated. If the house is well heated it matters not whether the plants be grown in pots or on mounds of soil, provided the latter can be placed directly on the slates or slabs overlying the bottom-heat pipes and fermenting material is not made use of. Should there be a deficiency of bottom-heat, and it is requisite to use fermenting materials to supply it in part or wholly so, then pots are the best medium to employ, as the roots can then be kept at home. The few roots that escape through the creek holes will not result in any harm being done. These pots should be prepared beforehand, and the compost for the plants to root into pounded hard, after which place them on a good firm basis, such as inverted pots or loose brick-built piers, which will avert all danger of their getting out of level and sinking when the bed subsides. The mounds of soil, too, should be made firm, and when planting see that the collars of the plants are kept above the level of the soil in the pots or mounds and slope the soil away from the stems so that water drains away at once. Place stakes to tie and train each plant to until they reach the wires and well water afterwards. As the plants advance in growth, attend to such matters as stopping and training, and endeavour to have the trellis well clothed with laterals, so that plenty of female flowers shall be open at one time, setting in the usual way when this takes place.

**AUTUMN CUCUMBERS.**—Where quantities of Cucumbers are in daily demand, it is a good plan to plant a house from which a crop of Melons has just been cleared, both to relieve the plants which have been in bearing during the summer months and to give a good supply until the close of the year, when they may, if the house be required for other purposes, be rooted out. If provision has been made to keep a good stock of young plants on hand, there will be plenty to select from, but if this matter has been neglected, seed should be sown at once, or, what is still better, take cuttings from the tops of some healthy growths found on existing plants and strike them under bell-glasses or in a propagating case. Cuttings root in a few days, and if put in before the cleaning and preparing of the house are carried out, there will be no delay. All that has been said with regard to the necessity of having plenty of heat for late Melons applies in an equal degree to these Cucumbers.

**WINTER CUCUMBERS.**—Towards the end of August a well-heated house should be set apart

and prepared for growing these in. I prefer a lean-to house and one that is partly sunk in the ground for this purpose, as such is more snug and less draughty than if built on the surface, while it also tends to economise fuel during cold weather. The interior of the house should be made clean. A good start with a clean house and good healthy plants at the outset will go a long way to keep matters right if cultural details are properly attended to; therefore the thorough cleansing of the structure cannot be too strongly emphasised. In the meantime sow seed and raise the requisite stock of plants, which should be grown well up to the light to prevent them becoming drawn.

**LATE-KEEPING GRAPES.**—Now that all danger of scalding is past, houses in which Lady Downe's is grown may be again syringed and damped down daily. Look to the borders, and if these are approaching a dry condition, water them sufficiently to moisten them down to the drainage, and give a stimulant at the same time. When scalding ceases to prove troublesome, we then know that the stoning process is completed, and that it is, therefore, now safe to finally thin out the berries in all bunches where they are as yet too thick. Each berry should have ample space not only to allow them to grow to a large size, but also to allow of a free circulation of air through the bunches, as in many instances these late Grapes have to be kept until the ensuing spring. Varieties other than Lady Downe's, such as Gros Colman, Alnwick Seedling, and Black Alicante, the berries of which attain a very large size, must be extra well thinned, otherwise they will bind at the finish, and then if a berry should happen to decay, those immediately surrounding it will very likely become affected before the mischief is detected. Look the Vines over about once a week, and keep lateral growths pinched in until colouring commences, when they may be allowed a little more latitude. On bright, warm days the house may be closed about 4 p.m., or early enough to run the mercury up to 90°, and to prevent the temperature falling too low at night, turn on a slight amount of fire-heat. When the weather will allow, a chink of air put on in the morning and allowed to remain on until the following morning does much good by affording the Vines a certain amount of rest, but it is best taken off at 6 a.m., and the house should then be ventilated, after damping down, in the usual manner. During such hot weather as that we have lately experienced the front ventilators need to be opened to a certain extent, but until colouring becomes general they should not be used too freely.

**PINES.**—The plants which will afford ripe fruits during the autumn months will need a considerable amount of attention in the way of watering, feeding and syringing in order to keep the fruits swelling. Other details, such as keeping the fruits in an upright position and pulling off suckers with the exception of one at the base, should be attended to, and afford the plants a sufficient amount of shade during the hottest part of the day. Plants started as advised when last writing about Pines will now be showing for fruit, when more water may be given at the roots, but unless the condition of the plants should demand it, withhold stimulants until they have done flowering, when they may have guano water each time they require watering right up to the time the fruits commence to change colour. Successional plants or those intended for spring fruiting should be encouraged to make free growth so that the same may be completed and the plants got to rest early in the autumn. These and later batches may have the benefit of guano or liquid manure each time watering is necessary until growth is finished, when in order to keep them in a quiet state through the late autumn and winter months, no more water must be given than will keep the roots and foliage in a healthy condition. Many err in keeping these plants too dry, and a greater mistake cannot be made, as numbers of the roots perish when subjected to such treatment. These should, if possible, be preserved, as they

prove of the utmost service when the plants come to be started at the beginning of the year. To keep up a good stock of plants continue to take off and pot up all available and likely-looking suckers, and if any of those taken within the past two months are well rooted give them a shift into larger pots at once rather than allow them to become pot-bound.

**SOILS.**—Where much fruit growing is carried on there is, as a matter of necessity, a great demand for soil of a suitable description to grow the various subjects in. This is best dug at the present season, as the carting of the same can be the more expeditiously carried out while the surface is in a dry and firm condition. The turves should not be cut less than 2 inches or more than 3 inches thick, and should also be as full of fibre as it is possible to obtain them. Old sheep pastures or the top spit from a deer park generally affords the best soil for this purpose. When much loam is required, steps should be taken to get the bare surface green again as soon as possible by scarifying and sowing it down with grass seeds. Neglecting to do this often leads to consent being withheld when next loam is required.

A. W.

### KITCHEN GARDEN.

**WINTER SALADS.**—The season has arrived when sowings of both Lettuce and Endive should be made for standing through the winter, or rather to furnish supplies during the greater part of it, other sowings being made later for spring and early summer use. Both Hicks' and Goldring's Cos varieties are very hardy and suitable for present sowing, though as a rule good blanched hearts are not produced until the spring. For mixing in salads, however, the young tender centres are generally preferred to those of the Cabbage varieties, as the latter are apt to flag and become tough after they have been cut a short time. A good-sized bed of each kind should be sown, as it is seldom the stock of plants is too numerous say after midwinter. Rich ground should be selected, dug deeply, and well broken to pieces, and the seed sown thinly in drills after the soil has had time to settle. Much time is lost before the seedlings become large enough for transplanting if they are not frequently watered during dry weather. In the meantime the site selected for their winter quarters should be prepared, so that all will be in readiness by the time the plants are large enough for putting out. South borders are generally given up to Lettuce and Endive, as they can be cleared off in time for sowing and planting early spring crops. A good dressing of manure now will not only assist the current crop, but the soil will be in good condition for most things next spring without any addition, especially for early Carrots. It is better to have the ground prepared a week or so before it is required, which not only allows time for it to settle naturally, but several light dressings of wood ashes and soot can be afforded before the plants are put in and there is less danger of their being attacked by slugs. Other positions, such as the foot of warm walls and other sheltered nooks, should also be got ready either for sowing a pinch of seed or for pricking out plants. To maintain a continuous supply of first-class salad throughout the winter, pits or frames become a necessity. These probably at the present time will be occupied with Cucumbers and other things, but any that are available should be prepared to receive as many plants as possible of both Lettuce and Endive. Where the frames have frequently been used for French Beans, &c., and the surface-soil has sunk a foot or more from the lights, more soil should be added, or in some way raised so that the plants will not be more than 9 inches from the glass during the winter. A few inches of fresh loam, with some spent Mushroom manure and wood ashes added, will greatly assist the plants to make stout foliage and better able to withstand severe weather. Among the Cabbage varieties for winter use there are few better than Lee's Immense Hardy Green when a true stock is

obtained. This variety finds much favour, I believe, with the large market growers. All the Year Round, Brown Dutch and Victoria are also excellent for autumn sowing.

**TRIPOLI ONIONS.**—A piece of ground should also be prepared for a sowing of these. By sowing the seed not later than the middle of August, sufficient time is allowed for the plants to become strong before winter sets in. Rather rich ground and a firm root-run are most desirable, as the plants are often lifted out of the soil by frost when the ground is loose and porous. It is not advisable, therefore, to dig in a quantity of partially decayed manure previous to sowing the seed, but a dressing of soot, lime, or wood ashes may be given, or if the ground be poor, a light one of fowl manure may be used. When the ground has settled somewhat, go over it and make it firm by treading, form the drills 9 inches apart, and sow the seed thinly.

**SPINACH.**—It is seldom this is too plentiful during the winter, neither can one sowing be trusted to yield the best results. Plants from seed sown in the middle of August often become too far advanced, should the weather be showery, to stand well through the winter, while seed put in at the same date may remain in the ground weeks before it germinates, owing to the want of moisture, and the plants will not be strong enough to withstand a hard season. A piece of ground that is in good heart and also in an open position should be selected. This should be forked over deeply and the seed sown in drills not closer than a foot apart. Another sowing should be made ten days later, and should there be any fear of neither of these not suiting the season, or being too forward, do not hesitate to put in more seed, as it is an easy matter to destroy the forward batch if not required. A great thing in preparing the plants to withstand hard weather is to thin them well out in the autumn. This allows room for the foliage and roots to develop, and stronger plants are obtained than would otherwise be the case if they were crowded the same as summer supplies.

**TURNIPS.**—This is another important winter crop, and if the sowing season is put off a week or two too long, it may mean a scarcity of roots not only through the winter, but well on towards the following summer likewise. In the midlands I found about the 15th of August a suitable date for sowing, but here I find a little later is better. Much, however, depends on the season, and, like Spinach, it is well to be prepared for making two or more sowings rather than run any risk of there being a scarcity. Ground cleared of second early Potatoes will be suitable for this crop, but it should be in a fairly good condition, or the seedlings will become starved, especially if there is an absence of rain, and more than likely suffer from fly attack.

**GENERAL REMARKS.**—The great heat together with a scarcity of rain in many parts has seriously affected different crops, especially such as Beans, Peas, and Cauliflowers. Each of these has received copious waterings and the soil between them has been mulched. Now that both French and Runner Beans are becoming plentiful, daily gatherings should be made, and none of the pods allowed to remain on the plants to form seed, or the supply will soon fail. The gathering of all vegetables, especially if they have to be packed and sent long distances, should always be done in the early morning if possible, especially during such hot weather as we have recently experienced; their quality as well as appearance is greatly improved thereby, and they last longer in a fresh condition. A good portion of Parsley which was sown in the spring should be cut over during dull, showery weather, and the new foliage which forms will stand better through the winter than that which was made earlier in the summer. Another pinch of seed may also be put in after the first shower, and the plants well thinned out as they come through the soil. These will furnish welcome supplies towards spring.

Goodwood.

RICHARD PARKER.

## FERNS.

### LOMARIAS.

This genus includes some beautiful and distinct species; there are also some good varieties of garden origin. The best known and most generally useful of the family is

**LOMARIA GIBBA.**—This is grown extensively for market, and though perhaps not so popular as some of the Pterises, it finds many admirers. There are several distinct forms of this, varying considerably in habit and size of fronds. The variety with pale green medium-sized fronds is one of the best, as it forms a compact plant and is not so prone to throw up fertile fronds prematurely as some are. The variety platyptera appears to originate from this. Although I have frequently sown what appeared good spores of platyptera, I have never succeeded in getting seedlings, though when raising the first-named I have several times had some plants of platyptera appear among them. In appearance this closely resembles one of the Blechnums, producing large, rather erect-growing fronds of a rich green, with no sign of red in the young fronds. There is also another good variety of strong growth, with a distinct bronzy red tint in the young fronds. To grow *Lomaria gibba* successfully the seedlings must not receive a check in any way from the time they are started until they have attained a useful size. Spores are rather uncertain in germinating, but when they do start they usually come up very thickly. The spores should be saved from plants grown in an open, exposed position, and old plants are usually more prolific than young ones. After seedlings get a good start, if potted in a light compost and given a good heat they soon grow on into useful-sized plants. They like a rather moist atmosphere, but not too much wet at the roots. A dry atmosphere will be sure to result in thrips making their appearance.

**L. CILIATA** is an old favourite, but not often seen now. Some two years ago I grew a fine batch, which proved quite as useful as *gibba*, but it does not usually furnish so well. Among a batch of seedlings of this I have had two very distinct varieties, one of which has received a first-class certificate from the Royal Horticultural Society. This bears a somewhat similar appearance to *ciliata* as *platyptera* does to *gibba*. It is named *L. ciliata grandis*. The basal fronds are broad and smooth, and the fertile (or rather semi-fertile) fronds are erect, crenulated, slightly contracted, but not so narrow as the ordinary fertile fronds of the species. *L. ciliata major*, which received an award of merit, more nearly resembles the parent, but is of a more robust habit, the basal fronds broad and spreading, the fertile ones growing more erect and contracted, as in the species. Should the former of these two varieties prove abortive, we may hope to get some good things from the latter, which has every appearance of maturing perfect spores.

**L. CYCADIFOLIA**, which is sometimes described as a variety of *Boryana*, is very distinct, the fronds being of a thick, leathery texture. When seen at its best it is very handsome, but unfortunately it is hard to manage, being liable to die off without any apparent reason. I have raised seedlings, but it is perhaps more difficult to get matured spores than to raise them.

**L. DISCOLOR BIPINNATIFIDA.**—This is one of the finest of all the *Lomarias*; indeed, it may be considered one of the handsomest of all Ferns; the beautiful feather-like fronds are gracefully recurved, and of a peculiar fresh green. Like many other garden varieties, it is difficult to get good spores. I have only known one instance of spores germinating, and among the plants raised there was great variation, some being quite equal to the parent, while others represented *nuda* and *falcata*, besides other intermediate forms.

Other *Lomarias* worthy of note are *L. attenuata*, the greatest attraction being the delicate shade of rosy pink in the young fronds, and *L. PHerminieri*, a delicate little Fern, the young

fronds having a very bright red tint. All the *Lomarias* require careful treatment, and when well managed they have few rivals among our cultivated Ferns. A. HEMSLEY.

KITCHEN GARDEN.

A HEAVY CROP OF POTATOES.

BEFORE the rains fell, or up to July 19, Potatoes in this district were "giving out" fast, and the greater portion would soon have matured prematurely. As it is I am afraid the crops in most gardens will be unsatisfactory, the rain not having come soon enough by at least a fortnight. As yet I have heard of no complaints of rot-tuberation, but fully expect that will be the effect of the late downfall. At Longleat, in Wiltshire, the Potatoes were looking remarkably well before the rains came. They had not ceased growing strongly in fact, and there is every likelihood of the crops being heavier than usual—a hot season suiting crops on a clayey soil. Having seen Potatoes on the same ground—a plot outside the garden walls, with Apple and Pear trees distributed about it—for several years in succession, I enquired and learnt that there had not been a change of crop for the past twenty years. I grew Potatoes for twelve years in succession on the same half-acre of ground, and the last crop was the best of all, but at Longleat Mr. Trollope easily beats my record. Bruce is the variety principally grown, and the estimated yield is 4 bushels to the "lug," as a square rod of ground is termed in these parts. Of late years that has been the average yield, and as before hinted, there is a good prospect of an exceptionally heavy crop this season. No solid manure of any kind has been used on the ground for years, but the Potatoes get the benefit of equal parts of mineral superphosphate (soluble phosphoric acid), kaimit (potash), and either nitrate of soda or sulphate of ammonia (nitrogen), carefully mixed and applied at the rate of one hundredweight to 20 square rods of ground—that is, 8 hundredweight to the acre. For medium and light soils nitrate of soda is recommended, but for clayey ground, sulphate of ammonia is to be preferred. This manure promotes a strong, but not gross growth of haulm, and when used for The Bruce, Magnum Bonum and other disease-resisting varieties, spraying with the Bordeaux mixture as a preventive of disease is uncalled for and may easily do more harm than good. I.

Somerset.

**Good dry weather Lettuces.**—Those who have a difficulty with summer Lettuce may with advantage try the Bath or Brown Cos. This will stand heat and drought better than any Cos variety I have grown. Sown monthly from April till July it is a superb variety, and the later sowing gives a long autumn supply. The best Cabbage variety is Continuity. This, like Brown Cos, is a dark-coloured form, and stands heat and drought better than any light kinds, needs the same culture as advised above, and remains fit for use a long time. It is a close, compact grower, and of good quality. There are other coloured forms, but the two above named have this season been my best, and it was the same last year with long drought and heat.—G. WYTHES.

**Tomato Carter's Outdoor.**—This Tomato is worth noting as exceptionally valuable to those who have a lot of fruit to supply as early as possible, and yet have hardly any facilities for indoor culture. With the view to thoroughly test its claims as an outside variety, I sowed it this year in pans early in March in a cool house and planted it out about the middle of May in a sheltered spot, the only protection given being a Seakale pot over each plant if the nights threatened to be cold. The first fruits were gathered July 16. Although not quite up to the Perfection type in smoothness and regularity, it is an evenly-shaped

fruit, a prodigious cropper, and of vigorous constitution. Its chief merit, however, and one that will make it a general favourite, is the quick setting and ripening.—E. BURRELL.

**Broad Beans and drought.**—Broad Beans, though looked upon as a common vegetable, are liked by many people. In seasons of drought the plants are often so badly attacked by fly that it is difficult to provide supplies in succession. The best preventive is to sow under a north wall for later crops or even under trees in a fruit garden if the trees are not too close; but even when treated thus there is a difficulty in preventing the Beans turning black and getting tough skins. It is this latter which makes Broad Beans disagreeable to many palates. There is a simple remedy, that is after the Beans are shelled, to remove the outer skin, this being of a greenish white, often tough and hard, and of a disagreeable taste. This, when removed, makes the Bean young, as it were, green, and tasty. I admit it needs a little patience to remove the skin from each bean or seed, but it is work well repaid, and this vegetable treated thus is much nicer. Broad Beans of late have increased so much in height, size, and number of beans in a pod that a quantity can soon be shelled. The skinning advised is not so tedious as many would think, especially when the quality is so much improved.—G. W.

**Pea Veitch's Goldfinder.**—For the past twelve years or more this variety has been grown in the West of England, giving the greatest satisfaction to all lovers of good Peas. It was sent out by Messrs. Robert Veitch and Son, Exeter, and was submitted by that firm to the Royal Horticultural Society for trial at the Chiswick gardens this season, for the first time presumably. It was thought to be merely either the true, or a well selected stock of that deservedly popular variety Ne Plus Ultra, and was passed over accordingly. As it happened what we may reasonably suppose to be the true stock of Ne Plus Ultra was growing on the same plot of ground for the purpose of comparison, and this row suffered considerably by contrast with that of Goldfinder. The latter was producing much the better crop of well-filled pods, but still was not considered distinct enough to entitle it to an award of merit. Undoubtedly the Ne Plus Ultra is the best type of main-crop and late Peas we have. No other type better withstands extremes of either drought or wet weather, and if the pods are not long enough to win prizes, their contents never fail to please the cooks and those they cater for. If, therefore, Goldfinder is only a good stock of Ne Plus Ultra it deserves to be recognised as such, and it will most certainly be popular long after showier certificated varieties have had their day and are forgotten.—W. I.

**Lettuces.**—Whilst we have so many varieties of Cabbage Lettuces, there are few really distinct Cos forms. The best known of these are Paris White, often found under numerous diverse names; Hardy Green Cos, very useful for winter work; Champion Cos, a tall pale green form similar to Ivery's Nonsuch, and far from being a reliable variety, but when well grown very large; the Black Seeded Bath Cos, so good too for winter growth, and the white seeded form which is much grown for winter use, but generally hearts so indifferently. A good stock of the Paris White, and that is generally found good now, and the black-seeded Bath Cos are the best and meet all requirements. Cos Lettuces have been very good this season where the ground has been well prepared for them, very rarely have I seen premature bolting stocks, and these may have been largely the product of bad treatment in the early stages of growth. As to Cabbage forms they seem to be legion, yet these may be reduced to smooth green, smooth red, and rough or curled of both colours, and usually large inclining to coarseness. Most of the varieties are good in their way, but all depends very much on treatment. Those stocks which stand well before running off to flower are best, but long standing is usually obtained at the expense of crispness of leaf and absence of flavour. To have Cabbage Lettuces good it is needful to sow seed

in small quantities often, so that the hearts may be fresh and crisp. It is rather surprising that the practice of laying thin canvas over the plants in the day does not prevail generally, as exposure to hot sunshine soon toughens the tender leafage, and also induces quick bolting to flower. Shading to keep the hearts cool is a most desirable feature, as the shading is then so much sweeter and crisper.—A. D.

**Late Broccoli.**—There is a conflicting opinion respecting the merits of Late Queen Broccoli by your correspondents Messrs. T. Cockerill and G. Bolas—on page 4 (July 3). The variety has been a universal favourite now for several years, so that to extol its merits seems altogether unnecessary, because so well known to everyone. This may account for the remark made by Mr. Bolas that he finds no reference to Late Queen when late Broccoli notes are perused. Mr. Cockerill evidently has not had the true stock of this estimable variety if, as he says, it turns in about the end of April or early in May, because its season extends from the middle of May until the same time in June. Seeds of this variety which I had obtained from a local source turned in at the time named by Mr. Cockerill, and showed characteristics altogether opposed to the true variety. This in my case turned out very convenient, because the past season's Broccoli crop was very erratic, and but for the early maturity of the so-called Late Queen, I should have been without any supply. If, however, I had depended solely on this for the end of May there would have been a considerable break between these and the early Cauliflowers, more especially so this year, when the latter were quite a fortnight late. Mr. Cockerill does not say, but I presume he alludes to Carter's Champion and Gilbert's Universal as being so far in advance of Late Queen. The true stock of Late Queen I have always found one of the most reliable and hardy of Broccolis, and, as far as my memory serves me, your correspondent is the first to under-estimate so valuable a variety as Late Queen. I cannot believe that he has based his convictions on experience gained from growing the true variety, which is very dwarf, distinct in foliage, very hardy and late—that is, when sown, as it should be, in May. Sutton's Bouquet and Model are two other favourites of mine for late cutting. They are both very hardy.—W. S., *Wills*.

TWO NEW VARIETIES OF POTATOES.

SOME friends of mine, enthusiasts in raising and cultivating new varieties as well as in growing the best old sorts of Potatoes, have spent years in the pursuit without having succeeded in introducing a variety of any real commercial value. Exception to this rule, however, must be made in favour of Mr. G. Wythes, who without being a Potato specialist has yet succeeded in raising at least two varieties of sterling merit and well worthy of a trial in most gardens. One, named English Beauty, was the result of a cross between Myatt's Prolific and Beauty of Hebron, and combines in itself the good qualities of both of these old favourites. It has the "Beauty" foliage, and the tubers resemble those of that parent in form, but are not so large, and are also white in colour. No fault can be found with either its cropping powers or the quality of the tubers when cooked, and seeing that it is as reliable as Myatt's Ashleaf on most soils, also maturing early, this variety should prove valuable alike to the private as well as market grower. What pleased me even more when at Syon was the grand breadth of Syon House Prolific there growing. In this variety we have a really good disease-resisting, heavy cropping Potato, that is destined to take the place of Bruce, Magnum Bonum, and the like in both private and market gardens. It was the result of a cross between Sutton's Seedling and Hinton's Prolific, a local variety of good repnte, but the growth more nearly resembles that of the Bruce, and is of a decidedly disease-resisting character. When well grown a sack of tubers to the square rod may

safely be anticipated. The tubers are moderately large, pebble-shaped, with few eyes, a rough skin, and quite handsome enough for exhibition. It is said to keep admirably, and has been proved to be of excellent quality when cooked. Grown in the Royal Horticultural Gardens, Chiswick, in 1895, and again in 1896, it was among the limited number selected for an award of merit. Both novelties were distributed by Messrs. J. Veitch and Sons last winter, and will therefore be well within reach of most growers next planting season. W. I.

**Potato Sharpe's Victor.**—With regard to "D. T. F.'s" note (p. 45), I must confess I may have omitted to green my seed as much as "D. T. F." would have me do. The two bushels of seed I had from a trustworthy source were not greened as much as my critic would advise, in fact, I fear they may have been similar to those in the heap he condemns. The seed was purchased from a large grower, and possibly he is unable to keep his seed Potatoes in thin layers. I am aware the tubers are best exposed before housing, but I do not place the failure to the greening. Why should Sharpe's Victor need special greening? I stated that others with the same treatment had not deteriorated, one I had twenty years, and I think loss of vigour was the cause of failure. On the other hand "D. T. F." quotes Mr. Cockerill's success (p. 4), and nothing is said as to whether he greened his seed, but he does not feed. I do feed, and my early crop in such seasons as we have just passed through would cut a sorry figure if I did not feed in a poor soil, not 18 inches deep, but 9 inches in some parts, not on rock but on gravel. I am obliged to differ from "D. T. F." on these points. I think "D. T. F." places too much importance on greening, as, if the skin of the tuber is sound that is what is needed. I thoroughly agree with him as to size of seed. It is necessary to have good sized seed, but I fear many cannot say Sharpe's Victor is a sure cropper and of the highest quality. I could name half a dozen early kinds superior. I do not think "D. T. F." can have given Ring-leader a fair trial, at least side by side with Sharpe's Victor. A few seasons ago, in fact, before the advent of Ring-leader, I noticed Victor less satisfactory than it should have been. This year I have several far superior to Victor in every way.—S. H.

## FLOWER GARDEN.

### ROMNEYA COULTERI.

THERE are few flowers more beautiful than those of this Californian Tree Poppy. The blossoms are so simple in form, so exquisitely delicate in the substance of their petals, which at first sight remind one of the finest white crêpe and flutter at the slightest breeze, their purity enhanced by the great golden boss of stamens from which they radiate. Many of the flowers are 6 inches and more in diameter, and when a dozen are open at one time form a wonderfully attractive picture. They also possess the additional charm of fragrance, and, indeed, in their qualities of perfume, form, and colouring are very near perfection.

The plant, though it does well in the south-west of England, can scarcely be deemed absolutely hardy even there, several specimens having been killed by the severe frost of two winters ago. A certain amount of protection is desirable, but undue coddling often leads to the plant rotting to the rootstock, and so perishing. It was suggested to me a short time since that Pine needles would form the best winter mulch for this subject, and I have no doubt that they would prove a most efficient protection, holding no superfluous moisture and allowing the air to percolate through them, whilst they kept the frost from entering the ground. I have found

the *Romneya* very impatient of root-disturbance, and have lost several seedlings in shifting them on, though this operation was most carefully performed. When plants have been put out in the border they have lost most of their leaves, though the ball of roots was left intact. When once established in the open ground, however, they grow strongly, the plant which the accompanying illustration represents having in two seasons attained a height of over 8 feet, and having increased considerably in size since the photograph was taken in the summer of 1896. The seeds of the *Romneya* take a long while to germinate. In one case ten months elapsed before signs of growth appeared. The plants may also be raised from root cuttings and layers. When growing in the rock garden it often sends out shoots at some distance from the parent stem, and only the other day I noticed a case where one such shoot had been taken off and planted in a neighbouring border, where it was flourishing finely and appeared to have relished rather than resented the root-disturbance involved in its removal. Probably the most advantageous site for *Romneya Coulteri* is a sheltered one backed by a wall, which enables rough protection, in the shape of a sus-

colour is most effective, especially when made up into a spray. In the flower garden it is equally striking, but must not be placed in the full sun. In the latter position the top petals very soon get scorched. In any position in which partial shade can be afforded all will be well. It is an excellent sort for both early and late displays.—D. B. C.

**Primroses and Polyanthuses.**—There has been a very good harvest of seed of these this year and the sample is excellent. Those who are wise will not leave sowing until the spring, as in the interval not only will the seed shells harden, but the germ will have dried up and become worthless. It is because of the long keeping of these seeds that so many failures occur from spring sowings, or if not absolute failures, germination at least is irregular. It is best, so far as practicable, to sow as soon as the seed has ripened. It is well all the same not to sow in the open ground until the chief summer heat is over, and for preference to sow about the middle of August. If the weather then be dry, a small bed may be prepared by well forking and cleaning it, leaving it a bit rough, then giving over-night a good soaking of water. So treated, next day the soil will break down well with a coarse rake. The seed should then be sown thinly, be well raked in, then lightly watered, and at once covered up with mats. If heat and drought continue, one

*Romneya Coulteri.* From a photograph sent by Mr. S. W. Fitzherbert, Torquay.

ended mat or other material, to be more readily and temporarily supplied than where the plant stands altogether in the open. The last two winters have been so mild, that even plants in the latter position have passed through them uninjured, but like immunity cannot be counted on during succeeding years. When in full growth the *Romneya* delights in an ample water supply. Up to the present time I have not obtained thoroughly ripened seed from plants grown in the open air. S. W. F.

**Tufted Pansy Magie.**—This is one of the 1896 novelties, and it has evidently come to stay. Several handsome sprays shown at the meeting of the National Viola Society doubtless assisted very materially those who used the variety. The flowers are rich rosy-crimson, of large size and freely produced. The growth is free and it is also fairly compact. We have no other Tufted Pansy of a similar shade of colour.—C. A. H.

**Tufted Pansy Sheelah.**—This is a pretty flower, and one which has suffered very much from the trying heat of the last few weeks. The colour is best described as pale rose with deep crimson centre and a neat yellow eye. This

or two waterings may be needful to keep the soil moist, covering up again at once. Germination is then quick and even. The mats may now be removed and the plants will become strong and sturdy, rooting deeply and will stand the winter admirably. Then if lifted carefully and planted out the following April they will produce huge clumps to bloom during the succeeding winter and spring.—A. D.

**Tufted Pansy A. J. Rowberry.**—It is a matter for regret that this handsome kind does not possess a better habit. We have no other Tufted Pansy of so deep and rich a golden yellow. The flowers are of large size and, except very early in the season, absolutely rayless. The constitution of this variety has over and over again been described as anything but robust, but I am inclined to think differently. My plants were all rooted outdoors without any artificial protection and on a raised bed with a northern aspect. Here they remained right throughout the winter and until spring planting commenced. Some of the plants were planted out in beds in the ordinary way, and as these beds were a piece of pasture land the previous summer, I anticipated trouble from the wireworm. All this batch has done well. In order, however, to prevent the total loss of this variety, which I quite expected would be the case if I trusted entirely to the

plants in my new piece of garden, I made up a series of rough frames without frame lights. With other varieties A. J. Rowberry was accorded a place here, and, except for a good mulching with rotten manure in June and an occasional watering during very hot weather, nothing exceptional has been done. At the time of writing I have a capital batch of this variety in the most robust condition. Does not this point to the fact that over-propagation in its early history is largely responsible for a weakened constitution during the first year or two of its existence? Many seedlings from this variety have recently been raised, and we may hope to get an equally good flower on a dwarfier plant.—GROWER.

#### BORDER CARNATIONS.

AMONG the many objects of interest that came under my notice during a short tour among gardens near London, none gave me greater pleasure than the beds of border Carnations to be seen at each place I visited.

##### SYON HOUSE.

It was at the Syon Gardens, however, where the finest display was made, and I was, fortunately in time to see them before cutting commenced for an extra large garden party, cut Carnations playing an important part in the decorations of reception rooms, tents, and the like. Last autumn Mr. Wythes planted ten beds, each 50 feet long and 4 feet wide, wholly with Carnations, and with few exceptions all have done well. Such well-known favourites as Ketton Rose, Duchess of Fife, Countess of Paris, Mrs. Muir, Gloire de Nancy, Pride of Great Britain, Germania, Raby Castle, Mrs. Reynolds-Hole, Uriah Pike, Leander, and Redbraes were all extensively represented, and were flowering grandly. The Old Clove was in better condition than I have seen it for a long time past. Either the treatment given suits this old favourite, or else Mr. Wythes has got hold of a superior form, for I noticed that the grass was exceptionally healthy and strong, and also that the blooms were large, of good form, without the usual bursted calyces. The beds of Douglas' strain of seedlings comprised a good percentage of really attractive varieties, superior, in fact, to many named sorts cultivated with far greater difficulty in gardens generally. Mr. Wythes believes in young plants of both seedlings and named varieties, also fresh soil, early planting, early mulching with old Mushroom-bed manure, and timely staking. In point of numbers, the seedling Carnations at

THE ROYAL HORTICULTURAL GARDENS, CHISWICK, come next, and as these are also all raised from seed supplied by Mr. J. Douglas, it need hardly be added that the strain is much above the average. In reality the variety is remarkably good, plenty of the plants fully deserving distinctive names and to be perpetuated by layering. The yellows are very handsome and among the most valuable, but there are also many good white, red, pink, and crimson forms, the blooms being extra large, yet not coarse, and borne erect on stout branching stems, while the foliage in some instances is nearly, or quite, as broad as that of a Malmaison. Mr. S. T. Wright has been very successful with this large batch of Carnations and is to be congratulated accordingly. At

##### GUNNERSBURY HOUSE

Mr. Hudson usually succeeds well with everything he takes in hand, and his grand bed of border Carnations does not suffer in the least by comparison with the other displays just previously commented on. Once more Mr. Douglas' strain has been favoured, and the same excellence in variety, habit of plants and quality of bloom is observable here as elsewhere. It is also worthy of note that fully 90 per cent. of the seedlings are double-flowered, and anything better than that cannot be guaranteed either now or probably in future years by florists generally. If I remember rightly, Mr. Hudson is an advocate

of rather early sowing. When the seed is sown in February it germinates more surely in heat than it does in March, with its trying bursts of sunshine, and quite as many plants are obtained from 100 seeds as when the seed is sown in a warm frame in April. Then, if the early-raised seedlings are properly treated, or not allowed to remain longer than is good for them, either in heat or in the seed-pans or boxes, grand plants are ready for the beds in July. When raised and planted out thus early it is astonishing what a number of blooms a single plant will produce the following summer. Hundreds instead of dozens are the order of the day, in fact, the plants in July are literally all bloom, little or no grass being formed, hence the necessity for raising a fresh stock of plants from seed every season. Beds of seedlings representing a good strain are far more pleasing to those growing them than the more formal display of named varieties, a lover of flowers finding much to admire even in the singles, and the expenditure, either in money or labour, is far less than in the case of forming and growing a collection of named sorts.

W. IGGULDEN.

#### WHITE TUFTED PANSIES.

ONE could not help noticing the marked advance made in the white forms of these beautiful hardy flowers at the recent exhibition of the National Viola Society. Preference certainly was given to those of the rayless type of the flower. A variety distributed last season under the name of Nellie was often in evidence. This is a very large flower, of beautiful form, pure white, with a small, neat orange eye. As a plant for garden decoration it is deserving of extended culture; its growth is vigorous, yet free from coarseness, and it is an ideal sort for the flower garden. It is also very free-flowering. Another variety seen in excellent condition in several stands was White Empress. This is one of the very latest introductions; the blossoms are very large and circular, the lower petal being somewhat cupped, thus giving a finish to the flower. It may be described as pure white, and, like the last-named variety, has a neat orange eye, the centre also being free from rays. Although a strong-growing sort, it is very compact in its growth. Several plants in pots were greatly admired. It does not appear to be quite so free-flowering as the variety Nellie. One of the best of the white flowers, however, was Christiana. This has a large orange-yellow centre or blotch on the lower petal, which enhances its appearance considerably. The flower is oval in shape and its form is distinctly good. As a type of what a Tufted Pansy should be, this is an ideal plant. The growth is beautifully dwarf and spreading, and it is also free-flowering. A variety with somewhat smaller flowers, yet very refined, was Ethel Haneock. The flowers are much whiter than those of most other white sorts and they have a rich yellow eye; the growth is compact and strong. A pretty flower was Devonshire Cream. As its name implies, this is a creamy white flower with orange centre. The habit is excellent and the growth wonderfully free, yet compact. A lovely spray of Vestal—one of the purest white Tufted Pansies in cultivation—was much admired. This is another of Dr. Stuart's gems. The flowers are of medium size, but they are refined and chaste, qualities generally characteristic of this raiser's flowers. The northern growers seem to have a partiality for large-rayed flowers, which did not for a moment compare with the smaller rayless blooms staged by their southern rivals.

D. B. CRANE.

**Campanula Hosti alba.**—Among the white Bellflowers this is perhaps the most worthy both for its wonderful freedom as also the numerous sprays of its pure white flowers. In a soil that is deep and rich it is doubtful whether we have any more beautiful or graceful subject for either the rock garden or border. Indeed, it is delightful anywhere provided an ample supply of moisture

is maintained during growth and flowering. Many years since, I noted this plant in excellent condition in the midlands in a rather stiff and moist clay, so moist, in fact, that *Primula japonica* was in the greatest luxuriance quite near. Some small plants of this kind were noted recently at the Drill Hall, but in small (3 inch) pots they give not the least idea of their beauty. It is one of those subjects that well grown may safely be placed in the front rank among hardy flowers, but in a poor, dry, or shallow soil the true character of the variety is lost. In size and purity of flowers it is far the best of its section, and established plants will reach to 2 feet high, bearing almost endless sprays of snow-white blossom on slender branches.

**Phlox Coquelicot.**—I happened to be at Kew on the 17th inst. (the day on which the notice of this variety appeared in THE GARDEN), and I was so struck with the extraordinary vividness of its scarlet that I was on the point of asking in these pages whether anyone could tell me where it is procurable. As for its identity with Lothair, as suggested by the editor, I should certainly be disposed to negative any such proposition, although the way such names get mixed and misapplied makes it difficult or impossible for anyone to answer with real authority on such a matter. I grew (or believed myself to be growing) Lothair for many years here. It was a beautiful Phlox of a high colour and strong growth, and, if I recollect right, it was one of the first noticeable high-coloured Phloxes to be introduced, but it was certainly unlike and altogether inferior in the vividness of the scarlet (which is real scarlet) to the variety now under notice, which is to my mind a "new departure" in these magnificent florists' flowers. There are a good many fine varieties in the Kew collection which are evidently from a French source.—J. C. L.

**Meconopsis Wallichii.**—The Indian Poppies are among the handiest plants in flower at the present moment. To obtain the fullest development in these plants, seeds should be sown early in the year, say in February or March, the latter quite soon enough where slight warmth can be had for the seed pan. An important point is that of growing on the seedlings briskly from the first, as a check in any of the early stages prior to planting out is calculated to do serious mischief. From the seed-pan the young plants should be potted into equal parts of loam and sandy peat in pots 4 inches across, transferring to their permanent positions as soon as roots reach the side of the pot. To delay planting out is to court failure, as the pyramid of blossom in the year ensuing will be in proportion to the development of the plant in the first year. A deep and rather moist soil should be provided, planting a dozen or twenty plants in an irregular group at 18 inches apart. These the first season make handsome rosettes of leaves that are quite ornamental in themselves. Of this fine Himalayan Poppy a nice group is now flowering in the Kew rock garden.

**Marketing Arum Lilies.**—Having many thousands of splendid flowers growing on the margin of a large pond, I thought it might be worth while sending them to London for the Jubilee festivities, and wrote to a leading flower dealer at Covent Garden, who replied "that at present they were fetching from 2s. to 3s. per dozen, but send them up and we will do our best for you." I at once sent forty-eight dozen, for which, after paying carriage, &c., he sent me 17s. 2d., saying the flowers were very poor, &c. A few days after I sent a box of flowers to THE GARDEN office for their verdict as to quality, &c., and that verdict highly praised the substance and quality of both flowers and leaves. The flowers sent were superior in every respect to the sample sent to you. They were carefully packed in six cases each 36 inches by 22 inches and 10 inches deep, well lined with paper, with layer of leaves at bottom, and every flower fastened down to prevent the possibility of shifting. The cases, costing 1s. each, were never returned. There was no complaint of the packing or the condition the flowers arrived

in, only that they were poor in quality. The amount received for them was a fraction over 4d. per dozen, and this during the Jubilee festivities. I was so disgusted with the transaction, that I determined to let them rot rather than send another flower to Covent Garden.—W. SANGWIN, *Trettsick, Truro.*

### IRIS GATESI AND OTHER CUSHION IRISES IN HOLLAND.

IN No. 1039 of THE GARDEN, vol. xl., I had the privilege to be able to insert a short article on Cushion Irises, giving the way I grow this most interesting group of Irids in Holland. Contrary to the advice of some of the most eminent English growers, whose experience and great success in most other gardening problems cannot be over-estimated, I there urged the necessity of taking up the rhizomes of these Irises every season in order to give them that complete period of rest, without which no proper flowering can reasonably be expected. The rhizomes are taken out of the ground as soon as the foliage shows signs of having fulfilled its task; they are then gradually dried off and are not replanted until late in the season—end of November.

These are the main points of our method of cultivating this most captivating set of Irids, and that the said system of cultivation works tolerably well in at least my garden no one can possibly deny who takes a look at the accompanying illustration, which the editor has been good enough to reproduce from a photograph sent by me, and representing a portion of my beds of *Iris Gatesi*. This species is unquestionably the prince of Irises, and it is a really remarkable coincidence that Herr Leichtlin, the prince of modern cultivators, has also been the first to place this royal flower within the reach of all. The photo shows a large lot imported by myself three years ago, the rhizomes having been collected for me in the mountains of Southern Armenia. Naturally, the first season the plants were weak, my collector having been obliged to dig up the specimens when in bloom, and it was only the second season that a few blossoms were produced. This season when the photograph was taken there were about 400 noble flowers in full splendour, with at least as many more to follow, which the numerous buds shown on the photo can fully testify. At the time of flowering we had a few warm, sunny, perfectly still days, causing the flowers to open without the least injury, and in the brilliant June sun the whole literally represented a sea of noble silvery blossoms, a sight more magnificent than which it would be difficult indeed to find. The sturdy, partially leafy stems attained a height of some 2 feet to 2½ feet, and the stately blossoms measured in some instances more than 10 inches from tip to tip, the lip being 4 inches across. It is not only with *Iris Gatesi* that I have been able to chronicle a success; of the quaint and interesting *Wolff's Fur Iris* (*I. lupina*) at least seven or eight plants out of every ten produced flowers, more than 1000 blossoms having been counted open at once, nearly all clumps of *Iris Lor-*

*teti* and *susiana*, a great many of *I. Bismarckiana*, *Marie*, *atro-fusca*, *atro-purpurea*, and a number of own raised intermediate forms having flowered. The closely-related group of *Regelia* Irises equally well responds to the said method of cultivation, hundreds of spikes of *I. Korolkowi*, with its varieties *Leichtliniana*, *concolor*, and *venosa*, numerous flowers of the bronzy *I. Leichtlini* and of the interesting polychromous *I. Suwarowi* and *vaga* having been produced.

It is difficult, or rather next to impossible, to lay down fixed rules in any matter regarding horticulture, the climatal conditions, the nature and substance of the soil, and hundreds of other often unknown circumstances sometimes leading to a decided failure where one fully had expected to get a victory; but it is certain that in our climate, with our deeply-dug, sandy nursery soil, no other system of cultivating the Cushion Irises can be adopted

were fully shown. I had previously seen the kind, for it is a distinct species from the well-known *speciosa*, growing in boxes as raised from seed at Long Ditton. There I found both deep blue and pure white, and also reddish tints, such as we have previously seen in the *speciosa* section. The plants do not seem to be of so branching a form as bedding *Lobelias* are, and, indeed, were largely used by Messrs. Barr and Sons for boxing, for which purpose the kind is admirably suited, not to hang down, but rather to intermix with other plants. This *Lobelia* will no doubt presently be largely used raised from seed for planting in mixed beds.—A. D.

**Coreopsis grandiflora.**—The tropical heat by day and cold parching wind by night have almost dried up everything in flower, but this plant is as fresh as ever. It is, in fact, a dry-weather subject, heavy rain soon spoiling the beautiful golden-yellow blossoms. These are produced very abundantly on long slender stalks, and are extremely useful for cutting. The pure white *Madonna Lilies* and this *Coreopsis* are a lovely combination in tall vases, while for small specimen glasses about five blooms of the *Coreopsis* loosely set and a sprig of *Maiden-hair Fern* are

*Iris Gatesi* in Van Tubergen's nursery at Zwanenberg. From a photograph sent by C. G. Van Tubergen, Junr.

which gives better and more encouraging results. C. G. VAN TUBERGEN, JUNR.

*Zwanenberg Nurseries, Haarlem, Holland.*

**Anchusa italica** is perhaps one of the best known of hardy perennials and also one of the freest flowering. It is worth growing for the display of colour, this among blue shades being most intense. Large plants produce a fine effect. In common with many Borage-worts, this plant may be freely increased in a variety of ways—seed, division, or root cuttings, the last a very quick method in this instance.

**Crinum capense** is now flowering freely, its strong spikes being nearly 2 feet high. The best position for this plant is in quite moist soil either in the bog garden or near the water's edge, where moisture may be assured. Moisture, however, or at least continuous moisture, is not absolutely essential, but in the growing season it requires it without stint, and, coupled with a deep rich soil, good results at flowering time will be had. The plants may be also grown in pots, and in the summer-time immersed half their depth in water.

**Lobelia tenuior grandiflora.**—The plants of this remarkably fine *Lobelia* shown recently at the Drill Hall by Mr. Ladhams were a little out of character, being rather drawn. In other respects the size and very flat form of the flowers

charming. *C. grandiflora* is a true perennial, but is easily raised from seed, and if the blooms are required in the best order it is as well to treat it as a biennial, sowing the seed in spring in boxes or frames, pricking out the seedlings, and later on planting in nursery beds, placing in their permanent places in autumn. In this way they throw a few blooms the first season, but the next year they form grand clumps 18 inches or more across, from which sheaves of bloom may be cut.

**Yucca angustifolia.**—In the Bamboo garden at Kew there is a large group of this *Yucca*, thriving admirably on a sunny sloping bank, and about a dozen of the plants are in flower. Although, according to "Nicholson's Dictionary," it was introduced in 1811, and there is a poor figure of it in an early volume of the "Botanical Magazine" (t. 2236), it is as yet one of the most uncommon of the hardy *Yuccas*. Yet the plant is itself, even without flowers, a striking and ornamental one. It does not form any distinct stem, but merely a crown near the soil from which springs a fine radiating mass of glaucous leaves, forming, as it were, a semi-spherical rosette. Each leaf is between 2 feet and 3 feet long, about three-quarters of an inch wide at the base, and tapers gradually thence to a long fine point, the margins beset with a few white threads, 4 inches or so long. The raceme is quite erect, averaging 4 feet in height, branching at the base, and the flowers are about the size

of these of *Y. gloriosa*, but not of so pure a white, the outside of the six perianth segments being strongly tinged with green. The species comes to us from Western North America, and is found in the states of New Mexico, Colorado, Iowa and Missouri. The dwarf habit of this *Yucca*, together with its striking appearance—so different from that of most hardy shrubs—ought to bring it into general cultivation. For rock gardens and sunny nooks it is especially well suited. —W. J. B.

#### GLADIOLI.\*

FIRST as to the question of soil. Nearly all writers on Gladioli recommend a light sandy soil as being the most suitable; in fact, some go so far as to make this an essential, and condemn heavy loams as being totally unfitted for the purpose. On what grounds they speak so decidedly I have never yet been able to ascertain, but I assume that, as Holland is a great centre of bulb growing, and as the soil there is mostly of a light and sandy nature, the writers in question take it naturally for granted that everything of the nature of a bulb or corm requires a light, sandy soil for its proper development, without ever putting the matter to the test. I have grown Gladioli in all kinds of soils and mixtures, and after careful consideration, have come to the conclusion that the best results are obtained on a somewhat heavy yellow loam of an adhesive nature, without any admixture of sand—a soil which I consider, if anything, even of too close a texture to grow Brier Roses in. On such a soil I am able year after year to keep up a vigorous and healthy stock of Gladioli, and, no matter whether the seasons be hot or cold, dry or wet, I have always a good measure of success in producing flowers and corms. Perhaps I ought to have stated earlier that my remarks have reference to the fine hybrids of the *gandavensis* section, and I think it may be taken for granted that whatever suits these, as regards soil and general conditions, will also suit the more recent *purpureo-auratus* hybrids and *Saundersi* varieties, and these three sections it will, I think, be admitted contain all the most beautiful late-blooming Gladioli worth cultivating for the beauty of their flowers. The actual species from which they have been obtained are poor things in comparison with the fine hybrids produced from them by careful hybridisation. In recommending a somewhat heavy loam for choice I know I shall be told that splendid flowers of Gladioli are produced in soils of a light, sandy, and even gravelly nature. I quite admit the fact, and I believe that as regards the mere production of fine flowers it may be done in almost any kind of soil whatever; but I should only consider a cultivator really successful when, in addition to fine flowers, he is also able to keep up a healthy stock year after year, and this is more likely, so far as my experience goes, to be attained in a good holding loam rather than in any other kind of soil, at all events so far as the drier and warmer counties of England are concerned. In the more northern counties, where the rainfall is excessive and the climate less warm and sunny, some modification of the foregoing opinion might be necessary, and a soil of a lighter nature might be found more suitable. But it is a matter of history how, when a clever gardener like the late Mr. Standish attempted to grow these flowers on the light sandy soil of Bagshot, he utterly failed to increase or even to keep up a healthy stock, and their cultivation had to be abandoned. Monsieur

Lemoine, on the other hand, has told us in his interesting lecture, delivered in this hall, how well he succeeds with his Gladioli in his nursery at Nancy, where the soil is stiff clay, and from which he distributes his hybrids in such rapid succession. And although it does not appear that the *gandavensis* hybrids flourish there on stiff clay, they succeed admirably with me near Cambridge on a soil closely approaching clay, but where the drainage is good and the rainfall light—an average of about 18 inches a year.

Closely connected with soil comes the question of

#### MANURE.

Excessive manuring is extremely harmful, and is likely to generate disease. Of this disease I will speak later on; but when I see recommended layers of 6 inches to 8 inches of manure, and mulchings of nearly the same, with frequent doses of liquid manure, I cannot help thinking it is greatly in excess of any of the requirements of Gladioli in a fairly average fertile soil, and I am sure that a portion of the manure and liquid would be much more profitably employed on some of the gross-feeding kitchen garden crops rather than in encouraging disease among the Gladioli. I mostly grow the bulbs, or rather corms, on ground which has been well manured for the previous crop, where, for instance, Dahlias or Roses have been grown the previous autumn, and this, I find, produces quite as good results as when I specially manured the ground for the Gladioli alone. An excess of humus in the soil is distinctly harmful, and the stock will remain far healthier in what is termed clean soil. My ground is manured with ordinary stable dung. I have at times applied moderate dressings of bone meal, fish manure, muriate of potash and other artificial manures, but all with doubtful results. I have sometimes given part of the stock a slight mulching with fresh straw litter, but have generally found those grown without any mulching to do equally well. I carefully avoid mulchings of close rank manures, and never employ liquid manure in any form whatever. Clean cultivation is the best.

Although the average rainfall is so light (not exceeding 18 inches), I rarely ever water the growing plants; in fact, they seem to prefer a dry spring and a somewhat dry, warm summer. The hot, dry summer of 1893, for instance, seemed to suit them to perfection, as the finest growth and flowers I ever had were produced in the early part of August of that year, when the plants had very little rainfall and great heat and no artificial watering. The extreme drought and dryness of the air during the present summer (1896) have been too great an extreme on the side of dryness, and the plants suffered during August from lack of rain and moisture in the atmosphere. Up to the end of July they never looked better, and were of wonderful health and vigour, but they appear to require a fair amount of moisture near the blooming period. That they prefer dry and warm conditions rather than those of an opposite nature seems to have been noticed by Dean Herbert in the earliest period of hybrid Gladioli. So far back as the year 1847, when writing of the greater hardiness of *psittacinus* (one of the parents of the present race of *gandavensis* hybrids) he goes on to state that it suffers much from July rains in many positions. With reference to the

#### FUNGOID DISEASE

which attacks the corms of these plants, and with which the whole genus appears to be more or less affected, no remedy for its complete eradication has yet been found. Various suggestions have been thrown out; amongst others,

that of breeding new races direct from the species, and some importance is attached to the re-introduction of *oppositiflorus*, a plant of considerable vigour. But I am strongly of opinion that the late Monsieur Souchet, the originator of the fine *gandavensis* hybrids, himself used *oppositiflorus*, or hybrids from it, in producing his earliest light-coloured varieties, and anyone continuing the work of raising seedlings from them will now and again have tall, light-coloured varieties springing up, with their flowers placed in opposite directions to each other, and all opening nearly at the same time, just like *oppositiflorus*, as some few others almost reproduce the typical *gandavensis*, although a great many generations removed from it. A Gladiolus with its flowers placed in opposite directions on the spike is a poor garden plant, compared to one with its flowers all facing in one direction, and I have no faith in going back to the species as a remedy for improving their constitution. As an instance of this I may mention that a hybrid was given to me for trial, a cross between a very vigorous variety and *Saundersi*, and this became so badly diseased the first season I grew it that it died outright soon after blooming, whilst many of the old hybrids raised more than twenty years ago, growing in the same bed and under exactly the same conditions, remained in vigorous health. There may not be much natural affinity between Gladioli and Potatoes, but both are plants more or less affected with fungoid diseases difficult to combat, and the latter serve the purpose of a good illustration on this point. Mr. Sutton, in his interesting lecture on the Potato delivered in this hall last year, related his experience of crossing varieties of Potatoes with some of the species of *Solanum*, without obtaining any good results in securing varieties proof against disease. Such, I think, would be the case with Gladioli, if we recommenced afresh from the species. As in the case of Potatoes, I would rather look to clean cultivation, and the selection of vigorous hybrids as parents, and the replacing of young stock to replace worn-out corms, as is done in the case of most garden plants. My own annual loss from disease barely reaches 10 per cent. Many people appear to have an idea that a Gladiolus should be propagated in the same way as a Narcissus, by the old bulbs increasing by natural division; and no doubt to a certain extent this is so; but this mode of increase invariably wears out, and it is to the young bulbets which cluster at the base that we must look for perpetuating varieties for an indefinite period. Otherwise named collections of Gladioli would not exist, where the stock of any given variety could be obtained by the hundred or thousand, as is the case with many varieties at the present time. A paper on Gladioli would hardly be complete without some reference to the

#### VARIOUS SECTIONS

of the flower. Many of the early varieties are pretty garden flowers; among these may be mentioned *Colvillei* and its white variety, known as *The Bride*, so largely grown for cut flowers; some few varieties of the *nanus* section and of the later summer-blooming *ramosus* section, followed by the fine hybrids of the *Lemoinei* and *Nanceianus* sections, which, thanks to the exertions of Monsieur Lemoine, have considerably prolonged the blooming season of Gladioli, as they fill up the gap between the *ramosus* and *gandavensis* sections. Many of both sections exhibit remarkable combinations of colours, and as they become more and more infused with the *gandavensis* blood, increase the number of flowers opening at the same time, and give

\* A paper read by Mr. J. Burrell, of Cambridge, before the Royal Horticultural Society, September 8, 1896.

a more erect habit of holding their flowers up, instead of looking at the ground, which is the fault of many. I believe we shall have at no distant date remarkable and new colours, including all shades of blue, and giving flowers and spikes equal in size to the fine *gandavensis* varieties, and, like the latter, opening a considerable number of flowers at the same time without loss of constitution. As many of the hybrids of *gandavensis* are as yet unrivalled in vigour, size, and beauty of flower and spikes, I do not fear loss of constitution by an infusion of the good qualities of these into other sections, in order to obtain a greater variety of novel colours.

## SOCIETIES AND EXHIBITIONS.

### ROYAL HORTICULTURAL SOCIETY.

JULY 27.

THE meeting on the above date was not so extensive as usual, but there was sufficient to occupy the time of those who take an interest in gardening. The chief feature as it pertains to the massing of plants was that of the *Begonias*, *Lilies* and fine-foliaged plants from Lewisham, which formed a long group through the centre of the hall, being of irregular outline, tapering towards each extremity, and consisting of good strains of the tuberous *Begonia*, bearing finely-developed flowers, these being the special feature. As at several previous meetings, hardy flowers were present in quantity, affording as the season progresses what are the best and most continuous blooming subjects for the hardy garden. Of special interest were the hardy flowering shrubs from Messrs. Veitch, more especially when such things are none too plentiful. Roses came from Waltham Cross and Cheshunt, and were representative of the best garden kinds. *Gladioli* made their appearance for the first time in quantity, and were likewise of good quality, affording a pleasing change. Tuberous *Begonias* all the way from Cork were of extra good quality, the flowers being large and fresh, with a good choice of colour. On this occasion the group of Ferns from Edmonton consisted of *Pterises*, and comprised all the most useful kinds of this fine genus. *Cacti* (curious, interesting, and in some instances beautiful) were shown in fairly good numbers. Orchids were chiefly represented by cut flowers, of which forms of *Cattleya gigas* were the most plentiful. At this season Orchids are never very plentiful. Fruit had as its most prominent feature a grand collection of Gooseberries from Messrs. J. Veitch and Sons, showing great diversity in size and in colour, the fruits being of high-class quality. Other fruits were not at all plentiful.

#### Orchid Committee.

A first-class certificate was awarded to—

*EPI-LELIA RADICO-PURPURATA*.—A remarkable hybrid, the result of crossing *Lælia purpurata* with *Epidendrum radicans*. The sepals and petals are each over an inch in length, taking the intermediate characters of the two parents. The colour is rich orange-yellow, suffused with deep rose, the lip  $1\frac{1}{2}$  inches in length, 1 inch in breadth, the ground colour yellow, suffused around the outer edges with deep purple, which shades to a rich golden yellow in the centre, with a brown stripe in the middle. The column is yellow, shaded with rose towards the base. The growth has the character of *E. radicans*. The flowers are produced on the elongated spike from the centre of the growth. It combines the qualities of both these lovely species. From Messrs. J. Veitch and Sons.

An award of merit was given to—

*CATTELYA WARSCWICZI* VAR. *MRS. E. ASHWORTH*.—A lovely form, with almost white sepals and petals, very slightly suffused with rose. The lip is of the same delicate shade of colour as

the petals, with a slightly deeper shade of pink in the centre. There are the usual white and yellow markings at the base, with the brown linings through the base of the throat. From Mr. E. Ashworth, Harefield Hall, Cheshire.

Messrs. J. Veitch and Sons sent *Cattleya Atalanta* (C. Warszewiczii × C. guttata Leopoldi), a lovely hybrid, the sepals and petals having the brown shade of *Cattleya guttata*, suffused with deep rose-purple. The spoon-shaped lip is wholly deep crimson-purple, the side lobes purple, shading to light rose at the base. *Lælio-Cattleya Clonia* (L.-C. elegans crossed with C. Warszewiczii), the [sepals and petals intermediate] in character between the parents, the petals deep rose-purple, shading to a lighter tint at the base, the front lobe of the lip rich crimson-purple, shading to yellow at the base; a fine form of *Sobralia Veitchii* and *Phalenopsis Hebe* were also shown. Messrs. F. Sander and Co. sent a large plant of *Angraecum Eichlerianum*, *Vanda Hookeriana* with two flowers, *Miltonia vexillaria superba*, *Masdevallia gargantua*, and a form of *Bifrenaria*. Messrs. Hugh Low and Co. sent a small group consisting of finely flowered *Cattleya Warszewiczii*, C. granulosa, a distinct form of C. Gaskelliana named Sunray, the sepals and petals splashed with deep rose through the centre as in C. Trianae Backhousiana; a grand form of *Odontoglossum crispum*, *Bulbophyllum claptense*, and various *Cypripediums*. The most distinct was C. Brilliancy, in the way of C. Youngianum.

Mr. E. Ashworth was awarded a silver Flora medal for a fine lot of cut *Cattleya* flowers, containing eighteen distinct forms of C. Warszewiczii, good forms of C. Mendeli, a good variety of C. Rex, and three flowers of *Lælia elegans Schilleriana*. Mr. G. Sloper sent a malformed *Cypripedium Charlesworthii* and a dark form of *Cattleya gigas*, and Mr. J. H. Kitson, Leeds, sent *Cypripedium leucocilium*. From Mr. J. F. Ebner came *Cypripedium Chapmani*. Major Joicey, Sunningdale Park, sent *Odontoglossum aspidorrhenum* with three spikes of lovely flowers, the sepals and petals yellow, spotted with brown, lip white with large purple spots; a finely grown plant of O. Schlieperianum with three spikes, and a good form of O. S. aureum. Frau Ida Brandt, Zurich, Switzerland, sent *Zygopetalum Lehmanni*, *Epidendrum* in variety, a good form of *Cattleya Rex* and *Odontoglossum Schlieperianum aureum*.

#### Floral Committee.

Awards of merit were given to

*CROTON SHUTTLEWORTHII*, a distinct variety with narrow pendulous leafage incurving somewhat at the extremities. It makes a pretty table plant. The colour of the stems is creamy yellow, the growth remarkably short-jointed, the predominating colours being creamy-yellow and olive-green with a suffusion here and there of vinous red. From Mr. A. Shuttleworth, Eastgate House, Lincoln (gardener, Mr. Bugg).

*VERONICA LA SEDUISANTE*.—One of the most beautiful of this class of plants, the flowering spikes being freely produced and of good length, the colour a rich purplish-violet, the leaf growth carrying a dark bronzy shading. Even where the plants are not hardy they can be strongly recommended for pot culture. From Messrs. Jas. Veitch and Sons, Chelsea.

*HIBISCUS CELESTIS* (*Althæa frutex* or *Hibiscus syriacus*, variety of).—A very decided novelty, and a distinct acquisition to its class by reason of its colour and larger flowers: the colour is a dark lavender-blue with a bronzy-crimson disc at the base. From Messrs. J. Veitch and Sons, Chelsea.

*HIBISCUS PAINTED LADY* (of the same section as the former).—This plant is a fitting companion to the foregoing, the colour being a pale flesh, in some instances almost white, whilst the disc is dark crimson—a very pretty plant. From Messrs. J. Veitch and Sons.

*PELARGONIUM (ZONAL) ANNA BATESON*.—A singularly dwarf and bushy variety with, in addition, quite miniature foliage, the colour of the flowers a deep salmon-pink and semi-double, being supported on stiff, wiry stalks; an excellent plant

either for boxes, pots, or marginal lines in flower beds. From Mr. G. Davidson.

*GLADIOLUS CARLTON*.—A splendid variety, each flower almost 6 inches across, the petals very broad and the form good, the lower segments beautifully feathered and spotted at the base on a creamy yellow ground, the colour of the flowers a clear salmon-rose. This variety shows its affinity to the Nanceianus section. From Messrs. Kelway and Son, Langport.

*GLADIOLUS J. G. CLARKE*.—Another fine seedling, the colour purplish rose with the purple pervading, and feathered on the lower segments with a creamy shade. Messrs. Kelway and Son.

*GLADIOLUS WHITE LADY* (*gandavensis* section).—The best beyond any doubt, with pure white flowers, which in addition are large and of good form, on long spikes. From Messrs. Paul and Son, Old Nurseries, Cheshunt.

*GLADIOLUS GENERAL DUCHESSE*.—Another fine addition to the Nanceianus section, each flower nearly 6 inches across, the colour a decided magenta shaded with purple, the petals very broad and well reflexed, with a large creamy yellow blotch on the lower ones. From Sir Trevor Lawrence, Burford Lodge, Dorking. (Mr. Bain, gardener).

*GODETIA GLORIOSA*.—An extremely dwarf variety, very dense and close in growth, not more than 10 inches in height, the colour a rich and glowing dark purplish crimson, very fine for massing or in lines. From Messrs. Dobbie and Co., Rothsay.

*PHLOX LORD RAYLEIGH*.—Very distinct by reason of its colour, a deep purplish blue, the flowers and spike of full size. Messrs. Paul and Son.

*ROSE (TEA) G. NABONNAND*.—A variety which, although not new (as the term goes), is yet well deserving of the award accorded; the flowers are of beautiful form and of average size. The colour in the bud stage is somewhat similar to, but paler than in *Gloire de Dijon*, and with age a pale creamy blush is the prevailing tint. It is a fine garden Rose. From Messrs. W. Paul and Son, Waltham Cross.

*ROSA RUGOSA ATRO-PURPUREA*.—A deep purplish crimson variety of and a fitting companion to the type. From Messrs. Paul and Son.

*HELIOPSIS PITCHERIANA*.—A deep golden yellow Sunflower of medium size and of good substance, the foliage and leaf-growth being sturdy. Messrs. Paul and Son.

The most striking and effective exhibit was a group of *Begonias* from Mr. H. J. Jones, of the Ryecroft Nurseries, Lewisham. This was arranged down the middle of the hall in undulating form, the general idea original and exceedingly good. The *Begonias* were very finely grown, both flowers and foliage being of splendid quality. Light Palms, Ferns and *Caladiums* of good colour were used as a relief to the gorgeous blooms (gold medal). A large collection of cut *Begonias* came from Messrs. Richard Hartland and Son, the Lough Nurseries, Cork, and were very little the worse for their long journey, most of the blooms being in a perfectly fresh condition. The collection was, on the whole, exceedingly good, the large, full, substantial blooms showing considerable cultural skill (silver Flora medal). Messrs. Paul and Son, Cheshunt, had a group of cut *Roses* and hardy flowers, the former including good examples of *Belle Siebrecht*, *Gustave Regis*, and a new red single, *Royal Scarlet*. Among the hardy flowers were *Acanthus longifolius*, *Polygonum molle*, and some fine flowers of *Rudbeckia purpurea* (silver Banksian medal). A charming group of cut flowers was staged by Messrs. Barr and Sons, Covent Garden, and comprised a fine collection of fragrant herbaceous *Phloxes*, *Delphiniums*, varieties of new *Sweet Peas*, and *Pentstemons*. The group was very tastefully arranged (silver Banksian medal). Mr. T. S. Ware, of Tottenham, also exhibited a very fine collection of hardy flowers, the arrangement of the colours being most pleasing. Several of the smaller varieties of *Sunflowers* were well shown, also *Matricaria grandiflora plena*, *Scabiosa caucasica*, and

some handsome varieties of Liliams (silver Flora medal). A large exhibit of Gladioli came from Messrs. Kelway, of Langport. All the flower-spikes were finely developed, bearing large, handsome blooms, well formed and well coloured. A few of the most striking varieties were Numa, white, shaded with cerise; Charterhouse, rich salmon-pink, a very long and graceful spike; Semolina, deep rose, veined with red, and Don Jose, a rich cardinal. A few very good miscellaneous hardy flowers were also in this collection (silver Flora medal). An interesting exhibit was that of Messrs. W. Paul and Son, Waltham Cross, consisting of new Roses. The most striking varieties were Empress Alexandra of Russia, which was described last week; Sylph, Francis Dubriell, a small Rose, resembling in form the Duke of York, but rich maroon in colour, a very effective variety; Mme. Abel Chateau, a very pretty and shapely pink; Mme. Carnot, a pale primrose-yellow, resembling Gustave Regis in form and growth; and Enchantress, which has already been noticed and described (bronze Banksian medal). A small, but interesting group of plants came from Messrs. Sander, St. Albans, and included *Watsonia iridifolia* O'Brieni, which has been shown at previous meetings; *Dipladenia atropurpurea*, with its rich dark blossoms; *Exacum macranthum*, *Lilium philippinense*, and *L. Henryi*. Messrs. Veitch and Sons, Chelsea, had a few good flowering shrubs, including *Spiraea callosa atrosanguinea*, *Spartium junceum*, *Cornus macrophylla*, single Hibiscus Painted Lady, bearing numerous beautiful flowers; *Vitis heterophylla variegata*, *Veronica la Seduisante*, a lovely rich purple variety; *Hibiscus coccineus*, with large dull blue blossoms; *Pavia macrostachya* and *Eucryphia pinnatifolia*, a very charming flower, very effective in the mass. The same firm also had a box of their beautiful javanico-jasminiflorum hybrid Rhododendrons, the trusses being perhaps rather larger and fuller than usual, and the colours exquisite (silver Banksian). Messrs. J. Cheal and Sons, Crawley, had a few early Dahlias, the Cactus varieties including Startish, Mrs. Kingsley Foster, Chas. Woodbridge, Fusilier, Mrs. A. Beek, and Cycle. The singles were Naomi Tighe, Polly Eccles, Phyllis, Donna Casilda, Demon, and Duchess of Marlborough. The pompons were Annie Holton, Sunny Day-break, Donovan, Bacchus, Lily Wheeler, and Nerissa. A small group of Lilies, including *L. nepalense* and *L. Wallichianum*, was staged by Messrs. Hugh Low and Co., Enfield (silver Banksian medal). Another very interesting exhibit was a group of Pterises from Mr. H. B. May, Upper Edmonton. Some of the most striking varieties were *Pteris ludens*, *P. hastata*, *P. tricolor*, *P. Regine*, *P. tenuifolia*, *P. tremula densa*, *P. involuta*, *P. scaberula*, *P. Duvali*, *P. aspericaulis*, *P. sagittifolia*, and *P. internata* (silver-gilt Flora).

In the Cactus show, Messrs. H. Cannell and Sons had the largest and best collection, including plants of *Echeveria metallica crispa*, *Gasteria angularis*, *Aloe plicatilis*, *Cotyledon pulverulenta*, *Cereus peruvianus monstrosus*, *Echinocactus longiramatus*, bearing three silky yellow blooms; *E. Grusoni* and *Mammillaria stella-aurata* (silver Flora medal). In competition, the first prize for a collection of Cacti went to Mr. W. Bodkin, Highgate, for a very fine exhibit, which also was given a silver Flora medal. The second prize was won by Mr. C. A. Bogg, Brighton Road, Croydon, a silver Banksian medal being also awarded. For twelve Cacti, Mr. W. Bodkin was again first, and Mr. E. R. Clifton a good second.

#### Fruit Committee.

An award of merit was given to—

**NECTARINE PRECOCE DE CRONCELS.**—A finely-flavoured variety above medium size and of a bright red colour, with numerous spots on the shaded side. It is an excellent kind for pots on account of its free-bearing qualities. From Messrs. Veitch, Ltd., Chelsea.

A large space was taken up with over 100 varieties of Gooseberries from Messrs. Veitch and Sons.

The fruits, shown in square trays, represented all the best kinds. This firm on many occasions has shown Gooseberries, but we never remember to have seen so fine a collection. Whinham's Industry, a red fruit noted for its earliness and productiveness, was shown in quantity, also Trumpeter, a heavy-cropping yellow variety. The best flavoured yellow fruits were Golden Drop, Pretty Boy, and Broomyard, the best white being Whitesmith and Champagne; the best green, Pitmaston Greengage, Early Green, and Green Walnut. Among the large-fruited kinds we noted, *white*, Progress, Transparent, Mitre, and Queen of Trumps; *green*, Random, London City, and Telegraph; *red*, Speedwell, Clayton, Monarch, Lord Derby, Registrar, and Bobby; *yellow*, Railway, Mount Pleasant, and Gipsy Queen. A dozen varieties of Currants, with Morello Cherries, and Neetarine Rivers' Early were also shown (silver-gilt Knightian medal). Some very fine Sea Eagle Peaches, sent by Mr. McAuslan, Leeds Castle Gardens, Maidstone, well merited the cultural commendation given. The Japan Wineberry was staged by Mr. Cundey, The Warren House, Cobham, Surrey. Melons came from Mr. Hudson, Gunnersbury House, and Mr. Taylor, Hardwick Grange, Shrewsbury. Messrs. Carter, High Holborn, staged eighteen varieties of Turnips, the most shapely roots being Jersey Lily, Cardinal (a red variety), and Swan's Egg. Messrs. Kelway, Langport, showed Duke of Albany Pea and a good dish of Bunyard's Exhibition Longpod Broad Bean. Mr. Wythes, Syon House, Brentford, sent French Bean Veitch's Early Favourite, to show its cropping qualities in the open ground. The plants were laden with pods. It is very early and stands drought well. Mr. Wythes also sent Improved Mohawk, a new Bean certificated at the trial of forcing Beans at Chiswick early this year. This is a very free-bearing and large-podded variety. A dish of Pea Trowbridge Hero came from Mr. Stokes, Prowbridge; this variety was given three marks at Chiswick last year.

### NOTES OF THE WEEK.

**Fuchsia macrostemma.**—This is one of the most elegant of its tribe, and the flowers are as dainty as the delicate twigs of which the plant is composed. The flowers are very numerous and have quite a pretty effect when seen in a bed on the lawn.

**Helenium pumilum.**—At Kew just now two groups in the hardy plant department amply illustrate the best side of this plant. Fully grown in good ground it is about 15 inches high, and the very pleasing soft yellow blossoms appear in almost endless numbers.

**Astilbe Lemoinei Gerbe d'Argent.**—Among moisture-loving plants this variety, recently exhibited at the Royal Horticultural show, seems likely to prove a most worthy kind. The inflorescence, erect and branching, displays the pure white plumes to advantage.

**Anemone japonica** has already opened its earliest flowers, and gives promise of a rich profusion by the appearance of almost endless buds. An excellent plant in the shrubbery border, where in its own way the plant will spread quickly in good soil, and ultimately provide a fine display of its rosy-red blossoms.

**Nymphæa alba candidissima** is, as may be gathered from the varietal name here given, a distinct white form, very pure in the large handsome, white blossoms that happily are produced very freely in the case of large plants. Where this variety can be secured it should take precedence of the original form.

**Asclepias tuberosa.**—This, one of the most distinct plants in flower in the garden now, is deserving of more extended culture. The heads of orange-scarlet blossoms are very showy, though only reaching about 18 inches high. A sandy and rather moist rich loam often suits it well, and by

the sea the plants grow even more vigorously. In peaty soil and leaves we have also grown it strongly.

**Platycodon Mariesi** is without doubt one of the finest hardy plants now in flower, and one suited alike to the border or the rock garden. The richly coloured blossoms are of large size, and from established plants very handsome. As yet the plant is not common, though in a variety of places batches are springing up.

**Calceolaria alba.**—Some small plants in pots of this singularly pure white kind are flowering in No. 4 house at Kew. Even in this small state they convey an idea of the value of the plant, and where large plants can be obtained they will be found excellent for cutting. The pure white blossoms are very distinct.

**Scabiosa caucasica alba.**—This novelty should be grown largely for the sake of variety. But while being an addition to good hardy plants, this is still wanting in purity. As a break it is valuable, and the plant should now be seeded freely in order to secure a pure white variety. The soft mauve-blue of the type is always admired.

**Inula ensifolia.**—This pretty rock species, which was freely shown among hardy plants on Tuesday last, is in striking contrast to some other forms of this genus. The plant is only a few inches high, bearing small yellow blossoms from a little tuft of narrow linear leaves. It is easily grown in good soil in the border or rock garden.

**Gypsophila paniculata.**—Those who only know this plant by solitary examples have no idea of its beauty when a huge cloud of its blossoms many feet across is seen. In this way the plant, though so easily grown, has an effect of its own, particularly when surrounded by suitable associations. At Kew just now are many fine, almost impenetrable, masses of this plant.

**Coreopsis verticillata.** On Tuesday last at the R.H.S. Messrs. Barr and Sons had bunches of this by no means common plant, the narrow linear leaflets in whorls on the slender stems being very distinct from those of other kinds. Though by no means so useful for cutting as *C. lanceolata*, the plant is worth a place in the rock garden, where its pretty yellow blossoms will be seen to advantage.

**Malva alcea fastigiata.**—A large mass of this at Kew shows the importance of groups even where the plants possess no special value from scarcity or other causes. The bold group of flower-stems 3 feet high, and crowded with blossoms of rose-pink, render it not only showy, but very desirable in all positions where room can be given it, or where space requires quickly filling up in summer.

**Tufted Pansy Queen of the Year.**—This is another of the newer varieties of the miniature type of these flowers, and although but a small blossom, it is one of great beauty. It is described by the raiser as a distinct shade of china blue, the centre being white with a neat yellow eye. The small flowers are almost circular in shape, and produced rather freely on short, erect footstalks on plants of neat and compact growth. The flowers are also sweet scented.

**Dianthus Heddeewigi.**—The improvement in this race of annuals has been very marked during recent years, particularly among the large self-coloured single forms. Some of the intense crimson shades are very handsome, with blossoms 3 inches or 4 inches across. The double forms, on the other hand, are wanting in a variety of ways, and certainly by no means so effective as the singles, these in large groups in the mixed border being very attractive.

**Campanula pyramidalis** (the Chimney Campanula) is one of the showiest of the genus with special value for the greenhouse where bold plants are required. Of its value in this way Mr. Geo. Wythes has at Syon House taken advantage by the free use of the white form, and by providing good culture the tall snowy-white spires of

blossom are both valued and effective. Treated as a biennial, a fine result is secured at its first flowering, and well repays the cost.

**Pereskia Bleo.**—This species is sometimes employed as a stock for grafting the hybrid Epiphyllums on to, though perhaps *P. aculeata* has been more freely used in the past. The above species, which is now flowering in the succulent house at Kew, evidently possesses greater vigour, and, judging by the sample referred to, has the merit of straighter stems, which would prove of value in such cases. The blossoms are very curious in form and of a lilac-rose shade.

**Tufted Pansy Joseph.**—We herewith send a spray of our new bronze Tufted Pansy Joseph. It has a good habit, is very free-flowering, and has a good constitution, being easily struck and kept during winter.—J. GRIEVE AND SONS, *Red-lobes Nurseries, Broughton Road, Edinburgh.*

\* \* A bronze-orange Pansy, distinct and pretty, if it will only keep with us, as all the true Tufted Pansies do. Our experience hitherto with all these bronze-coloured Pansies is that they are difficult to keep.—Ed.

**Mesembryanthemum pomeridianum.**—This lovely plant is employed at Kew as a ground-work on a bed of Lady Penzance Rose, and while in no wise enhanced by this particular association, has merits of its own that should commend it to all lovers of beautiful and easily grown plants. Obviously annual in character, the low-growing, freely-spreading plants flower abundantly, the blossoms, each about 2 inches across, of the most exquisite shade of deep sulphur-yellow. For hot and dry as well as sunny positions such plants possess considerable value, and for summer use would give excellent results.

**Sempervivum Reginae Amaliae** is perhaps one of the most distinct of the Houseleek family, particularly in the manner in which the rosettes cluster together. Usually there are from three to five crowns sideways on the stem, and in this respect unique. The flowers, which are greenish yellow, are well lifted up on a strong stem some 6 inches or so high. The plant has quite a distinct way of reproducing itself, a fresh crown forcing its way beside the old one. Sometimes a solitary crown will arrange itself in a fourfold way when fully grown, even before flowering, which in some species is responsible for this.

**Hollyhocks in London.**—Travellers on the South-Western Railway on nearing London cannot fail to note the freedom with which the single Hollyhock is used in quite small gardens, and the many colours that amid the dirt and gloom of this great city are especially bright and cheerful. It is the single kinds that are thus freely employed, and as they tower far above the boundary walls of many cottage gardens, they are very bright and cheerful. Any plant that will send up its flower-stem 6 feet or 8 feet high in smoky London cannot be ignored. Few plants could be more useful among shrubs in many London squares and gardens than Hollyhocks.

**Delphinium Belladonna.**—One of the finest displays of this unique Larkspur may now be seen in Mr. F. Gifford's Carnation nursery at Tottenham. The plant is unequalled both for its colour and the remarkable freedom of flowering. Here is a group, brilliant beyond compare, about 5 feet wide and 100 feet long, simply a mass of its slender bright blue spikes, the latter the most useful of all for cutting. Above all, the plant blooms perpetually, the present mass being the second crop this year, and still the stools are breaking up freely from below. The plant is more at home here under Mr. Gifford's care in rather light stony soil than we ever before remember.

**Lilium Wallichianum,** shown at the Drill Hall on Tuesday by Messrs. Hugh Low and Co., is a handsome species, producing its huge, slightly drooping, trumpet-shaped blossoms quite freely. The blossoms were each 8 inches or 9 inches long, some plants having three or more each, a somewhat rare occurrence in this lovely Indian form. Externally the blossoms are greenish white,

internally of a clear yellow shade, and nearly white at the slightly reflexing tips of the perianth segments. Though among the handsomest of the Lily family, it is unfortunately not a plant for the open garden in these islands. The most may be made of it, however, by growing it in the greenhouse in sandy peat and in pots of fair size. The pleasing fragrance of this fine Lily is certainly not the least of its attributes.

**Rosa setigera** (the Prairie Rose).—Except for a few belated blossoms, most of the wild types of Rosa are now past. Two or three species, however, are not at their best till late July, and of these this American species is the most effective. In the Rose collection at Kew a large mass is now in full flower. From all the numerous species of Rosa native of North America, this differs in its rambling mode of growth. It produces each year long, arching shoots, 8 feet or 10 feet long, from which the flowering shoots spring the following year. There are never more than five leaflets to each leaf, frequently only three, but they are unusually large, measuring 3 inches long and half as much wide, giving in themselves a distinct character to the species. The flowers—which, of course, are single—are 3 inches or so across and of a very bright shade of rose. They come in dense clusters, nestling amidst the rich green and abundant foliage. One thing, unfortunately, they lack, and that is fragrance; but in spite of that defect the species may be recommended as one of the most attractive of hardy shrubs flowering in late July.

**Genista æthnensis.**—Flowering during July, and even until August, when the bulk of hardy trees and shrubs is past, this Broom ought, one would imagine, to be one of the best known of the species. But in spite of its great beauty and the lateness of its flowering, it is comparatively rare. Of the Brooms that can be cultivated out of doors in this country, it is the tallest and most tree-like in aspect, growing 15 feet high and forming a main stem 6 inches in diameter. Its mode of growth is somewhat sparse, yet elegant, the thin terete branches being pendulous and bearing scarcely any leaves. What few leaves there are occur at long and irregular intervals on the young shoots, and are each about a quarter of an inch long and quite narrow. The flowers, which are very freely borne, are of a bright yellow, and the plants are in beauty for over a month. The species is a native of Sicily and Sardinia, and one of its habitats is the sides of Mount Etna at altitudes of 3000 feet to 6000 feet. It is quite hardy, however, in this country and thrives in almost any soil. Its value as an ornamental shrub may be judged now by numerous specimens that are flowering in the arboretum at Kew.—B.

**Plagianthus Lyalli.**—A large specimen of this New Zealand shrub, some 8 feet high and still more through, is flowering in the collection of malvaceous shrubs at Kew near the flagstaff. In our climate this shrub is considered difficult to flower away from a wall, but that it will do so is proved by this specimen, which has never been trained to a wall, but has been growing near one in a sunny nook. In this country (near London, at any rate) it is deciduous, but this appears to be merely a question of temperature, for in New Zealand it is evergreen at low elevations and deciduous after it reaches altitudes of about 3000 feet. The leaves are heart-shaped, varying in size according to the vigour of the plant on which they grow, but they are, as a rule, 2 inches to 4 inches long. The margins are irregularly toothed, and whilst the upper surface is glabrous, the lower one is sparsely set with stellate hairs. The flowers are produced from the leaf-axils near the ends of the shoots, two or three appearing in each axil. The flower-stalks are slender and about 1½ inches long, and the flower itself is the same in diameter, the five elliptical petals being pure white; they have a slight perfume. Its flowering is mainly dependent on the thorough ripening of the wood, and although it may occasionally bloom in the open, it is when trained against a wall that its full beauty can be seen. A coloured plate

by Mr. H. G. Moon appeared in *THE GARDEN* of July 8, 1893.

#### MISLEADING DESCRIPTIONS.

DISAPPOINTMENTS are of sufficient frequency among the fraternity of those who garden to induce, if taken aright, a certain equanimity of mind under adverse circumstances, invaluable when the losses, which will now and again occur, prove exceptionally trying, but it is difficult for even the stoic to refrain from outspoken criticism when a plant reveals itself, after many months of waiting, as totally unworthy of the glowing description under which it was sent out. This practice of exaggeration is, unfortunately, not unknown among our fellow-countrymen, but foreign firms are, in this respect, by far the greater offenders. Some time since I came across, in the catalogue of an American Company, descriptions of two new fruits, the Golden Mayberry and the Strawberry-Raspberry. Of the former, the following was written:—

The bushes are distinct from all others, growing like trees, 6 feet to 8 feet high, with spreading tops; all along the branches, large, white, well-shaped blossoms are pendent, which are soon followed by the great, sweet, glossy, golden, semi-translucent fruit. The plants when well established will surprise one with their abundance of fruit:

while the description of the Strawberry-Raspberry reads:—

This is indeed a remarkable fruit. It is said to be a hybrid between the Strawberry and Raspberry, and the habit of the plant gives strong evidence that this statement is correct. Its habit is that of neither of the fruits named, but a compromise of the two, it being a spreading, low-growing bush, producing its fruits in branching clusters of three or more at the end of the stems. In form and appearance the fruit is about as good a combination of a Strawberry and Raspberry as one could well imagine, in colour a crimson, equalling in brilliancy the most beautiful Strawberry.

The descriptions are distinct enough, but now that the plants, sent in response to an order, have developed they prove to be absolutely identical.

Another fruit, sent out by a French firm with a flourish of trumpets, was the Spineless Gooseberry. After a year's trial this Gooseberry, which is evidently grafted on the Currant, has in each case proved to be as spiny as the general run of smooth-skinned varieties that do not profess to be spineless, and appears destitute of any particular merit.

To the trade-grower, whose business demands that he should keep abreast of the times and make a trial of all the advertised novelties, such divergences between fact and fancy are doubtless of so frequent occurrence as to create but little annoyance and less surprise, but in the case of the amateur, who is occasionally tempted to order some specially-vaunted introduction, and who finds after a tedious wait that the reality entirely fails to tally with the advertised description, such discrepancy is provocative of considerable vexation.

S. W. F.

#### PUBLIC GARDENS.

**New open space.**—The Parks and Open Spaces Committee of the London County Council have recommended that, subject to the Wandsworth District Board agreeing to pay the Council a sum of £10,000, and to a further sum of £5800 being raised by subscription, the Council should purchase for £31,500 a plot of land abutting on the Putney Bridge Road, and having an extensive river frontage, with a view to its being laid out as a public park and recreation ground.

**Names of plants.**—*H. Kruse.*—*Stanhoepa Wardi* anra.—*Braduell.*—1, Rose Lamarque; 2, Rose Marie Van Houtte.—*C. P. B.*—1, *Centranthus ruber*; 2, *Centaurea macrocephala*; 3, *Lysimachia thysoides*; 4, *Salvia argentea*; 5, *Antemiss tinctoria*; 6, *Antennaria margaritacea*; 7, *Dicentra cucullaria*; 8, *Campanula Rapunculhus.*—*Arthur Tilley.*—Carnation not recognised.

## ORCHARD AND FRUIT GARDEN.

### STRAWBERRY PLANTING.

THE ground being now in splendid condition for planting, owing to the recent heavy, but welcome falls of rain, the formation of new plantations should be proceeded with, as the sooner the plants are got out, so much the sooner will they become established and be the better able to withstand the effects of a severe winter. This early planting also has other advantages, the foremost of which is that if good, strong and well-rooted runners are used, an excellent crop of the finest fruit is secured the first season. When planting is delayed until autumn sets in and nothing but naturally rooted runners are made use of, or such as may be found rooted in the ground between the rows of old plants, a whole season is lost, as such plants cannot and do not give satisfactory returns the first year. When the time and labour involved in preparing the site for a Strawberry bed or plantation are taken into consideration, it is certainly worth while to make use of such plants as will at once give a fair return and so recoup the planter for his outlay. Runners layered into small pots are without doubt the best to secure this end, and when once planted and watered home they give but little trouble afterwards. Therefore if the necessary number of plants has been layered and the ground on which they are to be planted has been prepared, all that remains to be done is to thoroughly consolidate it by treading the surface regularly all over. If the soil is of a light description, another treading in the reverse direction will be needed, for the fact that Strawberries can hardly have too firm a root-hold should not be lost sight of, and as soon as this is done planting may at once be proceeded with. It is a good plan to well water the plants some two or three hours previously, and then if the soil round the balls is watered so soon as plant-

ing is completed, they will not feel the effects of dry weather for some considerable time, especially if a mulch of some non-conducting material such as spent mushroom manure is laid between the rows. Planting is best done with a trowel, and the loose soil can as quickly be returned and placed all round the ball. The soil should be made firm round the balls, and see that the crowns are not placed too low down in the ground. A good guide is to place the balls just low enough in the holes so that they will be covered with a thin layer of soil and no more. When planting is finished it is a good plan to walk through the plot and tread the soil firmly round each plant carefully with the foot. A little extra care taken now in this way prevents the plants from being lifted and thrown out during the winter. The planting completed and the watering done, the surface may be mulched as mentioned above, after which they will not require much attention beyond the removal of runners and the suppression of weeds unless the weather should prove unusually dry, when of course watering now and again will be needed.

The distances at which to plant have not yet been touched upon. As a rule, 2 feet between the rows is the space generally allowed in gardens and 3 feet for field culture, this giving ample room for attending to their requirements. Regarding the distances at which the plants should be disposed in the rows, a space of 18 inches is the usual allowance, but if room is not restricted the more robust and stronger growing varieties may with advantage be given 2 feet.

A. W.

**Alpine Strawberry La Genereuse.**—This variety of a very interesting section that should be far more widely grown has nicely-sized, richly-coloured, and very pleasant fruits borne in great profusion and for a long season. The alpine forms give in flesh something so distinctly diverse in character and flavour from the ordinary garden Strawberry, that they are almost distinct fruits. When two or three batches are grown so that the

younger plants can be disbudded in the spring, the older ones being left to fruit, the disbudded plants fruit abundantly in the autumn, when they are most welcome.—A. D.

**Fruit crops in Monmouthshire.**—This has been a disappointing season. May frosts destroyed a magnificent bloom of both Pears and Apples, as also of Plums and Cherries. Gooseberries and Red Currants generally have poor crops; Black Currants almost a total failure. Peaches, Nectarines, and Apricots are utter failures; Filberts and Figs excellent. Strawberries lasted but a short time; my best both under glass and outdoors was Royal Sovereign. Macelean's Wonder was disappointing, and Noble not worth growing or eating. My best late kind was Latest of All.—G.WENT.

**Peaches on west walls.**—I noted with much interest Mr. Tallack's remarks on Peaches (p. 24). I do not think anyone need fear planting Peach trees on west walls either from a wood-ripening or fruit-producing point of view. At Taunton Park Peaches have not been grown on the south wall for many years. Formerly they did as well as Peaches could do, but in after years the springs being more uncertain, the blossom which expanded early on the south aspect was nearly always destroyed by frosty winds, which at that particular season are very prevalent in that part of Norfolk. On an east wall, however, Peaches do very well, excellent fruit being gathered. I believe the varieties are second early and midseason, as Mr. Tallack advises.—J. C.

**Peach blister.**—As most of your readers too well know, this malady has been very prevalent this spring on outdoor trees. The majority of my trees are on an east wall and suffered rather badly, while those on a south aspect have been quite free. About a month since I was looking over Sir Charles Cave's gardens, Sidbury Manor, about seven miles from where I write, and the trees on the Peach wall facing south looked deplorable; some of the trees appeared almost beyond recovery and the crop very scanty. I have had no experience with Peaches on a west wall. The trees here and at Sidbury were well protected with double fish netting while in bloom, and for some time after, though mine had the advantage of a glass coping, which must have

been advantageous to the trees. Most of my trees are carrying a crop on the eastern aspect, while those on the south are laden with fruit. This makes me favour the latter-named position.—J. MAYNE, *Bieton*.

**Strawberries in nurseries.**—Where probably 100,000 pot plants are needed yearly of some fifty varieties, it is evident that the greatest care must be exercised in keeping the runners true. When looking over Mr. George Banyard's nursery at Maidstone recently, I saw a huge breadth of all the best varieties being layered. The plants are put out early in the autumn in good clean soil, usually following Potatoes. The rows are 5 feet apart, and so arranged that in every case all the runners of any pair of rows come into the centre, so that there is left every alternate space free for walking, working, and, if specially needed, watering. In this way it is impossible for runners of adjoining varieties to become mixed. The small pots are filled with soil, then well watered. So soon as partially dry, the layering proceeds, each pot being sunk to its full depth in the ground and the layer pegged into it. So treated, little watering is needed; indeed, little can be furnished. In three weeks the layers are well rooted and may be removed to the home nursery.—A. D.

#### GRAPE PROSPECTS.

GIVEN a soil similar to that with which I have to deal, *i.e.*, very light and porous, little opportunity of providing anything heavier in quantity, all outside borders, and poor facility for watering, the season of 1897, following the wet autumn and early winter of last year, is one of the best I have had for Grapes. The borders had a thorough soaking last autumn, and a good surface mulching having preceded the rainfall, they have not been in the least dry. I also generally manage to give them an early summer top-dressing in the shape of two parts stiff road sidings and one of cow manure, and this was only on this year a couple of days when we had a tremendous downpour, giving the roots all the benefit of the stimulant. With a soil of the nature described above I find the rejuvenation of the rods is an absolute necessity, and some two seasons back dwelt in a short paragraph on the method adopted, *viz.*, bringing up a young cane from the bottom under the old rod, cutting off from the latter the old spurs for two successive seasons as the young cane was making its way, and finally removing it altogether when its successor was able to furnish the entire stretch of rafter. An old house in which such young rods are in their second season is just now rather interesting, two-thirds of the house from the front plate upwards being cropped from the younger canes, and the remaining third from spurs of the old Vines. A very great difference is perceptible alike in vigour of wood and foliage, in size of bunch and berry. It is, I think, evident that, given a soil on the light side, there is little prospect of producing good fruit from old spurs, but yet the recuperative power of the Vine is so great, that the end is at once gained by the introduction of young wood. I am having a little trouble just now with cracked berries on Foster's Seedling, and that despite the fact that a chink of air is left on at night. The reason is, however, not far to seek. The house is full of plants, and a great amount of moisture was generated alike naturally from these and from afternoon watering. So far as the latter is concerned, the danger is lessened by performing the work in early morning and allowing the chink of air to remain on during day and night. In the event of more rain coming I shall lay some shutters or sheets of galvanised iron on the border, and if more berries go, notch the shoots on one side to the pith midway between the main rod and the bunch. In the late house two varieties, Mrs. Pince and Lady Downe's, that are sometimes not up to the mark, the one in the matter of setting and the other in a susceptibility to scald, are this year extra good. Probably the better results are due to an in-

creased attention respectively to tapping and the use of the rabbit's tail, and to a slight shade accepted early in the season. All the late Grapes except Alicante are the better for a little shade, the vineries lying due south-east, and it is a difficult matter to get the foliage dry before the sun is on it. Alicante is, fortunately, a favourite, and I am gradually running up side rods of this to take the place of other varieties. Two Vines of Alnwick Seedling produce Grapes so wonderfully attractive to the eye alike in symmetry of bunch, size of berry, and perfection of colour, that I am rather loth to take them out, despite the worthlessness of the Grape from a flavour standpoint.

E. BURRELL.

#### GRAPE DUKE OF BUCCLEUCH.

"C." in THE GARDEN of July 17 gives some interesting notes of his experience with the Duke of Buccleuch Grape. Those of your readers who have seen it in perfect condition will agree with "C." that it is "a grand Grape." At the same time, it must be admitted that it has certain peculiarities of constitution that require special treatment. I have grown it here for twenty-seven years on its own roots, and had fine crops every year. There is no trace of spotting. The Golden Champion I admit used to spot with me a little, but never the Duke. The treatment I give the Duke is as follows: I maintain a succession of young rods, cutting out all old canes as soon as possible. When I say old canes I mean rods, say four years old. In the case of the Duke I look on that age as old, as there can be no doubt it does not fruit well on canes of that age or over. By running up young rods, by long spur pruning (say four eyes left), and by paying attention to the careful artificial impregnation of The Duke, I have never failed during twenty-seven years to obtain a fine crop of this noble Grape. In regard to flavour, I think the Duke is first-rate. Though not so sweet as the Muscat, it has a peculiar lusciousness of its own, which, I consider, makes it a Grape not to be beaten by any other kind for placing on the dinner-table or handing to the invalid. Taken all in all, I think that the Duke is well worth all the extra trouble that may have to be bestowed on it, and I am sure that those who have once seen and tasted it in proper condition will say that it is a noble Grape. Some may think that I am prejudiced in its favour because my late father was its raiser, but I can assure them that I judge the Duke on its own merits, and I have tested and proved it for many years.

JOHN THOMSON.

*Chorinford.*

#### NOTES ON GOOSEBERRIES.

THE Gooseberry crop is an important one in all gardens. It is astonishing the length of time the Gooseberry crop lasts. This year the fruits were large enough to gather for tarts, &c., in May, and I have been gathering regularly since that time and shall be able to continue well into August, and where they are grown on north walls and late kinds chosen, they may be had well into September. I am doubtful if there is another crop that can be made to pay as well. During the last ten or fifteen years I have been paying much attention to this crop, both as to their producing powers and also from a flavour point of view. I dress the ground every year, as the very heavy crops that we get need this to keep the bushes vigorous.

Regarding pruning, I find a moderate course the best. The shoots should be kept thin enough to get your hand between them. I do not like to see the shoots cross each other. I commence to gather the fruit as soon as large enough, and get off the largest berries first. I go over all the bushes, choosing those with the heaviest crop first, and continue this all through the season till ripening begins. This helps to relieve the bushes and causes them to crop heavily every year. It helps in another way—namely, gives them an opportunity to produce berries of the highest

flavour for dessert. I think that when a tree or bush has a too heavy crop the flavour is very poor. Some kinds are not worth growing for dessert, as they have no flavour, although they may be kinds that swell into a usable size early. Industry all will admit is a good kind, more especially for early work, but for flavour I consider it second-rate. A recent writer spoke highly of Whitesmith, and I quite agree with all he says. The late Mr. Wildsmith considered this one of the best for flavour. I have it now (end of July) in fine condition. Another kind I can strongly recommend is Hedgehog, a green hairy kind, not a large berry, but of the very best flavour. It is a good companion for Warrington, which is a splendid late kind. Ironmonger is a fine-flavoured kind. Early Yellow is fine when grown on strong bushes and well thinned in a green state.

J. CROOK.

#### PEACHES AT ORCHARDLEIGH.

I RECENTLY visited the gardens at Orchardleigh Park, Frome, the residence of the Rev. W. Duckworth, in which are many features of interest. What to me appeared a very prominent one was the heavy crop of ripe Peaches in the earlier of the two houses devoted to them. The structure, which would appear to have a long history, would seem to be well adapted to the trees under notice, judging from the very heavy crops borne annually by them and the high quality of the fruit. The two houses are about equal in length, one having a south-eastern aspect, the other facing south-west. The early house is some 90 feet in length by about 9 feet or 10 feet wide, and the crop borne by the half dozen trees therein was remarkable. Over 2000 fruits fit for dessert will have been gathered ere this beyond the many dozens of smaller ones used for preserves, of which no record is kept. But for the fact that medium-sized Peaches are the most appreciated, there is abundant evidence that very fine fruit might be produced with less strain on the trees, although these show no loss of vitality from the abundant crop they have carried. Two large trees of Royal George, one of Bellegarde, and some unnamed sorts were the varieties planted, the first-named being the most remarkable. The houses being narrow and lofty, they are furnished with front trees only. Mr. Clarke, the gardener in charge, evidently takes great pride in his trees, pruning away all old and useless bearing wood as soon as the crop is cleared, and in the winter the roots have the same careful attention in the removal of much exhausted soil, and new turfy mixture. This is not merely placed on the surface, but incorporated with the old soil to the depth of the border, and both the trees and crop speak volumes for the soundness of the treatment they have had. Mr. Clarke is favoured in having an abundant water supply, and the total absence of red spider shows that he does not stint water either at root or branch.

W. S.

*Wills.*

**Strawberry Latest of All.**—I was surprised to read of "R. D.'s" failure with the above Strawberry. With me it has cropped remarkably well this season. I consider it one of the finest flavoured and largest midseason varieties yet introduced. The soil here is very light and naturally poor, resting on sand, not an ideal one for Strawberry culture. I also find it withstands the drought well. Vicomtesse H. de Thury and Sir J. Paxton also do well here. I have discarded both Noble and Laxton's Competitor as being deficient in flavour, the latter, though an enormous cropper, being one of the worst flavoured Strawberries I ever tasted. The fruit is large, but very soft, and hollow in the centre.—G. W. HAXON, *Fowley Park, Liphook, Havts.*

—At p. 64 "R. D." complains of the behaviour in his own garden of this new Strawberry, and asks if others have found it unsatisfactory. I obtained plants last autumn which were small and badly rooted, yet in spite of this drawback they made good headway, and by

November had grown into ordinary-sized plants. This summer they have fruited well, and for the most part the fruit has been fairly well shaped, although I do not consider it one of the handsomest Strawberries. I have not seen any trace of the fungus "R. D." complains of, and I consider the flavour good for a late variety, although the slight muskiness perceptible might not be cared for by some. I think it would be a good variety for planting on a north border. It grows freely and produces abundance of fruit. My soil is light.—J. C.

**Potting Pine suckers.**—Where the old stools of Queen Pines have been well nourished, the suckers should by the beginning of August be stout and vigorous. They should be twisted off, not drawn out from the parent plant, using a leather glove for the purpose, carefully trimmed with a sharp knife and inserted, the largest into 8-inch and the smallest into 6-inch pots, using a compost of good sound fibrous loam, to which may be added a little bone-meal and charcoal. Animal manure is best avoided at this stage. The potting stick must be freely used, a firm condition of the soil being necessary, as if this is in a proper state—neither too wet nor too dry—water will not be needed until more roots are forming. If, however, potting is loosely performed the soil soon dries, rendering water necessary, which may result in partial or complete rotting of the base of the sucker. Potting completed, they should be transferred to the plunging bed. I prefer a sunk pit for suckers, as here the atmosphere can be kept more moist than in ordinary fruiting houses. The roof should be furnished with a roller blind, as the suckers need shade in sunny weather. Good Oak or Beech leaves are preferable to tan. Atmospheric moisture must be supplied by frequent dampings and by keeping the evaporating pans constantly filled. The foliage each sunny afternoon should be lightly syringed. Air must be admitted cautiously until new roots are formed, but a chink must be given on fine days to sweeten the house and lessen the liability to drip. As soon as the plants become established shading may be dispensed with and each plant well moistened. A bottom heat of 90° is a good one for suckers.—J. C.

THE LOGANBERRY.

I HAVE read with interest the remarks on the Loganberry in recent numbers of THE GARDEN, also the paragraph on misleading descriptions on p. 92 of the recent number.

On p. 50 in your number for July 17 I observe that the Loganberry was given an award of merit by the fruit committee of the Royal Horticultural Society, and the name of "Strawberry Raspberry" is given as a synonym, but this must be a mistake, though it does not appear to have been noticed. I received some months ago a plant of each of three new fruits advertised. These were the (1) Loganberry, described as a true hybrid between the Raspberry and the Blackberry; (2) the Golden Mayberry, said to be a true early yellow Raspberry with a tree habit; and (3), the Strawberry Raspberry, said to be a hybrid between the Strawberry and the Raspberry, of Japanese origin.

I observe that "S. W. F." in his remarks on misleading descriptions, speaks of his plants supplied under the names Golden Mayberry and Strawberry Raspberry, proving to be identical when developed. I conclude that he must have had plants of one kind sent for the two. There is no resemblance between the two plants received by me under the names mentioned. The Strawberry Raspberry seems to have a very intermediate appearance. The leaves remind me of those of some Spiræas, but the stalks are prickly. My plant started well, but has not fruited, and appears to be making little progress. The Golden Mayberry is a more healthy plant, but shows no sign of fruit as yet. Its leaves in shape are more like those of Gooseberries than those of Raspberries, but longer, less spiny, and more pointed. It is evidently more of a bush than the ordinary

Raspberry, but at present it is too small to form a very decided opinion upon. The descriptions referred to by "S. W. F." may prove exaggerated, but hardly so much so, I think, as he has inferred.

As to the Loganberry (or Blackberry Raspberry), I have a nice healthy plant. It has produced one good fruit with a wine-like flavour, and another is being developed at the tip of a leading shoot. I observe in Hooker's "Student's Flora of the British Islands" (1870), p. 110, under the heading sub-sp. *Cæsius* (Dewberry), the remark "R. pseudo-idaus, Lejeune, is probably a hybrid with R. *Idæus*." It would, therefore, appear that hybrids between the Dewberry, a form of the European Blackberry of marked character, and the Raspberry occur even in a wild state. It is not, therefore, so very surprising that the Raspberry should have been successfully, though it appears inadvertently, crossed with an American form of Blackberry. No doubt it is only the commencement of further improvements.

Chamonix, Teignmouth. EUSTACE F. CLARK.

APPLES AND PEARS FOR EXPOSED SITUATIONS.

WOULD BE planters of Apples and Pears are often debarred from carrying out their wish on account of the high and exposed position of their garden, and the fact that the soil is heavy and retentive, being under the impression that nothing but cider varieties of Apples and stewing sorts of Pears will do any good under such conditions. When, however, one meets with instances where even so-called delicate dessert Apples and capricious Pears are growing freely and bearing profusely under just such conditions, one is apt to come to the conclusion that after all it is to a great extent a matter of getting the young trees acclimatised, more, in fact, than any particular selection of sorts. An account of the collection of Apples and Pears growing at Hillside, Newark, may prove instructive generally. Hillside stands very high, and although a good deal of fresh opening material was added to the staple when the place was made, the natural soil is strong in the extreme and the subsoil by no means warm. Apples are grown in bush, pyramid and espalier form, and Pears on espaliers and walls. On espaliers the Apple that surprised me most was the old Ribston in fertile condition, and free from its common enemy even in light warm soils—canker. Cox's Orange does equally as well, and having tasted the fruit I can answer for the quality. Another so-called capricious French dessert Apple, and one which I failed after much trouble to grow in a light warm soil on a west wall, is Calville Blanche. The espalier tree at Hillside grows freely enough and crops almost annually, the fruit ripening up most satisfactorily. Lord Burleigh, an excellent medium-sized dessert variety, in season from November to March, is constant and good. King of the Pippins, capricious in many gardens in the sunny south, produces at Hillside some of the finest fruit I have ever seen. Bramley's Seedling, Bedfordshire Foundling, and Mère de Ménage do grandly as orchard trees. I also noticed a young tree of Newtown Wonder, which is sure to become a popular Apple, doing well, also one of Bismarck; both of these were grown as espaliers.

Pears are represented by Doyenné du Comice, Marie Louise d'Uccle, Pitmaston Duchess, Brockworth Park, and Princess on an east wall, the growth being robust and the fruit large and good. Those on espaliers are Belle d'Abries, a late spring Pear of large size, and in good seasons average flavour; Doyenné d'Alençon, a December to January variety of delicious flavour. This Pear is generally supposed to require the highest culture, but at Hillside, under the conditions described, it is excellent. That generally reliable late Pear, now grown by almost everyone, Olivier des Serres, is quite at home in the strong soil of the Hillside garden, the flavour being exquisite during February and March. That seldom-seen Pear *Passé Colmar* is also well represented, the Quince stock suiting it best. Josephine de

Malines in this strong soil produces extra large fruits and plenty of them. As cordons, Doyenné Boisselot, Beurré de St. Denis, two varieties procured from the neighbourhood of Paris, are fruiting nicely, and what surprised me as much as anything was to find the delicious, but often unsatisfactory, Thomson's doing well in every way. J. C.

APPLE CROP IN 1897.

IN this district it cannot be said that there is anything like a full crop, though in some places there is a fair amount of the early soft varieties. This no doubt is owing to the unfavourable weather in spring during the time the trees were in bloom. In some orchards there are heavy crops of Keswick Codlin, The Queen, Ecklinville, Worcester Pearmain, and Pott's Seedling, but as none of these are keeping varieties there may be a glut of them in the market, while later on good fruit will be scarce. With me Ribston Pippin, Claygate Pearmain, and some other choice kinds are carrying a fair crop, but many of the best kinds fail to give any fruit. There is but little difference in this respect between old and young trees, though the latter are producing by far the finest fruit. Warner's King, King of Pippins, Alexander, Stirling Castle, Irish Peach, Yorkshire Greening, and Northern Greening have all full crops with me, but in some orchards they are by no means plentiful. Lane's Prince Albert has never failed to give a good supply of fruit, and this season is no exception, as many of the trees are fully laden with fruit. It is often said that late-flowering varieties are more likely to produce a full crop than the earlier ones; this is not so this season, for Irish Peach, which is one of the first to bloom, has a fine crop of fruit, while Court Pendu Plat, about the latest of all, has scarcely an Apple on it. There is much to be said in favour of shelter for fruit plantations. Here a tree of Blenheim Orange that is sheltered from the north and north east by some large Fir trees is carrying a full crop of fruit, though others that are more exposed in the same orchard have scarcely an Apple on them. That our orchards in many instances are too exposed there can be no doubt, and those who are desirous of obtaining the finest results would do well to take this into consideration when planting is contemplated. The protection ought, however, not to be too close, as the roots from such trees would be a serious hindrance to the growth of those it was intended to encourage. Caterpillars have been less troublesome this season than for some years past, so that most of the trees have made a free, healthy growth. Canker in some instances is a serious drawback, for just as the trees are of a useful size the branches die off wholesale. This is particularly so with Stirling Castle, Ribston Pippin and Hawthornden. Bramley's Seedling is of no use at all with me. The tree is of rampant growth and scarcely ever has any fruit. This season there are not a dozen Apples on a whole row; the same may be said of Annie Elizabeth and Flower of Kent. The most useful varieties I have are Ecklinville, Stirling Castle, Lane's Prince Albert and Wellington, as it is seldom that any of them fail to crop freely. Keswick Codlin is usually a free cropper, but the fruit is too small. It is, however, not well to depend on too few varieties, particularly where a constant supply has to be kept up, and those who have room would do well to make a selection of at least two dozen of the best. H. C. P.

Buxted Park, Sussex.

**Scarcity of Plums and Apricots.**—So far as midland orchards and market gardens are concerned, so great a scarcity of Plums and Apricots has not been known for years. In the majority of gardens the Apricot trees are absolutely bare of fruit, and the same may be said of Plums. Even the hardy, free-bearing Victoria has failed to yield. The cold winds which prevailed for several weeks just as the Apricots were in bloom were no doubt the cause of the fruit failing to set

even where fish netting was used. Those who wish for Apricot jam will be forced to rely on foreign fruit, as neither the fruiterers' windows nor the open markets of the midlands will this year be able to supply home-grown fruit. No fruit is missed by lovers of high-class preserves than the Apricot.—C. C. D.

**Peach notes.**—I beg to thank "A. W." and "G. W. S." for their kind answers (p. 382) to my query about the selection of Peaches. "A. W." desires to know what difference there is between Royal George and Madeleine Rouge de Courson. I have waited till the fruits of these two varieties ripened. On trees bearing their first good crop I confess I cannot see any difference. The fruits on both are rather large and highly coloured. They have small flowers. During their blooming it seemed to me that the blooms of Madeleine Rouge de Courson were somewhat larger and of a different shade of colour, but it may be that I was mistaken. In the growth and leaves I cannot detect any difference whatever. I must add that in the first house, where the Royal George in question has as companions Amsden and Hale's Early, the first ripe fruits of Amsden were gathered on May 30, Hale's Early about two weeks later, and Royal George will ripen in a few days, that is, about July 25. In the second house, where Madeleine Rouge de Courson is grown with Montague Double and Grosse Mignonne Hative, and which has been started three weeks after the first house, Montague Double has given the first ripe fruits a few days ago, viz., July 17, also earlier than Royal George in the first house, and Madeleine Rouge de Courson will be ripe a few days later than Royal George. "A. W." advises me to take Dr. Hogg or Dymond; "G. W. S.," Noblesse, Dymond, Crimson Galande, and Barrington. Perhaps it would be more advisable, instead of planting three trees of one variety, to take three varieties. And if so, which of them? For instance, Dr. Hogg, Dymond, and Barrington; two trees of one kind and one tree of another. Are there other Peaches with larger fruits than the three named?—R. K., *St. Petersburg.*

## FLOWER GARDEN.

### HYBRID NYMPHÆAS AT KEW.

MANY of the lovely hybrid Water Lilies that M. Latour-Marliac has given to our gardens are now to be seen in excellent condition at Kew. All the varieties named below are to be found in the brick and cement tank at the extreme end of the herbaceous ground, which, to say the least, is utterly unworthy the beautiful set of plants it now contains. It may, however, be urged, and that with a good deal of reason, that in a tank of this kind visitors can better see the beauty and value of the plants individually than could be secured were they growing in an open pond or lake. The importance of the plants themselves would, however, appear sufficiently strong proof that a special tank or pond should be a necessity, so that the handsome specimens that now represent some of the best kinds may have still wider scope for development, and year by year see them attain to greater size and beauty. It is obvious that many of the larger and bolder forms are getting too large for the quarters to which they were consigned a year or two back, and that unrestricted play for root and branch alike would contribute materially to their future welfare. So far, however, the present quarters have been useful, inasmuch as they tend to illustrate that such things may be grown to a considerable size even without lake or pond, a piece of instruction that is doubtless wanting in many directions, and apart from this the plants are always at hand for examination. One cannot but view with satisfaction the general vigour and health-

fulness of these newer kinds, a condition of things certainly not contributed to by the excellence of the water in the tank in question, which is open to much improvement. That the dense carpet of vegetation clothing the sides of the tank has nothing to do with the army of aquatics therein is abundantly proved by other open tanks that contain none at all, and while it does not beautify in the least, it is satisfactory to know that it does no harm to these beautiful hybrid Nymphæas themselves. As my visit was rather late in the day I did not make a complete list, though the following may be accepted as the most conspicuous at the moment, and in the course of a few days, with a much larger number of blossoms expanded, these lovely flowers should be worth a long journey to see.

**NYMPHÆA MARLIACEA IGNEA** is very fine, with petals of a deep rosy crimson hue, and green sepals margined with rose and white. The foliage, too, is very beautiful, the young leaves of a deep bronzy hue and the older leaves blotched with crimson.

**N. M. CARNEA**, with a dozen or more of its buds in various stages, promises a long and welcome display of its flowers; indeed, it is the great profusion of flowers, at the moment indicated by a host of appearing buds, that gives these lovely Water Lilies a value of their own till far into the early autumn months. The lovely flesh tint of this kind is very beautiful.

**N. M. ALBIDA** is the giant of the white-flowered kinds, the handsome flowers reaching from 8 inches to 12 inches across; the growth also vigorous, as also very dense on the water's surface.

**N. M. FLAMMÆA** has many buds, but no expanded blossoms at the moment. The flowers are pink at first, and afterwards deepen to red in the centre. This kind is also vigorous and rather spreading in habit.

There are also several forms that belong to the *N. Laydekeri* group to be seen here, notably

**N. LAYDEKERI FULVA**, with several large buds that will open in a day or two; the blossoms are red on a creamy yellow ground, and have large mottled leaves.

**N. L. LILACEA**, while not large in size, is very charming and flowers abundantly, something like eighteen flower buds being noted. In growth this is very compact, while the purple-bronze of the young leaves makes it even more attractive.

**N. L. LUCIDA** has very large flowers of rose, vermilion and white, with a spreading habit of growth. In this, again, the young leaves are of a dark bronze, while the more mature leaves are green, with irregular, longitudinal blotches of dark chestnut near the margin.

Apart from those named I noted the dwarf-growing *N. pygmaea helvola*, a dainty kind in every way and especially suited to small aquaria, and *N. odorata sulphurea grandiflora*, with long-stemmed blossoms of large size, together with the older forms, such as the curious *Nuphar advena* and the common white Water Lily, *N. alba*, and its variety *candidissima*; this last still a fine and useful kind, with large pure white blossoms that are very striking. All these promise a display of blossoms for some weeks to come. These newer hybrids are invaluable, and anyone interested cannot do better than visit the Kew collection now in flower to see for himself what has been accomplished here under quite ordinary conditions of culture.

E. J.

**Eccremocarpus scaber.**—It is curious how many flower lovers fail to recognise this old inmate of our gardens, and which not so many years ago was extremely popular with window gardeners. The half-hardy climbers were once in great demand, and I should like to see them again come to the front. Planted against a wall or

fence, or staked in the way of Sweet Peas, they produce an effect which can only be obtained by things of similar growth.—J. C. B.

**Linum sibiricum.**—This slender-growing, hardy annual, bearing a profusion of light blue flowers, and its white variety I recently noted in fine bloom. One is a counterpart of the other, except in the difference in the colour of the blossoms, both growing to a height of 2½ feet. Seeds are readily obtainable, and they may be sown now, or at any time which is convenient. Preference is given to sowing in April and May, as then strong plants can be secured for flowering the following season. The blue form is preferable to *L. perenne*, which it resembles, but is deeper in colour.—R. R.

**The Tulip Poppy.**—This, known as *Papaver glaucum*, is a very striking annual Poppy growing to a height of from 15 inches to 18 inches, to all appearance much more successional in blooming than most of the annual varieties, the colour rich, bright reddish-crimson, the inner petals taking the form of a Tulip, hence its name. A small bed of this, or plants dotted about among other annuals are very effective. It is perhaps best to sow the seeds in the open and allow the plants to stand and bloom, but some thinning out is required if a good head of bloom is desired. Both this and the fine types of *P. Rhæas* do not transplant well, and though some succeed many fail, and that is why sowing where the plants are to stand is so much recommended. The better the soil and the more room given to individuals assist to produce not only fine, but successional flowers.—R. D.

**Carnation Salisbury.**—Those who value Carnations for their usefulness as hardy border flowers will find this very serviceable. It is very hardy, of free, vigorous habit, flowers profusely, and has stiff, erect flower-stems that do not really need support. The blooms are of medium size, but of good form and pure. It is perhaps the best white Carnation that can be grown for supplying a quantity of cut bloom. We want more Carnations of this description, and some experienced raiser should devote himself to raising varieties that bear their flowers on stout stems that require no support. Varieties like *Red-braes*, for instance, have stems so weak that the plants have to be gone over several times to maintain the flowers in an erect position. This renders Carnation culture rather expensive.—J. C. B.

**Lilies.**—I imported Lilies of various sorts from Japan last autumn. They were all planted in the same soil, a mixture of loam, peat, and silver sand, and are all doing well except *L. Batemanæ*, which looks very unhealthy. The leaves are turning yellow and some of the bulbs are actually dead. Can anyone suggest what I ought to do to save the remainder?—HIBERNIA.

\* \* It is not mentioned whether the plants of *Lilium Batemanæ* referred to are in pots or in the open ground. If in pots, it may be pointed out that this Lily, as a rule, resents such treatment; hence it cannot be recommended for pot culture, but in the open ground imported bulbs generally do well and flower in a satisfactory manner. The conditions most favourable to it are an open soil, such as a mixture of loam, peat, and sand, a well-drained spot, but at the same time one that is not parched up during the summer, and a partially shaded position, as it dislikes exposure to the full rays of the sun throughout the entire day. Little can be done now to save the remainder, the only thing being to leave them untouched till the stems decay, when they should be turned out of pots or dug up, according to the way in which they are situated, and every bulb thoroughly examined. Those that are decayed had then better be thrown away, while the sound bulbs can be stored in sand kept slightly moist till planting time. The advice to leave them untouched till the stems decay does not mean that if in pots they should be kept without water, as undue dryness will quickly injure any Lily bulbs.—H. P.

## ENGLISH GARDENS ABROAD.

SOME of the most delightful things in flower gardening are to be seen in the gardens of English people living in Madeira, the Riviera, Algeria, and countries generally permitting of beautiful flower gardening during the winter and with a season of many flowers throughout the spring. These are real gardens varied and full of beautiful colour, yet without any trace of the barren monotony characteristic of most gardens at home. The generally picturesque nature of the ground, the presence of graceful fruit and other trees, and the absence of any pretentious attempt to conform the whole to one set

mate makes the garden beautiful, as the way of planting is the main source of beauty here.

Borders are thick set with the good foliage of the Iris in many forms, and particularly the winter-flowering Iris, which has its home in Algeria, and its white variety found by Mr. Arkwright, both very charming plants. The Pelargoniums are in lovely bushes in light or shade. How well they look as hedges or groups, while Datura, Palm, Jasmine, Acacia, Fig, Lemon, Magnolia are happy in the sun, with masses of Cineraria here and there in half-shade, with many Violets, and even wild flowers of the country. Bougainvilleas and handsome Bignonias grace the

Some of the most beautiful garden effects we have ever seen were here, all the finer from the background of high cliffs above clad with evergreen Oak, Pine, and wild Olive, but the best lesson is not from the varied life in the garden so much as from the happy and natural way the whole is disposed.

In this way we have variety as well as pictures—as much variety as may be wished, of which there is an example in

## MR. HANBURY'S GARDEN AT LA MORTOLA.

This fine garden, the contents of which are so very interesting from a garden as well as a botanical point of view, we hope to be

*The Palazzo Orengo at La Mortola, Italy. From a photograph sent by Mr. Hanbury.*

idea lead to the simple and artistic garden. The garden of Mr. Arkwright at Mustapha, near Algiers, is a good example of the English garden in other lands, a garden full of beautiful things, and withal so placed that pictures are seen at every turn. Noble Tea Roses like Chromatella are fountains of bloom, sometimes running up a tapering Cypress, and sending out of it far overhead graceful shoots laden with noble flowers. Lamarque, the noblest of white Roses, grows and blooms about as freely as the Elder tree does at home. Many Tea Roses of all sizes are here, sometimes kinds are superb that rarely open well with us at home, such as Cloth of Gold and Jean Ducher. But it is not only the cli-

walls in free and pretty ways, while here and there the Algerian Ivy is seen, a noble climber, the fine qualities of which are not in the least affected by the hot sun in the summer here. We have never seen such rich banks of this Ivy as about Algiers; it ascends to high parts of the mountains there, which look arid enough and are terribly hot in summer. No one need despair of gracing a dry bank with a fine thing who takes the Algerian Ivy for that purpose. It may be its long sojourn in so dry a country has prepared it better for its work in the sun than the forms of the Ivy from the cooler north. There are several varieties of Ivy wild in Algeria besides the one we know as the Algerian Ivy.

able to discuss in more detail at a future day, and merely now give a short account of its creation. The variety is not in itself so much worth seeking as beauty, which is just what we lose when we commit ourselves to any one way of flower gardening. To be free to add or plant at almost any time of the year is a great advantage; whereas in the common flower garden the whole is set out and taken up at fixed times. The result is a dreadfully fixed one too, and if any beautiful bush, or bulb, or flower happens to come in our way that does not fit into the wretched system, so much the worse for it.

The fear of anything like a bush or low tree that governs the idea of many flower gardens at home at present does not exist

here, so that we have light and shade, many bushes and even low trees that give chances for surprises and changes. This is partly owing to the warmth which allows of the growth of many pretty bushes that may well grace a flower garden, but once free from the idea that a flower garden must be a flat surface seen at a glance, there would be no real difficulty in carrying out like ways of planting in our climate in which so many lovely bushes grow if we give them a chance. One minor charm of these English gardens abroad arises from the fact that any necessary stone-work is done in a simple way by the garden men. As the ground is often steep, steps and little walls or protecting corners are often wanted, but whenever the native gardener wants anything of this kind he does not go through a circumlocution bureau for inspiration and drawings to scale, but builds what he wants in a simple ready way with the stone nearest at hand, and the result is much better gardening than more elaborate and costly work.

La Mortola is the name of a very ancient Italian village about three miles east of the gorge of the Pont St. Louis, which forms the boundary between France and Italy. Cap Martin on the west and Cap Mortola on the east make the semi-circle known as the bay of Mentone, a lovely and perhaps the best sheltered spot on the Riviera, where the mildness of the climate is attested by the fact that the Lemon flourishes perfectly, and is the ordinary crop grown by the peasants, and where many species of Palms and Bananas withstand the winter without any protection.

The Palazzo Orenco, so named after the Orenco family, who owned the house for two centuries after 1620, when it passed to them from the noble family Lanteri, of Ventimiglia, was purchased in the year 1867 by Mr. Thomas Hanbury, an English merchant at Shanghai, who traces his descent from the Hanburys, formerly resident at the villages of Hanbury and Feckenham, in Worcestershire, and afterwards at Pont-y-Moil, in S. Wales.

Mr. Hanbury, finding no garden at the Palazzo Orenco in 1867, immediately proceeded to transform the steep hillside between the seashore and the Corniche road above by planting an immense variety of exotic trees and shrubs which he judged suitable for the climate. In this he was aided by his brother Daniel, the well-known pharmacologist, who, however, died in 1875.

La Mortola soon became well known to the public as the largest and most beautiful garden on the Riviera, and to scientific botanists as a garden of acclimatisation, where certain plants might be found flourishing in the open air which elsewhere in Europe required culture under glass. Although the climate is excessively dry in summer, it is found to be well suited to the flora of Australia, Mexico, the Cape, and the Canaries, and the collection numbers at present about 4000 species, all living in the open air.

The garden and grounds, which are about 100 acres in extent and occupy the entire cape, are thrown open to the public twice in the week. They are traversed at right angles by the ancient Via Aurelia, the only road along the coast in the time of the Romans and down to the early part of this century. A visitor in the month of January will find 400 to 500 species of plants in blossom, but the garden is seen to the greatest advantage in March and April. Invalids should be warned that the descent from the entrance gates to the sea is about 350 feet, and that no carriage can enter the grounds.

W. R.

**Phloxes.**—Where facilities exist for a good surface mulching and copious supplies of water,

given a light, dry soil and a hot summer, or on a soil naturally well adapted for their cultivation, I would advise the annual treatment of Phloxes, as spike and individual pips are certainly finer on young plants, but if after putting out the young plants they have to shift for themselves in a rather poor, light soil, I should say the best results are obtainable from established stuff. Naturally it is not advisable to let them occupy the same quarters for many years, and immediately there are signs of deteriorating, the old clumps must be removed and their number made up from young stuff, of which a supply should be always on hand. The above remarks in connection with the younger plants and their inability to stand the combination of a hot, dry summer and a light, dry soil were borne out this year by a small collection of newer varieties planted rather late, and which I have had to mulch and water to keep on the move. Good treatment is also conducive to a greatly prolonged flowering season. Touching this latter matter, it may be well to remind growers who are trying Phloxes for the first time that the pips are set on the spike very thickly. A great number of unexpanded flowers are waiting their turn, and as the pips go off they should be nipped out with the finger and thumb to allow of the development of those in the background—an apparently trivial matter, but, like good treatment, tending to greatly prolong the season. It will be found advisable to stake some of the newer varieties in their first season if the weather is rough and the situation very exposed. I do not like to do this more than is necessary, but it is preferable to finding some of one's finest spikes prostrate and probably snapped off close to the ground. No garden of any size should be without two or three beds of Phloxes, and a mixture of the early and late-flowering sections is advisable not only to prolong the season, but also that the difference in the heights may prevent a formality inseparable with a collection all of nearly the same size. A variety just now (July 20) at its best is Snowdon, a splendid truss with pure white flowers, the pip large and perfect in form.—E. B. C.

#### RAYLESS TUFTED PANSIES.

MY remarks on Tufted Pansy Waterloo in THE GARDEN of June 12 were founded upon a trial of a young batch of plants alongside a smaller number of two-year-old plants. The former were propagated late last autumn, and so far have been very disappointing. Comparatively little growth has been made, and the quantity of bloom has been very meagre. On the other hand, the two-year-old plants have done fairly well, each plant giving a nice lot of blossom and of a shade of blue that is now very welcome. Although these two-year-old plants have much more vigour than those flowering for the first time this season, there is something still lacking in the constitution of the plant, and which, I fear, we shall never get. Regarding several other varieties raised by Dr. Stuart, they are in almost every instance typical of what a Tufted Pansy should be. This is especially noticeable in plants grown on a second and third year, the plants being literally covered with charming medium-sized blossoms, and for general garden decoration invaluable. I quite agree with all that is said of Blue Gown. My old plants are from a foot to 18 inches in diameter, beautifully tufted and compact. Such a lot of plants shows well the value of this kind when cut back late in the autumn and allowed to flower freely during the spring and summer months. Florizel is indeed a gem, the plant blooming freely, the blossoms of large size, habit wonderfully dwarf and compact, while the colour—blush-lilac—is almost unique in these flowers, and very effective in the border. Christiana has been very fine for months past, and should be placed in the front rank as a creamy white bedding sort. The growth is spreading, the flowers large and of good form. Princess Louise, a new rayless yellow sort sent out by Mr. Andrew Irvine last season, is a distinct acquisition. Both this year's and last year's plants are now at their best. The blossoms

are only of medium size, but the colour is so rich and clear that their effect in the border is very pronounced. The habit of this sort is also very dwarf and compact. *Rosea pallida* has not made over large two-year-old plants with me, but this variety, like Florizel, is wonderfully free. Early in the spring there is very little difference in these two flowers, but as the season advances the colouring becomes quite distinct, and the beauty peculiar to each variety fully appreciated. As an individual flower Border Witch is very fine when the climatic conditions are not too warm, and because of this the best flowers are to be had early in the summer or during the cooler weather of late summer or early autumn. Two-year-old plants of this variety have been very fine for some time, but it is essentially a flower for the exhibition table, its want of fixity of colour telling against it for bedding. I have a number of plants raised from seed, of which Sylvia was one of the parents, and among these there are some very beautiful sorts. The blossoms are quite equal to, but not better than those of the parent, but they each have some distinct characteristic. In some instances the blossoming period is earlier than usual, in others the display may be later, and from one of these plants I gathered a beautiful spray of blossom during November last. The two chief properties are, however, possessed by these plants, viz., fixed colours and compact and spreading habit of growth.

There is a bright future in store for those interested in these plants for beautifying the garden.

C. A. H.

#### DURATION OF LILY BLOOMS.

WHERE a collection of Lilies is grown, the length of time that the flowers of some species will remain fresh and bright compared with others is very noticeable, while even the different varieties of one species vary a good deal in this respect. In the case of the upright cup-flowered section the blossoms of the different forms of *L. davuricum* or *umbellatum* are soon past their best, while those of the allied *L. croceum* and *L. bulbiferum* remain fresh and bright for a much longer period. Among the numerous varieties of *L. elegans* or *Thunbergianum*, the most fugacious of all is *lateritium* or *biligulatum*, a brownish red-coloured form, which in two days loses a good deal of its beauty. The bright crimson *Van Houttei*, on the other hand, is much superior in this respect. One of the showiest of all the *elegans* group is *bicolor*, a rich yellow flower flamed with red, but its beauty is very short-lived, the petals being much thinner in texture than in many others. I have been considerably impressed during the present season with the great length of time that the gracefully disposed nankeen-coloured blossoms of *L. testaceum* retained their beauty despite heavy showers, a burning sun, and occasionally rough winds. In lasting qualities the flowers of *L. testaceum* greatly surpass those of the *Madonna Lily* (*L. candidum*), one of its parents, but, on the other hand, the second parent (*L. chalconicum*) is in this respect equal, if not superior, to any other Lily. The petals of this almost appear as if they are cut out of wax, so great is their substance; hence, though this Lily does not flower till July—the hottest portion of the year—they remain fresh a long time. Of another group with thick petals much the same may be said, but not to the same extent as in the case of *L. chalconicum*. This is the *Martagon Lily* and its varieties, with the allied Japanese *L. Hansoni*, all small and long-lasting flowers. One of the most striking of all the varieties of *L. auratum* is *rubro-vittatum*, in which the golden band, which extends down the centre of the petal in the normal form, is replaced by a broad crimson one. When first expanded the marked contrast between the glowing crimson and the rest of the flower is very striking, but after two days or so the red portion changes to a kind of brown papery tint, and the flower then loses a good deal of its effectiveness. The pure unspotted form known as *Wittei* or *virginale*, on the other

hand, remains clear until the petals drop, and it is certainly the most elaste and beautiful of all the forms of *L. auratum*. Many of the Lilies are of an average duration of bloom, and of them

know four varieties of *Sidalcea malviflora*, all distinct in appearance and character. (1) The type, with short, close spikes of dark pink flowers and a leafy habit,

early. (2) A rose-coloured variety, with long, loose spikes of large pale rose flowers and very few leaves: this I call Warley Rose, later than No. 1. (3) A dark-coloured variety, with large flowers and upright spikes, flowering later still. I first met with this in Dickson's Chester nurseries, and I call it James Dickson. (4) Var. *Listeri*, of which as yet I know very little. I have frequently raised 2 and 3 from seed, and find them true and constant.—C. W. Dob, *Edge Hall, Malpas*.

**Self Carnation Royalty.**—Let me commend this truly magnificent self Carnation to the lovers of what is good in this way. It was raised by Mr. J. S. Hedderly, Sneinton, Notts, an old Carnation grower, to whom we are also indebted for Sportsman, scarlet flake, a sport from s.b. Admiral Curzon, which originated as far back as 1885. Royalty is of a rose tint, a strong grower, free blooming, with fragrant, large, full flowers, and finely formed shell petals. It does not split its calyx, as is the manner of some. I can strongly recommend this fine self, having grown and bloomed it this season.—R. D.

**Primula Trailli.**—It appears to me that Mr. H. Selve-Leonard endeavours to confuse a simple issue by weaving about it a web of specious rhetoric. The matter appears to be obvious enough. Let me ask, Was any evidence forthcoming to the floral committee to the effect that there is a distinctly recognised species of *Primula* known as *Trailli*; and, secondly, did the specimen shown as *Trailli* "differ structurally more or less from those hitherto tabulated," entitling it to specific rather than to varietal rank? The floral committee assumed without evidence that the specimen was *P. Trailli*, and they exalted it to specific rank, though I called in question its distinctness from *P. involucrata*, and recommended that before recognising it as a species and granting it an award of merit it should be referred to some standard authority, such as Kew, to determine whether the plant was entitled to specific rank before it was accepted as a distinct species by the floral committee. That was my simple contention, and I think it unfortunate in the interests of Mr. Wilson, as well as for the credit of the floral committee, that that course was not adopted. When at a subsequent meeting I placed on the table a flowering specimen of *P. involucrata*, the committee, practically conceding the point that they had been too precipitate, recommended that *P. Trailli* should be referred to Kew, and thanked me for producing the specimen of *P. involucrata*.—R. DEAN.

**Fuchsias at Sandhurst Lodge.**—Few plants are more beautiful than these, especially when a suitable place can be given them. At Sandhurst Lodge groups are placed on the turf at good distances apart, 6 feet to 8 feet, so that the plants can be seen all round. These groups are placed on a sloping piece of lawn with a walk on the lower side. Many of these plants are very large, some being grown as standards and others as half standards. They are grown in pots and plunged in the turf. At the time of my visit they had only just been placed out, but from the clean healthy leafage and strong shoots I could see they would give a good account of themselves during the

summer. I observed many other plants were used for placing on the turf as big plants. Amongst them worthy of note were several kinds of scented *Pelargoniums*, such as *quercifolium*, *Shrubland Pet* and others. These were very large plants, 5 feet or so high.—J. CROOK.

SINGLE HOLLYHOCKS.

SINGLE-FLOWERED Hollyhocks constitute a very beautiful race of hardy garden plants, and are even more decorative than are the doubles. A double Hollyhock is of course the florist's correct form, and the fuller and doubler the petals the more is it liked. I find these singles growing almost everywhere in small gardens, especially in suburban districts. Recently when taken all over the Carshalton and Beddington district I found them cropping up in little gardens everywhere, exhibiting such varied and beautiful colours that I was charmed with them. We see in strains of these three or four times the variation in colours found in the doubles. The direction in which crossing in able hands should be directed is in enlarging the flowers, still further varying the colours, and in obtaining if possible distinctly fringed edges. One variety which I thought very beautiful had flowers of a glossy claret hue edged with white. It served to show what variations and markings in these singles are possible. I am glad to see

*Acacia cyanophylla* in bloom in April in Mr. Hanbury's garden at La Mortola. (See p. 97.)

*Fourcroya Bedinghausi* in bloom at La Mortola. (See p. 97.)

that seed can be purchased cheaply. That fact probably explains why these flowers are so largely found in small gardens, although it is also possible that neighbours seeing them standing up so very prominently in a local garden beg seed, and thus the plants are widely spread. That form of increase, however, is not likely to lead to high-class selection. It is a good time to sow seed outdoors now, or, indeed, it may be sown up to the end of August, the plants standing in the seed-bed all the winter, transplant-

there is nothing particular to say. As the summer's heat is on the wane when the blossoms of *L. speciosum* commence to expand, they, of course, last a good deal longer than many of those species that bloom during the height of the summer. In the open ground, however, the heavy autumnal dews frequently disfigure the later blooms. That the season of the year at which the flowers expand has a good deal to do with their duration is shown in the case of the Neilgherry Lily (*L. neilgherrense*), that will sometimes flower as late as November, when the blossoms will in a greenhouse last for nearly a month, yet blooms that open in August are no longer lived than those of *L. longidurum* under similar conditions. H. P.

**Sidalcea malviflora.**—Last autumn a variety of this was described with large pale rose flowers as having been certified under the name of var. *Listeri*. From the description I thought it the same as one I have cultivated for many years which comes true from seed, and which I have since last autumn distributed as var. *Listeri*, but Mr. Barr has now sent me flowers of var. *Listeri*, and I find it different from mine, especially in the colour of the stigma. I now

ing early in the spring to the borders, where they will flower. No plants should remain to bloom longer than a second season, as it is when standing too long in the same ground that the soil gets dry and impoverished, and the Hollyhock fungus preys upon the stems and leafage. The more branching the plants are the better, as numerous spikes of moderate height are better than are fewer very tall ones. I hope it will not be suggested that spikes of these Hollyhocks would look well at flower shows. I hope someone will take these single Hollyhocks in hand and improve them largely. There is no telling what may be ultimately evolved. Selection may do much, and inter-crossing perhaps more. A. D.

#### CARNATIONS.\*

THE Carnation to-day is one of the most popular garden flowers, and regard for it has entered so deeply into the hearts of flower lovers that no mere caprice of fashion will ever appreciably lower it in public favour. The early stages of its evolution into a flower of such varied beauty were hardly chance results, for we know the wild type and parent, and one may see it to-day growing upon old castle and fortress walls, as at Rochester, in England; whilst across the Channel, in Normandy, high up on the ruins of ancient fortresses, it lives on, braving the storms in winter, in summer perfecting its by no means attractive flowers and ripening seeds that find a suitable seed-bed in the flint masonry. Here it knows no spot nor rust, and caterwauls and wireworms have not to be reckoned with. Such are the conditions under which grows *Dianthus caryophyllus*, which botanists agree is the type and parent of the Carnation. The Carnation was cultivated in England during the reign of Edward III. (1327-1357). Chaucer mentions it in 1386, calling it the "Clove Gilofre." The modern name Carnation was mentioned by Henry Lyte in 1578. Gerard, in his "Herbal," published in 1597, mentions a yellow Carnation that a merchant of London procured from Poland, "and which before that time was never seen nor heard of in these countries." In the beautiful flower pictures of the early Dutch painters Carnations are unmistakably and admirably portrayed. To-day we have several distinct classes diverse in constitution, in habit of growth, period of blooming, form of flower, and variety of colouring. Most interesting and instructive especially is the latest acquisition of a race adapted to the requirements of the cultural systems practised in this country.

It will be interesting to growers in this country to briefly review the several classes of

#### EUROPEAN CARNATIONS.

The earlier Carnation fanciers appear to have favoured the bizarre or oddly coloured varieties, for as early as 1769 the Carnation was classified according to colour vagaries under the names of flukes, bizarres, Picotees, and Painted Ladies. The varieties belonging to the three first named classes found many admirers; they became "florists' flowers," their improvement was taken in hand by a small body of enthusiastic florists who set about evolving their ideal Carnation in form as precise and perfect as though cast in a mould, its petals smooth and without fringed edges, the several colours as clearly and as sharply defined as though lined out upon a colour chart, and to assist the eye in seeing all the good points of the flower when placed upon the exhibition table, its petals were severally arranged with tweezers, supernumeraries with-

drawn, and when the "dressing" was complete the bloom was inserted in a round white paper disc. You may see this done yet at the annual shows of the English Carnation Society, and there is a tolerably large body of enthusiasts who take a delight in it, but it is not the type of Carnation that appeals to the great flower-loving majority. It represents, however, many years of patient work, and it is a wide gulf that separates the single one-coloured wild Carnation from the most perfect refined high-bred bizarre or fluke of to-day. A very old class is the Clove, the name having reference to the clove-like odour of the flowers, which are self or one-coloured. There are now many varieties belonging to this class in which we may embrace all selfs, and it is these that have been mainly instrumental in bringing about the greatly extended popularity of Carnations that marks the last decade. The flower, quaintly variegated in colour, did not appeal to many, but when it was to be had in clear, bright, and simple colours, wedded to a charming fragrance, it soon came into general request. In some of the best English gardens the Carnation, in fine self-coloured varieties, has been elevated to its rightful place as second only to the Rose, which it succeeds, in time of blooming. Carnations are distinctly summer bloomers, with a few exceptions, and to what extent they are fitted for outdoor culture in this country has yet to be determined. At a future date I may be able to speak of their behaviour, having some on trial. The so-called Tree or perpetual-flowering Carnations form another distinct class. In England they are grown in pots and pass the summer in the open air, being housed for the winter flowering. In their season of blooming, and its long continuance, they possess fixed characteristics. This class has its counterpart in this country, embracing those varieties now flowering on the benches. But whilst there are wintering-flowering Carnations in England and America, they form two well-defined classes.

The history of Carnation culture on this side of the Atlantic should not be hard to write. I believe that these American varieties sprang from the perpetual-flowering varieties raised and sent out by M. Alegatiere in France, as also did most of the winter-flowering kinds first grown in England. The varieties of European growth make large plants. They have a main central stem, and I have often seen plants 3 feet in height well furnished with side shoots, which produce the flowers on comparatively short stems. Here we have varieties of a close and tufted growth naturally inclined that way, and rendered more so by summer pinching, and when they flower, the flower-spike disbudbed to the terminal bud attains a length of from 12 inches to 24 inches or more, according to the kind, and if well grown the stems are strong enough to stand erect and support the flower. These stems are cut right down to the base, and when cut are quickly succeeded by others, and this continues for months. All the varieties in cultivation here partake of the characteristics of the earlier types of Carnations in having fringed petals and more or less of fragrance in the flowers; in short, they are more satisfying to the majority of flower lovers than the smooth-edged, geometrically-formed type of flower. So much for the American Carnation as a distinct type.

We may now briefly look at some of the individual varieties. It is not my intention to say much about them, for those generally grown to-day are superseded and discarded a year or two hence by novelties not always of superior merit. In the matter of cultivation, we have first to consider the

#### PROPAGATION.

If you would have the finest flowers a year hence begin now with select cuttings for stock. Choose for cuttings only healthy shoots from healthy plants. If you observe a plant with flowers deficient in size or colour avoid it, and you will then have no cause to complain of deterioration of varieties in cultivation. After the cuttings are taken get them into the cutting bed, which should be composed of good sharp sand. The cuttings need little preparation, but it facilitates rooting to shorten back the leaves by cutting off their tips. I used to think that the only advantage derivable from this was a slight check to the evaporation of the cutting's moisture, but an experiment with two batches, one tipped, the other not, proved that the cuttings that had their leaves shortened rooted four days in advance of those not so treated. After insertion give them a thorough watering, shade from strong sun, maintain a temperature of about 50°, and one's own judgment must suggest what other attention they need till they are ready to take out of the sand and prick into flats.

There is another fascinating method of raising Carnations, that is

#### FROM SEED.

Here, again, haphazard work is of no account. A law of nature shows the "like seeks to beget like," but in the Carnation there is a latent possibility of wonderful degeneration at one remove. I had a very fine collection of Carnations flowering in the garden, and there was not even a second-rate kind among them. A score of varieties in groups of from fifty to 100 plants of each represented a rigid selection from 100 kinds tried the previous year. I noticed many of them were forming seed-pods, so I selected some, watched them daily until the ripening, harvested good seed, sowed it the following spring, and in late summer planted out for next year's blooming 2000 as good plants as anyone would wish to see. I anticipated a grand series of seedlings, but was doomed to disappointment. Twenty-five per cent. of the progeny produced only single flowers; 50 per cent. of the remainder were double, but not so good as their parents. A few of the remaining 25 per cent. were selected and grown the following year, but the Carnation world is none the richer for that attempt to increase its riches. Profiting by this lesson, I went to work again, but resolved to trust to no chances. I carefully crossed the flowers chosen for seeding, hand-fertilising every one, and secured a number of fine pods of seed. The seeds were sown, good plants obtained, that ultimately came to the flowering stage. In this batch of 2000 plants only two plants produced single flowers; the rest were as good as their parent, and reds predominating in the seed parents, there was in the progeny the finest series of red seedlings I have ever seen. Quite a number were selected for another year, but I handled them no longer. I do know, however, that a few of them are still in cultivation, and one or two of the finest were named and distributed. There is here ample proof that if you would raise fine kinds you must select the parents and work with an object in view. The new kinds offered us each season by specialists are the outcome of the same careful crossing and systematic working on the part of their raisers. Even then, however, the blanks are many, the prizes few. The only justification for putting another kind on the market is either the possession of qualities superior to those of the variety it most resembles, or, if unlike any on the market, it conforms with them in every other point that goes to constitute the existing standard of highest merit.

\* Pa. e-r read by Mr. A. Heinington, Madison, N.J., before the M. ris Co. (N.J.) Horticultural Society, January 13, 1897.

## SUMMER TREATMENT.

Turning to the young plants that are raised from cuttings, the aim of the cultivator in summer should be the growth of a strong plant, calculated to yield the fullest possible crop of winter bloom, and this is best accomplished by planting out the plants in the open ground at such time as the season and locality warrants, May usually being a favourite month. The summer site and soil for the plants are important matters to consider. I remarked at the commencement that the wild Carnation grows up high and open, where it never suffers from a superabundance of moisture, and always enjoys a free circulation of air. Just as much does the cultivated Carnation want an open, airy situation and a free, well-worked soil of medium texture, neither too adhesive nor too gritty, well enriched, but not with fresh rank manure, which is peculiarly distasteful to the plants. If Carnations can be planted in succession to some crop for which the soil was previously well manured, it will be found quite rich enough, all it needs being deep digging or ploughing of the soil. If fresh food for the plants be absolutely essential at planting, give it in concentrated form, as, for example, bone-meal or wood ashes; separate or in mixture, both are first-rate Carnation manures. After planting, the chief details of summer treatment are keeping down weeds and pinching the main stems as they advance in length. The ideal plant to try and secure is one of low and tufted growth, with from six to eight shoots as near the ground as possible. If one has a large quantity of plants, it may be desirable to spray them with sulphate of copper once a week, since prevention is better than cure, but in private establishments, with but a limited number of plants, due selection of cuttings and proper care for the infant plants bring its reward in a comparative immunity from fungoid diseases. Soil that will grow good Roses will likewise grow Carnations, so it is needless to enlarge upon the preparation of the compost heap wherefrom to fill the benches. Lifting from the ground and planting on the benches can begin with safety in August; indeed, I am informed by one of the best growers that he likes to get all his plants planted on the benches in that month. This grower further advises what I would have hesitated to practise the shaking off entirely from the roots of all the old soil in which the plants grew in the field, as they thus start the more readily in the fresh compost. The quality of his stock warrants me in concluding that his practice on this point is sound. With bright, hot weather prevailing in August, slight shade and free syringing will be important factors towards future good results; but when the plants show evidence of getting established, less overhead moisture and abundance of light and air should be given. Given a light house that receives every possible ray of direct sunlight during the winter months, and an equable temperature of 50° to 55°, the chief winter items of labour are disbudding, watering, and syringing. If these matters are attended to, and later on food given to the partially exhausted soil, you need have no fear of failure.

**Cut flowers.**—A splendid assortment of outdoor flowers is available from the middle of July until the middle of August, and when preparing to stage some fifty varieties (not species) the other day the difficulty was not how to find them, but what to pick for the most effective display, and these flowers are now so much appreciated that I venture to send a short list. Phloxes were represented by Snowdon, A. McKinnon, Mrs. Miller and J. Thompson, and Pentstemons by four of

gloxinioides seedlings in different shades. *Galtonia candicans* and *Achillea* The Pearl supplied bold masses of white and were flanked respectively by *Eryngiums* and *Montbretias*, and other large vases were filled with cluster Roses and the early-flowering Sunflowers, *Helianthus rigidus* and *Heliosis levis*. A good selection of perennial *Gaillardias* gave brilliant colouring to another row, together with good forms of Stocks, *Antirrhinums* and the taller *Bellflowers*. Some of the best of the Carnations staged in separate varieties formed a good face to the taller things behind, *Uriah Pike*, *Ketton Rose*, *The Pasha* and the old white *Clove* looking remarkably well. Associated with these were Sweet Peas and the blue and white forms of *Platycodon Marietii*. The point as to species in collections of cut flowers at cottage shows has again been a difficult question, and where the wording of the schedule states distinct species, it is almost impossible to get cottagers to abide by it. In one instance where six collections had been staged only one exhibitor had adhered to the rules, and his, unfortunately, was a long way from the best. Remarks the reverse of flattering follow disqualification, which is, however, necessary in such cases, and I think varieties should in all cases be substituted for species until cottagers are better able to classify their productions.—E. B. C.

## KITCHEN GARDEN.

## MID-WINTER TOMATOES.

**TOMATOES** with me are much in demand all the winter. A few plants raised now for the December supply will be of great use to those who provide vegetables in quantity and need a varied supply. Plants are raised with so little trouble, that only a few words are needed on this point. It is useless to grow too late plants, as unless the fruits are set before October closes they will probably not set at all. For early spring fruiting late plants are valuable, as those kept quiet through the winter will come into bloom in February or early March. So far as my experience goes I have not been able to set the blooms from November to January. My first success with what may be termed mid-winter fruiters was gained by a simple experiment and at small cost. For many years I had struck cuttings for an early winter supply, but owing to a mishap I lost the stock and potted up some very poor seedlings which had been standing in seed pans for some time. With only cool house treatment from August to October these did well, set some fruit, though not placed in heat, and gave much better crops than I ever had from plants grown specially from cuttings. I have never struck a cutting since that date for winter fruiting. For mid-winter supplies plants ere this should be raised and fit to pot on. There are often a few surplus plants left over from a late spring or what is termed an early summer batch to provide a late supply, and good use may now be made of these. Avoid heat as the hardier they can be grown the better. My plan is to pot up, place in cold frames till the roots reach the sides of the pots and then expose freely night and day. Indeed, night exposure is important, as the night dews keep the plants clear of insect pests and induce a short compact growth. At this season I pot up into 6-inch pots, or if the seedlings are in say 5-inch pots they may be placed direct into the fruiting pots. In doing this care is needed in watering for a time. Do not give any manure; only a little bone-meal is mixed with the soil. Nine-inch to 10-inch pots are large enough to fruit the plants in. Pot very firmly and leave a fair space at the top to allow for later top-dressings and feeding when the fruit is formed.

I damp the plants overhead when the sun declines, and this is continued till the weather gets cool and the plants are removed to their fruiting quarters. If they set freely, which they should do by September, weak food, such as liquid manure, is given and the syringe less used as the flowers open. The plants to be a success must be studded with fruit at the time they are housed. They certainly set a few fruits when given more favourable treatment, but it is not wise to rely upon the crop secured too late. I place in low pits, not the best structures possible, but in gardens many shifts have to be made. The chief thing after housing is to air freely in favourable weather, leaving air on all night. Keep the plants clear of white fly, one of the worst pests the grower has to contend with. This is readily kept down by the useful X L All fumigator; one dose a month will effect a clearance, and is far superior to tobacco paper, which does not always kill the pest. The plants are trained to a single growth not too far from the glass, and the winter temperature after housing is 55° at night and 10° higher by day, with air on all favourable occasions. My aim is to secure medium-sized fruit and a medium crop, as the season is not favourable to a heavy strain on the plants. There is no difficulty in securing a heavy crop, but there is in finishing. I have had plants collapse when allowed to bear too much. Far better get a succession. When the large fruits are gathered the smaller swell freely. Exhibition fruits are out of the question. Grow medium-sized kinds, not those noted for mere size, as at the season named one never minds a ripe Tomato being medium-sized if of good quality. For years I have found *Conference* one of the best winter fruiters; *Early Ruby* and *Frogmore Selected* are also excellent. These are larger than *Conference*, but very free setters and of good quality. From plants which fruited in December I have obtained a second crop in April by getting new growth and giving ample food. To do this, it is necessary to keep plants warmer than advised after the fruit is cleared, but I do not recommend this plan, as by making a sowing at this season and growing plants for the purpose, a better crop is secured. These are not allowed to fruit till early spring. They are placed in their fruiting pots in October or February, according to their strength. Such plants are far superior to those sown, say, in December for first crop, give less trouble and need less heat.

G. WYTHES.

**Lettuce bolting.**—Has "S. H. B." (p. 55) tried *Continuity Cabbage Lettuce*? This is a long way the best I have had from a non-bolting standpoint. A batch on a south-east border has been firm and solid for some time, and not one of them has run. I look upon this as a first-rate variety, for, in addition to the excellent characteristic above noted, it grows to a great size and is very crisp and fresh eating—in fact, more like a *Cos* than a *Cabbage*.—E. B. C., *Claremont*.

**Autumn-sown Onions.**—These constitute an important item at all vegetable exhibitions at this time of the year, and they invariably present strong features on allotments or in cottage gardens. When being judged, as in July, they are usually in their finest form. But, all the same, it is but natural to ask what useful purposes do these large bulbs serve in domestic economy, for if not profitably used they can have no real garden value. That the bulbs have a very short life is well known. Some of the white-skinned varieties are no sooner ripe than they become soft and useless. The practice of growing soft *Tripoli* and Italian varieties in preference to good hard keepers generally prevails. Now that it is so much the rule to raise some plants of the finest

varieties by sowing seed under glass in January and transplanting outdoors in April, it seems hardly worth while to trouble about autumn sowings at all, except to give green plants for pulling in the winter and spring.—A. D.

**Endive.**—The time is now at hand when the earliest batches of Endive will be sown. Care as to dates is of more importance with Endive than with some autumn-sown crops, as if sown too soon the plants in ordinary seasons grow too large before lifting time, and the result is running to seed early in the spring. On the other hand, late plants do not reach a normal size, especially if the autumn is wet and cold, and the plants are hardly worth blanching. In this locality from July 20 to 25 is a good time to sow for main crop, and, as with Coleworts, so with Endive, a north border is a capital place. Here the seed quickly and freely germinates, and an occasional watering keeps the young seedlings moist and in a growing state. Few gardeners grow very much of the Moss or Green-curl'd varieties, as they stand frost and damp so badly. My favourite variety is Fraser's Broad-leaved. This is a fine sturdy strain and easily blanched, nor does it run to seed so quickly as some.—J. C., *Notts.*

**Tripoli Onions.**—The season is fast approaching for sowing the Tripoli section of Onion to stand the winter, and the sooner the ground is got ready the better the crop will stand, as the seedlings always seem to make a better start in firm ground; indeed, several gardeners who had for years experienced great difficulty in securing a respectable crop of Tripoli Onions found a way out of the difficulty by sowing on ground from which Strawberry plants had been cleared. The same individuals covered a portion of the Strawberry plot thickly in autumn with cow manure, allowing it to remain on through the winter so that the rains might wash down the nutriment, removing it in March and sowing their spring Onions in drills without digging of any kind. No crop is more injured by thick sowing than Onions, as when crowded together it is utterly impossible to remove the surplus seedlings without loosening those that are to remain, and when blown to and fro by high autumn winds they seldom winter well. Even when sown fairly thin early thinning is advisable, as soon, in fact, as the young seedlings can be handled. All points considered, perhaps the best variety is the old Giant Rocca. It grows to a large size, is of fine globular shape, the skin bright brown, flavour mild and delicate, and last, but not least, a good keeper. Red Italian is another capital Onion. For using early in the spring, Early White Naples and The Queen are grand silver-skinned varieties.—J. C.

#### PEAS AND DROUGHT.

FEW vegetables suffer sooner from heat and drought than Peas in light soils, and this summer they have felt the dry weather severely. Some kinds suffer more than others. I notice those of a dwarfer and stouter build, with thicker stalks, are the best in dry seasons. I am aware mulching in a measure will greatly assist the plants. I strongly advise this before the Peas pod, as once the pod-growth ceases mulching is not of much use. It may assist in filling the pods, but it does not add to new growth, with the result that a portion of the crop, which would have been preserved had mulching been done earlier, is lost. Several dry summers in succession show the value of sowing the later crops, or what may be termed the July Peas, in trenches. Treated thus, one in a measure defies drought. There must be a liberal supply of decayed manure in the trenches for the roots to lay hold of, and though I have seen this latter treatment objected to on the score of failing in wet seasons, I do not think it can be termed failure, as though the haulm certainly makes a gross growth, it also bears a much heavier crop, and one can easily check growth by stopping and sowing much thinner. Peas sown too thickly are the first to feel the effects of drought. In wet seasons the same difficulty

occurs, as though there is less root trouble. top-growth is so gross and attains such proportions, that pod-bearing is delayed. I am aware, no matter how much one cares for certain kinds of Peas, in a hot, dry season they are soon over and the Peas when cooked are deficient of flavour. There is need of more careful selection of varieties in dry, poor soils. Fortunately, of late years the Pea raiser has given us better habit, and though size of pod is looked upon with more favour than it deserves, we have a good selection of high-class Peas. Some of the very large-podded varieties are not the best flavoured. The best flavour will be found in Peas of medium size and what are known as continuous bearers, that is, those which bear from the base, or nearly so, and which have a later crop on the top of the haulm. I do not condemn the largest varieties; they have their use, but in dry seasons I find

A group of Echiniums from the Canary Islands at La Mortola. (See p. 97)

them less valuable when Peas are required in large quantities. S. H.

#### SHORT NOTES.—KITCHEN.

**Pea Alfred the Great.**—This is one of Laxton's fine varieties that seems not to have got largely into cultivation, yet it is finer in pod than is Ne Plus Ultra, to which it bears close resemblance in growth and in quality of Pea. It is really one of the good varieties that has not earned fame, probably because it is not a show one.—D.

**Pea Bunyard's Early Dwarf** is a very hardy variety, as in Kent it is a common rule to sow it late in October or early in November, the plants usually wintering well. So treated it crops very early. It is a heavy podder and the Peas are of excellent quality. As it is but 2 feet in height when staked, a large quantity can be grown on a small area of land.—D.

**Pea Boston Unrivalled.**—But recently put into commerce, this fine Pea is giving great satisfaction. It bears some resemblance to Telephone, but has longer and better filled pods and is all round a greater cropper. It is best staked, as it grows from 4 feet to 5 feet in height in good soil. This and Alderman represent two of the finest podded Peas now in cultivation.—D.

## GARDEN FLORA.

### PLATE 1130.

#### RHODODENDRON MRS. THISELTON-DYER.

(WITH A COLOURED PLATE.\*)

THIS Rhododendron is one of a new race which promises to add much to the beauty and variety—great as these already are—of the hardy garden Rhododendrons. Their chief interest and value consist in their bringing into the field a species which hitherto has had no share in the origin of hardy varieties of Rhododendron, and is, moreover, absolutely distinct from those that have. This species is *R. Fortunei*. It is a native of China, and was discovered and introduced by Robert Fortune about forty years ago. The following communication from him to the *Gardeners' Chronicle*, Oct. 29, 1859, regarding its discovery reads curiously to-day, when so many Rhododendrons have been discovered in China, that this country is now considered as likely to prove the headquarters of the genus, so far as number of species is concerned:—

When on one of my long journeys in the province of Chekiang (west from Ningpo) I accidentally met with this fine species amongst the mountains, about 3000 feet above the level of the sea. The discovery was most unexpected, for although the lower parts of these mountains are covered with the allied genus *Azalea*, no Rhododendron has been known to exist in this part of China. The specimens I met with were of all sizes, from a year's seedlings to full-grown plants, the latter being 10 feet to 12 feet high. The large plants had been covered with flowers a short time before, and the ground underneath was now strewn with decayed blossoms. I was told on all sides by natives that the plants were most beautiful objects when in full bloom. When I returned to the same place in the autumn I found an abundance of seed, which has vegetated freely in Mr. Glendinning's nursery at Chiswick. The only other species of Rhododendron known in China is *R. Championæ*, a pretty plant discovered on the Hong-Kong hills.

Instead of there being only two Rhododendrons known in China, Mr. W. B. Hemsley, in the "Index Flore Sinensis," enumerates over sixty species native of that country. But of all the sixty or more Rhododendrons that have since been discovered, none can be said as yet to give promise of equalling Fortune's species as a useful and beautiful garden plant. The largest specimen at Kew is about 8 feet high and more through; its leaves are smooth, of a rather light green above, slightly glaucous beneath. The flowers are produced in early May in loose trusses, and are of a lovely blush colour on first opening, afterwards becoming

\* Drawn for THE GARDEN in the Royal Gardens, Kew, by H. G. Moon. Lithographed and printed by J. L. Goffart.

PHODODENDRON MRS THISELTON-DYER

almost white. Two characters it possesses which, taken together, distinguish it from all the remainder of the true Rhododendrons (as distinct from the Azaleas) grown outside; these are, first, seven segments to the corolla (instead of the normal five), and, second, a very pleasant and slightly spicy fragrance. When the large plant in the Rhododendron dell at Kew is well in flower—and this year it bore many scores of trusses—the fragrance is perceptible several yards away, especially on dewy mornings. It is a near ally of *R. Griffithianum* (Aucklandi),

W. T. Thiselton-Dyer—was obtained. It flowered at Kew in May, 1896, and bore numerous trusses of the type here figured. The truss is more compact than that of *R. Fortunei*, and the flowers—individually measuring between 3 inches and 4 inches across—are of a lovely shade of rosy pink, relieved by a blotch of rich maroon at the base.

Shortly after Mr. Luscombe commenced working with *R. Fortunei*, Mr. G. Paul, of Cheshunt, made an extensive series of crosses between that species and some of the best garden varieties, one

(Luscombe), *Luscombei* (Luscombe), *Luscombei splendens* (Luscombe), *Luscombe No. II.* (Luscombe), *Duke of York* (Paul), *Duchess of York* (Paul), *H. M. Arderne* (Paul), *Helen Paul* (Paul), *Profusion* (Paul).

What some will consider a defect in this new breed of Rhododendrons from a garden standpoint is their flowering so early in the season (the first week in May), which renders them liable to damage by late frosts. But their delicate and lovely colouring, their freedom in flowering, and the fact that they introduce a

*The yellow Banksian Rose covering an ancient arch at the entrance to the pergola, La Mortola. From a photograph sent by Mr. Hanbury. (See p. 97.)*

which is, perhaps, the noblest of all Rhododendrons.

The first to make use of the species for purposes of hybridisation appears to have been the late Mr. Luscombe, an enthusiastic amateur cultivator of Rhododendrons living in Devonshire. He crossed it with *R. Thomsoni*, which produced the fine varieties *Luscombei* and *Luscombei splendens*, which have been alluded to in previous numbers of THE GARDEN. This cross appears to have been made about 1880, and about the same time he also crossed the species with several varieties of the ordinary garden type, and it was from one of these that the beautiful Rhododendron now figured—Mrs.

of which, curiously enough, produced a variety identical with the *R. Mrs. W. T. Thiselton-Dyer* raised by Mr. Luscombe. Visitors to the May fortnightly meetings of the Royal Horticultural Society and to the Temple show, both last year and this, will remember several other of these *Fortunei* hybrids being exhibited by Mr. G. Paul. Some of the best have obtained awards of merit, and two—called the *Duke of York* and *Duchess of York*—were given first-class certificates at the Temple show of 1895. The following is a list of the *Fortunei* hybrids known to me, although Mr. Paul has doubtless named several others: *Mrs. Thiselton-Dyer* (Luscombe and Paul), *Frances Thiselton-Dyer*

new type into our gardens will commend them to lovers of hardy shrubs. Some of Mr. Paul's plants have distinctly fragrant flowers, and some have six or seven segments to the corolla.

W. J. B.

**Tufted Pansy White Duchess.**—This, the most refined flower of the *Duchess of Fife* family, was seen in fine form at the recent show of the National Viola Society. Blossoms of *White Duchess* are usually of even form and somewhat oval in shape, while the edges of the flower are very regular. The blossoms are white, distinctly and irregularly edged blue, with a yellow eye and a faint suffusion of the same colour on the lower petal. There appears to be another flower bear-

ing the same name, but sufficiently distinct from the original to permit of a separate name being given to it. The flower is of the same shape as its prototype, but slightly corrugated at the edges, while the colour markings are much deeper and more distinct. I have the two plants growing almost side by side, and there is no doubt about their distinctness.—D. B. C.

## THE WEEK'S WORK.

### KITCHEN GARDEN.

**LATE PEAS.**—Although there have been frequent rains of late in different parts, we have unfortunately had next to none in these gardens for upwards of three weeks, and at the present time many crops are suffering through the dry state of the ground. Some of the midseason Peas were attacked with thrips, but fortunately the later crops are so far free of this pest. Watering and more mulching have been necessary in our case to keep the haulm clean and healthy, but this extra attention is not begrudged so long as good crops are secured. Any rows of the tall growing varieties whose haulm is likely to fall away from their sticks should have additional supports, either by using some more tall bushy sticks, or perhaps, what is better, driving in some light Larch poles on each side of the row 18 feet to 20 feet apart, and looping the growth up with stout cord.

**MUSHROOMS.**—In many gardens the culture of Mushrooms is only attempted during the autumn and winter, when they can be produced much more freely than is possible through the heat of summer. Where the manure has to be collected piecemeal and several weeks elapse before sufficient can be obtained to form a bed, care is necessary that it does not become overheated or too dry. It should be spread out 9 inches or a foot in depth in an open shed or where it is protected from rain and turned twice a week. If there is a danger of its getting too dry, cover it with some old sacks or matting. In the meantime the house should be prepared in readiness for forming the beds. Very often a quantity of rubbish is allowed to accumulate in the Mushroom house, which tends to the increase of woodlice and other vermin, which often prove destructive to the crop just as the small "buttons" are pushing through the surface. Where these have been found troublesome, endeavours should be made to destroy them either by trapping or some other means before the new beds are formed. A few Cabbage or Lettuce leaves placed on the floor in the evening will entice many to collect, when they can easily be killed with hot water. The walls, too, will be all the better for a dressing of hot limewash, which will keep the house sweet. If the building used is heated with hot water, see that this is in working order, so that no hitch is likely to occur at the approach of severe weather. It is unwise to use up old spawn left from last year, as this may fail to produce a single Mushroom and all the time and labour will be in vain. Endeavour to obtain the spawn from the most reliable source, even though a high price be charged for it.

**CABBAGE.**—Keep a sharp look out on seed beds of this and other Brassicas, and protect them from the ravages of birds and other vermin. Plant out good batches of Coleworts and others of the same family as ground is cleared, and they will come in useful during the early winter months after Peas, Beans, and the like are over. Another sowing of Ellam's Early should be made, especially if those put in a fortnight ago have not come up so well as one would wish. Plantations of Cabbages that have furnished a supply during summer will yield a serviceable second crop in the autumn if the old stools are freed from decaying foliage and the ground between them kept free from weeds, and the surface soil made loose by frequent hoeings.

**TRIPOLI ONIONS.**—These will now be as large as one requires, whether for exhibition or home

use. It is best to lift the bulbs carefully as the tops show signs of ripening, and store them in a position where they will mature gradually if not required for immediate use, as there is a danger when they are left in the ground and heavy rain follows of new roots forming and the bulbs splitting, when they are useless for the exhibition table, and they also fail to keep properly for any length of time. I hear of several instances where mildew has played much havoc with spring-sown crops. This is always regrettable, as it is seldom any really sure remedy can be applied to save the bulbs. A dusting of sulphur may sometimes arrest the spread of the disease, and on no account should the crop suffer by being over-grown with rank weeds.

Goodwood.

RICHARD PARKER.

### HARDY FRUIT GARDEN.

**FIGS.**—The young wood on wall trees should be kept thin, as the shoots which will bear another season must have every opportunity of becoming properly ripened. If the trees have become at all crowded, the growths should at once be thinned out, retaining those of medium strength, as such will bear the best and most fruit next year. Trees carrying good crops may be assisted with liquid manure if their roots are confined to narrow borders. Barren or nearly barren trees should not be watered, especially if they are making quantities of gross sappy wood, and such should be rigorously dealt with by root-pruning and confining their roots to a circumscribed area in the autumn. On warm days the trees will appreciate a wash with the hose or garden engine, but this must be discontinued once the fruits commence to ripen, otherwise spotting and decay will soon set in.

**OUTDOOR VINES.**—These are still to be met with growing on old farmhouses and cottages, and during the past week I have seen many such bearing excellent crops of fruit. If the autumn should prove fine and warm, the Grapes will ripen and prove fit for eating. The bunches should now have all the light and air possible, and all young growths should therefore be kept persistently stopped. Hardly anyone thinks of thinning out the bunches on outdoor Vines, nevertheless it is a good plan to do so, as the remainder not only benefit by it, but the berries also grow to a larger size and ripen all the more quickly. Vines growing against chimneys and under wide overhanging eaves are apt to become excessively dry at the roots unless watered occasionally, more especially if the border in which they are planted is largely composed of mortar rubbish and brick-bats. A thorough soaking of water in such cases proves beneficial, and if this is followed up with a soaking of diluted liquid manure a few hours afterwards, very much better results will follow in the shape of finer fruit.

**RASPBERRIES.**—The fruit having been gathered from the summer fruiters, the old canes are no longer of the slightest service. They should therefore be cut out, and the young canes if thinned out as advised, should afterwards be fastened to the stakes or trellis. If thinning has not had attention, get it done at once, leaving just as many as are required and no more, and avoid overcrowding. If sewage or liquid manure be plentiful the plantation may be soaked with it when properly diluted again and again during dry weather, as this will ensure excellent results another season and give a further mulching if necessary. Autumn fruiters are making strong growth and promise an abundant crop. To secure the best results, the canes must be kept moderately thin, whether several are tied together and secured to stakes, or trained on wire trellises. If allowed to become crowded much of the produce becomes spoilt should the autumn prove a wet one. Thinning if requisite had better be done without delay, and attend to tying as the canes lengthen out, both to prevent them from being blown about and broken with the consequent loss of fruit, also to preserve a neat and

tidy appearance. Liquid manure is also of the greatest service to these, especially if the stools are aged and the canes thin and weak.

**MORELLO CHERRIES.**—If black fly has taken possession of the points of the young shoots, the nets had better be removed for the time being, and after damping the affected parts of the trees lightly with a syringe, dust tobacco powder over the fly pretty thickly. In a few hours' time or after the powder has had time to do its work, well wash the trees with clean soft water, and if one application is not sufficient to rid them of the insects, repeat the dose next day. The water must not, of course, be applied with too great a force, or the ripening fruits will be injured, but if care is exercised the washing can be done without harm resulting. If these Cherries are required to hang late, they must be closely netted. Many people greatly appreciate Morellos when fully ripe, especially when the fruits are dipped in clear syrup and dried before being sent to table. For bottling they must not be allowed to become too ripe, and just when they assume a dark purplish hue is the right time to gather for this purpose.

**APRICOTS.**—As these are ripening fast, the trees will need a look over every second day, when the ripest and largest should be held over for dessert, the smallest sent to the kitchen, and the medium-sized ones used for bottling in a whole condition. For the last purpose they must not be too ripe, otherwise they break during the process of bottling, and the same remark applies to fruits that are to be preserved in syrup. When all the fruits are gathered, give the trees a thorough washing, as it is a great mistake to run away with the idea that further attention is unnecessary because the crop is done with. Root watering should also have the same attention as heretofore, and see that all breast-wood is kept pinched in.

**PEACHES AND NECTARINES.**—The trees now need another look over both to regulate and fasten back the young wood and also to keep lateral growths on the same pinched. Trees on which fruits are fast swelling should have all the moisture they need at the roots, and a stimulant also if the age of the tree, want of vigour or weight of crop should demand it. The leaves should also be turned or tied on one side, as I am no advocate of the barbarous method of cutting them off altogether, so that the fruits are fully exposed to facilitate ripening, and until they commence to soften, syringe or wash these and the other trees also regularly whenever bright warm weather prevails. The trees of early varieties should be overhauled as soon as relieved of their crops, when, in addition to cutting out the now useless bearing wood, remove surplus shoots should there be any so as to give the remainder every chance of becoming thoroughly ripened. See that they get a sufficient quantity of water at the roots, and if necessary renew the mulch. Should wasps, bees and flies prove troublesome, traps consisting of bottles partly filled with sour beer and portions of damaged fruits cut up and mixed with it, suspended on the walls, generally answer well and kill great numbers. Wasps' nests should also be searched for and destroyed within a radius of a mile from the garden. A few pence paid as a reward for their destruction acts as a great incentive towards keeping these pests within limits.

**OTHER WALL TREES.**—These will require another look round to keep them in good order. If the attendant carries a nail bag or a few strands of raffa with him, young shoots in need of further support in the way of tacking in or tying back can be attended to at the time the stopping is being done. In woodland districts the earliest varieties of Pears and Plums must be netted, otherwise birds will soon devour the lot—at least, such is my experience.

**LATE STRAWBERRIES.**—As the beds become cleared of fruit, store the nets away and trim up the plants if a sufficient number of runners has been secured. Some late varieties, such as Oxonian, are best treated as biennials, as the returns are poor indeed if such are kept the third season. A. W.

ROSE GARDEN.

ROSES UNDER GLASS.

It is surprising that amateurs and gardeners have not taken more to the culture of Roses in pots, considering the very effective displays that visitors to the Temple shows of the Royal Horticultural Society have been accustomed to look for for several years past. The large market nurseries for the production almost exclusively of cut Roses in the early months of the year are evidence, if any were needed, of the popularity of the flower, notwithstanding that the summer and autumn furnish an abundance outdoors. The lovely Tea Rose is always welcome, be it for bouquet, wreath, or house decoration, and as the fashion is extending in cutting Roses with long stems, their true decorative character is at once apparent. I am convinced that the failures in the past in the cultivation of pot Roses can be mainly traced to the method adopted of growing them in a greenhouse of mixed subjects. It would be far better to devote a house or houses entirely to their culture, be the structures ever so small.

STRUCTURES.

The one I have found the most useful is the span-roof running north to south. The length may be from 50 feet to 100 feet or less, and the width about 18 feet to 20 feet. Ventilation is a very important matter, and should be carefully provided. The top ventilators I prefer on both sides, east and west, but instead of the hinges being placed near the ridge, they should be at the bottom of the light. This will enable us to keep the plants from the cold gusts which sweep down on them when the lights are hung from the ridge, as in the method I recommend the wind passes over the house and the air is admitted very gently. Side ventilators are advisable, although for early forcing they will not be often needed. The top lights composing the roof should be movable. This is of great importance if the Roses are planted out instead of being grown in pots. We are then enabled to give our plants the beneficent rains and dews. Roller blinds would also be of great benefit for shading, for although Roses dislike shade when growing, there are times when we desire to keep the blossoms back, and then shading is necessary in some form. For pot work the sides should have staging fixed for dwarf plants, and a brick bed in centre for standards, half-standards, or climbers. A path should run round the house between centre bed and side staging. A row of 4-inch pipes would be necessary and would (unless very hard forcing were desired) be sufficient. A tank for water is very important, as it is then chilled and can be given to the plants at the same temperature as that in which they are growing.

PLANTS TO COMMENCE WITH.

If the desire is to go in for exhibition, the largest proportion should be of the H.P. or H.T. class, as they are more lasting and would blossom without much heat about the time that the chief exhibitions are held. The H.P.'s and H.T.'s are best grown one year outdoors previous to bringing into the house. Plants should be potted in October from the open ground. Plunge them up to the rim of the pot in ashes or cocoa fibre and carefully protect from May frosts. Give them frequent weak doses of liquid manure during summer. They will not require repotting the first year provided the drainage is looked to in the autumn. Keep the plants outdoors till November, then remove to a cold pit or house. The Teas are best grown under glass. Standard Teas can be planted out or grown in pots. I would prefer to plant them out. It is well known that the finest Teas are produced on standards, although for cutting, the extra-sized plants are good enough. It will thus be seen that to grow the H.P.'s and Teas together in one house would be detrimental. The H.P.'s are finer in quality

in every way if grown very steadily, merely using sufficient artificial heat to keep out frost and to keep the atmosphere buoyant. A very important matter in the culture of Roses under glass is the

PRUNING.

of the plants. The time to do it must be regulated by the period at which they are required in flower. If early blossoms are wanted say by March, prune the plants about the end of December. This applies to Teas and Chinas only. If H.P.'s and H.T.'s which partake more of the H.P. character are required in March, then November would be the time to prune. Of course these plants should have been brought under cover a month previous to this. The H.P.'s need rather hard pruning, but the Teas must be very sparingly cut unless show blooms are wanted. If the latter, I would recommend cutting back to good plump buds, but if flowers for cutting are desired, then a good thinning of the weak shoots will be sufficient combined with moderate pruning back of the stronger growths. Climbers need different treatment. Climbers grown in pots can be splendidly flowered if their long shoots are trained spirally around three or four sticks placed in the pot. They will blossom from nearly every eye, and each season these laterals can be cut back ready for another supply. Semi-climbers are very pretty objects when trained in pillar form, and produce an abundance of flowers by this method. Such plants need very little pruning, simply removing milfy growths. When plants are pruned, the next point to consider is their

TRAINING.

I am very much averse to so training any plant that by so doing the character of growth is altered. There is absolutely no need to distort plants into the hideous, one-sided objects sometimes seen. The chief consideration in training a plant, in my opinion, should be to enable its foliage and flowers to perfectly develop. After pruning, tie a string round the under side of rim of the pot, then tie raffia on the shoots and gently draw them down to the string, just enough to shape the plant. When the plant has made shoots and these shoots show the buds, then sticks can be placed in the pot and shoots tied to them. A taste for form will soon tell us what is the most suitable shape to fashion the plant to. Standard Teas of a climbing nature produce more flowers if their shoots are bent in an umbrella fashion. Roses of the Polyantha and China tribes I prefer to grow naturally, merely tying out the skeleton plant when first pruned. When this first tying out is accomplished the plants should be carefully arranged in the house, so that the sun is enabled to shine on all of them. I prefer to place the plants (if in large pots) upon bricks or pots, taking care not to impede drainage or admission of air to roots through the hole in bottom of pot. If a side stage is used to bring plants near the glass it should be made so that it can be covered with ashes. When plants are syringed these ashes absorb some of the water, which enables a nice moisture to arise around the plant in the hot part of the day. The

TEMPERATURE

of the house is of great importance. It must always be borne in mind that we have, as it were, to make the weather under glass what Roses delight in outdoors from March till June. I am no advocate for strong heat for Roses under glass, believing that the best quality is produced in a moderate temperature. Especially is this the case with the H.P.'s. The finest specimens I have ever seen of this class under glass were grown on what is termed the cool system, giving all the air possible on most days, and just sufficient artificial heat at night to keep out frost and to give a buoyancy to the atmosphere. The Teas, however, are the better for quick growth. For most varieties of Teas a night temperature of about 50° to 55°, rising in the daytime to about 60°, is suitable. Of course a few degrees more would be allowable if bright sunshine prevailed.

Another very important matter in the successful management of the Rose house is

VENTILATION.

Roses dislike cold draughts, but, on the other hand, they delight in a buoyant atmosphere, free from stuffiness. I like to mure my plants from the commencement to plenty of air, and there are very few days and nights when I do not leave more or less top air on. Even if Roses are grown without artificial heat by day, a little should be turned on late at night, and this, combined with a small quantity of top air on, is a good preventive against the formation of dewdrop on the foliage, a sure precursor of black spot, so injurious to Roses. To avoid failures in pot Rose culture there must be no sudden checks. If a bright day is certain, do not wait until the sun raises the temperature rapidly, but give top air early, certainly when the thermometer stands at 65° in the Tea Rose house and about 55° in the H.P. house. If a commencement is made by giving side air, even with the Teas, it is surprising how they become accustomed to it, but grow Roses on without side air, with the consequent tender foliage, and then admit side air because it is a fine day, and a crop of mildew will be the result.

WATERING AND SYRINGING

must not be deputed to just anyone, but the most careful man should always undertake the watering and syringing of the Roses. No water will be required until plants have made about an inch of growth. They will have the appearance of being extremely dry, but it is better for the young roots that they should be kept so. The first watering should be a thorough soaking. If plants are not too large, immerse them in a tub or pail until water runs out at the bottom and the air bubbles cease to rise. If this is not practicable, give three or four good waterings in one day until thoroughly soaked. After this great care must be taken with the watering. I like to look the plants over each morning before syringing. After the first watering we shall find a syringing amongst the pots will be all the water needed for some time. Until plants are well advanced in growth, it is better to keep them rather on the dry side. Syringing the foliage must only be done on bright days, and then early in the morning, say about 9 o'clock, so that any excess in moisture may be dried up before evening. The soil should be frequently stirred after watering to keep it sweet. If plants are put on bricks or pots, so that water can pass away freely, the air will follow the water to the roots to their evident benefit. Of course, lengthening days will increase evaporation; consequently, more moisture must be given. Liquid manure is very beneficial to pot Roses, but weak doses and often are better than strong ones. Avoid strong artificial manures. Generally speaking, Roses do not require liquid manure until the buds appear; then they can have some about once a week. Do not imagine because a plant is strong and vigorous that it requires no stimulant. It is such as these that do require it; whereas weak plants, if we tolerate them, should have it withheld. Urine from the stables is good, but it is very strong, and the water must only be tainted with it at first. Sheep droppings make a splendid liquid manure; so also does cow manure. Some fresh cow manure, bone-meal and wood ashes put together in a tank would make a grand liquid manure if carefully applied in weak doses. A little liquid manure sprinkled on paths at night is helpful to the foliage, but it must not be overdone, or we shall have fine foliage and poor flowers. A good sign of health in a pot Rose is fine dark green leathery foliage, and when the plant dries up quickly we may know there is healthy root action.

DISEASES.

such as red spider and green-fly, are the worst enemies. The former can be best combated by water, but it is of no use spraying overhead. A good force must be directed upon the underside of foliage. Vaporising is the best means of settling

the green-fly. Worms are often troublesome, and if allowed to go unchecked they soon choke up the drainage. A watering with lime-water will move them and do no harm to the roots. Mildew is one of the very worst enemies the Rose grower under glass has to contend with. There are endless so-called remedies, but the best plan is to carefully avoid giving a check to the plants. This check can be given in several ways: a sudden rising or lowering of the temperature, unchilled water, or too strong doses of liquid manure. Avoid these and inure the plants from the commencement to judicious ventilation, and little trouble will be caused with mildew. If it should come, sulphur and lime applied to the pipes is a safe remedy. I have not much faith in dusting the plants with sulphur; I believe the sulphur fumes to be the best method of destroying the fungus. A very safe plan is to syringe plants with a fairly strong solution of soft soap-water. Let it remain on about half an hour, then syringe off again, using soft or rain water each time.

#### REPOTTING.

After flowering, the H.P.'s and H.T.'s should be turned outdoors, standing them on bricks and surrounding the pots with coal ashes or old fibre, and after a week or two they may be repotted, although many defer this operation till autumn. The Teas should be kept in the house to make a second growth; then they can be put outside. It is this second growth, well ripened, that will produce the finest Roses the next season.

I believe the best time to be July for repotting this class of plants; they are then enabled to lay hold of the new soil and build up the buds for next season. During summer and autumn the plants must not be neglected. If plunged they will not need so much water, but care should be taken to prevent them drying too much. Weak doses of liquid manure are also beneficial at intervals, and all flower-buds should be kept picked off. By potting when wood is ripened, less check is caused to the plants than if covered with young growth, as they frequently are in autumn. The compost I employ for pot Roses is good fibrous loam three parts, well-decayed cow manure one part, leaf-soil one part, a small quantity each of bone-meal and wood ashes or powdered charcoal. The pots should be scrupulously clean and well crocked. On to the crocks some turfy pieces of the loam should be placed, and in potting see that the soil is well rammed in, that is, supposing it is in a good condition, neither too dry nor too wet. It is as well to mix up soil a week or two before using it and put in a covered shed with open sides.

#### PLANTING OUT

Roses under glass is a grand way of growing them, and for cutting perhaps the best if house room is no object. A correspondent said the other day that he was not successful with La France under glass. He should see a house of this variety and Duchess of Albany at Messrs. Beckwith's cut flower nursery at Hoddesdon, and he would not soon forget the sight. Some hundreds of plants planted out produced last April quantities of grand blooms, which could be cut with 2 feet to 3 feet long stems, a method of cutting, by the way, which is in much request for table decoration, and particularly suited to fine massive Roses of this type. It would not do to attempt it with pot plants unless we were prepared to discard them after the second season, but planted-out Roses seem to have the power of recompensing themselves if the lights are movable and heavy mulchings of cow manure and bone-meal are given. Such kinds as General Jacqueminot will make shoots 8 feet to 10 feet long in one season. If these are bent over, an immense crop of flowers can be taken, afterwards cutting back hard. The plants will then make another lot of long shoots, which will be well ripened during the summer for another season's crop. If possible, a selection for site of house should be upon a well-drained meadow. Trench land about 2 feet 6 inches deep, putting all turf at the bottom, grass downwards, a good proportion

of half-inch bones or bone-meal and some well decayed cow manure. Trenching is best done several weeks before we want to plant out. Pot plants would be best, but plants from open ground would do, especially if lights were movable and we could grow the plants almost naturally the first year. Climbing Roses planted out under glass are best run horizontally the first year. I will give my idea of growing Maréchal Niel. I would select a good young maiden standard. Plant it in early autumn, cut back growths right down to the base of shoots, leaving about one eye on each of two shoots. As they grow, train these young growths to wires right and left of the plant. Of course, good heat must be maintained and

#### BOOKS.

##### THE YEW TREES OF GREAT BRITAIN.\*

THE noble Yew well deserves a book to itself which could be in the hands of everybody interested in our native trees, and it is fortunate in having a biographer who was equal to the task he set himself to perform. We have no hesitation in saying that Dr. Lowe has given us a book worthy of the subject. He has taken great pains to see and measure for himself where possible a great number of the finest trees in many parts of the country, and of those

The Abyssinian Spurge (*Euphorbia abyssinica*) at La Mortola. (See p. 97.)

plenty of moisture in the atmosphere. If the plant is in good soil as described above, wondrous shoots will be made by the fall. The growths should be well ripened in the autumn. The next season these two long shoots will give some good Roses, and after flowering, growths can be taken at intervals along the main shoot and trained perpendicularly up the roof. The next season these growths will give an abundance of good Roses of wondrous colour if well fed. After flowering gradually cut back growths to main arms again to encourage more young growths for the next season's flowering. Most climbers of vigorous habit are best flowered upon this system.

PHILOMEL.

he has been unable to examine personally he is enabled to give adequate data by corresponding with people more favourably situated. His researches included all trees in the United Kingdom of 10 feet girth and upwards. Of the trees 30 feet in girth and upwards, three are in Worcestershire, four in Sussex, one in Surrey, two in Shropshire, five in Monmouthshire, one in Middlesex, three in Kent, four in Hants, one in Gloucestershire, two in Derbyshire, one in Devon, two in Dorset, two in Carnarvon and

\* "The Yew Trees of Great Britain and Ireland." By Dr. John Lowe. London: Macmillan and Co.

one in Berks. These should be sufficient to give all the information which is necessary for the practical purpose of awakening in gardeners, planters and amateurs, the interest which the subject of this little book deserves. In introducing his book the author observes:—

There is no English tree which has gathered round itself so much of historic, poetic and legendary lore as the Yew; none is so closely associated, directly or indirectly, with events, persons and buildings which are famous in our national history. In early and mediæval times it was the source of our country's greatness and supremacy by supplying the bows and arrows with which our great victories were won; but, in spite of this, it has never attained that love and veneration in the popular mind so lavishly bestowed on its rival the Oak.

Apart from sentimental and historical considerations, too much can hardly be said to recommend the Yew tree as a garden tree. Its fine effect if intelligently planted, its unrivalled merit as an evergreen tree, preserving its beautiful soft tones in the hardest winters, and its value for shelter and as a screen from cutting winds are qualities which were recognised in old days perhaps more than in the present, although our forefathers subjected it to a good deal of indignity by cutting it into fantastic shapes, a fashion which prevailed for several centuries, despite the voice of common sense which occasionally made itself heard in the land. Thus Lord Bacon wrote:—

I, for my part, do not like images cut out in Juniper and other garden stuff; they be for children.

Pope and Addison also ridiculed the practice of turning trees into birds and beasts, and still more ignoble objects. No doubt there is a certain charm in lines of clipped Yew hedges and old avenues forming soft green backgrounds for brighter things, and we are inclined to agree with Dr. Lowe, that many old-fashioned gardens have suffered in losing the quaint forms of cropped Yews. From its association with churchyards, the Yew no doubt came to be looked upon as a melancholy sort of tree, which wanted the quickening touch of the gardener's shears to make it presentable. The hand of man placed it in the churchyard; its natural abiding place was not so much in low ground as in rugged scars and clefts on the sides of hills. In her charming book, "The Pilgrim's Way from Winchester to Canterbury," Julia Cartwright (Mrs. Ady) writes:—

Once more upon the hills, we can follow the lines of Yews which are seen at intervals along the ridge from Saint Martha's Chapel, by Weston Wood, and the back of Albury Park, turning a few steps out of our paths to visit Newland's Corner, one of the most beautiful spots in the whole of Surrey.

Many of our readers must know this spot, which is not far from Guildford. The ancient Yew grove there is mentioned in Domesday Book. It goes without saying that individual Yew trees are often of great antiquity, but many erroneous views obtain on this head. There have been various modes suggested of estimating age, right and wrong. De Candolle's come under the latter category. He assumed that the tree's growth took place by a regular deposition of concentric layers. This, as Dr. Lowe points out, is true in the case of the young trees, but, as with other created beings (not to particularise), after a certain stage in life is reached the means of ascertaining age become more a matter of conjecture.

It has been questioned whether some trees may not produce more than one ring in a year. In this country it is certain that only one annual

ring can be produced in young trees, but then it seldom happens that a Yew exceeds 200 years without having the main stem injured by storms or disease, and it is impossible beyond this period to depend upon the number of rings as a test of age.

Up to 200 years and a little over in uninjured trees the number of annual rings may be taken to represent the age. Estimating the age of trees by measuring their growths and comparing them with those of trees of known age is another way, but not always accurate, as the rate of increase varies considerably according to locality, climate, and soil. The late Sir R. Christison thought a foot in seventy-five years was about the average rate of growth, but many English trees far exceed this. A third way is by measurement of increased girth at a fixed point and at stated periods, a method which gives a ratio of 1 foot of diameter in about fifty-six years—a much higher rate than that arrived at by Sir R. Christison. The author has no faith in the *trephine*, or trepan, as a means of computing the age of Yews, and his doubts will be found at p. 57. Traditional accounts again are not always to be trusted, owing to the natural human tendency to exaggerate age in certain objects. Thus the Abercairny tree in Perthshire, which is said at one time to have sheltered the Marquis of Montrose (1640), is 10 feet 7 inches in girth at 5 feet from the ground, and is probably not much over 200 years old. Another fallacious method, again the discovery of De Candolle, is to ascribe to a tree the age of an adjacent building. The author gives several conspicuous examples of its absurdity.

There is an instructive chapter on the causes of variation in growth, overcrowding, pollarding, and insect foes. From the attacks of insects the Yew tree, owing to its poisonous nature, appears to be singularly free; the vulnerable spot is the points of the young shoots, and these in certain localities are often attacked by a gall-fly, which, by inserting its eggs in them, arrests their growth, the leaves being developed in the form of a cone.

To account for the practice of planting Yews in churchyards several reasons are given. One ascribes it to Druidical custom; another to the fact that branches of it were often carried in procession on Palm Sunday in lieu of Palms. Yew trees in churchyards in East Kent, and also in Ireland, are even now called Palms. Ablett says the branches were carried over the dead by mourners and thrown beneath the coffin in the grave as a type of immortality. A more cogent reason than any, the author thinks, was the necessity of providing a supply of bow staves for our bowmen in old days before the "clothyard shaft" was finally elbowed out by the "villainous saltpetre." The Yews of our churchyards would then be the few that survived the severe cutting to which Yews were subjected in old times. Even in Elizabeth's reign

the Yew had become so scarce. . . . that bowyers were directed to have four bows of Witch Hazel or Elm to one of Yew, and no person under seventeen, unless possessed of movables worth forty marks, or the son of parents having an estate of ten pounds per annum, might shoot "on a Yew bow."

However, the author is careful to state that, according to Giraldus, the practice of planting Yews in churchyards was common long before "Yew bows" were in general use.

The etymology of the word Yew is variously ascribed. According to Dr. Johnson it is derived from the original Anglo-Saxon, or from the Welsh *yw*; Dr. Price from the Latin *Iva*,

which also signifies the Ivy. According to Mr. J. G. Cumming, Yew is ancient British for existent and enduring, having the same root as Jehovah; and Yew in Welsh means "it is." An ingenious inquirer in "Notes and Queries" (1887) suggested "view," and quoted several instances of the trees being called "view" trees; but, as Dr. Lowe points out, this was probably a mistake due to the interchangeable use of the letters *y* and *v*, which sometimes occurs in old writings and speech, and which still obtains in Norfolk, "where it is not uncommon to speak of the Vine of the Grape wine, meaning the wine of the Grape Vine."

Poetical allusions to the Yew are, of course, frequent. Thus Chaucer:—

With many high lorer and pyu  
Was renged clean all that gardyn  
With Cipres and with Oliveres,  
Of which that nigh no plente here is  
There were Elmes grete and strong,  
Maples, Asshe, Ook, Asp, Planes longe,  
Fyn Ew, Popler and Lindes faire,  
And other trees full many a payre.

Spenser, also, in the *Faerie Queene*:—

The Firre that weepeth still,  
The Willow worne of forlorne paramours,  
The Eugh obedient to the bender's will.

In more warlike strain, Michael Drayton (*Ballad of Agincourt*):

With Spanish Yew so strong,  
Arrows a cloth-yard long,  
That like to serpents stung,  
Piercing the weather.

Shakespeare often introduces the Yew in incantations and in passages full of melancholy and forebodings. In one place he speaks of it as "double fatal," in allusion, doubtless, to the poisonous nature of the tree. Thus (*King Richard II.*, act iii.):—

Thy very beadsmen learn to bend their bows,  
Of double-fatal Yew against thy state.

Poetical allusions to the Yew might be instanced almost *ad infinitum*, but the following one from Wordsworth's poem, *Yew Trees*, is perhaps the most graphic, and with it we bring our selections from Dr. Lowe's list to a close. After telling us that

There is a Yew tree, pride of Lorton Vale,  
he continues:

But worthier still of note  
Are those fraternal four of Borrodale,  
Joined in one solemn and capacious grove.  
Huge trunks! and each particular trunk a  
growth  
Of intertwined fibres serpentine,  
Up-coiling and inveterately convolved,  
Nor uninformed with phantasy, and looks  
That threaten the profane: a pillared shade,  
Upon whose grassless floor of red-brown hue,  
By sheddings from the pining umbrage tinged  
Perennially—beneath whose sable roof  
Of boughs, as if for festal purpose, decked  
With unreforming berries—ghostly shapes  
May meet at noontide.

The poisonous properties of the Yew are now well established, only the "sweet mucilaginous cup" surrounding the seed is quite harmless. It is doubtful whether birds even eat more than a certain quantity, if at all, of the seeds, although the latter are less poisonous than the leaves. It is on record that 800 grammes of the seeds administered to a fasting horse produced no ill-results. The wood and bark are less poisonous than the leaves, as is the highly noxious qualities of which all authorities agree.

"The Yew Trees of Great Britain and Ireland" ought to find a place in the library of every country house as a work of reference. It is well printed and is full of illustrations.

## STOVE AND GREENHOUSE.

## LILY OF THE VALLEY FORCING.\*

OF the thousand and one plants which readily submit to be forced into flower out of their ordinary season it may be doubted if there is one having anything like the universal popularity which the Lily of the Valley enjoys. Half a century ago clumps of Lilies were grown in Berlin and Hamburg in a small way to get a few blooms for Christmas and new year. By 1856 between twenty and thirty nurserymen in and around Berlin had taken up the cultivation, but in all cases only on a small scale. In 1859-60 the largest quantity of flowering crowns that any one nurseryman produced annually was 60,000; but this gradually increased, until in 1870 seventy-two acres of Lilies were under cultivation outside the city of Berlin. At the

owing to the nature of the soil, they are kept growing too long, and do not ripen off early enough. The ground must be deeply dug and well broken at the same time, working in plenty of old hotbed manure, linings, rotten leaves, &c., all well decomposed and crumbled to pieces. This work should be done in the autumn in dry weather, in order to be ready for planting as soon as crowns can be obtained. I greatly prefer autumn planting, considering that the sooner the crowns are in the ground the better. Nothing is more injurious to the roots of Lilies than exposure to sun and wind. I have been compelled sometimes to plant in March in drying east winds with bright sunshine, when it has been impossible to get the roots covered quickly enough to prevent their getting dry, and the consequences have been disastrous. The ground having been prepared, the best and quickest method of planting is in rows 7 or 8 inches apart, the plants being about 1 inch apart

summer. Thus when they are fit to lift as flowering crowns their actual age is three and a half years. It is true that by good cultivation many of these crowns will bloom in two years from the time of planting, and many growers have been tempted to lift them at that age; but experience has taught me that the percentage of flowering crowns is smaller and the increase of planting crowns less than when they are left a year longer undisturbed. It is generally understood that Lilies of the Valley must be three years old before they bloom, and they will then flower every alternate year. This is the rule, but there are exceptions. By good cultivation, *i.e.*, high feeding at the proper time with liquid manure, and if special care is taken to remove the flower as soon as ever it is open, by pulling its stalk right out of the crown, such crowns will bloom several years in succession; and hence it is obvious that Lily crowns can be

A group of Agaves, Aloes and Yuccas in the garden at La Mortola. From a photograph sent by Mr. Hanbury. (See p. 97.)

present moment there are on the Continent and in England many thousands of acres devoted solely to the production of Lily of the Valley crowns. In order to be successful in forcing Lilies of the Valley, the

## CULTURE OF THE CROWNS

demand the first consideration. I have seen Lilies grow in almost every kind of soil and situation, doing better in some than in others; but experience has taught me that the best soil for growing crowns for forcing is a light sandy loam with a damp subsoil, and the best situation is an open one to the south and west, sheltered, if possible, from the east and north. In cold and heavy clay land they will not do well; they will grow, and sometimes produce very strong crowns, with but few fibrous roots; but such crowns are not fit for early forcing, as,

\* Paper read by Mr. T. Jannoch before the Royal Horticultural Society, August 25, 1896.

in the rows: paths of 15 to 18 inches wide may be left between every eight rows for the convenience of weeding. In planting, which is done by throwing out trenches about 5 inches deep, take care that the crowns are not set too deep; they should be only just deep enough for the tips of the crowns to be level with the surface of the ground. A good mulching of cow manure, or, if this cannot be had, well-rotted stable manure, completes the work, and nothing further is required but keeping the beds free from weeds and giving them plenty of water in dry weather during the summer. If one-year-old crowns have been selected for the start, they will require three seasons of growth before being fit to be lifted for forcing. It must not be supposed that so-called one-year-old crowns are actually twelve months old: they really represent only four to five months' growth, the rhizomes beginning to grow in June or July, forming the crown under ground during the

made to bloom twice within twelve months, *viz.*, once at their natural time in May, and again taken up the following autumn and forced into bloom before January.

## FORCING.

To force Lily of the Valley successfully it is of the utmost importance to have well-ripened and well-matured crowns that have fully completed their growth and are perfectly at rest. Before they have undergone a period of rest, be it ever so short, you cannot force them, no matter what amount of heat you may give them. Much also depends on where and how the crowns have been grown. The best are undoubtedly those that have been grown in light sandy soil, heavily manured and well exposed to the sun, as they will complete their growth and go sooner to rest than those grown in heavy soil and shady places. Forcing may commence about the end of October or beginning of

November; the methods adopted are various, but for early flowers, in November and December, a close propagating or forcing pit is absolutely necessary in order to maintain a moist and even temperature. If pots are used, plant about twelve crowns in a 5-inch pot in the following manner: Place four crowns in the palm of your left hand, then a layer of soil on the roots, again four crowns and more soil, and then the remaining four crowns, keeping the crowns all level; close your hand and drop the whole into a 5-inch pot, working the soil well in between each crown, so as to have them equally divided and all crowns standing level just above the brim of the pot. Give them a good watering, and plunge the pots in a bed of either Moss or cocoa-nut fibre; cover lightly with 2 inches or 3 inches of clean Moss, and close the bed with boards to keep it perfectly dark. Bring the bottom-heat up to 80° Fahrenheit at once, and gradually increase to 95° within a fortnight, maintaining a regular and even temperature the while. Never allow the thermometer to rise above 100° or to fall lower than 80°, or much harm will be done. Examine the pots daily, keep a moist atmosphere, and water (when necessary) with water of exactly the same temperature as the bottom-heat in which they are plunged. When the crowns start into growth and are about 2 inches high, remove the top covering of Moss and gradually inure them to the light, still, of course, maintaining a high temperature. As soon as the bottom bells begin to open remove to a cooler temperature and discontinue syringing overhead, as moisture hanging on the blooms is apt to spot the bells. Another method, more usually adopted, and which saves much labour and room, is to plant the crowns an inch apart in boxes of a convenient size and treat as above. Still another plan, but one not often practised now, is to plant the crowns in forcing beds thickly together, and when they have grown 2 inches or 3 inches to transplant them into pots. It may be here mentioned that actual flowering can be retarded, when so desired, by the boxes in which the crowns are forced being removed from the forcing house into a cooler one of genial temperature. The heat, however, must be always even and not too low, or else the damp will speedily ruin the flowers. The foregoing methods refer principally to the early period, before Christmas; later in the season, and as the spring advances, forcing is an easier matter. The temperature need not be kept so regular, and all that is required is warmth and moisture, which will soon start the crowns into growth. More attention should at this later time be paid to the hardening off, shading from bright sunshine, and never allowing them to get dry at the roots; they should also have more room by planting the crowns wider apart, as more leaves will now appear than before Christmas. Finally, it should be pointed out that if temporary frames are placed over the beds of flowering crowns out of doors in March their blooming will be hastened by two or three weeks. For this purpose keeping them close and watering as required are the only necessary directions. It is quite immaterial in what soil the crowns are planted for forcing, as absolutely no new roots are formed during this period; anything, in fact, which retains moisture will do. You cannot improve the blooms by planting the crowns in the very best of soil or by giving them manure water. All the nutriment required for the development of the flowers is gathered during the previous growing season and is stored up in the roots. It is not generally known that forced Lilies will bear almost any rough treatment. They can be pulled out of their boxes or pots

when in full bloom for making up into fancy stands, ornamental pots, and nicknacks of any description without flagging or spoiling. They can be sent by post or rail hundreds of miles packed in a little damp Moss, when they may be again planted and will look as fresh as if they had never been disturbed. I once sent a quantity in an hermetically-sealed box to Pietermaritzburg, where they arrived after their long ocean and land journey as fresh as if they had only travelled a few miles. As regards the

## VARIETIES

best adapted for forcing, that known as the Berlin is unquestionably the best for early work. The Dutch and Hamburg ones are good for late forcing, but my experience is that they do not approach the Berlin strain for forcing before Christmas. These three varieties are said to be seedlings, or possibly "sports," from the common or wild Lily of the Valley, on which they are immense improvements. No amount of cultivation would ever transform the wild plant into a rival of either the Hamburg, the Berlin, or the Dutch forms. The Dutch variety is of more spindly growth than the Berlin, and has, moreover, a weak and drawn appearance.

Retarding Lily of the Valley crowns is now done both extensively and successfully. The movement, however, is still in quite its infancy.

**Lindenia rivalis.**—This is a pretty stove or warm greenhouse shrubby plant, bearing long tubular white flowers so freely that it seems to be nearly always in bloom. The tube is 4 inches or 5 inches in length, pure white at the mouth, reddish below, the evergreen leaves about 3 inches long. It does well in a moist stove heat, and a nice plant is in bloom at Chelsea in the Ixora house. It is a native of Mexico, and was introduced in 1856.

**Ericas at Clapton.**—Although but few of the Ericas are now in flower, a look at the plants at Messrs. Hugh Low and Co.'s nursery was very interesting. Thousands of plants in great variety and all sizes are to be seen, each one a model of good culture, and not one in a thousand showing as much as a brown leaf. The majority are stood outside in the full sun, and so arranged that while not crowding each other the foliage of each makes a little shade to the pot next to it. *E. hymalis* seems here, as everywhere, a great favourite, there being apparently tens of thousands of it. The only species I noticed in bloom was the bright and showy *E. cerinthoides coronata*. This too is very largely grown, and one can easily imagine that it meets with a ready sale, the bright scarlet blossoms having a really fine effect upon the dark green foliage.—R.

**Zephyranthes carinata.**—Given the same treatment as *Vallota purpurea*, this *Zephyranthes* forms an extremely attractive object in the greenhouse during the month of July and sometimes well on into August. The bulbs of this are small, not much larger than a good-sized Snow-drop, and the grass-like leaves, though 8 inches or 9 inches long, are arranged in a spreading manner, and consequently do not rise very far above the soil. The flowers, which are borne on stems usually less than a foot high, are a great deal like those of the *Vallota*, but of a beautiful rich deep rose shade. Each flower is borne singly on a stem, but, as the bulbs increase quickly, they soon form a mass or clump, and a succession of blossoms is in this way maintained for some time. As so many bulbous plants come from South Africa and this *Zephyranthes* bears such a great general resemblance to *Vallota purpurea*, it is often assumed to be a native of the Cape region, instead of which it hails from Mexico, from whence it was introduced in 1824. It succeeds well in an ordinary greenhouse, or even in a cold frame from which frost is just excluded.

About half a dozen bulbs in a pot 5 inches in diameter will form an effective little clump, or larger masses can be arranged in the same way. The soil employed should be principally sandy loam, such as will remain in good condition for years, as this *Zephyranthes*, like many other bulbous plants, is most satisfactory when allowed to remain undisturbed at the roots. A second species, *Z. candida*, is hardy in a sheltered position, but to ensure a display of bloom it must be in a sunny spot. The flowers of this, which are white and not unlike those of a *Crocus*, are borne in great profusion towards the end of August or even later.—H. P.

**The Oleander.**—Among the many classes of plants whose merits are totally overlooked at the present day must be included the Oleander, of which there are several varieties in cultivation, but, except occasionally in some old-fashioned garden, none of them are ever met with; and though to a limited extent kept in stock by a few of our nurserymen, there is really no demand whatever for them. Notwithstanding this, the Oleander is a really beautiful shrub, that will flower year after year with but little attention. Grown in pots or tubs, it may be wintered in the greenhouse or conservatory, and during the summer can be placed out of doors in a sunny spot. Such conditions are favourable to the production of blossoms, which expand about July, the plant then being particularly attractive. When in flower they may be allowed to remain out of doors or removed to the conservatory if they are needed at that period. A loose, open-growing shrub it naturally is, and any attempt to alter its character in this respect will only end in failure. If a specimen is cut back, at least one year's crop of blossom will be sacrificed. The cultural requirements of the Oleander are in no way exacting, for cuttings strike root very readily either in soil, sand or water if they are kept close for a little while, and they grow away freely in any ordinary potting compost. In commencing with young plants, the tendency to run up tall and naked should be particularly borne in mind, and to obviate this they must be freely stopped during their earlier stages, as in this way the foundation of an effective specimen is laid.—T.

## LILIUM ALEXANDRÆ.

It is now four years since this beautiful and distinct Lily made its appearance in this country, and it was shown in such grand condition on July 11, 1893, that a first-class certificate was bestowed upon it. Since then it has been seen but little till the present year, in the early part of which some importations were disposed of in the London sale rooms, and it is probable that some at least of the many examples that I have met with recently were obtained in this way. Its comparatively dwarf habit is to many a great recommendation, for numerous examples have come under my notice this season not more than 18 inches high, yet each plant was carrying three or four of its massive blossoms. When first public attention was directed towards this Lily, it was stated to be a hybrid between *L. longiflorum* and *L. speciosum*, but when in flower, *L. auratum* and *L. longiflorum* were suggested as the probable parents. This latter view I am inclined to favour, for it is in many ways about intermediate between these two last-named species. Firstly, the bulb, which is of a yellowish white colour, would almost pass for that of *L. longiflorum*, though there is somewhat of the auratum appearance about it, but no trace whatever of *L. speciosum*. The flowers, again, are shorter than the Japanese forms of *L. longiflorum* and more tubular than those of *L. auratum*, while the anthers are not invariably of a brown tint, as in a few instances I have seen them nearly as yellow as those of *L. longiflorum*. The fragrance, too, suggests a nearer affinity to this last-named than to either *L. speciosum* or *L. auratum*.

There is a certain amount of difference to be found among the individual plants of *L. Alexandræ*, as, apart from the anthers just noted,

some flowers are longer than others, while the segments reflex differently and foliage distinctions may also be noticed. This Lily was at first known as *L. Uke-uri*, but it is now generally known as *L. Alexandre*. Whether an artificial or a natural hybrid, a considerable amount of confusion seems to prevail with regard to its origin, but in any case it occurs in an apparently wild state on Uke Island, the name *Uke-uri* signifying the Uke Island Lily. The bulbs are not large, being about the size of those of an average sample of *L. longiflorum*, and such as these will produce three or four fine blossoms. It is a particularly desirable Lily to grow in pots for the decoration of the greenhouse or conservatory, as it does not run up tall and weak under glass, added to which it is not too strongly scented, while the massive wax-like petals retain their freshness for a longer period than many other Lilies. Like *L. longiflorum*, it starts into growth early in the year, and though Japanese importations sometimes reach here as late as March in good condition, yet in purchasing dormant bulbs at that season they should be carefully examined to see whether they have suffered in any way by being kept out of the ground so long. T.

#### SHORT NOTES.—STOVE & GREENHOUSE.

**Primula obconica.**—On a recent visit to Sandhurst Lodge, Wokingham, I noted a batch of *Primula obconica* of a good rose colour, and, as far as I could see, the strain was fixed. The plants showed they had given an enormous amount of bloom. It is a great advance on the *grandiflora* type in colour.—J. C.

**Browallia speciosa major in pots**—"H. P." at page 65 speaks in high terms of this plant. I quite agree with all he says as to its value as a pot plant for house embellishment. Recently I saw some grand pots of this *Browallia* at Sandhurst Lodge. These were growing in 5-inch and 6-inch pots, nice bushy plants full of bloom.—JOHN CROOK.

**Achimenes at Sandhurst Lodge.**—The *Achimenes* is a great favourite here. The plants are grown in 5-inch and 6-inch pots. As I liked these with their numerous shades of colour I regretted they are not more often seen. The following are a few of the best kinds: *Coccinea*, flowers very bright, but small; *Carl Walporth*, *Dazzle*, *Meteor*, *Ambroise Verschaffelt*, *Longiflora major*, *Sir Treherne Thomas*, and *Rose Queen*. This last is amongst the most useful, as it needs no stakes when well grown.—J. C.

**Aristolochia gigas.**—In a warm house against a back wall at Sandhurst Lodge I noticed a nice healthy plant of *Aristolochia gigas*. It had three large blooms open. At another end of the house in a narrow border *Begonia corallina* was planted and trained over the roof. It was in full bloom, and as the blooms hung down with their long foot-tendrils they were very effective. This is a strong-growing kind, and just adapted for planting out to cover walls and roof trellises, &c. It is a continuous blooming kind, and should be more often seen.—J. CROOK.

## ORCHIDS.

### BURLINGTONIA CANDIDA.

As an easily grown and free-flowering species this *Burlingtonia* would be hard to beat among the smaller-flowered Orchids. The habit is dwarf, the pseudo-bulbs flattened, bearing stiff, dark shining green leaves. The flowers occur on arching or semi-erect racemes that spring from the base of the pseudo-bulbs between the sheathing foliage and are of the purest glistening white, with a stain of golden yellow on the lip. The flowers appear at various times during the spring and summer, and if not kept too hot or damped with the syringe, last a long time in good condition. Being a dwarf plant, the amount of room it takes up is little; indeed, in a well-flowered medium-sized specimen one can hardly see the leaves, the flower-spikes almost hiding them. Such plants have a very pretty effect suspended from the roof in wooden

baskets, and owing to the amount of air and light they get in such positions they are usually satisfactory. The latter points are perhaps the most important in its culture, for the plant grows naturally upon the highest trees. With regard to compost, an ordinary peat and Moss mixture kept open suits it well, but it is a difficult plant to keep at home. The roots are very freely produced, and many are pushed almost erect, so that it is impossible to bury all of them. But as long as the base of the new growth is resting on the compost they will take no harm, as a fair number are sure to enter it. To let it ramble away at will, on the other hand, is to court failure, for valuable as air roots are as accessories to those in the compost, they are not to be depended upon. No harm comes from cutting partly through the rhizome and bending this round to bring the pseudo-bulb nearer the centre of the plant, or to cover a bare place in a large specimen, but avoid breaking it more than necessary. Pans or pots may also be used for growing it in, and the temperature of the *Cattleya* house or even of the East India house is not too high for them when growing. During this time give a very free supply of water, but when at rest this may be sensibly diminished, not altogether withheld, as this would cause the growths to be weak in spring, but much less than when growing freely. Its worst insect enemy is a small white scale that is very difficult to thoroughly eradicate, though it may be kept in check by timely sponging and frequent light syringings overhead when growing. Its stronghold is in the sheathing bases of the leaves, and these should have attention when cleaning. This *Burlingtonia* comes from Demerara, whence it was introduced in 1834.

**Gongora Loddigesi.**—This species is now in flower with Messrs. Veitch. It grows and blooms after the manner of *G. atro-purpurea*, but the pseudo-bulbs are more conical and less ribbed. The leaves are stiff, deep green, and each about 6 inches in length. The spikes carry from nine to a dozen flowers on each. The colour is a pale sepia-brown, with overlying tints of a deeper hue, the segments being almost transparent in appearance. The plant is carrying five fine spikes.

**Odontoglossum cristatellum.**—Whether or not this is distinct enough to warrant specific rank is a question; it is certainly distinct as a garden plant. The sepals and petals are yellow, but the ground colour is nearly hidden by the large brownish-purple blotches. The lip is yellow, brown at the point, much crested, the blossoms being very sweetly scented. It does well in a cool, moist house the whole year. Though introduced nearly twenty years ago, this plant is still not common, and it makes a nice feature in the cool house just now.

**Cypripedium Clinkaberryanum.**—This is a very handsome *Cypripedium* raised from *C. Roebelinii* and *C. Curtisi*. A fine plant is now in flower at Messrs. Veitch and Sons' nursery. The scape is tall, reddish, and hairy, the dorsal sepal having lines of purple upon a whitish ground; the lower sepal is paler in its markings and greenish. The petals are long and drooping, so closely coloured with crimson-purple that the white ground is hardly seen. *C. Clinkaberryanum* was raised by Messrs. Pitcher and Manda.

**Oncidium phymatochilum.**—This is in first-rate order at Messrs. Veitch's, the spikes carrying an immense number of flowers and having a remarkably fine effect. They grow erect, but the crowds of blossom hang around very gracefully. The sepals and petals are yellowish green, with a few reddish spots, and the lip is white on the front lobe, yellow at the sides. The flowers last a long time in good condition. It is not a difficult plant to grow, thriving in medium-sized, well-drained pots of peat and Moss in the *Cat-*

*tleya* house. It is a native of Brazil and was introduced in 1843.

**Dendrobium d'Albertisi.**—The singular habit and blossoms of this plant should make it a favourite were it better known. A fine plant in bloom at Messrs. Hugh Low and Co.'s nursery is carrying several spikes of bloom. The petals grow erect, are pure white at the base, becoming green at the tips. The lip is lined with purple and the sepals are pure white. The flowers are very lasting, and the plant being a native of New Guinea requires abundant heat and moisture while making its growth.

**Disa grandiflora.**—This is bright and effective in many collections just now, and may be seen in variety at Mr. Bull's, a pretty contrast with the typical form being *D. grandiflora Barrelli*, a variety introduced by him from the Cape. In place of the usual crimson tint the outer segments are orange-scarlet, the lip being much paler than that of the typical form. Both are beautiful cool house kinds if well done, requiring to be potted in a nice open description of compost in thoroughly drained pots or pans. Plenty of water at the root and abundance of air are needed all the year round.

**Odontoglossum læve.**—This comes from a correspondent for a name. It is a useful plant, strong growing and free blooming, and the flowers much resemble those of a *Miltonia* in the smooth, almost crestless lip. It comes from Mexico, whence it was sent to Chiswick in 1841 by Mr. G. Ure-Skinner. It does with rather more compost than the cool *Odontoglossum* generally, being very free rooting when in good condition. It should be grown near a ventilator and in a light position, this ripening it well and making it very free blooming. The flowers last a long time and are at first sweetly scented.

**Epidendrum Brassavola.**—As indicated by the specific name, the flowers of this plant bear a considerable resemblance to those of a *Brassavola*. They are produced from the apex of the pseudo bulb upon a tall erect scape, and are each upward of 4 inches across. The sepals and petals are rich brownish yellow, the narrowly heart-shaped lip being rosy-purple in front, yellowish white with deeper lines at the base. It makes a handsome specimen when well grown, a very fine piece being now in flower in Mr. Bull's nursery at Chelsea. It is by no means a difficult plant to grow, thriving well at the coolest end of the *Cattleya* house and needing plenty of water while growing.

**Cycnoches chlorochilon.**—This I have noted in several collections this week, the varieties differing a little in size and colour. The best form I have seen is at Messrs. Veitch's, the flowers being very large and the colour almost a golden yellow on the broad segments. As usual when the individual blooms are large but few are produced, the longer spikes having always smaller flowers. *C. chlorochilon* likes a good substantial compost, a fair quantity of good sound loam being of assistance. It may be grown in baskets or pots, these being well drained and clean. Plenty of heat and moisture is necessary all through the growing season, but during the winter the plants must be kept on the dry side.—R.

**Cœlogyne Sanderiana.**—This species was introduced about ten years ago by Messrs. Sander and Co., but does not appear to be very popular. It is a fairly large grower, the blossoms appearing now from the side of the oval pseudo-bulbs. Each bears five or six flowers, whitish on the sepals and petals, the lip pure white, with a yellow centre and lines of reddish brown. The foliage is bold and striking, and when in good condition it is one of the most beautiful species in cultivation. Being a native of some of the islands about Java close to the Equator, it likes more heat than the majority of *Cœlogynes*, and a shady moist house suits it best.

**Cattleya gigas.**—Among a large number of plants of this fine species noted during the last few weeks at the principal nurseries there is considerable variety. *C. g. Regina* is a magnificent

flower, the beautiful lip well shown owing to the flexed outer segments. It is like *imperialis* in shape, but more deeply tinted, while in *C. g. marginata* a distinct margin of rosy-white surrounds the deeper tint of the lip. *C. g. Sanderiana* is another fine and better-known form, a rather fancifully named one I came across being called *aurea* owing to a more widely distributed blotch of yellow than usual. The species generally is in capital form this season, and each year it seems to increase in favour.

## NOTES OF THE WEEK.

**Sedum maximum purpureum** is now conspicuous among its tribe by reason of its dark purple leaves and tall growth. In the latter respect it is nearly as vigorous as *S. spectabile*, and the two by association could be made very effective in the rock garden or border.

**Rosa rugosa**.—Two plants of this are just now producing very fine large fruits. I have read somewhere that they are edible and make a good preserve. I should be glad to know if any of your readers have tried them and found them good and wholesome.—EUSTACE F. CLARK.

**Delphinium Willdenowii**.—This is one of the choicest of the single kinds, and produces fine handsome spikes of clear bright blue flowers, the latter of a shade akin to those of the lovely *D. Belladonna*. The flowers are of a lustrous shining blue, a shade of colour that tells well in the garden.

**Ita virginiana** is a compact bush bearing numerous spikes of white blossoms very freely even on quite small plants. The plant when in good condition will reach from 4 feet to 6 feet high, flowering abundantly. It is quite hardy and deciduous, growing best in a bed of peat and sandy loam.

**Monarda didyma**.—Apart from the pleasing aroma arising from its leaves under friction, this produces abundantly fine heads of scarlet flowers that are a long time conspicuous in the garden. The plant is of the easiest culture, growing and flowering freely in any garden soil. The above is perhaps the best of all this group.

**Anthericum graminifolium**.—This has a beauty of its own in the border or even on the margins of sloping grassy banks. In any of these positions the profusion of its graceful spikes is very pretty, with their succession of pure white, though small blossoms. The plant does well in quite ordinary soil if the latter is fairly good.

**Carnation Edith Leadenham** is perhaps one of the finest pure white kinds in the border section of these flowers. Rather taller in habit of growth than many kinds is a good fault in the event of heavy storms that frequently mar the beauty of very pure flowers. It should make a very fine group, and is certainly an acquisition to choice whites.

**Lilium nepalense**.—This handsome Lily with yellow and black flowers was exhibited in fine condition at the Drill Hall a week ago by Messrs. Low and Co., of Clapton. The finely flowered plants were 6 feet or more high, and in company with the even more towering Trumpet Lily, *L. Wallichianum*, made a most imposing display.

**Hibiscus cœlestis** is a handsome form of this family, with large blossoms of deep mauve that are the more conspicuous from the fact of their having a base of crimson-purple. Such showy plants are worth cultivating freely, particularly in isolated groups on the grass, or the well-kept shrubbery could be made very showy by adding a few such things.

**Spiræa kamschatca** is perhaps one of the giants among herbaceous Spiræas, and though not showy, possesses an imposing appearance when towering several feet high. At the recent Drill Hall meeting Messrs. Paul and Son had examples of this. For marshy ground or the margin of the

lake it should prove of service. The examples in question were fully 7 feet high.

**Tritoma pauciflora**.—Though small and scarcely showy when compared with the giant inflorescences of this group in general, this plant is still interesting by reason of its pretty spikes of yellow cylindrically formed flowers. In a choice collection of rare plants this is worth growing, or in the rock garden, but it will scarcely impress one when seen only in solitary examples in the border.

**Heliopsis Pitcheriana**.—This handsome plant, exhibited by Messrs. Paul and Son recently at the Royal Horticultural show, and deservedly given the award of merit, should prove of considerable value in the garden. The blossoms, each 2 inches or 3 inches across, of the deepest golden orange, the ray florets firm, of good substance, are freely borne on a bushy, compact habit of growth.

**Michauxia campanuloides**.—This very peculiar plant, though curious and interesting, is certainly not the useful subject that may be expected from descriptions of the plant. Tall almost to ungainliness, it produces a thinly formed and branching inflorescence sometimes as high as 10 feet, but there is little beauty in the general habit or character of the plant, and still less of utility for the flower garden or border.

**Veratrum nigrum**.—Among fine-foliaged plants this is now conspicuous. The handsome foliage is quite exceptional in the garden, and when in early summer the pyramidal head of blossom appears it is quite a feature. For the wild garden the Veratrum are well suited and require but little care, being very hardy and vigorous. They require establishing in a deep soil before they flower well, when they attain some 5 feet or so in height.

**Eucryphia pinnatifida**.—The free-flowering examples of this plant that are occasionally shown by the Messrs. Veitch at the Drill Hall plainly show the plant to be under their care at least vigorous and free flowering; but to secure plenty of flowers on this plant, a deep, fairly rich soil and pure air appear almost if not quite essential. Well-flowered bushes of such things, however, are not common, and its cultivation may with advantage be considerably extended.

**Hunnemannia fumariæfolia**.—Among half-hardy annuals this member of the Poppy tribe is now very showy. Its distinct habit of growth and rather glaucous, triternate leaves make an excellent setting for the clear yellow blossoms, that are borne singly on the erect branching stems. The plant requires a good rich soil to attain perfection, and will grow to 2 feet high in such and flower profusely. Seeds should be sown about February, and the plants be grown on in frames till May.

**Campanula carpatica pelviformis**.—Among the members of this numerous family none are more distinct and worthy of general culture than this, which is said to be a selected seedling from *C. turbinata*. Instead of the well-known flowers of this latter, however, the above plant produces numerous large blossoms, deeply saucer-shaped in form, in rather lax panicles on freely branching stems, that are a foot or more high in established plants. The above should be found in every collection of good hardy plants, for it is certainly one of the best of its class, and both compact and free flowering. The blossoms, each about 2 inches across, are pale lilac.

**Flowers in Hants**.—The things look lovely and such pretty mixtures make themselves. There was a *Pyrus salicifolia*, silvery leaf, into which a yellow *Silphium* and a pink *Spiræa Nobleana* had twined. Then a brilliant red *Rose Campion* was peeping through a *Milkmaid Holly*. *Potentilla Rollissoni* is still in bloom. The double pink *Bramble* and yellow *Japanese Honeysuckle* in a large mass at my entrance gate are admired by the passers-by. *Lonicera grata* is lovely, and so is *L. gigantea*. *Chelone barbata antwerpensis* is magnificent. *Hedychium Gardnerianum* is

lovely, and *Melianthus major*, *Platycodon Mariæi* about as handsome as anything. I have a *Phytolacca* which seems better than *P. decandra*. *Asclepias cornuta* is nice coming up through shrubs. *Veratrum nigrum*, 8 feet high, is splendid.—M. A. ROBB, *Liphook*.

**Androsace lanuginosa** is now among the more freely flowered of alpinics in the rock garden. Generally speaking, it is not a plant that covers much space owing to the trailing manner of its growth, but where large plants exist or such as were pinched at the point earlier in the season, a more spreading habit will have been secured. Best of all, however, is to plant the cuttings, which root freely in sand, rather closely together in groups, so that they may grow and form one large, important group. It may not be generally known that by a system of pruning back the old stems to near the base each year a stronger growth is secured, and as a result larger heads of bloom; otherwise the rather elongated stems assume a straggling form, and not unfrequently the blossoms suffer in proportion. This method is suited to all the varieties of this kind. Seeds should also be carefully preserved, for this is an excellent mode of increasing these beautiful plants.

**Crinum Powelli album**.—Among bulbous plants and in these gardens where they are hardy with only a minimum of protection nothing can surpass this handsome kind. For the open garden, however, it should only be planted in the more sheltered positions, such, for example, as against a greenhouse or a south wall. At the present time at Kew are some of the handsomest flowering groups we have seen. These are all planted against the wall of the large Palm house at either side the entrance. The position of course is a most favoured one, yet it would be difficult to produce a finer group with the best culture in a greenhouse. Some of the flowering scapes were about 3 feet high, and bearing as many as eighteen flowers in an umbel. These are of the purest white and beautifully fragrant. Another handsome group is of hybrid origin, the result of crossing *C. Moorei* and *C. capense*. In this instance the stems were nearly 4 feet high, and the plants flowering freely made a really fine display of what in the open garden cannot be called an every-day occurrence.

**Campanula isophylla alba**.—Among hardy plants of a trailing or drooping habit this lovely form is almost, if not quite, unique; indeed, nothing that we know can compare with the abundance of its pure white blossoms produced on trailing stems upwards of 2 feet in length. Thus seen it is one mass of the purest white, and quite alone even in the much varied group to which it belongs. For the rock garden its trailing masses of bloom are indispensable, while for window boxes or hanging-baskets nothing can equal it. Two-year-old plants flower earlier and more abundantly than younger plants. The typical species, *C. isophylla*, seems a scarce plant, and one much more difficult to obtain true to name, even where hardy plants are a feature. The name is freely catalogued notwithstanding, but the plant usually supplied is more nearly related to *C. fragilis* than the above. The forms of *C. fragilis* are more procumbent in habit besides being distinct in leaf and other points. For the purpose here indicated the latter is also a much inferior plant.

**Pentstemon hybridum**.—The hybrid forms of this group that have originated from *P. gentianoides* and other species are now among the showiest plants in the garden, the flowers bright and varied. At the R.H.S. recently Sir Trevor Lawrence exhibited a fine assortment of these useful plants as cut flowers. These were a marked improvement upon the named varieties of a few years since. Indeed, it appears somewhat a waste of time, in a group so usually good, where a reliable strain obtains, to go to the trouble of naming at all, the more so when the merits of each entitle one and all to equal recognition. For the garden, however, they are invaluable, and as seed-

ings may be sown and brought into flower in something less than six months, it is scarcely worth while to purchase so-called named varieties, many of which are quite inferior, and decidedly less vigorous and free flowering than a large majority of seedlings of a good strain. Seed may be sown in January or February prior to planting in May; meanwhile the plants should be grown on quickly and at the same time as hardily as is consistent with discretion and good culture.

**Olearia Haasti.**—In many parts of the country, even towards the south, this New Zealand composite was badly cut back during the severe frosts of January and February, 1895. Now, however, it has quite recovered and is at the present time finely in flower, some of the bushes being completely covered with a sheet of white blossoms. It is a really valuable shrub and quite hardy in the home counties, except during winters like that just mentioned, which, happily, occur but seldom. It is of neat rounded habit, and its small Myrtle-like leaves are of a lustrous dark green above and silvery grey beneath. Without considering its beauty as a flowering shrub, it would be worth growing as a compact, dwarf, and slow-growing evergreen, interesting also as one of the comparatively few hardy composites of a woody nature. It bears its flowers in short corymbose clusters 2 inches or more across, the ray petals being few, but comparatively large and almost pure white. In New Zealand, where it is a native of the mountains of the Middle Island at altitudes of 4000 feet to 5000 feet, it grows ultimately into a small bushy tree. It was introduced by the Messrs. Veitch, of Exeter, in 1858.—B.

**Hemerocallis aurantiaca.**—Can any reader of THE GARDEN, speaking from experience, say whether a plant bearing the above name is in cultivation in gardens generally or otherwise, and where it may be obtained? I am not now referring to the handsome kind which is known by the name of major. Yet it is this very name that would lead one to suppose the existence of a typical species, and, indeed, such a plant has, I believe, been described some years since in a contemporary. Such a plant was doubtless described from living specimens, and yet the curious part is that no such plant appears to be known in nurseries. Under the circumstances, one may be right in inferring that only a small plant of the typical species existed, and in some way or other has never found its way into trade collections. That such a plant when once introduced could be lost entirely seems somewhat beyond reason in a group like the Day Lily, so characteristically vigorous. At the same time, there is the knowledge that such a plant existed years ago, sufficiently distinct, too, to be worthy specific rank, and yet unknown to our gardens. Years ago such a plant would have enriched the genera to which it belongs, but now the presence of the major variety in a measure precludes this. At the same time, any information as to the whereabouts of the type, its habitat, or introduction could not be without interest. Is it an overlooked plant in any botanic or private garden?—E. JENKINS.

**Cytisus nigricans.**—Among the later flowering Brooms—which, unfortunately, are not many in number—none deserve a wider cultivation than *C. nigricans*; not one of them certainly remains so long in bloom. Commencing to open its flowers during June, it is in full beauty through the entire month of July, and even now in August it has lost but little of its showiness. It bears long, erect spikes, which commence to flower at the bottom, and as the lower ones fade the upper ones keep opening, so that a single spike may bear fully-formed seed-pods, flowers and unexpanded buds simultaneously. Some of the longest spikes are 9 inches long, and the short-stalked flowers, which all point downwards, are of a clear bright yellow. The leaves are abundant, dark green, and consist of three obovate leaflets. The plants will attain from 3 feet to 6 feet in height if allowed to grow at will, but we find it best to keep them comparatively dwarf

by cutting the shoots that are now bearing flowers back to 2 inches next spring just as there are indications of renewed activity. They flower on the current season's growth, and the spikes are larger than on unpruned plants. There is a large hed in the arboretum at Kew that has been in flower for six weeks past. The species comes from the mountains of Central Europe, but although it has been in cultivation since 1730, it is not so often seen as its beauty, the length of time it flowers, and especially the season at which it is at its best would warrant.—B.

**Romneya Coulteri.**—About a year ago, during a visit to the extensive and very interesting nurseries of Messrs. Dickson, of Chester, I was much struck by the fine stock of this Californian Poppywort. It appears to thrive there outside in perfection, certainly better than I had seen it anywhere so far north, although in Devon and Cornwall it may be seen equally fine. When at its best it makes a really magnificent and striking shrub. One of the plants at Chester, if I remember rightly, was a spreading, loose-growing bush 6 feet or 7 feet high, and had borne several dozens of flowers open at one time. The species, however, is rare, and has never got a real foothold in English gardens. It is scarcely hardy in most parts of the country without winter protection, and when grown permanently under glass it grows lanky and does not flower freely—at least in my experience. Its stems are herbaceous and of a glaucous colour; the leaves also are glaucous, 3 inches to 5 inches long, deeply lobed, and have a few bristly hairs at the margins and on the stalks. The flower is very showy, being 6 inches across, with six pure white petals, beautifully crimped, surrounding a large spherical tuft of yellow stamens; it has a sweet and very pleasing odour. The species, which is the only one in the genus, was discovered by Dr. Coulter about fifty-three years ago in the San Diego County of California, where it occurs near the borders of streams. The generic name commemorates Dr. Romney Robinson, astronomer at Armagh in those days. Some small plants are in flower now at Kew.—B.

**Amorpha canescens.**—In the United States this little shrub is known as the Lead Plant, a name which it has obtained from the belief once held that its presence indicated the existence of lead in the soil. It bears but little resemblance superficially to the better-known *A. fruticosa*, being a dwarf shrub ranging from 2 feet to 4 feet high, and very distinct on account of the dull silvery hue of its foliage. The branches are erect, and except in mild winters die back to the ground each year; they are abundantly furnished with the finely pinnate leaves, and covered with a short soft pubescence. The flower-spikes are borne at the ends of the branches and in the axils of the leaves near, forming one large, compound raceme, which is 8 inches or more long and about half as much in diameter. The flowers are small, but very numerous, and the purplish-blue colour contrasts well with the grey and minutely divided foliage. The plant belongs to the leguminous family, but, as in all the *Amorphas*, the flower consists of the standard petal only; those parts of the corolla which in the papilionaceous section of the family are known as the keel and wings are altogether absent. The species has a wide distribution on the eastern side of North America, and extends from the region of the Red River in Canada to the Southern United States as far as Florida. It is not easy to propagate except by seeds, and in this country it flowers rather late for it to ripen them regularly every year, but during the last few hot seasons it has done so. It is naturally a deep rooting plant, and will stand drought better than most hardy shrubs.—B.

—The Messrs. Veitch showed this beautiful deciduous shrub in capital form at the last Drill Hall meeting of the Royal Horticultural Society. It is a very graceful plant, of 3 feet or 4 feet high usually, the frail twigs being freely covered with pinnate leaves, and producing numerous violet-coloured Heath-like blossoms in rather dense picate racemes.

## PUBLIC GARDENS.

**New open space at Hampstead.**—London County Council has just completed the purchase of Fortune Green, West Hampstead, which is to be used as a recreation ground, for £8000. The green comprises about three acres to be maintained as an open space by the Hampstead Vestry, which has agreed to contribute £3000 towards the purchase, a similar sum having been given by the Council, and the remainder raised by subscription.

**Wandsworth recreation ground.**—On Friday last, at a meeting of the Wandsworth Vestry, Dr. T. A. I. Howell read a letter from Dr. Longstaff announcing that he would have much pleasure in giving a sum of £5000 towards the £6000 required to complete the purchase of a large tract of land in the Putney Bridge Road playing fields for Wandsworth. Dr. Howell explained that the land was over nineteen acres extent and had a frontage to the river of nearly 1500 feet. The purchase price was £31,300, a part of this amount the London County Council had voted £15,500, while the Wandsworth District Board had voted a sum of £10,000 towards the purchase. The balance therefore left was about £6000. Now that Dr. Longstaff had given the handsome sum of £5000 they only required £1000 to complete the matter, and he felt confident that they would soon get that amount.

**Kew Gardens.**—Mr. Akers-Douglas, Friday last received a deputation from the Richmond Town Council to urge upon him the desirability of throwing open Kew Gardens to the public on week-days. Mr. Akers-Douglas, in reply, while promising to give the views of the deputation careful consideration, held out hope of their request being complied with. Subsequently, the First Commissioner of Works received a deputation on the same subject from the Kew Gardens Earlier Opening Committee. A petition signed by 5000 memorialists from parts of the kingdom in favour of the concession was handed in. Mr. Akers-Douglas, replying to the deputation, said the *raison d'être* of the existence of Kew Gardens was the valuable scientific work it did, and he could not be expected to do anything in the way of extending the hours of opening which the gardens were open to the general public if it would interfere with that work. The financial question did not weigh with him at all for if he were convinced that the interest of science would not suffer by the earlier opening he should endeavour to persuade the Treasury to grant any extra money required. The sole question for consideration was whether the interest of science could be combined with the desire of the people for the earlier opening, and he regretted to say that the scientific men whose opinions had obtained were entirely opposed to the proposal. From a scientific point of view the experiment had not been a success in Edinburgh, and they had no reason to anticipate any better result at Kew.

**Royal appointment.**—We learn that Henry George Smyth, of Goldsmith Street, Drury Lane, has been appointed by royal warrant hereditary cultural sundriesman to Her Majesty. This, we believe, is the first appointment of the kind which has been made.

**Royal Horticultural Society.**—The next fruit and floral meeting of the Royal Horticultural Society will be held on Tuesday, August 11, in the Drill Hall, James Street, Westminster, from 1 to 5 p.m. A lecture on "Cross Fertilisation of Florists' Flowers" will be given at 3 o'clock by Mr. James Douglas.

**Names of plants.**—*Henry Haines*.—1, *Eclipta* sp.; 2, *Olearia Haasti*; 3, *Teuila Helenium*. G. A.—The Plume Poppy (*Bocconia cordata*).

**Names of fruit.**—A. J. M.—*Rubus laciniatus*

## ORCHIDS.

### STAGING ORCHIDS.

THE appearance of Orchids and also their well-being under cultivation are much affected by the way they are placed in the houses. In many structures that are unsuited for them they may, if judiciously arranged in suitable positions, make much better progress than if set up in a promiscuous style, as is unfortunately too often done. Many houses are built too narrow to allow of a central stage, or, rather, head room to get round it, and in consequence the staging is placed on either side of the central walk, a capital plan for small plants of such as Odonoglots, Masdevallias, Oncidiums, and many others, but one fraught with a great deal of inconvenience when a collection of plants of various sizes has to be arranged. If one arranges the larger plants of such kinds as Cattleyas and Laelias along the front, it is difficult to get behind them in order to deal with smaller plants: while, on the other hand, if the large ones are at the back, they keep the light away from smaller ones. It is difficult to know how to arrange such houses, and the best way is an intermediate plan. Place one large plant in a position suitable to it and arrange smaller ones round it, those liking a shady position being kept to the front where the large specimen in a measure shades them, the kinds that like more light being placed behind, where, owing to the slope of the roof, they are nearer the glass. The individual large specimens will not be exactly in a line, but placed alternately, so that every one keeps a minimum of light from those round it.

A much better arrangement can be effected where there is a central stage with small side stages around it. Here positions may be chosen to suit plants of all kinds, from the shading Celogyne, Cymbidiiums, Lycastes and Cypripediums to such as Dendrobies and Saccobabiums, that delight in sunshine almost unalloyed. Small plants in most cases need to be

elevated a little, not only on account of light, but because it is very difficult to damp between them with the syringe without wetting the surface compost continually. This causes it to be moist when the time for watering comes round, the plants are missed, and the lower part of the compost and roots go on getting drier until the plant suffers. The pieces of lattice-work raised above the solid portion of the stage are good if only small plants are cultivated, but where small and large are grown together it reduces the head room, a better plan in this case being to set the large plants down on the shingle or slate and put the smaller ones on inverted pots. All plants suspended from the roof, whether in pots, baskets or on blocks, ought to be hung just over a path or a water tank, never over other plants if it can by any means be avoided. It is a bad plan to hang them from eyes driven or screwed into the rafters unless the latter are provided with drip grooves. A better plan is to run a wire or small rod the whole length of the house and hang the plants to this. Every plant, in whatever position, should have sufficient room about it to allow of its being turned round for examination, and, where possible, no one plant should be allowed to touch its neighbour. Such things as Panicums, Tradescantias and small Ferns are often planted about Orchid houses to a very injurious extent, harbouring insects and keeping the air from circulating freely about the Orchids. A few cuttings of Panicum dibbled into the shingle on the stage do no harm if not allowed to get too large, but when it comes to hardy and cool greenhouse Ferns growing in tropical houses, it is carrying the thing too far. Many a troublesome attack of black thrips among Orchids may be traced to this practice.

**Oncidium phymatochilum.**—Under the head of Orchids in the issue of July 10, *Oncidium phymatochilum* is mentioned at Mr. Bull's with the spikes rising to the height of 18 inches. It may interest your readers to know that I flowered a spike 9 feet 7 inches long—the longest side

branch 2 feet 8 inches, and from tip to tip of basal side branches 5 feet; there were thirty-eight side branches of inflorescence. It was shown at the last meeting of the Royal Botanic Society of Edinburgh.—SIR A. B. HEPBURN, *East Lothian, N.B.*

**Grammatophyllum Ellisi.**—This is not so large growing as some of the other species, but as handsome as any when in flower. The pseudo-bulbs seldom exceed a foot in height, the leaves rather longer, and the flowers, thirty and upwards together, occur on an arching raceme. The sepals and petals are yellow with brown blotches, the lip rosy white, and the whole flower has a shining varnished appearance. Being a native of Madagascar, plenty of heat and moisture is necessary, and the plants need only be shaded from the very brightest sun. The plants are very free rooting, and may be grown in peat fibre and Sphagnum, with good drainage. Plenty of water while growing and a distinct resting season are necessary to ensure their flowering.

**Cattleya superba.**—This fine plant is again in flower, but the growth this season is not so hard looking and solid as I like to see it, and cultivators must be careful to allow plenty of sunshine from now onwards. Often while in flower, if the plants are removed to a drier atmosphere, a certain degree of ripening goes on that is beneficial, and tends, too, to conserve the flowers. The flowers are of medium size, very bright and effective in colour, and occur on spikes of about four or five from the top of the bulbs. To grow this fine Cattleya, plenty of heat and moisture and a light position are necessary, and the roots must not be disturbed oftener than necessary. Too large pots or pans are a great mistake, and a well-known and successful cultivator recommends growing the plants on blocks of Tree Fern stems. *C. superba* is a native of some of the warmest parts of South America, and was introduced in 1838.—H.

**Pilumna fragrans.**—This is very erratic in its time of flowering, but the pretty and fragrant blossoms are always welcome. The pseudo-bulbs are very much flattened, deep green, the foliage thick and almost leathery in texture. The spikes, which spring from the base of the last-formed pseudo-bulbs, are erect and carry about half a

dozen pure white blossoms with a dense orange-yellow eye. The plants when newly imported are not difficult to establish, but when they get out of condition under cultivation, more trouble will be found to get them to start again. Often when I have purchased plants from nurserymen or at sales I have found when examining them that they have not a single living root, owing to the compost having become sour. This is of course a serious drawback, and should be prevented by using the best of material only when potting and watering judiciously, yet freely. Good drainage is required, and everything about the plants must be clean. It thrives well in the cool house if carefully treated, but is perhaps safer in a house a few degrees warmer. No dry rest is necessary, though of course during winter the plants will not dry so quickly and will consequently need less water.

**Vanda Parishii.**—This plant has not the grace and elegance of some of the other Vandas, but is a distinct and beautiful plant notwithstanding. In habit it is dwarf and stout, the oblong leaves very thick and leathery, the bloom spikes much stiffer than usual in the genus, and containing fewer, but larger flowers. In the typical form these are each 2 inches across, the sepals and petals yellowish, thickly covered with reddish brown spots, the lip white, marked with orange and pink. To grow *V. Parishii* well, a fairly large receptacle is needed, as the roots are easily snapped if much bent about, and seem to delight in growing in straight lines. Clean Sphagnum Moss is the best material to grow it in, adding to this enough broken charcoal and ballast to keep the whole porous. It may be repotted in early spring, as less damage will be done to the roots at this time than when the latter are in active growth. Plenty of heat, plenty of light and a moist, well-balanced atmosphere it delights in, these conditions causing the emission of fine healthy roots in the atmosphere and a satisfactory state of health all round. In a cool or draughty house it is perhaps more likely than almost any other species to be attacked by spot. *V. Parishii* was originally discovered by the Rev. C. S. Parish, who found it in Moulmein in 1862. It was not, however, until some years later, when Messrs. Hugh Low and Co. imported it, that it became known to Orchid cultivators in this country.

#### UTRICULARIA ENDRESI.

The Bladderworts are such interesting and graceful-looking plants that it is difficult to account for their scarcity in gardens. One may go into scores of places and not see a plant of any of them; consequently a fine basketful of the pretty species named above came as a pleasant surprise recently. The scapes contain about half a dozen flowers of a delicate lilac tint, and the stems or pedicels being so very slender, these appear to be floating in the air. *U. Endresi* is not by any means a difficult plant to grow, but, like so many things of a like nature, it is apt to be forgotten when the leaves have fallen in winter. The rhizomes and roots have nothing in them to allow of the compost being kept dry for any length of time, and if this drying off is practised it will assuredly mean their ruin. Keep the material about the roots just moist not wet—during the time the plants are resting. This keeps the buds at the end of the rhizomes plump and ensures their starting strongly in spring. The best material to grow this plant in is a similar compost to that used for the usual run of pseudo-bulbous Orchids. Sphagnum Moss three parts and an elastic fibrous peat one part, with finely-broken crocks and charcoal in abundance, will grow it admirably, and the less the roots are pulled about the better. When well started into growth in spring, a free supply of soft water is necessary, and from this time onward until the foliage begins to turn the roots must be kept wet. I am not sure that hard water injures the plant itself; only indirectly by spoiling the Sphagnum around the roots. A shady corner—over a water-tank if possible—is the best place to grow it, and as it re-

quires stove-heat, the East India Orchid house will suit it admirably. But though it likes shade, it is not so satisfactory if placed a long way from the glass as it is hung up within a couple of feet of the roof. In winter it is safe in a house that does not fall below 60°, and at this time as much air as possible should be allowed. R.

#### EPIDENDRUM NEMORALE.

In its best forms this species is worthy of a place in the most select collections. The habit is somewhat peculiar, the pseudo-bulbs being only a few inches high, yet bearing very long bright green leaves, each about an inch or less in width. The scapes are often 2 feet high, the upper portion closely studded with the pretty reddish mauve blossoms, the narrow sepals and petals and broader lip being similar in ground colour, the latter much overlaid with lines of a deeper purplish tint. It makes a fine show when well grown, but requires a certain amount of care. The roots require fairly liberal treatment, but at the same time are easily injured by any excess of moisture or closeness in the compost. The drainage on this account must be exceptionally good and protected by a layer of rough Moss, over which a couple of inches of compost are ample, this consisting of the best quality peat fibre and Sphagnum Moss. In removing the old material from about the roots care is necessary that these are not damaged or disturbed more than is absolutely necessary. In fact, the first sign of failing with this fine species has often been when repotting, and when once it is severely checked it is no easy matter to bring it round again. The plant is not always constant in its habits of growing, resting, or blooming, and the time for repotting must to a certain extent be left for individual consideration. But it is better in all cases to be early rather than late, and thus to give the plants the best possible chance of getting well established before the winter, when scarcity of light and oftentimes unsuitable atmospheric conditions militate against its well-being. During this latter season it is best grown in a house where plenty of light reaches the plants all round and where the air currents are free. Even in summer it is surprising how little shading is required provided the plants are healthy and well watered and the atmosphere kept moist. Some plants I have seen do well in a cool house, but as a rule the Cattleya house, or at all events the Mexican house, suits it best. Endeavour to consolidate the growth as it is made rather than rush into quick changes of atmosphere and temperature. If a good solid growth is made and the plants kept clean and healthy, it can hardly fail to bloom profusely, the fragrant blossoms lasting well over a long period. *E. nemorale* is sometimes known as *E. verrucosum*, owing to the warty appearance of the flower-stems, but the true *E. verrucosum* is a little-known and inferior plant from Jamaica. The subject of this note is an old species, having first been imported in 1843 by Messrs. Loddiges. Its native home is a wide area in Mexico, where it is found growing on the tallest trees. H.

**Phalænopsis violacea.**—This pretty plant I have noted in several collections this week, the whitish purple-tinted blossoms having a fine and distinct appearance. It is one of the most free-blooming of Orchids, and should be grown by all. It is a dwarf plant with bright green leaves, each about 8 inches in length, and requires care to grow it well. The best position for it is in baskets not far from the roof glass in a hot, moist house, and the leaves must be shaded from bright sunshine. It comes from Sumatra and has been known since

1859, but it did not flower in England until 1878.—R.

**Aerides affine.**—Several nice specimens of the true type of this plant are now to be seen at Clapton, the long pointed racemes of flower being very attractive. It is a dwarf-growing plant easily distinguished from other *Aerides* by the colour of the flowers, a pretty bright purple-rose and the shape of the lip. It is often met with under the name of *A. multiflorum*. Though previously known, Messrs. Loddiges, of Hackney first flowered this species in 1837.

**Bulbophyllum claptonense.**—Under the name there is a very distinct looking *Bulbophyllum* in bloom with Messrs. Hugh Low and Co. In habit it comes nearest to *B. Lobbi*, but the flowers are larger and the plants stronger in growth. The scapes bear a large number of blooms, the sepals and petals being a brownish yellow, with good many lines of dark sepia-brown. The lip reddish purple in front, the centre yellow and the margin rose—a peculiar, but not unattractive combination.

**Catasetum Christyanum.**—All the *Catasetums* are quaint and interesting Orchids, and this species now in flower with Messrs. Hugh Low and Co. is no exception to the rule. It is a stout grower, the pseudo-bulbs tapering upwards, bearing fine deep green foliage. The flower-spikes erect, carrying over a dozen blooms, the sepals and petals of which are chocolate-brown. The lip of the usual structure, with sensitive horns near the column, and in colour a bright green and purple.

**Bletia Shepherdi.**—One of the oldest Orchids in cultivation, this is still well worth a place, and I have noticed its brilliant flowers in several collections lately. It blooms at various seasons, the blossoms occurring on tall erect scapes, each one about a couple of inches across, bright reddish-purple with deeper crest and a yellow centre to the lip. It is of the easiest culture, requiring only moderate heat and to be grown as strongly as possible. After flowering the foliage soon shows signs of decay, when the pots may be turned out of doors and kept a little on the dry side until again starting into growth.

**Sobralia xantholeuca.**—The blossoms of this Orchid are fairly large, the colour a lovely combination of yellow and white, the centre of the lip being the deepest part. Dwarf in habit, free-flowering, and easily grown, it has but one fault, that is the fleeting character of the flower. In the small-flowering house at Messrs. Veitch it is now quite a feature blooming alongside *S. Lucasiana*, *S. Wilsoni*, *S. Veitchi*, and several others. The last-named is a lovely form with pure white sepals and petals, the lip yellow in the centre, white around the outside with a faint flushing of violet-rose on the margin.

**Lælia Lindleyana.** This distinct and rare species was recently in bloom at Messrs. Hugh Low and Co.'s nursery at Clapton. It grows about 1 foot high, producing from the apex of the terete pseudo-bulb a scape usually containing one flower only. This is about 4 inches across the segments narrow and pointed, giving the flower a star-like appearance; the lip white, with a purple blotch on the middle lobe, this being also spotted with a deeper tint. It requires Cattleya house treatment, and does best in rather small pots. Its native habitat is Santa Caterina, in Brazil, whence it was first introduced in 1857.

**Phalænopsids at Clapton.**—In a large, low span-roofed structure at Messrs. Hugh Low and Co.'s nursery at Clapton there is a very large stock of *Phalænopsids* in all the leading varieties. Not many plants were in bloom at the time of my visit, but the appearance of the plants is abundant testimony that their wants are well known and catered for. Fine pieces of *P. amabilis* had made remarkably fine growth, and this as well as *P. violacea*, *P. intermedia* and *P. rosea* were in bloom. The beautiful foliage of *P. Schilleriana* and *P. Stuartiana* was in good form, while the roots of all were very vigorous and

ective. Hybrid raising was going on briskly, several of the plants having arrived at flowering size, while hundreds of smaller ones are in every stage of development.—R.

NOTES OF THE WEEK.

**Pelargonium King of Denmark.**—This kind promises to prove of considerable value in the garden, the handsome trusses of deep salmon-tinted flowers being produced in large numbers. In a cut state it is also most effective.

**Tritoma Solfaterre.**—Though distinct from the majority of this fine group, this is scarcely a plant for effective gardening, the flowers of a pale greenish white or creamy tint, together with its dwarfer habit, being quite inconspicuous.

**Verbena Tresserve.**—This is the name of a very pretty and showy Verbena exhibited this week at the Drill Hall by Mr. J. T. Bennett-Poë. In colour it is very attractive, being of a clear rose-scarlet shading to white in the centre. The flower-heads are of medium size, and in a mass very bright and cheerful looking.

**Crinum longifolium.**—This very neat species has noted recently in flower at Kew adjacent to the large Palm house. The flowers are white with a flush of pink externally, and freely produced in umbels, the perianth tube, as also the potstalk, being rather more than usually elongated, and the nearly erect blossoms very pleasing in form.

**Carnation Mrs. F. Gifford.**—Despite the fact that the petals of this variety are slightly tinged—in other respects, *e.g.*, its fine form, pure white petals, and remarkable size and fragrance—it promises to be a most useful variety for cutting for the border. For such free-flowering and fragrant whites there is yet abundant room in any garden.

**Carnation Andrew Noble.**—One of the improvements in the Carnation that the florist has fixed his mind upon recently is that all the petals shall be as nearly uniform in size as possible throughout the flower, an ideal that the above variety appears perfectly to attain. In other respects also it is a fine Carnation, particularly in its size and the salmon-rose tint of its flowers.

**Astilbe Thunbergi.**—The large, slightly arching plumes of creamy white flowers characteristic of this plant are now very showy among good herbaceous plants. Of a perfectly hardy, vigorous, and free growing character, this handsome perennial should be freely employed, not only in the border or rock garden, but in semi-shade and moist positions where such things usually attain their fullest development. In heavy, moisture-holding soils these Astilbes are generally a success.

**Campanula Scheuchzeri alba.**—This is a capital kind that is only rarely given in lists, and still more rarely is it seen true to name. At first sight the blossoms are not unlike those of *C. rotundifolia alba*, though rather larger and slightly bolder in the bells. In habit the plant is distinct, growing when established about 18 inches high, and producing freely its pure white bells in profusion. The rather narrow linear leaves, as also the stems, have a close pubescence by which it may be distinguished at a glance.

**Echinacea purpurea** is now a striking piece of colour almost unique in the garden just now. Its fine tufts, 3 feet high or more, self-supporting by reason of the fine habit of growth, and crowned with the large, handsome rosy-purple blossoms, are not easily matched in the garden at this time. Not the least valued of many fine plants is the well-balanced and branching character of the flower-stems, the latter erect, safe and rigid, and supporting large numbers of flowers. At the present moment it is one of the most desirable of hardy flowering plants, exceedingly fine in the general effect and conspicu-

ous at some distance. Besides this, the plant flowers abundantly.

**Bocconia cordata** (the Plum Poppy) is now a striking object in the border. Individually the blossoms are small and by no means of a striking colour. On the other hand, however, where many of its large terminal inflorescences are seen together the effect is excellent. The foliage alone is handsome, and when the groups are placed on a sloping grassy bank in proximity to the rock garden, the plant will hold its own against many far more costly things by reason of its beautiful foliage. This is always seen to best advantage when planted in a group on the grass.

**The Creeping Fig in fruit.**—I am sending a fruiting branch of *Ficus repens*. This is from a plant growing under glass. A few years ago it threw out strong shoots from the top, and has fruited this year for the first time; the rest of the plant is still small in leaf and clings to the wall. I may mention that there is a plant here which has been growing out of doors for the last ten years or more. I am also sending some flowering sprays of the *Eucalyptus Gunnii*, or what I believe to be that. We have two plants in a shrubbery, but only one has flowered. They seem to be quite hardy, as they have been growing for the last five years or more, and so have survived some exceptional winters.—DANIEL C. A. CAVE, *Sidbury Manor, Sidmouth.*

**Lilium platyphyllum var. virginale.**—There are few Lilies that can in any way compare with this noble and chaste variety of the well-known *L. auratum*. The giant flowers of *L. virginale* are without a spot of any kind, the segments very massive and pure in tone, a fact only enhanced by the creamy-yellow band that runs through the centre of the petals. In common with *L. platyphyllum*, there is an increased vigour in the above kind, which, coupled with its handsome pure white flowers, can scarcely be excelled. As a pot plant in limited quantity in the conservatory, or in groups among the Rhododendrons in the garden, this noble kind is worthy attention. It was well shown by Messrs. Wallace at the Drill Hall on Tuesday last.

**Hymenocallis Macleana.**—Among many interesting bulbous plants flowering in the open near the Palm house at Kew is this charming species, which may be recognised as *Ismene Macleana* by some readers of THE GARDEN. It is a beautiful species, and would prove most welcome for its blossoms could the latter be produced in quantity with some degree of certainty. The outer segments are pure white, tube greenish, excepting the tip, which is also white, thus producing a very pretty effect. The plant is nearly hardy, and may be well grown if planted out in a frame or handlight. Indeed, a small frame filled with this and similar plants would provide a variety of interesting material during the year if a careful selection were made.

**Gentiana septemfida.**—Among the summer-flowering Gentians this is always very fine, and at the same time duly appreciated. Large examples, however, despite the fact that it is easily cultivated, and that it may also be raised somewhat freely from seeds, are not common. This species is well suited to the rock garden, where a deep crevice of very rich sandy loam should be given it. The position should be rather moist, or, failing this, water should be freely given during the season of growth. For two or three weeks this lovely species has given freely of pretty pale blue and white blossoms, the segments of the latter crested internally in the most pleasing manner. The plant is of somewhat procumbent habit and produces its nearly cylindrical blossoms in terminal clusters.

**Nymphæa Marliacea flammea** is another of the splendid series of Marliæe hybrids that are being so well received in this country, and at the same time honoured as they justly deserve with the highest possible awards. The above kind, exhibited before the Royal Horticultural Society on Tuesday last, obtained a first-class certificate, the flowers being of medium size and of a reddish-

purple shade, varying in intensity with the age of the blossoms. Such distinct and striking patches of colour will afford great contrasts in the future in our ornamental lakes and ponds, and to those who desire their young plants to make the greatest headway, it may be well to suggest that the flower-buds be gathered as soon as they appear, thus concentrating for a year or two all the energies to developing larger plants.

**Romneya Coulteri.**—In reference to "S. W. F.'s" interesting article on the *Romneya Coulteri*, I am pleased to say this beautiful plant so rarely met with does well here. I planted one about four years ago, and it has flowered every year since, but this year it has been exceptionally fine, as many as nine blooms being fully expanded at one time. As it is planted in the open I protect it through the winter months by placing a layer of coal ashes with a dusting of lime over the surface, and then thatch the whole of the plant with straw. This is done in November and removed in April, when it commences growth. In this way it came safe through the severe winter of 1894-5, when on one occasion we had 36° of frost. I noticed Messrs. Dickson's had a nice group of this beautiful plant in pots at the Chester show.—G. J. SQUIRES, *Llangwynn Gardens, N. Wales.*

**Gloriosa superba.**—As a trailing or climbing plant for the greenhouse this is one of the most worthy. It is generally an easily managed plant, though one or two points are perhaps essential in its cultivation. These are a good open compost of fibrous peat and loam, rather rough in both instances, and careful treatment in the early stages, *i.e.*, when starting the plants into growth. Indeed, like many other things having fleshy, tuberous or bulbous roots, quite a little moisture will be found sufficient till growth has become quite active. At no time will the plant bear excessive supplies of moisture, and to prevent this plenty of drainage should be given. This, combined with warm greenhouse treatment and frequent use of the syringe till the near approach of flowering, will help to keep insects in check. There is something very ornamental as well as distinct in the strangely formed flowers of orange and gold, while the wavy margins of the perianth segments render the flowers even more attractive. Though the plant has long been known to cultivation, it is not of frequent occurrence in gardens. During the present year, however, we have seen the flowers employed quite effectively in dinner-table decorations, also in epergnes and as sprays for the hair and such like.

**Campanula Van Houttei.**—Among border Bellflowers this is certainly one of the finest, the plant quite distinct with handsome drooping bells nearly 3 inches long. Happily, too, it is of the easiest culture. It is well not to allow the plants to remain too long in the same position, as by dividing and replanting in February or March each year renewed vigour with greater freedom of flowering is ensured. In deep, rich, and rather moist sandy loam such fine plants as this are capable of creating a good display, and the flowers of a dark lilac-blue shade are not easily matched. This fine plant is of hybrid origin. It is frequently referred to under *C. latifolia*, and it is not unlikely that this somewhat coarse plant may have been one of its parents. I am not aware of the origin, but, judging by the manner of reproduction from the base, as also its more refined character of leaf and blossom, it seems likely that *C. punctata* or *C. nobilis* may have participated. The creeping underground stems or shoots in *C. Van Houttei* are quite unlike those of *C. latifolia*, while it resembles in a greater or less degree each of the other kinds here named. But whatever its origin or parentage, it should be found in all good herbaceous borders, and, while producing underground stems, it is only in a minor degree, as these never stray from the plant but a few inches.—E.

**Erythrina crista-galli.**—It is to be regretted that gardeners generally do not endeavour to grow this plant more frequently in the open ground. In many districts the plant is practically hardy in

all but the very occasionally severe winters, and then a timely covering of the resting stools is all that is required. We are reminded of the importance of this handsome species by a recent experience in a garden quite near Hampton Court, and, of necessity, the river also. This specimen, we were informed, has stood out for several winters and blossoms regularly each summer; indeed, it was fast approaching this stage when we noted it recently. All that is needed is a warm position at the base of a greenhouse wall, with a depth of good soil and fair drainage, and when winter approaches to cover the crowns with cocoa fibre or ashes. A year or two since we saw it in splendid condition in a nursery near Hereford, and here, as usual, the plants were against the wall of the greenhouse, the growths between 6 feet and 7 feet high, with many of the striking coloured blossoms on each growth. It may be said that such positions are not suited to so good a plant, and this may be true to some extent. In this case the example set at Kew each year of growing the plants in large pots or tubs should be followed, plunging them in groups in some conspicuous positions in the flower garden, and wintering the stools in any frost-proof place. In this way, if carefully attended to with water, such groups could not fail to prove both attractive and interesting. At the present time many fine examples are quite a feature at Kew.

#### ORDERS OF MERIT FOR FARMERS AND GARDENERS.

APROPPOS of what we think the doubtful action of the Royal Horticultural Society in instituting an order of merit, the following may be interesting. In France we believe these orders are under State control, and if societies have the power to create honours of this kind, where are such things to stop? We shall soon have the barbers or any other society of men establishing fountains of honour.

The love of decorations is a national disease in France, from which even the highest do not escape, and an anecdote which is told of the Chancellerie is characteristic of this. When the Order of Merit for farmers was created, General Rousseau, who was chief secretary of the Legion of Honour, placed himself on the first list as officer of the new order of merit. General Faidherbe, the distinguished soldier, was the Grand Chancellor of the Legion of Honour, and as such this list came under his notice. He sent for the chief secretary.

"How is this, Rousseau?" said he; "you, who possess every imaginable and possible decoration, assign to yourself the Agricultural Order of Merit also."

"Well," replied the excellent Rousseau, "but it has been created."

"But it is a decoration for farmers only."

"Yes, for farmers, and for others also, like all decorations."

"Oh, is that so?" said Faidherbe: "now I understand." And before returning the document to the Ministry he struck out the name of General Rousseau and put in his own!

It will, we fear, be a little ridiculous to see gardeners swaggering about with decorations of any kind. There may be a few distinctions worth keeping up, such as, say, the Victoria Cross, but all such honours are better under State control. But if doubtful in its higher forms, what are we to say to this extending of the false jewellery of honours to men like gardeners and farmers? Its effect in various ways will not be good, and, not least, in ignoble waste of time in seeking such distinctions, which are, we fear, in the long run given to those who seek them most and take the trouble to worry people to aid them in getting such baubles. In France it is more excusable perhaps than with Britons,

as the French have a mania for decorations, though some Frenchmen hold that among the many evils inflicted on France by the first Napoleon, the institution of the Legion of Honour was by no means the least.

#### FERNS.

##### SOME NEW ADIANTUMS.

THE Maiden-hair Ferns are, perhaps, the most beautiful and certainly the most popular. Although we have such a large number of distinct species, we are constantly getting further additions in the way of garden varieties. Many of these are most interesting, and it is very difficult to account for the variations which occasionally occur, for, as a rule, there is little variation even among seedlings of garden varieties. Take as an instance *A. cuneatum grandiceps*; this prettily tasselled variety may be readily obtained from spores, and among thousands of seedlings scarcely any variation will be found. *A. cuneatum grande*, *A. versailleense*, and *A. c. erectum* are other examples. In some cases, however, it is difficult to raise seedlings of hybrid origin. Although I have tried many times, I have never raised *A. Veithei* (the beautiful crimson tinted Maiden-hair) from spores, at least not to get it true. I have had seedlings which have proved to be a bad form of *decorum*. Some other garden varieties are equally difficult. I only know of one instance where what appear to be good spores are not produced, and this is the beautiful *A. Farleyense*, which although imported from Barbadoes is undoubtedly of hybrid origin. I have for many years used every opportunity of searching for spores, but have always failed. To revert to varieties raised from spores, one of the most remarkable instances I have known was a batch of several hundred seedlings raised in Mr. H. B. May's nursery a few years ago. The spores sown were from *A. æmulum* and *A. Waltoni diffusum*, which had been accidentally mixed together. Whether this resulted in cross-fertilisation or an ordinary freak of nature is uncertain, but a more variable batch of seedlings I never saw, and several of them have proved to be distinct novelties, and have been recognised by the Royal Horticultural Society, two having received first-class certificates, and four awards of merit. Of these, *A. elegantissimum* is very distinct, having much divided fronds, with very small, deep, wedge-shaped pinnules, the terminal ones being larger; it has black stems and the deep green shade of *A. æmulum*, to which it is undoubtedly allied. *A. fasciculatum* (F.C.C.) is erect growing, irregularly branching from the main rachis. The pinnules, closely set, vary in size, the terminal ones being much broader; it forms a symmetrical plant of a rich deep green. *A. Hemsleyanum* (F.C.C.) partakes more of the habit of *A. Waltoni diffusum*, but is more erect in habit. It may be grown from 15 inches to 18 inches high in a 4½-inch pot; the large, finely-cut fronds droop over just enough to give it a light and graceful appearance. *A. plumosum* (A.M.) is of dwarf habit, with small, nearly triangular fronds of a soft pale green; the medium-sized pinnules are deeply lobed. *A. Schneideri* (A.M.) is of similar texture, with long, erect stems, the soft pale green fronds slightly deflexed. *A. tenellum* (A.M.) is a very pretty variety with broad spreading fronds, the pinnules being deeply cut. Besides those named above, many others might have been selected as being worthy of distinctive names. With many seedling Ferns, variations will be found from year to year; in some instances they do not show their distinct characteristics until they are two or three years old. This is particularly the case with some of the *Adiantums* of *A. cuneatum grandiceps*. Plants two years old form much prettier tasselled fronds than younger ones do. Even with *A. elegans*, young plants are rather inclined to be loose and straggling, but the second year they make much more compact plants.

A. H.

#### PARK AND WOODLAND.

##### GERMAN WOODS.

A good deal has been written and said on this subject of late, and those who read papers on forestry know that something akin to revolution in forestry practice is in progress in this country at the present time. The "standard" British books on forestry that have done duty for generations and been implicitly followed by owners of woods and their foresters are withdrawn from circulation, acknowledge to be radically wrong, and German authorities substituted in their place by arboricultural societies and responsible teachers of forestry; will be admitted, I think, that "revolution" the only word for it. A few foresters have been long enough acquainted, theoretically, with German forestry, conducted for the production of timber, but actual examples in this country except where accidental and on a small scale, would be difficult to find; hence one has to go abroad to see examples, and one visit is enough to enlighten and convince any forester with mind open to conviction as to the superiority of the Continental system. It was in that mind that the writer undertook the journey about to be described. Going with organised excursion is not the best way to see the forests, because time and critical personal observation are curtailed thereby; nor are the tourist agencies much use, because they skip the forests. I could not get tickets to my destinations at any rate I was indebted to the kindness of Dr. Schlie of Cooper's Hill College, for advice where to go to see good average examples of forests, and Dr. Konig, of Lauterberg, Oberforster in the Hartz Mountains, and Oberforster H. Kallebach, of Thuringia Waldt, Eisenach, for arranging the programme of the journey, and I shall not forget the kindness of these gentlemen, for they took infinite pains to satisfy somewhat inquisitive inquiries.

##### EXTENT OF GERMAN FORESTS.

Those who wish to get an idea of this should travel by day, and not by night. A very good deal can be seen from the railway as the forests recede from or approach the line, according to the character of the country. Every morsel of land not suitable for agriculture seems to be covered by dense forest right away to the summits of the highest and most distant mountain where a good glass reveals the tops of the dense masses of Firs or Beech with which they are clothed, and when you reach those mountains on which, in the distance, the trees look like coppice wood, you find yourself in dense, dark woods where the trees often run up to over 100 feet in height. I calculated that in a single journey through part of Westphalia, Hanover, the Hartz, Thuringia, and onward till one emerges on the upper reaches of the German Rhine, I saw nearly 1000 miles of continuous forest. I saw few or no bare hills, no heather, nor no underwood in the English sense of the word. Central Germany is a high table-land to begin with, and the mountains do not look as high as the Scotch mountains do, which rise almost from sea-level, and, being wooded to their tops, the German hills look more rounded, but they are lofty nevertheless—the Brocken, which stands in the middle of an almost unbroken stretch of wooded mountains, being nearly as high as Ben Lomond. One soon realises how 26 per cent. of the land in Germany is covered by forests and only 4 per cent. in Great Britain and Ireland, but when we compare the density of the German forests

with our own, I feel quite sure that 2 per cent. could represent the latter much more accurately. Let the traveller imagine himself travelling from the south of England to the north of Scotland along the skirts of the Penine range, down one side and back up the other, and all the hills covered with forests, all managed on one strict system, and he will have

the limit mentioned as worth while planting up to. In the

HARTZ MOUNTAINS,

however, in about the same parallel as England and Ireland, they plant Firs much higher up, and I saw forests of Beech trees 80 feet to 90 feet high 1800 feet above the sea. Probably neither in Britain nor Germany would isolated trees ever reach such dimensions at such altitudes, or even timber size, and the stunted trees at the edges of the German woods show this plainly. For shelter reasons alone the margins are more like hedges in density, the trees often about 2 feet apart only, or less. These remarks apply also further north than any I saw.

In these forests and elsewhere I found our old friends that keep down prices at home, viz., telegraph and scaffold poles, pit props, and deals in all stages of growth and preparation. I have often wondered how they could afford to peel the dead bark of the poles delivered so cheaply in this country, but it is a simple and speedy operation, the workman just running his little axe along the pole and stripping the bark off in

long ribbons, heaps of which cover the ground where the trees fall. The timber that comes from Germany to this country does not come so much from the Hartz, but from the States further north. Germany uses a vast quantity of its own timber, and Central Germany sends much to Holland. Still, one can understand, from what he sees everywhere, how it comes about that, of the total quantity of timber sent

to Britain from Germany, £15,000,000 worth represents Scotch Fir and Spruce alone. After all, what we get is but a flea-bite to German production. Holland has been, and still is, a large buyer, its forests being of comparatively small extent and still young. Between Amsterdam and the Prussian frontier in North Holland the country is practically treeless, with vast tracts of sand-dunes fit to plant, and at present a desert; but in the south, extensive plantations of Scotch Fir have been made, strictly managed on the German principle of dense planting and no thinning. In numerous cases the owners of small holdings have planted these up to the edge with Firs, and as the plots are usually perfectly square, these occasional plantations have an artificial look standing among corn and other crops. The Scotch Fir seems to thrive amazingly in the pure sand lands. In the Hartz Mountains Spruce and Beech predominate, but in Thuringia and further south towards Frankfurt - on - Main Scotch Fir about equals all other species put together, and covers the tops of hills where it almost dovetails into the vineyards further

down. Huge rafts of Scotch Fir are to be seen floating down the Upper Rhine.

The Germans use much of their own timber for building, whole villages apparently consisting of little else than lath and plaster. Some of the gable ends between houses I noticed, even in Eisenach, were of boards inside and out, filled in between with wattlework and mud. Most of the furniture of somewhat pretentious hotels and houses is made from the timber grown close by. The doors, windows, stairs, floors and other fittings are mostly of Spruce, Scotch Fir or Beech, and even such things as wardrobes are made of these Spruce deals nicely varnished outside. Timber seems to be a general substitute for stone and bricks, and there is a wealth of wood carving and ornamentation in private houses and in hotels unknown in this country.

THE CONTROL AND PLAN OF GERMAN FORESTRY.

A broad distinction must be made between German agriculture and German forestry. We have little or nothing to learn in the farming line, except the small-holding system (allotments would be a better name), long hours of labour in the fields, where the women work as much as the men, the total abolition of fences and hedgerow timber, and a thorough utilisation of every inch of ground, compared to which the practice of small holders in England is slovenly. The German agricultural methods and tools are, however, rather primitive, and German agricultural science is apparently made for British consumption. Much of the work on the land is done by the spade and hoe. I saw women, wives of the farmers, digging with shovels. One is puzzled where the pasture and cattle come in, because in a long journey through Westphalia, Hanover, and by Erfurt, Frankfurt, and on the Rhine the farm-lands seemed one unbroken patchwork of Rye, Potatoes, Chicory, Beet, Vines, &c. It is very different in the forests; these are mostly owned or controlled by the State or the Duchy in which they lie, are of paramount importance to the nation,

In a German forest. Edge of a clear cut. Trees 120 feet high. From a photograph by Mr. J. J. Simpson, Wharcliffe Estate Offices, Neutyle, N.B.

some idea of these German forests as compared with ours. From the railway the different timber crops, "compartments," can be distinguished as plainly as farm crops. From one point in the Hartz, the summit of the Knollen, a hill over 2000 feet high and next door to the Brocken, an unbroken expanse of forest-clad hills, embracing at least 500 square miles, can be seen, looking over the summits, and not including the ups and downs of hill and dale, and only allowing for a moderate sweep of the eye of twelve miles or so from the point of view. Up here the unthinned Spruce, less than 3 feet apart, three planted in a row ("bush planting"), over thirty years of age, about 20 feet high, was so dense, that I had to take off my hat and crawl under on my hands and knees to get inside. Talk of destruction by storms in Scotland; I never saw anything like the destruction that I saw here caused by "snow-breaks" alone. The snow lies many feet deep for months, and the trees are broken and smashed in all directions, and the damage would be greater if the trees were not so dense and could not lean upon each other. The dense planting is relied upon to ensure a sufficient crop in the end. Wind does not do so much damage, because the crops at all stages are too dense, but the wind-storms are there as well as with us, and the oberforster pointed out to me places where clear gaps had been made by wind where roads had been made and the wind had got in. The margins of the woods are denser than the inside for protection. Were it not for the dense crop, such tall trees with a slight root-hold would not stand even a moderate gale. It is not quite realised in this country how tall trees will grow at high altitudes when crowded together for protection. It was once stated in *Woods and Forests* that the Beech would not succeed on exposed situations, and in the Parliamentary forestry evidence I think considerably under 2000 feet was

In a German forest. Trees not yet thinned; about thirty-five years planted.

and their superintendence is almost as strict as that of the army. In fact, the forest administration is military. It is easy to see how this affects the management. The forester's work is cut out for him. The system of management is the same everywhere, and he must conform to it. German forest management is no recent thing. Experiments are on record that have

and their superintendence is almost as strict as that of the army. In fact, the forest administration is military. It is easy to see how this affects the management. The forester's work is cut out for him. The system of management is the same everywhere, and he must conform to it. German forest management is no recent thing. Experiments are on record that have

continued for several generations, and experimental plantations of trees, now 100 feet high or thereabouts, planted nearly a hundred years ago, are still going on, the "Star Plantation" in the Thuringia Waldt, near Eisenach, being an example of this kind. Conferences of forest officers are held from time to time where subjects of interest are discussed, but German forestry is very conservative in principle. New introductions in the shape of exotic forest trees are not common in the forests, the Weymouth Pine being about the only species that has become established, and which promises well. Forestry practices seem to have altered but little, one oberforster following another, and each perforce following in the footsteps of his predecessor. There are promotions in the service, and it is not unusual for an oberforster to be transferred to another and a higher charge in some other district. One oberforster's charge generally extends to about 10,000 acres. A certain percentage of the forests are common woods, belong to the villages, and some belong to private owners, but in all, the management is, as a rule, the same—all are conducted to the best advantage by expert forest officers. One oberforster that I met had, in addition to his regular charge, 5000 acres of common woods under him. A large percentage of the timber goes for firewood. What we call "cordwood" here—"top and lop"—all goes for firewood, nothing being lost. Sometimes women from the villages are permitted to gather the small branches and tops, which they carry for miles on their backs to their homes, but as a rule the top-wood is cut and ranked and sold for firewood, per cubic mètre, for about the cost of collecting. The forests are consequently clean, and, owing to the dense canopy overhead, undergrowth is very scant or entirely absent, so that when the regeneration period arrives, the surface of the ground, covered deeply with humus, presents one of the most favourable seed-beds that could be imagined. In our over-thinned British woods the rank weeds and undergrowth smother the young seedlings to death, but in the German forests one wades knee-deep through miles of young self-sown trees that are to produce the next crop. In the State forests the oberforsters (forest officers) are also the gamekeepers, and conduct the sporting expeditions. One of these officers showed me a beautiful pin set with brilliants presented to him by the present Kaiser on one of these expeditions. The care of the game is not, however, arduous work. The game consists of deer, mainly, and now and then a wild boar, with a sprinkling of hares. Rabbits there are none, and no pheasants are seen. The deer are the chief four-footed enemies of the trees, and the destruction they work is enormous in some places. They are the perquisite of the oberforster. The rabbits are scarce because they cannot survive the severe winters and deep snows. They are unknown as an article of food. When explaining to a German forester our "happy-go-lucky" style of forestry in this country, and how it was mixed up with fox coverts, rabbits, pheasants, and sport, he seemed to be incredulous, especially about the number of rabbits tolerated in the woods. Our irregular system of management, differences of opinion and practice on different estates, over-thinned woods and want of plan seemed also to be incomprehensible. Pointing to a mass of Spruce over thirty years of age not yet thinned, a mass of dead under-branches, I said that would condemn any forester in Scotland as an example of neglect and bad management. My listener stared. I was asked why our county councils or other similar authorities did not ap-

point oberforsters to supervise whole districts, with the consent of private owners, and organise some recognised system of management to which foresters would have to conform. This idea seems a good one if it could be put into force, and would provide a shorter cut to better forestry than our schools and lectures. The Germans have forestry schools, but the whole practical art as practised by them is simple in the extreme. It is in the uniformity of practice and continuity of plan and its execution where they beat us. Thirty or forty years of such a system here would change the aspect of our forests. The great tracts quite recently covered by the Dutch show this conclusively. They have simply gone to work. On the German system of close and dense successional cropping, the quantity of timber on most English estates would be doubled or trebled, and in some cases quadrupled, as will hereafter be shown. The

#### ROTATION SYSTEM

followed in German forests, and on which so much depends, has been in this country confounded with the rotation of crops of different species, as in farming: whereas in Germany the period of rotation in forestry means the time one crop of trees shall occupy the ground up to the final clearing, and be followed by another not necessarily of a different species. Beech has followed Beech for generations in Germany, and so have the Firs. The final crop of Scotch or Spruce is cleared off at the end of 100 years, Beech at 125 years, and Oak at 150 years. Timber of great size is not so much aimed at. The timber is more remarkable for its length, cleanness, and the almost cylindrical shape of the trunks than anything else. The Fir deals used for flooring and other purposes are often 18 inches broad, but by far the largest proportion are 12 inches or under, such as stock private and other wood yards in England. In all the forests the trees vary in girth considerably, but as firewood has to be supplied as well as timber, the small poles and tops come in for that purpose. In the hard woods, indeed, very thick boughs, which we would here consider much too good for cordwood, are sawn and split in the woods for firewood. The oberforsters are provided with good maps of their charges, in which the compartments are numbered and described and their forest books correspond, a complete record of every transaction being kept.

It is strange that our own Government should do so much for our Indian forests and so little for those at home. Students—both English and native East Indians—are met with as pupils living with the oberforsters preparing for India. German pupils are recruited from the better classes, and are everywhere distinguished, at work or in society, by their uniforms. An oberforster's berth is a prize. At one place I visited, two young German princes were studying forestry under the oberforster. British landowners are also moving in the matter. Just previous to my visit at one place, a well-known Scottish landowner and member of the Highland Society had inspected the forests and been impressed, and others were heard of.

J. SIMPSON.  
*Gardens, Wortley Hall.*

(To be continued.)

*Vitis heterophylla variegata.*—This pretty little variegated-leaved Vine is quite distinct from any of its allies, and is a very useful plant in many ways. Though of climbing habit, it branches freely, and when employed in the flower garden, as is sometimes done, it forms quite a dense mass of foliage, whose variegation is more pronounced during bright hot summers than if the weather is

dull and wet. Under glass it may be turned account in several ways, such as draping a stage, clothing a screen, or serving to hide any tall, naked stem. I recently saw a very attractive group it employed for conservatory decoration, the plants being grown in 6-inch pots and secured a single stick about 2 feet high. As the plant branched out freely they formed very effective specimens, of a loose, graceful character a totally distinct from anything else in the structure. They had been in full leaf from April to the present time, and the foliage was as fresh and bright as ever, and would continue so for some time. The manner in which the leaves are variegated is a notable feature of this Vine, but as a rule the ground colour is green, which is mottled and marbled in different ways with white. The purplish tint of the young shoots is also very noticeable. Propagation is effected by cutting which root readily during the spring months.

#### KITCHEN GARDEN.

##### NOTES ON PEAS.

THE season, so far, has been a suitable one for garden and field Peas where conditions have been favourable, but it is doubtful whether the market grower has found them a remunerative crop when the prices received and the quantities on hand are taken into account. I am told that quite recently many sacks of Peas were lying in a provincial market at the end of the week practically without a bidder, even when offered at ruinously low prices. The worst field Peas, probably of the round variety and poor in quality. With me early and second early sorts did best; mid-season sowings for the effects of the great heat which we experienced a few weeks since. In light sandy soil the drought penetrated deeply where strawy manure was available for mulching bringing growth to a standstill; and the change from heat to a cooler atmosphere brought mildew, and thus the supply, which had been abundant, was reduced so much as to be scarcely equal to the demand. Among the early sowings, Chelsea Gem, May Queen and Veitch's Earliest Marrow did remarkably well so also did Veitch's Early Selected Round a quart of seed producing 18 pecks Peas. Stratagem is an old favourite, and this, sown at the same time as Hollow Rival, gave me the best crop of the year the latter, viewed from the end of the row presented a wondrous profusion of pods, which although not over large, are full of good-sized and well-flavoured Peas. Sutton's Empress of India is a fine-podded sort, and as showing the quality of the dry seed, slugs attacked these more severely than any other sown; indeed, the row were so thin and ragged that several had to be taken up to make up two. It was the most remarkable as seed of this sort was sown on borders some distance apart, and in each case the results were the same. Other varieties grown alongside escaped almost untouched. I do not remember a similar case when slugs discriminated so completely in the choice of Peas for attacks. Another enemy whose acquaintance I had not made until this year was the Pea weevil. I lost between weevils and slugs several long rows of Peas, notwithstanding that soot, lime and dry wood ashes were frequently sprinkled over them when in a moist state. Criterion, Mainerop and Autocrat did the best in the main-crop section. Duchess, Shropshire Hero and Prodigy became badly attacked with mildew. Duke of Albany, too, was equally bad, and neither of the four last-named will be

wn again. At Orchardleigh I saw, in July, the fine rows of the old Champion of England, the Plus Ultra and British Queen entirely free from mildew and bearing a wonderful crop. I could scarcely resist a resolution to grow these in future in spite of their height. On fresh soil British Queen had gone up to the usual height of 10 feet and the crop was proportionate.

At p. 55 "J. C." says "many people object to extra large Peas; as the majority of the new varieties are of that type, one has to go back to older sorts." This must be an isolated experience, or rather not a common one with Pea growers, for I have never yet heard or read of anyone objecting to large Peas. There is, according to my experience, a more frequent inquiry for large than medium ones, and if this were not so, the newer introductions would not find the favour they do, and it would be useless to extol the virtue of possessing large seed consumers preferred smaller Peas. What is the objection in one establishment is looked for

gardens is a step in the same direction, and is what Peas enjoy. I once had William I. nearly 8 feet high on freshly-trenched soil. I agree with "S. M." that Duke of Albany is, or has been an over-praised Pea. It is very seldom one sees a full crop of this sort, and when it happens it is very quickly over. W. S.

*Wills.*

**Pea Danby Stratagem.**—I have grown this Pea this season, and consider it a decided improvement on the original strain, good as that is. The pods are longer and the colour equally good, there being an entire absence of whitish-coloured pods, which one frequently gets in ordinary Stratagem. This percentage of light-coloured pods was the only fault that ever could be found with this noble Pea, and several good firms have done their best to rid their stock of it. The Danby selection appears to possess even a more robust constitution, the haulm being very stout and the foliage large and vigorous. Stratagem is a good dry weather Pea and suits light soil, being also much less liable to rot when sown in

Tomatoes, but if any reader is contemplating adding another variety to his list, I would advise a trial of Sensation, procuring the seed from a reliable firm. When well grown Sensation is hard to beat on the exhibition table.—GROWER.

**Rosette Colewort.**—I am glad Mr. Temple sets so much value on this grand winter vegetable. My kitchen garden is limited in extent, and I had long since given up growing many mid-winter varieties of Broccoli, as these in hard winters are so apt to collapse, and if one has not plenty of other things to fall back on there is bound to be a blank. I always plant as many Coleworts as possible, as they are a favourite vegetable in the dining-room, the flavour being simply delicious. I first learned of their extreme hardiness from an old Essex gardener, who informed me that in one terribly sharp winter, when not only all the Broccolis, but also Brussels Sprouts and Scotch Kale succumbed, the little Colewort remained practically unharmed. After that he always took care to grow large breadths.—J. CRAWFORD.

**The Carter Spinach.**—Were I confined to one variety of Spinach, I should certainly grow The Carter. In hot shallow soils it does remarkably well, the extra large sappy leaves accounting for this. In a garden not far from here, where Spinach is in great request, this sort alone is grown. The quantity of leaves which may be gathered from a fairly long row is astonishing. I feel inclined to give this variety a trial for winter, as I have several times sown the ordinary round-seeded or summer Spinach in autumn, and found it to succeed equally as well as the prickly or so-called winter variety. Perhaps the old-fashioned, smaller-leaved strains would stand a severe winter better.—A MIDLAND GROWER.

**The Celery fly.**—So far Celery plants in this district (Notts) are quite free from any attack of this pest. Not that it is too late for it to commence its work, as I have known the foliage attacked at all stages of growth. I have had to contend with it in a good many different gardens, and have never yet discovered any remedy save hand-picking. I confess this is a tedious operation, and one that is apt to be postponed, but it pays in the long run, and a handy lad can go over several long rows of plants in a day. Some gardeners dread its attacks up to the time it is fit for earthing up, but ignore it after that date. I have observed that if allowed to be badly disfigured even then, the Celery will not keep so well after.—GROWER.

In a German forest. One fall taken out, ninety years of age; elevation 2000 feet. Photograph by Mr. J. J. Simpson.

another, and no doubt this is what "J. C." means when he says many object to large Peas. No vegetable repays for fresh ground like Peas. Of this I have had convincing proof this year, both in this and other gardens. In one, about two miles distant, there is not sufficient arable ground for the earliest Peas without wanting these every alternate year, and the contrast between the produce and that grown on quite fresh soil bears no comparison. In small gardens it is difficult to keep up a constant change for Peas, and particularly does this apply to warm borders. In my own case a path border had been occupied with Strawberries three years, and was temporarily topped with early Broccoli last autumn so as to bring it into condition for early Peas. These have been much the best crop of the year. An old adage is to use the same ground for Peas once in seven years, but it rarely happens that such a long rest can be given. I think four years would make a very good limit. Where close cropping must be adopted, I believe the older kinds would give larger returns, speaking generally, than many of the newer and less robust sorts, and no doubt the Celery trench system of growing them does away with the necessity of radical changes in the ground available for Peas. Deep trenching, too, in small

the open garden in February. When sown at this date it comes on more rapidly than many of the so-called second early Peas, and forms a good succession to such as William I., &c.—J. CRAWFORD.

**Tomatoes trained up strings.**—I recently saw a large number of Tomatoes trained up stout string, the use of stakes being thus rendered unnecessary. The house was a lean-to, having a bed in the centre and a path all round. The plants were arranged so that a pathway went down between every four rows of plants, two rows of plants could then be reached, watered, tied, and the fruit gathered from either side. The cord was attached to the stout, short stick to which the plant was tied when young, and again to wires running lengthwise just under the roof glass. Thus plenty of sun and light could reach the plants. Hathaway's Excelsior was the variety grown.—J. C.

**Tomato Sensation.**—This is not a new Tomato, but it is certainly a very good one, and would please all who are fond of a medium-sized handsome-shaped fruit. The quality is also good, and no fault can be found with its bearing qualities when a light house and suitable atmosphere are given. It very much resembles a good type of the old Perfection. I have never tried it in the open air, but a gardener in Wales has had great success with it on a sunny wall. One is apt to tire of reading about so many different

CUCUMBERS FAILING.

WILL you kindly inform me through your columns what is the cause of my Cucumber plants suddenly collapsing a few days after planting, the same as enclosed specimens?—E. J.

\*\* Plants to be examined ought always to be packed in damp Moss. Those sent by "E. J." had shrivelled badly when they reached me, and the cause of failure was more difficult to determine accordingly. A disease commonly termed slime fungus sometimes attacks the stems of Cucumber, Tomato and other plants, causing a sudden collapse, but if this had been the case with those before me the stems would have been rotten rather than shrivelled. Sometimes wireworms eat their way up the stems, the flagging of the plants being the first indication of this trouble, but no wireworms had entered the stems sent by "E. J." Early this season a few of my plants collapsed similarly to those before me. They appeared all right one day and flagged badly, never to recover, the next. The underground portion of the stems had perished. Two days previously all the plants in a long house had been top-dressed with fresh compost. The compost was not warmed through prior to use. It was to the use of this cold soil that I, whether rightly or wrongly, attributed the collapse of the plants. There could not have been much wrong with the soil other than coldness, or otherwise fresh plants put out into some of the mounds would not have

grown so strongly and healthily from the first as did others in the old soil dressed with lime or else watered with well-diluted soluble phenyl. "E. J." may have given his plants a chill, watering with cold water, for instance, or he may have injured the stems by surrounding them with soil to which a strong chemical manure had been too freely added. An overdose of kaimit greatly injured a batch of plants owned by a gardening friend of mine, and a too free use of either nitrate of soda or sulphate of ammonia would prove equally injurious. Had the plants received been large enough to produce fruit, I should have expected to find either eel-worm in the roots or canker, similar to what affects Melon plants, in the stems, but am of opinion that neither of these evils was responsible for the mischief. All things considered, I think "E. J." will do well to start afresh with good, sweet, loamy compost, and if the plants are kept uniformly moist at the roots, only avoiding saturation, success will most probably reward his efforts. Cucumbers ought never to be planted in large masses of soil. Commence with small heaps and add more compost as the roots give signs of requiring more.—W. I.

**Cabbage sprouts.**—Cabbage sprouts are often invaluable in winter, affording a change in the dining-room, and are found useful even where a good breadth of Rosette Colewort is grown. The great point, however, is to select the right batch of summer Cabbage to save for sprouts. A secondary batch, or one that came into use in July, is the best for producing good succulent side growths in November and December. In any case the bed should be gone over in August, all old leaves removed and straggling stems cut back close to the ground; this applies more particularly to beds that were fit for use in May and June, and that have produced numerous smaller side Cabbages. It is astonishing what a quantity of Sprouts an ordinary-sized bed will produce later on if so treated.—C. C. D.

**French Beans in autumn.**—In the autumn when Peas and other vegetables are getting scarce Beans come in most acceptably. I am aware Peas are more plentiful in the north well into the autumn, and there may be less demand for French Beans. This year, for instance, in the south, owing to heat and drought there has been a short Pea supply, but at the time I write, the last week in July, French Beans sown to follow early Peas are doing grandly, and in many gardens with a light soil are of great value to the grower. There is no great difficulty in having dwarf Beans for a much longer period if grown specially for late supplies, and now is a good time to sow for the late lot, provided good soil and means to apply moisture exist. Late Beans having to make their growth in a short time need rich soil, and if at all dry plenty of moisture to assist rapid germination of the seed. Above all thin sowing is a necessity, as if crowded so late they fail to set. I find it best to sow at the end of July, or as early in August as possible, in short rows, as should early autumn frost follow it is a simple matter to cover at night and remove the cover in the morning. Of course when movable frames can be afforded so much the better, and in cold or northern districts a sowing may with advantage be made in cold frames for a late supply to eke out those sown in June. I have used turf pits to great advantage, covering over with thatched hurdles, and the plants bore well into the autumn at a time there was a good demand. Pits used thus come in useful later on for Lettuce, or to preserve early Broccoli or late Cauliflowers. It is well to use a quick growing kind. Syon House or Early Favourite is good for that work.

#### SHORT NOTES.—KITCHEN.

**Pea Walker's Perpetual Bearer.**—What a really first-rate long season Pea this is. It runs to about 3½ feet in height, pods abundantly, and kept hard gathered, continues to do so over a long time. It is one of the very best small garden Peas if but for

this reason. The pods are of good size, well filled, and the Peas keep tender and sweet for a long time. We have plenty of Peas carrying finer pods, but few are more generally useful.—D.

**Early fruiting Tomatoes.**—I have several varieties under trial, but the one that pleases me most is Lightning. This is not only extra early, but it is a very heavy cropper, producing as many as sixteen and eighteen fruits in a bunch. A very remarkable character in this sort is that the first bunch of fruit is formed on the point of the stem. The plant, however, quickly develops side growths below the bunch of fruit. The fruit is round and fairly handsome.—J. C. CLARKE.

#### JULY IN SOUTH DEVON.

In a sheltered garden a large plant of *Abutilon vexillarium* is now in fine bloom, its slender curving shoots being thickly strung with crimson and yellow blossoms, while hard by against a wall *Rhynchospermum jasminoides* is white with its fragrant flowers. *Achillea ptarmica* fl.-pl. The Pearl has remained in flower throughout the month, and the rose-coloured spiny globes of *Acaena microphylla* have thickly covered the dense foliage that here and there carpets the rock garden. From its shapely leaves the great *Acanthus* has reared tall spires of bloom high upon 6 feet high in a corner of the wild garden, while *Agapanthus umbellatus* and its white variety are to be found in favoured spots flowering in great clumps on the lawns. Where this fine plant does not succeed planted out, a good supply in tubs creates a wonderfully decorative effect in the garden through the summer months, as the umbels are very lasting and the tint of blue pleasing to the eye. *Anemone japonica* Honorine Jobert has already commenced its flowering period, some of the plants being considerably over 5 feet in height and covered with buds. The blooming of these autumn flowers—for the Michaelmas Daisy (*A. Amellus bessarabicus*) has opened its large purple stars, and many of the perennial Sunflowers are in bloom—gives an unwelcome hint of the passing of summer. *Antennaria margaritacea*, the "Pearly Everlasting," is pretty in masses as sometimes seen in cottage gardens, where the Sweet Williams and double Rockets have been flowering grandly. The hybrid *Alstroemerias*, with their beautiful colour gradations, were at their best at the commencement of the month, while later on *A. psittacina* and *A. aurantiaca* came into full flower. A very beautiful floral arrangement can be formed by the association of the latter flower with the Caucasian Sea Holly (*Eryngium Oliverianum*), the orange of the *Alstroemeria* and the iridescent steely blue of the *Eryngium* making a delightful contrast. The white *Antirrhinum* is still decorative in masses, especially where the seed-pods are cut off as soon as formed, and the breadths of *Aquilegia chrysantha*, though less striking than during the latter days of June, have given a pleasing note of pale saffron. The *Anthericum* have flowered through the greater part of July, and the bright Sea Pink (*Armeria bracteata rubra*) still produces its rosy flower-heads. *Anchusa italica* showed signs of waning beauty after the first week of the month, throughout which the quaint *Astrantia maxima* has been in flower. The tall feather-plumes of *Arundo conspicua*, gently swaying with every breeze, are now at their best, the beauty of some plants, however, having been marred by a torrential downpour that occurred during a thunderstorm. In dry, sunny spots

#### BABIANAS, INTAS AND SPARAXIS

have been in bloom, and the tuberous *Begonias* are week by week affording a more brilliant display. The old red Bergamot (*Monarda didyma*) has been a mass of fragrant crimson flower-heads, and its white variety has also been blooming freely, as has the less pleasing *M. birta*. The Plume Poppy (*Bocconia cordata*) has been very ornamental, growing between Bamboos to a height of nearly 8 feet, the mixture of ivory-white and burnt-almond tint of its pyramids of

inflorescence being very effective. This subject is much appreciated for indoor decoration, and the stems are cut at full length and loosely arranged in a Lucca oil jar, or other simply shaped receptacle, will be found most decorative, last a week or ten days in water. Towards the end of July the tall Chimney Campanula (*C. pyramidalis*) showed its stately beauty, and *C. carpatica*—which some strains possess much finer flow than others and *C. turbinata* expanded their fragile bells. In a rock garden before alluded to in these columns, *C. polviformis*, with its spread, pale lavender cups, was very beautiful, and both *C. Raineri* and *C. Waldsteiniana* were flowering. There also the dazzling Calandrinia *umbellata* was in bloom, as was the handsome *Callirhoe involucrata*; while in another garden *C. Papaver* was in fine flower. Some brilliant effects are now produced by the new lavender-flowered *Cannas*, the vermilion being very vivid and the yellow and orange clear. The older *iridiflora* *Ehmanni*, with its large, Musa-like leaves and pendent, rose-lake blossoms, is, however, to be despised, since to the beauty of its flower added a charm of outline far nobler than is found in the new race. Carnations have in many gardens been very good, a mass of Mrs. Reynolds Hole many feet through that I saw in mid-July creating a charming colour-effect, the plants being healthy and the individual flowers large and shapely. Sir B. Seymour (flesh-pink) appeared good for massing. In one garden, however, the old Crimson Glove was badly affected with spot. The *Centaureas* (white, purple, red) have been blossoming in the wild garden and *C. cyaneus* (the blue Cornflower) still adds valuable note of colour to the borders, while *moschata* (the Sweet Sultan) is in full bloom. A yellow variety of the latter flower contrasts admirably with the blue of the Cornflower, and a combination of the two will be found effective indoor decoration. *Celsia cretica* is a plant rare seen in gardens, but its yellow flowers are handsome, and well entitled to a place in the border. *Chelone barbata* has thrown up its tall scabrous flower-spikes, and is a decided acquisition to any sheltered nook, where the flower stems may be left unstaked, the bareness of stems rendering it difficult to afford support that is not objectionably apparent. *Chrysanthemum maximum* has commenced to flower, but is equal in beauty to the later-blooming *Pyrethrum uliginosum*, which is more valuable both for border and for indoor decoration. The handsome *Cimicifuga racemosa* has produced its white flower racemes, and is very striking when in bloom. *Coreopsis grandiflora* has been a splendor of gold throughout the entire month, and the white variety of *Cosmos bipinnatus*, with Nigella-like foliage, has been very taking. *C. matis Davidiana* and *Convolvulus encorium* are habit decidedly unlike what might be expected from their names, neither being a climber. The first is an herbaceous plant that produces small blue scented flowers at the axils of the leaves while the second is a pink-blossomed shrub. *Crinum capense* is now in bloom in some gardens. Slugs are very fond of the succulent leaves, where they are allowed to pursue their raven unchecked, soon deprive the plants of much of their decorative value. The beautiful little

#### CYPELLA HERBERTI

has been flowering on and off through the whole of the month. The individual blooms last only a day but are quickly succeeded by others, so that the flowering period is an extended one, which, apparently, will not conclude for another fortnight. Johnson's "Gardeners' Dictionary" gives the colour of the flower as vermilion, which is correct, the tint being an apricot-yellow. Through the courtesy of Mr. Archer-Hind I was enabled to inspect plates of this *Cypella* which had appeared in the *Botanical Magazine*, the *Botanical Register*, and "Sweet's," in all of which the colour is yellow. It is also known under the synonyms *Tigridia Herberti* and *Morea Herberti*. The plant in question is growing very strongly, and has been in the border for two years, and will, I trust,

andure another winter in the open. This is the first occasion of its flowering in my garden. The All blue Delphiniums were handsome at the commencement of the month, and a few large composites of *Doronicum plantagineum* Harpur-Crewe have been produced from plants whose old flower-stems have been removed. *Dianthus Napoleon* II. has retained its brilliance, but an even more vividly-hued Pink is *D. Atkinsoni*. The Sea Hollies have been most effective, their colouring being quite unique in the garden. *Eryngium methystinum*, *E. Bourgati*, and *E. Oliverianum* are all worthy of culture for garden adornment, whilst they are equally valuable for cutting. The Cactus Dahlias, though not at their best, are commencing to bloom, and very handsome are some of the flowers, many showing the true Cactus form of Juarzi, which seemed lost in subsequent productions. In a rock garden the Rocky Mountain Willow Herb (*Epilobium obcordatum*) is seen charming, while *Erigeron speciosus* and *macronatus* are blooming bravely on, and show no signs of ceasing to flower. The Globe Thistle (*Echinops Ritro*), with its blue spiky flower-heads, is now decorative in the wild garden, and the Everlasting Pea (*Lathyrus latifolius*) and its white variety garland many cottage porches with their profuse blossoming. The yellow Foxgloves have bloomed well, but lack the stately beauty of their white sisters. Anemones are in bloom, but their charm lies chiefly in the colour and contour of their leafage. *F. eboldi*, with its large, cordate, glaucous leaves, being the most valuable, while *F. grandiflora* and *F. ovata* and their variegated varieties are very generally grown. *Galega officinalis* and *G. alba* have both been covered with bloom, the plants of the latter being especially effective when associated with vividly-coloured subjects, such as *Lychnis chalcidonica* or *Gladiolus onchelyensis*. *Gaillardias* and *Gazania splendens* have been bright, and the graceful Cape Violets (*Galtonia candicans*) has borne aloft its prly bells above the blue of *Salvia patens*. Two *Antennas*, *A. asclepiadea* and *G. septemfida*, have been in bloom. I have never, as yet, seen the handsome *Gerbera Jamesoni* in flower in the open, but its large orange-scarlet blossoms are sufficiently striking to merit a trial being given to the plants in dry, sheltered positions in the south-west. *Gaura Lindheimeri* is an herbaceous plant which seldom met with in gardens, but its tall spikes of white and claret flowers are handsome, and in Devonshire, at least, it is perfectly hardy. *Gultheria procumbens* in the rock garden has produced its drooping white flowers, which ere long will give place to equally attractive berries. *Gnista schipkensis* has also been in bloom. The red-coloured *Geranium lancastriense* has been in flower and at Coombefishacre I saw the white variety of *G. sanguineum*, alluded to by Mr. Archer-Hind on page 6. Here I also saw the plant of *Ostrowskia magnifica alba* mentioned in the same note. It was out of flower, as was *Incvillea Delavayi*, but was, seemingly, in robust health and nearly 4 feet high. Although I have tended for five years I have never yet succeeded in flowering the *Ostrowskia*. Lemoine's *Gladioli* and the well-known *G. brechleyensis* are at present very handsome, several superb spikes of the latter in full bloom amongst a colony of *Yucca filamentosa*, of which many were flowering, presenting a wonderful effect in the direct contrast of brilliant scarlet with the ivory white of the Yuccas. The season has now arrived when the charming *Gypsophila paniculata*, with its billows of flower-lace, is approaching the zenith of its beauty. It is a delightful subject in the garden, but is even more in request for indoor decoration, in which it is now grown largely, its delicate rays associating with almost any form of floral arrangement and possessing the merit of retaining much of their beauty even when quite withered. Of the

#### PERENNIAL SUNFLOWERS

many are in flower, *Helianthus latiflorus*, *H. multiflorus*, *H. m. Soleil d'Or*, and *H. rigidus* amongst the number, but *H. rigidus* Miss Mellish has not as

yet unclosed a blossom. The annual Sunflowers in wayside gardens have a pleasing effect, the light, primrose-coloured variety showing off the dark disc to perfection. Many fine Hollyhocks are also to be seen in the best of health, a row of singles in full bloom that I saw the other day exhibiting no trace of disease, which, however, has appeared with almost its old virulence in some gardens. The common St. John's Wort (*Hypericum calycinum*) has covered an almost perpendicular bank, 20 yards in length, with its yellow flowers, and each year usurps a further space of stony territory. *H. olympicum* I have also seen in fine bloom. *Hemerocallis Kwanso* fl.-pl. and its variegated variety are also flowering well, in some cases growing fully 4 feet high. *Helenium pumilum* has also given its mass of bright yellow in the herbaceous border, and *Hydrangea hortensis* has commenced its season of autumnal beauty. *Indigofera floribunda* I have seen lately covered with its pink Pea-shaped blossoms, and the bed of *Jaborosa integrifolia*, alluded to in June, has produced its flowers in like profusion through July. The Ivy-leaved Pelargoniums, especially *Souvenir de C. Turner*, brighten the borders wonderfully, the brilliant Cherry-pink of the variety named showing to the best effect against a grey, stone edging. The *Kniphofias* have also thrown up their fiery flower-heads, the sulphur-coloured *K. Lachesis* being a very beautiful introduction. *Lavateras*, at the back of the borders, have blossomed profusely, and are very effective both in the garden and as cut flowers. Of Lilies, *L. candidum*, in fine form, was in bloom at the opening of the month, and *L. auratum* is better this year than for some seasons, the bulbs planted in '92 having all flowered. *L. croceum* has been over 6 feet high, while *L. pardalinum* has considerably exceeded this height. *L. canadense* and *L. superbum* have also bloomed, though not as satisfactorily as usual. *L. Humbolti* has been very beautiful, as has the brilliant vermilion *L. chalcidonicum*, while the buff-hued *L. excelsum*, or *testaceum*, has grown and flowered excellently, and towards the month's end *L. tigrinum* commenced its blossoming. The white-flowered *Linaria repens alba* is pretty on a rockery, where the yellow *Linum flavum* and the taller blue *Linum narbonneense* also flourish. The purple *Lindlofia spectabilis* is seldom grown, but is pretty when in bloom. *Lychnis chalcidonica* with its scarlet flower-heads was a brilliant sight in the early days of July, and a large-flowered variety (*L. c. grandiflora*), with blossoms 2 inches across, is a decided acquisition, while *L. diurna rosea* is still bright, and by the waterside the *Lythrums* have thrown up their bright pink flower-spikes. The green-leaved *Lobelia cardinalis* is now in flower, some time in advance of the dark-leaved variety. Two Mallows that I lately saw in flower are *M. lateritia*, bearing very beautiful blossoms of flesh-white marked with salmon-pink, and *M. Munroiana* with red flowers.

*Matthiola bicornis*, the Night-scented Stock, one of the most fragrant flowers of the garden at eventide, has also been in bloom, while long lines of *Nicotiana affinis* make the summer nights odoriferous with their delicious perfume. Many *Enocheras* have dowered the month with their beauty; *E. fruticosa*, *E. Youngi* in the earlier days, quickly followed by *E. pumila*, *E. marginata*, *E. macrocarpa*, *E. speciosa*, beautiful in the rock garden, and *E. Lamarekiana*, while *Oxalis floribunda rosea* has continued in bloom.

#### POPPIES,

though not so plentiful as in June, gave us many blossoms in July, Iceland, Oriental, Welsh, Opium, Shirley, and *P. pilosum* all contributing their quota. On the seashore the Horned Poppy (*Glaucium luteum*) made the pebbly beach beautiful with its blue-green foliage and yellow blossoms, while in the green of the growing wheat the scarlet stain of the field Poppies flamed afar. The Californian Poppy (*Romneya Coulteri*), after a mild winter, has done well in many gardens, and yesterday I saw the plant from which the photograph that appeared on p. 86 was taken, and which is now 10 feet high and blossoming finely.

*Platycodon grandiflorum* and *P. Mariesi* have flowered well, and the herbaceous *Ploxes* are this season particularly fine. Of these a careful selection should be made, as many of the colours in commerce are not calculated to beautify the garden. *Phygelius capensis* has opened its first flowers, while the *Polemoniums*, *Polygonum capitatum*, and the *Pyrethrums* are still in bloom. The single white Macartney Rose opened its first blossom on July 2, when the Musk Rose was in full beauty, while the beautiful double Brambles, pink and white, were at their loveliest towards the close of the month. *Ranunculus acris* fl. pl. is still bright, and the "Fair Maids of France" (*R. acitonifolius* fl.-pl.) did not cease their flowering till well on in July. The tall yellow *Rudbeckias* and *R. purpurea* were in bloom by mid-July, and *R. Newmani* is now entering upon its blossoming season. Of annuals the *Salpiglossis* stands pre-eminent in the wondrous shot-silk colouring of its blossoms, and when this flower is associated in the border with the gorgeous *Tigridias* the colour effect is marvellous. The light blue *Scabiosa caucasica* and the yellow *S. lutea* have both been charming, and on the rockery the purple *Scutellaria alpina* has been flowering. Many *Spiraeas* have been in bloom, fine bushes of *S. arifolia*, *S. Lindleyana* and *S. flagelliformis* having been laden with blossom, while *S. Antony Waterer*, *S. rivularis*, *S. japonica* and *S. venusta* have also been ornamental in the garden. *Solidago virgaurea nana* has come into flower, and the handsome *Stactea latifolia* is nearing perfection. *Tradescantia virginica* has not yet ceased to bloom, and the yellow *Trollius* is still bright, while the pink *Tunica Saxifraga* has been pretty on light soils. *Verbascum phoeniceum* was flowering early in the month, and the shrubby *Veronicas*, now in full bloom, are objects of beauty along the south-west coast. *V. Lyalli* has also flowered well. Of climbers, *Solanum jasminoides* is studded with white flower-clusters, and *Physianthus albens* is blossoming freely, while *Clematis*, *Jasmine* and *Tropeolum speciosum* have all their flower-wreaths on arch and wall, and the *Wistaria* has produced a second crop of pendent lilac bloom. Amongst the shrubs some of the most noticeable have been *Carpenteria californica*, *Desfontainea spinosa*, the double *Deutzia*, *Olearia Haasti*, the beautiful *Philadelphus mexicanus*, with its fragrant white-cupped blossoms, and *Rhus Cotinus* (the Venetian Sumach), with its purple feather-like inflorescence, which has earned it the title of Smoke Bush. The standard *Magnolia* is now in full bloom, and is yielding its white chalice in plenty day by day.

S. W. F.

## STOVE AND GREENHOUSE.

### RONDELETIA SPECIOSA.

Most of our beautiful old hard-wooded greenhouse plants have been put on one side to make room for quicker-growing present-day favourites, and apparently it will not be long before the majority of the stove species will be the same. This *Rondeletia* is one of the latter that I should be sorry to see the last of, but even now it is very seldom seen and presumably its extinction is only a question of time. Yet what could be brighter than a free open bush of it, covered with the vermilion and orange flowers produced in small corymbs from the tip of every shoot? There are several reputed varieties of it more or less distinct by reason either of the size or colour of the flowers; a form called *brilliantissima* I remember growing for several seasons in an East India Orchid house. The plants were often tied out into various shapes, but as trained specimens they could never be quite a success: the flowers seem to want to hang loosely to show themselves to the best advantage. Propagation of the plant is easily effected by cuttings of the young wood before it

commences to bloom, and although growth is rather slow in the earlier stages, the plants flower while still in a young state, and every season increase in vigour. The roots are very fine, like those of a Heath, consequently the potting compost must be something of the same nature and placed very firmly. It may with advantage be made a trifle richer than for the last-named plants, a good percentage of a fibrous loam being of great assistance. Drain clean pots thoroughly, and over the crocks place a layer of rough peat, making it firm with a potting stick. In repotting vigorous young plants, give a shift of about  $1\frac{1}{2}$  inches all round, and see that the compost is made firm in every part of the pot. See, too, that the plants are not dry at the root for a start, for if the old ball gets dry after potting, nothing but immersion in water for a day or two will thoroughly moisten it. Young plants from the propagating case need not be quite so firmly potted as older ones, but a smart rap on the potting bench after the soil is pressed down is advisable. All this class of plants requires very careful watering, the roots being easily damaged either by excess or scarcity of moisture. A sunny spot in a moist stove best brings out the characteristic deep green of the foliage, upon which the flowers have such a telling appearance. If carefully attended to in the first years of their life with regard to stopping, a good bushy habit is formed, and leggy old specimens—such as do so much to bring the plant into disrepute—are prevented. Feeding at the roots should be gone about with caution, or the result will be seen at the next potting time in the points of the roots. A judicious application of any good concentrated manure is of assistance, especially to old or root-bound plants.

**Plumbago capensis.**—This is well known as one of the best plants for the greenhouse, and it is also used for the flower garden with good effect. Old plants get stunted and unsightly, but if propagated annually and grown on under favourable conditions it makes a very nice pot plant, especially for autumn use. Good cuttings may generally be had in February. An old plant cut back and put into a little warmth will soon give a good supply of cuttings. Short cuttings treated similarly to those of Fuchsias will succeed well; they should be potted singly as soon as established. It may be grown in quite a cool house, but will make better progress in an intermediate temperature. Stopped as required, bushy plants are soon formed. I have had quite dwarf plants with several good heads of bloom in  $4\frac{1}{2}$ -inch pots, and when given a little artificial manure they go on flowering for a considerable time. The white variety is very pretty, but the type, I think, is the better of the two.—H.

**Swainsonia galegifolia alba.**—This is an old introduction which does not often meet with the treatment it deserves. Let go its own way, it does not make a very serviceable plant, but with a little attention it may be grown as a compact bush, and will keep up a succession of pure white blossoms for a considerable period; in fact, it may be had in flower nearly throughout the year. For autumn flowering the spring-struck cuttings will make nice plants, cuttings from plants which have been cut back and made a fresh start striking freely in the ordinary stove propagating pit or on a hotbed. They may be potted singly in a good loamy compost as soon as they are well rooted. Grown on in a cool house or pit and kept stopped from time to time until they have made bushy, compact plants, they may then be left to come into flower. As a pot plant for the cool greenhouse the Swainsonia has few rivals, as it keeps up a succession of bloom through the autumn and well-nigh through the winter. It must be grown in a cool place, as red spider being its greatest enemy, a dry atmosphere must be

avoided. In addition to being a useful pot plant, it is also valuable for cutting from. If put into water as soon as cut the flowers will last well.—A. H.

**Vallota purpurea.**—A few well-flowered examples of this afford a pleasing variety in the greenhouse at the present time. I am, however, under the impression (which is confirmed by others) that, generally speaking, the Vallotas of the present day are inferior varieties compared with those grown a generation or more ago. This is in all probability owing to the fact that large numbers are now imported every year, and though many of them die, yet some become permanently established. In these imported bulbs, as a rule, the flower-stems are taller and the segments of the bloom narrower than in the old Vallota of twenty or thirty years ago. An opinion seems very generally to prevail that the Vallota will put up with any amount of rough treatment, but that is by no means the case, and this erroneous idea is doubtless the cause of many losses. Two things in particular very detrimental to the welfare of the Vallota are over-potting and disturbing at the roots more than is absolutely necessary. The plants may be kept in good condition in the same pots for years, and consequently the soil employed should be of a lasting nature. Good fibrous yellow loam and sand, lightened if necessary by a little well-decayed leaf-mould, is a very suitable compost for the Vallota, and in such as this the roots will remain in good condition for a very long time. Imported bulbs are sometimes affected with an insect after the manner of the Eucharis mite,

*Crinum Moorei album.*

and considerable numbers have been lost in this way. By importing bulbs of the Vallota we often have them in bloom at a different time of the year from that in which we are usually accustomed to see them in flower. They generally reach this country in the summer, and if potted at once, a few may bloom in the autumn; then about the month of May many of them will, as a rule, push up their flower-spikes. A few years ago numerous examples were exhibited at the Temple show. Sometimes pink forms crop up among these imported bulbs, but they are more difficult to establish than the ordinary kinds. I have raised a considerable number of Vallota seedlings, and find that, as a rule, they grow away in a very kindly manner. The flowers, however, are not all of equal merit, and a good deal of variation exists among them. The Vallota is essentially a greenhouse plant, and a good light position, such as a shelf near the glass, suits it best.—H. P.

**Coronilla glauca.**—Since Chrysanthemums have commanded such attention some of the old-fashioned useful winter-flowering subjects have been discarded, or now receive but little notice. One of the most serviceable for either conservatory decoration or for cutting is Coronilla glauca, the value of which is greatly enhanced by its having yellow flowers, which, if we set aside Chrysanthemums, are none too common during November and December. When well grown, the deep green, dense foliage contrasts pleasingly with the bright yellow Pea-flower-shaped blossoms. A stock may soon be raised by potting several small plants into a 6-inch pot, these in a

couple of seasons forming dense flowering bushes some 3 feet in height if shifted into a 9-inch or 10-inch pot and liberally fed during the growing season. Plenty of drainage, good loam, some rotten manure, and road grit or coarse sand suit the plants well. From the commencement of June until the end of October a position in the open air suits them best, having, in fact, the same treatment in every way as Chrysanthemum. They look best when one stout stake only is inserted in the centre of the pot for support, and all outer branchlets allowed to fall down in a free and natural manner. The rich yellow blooms are then displayed to advantage. Small sprays look very cheerful arranged in glasses, and they are also very useful for dinner-table decoration. The plants will continue in good health for five or six years, after which young plants should be brought on. They will take no harm in winter if frost kept from them.—J. C.

## GARDEN FLORA.

### PLATE 1131.

#### CRINUM SANDERIANUM.

(WITH A COLOURED PLATE.\*)

THIS is one of the best of the thirty species of Crinum found in Tropical Africa and exclusive of those found at the Cape, of which there are about a dozen, the two most familiar these being C. Moorei and C. longifolium (capense). I consider C. Moorei the best of all Crinums in a garden sense, its blooms lasting exceptional long and its flowering season being the summer through. In this respect it differs from all the other species known to cultivators except C. longifolium, which is equally free flowering and lasting, but a long way inferior in beauty. C. Sanderianum was first introduced in 1884 by Messrs. F. Sander and Co., St. Albans. It is a native of the west coast of Africa, i.e., Sierra Leone, &c. Its nearest ally is C. zambanicum (Amaryllis ornata of Botanic Magazine, t. 1171), which, according to Mr. Baker, is widely spread in Tropical Africa and Tropical Africa, and which

one of the best known of tropical garden Crinum. Another near ally is C. Kirki, introduced from Kew from Zanzibar in 1879 by Sir John Kirk and a familiar plant in the houses at Kew still. C. scabrum, another African species grown in English gardens, is also nearly allied to C. Sanderianum. These are all characterized by a globose, short-necked, purple-tinged bulb long strap-shaped, bright green leaves, which are deciduous, the new leaves accompanying preceding the flower-scapes, which are stout from 1 foot to 2 feet long, with an umbel from six to twelve fragrant flowers more or less funnel-shaped, with oblong, not spreading, segments and a curved tube. In C. Sanderianum the tube is about 5 inches long, and the segments 3 inches to 4 inches by 1 inch, white with a band of bright red down the middle of each.

This and all its allies require a stove temperature, a rich loamy soil, plenty of water whilst in growth, and little, or none, whilst at rest. W. W.

**Dabœcia polifolia.**—There are few of our dwarf evergreen shrubs of which more can be said in favour than of this little ericaceous plant, hardly as the common Gorse, of neat habit, flower

\* Drawn for THE GARDEN in Messrs. Sander's nursery, St. Albans, by H. G. Moon. Lithographed and printed by J. L. Goffart.

ing freely and throughout a long season, and withal easily propagated and cultivated, it unites in itself pretty nearly all the virtues one could wish for in a hardy shrub, for its beauty is unquestionable. It is not a native of Great Britain, but is found wild in the west of Ireland, also in several parts of South-west Europe. Its small leaves, each half an inch long and narrow-ovate, which crowd the hairy stem are of a glossy and very dark green above and blue-white beneath. The raceme is erect, terminating the branches, and bears numerous drooping urn-shaped flowers. The flowers are of three different kinds: in the typical form they are purple, in flore-albo they are white, whilst a third form bears flowers both purple and white, both colours frequently occurring in the same flower. It lasts from June to September in flower, and is easily propagated by seeds.—B.

## THE WEEK'S WORK.

### KITCHEN GARDEN.

**CELERY.**—Frequent and copious waterings have been necessary to keep the plants from suffering

*Crinum capense.*

from the excessive heat and the parched state of the ground. In gardens where there is a scarcity of water, or labour to apply it, this crop will have made little progress; indeed, the plants will probably have lost their healthy green colour and have a stunted appearance. Celery is naturally a moisture-loving plant, and to obtain heads of the finest quality later on, no trouble should be spared during the present spell of dry weather to keep the roots well supplied with water. Mere dribbles once or twice a week are next to useless, and to be of any use to the plants the trenches should be almost flooded as often as possible while the dry weather lasts. Although it would be well to draw a little fresh soil round the plants if they are growing fairly well under the present circumstances, this should be confined chiefly to the early batches that will be required at the end of the present month, but mid-winter and late supplies would be better left as they are until they have had several good showers sufficient to penetrate the soil well below the roots. Where the earliest supply has not been moulded up as yet, a thorough soaking of liquid manure would prove most valuable, as it would assist rapid growth,

and result in the Celery being more crisp later on when required for use. A slight sprinkling of salt once a week and well watered in is also beneficial, and may be used as a substitute for the former where this is not at command. It is not too late to plant out a late batch, but it would not be wise to disturb the plants until we get rain, when with a few cloudy days they would soon take to the new soil, and little or no check would be experienced. In the meantime, however, the plants should not be neglected, and should be well watered as often as necessary.

**SEED-BEDS** of spring Cabbage, Lettuce, and Endive are also suffering from the dry state of the ground, and it is only by frequent waterings that the seeds will germinate and a good stock of plants be obtained. It is not altogether safe to wait for rain before sowing more seed of each, as the season may be too far gone before the plants are large enough for putting out, therefore all attention should be paid to those already sown, so that a good store of plants will be ready for putting out when the state of the weather permits. In spite of frequent waterings, the sun has such power that the young seedlings will push through the soil slowly unless a fairly shaded border was selected for forming the beds. A few

moisture as possible. As a further means of conserving this, it is a good plan to lightly tread the ground the following day, which will also make it in a better condition to receive the plants or seeds when the time arrives for putting them in.

**PEAS**, I am afraid, will have collapsed in many gardens before now where it was not possible to keep them well supplied with water, and those who were careful to trench the ground in the spring for late summer supplies will now be reaping the benefit of the extra labour then incurred. Much depends, however, on soil and locality, as, in spite of all the attention, some ground is so poor and thin that it is impossible for this crop to grow freely after a long spell of hot weather. In such cases it would be wise to pay extra attention to other things which are better able to stand dry weather, provided their roots are regularly supplied with moisture, especially in the form of liquid manure. A most important crop now for keeping up a supply until cut off by frost will be

**SCARLET RUNNERS.**—It is surprising what an amount of growth these will make when liberally supplied with manure water, even when grown on poor land. Ridges of soil should be drawn up quite 6 inches high on either side of the rows, and not less than 18 inches from the base of the plants. Place a good layer of decayed manure in the trenches thus formed, and afford a thorough soaking. A few inches of dry soil should be spread over the manure afterwards to conserve moisture, and also to be less inviting to the attack of birds. Keep the Beans gathered even though they may not be required, as their removal relieves the plants and induces them to continue flowering.

Although I have pointed out some of the drawbacks resulting from dry weather, one should not overlook the advantages, as such a season is most favourable for the destruction of weeds. All weeds that have been allowed to reach the stage when the seed is nearly ripe should be carefully pulled up and burnt at once.

RICHARD PARKER.

### FRUIT HOUSES.

**EARLY VINERIES.**—The Vines in these houses should now be in fit condition for a partial pruning in the shape of a shortening back of the laterals to about half their length. This partial pruning has a very beneficial effect, inasmuch as it not only induces the Vines to plump up their basal buds, but also assists in the early maturation of the same. Laterals which have borne bunches of Grapes will not need shortening back if a portion of each was removed when cutting the bunches. After this partial pruning has been carried out, syringing of the foliage had better be discontinued, as it might have the effect of causing premature bursting of the buds; but root waterings must not in any way be neglected, particularly if the hot weather should continue. Towards the end of the month the top-dressing of borders may be taken in hand, also such work as adding to, renovating, or making new borders. In the meantime the necessary quantities of the required materials should be prepared for forming the borders, also for the top-dressing, &c.

**MIDSEASON HOUSES.**—From many of these the crop will have been cleared, and as it is so very essential that the first leaves be preserved in good health as long as possible, they must be well washed occasionally to prevent possible attacks of red spider. The borders must also be watered whenever they approach a dry condition, and keep a fair thickness of mulching on the surface to prevent moisture evaporating too quickly. In course of time these Vines may be treated as advised above for earlier houses, the ripening of the foliage and cessation of sub-lateral growths forming a good guide as to when it may be performed. Other houses in which the Grapes are ripe must be kept shaded whenever bright to prevent the black kinds losing colour. The borders must also be kept moist, otherwise the berries will shrivel; and as an aid towards maintaining the berries in a plump condition, the internal air should be

bushy Pea sticks laid on the surface, or a Strawberry net of several thicknesses raised a few inches from the ground, will afford a certain amount of shade, as well as keep birds from doing any harm.

**DIGGING AND MANURING.**—Unless the ground has become foul and requires cleaning before a crop can be put in, I would not recommend disturbing it to any depth while the dry weather lasts, as, apart from this allowing moisture to escape, the influence of sun and wind will also exhaust much of the feeding properties contained therein. It is better to defer digging under such circumstances until the time arrives for putting in the crop, when a change for the better in the way of weather may have arrived. The same may be said in manuring land. To expose the manure by spreading it over the ground which requires digging, if only for a day, means so much loss of strength and moisture. Where it is really necessary to manure and dig ground for Cabbage or Spinach, wheel the manure in heaps and protect it from the sun with Pea haulm or some other material, working it into the trenches as the work proceeds, so that it retains as much

kept as cool as possible and the floors damped at least once a day during fine weather. Wasps, bees and flies, where numerous and troublesome, must be excluded from these houses, or they will soon work a considerable amount of mischief. The best plan is to tack muslin or netting over the ventilators, which if properly done will prevent these pests entering. This method is infinitely superior to that of enclosing the bunches in muslin bags, while the handling of the bunches, with the attendant loss of bloom consequent on the use of bags, is avoided. In lieu of this, saucers partly filled with sour beer and a few damaged berries will trap a good many, as will also the employment of the mixtures sold under the name of wasp destroyers, but absolute exclusion is the best remedy.

**MAIN-CROP MUSCATS.**—Here the Grapes will be ready for cutting, and as the supply will in many cases have to be prolonged as late as possible, steps must be taken to keep the Grapes in a sound plump condition. Aids to this end are: shading the roof during the hottest part of the day, keeping the borders quite moist, with a free circulation of dry air during fine weather, and closing the house altogether on wet days and foggy nights. Sprinkling water on the floors about the middle of the day cools the air and corrects aridity, but the moisture generated by its adoption will have evaporated long before nightfall.

**LATE MUSCATS.**—If these are on the point of colouring and the borders are in a condition to receive water, they may have a final application of artificial manure. If liquid manure is preferred, this may be used and continued some little time longer, but I do not advise its use once the Grapes commence colouring freely generally. Give every attention to air-giving making use of the front ventilators during the forenoon when colouring becomes general, and attend carefully to matters of routine, such as stopping and damping down, gradually dispensing with the latter as the berries assume an amber tint.

**LATE HAMBURGS.**—With such hot weather as we have had to contend with lately the greatest difficulty has been experienced in trying to prevent these late Hamburgs getting too advanced, and it is to be feared that in spite of shade and abundant air-giving they are in many cases in too forward a condition. There is, unfortunately, no remedy for this, and the only thing is to continue the same kind of treatment as regards shade and airing, and when finished to keep them as cool as possible, and trust that their well-ripened condition will enable their being kept as long as may be desirable. In the meantime see that the borders are kept sufficiently moist both inside and out, and if they dry up more quickly than is desirable, increase the mulch on the surface.

**EARLY PEACH HOUSE.**—The time has arrived when the consideration of such matters as lifting, top-dressing, additions to existing borders, and new borders should receive attention. In the first place, root-lifting is an excellent method of dealing with trees which make gross wood, cast their fruit, or are subject to that great evil, stone-splitting. Lifting the whole of the roots with a good ball of soil attached in bad cases, or a partial lifting in others when not of such a severe character, acts as a corrective in nine cases out of ten, and considerably prolongs their life and usefulness from a fruit-bearing point of view. Lifting must be done quickly, so that the roots are exposed to the drying influences of the outer air for as short a time as possible. Again, on the other hand, when the soil in existing borders has become partly exhausted, it is sometimes advisable to cut away the front portion to the width of 3 feet or 4 feet and to replace this with new soil, in which the roots should be carefully laid out. Top-dressing of borders is of great benefit when the trees are established and healthy, as the addition annually of a little fresh soil keeps the roots feeding up near the surface. One thing should always be observed in top-dressing, and that is to remove a certain proportion of the old

surface soil before applying the new, and the quantity of the latter should not exceed the former in bulk, otherwise the borders will become elevated above their proper level. Additions to borders are generally needed when new trees have been planted and it has not been thought necessary to make the border more than 3 feet or 4 feet wide at the outset. If the trees have done well, an addition of another 3 feet to the width of the border will be beneficial. Entirely new borders are generally required in the event of a tree dying, or when the replanting of a house with fresh trees becomes necessary, and, lastly, when planting a new house. In this latter case the borders can be made piecemeal, 3 feet or 4 feet at a time, but in the other cases the borders, as a rule, have to be constructed of full width at the outset, particularly if full-sized trees are lifted and brought in from outdoors. Such are the common reasons for lifting and border-making, and when either is necessary the materials for concreting the base, brickbats and rubble for forming the drainage, and the soil constituents for building the border with should be prepared, so that the work can be undertaken either at the end of the present month or the beginning of the next, according to the condition of the trees. In any case it should be done while the trees retain their leaves, as if these remain on but a few weeks afterwards, they greatly assist in the formation of new roots. A. W.

## FLOWER GARDEN.

### TREE LUPINES.

**CONSPICUOUS** among the flowers of June come the Lupines. Their elegant leaves, their usually good habit and their handsome spikes of pretty flowers render them welcome to nearly everyone. One never tires of the yearly display of the best varieties of *Lupinus polyphyllus*. Less enduring, but not less handsome, are the varieties of the Tree Lupine (*L. arboreus*), with their lavish display of yellow, creamy white or lilac spikes of honeyed flowers. Natives of California, these Tree Lupines seem to find our climate less congenial than that of the golden land from whence they come. They flower well for a year or two, but usually depart when we have begun to think that they mean to stay with us for many years. It may be that in their own sunny land they are not long-lived either. It may be that even there the burden of seed-bearing may be too great for longevity, but here, at least, their life is all too short. One is not disposed to attribute this short life to severe winters alone. Large plants sometimes survive a hard winter, only to succumb in a succeeding and milder one. These shrubby Lupines are not biennials, neither can we say how many years they will live. This does not appear encouraging nor likely to induce any to add the Tree Lupine to their shrubberies or borders, and yet it is so easily raised from seed or from cuttings, that there is no difficulty in retaining a stock to replace the plants we have lost. It must be some ten years or so since I bought a packet of seed, and this one introduction has never failed to give successors enough and to spare. Self-sown seedlings are produced freely and have often to be thrown or given away owing to want of space. The plants vary from seed, and where a variety which it is desired to retain appears it is well to propagate it by means of cuttings taken off immediately after flowering if the shoots are ripe enough. Of all the colours none are so much esteemed as a good bright yellow. Some of the paler shades look washed-out, and shades of lilac and blue are so plentiful among the other plants of the genus, that they are not so much appreciated in

this shrubby species. The deep, bright yellow is, on the other hand, a welcome colour, and a well-grown plant covered with its grey-green leaves almost hidden by the countless flowers is always and justly admired.

It is not difficult to find a place for the Tree Lupine. It is perhaps at its best among dark-leaved shrubs, against a hedge, or on a steep bank, where its spikes of flower will be seen to most advantage. It is not out of place in the border where, in its season, it is almost unsurpassed for profusion of bloom and its mass of colour. It likes a light soil with shelter from cold and cutting winds. With these afforded, a Tree Lupine will in its second year attain from 3 feet to even 6 feet in height, and produce an almost incredible number of spikes of flower. It does not object to pruning in spring, but, as a matter of course, this must be carefully done, or a stiff appearance will take the place of the natural grace of the bush. Seeds ought to be sown early in spring either in pots or in the open ground. The latter is the preferable course, and if possible the seeds should be sown where the plants are to flower. This will prevent any check to the growth. For cuttings, the little shoots on the main branches taken off with a heel when slightly hard at the base usually strike well if inserted in pots of sandy soil placed in a shaded greenhouse or frame. After flowering, plants in borders look a little untidy if allowed to retain all their seed-pods, and the most of these may be removed, only allowing any to remain which may be wanted to keep up the stock in case of the loss of the parent plants. The Californian Tree Lupine, in common with the other members of the genus, when shaken or touched when in seed makes a rattling noise.

Even taking into account the shortcomings or defects of the plant, the Tree Lupine is worthy of more extended cultivation than it has received during the hundred or more years it has been grown in British gardens.

S. ARNOTT.

*Carsethorn, by Dumfries, N.B.*

**Herbaceous Lobelias.**—These are exceptionally good this season, and as they are perfectly hardy with me, they rank among the most useful summer flowers. When at the end of a season any new arrangement in which they are to take part is contemplated for the following year, the old clumps are split into two, three, or four pieces, as their size allows, and replanted at once in the required site, a mulch 2 inches thick of leaf soil, or, better still, of peat moss manure if this is available following the planting. For a large bed in a prominent position let me recommend irregular clumps of *Lobelia* on a groundwork of William Niel Tufted Pansy. The colour contrast is very effective, and as this carpet plant is one of the very best of the Tufted Pansies alike for freedom and endurance, one has a very charming bed right away to the end of the season: indeed, it is at its best through August and September, when the spikes of the *Lobelia* are well developed.—B. C.

**Tufted Pansies.**—It is sometimes argued that the propagation of Tufted Pansies by offsets or division—a general break up, that is, of the old plants either in late autumn or in spring—is preferable, so far as after results are concerned, to propagation by cuttings. It may be so on some soils. It certainly is not here. Division was in the case of several varieties rendered necessary this spring on account of a failure with the cuttings, and an after comparison of the plants obtained from the two methods has consequently been afforded. There is no comparison between them; cuttings come earlier into flower, are far more vigorous, bloom with greater freedom, produce better blooms and last much longer.

have had a fine display this year on all the favourite varieties, and there has been less tendency to run out in several sorts that are, as a rule, offenders in this respect. Early in the season when there were indications of a long spell of dry weather the plants had a mulch of peat moss manure and a good soaking. This set them well on the move and was instrumental in producing a fine lot of early flowers, and just when they were showing signs of going back the heavy storm came and gave them a new lease of life. A rapid run through to remove any seed-pods and dead flowers clearly showed how quickly they picked up and started again with renewed vigour. A noteworthy point when growing them on the soil with which I have to deal is the advisability of the occasional renewal of the stock from a heavier soil. Despite dressings of road sidings and cow manure, I never get the vigorous foliage and large blooms obtained from a naturally heavy soil, except it may be in a wet summer, and then the profusion of flower is not forthcoming.—E. S.

#### CARNATION NOTES FROM WOKING.

THE cultivation of Carnations has been taken up in earnest by Mr. F. A. Wellesley only two years, but in his garden at Honeybots there is now one of the choicest collections yet got together by an amateur. About 1000 plants are grown in pots and flowered under glass, a large space being devoted to seedlings in the open border. Among the latter there are many promising kinds. Carnations bloom in the tropical sun of the past few weeks have looked anything but happy on the hot, sandy soil of this neighbourhood. Outside it seems quite impossible to cope with numberless thrips which attack them. I have had several opportunities of comparing the varieties in Mr. Wellesley's collection as well as noting his methods of culture. The young plants are kept perfectly clean throughout the winter months, at which time they occupy the stages of green-houses. This is an advantage over cold frames, because one may be working among his plants, however bad the weather. Not less than once a week each plant is examined, and if a "spotted" leaf is seen it is promptly removed. In the case of green-fly, either a dusting of tobacco powder is applied or the house is fumigated. Early in March the plants are potted into the size in which they flower. The size known as 16's, a trifle over 8 inches in diameter, is used. From two to four plants are placed in one pot, according to the strength of each variety. Several sorts of compost have been tried—loam and grit, a mixture of loam and manure, also that charged with various forms of fertilisers. Mr. Wellesley is convinced that fertilisers are not necessary and that Carnations object to high feeding. Sweet fibrous soil, with a fair proportion of rubble or gritty material, is all that is needed. The blooms resulting from such a soil are pure in colour, of good form, and most refined in their glossy texture. Self-coloured flowers appeal to me, and I will therefore mention these first. In pure white sorts there is not one to compare with Mrs. Eric Hambro. It has all the qualities of a perfect flower. Not over large—for huge Carnations become coarse—pure in colour and excellent in form and substance, it combines a most desirable habit of easy and sturdy growth. Miss Ellen Terry is a good white variety, but the blooms are too large to develop without a split calyx. This is a fault which Mr. Wellesley cannot overlook; hence many popular kinds such as the Malmaisons are not cultivated. Niphotos, again, is a nice white flower, and the plants bloom freely. Blush-white flowers are represented by Waterwitch, Her Grace and Seagull. They are all very fine. The last-named, perhaps, has the greater substance. Passing to a deeper shade, Burn Pink and Ketton Rose may be noted. These are free-flowering, useful kinds, now well known, but altogether inferior to such sorts as Exile and Braw Lass, two bright rose-coloured Carnations. Hayes' Scarlet cannot well be beaten in that shade. King Arthur has very large

blooms and is exceedingly showy. King of the Crimson is good in that colour, but by far the finest dark crimson sort is Mephisto, which is good in every way. Bendigo is a striking flower of a rich purple tint, and should be added to the choicest collections. Germania is an old kind that holds its own as a yellow, but one could wish the growth of a sturdier nature. Corinna beats it in this respect and has a nice flower. Miss Audrey Campbell is a fine yellow self. Duke of Orleans is also a showy one, but it must be placed among those that are rather large to be handsome. Among the apricot-tinted kinds there are some especially pretty flowers. Mrs. Reynolds-Hole, so generally esteemed, does not, however, compare favourably with The Pasha; this is rich and fine. Nabob is a trifle less bright, but is a charming sort. Winifred and The Hunter may also be included, the former being the better of the two. I noted Carolus Duran and was pleased, because its praises had at various times been recorded in THE GARDEN, but I am much disappointed with it. Neither in form, colour, nor growth can it be compared with any of the shade named, and I have now no wish to grow it. It may be that in the north others succeed with it.

#### YELLOW GROUND PICOETTES,

as they are called, have within recent years been very much improved. They are a delightful class of flowers, and, what is of not less importance, their growth is easy, the constitution of all those I shall name being robust. The ground colour is yellow, but varying in intensity, and the borders and flakes of rose, red, or dark crimson are produced in the flowers, in some instances slightly, in others heavy. Golden Eagle so struck me with its refined and charmingly formed blooms, that it is named first, although Mrs. Robert Sydenham is generally regarded nearest perfection in this class. Eldorado is very fine, so is Ladas. Mr. Nigel is a variety rich in its dark markings and with excellent form. Voltaire is also handsome. Cowslip is a beautiful kind, and the same remark applies to the variety Mrs. Douglas. Besides those named, Mrs. Alfred Tate, Mrs. Dranfield, Countess of Jersey, and Xerxes must be included, also Monarch, a variety that appears to be but little known. This last is a splendid flower.

Under the heading of "fancies" one may note several kinds that are certain to please most tastes. Garville Gem is one. This has slate-coloured blossoms of pretty form. Distinction is light purple, spotted with a deeper shade. Cardinal Wolsey has flowers in which a rich red accompanies yellow; this is extremely showy. So, too, is George Cruickshank, buff and red. The Dey is a most distinct kind—a combination of buff and rose.

I will not take up space by naming the various "class" flowers—the bizzares, flakes, edged Picoettes, and so on—for the reason that varieties which were the best a dozen years ago are the leading ones now. From time to time an improved form may spring up, but one might desire something of an improved growth. Compared with the varieties I have named, they are generally neither sturdy nor easy to grow, although the blossoms when at their best are beautiful. H. S.

**Pentstemons.**—The experience of the last three years has led me to place Pentstemons quite in the front rank among summer flowers, and the variety gloxinioides is exceptionally useful alike for the fine flowers produced, the many and varied shades, and the ease and rapidity with which it flowers in the one season. The seed is sown early in February in boxes, the latter being placed on the shelf of ainery just started. Old soil from the potting-bench is a capital compost alike for these and things sown at the same time, such as Carnations, Antirrhinums, Iceland Poppies, &c., and if it should be a bit on the heavy side, leaf soil and sand may be employed to make it lighter. The plants are pricked out into other boxes or into frames as soon as they can be handled, and should be grown on as quickly as possible, that is kept a bit close and receive atten-

tion in the way of judicious watering and be gradually exposed so as to secure good sturdy stuff by the beginning of May. The variety is not quite hardy. Old plants will not come safely through any but an exceptionally mild winter, or cuttings from the same unless well protected. As noted above, capital things are always obtainable from a packet of seed, but if exceptionally good forms are found, the same may be perpetuated by cuttings. To obtain a quick succession the first spike should be nipped off as soon as it shows signs of seeding. The side spikes quickly develop, and from these a goodly show is obtained until the end of the season. It is not advisable to plant too thickly, just a little daylight between the plants being conducive to sturdier growth, and where special kinds have been retained and propagated from cuttings they can be planted still more thinly on a dwarf carpet. Tufted Pansies, especially the Violetta section, are very useful for this purpose. If cuttings are not taken until the spring and there is any doubt as to the hardness of the stock, old plants can be lifted and stored in a cold frame. They will come through safely if frost is just excluded.—E. B. C.

#### NOTES ON HARDY PLANTS.

**Incarvillea Delavayi.**—Plants grown in partial shade are showing seed-pods freely, but there is no seed on fully exposed plants.

**Sidalcea malvæflora Warley Rose.**—This is decidedly a border flower to make note of. The delicate rose-coloured large flowers are freely produced, and are attractive as seen in the garden or when cut. No sticks are needed owing to the flexibility of the tall stems. I was especially struck with the rich and pleasing effect of a group of this which chanced to be close to a group in flower of *Linaria vulgaris peloria*.

**Linaria repens alba.**—This is a rare and desirable form of a species which in the type harasses many of us by its persistent running habit, and so has become a thing to despise, and yet in many places, as on dry banks and old walls, it proves an ideal plant, for there it keeps very dwarf and flowers all summer; the running roots somehow find their way along the joints of the stones both ascending and descending. There is also a delicate soft mauve-coloured variety which has occurred here, as well as one with a creamy variegation of the foliage. The white-flowered sort is the most charming, and it has all the vigour of the type, the flowers as plentiful and pure, a succession being kept up for some time. It only needs to be seen to be admired. Even if it should prove to run a great deal, we can do with broad masses of white flowers in the latter half of summer, especially in the case of a plant which does not leave any litter to detract from the effect of white flowers.

**Stobæa radula.**—There is something most attractive, to my mind, about this, in which, though a composite, the heads are neither like those of a Daisy nor a Sunflower; even the yellow is peculiar, and in a head nearly 3 inches across it need not be said that it is striking. The perfume, too, is just as singular. I should describe it as of Stockholm tar and honey, and very pleasant. I tested the plants in the severest possible way last winter for hardiness and not a plant succumbed.

**Hemerocallis aurantiaca major.**—This, no doubt, is one of the new introductions which have come to stay; the flowers are glorious in both rich colour and size, and they last longer than those of most other kinds of Day Lily; in fact, this is a good flower for many a day in moderate weather.

**Achillea eupatorium.**—How splendidly this stately old plant shows up in the border of tall things. It revels in plenty of sunshine, and this summer has attained larger dimensions in all its parts than usual, being, for instance, quite 5 feet high and topped with its big, old gold-coloured corymbs. Perhaps the most useful feature about

this plant is the great length of time the flowers last. As with many other strong growers, the better way is to transplant a few offsets every year; these attain their best form in two or three years. The big, flat corymbs may be tried for indoor use in vases. Not everyone would imagine the rich effect.

**Hypericum nummularium.**—This is one of the brightest and most pleasing of the rock garden plants. Even in the present fierce sunny and dry weather it keeps up a telling succession of bloom. I know nothing that could be more profitably planted on the score of both colour effect and season, for about this time we find we have none too many reliable plants for keeping the rock garden gay.

**Cistus alyssoides.**—This is one of the smaller-leaved species, grey, almost silvery in the foliage and very dwarf. The more conspicuous and pleasing features are the brightness of its yellow flowers and their long succession, which lasts quite six weeks in strong plants, and another good point is that you get this to quite an effective size, because it can remain for years without the necessity of lifting it in the autumn. In Yorkshire it is perfectly hardy, it having stood with me in one position for five or six years without the least protection. Stature 9 inches, habit procumbent. J. Wood.

Woodville, Kirkstall.

### IRIS MACROSIPHON.

THIS is a native of California, where it grows in company with *I. bracteata* and *I. californica*. The foliage is narrow, grass-like, about a foot long, tough, and hard to the touch. The flowers, which appear in May, are of an uncommon form, falls and standards being very long, undulated at the margin, and when opening of a bright ochraceous yellow, with a delicate network of brownish crimson. When fading they turn to creamy white and the dark network to rose. It is a very beautiful sight to see on a big plant these flowers in all the different shades. As will be seen from the photo, it is very free flowering, and, all in all, a handsome and striking plant. On one group I counted as many as seventy-three flowers open at one time, and many more to come. It is perfectly hardy, and prefers a loamy soil and a sunny and dry situation. *I. bracteata* has somewhat larger flowers of the same colour, but the network is more delicate. *I. californica*, which is new to cultivation, occurs with white, mauve, blue, violet, and lilac colours in all shades, and is also a pretty free-flowering species. MAX LEICHTLIN.

Baden-Baden.

**Hemerocallis aurantiaca** (type).—In answer to Mr. Jenkins, this was described by me in vol. viii. of the new series of the *Gardeners' Chronicle*, p. 94, from specimens now in the Kew herbarium, from a plant in full flower in Kew Gardens, July 14, 1890.—J. G. BAKER.

**Montbretias.**—The border in which my Montbretias had remained for several years having become overrun by an objectionable weed introduced by chance with a surface planting of alpine Phlox, I was obliged to make a clearance last autumn in order to get rid of the same. After carefully picking it out, some rough manure was put on and dug in deeply; holes were then made 9 inches apart and 6 inches in depth, and the best corms of the Montbretia selected and replanted, making the bottom of the hole moderately firm, so that the corm rested on a sound basis. About 2 inches of rough leaf soil were put on after the holes were filled in, and the border completed by dibbling in thickly a lot of rooted cuttings of the Phlox, that forms an admirable carpet to the Montbretia. The Montbretia has benefited greatly from the lifting and replanting, and as

there was no check this spring to growth, flower-spikes were early and are very fine. The fact that the several side-sprays springing from the centre spike are much later in opening has a tendency to greatly prolong the season, and the display on such a border is of several weeks' duration. There are few more charming combinations for large vases than well-grown spikes of Montbretia rising out of a groundwork of Gypsophila, and I can recommend these to the notice of all gardeners who have to supply an abundance of cut flowers.—C. P. S.

### CARNATIONS AT MONTAGUE NURSERY, TOTTENHAM.

It is not yet a decade since Mr. F. Gifford made a beginning in the above nursery for the express purpose of growing the border Carnations, and by raising some thousands of seedlings each year to endeavour also to raise the standard of excellence in these all-increasing popular summer flowers. He has been very successful, particularly in the high standard that now prevails in nearly all sections of the flower. For proof of this we have but to examine the thousands of seedlings that are

sure to appear from time to time. All this rigid selection of the best and most worthy from all points cannot fail to be esteemed by those amateurs who make a leading feature of these plants, particularly for the open garden, where only the hardiest and most vigorous types are sure of making a display worthy the plants themselves.

In these respects Mr. Gifford's collection is noteworthy, from the fact that the whole of the plants are grown in the open ground, and in a soil, by the way, that does not impress one at the first view. But soil that is light and somewhat stony is eminently fitted for the Carnation in winter, and if to this be added the gentle slope of the nursery itself, we imagine that not a few would like such a garden for the purpose. And whatever first impressions to the contrary one may get, all such must be quickly dispelled, not only by the general vigour of the thousands of plants in the collection here, but also of the seedlings. One point in particular to which Mr. Gifford attaches importance is height, so that the flowers may suffer the less from pelting rains. A thunderstorm the day previous to our visit had ruined all the flowers within 12 inches of the earth, while the taller sorts were free. Quite a large number

of the kinds grown here are seedlings of Mr. Gifford's raising—a fact that speaks well for the excellence of his strain. Of the latter, the beds of seedlings also testify largely, there being about a dozen beds some 60 feet long filled with the plants. The whole of the named collection, for convenience of layering and otherwise, is in narrow beds or lines, and in this way all the kinds are readily inspected. Some of the more prominent of recent novelties are W. J. Fish, a most brilliant scarlet, a great advance on King of Scarlets and non-bursting. Lord Leighton is also fine, possessing the same blush tint as Waterwitch, but said to be an improvement upon it in the open. It is certainly a very fine flower. Lady Cook—a clear soft yellow, with faint, bright scarlet edge—is charming, and with its sweet perfume and symmetrical blossoms most telling. Hodgson Pratt, a crimson-scarlet, with bars of a deeper shade, is a handsome and full flower and of fine habit; while Frederic Harrison, near by, strikes one by its deep golden and almost globular flowers, that are slightly

*Iris macrosiphon.* From a photograph sent by Herr Max Leichtlin, Baden-Baden.

flowering at the present moment, and though constantly halting to remark this or that fine form or colour, to find less than 5 per cent. marked as worth retaining. This does not, however, prove the inferiority of the strain, but just the reverse, and the more so in a collection so rich and varied as here obtains. A dozen years ago, perhaps 90 per cent. of the double Carnations, which, by the way, are mainly of self colour, now in flower here would have been selected as improvements on existing kinds to be sent forth with glowing descriptions, but now next to useless when they appear in competition with the best things in any good collection. And what must undoubtedly appeal to many as so much waste time in the raising and proving of all these seedlings year by year is but the florist's own exacting ideas of what this or that flower must be. For, be it remembered, the florist himself fixes the standard to be achieved; next, he achieves it invariably to his complete satisfaction, and then, espousing further possible grounds for improvement, again commences on the self-imposed task and accomplishes this also. And so on by degrees and with years, till now, in many classes at least, further improvement appears well-nigh impossible. To the florist, however, the latter word is unknown, as unexpected breaks and new shades of colour are

edged carmine. This is one of the fancy sorts that are becoming popular. Another splendid thing is Andrew Noble, rosy salmon in colour and among the most handsome; the petal is very fine and the flower full. Wanda, Clive Brook, Donnybrook, Gordon Stables and Joe Willett are all scarlets of very high order that cannot fail to satisfy the most exacting, while J. R. Lowell, Laureate and John Davidson represent those of salmon shades, the last with powerful clove fragrance also. Bret Harte is a handsome crimson of intense hue, as vigorous in growth as it is free and fragrant of blossom.

White-flowered kinds are especially good, and among these Wilfred Laurier is conspicuous in the novelties; this is of the purest, and possesses finely-formed petals and full flowers as well as a vigorous constitution. Especially good is Edith Leadenham, of rather taller growth, but its erect, free-branching character is seen above all else in the pure white mass of its flowers. Even here in the open sharing with the veriest weeds the great parching heat and heavy, pelting storms of rain and hail this splendid-habited plant was but little worse. Other whites are Mrs. Gifford, with large flaky blossoms of immense size and beautifully fragrant and free. Mrs. Eric Hambro and Miss Ellen Terry are both first-rate. Sigard is best

described as Mrs. R. Hole improved, and W. M. Thomson, apricot-bud, heavily marked with red-dish scarlet, is a very attractive flower. Pelham is a mixture of dark and bright crimson, and Sarasate is scarlet with crimson stripes with fine habit. Mrs. C. W. Townley is also a striking flower and freely produced; it is margined and flaked with crimson on white ground. Apart from these, the most of which have been raised by Mr. Gifford, are to be found the choicest of those raised by Mr. Martin Smith and other well-known specialists of the flower. The whole collection is grown without the least protection, and the abundance of fine vigorous grass that is being put down gives the most satisfying evidences for success next year.

**Iceland Poppies.** To appreciate the beauties of these they want to be seen in large patches. Such patches present to view hundreds of blossoms, white, yellow, and orange-scarlet. A more beautiful or useful group of perennial Poppies can scarcely be imagined, and if the seeds be sown in March and the seedlings carefully looked after they will bloom the same season. The blossoms, extremely bright and showy, are borne on slender stems about a foot in height, and if cut in a young state they are very useful for table decoration and are much employed for the purpose. The orange-scarlet form known as *Miniatur* is inclined to be sportive, but a considerable percentage of the seedlings will come true to character.—R. D.

**Annual Xeranthemums.**—The double purple and the double white varieties make charming subjects to cut from. In a good and airy light soil they grow to a height of about 2 feet and bloom with remarkable freedom. There is a rose-tinted variety also which it is thought originated from the purple, but it does not always come true. In addition to their value in the garden, the Xeranthemums are useful Everastings, and, as in the case of the Helichrysum, the flower-stems should be cut when the flowers are about half expanded, the stems tied together at the ends, and then hung up in a dry, cool place, where they become rigid and the flowers fully expand. The flowers come in very useful for home decoration at Christmas. The seeds can be sown and the plants allowed to stand where they are to bloom.—R. D.

## ORCHARD AND FRUIT GARDEN.

### FRUIT-TREE BUDDING.

WILL you tell me when and how to do fruit-tree budding, as unfortunately I have been unsuccessful in my previous attempts, chiefly, I fancy, from my ignorance when the buds to be inserted are in their best condition?—A NOVICE.

\*\*\* July and August are the months in which fruit-tree budding is most successfully carried out. The operation is no more difficult than that of budding dwarf Roses, and is performed in much the same manner. Buds may then be inserted in firm young shoots, as in the case of budding standard Roses, in the stems of young suckers layered, or on seedling stocks in the same way as *Manetti* Rose stocks are budded. Although nurserymen persevere with this delicate work in hot weather such as I have lately experienced with satisfactory results, amateurs are advised to select, as far as possible, a dull, showery weather for budding. It is of importance (1) that the stocks run freely, the bark not clinging to the wood when opened; (2) that the bark to which buds are attached parts readily from the wood, and (3) that the buds selected are suitable for the purpose. Where only a few dozen or scores of stocks are budded, the sap can be sent up into the wood by freely

watering the ground about them, budding taking place a day or two later. The buds can be detached from the wood with a minimum amount of trouble when the trees from which the shoots are cut are kept moist at the roots, while the most suitable buds are obtained from about the middle portion of strong (not gross) well-matured shoots, those near the base being too ripe, and those nearer the points of the shoots immature. If the buds are obtained from a distance, the shoots to which they are attached should be lightly topped, have the leaves shortened to near the footstalks, and be packed in damp Moss. Those cut from home-grown trees ought also to have their leaves reduced to one quarter their original proportions, and be kept in a can of water till they are done with, buds dragged from shrivelled wood seldom if ever "taking." Before describing the operation of budding something more must be said about the stocks. A judicious selection and careful preparation of these contribute largely to ultimate success. If large trees of Apples are desired, the stock selected is the natural or Crab stock, but more precocious, if smaller, trees can be had by budding on the surface-rooting *Doncin*, English and Broad-leaved Paradise stocks. The wild Pear is the best stock for choice Pears if large trees are wanted, while smaller, quick-bearing trees result from budding on the Quince stock. Apricots are principally budded on the Mussel Plum stock, the *St. Julien* Plum being recommended as a stock for Peaches and Nectarines in preference to the Almond stock. For choice Plums, the *St. Julien*, *Mussel*, and *Myrobalan* Plum stocks are recommended, though both these, Apricots, Peaches and Nectarines are frequently budded on ordinary Plum sucker growths duly prepared for the purpose, and to the use of which much of the trouble with suckering growths may be attributed. Cherries are budded on both the wild Cherry and the common dwarf species, the former imparting the most vigour to the scion.

Stocks transplanted last autumn or spring ought to be fit for budding this season. A single bud should be inserted in each stem if comparatively young, but the lateral growths or larger older stocks may also be budded; also young growths on large trained or other trees the characters of which it is desirable should be changed, or for the purpose of testing either seedlings or novelties quickly. There ought not to be a great difference between the age of the wood to be budded and that from which the buds are taken. The buds are in their best condition when about half ripe and plumped up. It is just possible "A Novice" failed to distinguish between wood buds and fruit buds. Only the former are suitable. They differ from fruit buds in that they are longer and more pointed, fruit buds being, as a rule, round and somewhat flattened. In the case of stone fruits (Apricots, Plums, Peaches, Nectarines and Cherries), medium-sized shoots frequently produce triple buds, the central one of these being a wood bud, and these buds may be used accordingly. Some few Apples, *Bismarck* in particular, frequently form twin buds, one wood and the other a flower bud, and thousands of newly-budded stocks have actually produced a fruit and a strong wood growth during the summer following budding. Neither single-stemmed stocks to be budded near the ground nor lateral growths to be budded similar to *Briers* should be headed down, but they may be cleared of spray and lightly topped. Nothing should be done to force the buds into growth this season. If they did start, the growth would be feeble; whereas if they

become well attached to the wood this summer, heading down the stocks or shortening lateral growths in the autumn or winter to near the bud, long and strong shoots will be pushed out next summer.

The operation of budding is delicate, yet simple. The wood with buds attached should be in a can or bucket of water close at hand. A sharp budding knife and raffia for tying, together with good stocks, are all the accessories needed. First prepare the bud. With the knife cut off a thin slice of bark and wood  $1\frac{1}{2}$  inches long, commencing at the lower side and having the bud in the centre. With the handle of the knife remove the wood, commencing this time from the upper end. If this is successfully done there will be no hollow eye in the bud, but if the eye is open, owing to the pith coming away with the wood, a vacuum would be formed and the inserted bud would perish. When ready keep the shield with bud on the tongue till wanted for insertion. In a clear portion of stem or lateral growth, as the case may be, make the usual cuts in the form of a T and raise the bark carefully, commencing at the angles on both sides. The shield with the bud facing upward in upright stocks, but outward in lateral growths, should be inserted under the bark, the footstalk of bud coming in handy for pushing it down, and when in position only the thin bruised end of shield should protrude. Cut this off so that the top of the shield of bark fits tightly (butts against) the top of the cross cut or top bar of the T cut and see that it does not shift when bound up, as it is there where the union most quickly takes place. Bind up with either raffia or worsted, taking care not to unduly press against the bud. If the leaf footstalk connected with the bud remains fresh and green a week or more, the bud is all right, but if it shrivels during the next day or two the chances are the bud has not taken, and if the season is not too far advanced, a second bud on the opposite side of the stem may be inserted. Nurserymen usually commence budding Cherries first, following with Apricots, then Plums, Apples and Pears, with Peaches and Nectarines last. "A Novice" ought to commence operations at once.—W. I.

### A BATCH OF NEW STRAWBERRIES.

WE have had several of late and still they come, and so long as the new are different, or better in season, size, colour or quality than the old, the more the better. The cry is also raised that some of the old sorts are getting worn out, and that new varieties are needed to take the place of such as *Keens' Seedling*, *Elton*, *British Queen* and *Sir Joseph Paxton*. Be that as it may, Messrs. Laxton, of Bedford, are doing their best to supply all our wants. Take four of their recent novelties—*Early Laxton*, *Monarch*, *Royal Sovereign* and *Latest of All*. Of these four, *Royal Sovereign* promises to become as popular as *Keens' Seedling*, and here in Edinburgh we have Mr. Carmichael offering four new Strawberries. These are the *Prince* and *Princess of Wales*, *Queen of Denmark* and *Richard Gilbert*. These almost cover the Strawberry season from first to last. *Veitch's Perfection* is also rapidly establishing itself in public favour, while Mr. Allan's earlier seedlings, *Gunton Park* and *Lord Sutfield*, are taking higher rank in private gardens and being grown for market. Mr. Allan does not believe in finality in the improvement of Strawberries, hence he exhibited another novelty (*Lady Sutfield*) at the great show at Norwich the other week, where it obtained a first-class certificate. This is a cross between *Lord Sutfield* and *Empress of India*. In flesh, flavour, colour and aroma *Lady Sutfield* is the most unique Strawberry I have yet eaten. The flesh is also firm and of a dark crimson colour throughout.

Several new Strawberries have also recently been before the Scottish Horticultural Association at their recent meetings. Thomas Carlyle, a cross between Garibaldi and Dr. Hogg, has the fine habit and enormous fertility of the former, with a dash of the superior flavour of Dr. Hogg. It is also as early as V. H. de Thury, and seems to continue longer in bearing. W. E. Gladstone was shown by James Grieve and Sons, of the Redbraes Nurseries, Edinburgh, who hold the stock of this large fine-looking Strawberry. In certain parts Elton is still grown as one of the most profitable and popular late Strawberries. In others, Frogmore Late Pine is run abreast of Waterloo, Lord Suffield, and Latest of All. With all our additions, however, some of the older sorts hold the field, V. H. de Thury being still the most popular Strawberry north of the Tweed, and Paxton south. Royal Sovereign is making rapid progress alike in Scotland and England. It will be several years before it assumes the place or area devoted to these two popular favourites. Fruit growers and consumers are, in fact, so intensely critical as well as conservative, that there is no danger of being overrun too rapidly with novelties, however meritorious. The difficulty and danger are all the other way, as those find to their cost who try to place a distinct Strawberry like Waterloo on our markets.

D. T. F.

### RASPBERRIES.

THE Raspberry is one of the few fruits that travel badly, and each district has, therefore, to grow enough for local use. Fortunately, the Raspberry is by no means fastidious as to soil if only there is depth enough to afford a sufficiency of food and moisture during the time the fruit is swelling and ripening. Even when the soil is shallow, resting on a hot or gravelly subsoil, the plants can frequently be kept in a healthy, productive state by means of heavy mulchings of strawy manure, these keeping the ground cool and moist. Raspberries are also liable to fail early on heavy, badly-drained soil. On a moderately deep, fertile, loamy soil the plantations can be kept much longer in a profitable condition, but, as a rule, fresh plantations should be made every few years, these taking the place of those showing signs of failure. It is worthy of note that when Raspberries are planted among standard fruit trees, all growing up together, they succeed well for a considerable number of years, the partial shade afforded by the fruit trees benefiting the Raspberries rather than otherwise. It is not to be expected, however, that planting among fruit trees after the latter have grown to a large size will turn out so satisfactorily. On the contrary, comparatively puny canes result from this planting on ground already exhausted of much that makes it fertile, and the shade is also too dense. There should, however, be no digging in of manure among the lines of canes, as this means the wholesale destruction of many fibrous roots with which the surface soil ought to be crowded. Hoe and rake off weeds, if need be, and then mulch heavily with either strawy manure, peat Moss litter (using this less freely), spent hops, spent tanner's bark, or decaying leaves. Anything of a very forcing nature ought not to be used other than sparingly. For instance, it would be a mistake to mulch with kiln-dust or charred Barley sprouts obtained from maltings. A free application, or enough to act as a mulch, once, to my knowledge, had the effect of forcing young Raspberry canes to a height of 9 feet, and their owner was very proud of them. It proved the ruin of the plantation, the plants not being equal to the strain of producing a crop in the following year or of forming good serviceable canes. Neither nitrate of soda nor sulphate of ammonia ought to be used heavily by way of manure, as these

also are liable to force the young canes into undue luxuriance. One part of either of these nitrogenous manures ought to be sufficient for mixing with two parts each of kainit or other potash salts and superphosphate of lime, applying the mixture in February, March, or early in April at the rate of 3 oz. to the square yard. Liquid manure may be applied with advantage to poor, well-drained soils during the winter and early spring months, and where solid and other manures are but sparingly used, liberal

market-grower's fashion (that is to say, without supports of any kind), should be shortened and laid in at least of three different lengths, the smallest of those reserved at the preliminary thinning being the hardest cut. Shorten the latter to a length of 18 inches, leaving others to from 30 inches to 3 feet in length, and in the case of the taller growers the strongest cane may be left to a length of 5 feet or rather less. In this way perfect columns, fences, or hedge

of fruiting growths are had, and a greater weight of fruit obtained than by shortening and training in the common fashion. It is true some what hard pruning is apt to favour sucker growth from the roots, varieties of medium height being particularly liable to produce far more sucker growths than desirable. This may to a certain extent be checked by either hoeing or hand-pulling those left in the rows near to the old canes, requiring to be timely and freely thinned out. The must be no hesitation about pruning newly planted canes. Unpruned or only lightly shortened canes may and do produce fruit, but it is usually of an inferior character, comparatively worthless, added to which the plant will be exhausted in the attempt, and form young canes worthy of the name. Cut them down to within 6 inches of the ground, and if they were properly planted all will push up strong young canes equal to bearing fruit next year. In this way the foundation of profitable rows of plantations of Raspberries will have been laid. New planted canes should be mulched, as owing not having had time to send their "anchor" roots down deeply into the soil drought will quickly afflict them. They ought further to be assisted by watering during dry, hot weather.

### VARIETIES.

Reference has been made to the market-grower's plan of growing Raspberries without stakes, but it must be remembered that the

*Carter's Prolific Raspberry.*

applications are of great assistance when the crops are swelling.

There has hitherto been too much rule-of-thumb business in the matter of

### PRUNING AND TRAINING

Raspberries. We are too fond of shortening all the reserved canes to one height, and, as a consequence, there are usually thickets of fruiting shoots at the tops of the stakes or fences and few lower down. The canes, whether trained to single stakes, fences, or espaliers formed with either wires or stakes, or grown

Beehive or Fastolf and any other tall-growing variety is unsuitable for this method of culture. If these were grown without support they would have to be arranged in rows not less than 5 feet apart, and even at this distance they would sprawl badly. As it happens, the growers can be wholly dispensed with, as there are at least four good varieties that are suitable for the purpose. One of the best of these is

CARTER'S PROLIFIC, a good illustration of which accompanies these notes. This deservedly popular variety attains a height of about 4 feet, and may be shortened to 3 feet, and the sturdy canes

en remain nearly or quite erect. It is a heavy cropper, and the fruits are large, firm in flesh, deep red in colour, and of excellent flavour. In BARMFORTH'S SEEDLING we have a good companion for Carter's Prolific, this also forming a sturdy, somewhat branching canes, which are rarely injured by frosts. When the ripened canes are shortened somewhat severely this induces an extra early strong growth of young canes, many of which produce fruit freely in the autumn. The fruits are large, firm in texture, dark red in colour, and richly flavoured. This and the foregoing variety are good travellers, and among the best to send to a distance for dessert. HORNET belongs to the same category.

SUPERLATIVE is intermediate between the medium and tall growers, and is suitable for either training to stakes and espaliers or for the market-grower's method of growing, the sturdy canes when shortened moderately hard standing well without supports. It is a heavy cropper, and has large, rich red, finely-flavoured fruit.

FASTOLF, an old favourite, is not generally reliable, and, in my opinion, is inferior to Northumbrian Fillbasket. K.

#### PLANTING OF GLASSHOUSES IN MARKET GARDENS.

In the case of *Smith v. Richmond*, surveyor of taxes, before Mr. Justice Collins and Mr. Justice Kelly, sitting in the Queen's Bench Division, was of considerable importance to market gardeners. His case was stated by the quarter sessions for West Sussex on an appeal by the overseers of the parish of Worthing from a decision of the assessment committee of the union of East Preston under the Agricultural Rates Act, 1896 (59 and 60 Vict., c. 16). The case raised a question as to the rating of glasshouses over market gardens. By section 1 of the Agricultural Rates Act, 1896, "the occupier of agricultural land in England is made liable, in the case of every rate to which the Act applies, to pay one-half only of the rate in the land payable in respect of buildings or other hereditaments." The facts were as follows: Robert Piper was a grower of fruit, vegetables and flowers at Worthing, and described himself as was commonly known as a market gardener and nurseryman. He was the owner and occupier of land rather more than four acres in extent, on which fifty-seven glasshouses or greenhouses of various sizes were erected. The houses were used by the appellant for the purpose of growing tomatoes, Cucumbers and Grapes, and to a smaller extent other vegetables, for the purposes of sale. The plants and crops grown therein were watered and heated by artificial means, and grown on soil placed upon prepared beds inside the houses, and matured much earlier than in the open ground. The Vines are planted inside the houses, and the roots run partly in the soil under the houses and partly pass through apertures in the walls into the soil outside. Fifty-one of the glasshouses are thus used for growing Vines. Of the Cucumber houses (which are six out of the fifty-seven houses) there are inside the houses dwarf brick walls supporting corrugated iron sheets, upon which sheets earth taken from the other parts of the nursery ground is placed. In this earth so placed upon the iron sheets the Cucumber plants are planted. Beneath the iron sheets and between them and the ground there are hot-water pipes. The area actually occupied by the fifty-seven houses is rather more than two acres. The rest (rather more than two acres) consists merely of Vine borders, paths and the like-holes. The whole of the houses are built upon dwarf brick walls like an ordinary greenhouse. It is provided by section 9 of the Act that "the expression 'agricultural land' means any land used as arable, meadow or pasture ground only, cottage gardens exceeding one quarter of an acre, market gardens, nursery grounds, orchards or allotments, but does not include land occupied, together with a house as a park, gardens other than as aforesaid, pleasure

grounds, or any land kept or preserved mainly or exclusively for purposes of sport or recreation, or land used as a racecourse." For the purposes of the Act section 6 (1) requires certain returns to be made to the Local Government Board. In pursuance of subsection (3) the Local Government Board by the Agricultural Rates Order, 1896, have made regulations. By Article IV. the overseers are to serve to the assessment committee and the surveyor of taxes a return showing, as regards each hereditament separately valued in the Valuation List, which is partly buildings and partly agricultural land, the gross estimated rental and rateable value of the parts not being agricultural land. In this case the overseers returned Mr. Piper's property as agricultural land. The assessment committee, however, on the objection of the surveyor of taxes, decided that the statement, to the extent to which it includes land partly covered with glasshouses, was incorrect, and corrected it by striking out that entry.

Upon the hearing of the appeal before the quarter sessions it was contended for the appellants the overseers that the particulars of the gross estimated rental and the rateable value of the hereditaments in question were correctly entered by them in their statement under the heading of "agricultural land," and that the decision of the assessment committee to correct the statement by striking out the entry was wrong, and in support of their contention they cited the case of "*Purser v. Local Board for Worthing*" (18 Q.B.D., 818). For the respondent it was contended that the case relied on by the appellants did not decide that the glasshouses were not buildings, but merely that the land was not the less used as a market garden because the glasshouse had been placed upon it, and that, moreover, the definition of agricultural land in the Agricultural Rates Act, 1896, was to be read subject to the context, and that the context in the Act required that any buildings should be excluded from the term agricultural land, that the glasshouses were buildings within the meaning of the Act, and that it followed that either the whole of the hereditaments in question should be excluded from the overseers' statement, or, alternately, that so much thereof as consisted of buildings should be inserted under the heading of "buildings not being agricultural land." The quarter sessions were of opinion that the contention of the appellants was right, and allowed the appeal, and ordered the statement of the overseers to be altered by restoring all the items which formed the subject of the appeal to the condition in which they were before they were altered by the assessment committee, subject to the statement of a case for the opinion of the Court. The following section of the Act in question, 59 and 60 Vict., c. 16, is material: 5. (c) Where any hereditaments consist partly of agricultural land and partly of buildings, the gross estimated rental of the buildings when valued separately, in pursuance of this Act, from the agricultural land shall, while the buildings are used only for the cultivation of the said land, be calculated, not on structural cost, but on the rent at which they would be expected to let to a tenant from year to year if they could be so used. The Attorney-General (Sir Richard Webster, Q.C.), Mr. Day, and Mr. Trevor appeared for the surveyor of taxes; Mr. Joseph Walton, Q.C., and Mr. Clavell Salter for the overseers; and Mr. A. Glen for the occupier. The Attorney-General said this was a test case of importance. The distinction drawn in the Act was between land and buildings and not between buildings and agricultural buildings. The buildings here should be liable to the full rate. The case relied on by the overseers was on another Act. Greenhouses in a cottage garden were fully rateable. The question was not one of assessment; it was whether the buildings had to pay half rates or whole rates. There were no buildings of any kind in the Act which had only to pay half rates. He referred to "*Purser v. Local Board of Worthing*" (18 Q.B.D., 818), "London and North-Western Railway v. Llandudno Improvement Commissioners" (1897, 1 Q.B., 287). The strip where the Vines grow

might, perhaps, be treated as agricultural land. Mr. Joseph Walton said section 1 of the Act was the guiding section. In that agricultural land was defined as meaning, *inter alia*, market gardens. The land here was market garden. It was therefore only liable to half rates. He would admit for the purpose of this case that a building which was not part of the garden even though in the garden was not to have the benefit of the exemption. But anything that was garden was entitled to exemption. Section 5 (c) had really very little to do with the matter; it only related to the mode in which buildings—not agricultural land—were to be rated. Mr. A. Glen's appearance on behalf of the occupier was under the Agricultural Rates Order, Article IX., rule 3. The Attorney-General took the objection that that rule, which permitted the occupier to appear at quarter sessions, did not authorise him to argue here, especially after the argument for the overseers. Mr. Glen cited "*Re Justices of Montgomeryshire*" (44 L.T., 310; 50 L.J., Mc. 52), and said that this was the appeal. It would be ridiculous if the party interested could not appear here. His client certainly was the party interested. The Court, after some consideration, thought he was entitled to argue for his client. Mr. Glen continued the arguments for a short time. He said it was begging the question to rely on section 5 (c).

The Court in the result disagreed, but Mr. Justice Ridley, according to the usual practice, withdrew his judgment, with the result that Mr. Justice Collins's judgment in favour of the market gardener prevailed. Mr. Justice Collins said: This case raises a question whether glasshouses used in a market garden and constituting in themselves market gardens are entitled to secure the benefit attached to agricultural land in the Act of 1896. The quarter session, overruling the decision of the assessment committee, held that glasshouses were not buildings within the Act, and against that decision the appeal came to this court. His Lordship then read the first section of the Act, providing for the occupier of agricultural land paying one-half only of the rate payable in respect of buildings and other hereditaments, and section 9 defining agricultural land as including market gardens, and continued: It follows from this definition that if the structures in this case are market gardens they are entitled to exemption. Is this, then, a market garden? His Lordship read the facts as set out in the case, and continued: From the above it appears that one-half of the property was covered with glass buildings. Was that hereditament a market garden? A great deal of light is thrown on the matter by the case of "*Purser v. Local Board for Worthing*" (18 Q.B.D., 818). On the authority of that case it is clear that this property is not hindered from being a market garden by reason of its being covered with glass. Up to that point, then, this is a market garden. The Attorney-General, however, pressed some arguments based on the provisions of sections 5 (c) and 6 (2), which sections, he said, had the effect of excluding any buildings from the benefits attaching to agricultural land. The cardinal point in the Act being the distinction between buildings and land, I do not, however, consider that well founded. So far as buildings are concerned, the object of section 5 is to give them a qualified exemption. It then goes on to buildings "used only for the cultivation of the said land," and gives them a qualified exemption, which explains why the distinction is drawn between agricultural land and buildings. In the section market gardens and buildings are mutually exclusive, as it deals with buildings excluded out of agricultural land. Therefore, when once I arrive at the conclusion that the premises in question are market garden I am not pressed by the provisions as to buildings, because they are excluded out of agricultural land. The other case cited strengthens the views that the platform and roof over a railway line were held to be part of the railway, and the distinction was drawn between the line and buildings ancillary thereto. When, as here, the

structures are part and parcel of the market garden the exemption applies, and you have to get them out of the category of market gardens before the provisions as to buildings apply. Any other view would defeat the object of the Act. The Legislature had swept "market gardens" into the category of agricultural land. It must have been known to the Legislature that they were oftentimes covered with glass. I think, therefore, that the buildings in question are to be regarded as part of the market garden, and are only liable to half the rates. Mr. Justice Ridley said he differed with diffidence, but felt bound to state the opinion he had arrived at. The whole scope of the Act was to relieve agricultural land. See the preamble, sections 1, 5, 6, and the definition clause 9. Occupiers of agricultural land were to pay only half the rates charged on buildings and other hereditaments. The object evinced by those and other sections was to contrast the land with the buildings. In the Act no buildings were entitled to the same relief as the agricultural land. As to them the law remained as before, except in respect to the buildings in section 5 (c). It was not likely that it entered into the mind of the draftsman that buildings would stand on the very land which was being cultivated. Such buildings were none the less buildings because they did so. Those market gardeners who were wealthy enough to erect glass-houses all over the land were not the class of persons for whose relief the Act could have been intended. — *Times*.

## SOCIETIES AND EXHIBITIONS.

### THE MIDLAND CARNATION AND PICOTEE SOCIETY.

AUGUST 5 AND 6.

THE annual exhibition of this society took place in the Botanic Gardens, Edgbaston, Birmingham, on the 5th and 6th inst., and proved a great surprise, for the extent and quality of the blooms staged were much beyond what could have been expected, as it was feared that the hot weather of the previous few days would have seriously affected them. The midland show was in remarkable contrast to that held in London a short time ago. In the light and airy exhibition house of the Botanic Gardens the blooms could be arranged to considerable advantage; the light was excellent and the convenience for seeing much better. The weather was favourable, and a supplementary exhibition was provided in the various plant houses by the curator, Mr. W. B. Litham, the flowering houses being especially gay with subjects of a very high order of merit. The yellow Carnations Germania and the dark maroon Uriah Pike, both grown in pots, were really superb. Fuchsias formed an excellent background to the Carnations on the exhibition stages, and in one part a magnificent specimen of *Bougainvillea glabra* trained to the roof overshadowed a considerable number of the cut flowers.

There is no large class at Birmingham for Carnations as in London; a twelve stand is the largest, and in the class for this number of Carnations blooms Mr. J. Edwards, Blackley, Manchester, was first, having J. S. Hedderly, James Douglas, Mrs. Rowan, Robert Houlgrave, Sportsman, Sarah Payne (this fine old variety being shown in good character), Master Fred, Ellis Crossley, Lord Salisbury, Edward Rowan, Mrs. Gunn, and Joseph Lakin. Mr. T. Lord, florist, Todmorden, was awarded the second prize, and Mr. Robert Sydenham the third, both with very good blooms. Out of seventeen entries for six Carnations fourteen were staged. Mr. C. F. Thurstan, Wolverhampton, taking the first prize with charming blooms of Edward Adams, William Skirving, George Melville, Flamingo, Robert Houlgrave, and Crista-galli. Mr. A. R. Brown, Handsworth, was second, and Mr. J. W. Bentley, Stakehill, Birmingham, third. The white ground Picotees were, as they always are, very attractive from their softness and delicacy, and always

command considerable attention. They offer sharp contrasts in the breadth as well as in the bands of colour round the petal edges. The best twelve blooms came from Mr. R. Sydenham, these consisting of Ganymede, Mrs. Payne, Clio, Jessie, Pride of Leyton, Muriel, Esther, Favourite, Thomas William, Little Phil, Somerhill, and Scarlet Queen. Mr. T. Lord, Todmorden, was second, having most of the foregoing varieties. The best six, a superb half dozen, came from Mr. A. W. Jones, Handsworth, who grows in a district surrounded by chemical and other works, where the atmosphere is decidedly impure. He had Little Phil, Muriel, Mrs. Openshaw, Madeline, Somerhill, and Heart's Delight. Mr. T. W. Goodfellow, Walsall, was second. The growing popularity of the yellow grounds and fancy varieties was seen in the number of stands of twelve blooms staged and in their size and beauty. Mr. A. W. Jones, who makes a speciality of these and the white ground Picotees, was first with superb blooms of Voltaire, The Gift, The Dey, Cardinal Wolsey, George Cruickshank, Xerxes, Harlequin, Eldorado, Golden Eagle, Ladas, Mrs. R. Sydenham, and Mrs. Nigel, a very good representative collection. Mr. R. Sydenham was second with flowers only just inferior, among them Yellow Hammer, Monarch, Virgo, London, and May Queen. Mr. A. R. Brown was third. There were fifteen exhibitors of six blooms, Mr. C. Thurstan taking the first prize with fine blooms of Eldorado, Yellow Hammer, Golden Eagle, Voltaire, Mrs. Douglas, and Cardinal Wolsey.

In the class for six blooms of yellow ground Picotees, Mr. A. W. Jones was again first with Voltaire, The Gift, May Queen, Golden Eagle, Xerxes and Mrs. R. Sydenham. Messrs. Thomson and Co. were second, they having, different from the foregoing, Eldorado, Ladas, and Mrs. Douglas. The selfs were also very fine, and in the class for twelve varieties twelve dozen blooms were staged. Mr. A. R. Brown was first; he had Britannia, Little John, Mrs. Eric Hambro, Bendigo, one of the best purple selfs; Braw Lass, Her Grace, blush, a beautiful variety; Hayes' Scarlet, Germania, Royal Purple, Lady M. Currie, Nabob and Topsy. Mr. R. Sydenham took the second prize and Messrs. Thomson and Co. the third. There were fourteen collections of six selfs. Mr. A. W. Jones was first with Fiery Cross, Britannia, Mrs. E. Hambro, Seagull, Miss A. Campbell and Germania. Four classes were set apart for single blooms of Carnations and Picotees of the different sections in twelves and sixes, occupying certain allotted spaces, a large table being filled with them, only a limited amount of dressing being permitted. The blooms staged were mostly seedlings and very few were named. The spaces allowed were not large enough; consequently the flowers were crowded and the best among them did not show themselves off to the best advantage, while a good many of a somewhat poor character were staged. There were also several classes for border Carnations shown in trusses of three or five. Exhibits were numerous, but few really good. There was indeed so much of an inferior character, that some modification of these classes appears necessary to prevent this. There were also classes for single blooms in the various sections of Carnations and Picotees, and a great many were staged. Such classes have an interest for experts more than for the general public. Carnations in pots were also shown in two classes.

Shower bouquets formed of Carnations and suitable foliage—of which there were several exhibits—formed a very pleasing feature. That shown by Mr. C. Blick (gardener to Mr. Martin R. Smith, Hayes) was made up of pale rose and yellow ground Carnations in a highly artistic manner, suitable foliage being employed. Mr. W. F. Gunn, of Nottingham, came second with one made up entirely of white Carnations and foliage. Soft-tinted Carnations were mainly employed in all cases. Sprays and button-holes made of Carnations are pretty certain to be of a somewhat formal character.

Floral arrangements on tables 6 feet by 3 brought seven competitors, Carnation blooms only being allowed, but any kind of suitable foliage could be employed. The first prize was to Miss E. Mayell, Acocks Green, pink and light colours predominating. As is usual, there were centre and two side pieces, with a few appropriate small vases in suitable places. Miss Sydenham, of Birmingham, was second, and Miss A. Kemp, Edgbaston, third. All were very pretty, in one or two cases dark flowers were used with excellent effect. Epergnes of Sweet Peas were numerous and good, some very pretty arrangements being staged, soft tints generally prevailing, though here and there a few dark varieties were judiciously intermingled. Miss A. G. Kemp was first and Miss Lovatt second. Evidently, epergne means any centre-piece, as interpreted at Birmingham.

Prizes were offered in two classes for Sweet Peas in bunches: in that for nine distinct varieties there were sixteen entries, and in that for two bunches, competing for special prizes offered by Mr. H. Eckford, there were five entries. Most of the bunches were arranged in glass vases with suitable foliage, and they formed a very pleasing feature. Some of the most striking varieties were Emily Eckford, New Countess, Blue Burpee, Stanley, Aurora, Her Majesty, Victoria, Countess of Radnor, Royal Robe, and Princess Wales. There were also classes for twelve bunches of herbaceous perennials, Mr. John Walker, taking the first prize. Owing to the hot weather the exhibits were very few and the flowers not their best.

The society's challenge cup was won outright by Mr. R. Sydenham, and the Turner Memorial cup by Mr. A. W. Jones.

Miscellaneous exhibits were of an interesting character. Mr. J. H. White, nurseryman, Worcester, was awarded the Botanic Society's silver medal for a superb bank of hardy and flowers. Silver medals were awarded to Messrs. T. Hewitt and Co., Solihull, for a collection of plants and cut flowers, Carnations predominant to Mr. B. R. Davis, Yeovil, for brilliant Bego of fine quality; to Messrs. W. and J. Birkenhead, Sale, for a fine and interesting collection of Ferns and to Mr. Henry Eckford for a large collection of Sweet Peas. A bronze medal was awarded Mr. W. F. Gunn, Nottingham, for a collection of hardy flowers.

### ROYAL HORTICULTURAL SOCIETY.

AUGUST 10.

THOUGH in point of number of exhibits the meeting on the above date was perhaps the smallest of the present year, there was certainly no lack of interesting subjects, especially for the outside garden. Hardy plants, indeed, were the most conspicuous as well as the most interesting feature of this meeting. Of more than usual interest—though perhaps crowded somewhat owing to want of room—was the collection of autumn flowers from Messrs. James Veitch and Sons. This array of beautiful and easily-grown plants attracted considerable attention, so replete was it with the good things this class comprises. The same firm also exhibited one of their usual highly interesting groups of flowering shrubs that invariably interest quite a large number. From Langport Messrs. Kelway brought a group of cut Gladioli, many of them very good, though scarcely up to the standard of excellence at the previous meeting. It is, however, with regard to that we note a departure in the mode of exhibiting these flowers; and in place of the simple, almost natural arrangement so closely associated with these flowers for many years past, the firm in question had nailed them fan-shaped on to baize-covered hoardings—a method for which we have not the least sympathy. A great deal of the beauty of the fine spikes was lost by the half-circular arrangement to which we refer. Trevor Lawrence had a group of Cannas cut for the open, also fine spikes of Gladioli and a pure white form of *Crinum Powellii*. Dahl

very good and in considerable quantity also. Apples, as usual at this season, were not numerous. Some good Apples were also counted, but other fruits were the reverse of abundant.

### Orchid Committee.

Awards of merit were given to the following:—

**ODONTOGLOSSUM PESCATOREI HARRISIANUM.**—A lovely form with a large branching spike of twenty-flowers. The sepals are white, slightly suffused with rose, and thickly spotted at the base with rose purple; the petals white, the centre of the basal half thickly spotted with purple as in the sepals, the lip white, shading to yellow and thickly covered with rich purple at the base. It is very much in the way of the lovely *O. P. Vichi*, but distinct from that variety. From Messrs. J. Veitch and Sons.

**LALIO-CATTLEYA ELEGANS SCHROEDERIANA.**—A good form. The sepals and petals rich crimson-purple, the lip rich velvety crimson with numerous raised lines, the side lobes deep purple, shading to rose at the base. A cut spike of four flowers was exhibited by Mr. E. Ashworth, Hefield Hall.

**ANDROPHUM VICTORIA REGINA.**—In the fine variety of this shown the sepals and petals, each about 1 inch in length, are pale violet-blue, veined with a darker shade of colour at the apical half and white at the base. The lip is rich violet, shading to white at the base, where there are numerous pale lines. From Mr. T. Statter.

**CYPRIPEDIUM CALLO-ROTHSCHILDIANUM.**—A hybrid derived from the species indicated in the name. The dorsal sepal is pale green, heavily veined with dark brown, the petals greenish white, thickly covered with large purple-brown spots; the lip rich brown, veined with a darker shade of colour. The plant bore two flowers on the spike. From Mr. J. Gurney-Fowler, Giebelands, South Woodford.

Messrs. H. Low and Co. sent a neat and pretty group, prominent among which were some grand forms of *Oncidium Papilio*, well-flowered plants of *O. Jonesianum*, and several fine forms of *O. Laccanum*. Among the numerous *Cattleyas* were good forms of *C. Warscewiczii*, *C. Gaskelliana*, *C. Loddigesii*, and a good form of *C. bicolor*. *Odontoglossum crispum* was represented by a good form with white sepals and petals, the sepals spotted with reddish brown, the lip white shading to yellow, and having a large brown blotch in the centre. *O. Pescatorei* was represented by a grand form, with rich purple spots on the edges of the lip. *Cypripediums* (both hybrids and species) were extensively shown, the most prominent being finely-flowered *C. Charlesworthii*, a good form of *C. macropterum*, *C. Canhamianum* and *C. oenanthem superbum*. A bronze Banksian medal was awarded. Messrs. J. Veitch and Sons, Ltd., sent five hybrid *Cattleyas*. Two good forms of *L. C. Atalanta* and a grand form of *L. C. callistoglossa ignescens* (*L. purpurata* × *C. Warscewiczii*), the sepals and petals deep rose, the lip rich crimson-purple, shading to rich orange-yellow in the throat, were also shown. Messrs. F. Sander and Co. sent some dwarf forms of *Sobralia xantholeuca*, *S. leifordii*, a dark form of the *S. maeranthana* section, a fine specimen *Odontoglossum bicornis album* with six spikes of flower, a grand plant of *O. Schleiperianum*, *O. Kramerianum*, *O. Pescatorei* var. *conspicuum*, a beautiful form with pure white sepals, lip white, thickly covered with deep purple, and *Cypripedium Lawrence-Druryi*, a new hybrid derived from the parents indicated in the name.

Mr. J. Gurney-Fowler sent *Cypripedium Neptunea* (var. *lorandae* × *Rothschildianum*), the dorsal sepal pale green, spotted with dark brown, the petals pale green, thickly spotted with dark brown and heavily suffused with purple hairs on the outer edge, the lip purple-brown, shading to pale green. *C. A. de Laurence* (*Curtisi* × *Rothschildianum*) is very similar to the above, but with less density in the markings. *C. Massaianum* (super-

cilare × *Rothschildianum*) is much larger than the two above referred to, the ground colour being pale green and the markings more regular. It had previously been certificated. A fine branching spike of the lovely *Renanthera Storei* was also included. Mr. R. J. Measures sent a fine form of *Lalio-Cattleya Andreana* (*C. bicolor* × *L. elegans*), the sepals and petals pale rose, the lip intermediate in character between the two species, the front rich purple, shading to pale rose at the base. Mr. Reginald Young, Liverpool, sent *Cypripedium Eyermani* var. *Hermione*. Mr. G. W. Law-Schofield sent *Lalio-Cattleya elegans* (New Hall variety), sepals and petals deep rose, with a rich crimson-purple lip, shading to rose on the side lobes. Sir T. Lawrence sent a finely-grown and flowered plant of *Platyclinis filiformis*, showing some scores of spikes of its rich golden flowers, a finely-grown plant of *Masdevallia infracta purpurea* and the lovely terrestrial Orchid, *Eulophia guineensis*, the sepals and petals rich purple, margined with rose, the broad lip pale rose shading to white at the base, and veined with a deeper rose in the centre. The erect spike carried eighteen flowers. Sir F. Wigan, Clare Lawn, East Sheen, sent a grand variety of *Lalio-Cattleya elegans*, four spikes being cut from one plant, a good form of *Lelia crispa* and *Masdevallia macrura*. Mr. W. H. Lumsden, Aberdeen, sent *Cypripedium Balmedianum*. It has a great deal of the *C. Stonei* in it, but no traces of the other parent, *C. Fairieanum*, could be discovered. It is very much in the way of *C. Numa*.

### Floral Committee.

First-class certificates were granted to the following:—

**CALCEOLARIA ALBA.**—A lovely Chilean species, with white blossoms of medium size and produced in the greatest profusion. The plants were splendidly grown, and not only displayed high cultivation, but also revealed the value of the species for greenhouse decoration. The plant is so nearly hardy, that it deserves to be freely grown for its value in the garden or for cutting. A coloured plate of this species was given in THE GARDEN, January 23, 1897 (page 60). From Mr. J. T. Bennett-Poë, Cheshunt.

**NYMPHLEA MARLIACEA FLAMMEA.**—One of the beautiful *Marliacea* hybrids, with reddish crimson flowers. A splendid addition to these things. From Mr. J. T. Bennett-Poë.

**CRINUM POWELLI ALBUM.**—Two giant spikes of this newly hardy species, with a dozen or more blossoms on each umbel, were shown. Individually the blossoms are very large, and the stems attaining to 3 feet high render it a bold and conspicuous object in the garden, where a sheltered spot should be given it. From Sir Trevor Lawrence (gardener, Mr. Bain).

Awards of merit were recommended to:—

**RUDBECKIA LACINIATA GOLDEN GLOW.**—A showy and useful new plant, with blossoms like those of a medium-sized Sunflower, but requiring the highest culture to attain perfection. From Mr. M. Prichard, Christchurch; also Messrs. Barr and Sons and Messrs. Kelway and Sons.

**HOLLYHOCK LEANDER.**—A bronzy yellow, with large, double, well-formed flowers. From Messrs. Webb and Brand, Saffron Walden.

**GLADIOLUS COUNTESS AMY.**—Warm purple with a white base. Messrs. Kelway and Sons.

**GLADIOLUS MIKE LAMBOURNE.**—A rich deep crimson-maroon, flowers very large. Messrs. Kelway and Sons.

**GLADIOLUS COUNTESS OF LEICESTER.**—White, striped lilac-purple, and streaked with scarlet. Messrs. Kelway and Sons.

**DAHLIA DAFFODIL.**—A Cactus kind, with medium-sized blossoms of a clear yellow shade. From Mr. James Stredwick, St. Leonards.

**DAHLIA MISS AGNES BOX.**—Also of the Cactus type, and of a fine rich crimson. From Mr. James Stredwick.

**PHLOX EUGENIE DAUZANVILLIERS.**—A soft lilac-blue shade with white centre. Kelway and Sons.

**PHLOX LA MATILDE.**—A fine, handsome form with purplish blossoms. From Mr. T. S. Ware, Tottenham.

**VERBENA TRESSERVE.**—Of a clear rose-scarlet shade with white-shaded centre, flowers and truss of large size. Mr. J. T. Bennett-Poë.

One of the most interesting features of this meeting was the large array of annuals from Messrs. James Veitch and Sons, in a cut state for the most part, and comprising the leading families and varieties in these all-important summer flowers. This was an interesting as well as fresh and bright-looking exhibit (silver-gilt Banksian). From Langport, Messrs. Kelway and Sons brought a most extensive display of *Gladioli* arranged in fan-shaped design on boards as noted above. A few of the best and most distinct apart from those that received certificates of merit were Mrs. Langtry, Empress of India, Duke of Buccleuch, a most beautiful shade of salmon-pink; Cardinal Newman, Henry Irving, yellow flushed scarlet; Chopin, Shazada and others. The same firm also had an assortment of *Gaillardias* and other hardy things, for which a silver-gilt Banksian was awarded. From Tottenham Mr. T. S. Ware brought a varied lot of the best hardy flowers in season, mainly in bold telling bunches on long stems. Prominent among these were *Echinacea purpurea*, a very fine form of this almost unique plant; *Veronica longifolia subsessilis*, *Scabiosa caucasica*, *Pentstemon glaber*, very beautiful in the azure tint of its flowers; *P. barbatus Torreyi*, *Hyacinthus candicans*, with snowy drooping bells; *Campanula Van Houttei*, a fine Bellflower too rarely seen; *Statice latifolia*, the best of the hardy sorts; *Campanula G. F. Wilson*, *C. Hendersoni*, a really good plant, forming a perfect cushion when growing freely; *Lilium tigrinum* and others (silver Flora medal). Another very beautiful lot of hardy flowers was that from Mr. M. Prichard, Christchurch, Hants. Mr. Prichard's group contained several fine bunches of the newer kinds of *Montbretias*, together with handsome flowers of *Scabiosa caucasica alba*, the flowers finer and decidedly purer than any we have yet seen and of especial value for cutting. *Phloxes* of several kinds, *Ball of Fire* and *Etna* being especially good; *Cimicifuga cordifolia*, with erect, compact spikes of creamy-white flowers; *Echinops Ritro*, with globular heads of steel blue; the pure white *Everlasting Pea*, *Dianthus Atkinsoni* and *Delphinium Zalil* with pale yellow blossoms, though unfortunately not a good do r, were also noteworthy. Very conspicuous was Mr. Prichard's lot was a Mexican Thistle (*Erythrolena conspicua*), said to be a grand thing for the wild garden, and having a much-forked inflorescence and purplish-magenta flowers, as far as could be seen by the unopened buds. Unfortunately, the plant was drooping, and, being cut, failed to satisfy the committee. Such plants, indeed, if worth exhibiting at all, are well worth showing as growing, so that a fair estimate may be obtained of their worth (silver Flora medal). Cactus and other Dahlias were very fine from Mr. S. Mortimer, Farnham, particularly the former, the best of these being *Starfish*, *Matchless*, *Princess Ena*, *Countess Radnor*, *Bertha Mawley*, and *Mrs. Francis Fell*. Among the show and fancy kinds, Mrs. Saunders, Glowworm, Harrison Weir, Duchess of York, Mrs. Gladstone, John Keynes, and *Sunset* were notable (silver Flora medal). Another collection of Dahlias came from Mr. J. Walker, Thame, Cactus and show kinds being about equally represented and in capital form, the varieties not differing materially from those in the previous group; a silver Banksian medal was awarded. A small group of *Marigolds* from Messrs. Dobbie and Co. received a bronze Banksian medal, the varieties being *Lemon Queen* and *Prince of Orange*. From the garden of Sir Trevor Lawrence (gardener, Mr. Bain) came a fine batch of *Cannas* from the open ground, also *Gladioli*. Among the latter was one named *G. A. King*, a large spreading flower of purple-crimson hue, lower petals white, with numerous dots. In the same group, *Lobelia Crimson Gem* and *L. Carmine Gem* were exceedingly fine, as also the lovely spikes of *Crinum Powelli album*, already

referred to, the group receiving a silver Banksian medal. As usual, a very interesting batch of hardy flowers came from Messrs. Barr and Sons, Covent Garden, the major portion comprising Phloxes and Delphiniums. Of the former we noted *Etna*, *Embarrassment*, *W. Robinson*, a pale salmon shade, with flowers of large size; *Diadem*, *Parachute*, and others. The blue and white forms of *Agapanthus* were also noted, together with *Rudbeckias*, *Helianthus*, *Montbretia crocosmiiflora*, very fine; *Lilium auratum rubro-vittatum*, and others. There was also a good assortment of *Gladioli*, and not least among these the fiery-scarlet spikes of *G. brenehleyensis*, for which a silver Banksian medal was awarded.

Messrs. Wallace and Co., of Colchester, had a very beautiful lot of *Liliums*, principally of the speciosum group. In this lot crowding had been entirely ignored, the intervening spaces being filled with *Asparagus* growths that materially assisted to a light arrangement. Indeed, in view of the taste displayed, as also the material used, we are inclined to regard it as one of the best groups at this meeting, and deserving greater distinction. The *Liliums* included of speciosum varieties *Melpomene*, the pure white *Krätzeri*, and *album novum*, the best of this class, together with a specimen in a pot of the latter with five stems. There were also *L. superbum*, *tigrinum* in several varieties, the lovely *L. Henryi* in plenty, as also *L. auratum*, together with *L. a. platyphyllum* and the massive pure white *L. a. platyphyllum virginale*. At the one end was a group of some half dozen of the newer *Montbretias* in variety with *Gladioli* at the other, and, towering above all, the noble spikes of *Kniphofia nobilis*, perhaps the grandest of all the set. A silver Banksian medal was awarded. For a group of *Cannas* in variety, with occasional pots of *Lilium nepalense* and *L. Wallichianum*, Messrs. Hugh Low and Co. also received a silver Banksian medal.

The Messrs. Veitch and Sons had a series of flowering shrubs, the most worthy being *Clerodendron trichotomum*, *Coprosma acerosa*, with bluish and almost transparent berries, like a gooseberry in miniature; *Hypericum aseylon*, some 4 feet high, with heads of yellow blossom; *H. floribundum*, a bushy kind, with numerous golden flowers; *Colutea arborescens* and its variety *purpurea*, *Abelia rupestris*, *Rhus glabra laciniata*, and *Ptelea trifoliata*. From Stevenage Messrs. A. W. Young and Co. brought bunches, said to be cut from the open ground, of *Pelargonium King of Denmark*.

#### Fruit Committee.

There was only a limited number of exhibits, but these were mostly good.

Awards of merit were given to the following:—

**GOOSEBERRY GOLDEN GEM.**—A seedling, the parents being *Antagonist* and *Whitesmith*. It is of excellent flavour, the flesh rich and sweet, skin thin, bright golden. It is an erect grower and very heavy cropper. From Messrs. Veitch, Ltd., Chelsea.

**BLACKBERRY THE KITTATINNY.**—An American variety. The fruit is sweet and freely produced. Growths from 5 feet to 6 feet, laden with berries quite ripe, were sent. It requires a damp, heavy soil. From Mr. Wadds, Cliveden Gardens, Maidenhead.

Messrs. G. Bunyard & Co., the Nurseries, Maidstone, sent thirty-six dishes of early Apples, some remarkable fruits being staged for so early in the season; some kinds, such as *Lady Sudeley*, *Cardinal*, *Oker*, and others, had no doubt been at some period under glass. Mr. Gladstone, *Qurrenden*, and *Red Juneating* were remarkable for their splendid colour. There were some very fine cooking fruits, the best being *Grenadier*, *Sugar Loaf*, *Lord Suffield*, *Domino*, *Gold Medal*, *Stirling Castle*, *Lord Grosvenor*, *Potts' Seedling*, *Golden Spire* and *Ecklinville*. Some good Peaches were staged, *Early York*, *Early Grosse Mignonne*, and *Hale's Early* being the best, with good *Hemskirk*, *Blenheim*, *Moorpark*, and the *Peach Apricots* (silver Knightian medal). Mr. Miller, gardener to Lord Foley, Ruxley Lodge, Esher,

sent eighteen dishes of fruit, including *Brown Turkey* and *Brunswick Figs*, *Royal George*, *Violette Hâtive*, *Noblesse*, and *Alexander Peaches*, *Hemskirk Apricots*, *W. Tillery Melon*, *Apples*, *Mulberries*, *Cherries*, *Gooseberries*, and two varieties of *Grapes* (silver Banksian medal). A grand box of *Royal George Peaches* came from Mr. Kelf, gardener to Mrs. Abbot, South Villa, Regent's Park, well meriting the cultural commendation bestowed on them, the fruits being large and of grand colour. Mr. Wadds, Cliveden Gardens, sent *Blackberry Wilson Junior*. Not a single Melon was staged on this occasion for certificate. A Tomato named *Sutton Beauty*, a distinct fruit of medium size, was sent by Mr. J. Moody, Sutton House Gardens. It was asked to be sent to Chiswick for trial. Mr. Smyth, The Gardens, Basing Park, Alton, sent two distinct types of dwarf French Beans. One was a very prolific variety, a cross between *Smyth's Seedling* and the *Scarlet Runner*, with long, straight pods, the growth about 2 feet. It is a promising variety, and was asked to be sent to Chiswick for trial. The other was very dwarf and named *Goliath*, but not considered so good. Mr. Wythes, Syon House Gardens, Brentford, sent *Lady Sudeley Apple* and *Jargonelle Pear* for the Veitch prizes for flavour. The second prize in each case was awarded.

A meeting was held at the society's gardens, Chiswick, on the 5th inst., when a good number of early varieties of Potatoes were examined. Some nine varieties were good as far as cropping was concerned, but only one satisfied the committee when cooked. The Tomatoes were next gone through, but not considered forward enough for classification. Some Aubergines from Dr. Bonavia were next examined. These were considered good. Some new Vegetable Marrows from Constantinople, sent by Mr. Toogood, Southampton, were not considered equal in quality to our own well-known varieties.

An award of merit was given to—

**POTATO SUTTON'S HARBINGER.**—This is a very heavy cropper and very early. It was obtained by crossing *Early Regent* and *Pillbasket*. It has white flesh, shallow eyes, roundish tubers, strong haulm, and is an excellent cooking variety, being floury and of superb flavour. From Messrs. Sutton and Sons, Reading.

## PUBLIC GARDENS.

**The opening of Kew Gardens.**—The Director of Kew Gardens has written the following letter to Mr. E. S. Payne, a member of the Hampstead Vestry, with reference to the earlier opening of Kew Gardens to the public:—"Royal Gardens, Kew, August 3, 1897. Dear Sir,—Kew is open in the morning to those who wish to examine the collection for any definite purpose, and facilities are given to them which could not be extended in the presence of the general public. The privilege is largely used. It is admitted that with an earlier hour of opening to the general public the existing arrangement would virtually come to an end. This would be a serious deduction to the public utility of the establishment. The question then arises whether the public demand for an earlier hour of opening is sufficiently definite to justify the sacrifice. In my opinion it is not. The number of visitors who enter the gardens between noon and 2 p.m. is annually very small—only a few hundreds. Kew is, in fact, an afternoon place, and as our average totals have now risen to a million and a quarter, or one out of every four of the population of London, Kew does not hide its light under a bushel, and I am satisfied that the public generally is satisfied with things as they are. The administrative difficulties in making a change in so complicated an establishment are very considerable. My mind is, however, open on the subject; but I want more definite evidence than is at present forthcoming that any definite change is really demanded.

## OBITUARY.

### MR. ALFRED SUTTON.

WE regret to announce the death, at the age of 79, of Mr. Alfred Sutton, at his residence at Reading on Saturday morning, August 7. Both Mr. Alfred Sutton and Mr. Martin Hop Sutton, his elder brother, who founded the firm and who survives him, retired from business in 1888, making over the business to the sons, the present partners. Mr. Alfred Sutton took principally what may be termed the home part of the work. Mr. Sutton took the deeper interest in education, and was a member of the Reading School Board for fifteen years. The British School and other scholastic institutions had in him a warm supporter. He was also a liberal subscriber to all institutions having for their object the relief of distress and suffering. In thrift societies, too, Mr. Sutton was much interested, and he rendered valuable help in the management of the Reading Savings Bank. A religious movements, especially those established for the benefit of young men, were dear to him. His widow and ten children (seven sons and three daughters) survive him.

**The weather in West Herts.**—A very hot week, the highest temperature in shade exceeding 80° on four days, while on two of these days the readings were respectively 84 and 86°, both which are the highest shade temperatures recorded here during the present summer. The nights, on the other hand, were only moderate warm for the time of the year, so that the range in temperature has been very great, and on several occasions exceeded 30°. The temperature of the ground at 2 feet deep is now 5° and 1 foot deep 8° warmer than is seasonable. For more than three weeks no measurable quantity rain-water has come through either of the percolation gauges, and none at all for nearly a week. Throughout the last five days the record of bright sunshine has averaged about 11½ hours a day. July proved unusually warm. In fact, in the eleven years there have been only two Julys as high a mean temperature, viz., those of 18 and 1896. It was also extremely dry. Rain fell on but five days, and to the total depth of only about half an inch, making this the driest July in Berkhamssted for twelve years. The sun shone on an average for 8 hours a day, which, with one exception (1887), is the highest record for a July during the same twelve years.—E. A. Berkhamssted, August 7.

—The past week has again proved very warm, making this the seventh unseasonably warm week we have now had in succession. On the 5th the reading in shade rose to 86°, but since then the days have been much cooler. On the other hand, the nights were warmer than in the preceding week. The ground temperatures still remain very high, being at 2 feet deep 5°, and 1 foot deep 6°, above the August averages at these depths. Rain fell on only two days of the week, and to the total depth of but little more than a quarter of an inch. The air was, as a rule, very dry, and the record of bright sunshine remarkably good.—E. M., Berkhamssted.

### BOOKS RECEIVED.

"Shade Temperature." By Edward Mawley.  
"Hand-List of Tender Monocotyledons, excluding Orchideæ grown in the Royal Gardens, Kew." 188 Eyre and Spottiswoode.

**Month's numbers of The Garden (48th subscriber of Nearly Thirty Years).**—The July number which is published at the beginning of July, can only contain the numbers for June.

**Names of plants.**—*J. G. Squibbs*.—*Calyspteryx hederacea* fl.-pl.—*E. Baddeley*.—1, *Vanda cœrulea*, 2, *Phalaenopsis amabilis*. Both remarkably good forms more particularly the *Vanda*.—*W. Shaw*.—1, *Kentia japonica*; 5, *Olearia Haasti*; 6, *Hypericum calycinum*; 8, *Picea nobilis*; 9, the *Tamarisk*; 10, *Geranium Andrei*. Please send better specimens of others.

## ORCHIDS.

### RODRIGUEZIA SECUNDA.

Not so small, and by some considered a second-rate species, I know of nothing prettier at this season than this bright and effective little Orchid. The pretty rose tint of the blossoms is much enhanced by the glistening surface, which looks like hoar-frost or dew. It is seldom seen in anything approaching good condition, but this is as often as not the fault of the cultivator, for it can be grown, and grown well, with as little trouble as most things, hanging it up close to the glass on a bare rock is starvation to it, and, no matter how carefully attended to, there are sure to be times when it suffers from want of moisture. A much better plan is to place it in a wood basket, allowing a fairly thin layer of compost, this consisting of equal parts of peat and Sphagnum moss, with plenty of crocks and charcoal. In habit *R. secunda* is not unlike a Burlingtonia, and, like this plant, it will if not prevented grow away so far from its root-hold that the young pseudo-bulbs get weaker yearly from want of sustenance. To prevent this, let the basket used be fairly wide, and every season cover the plants, carefully pegging down the sides to the compost. I have even gone to the length of tying a little Moss over the outside of the basket, in order to afford the pots a chance to get hold, but this is not often necessary; nor, indeed, is it requisite that every root should enter the basket, for it is the habit of *R. secunda* to push roots out into a congenial atmosphere, where they feed upon the moisture and ammonia it contains. The small white roots at this season when the flowers are open have a quaint and distinct appearance. Though not liking too great heat, *R. secunda* will not thrive in a cool house, such suits many plants from New Grenada—its habitat. A mild, moist temperature, with plenty of ventilation and not too dense shade, suits it admirably, the foliage in such an one tak-

ing on that deep russet tint that is indicative of vigour, and the bloom spikes occurring with freedom. At no time should the plants be heavily watered, but all the year round they require a little moisture. Anyone having large specimen Tree Ferns may do worse than plant a few bits of this Orchid upon the stems, securing them in position with a little fine copper wire until roots form, when they would become self-supporting. The effect when in bloom would be striking and pretty, while no kind of root-hold could suit the plant better. R.

**Dendrobium rhodostoma.**—This is one of the prettiest hybrids ever raised, and a fine plant of it was recently in flower with Messrs. Veitch. It is a cross between *D. superbum* Huttoni and *D. sanguinolentum*, the flowers being only about 2 inches across, and produced freely upon the stem-like pseudo-bulbs. The sepals and petals are white, each having a bright crimson purple tip, this making it extremely showy. The lip is rosy-purple with a yellow centre. It appears to be very free in growth, and succeeds best in the warm house.

**Mormodes pardinum.**—This singular plant I recently noted in good condition with Mr. Bull. It is a fairly strong grower, and the blossoms appear principally upon the upper part of the scapes. These are yellowish with crimson spots, the pointed sepals giving them a peculiar appearance. Plenty of heat and light and a brisk, moist atmosphere are what this species delights in. It may, in fact, be treated like a *Dendrobium* while in active growth, abundance of water being afforded as soon as the young shoots are out of danger.—H.

**Maxillaria venusta.**—I have noticed this fine old species blooming in several collections lately. It is a strong-growing, free-flowering plant, not unlike *M. grandiflora* in habit. The flowers occur on erect scapes each about 6 inches in length, and have the segments pointed in front, broad at the base, pure white except the lip, which has a yellow centre and is spotted with crimson. It is worth growing in any collection of cool-house Orchids, the foliage being broad and ornamental when the plant is not in bloom. It requires plenty of moisture at the roots and in

the atmosphere all the year round. It is a native of Oceana, and was introduced in 1872.—H. R.

**Epidendrum cinnabarinum.**—Like most of the upright-growing section, this species continues to bloom over a long season, the flower-spikes lengthening as the blossoms fade, and producing others successively over a long season. These are about 2 inches across in the best forms, of a bright red on the outer segments, the lip having a deep yellow centre. It is a free-growing and easily cultivated plant if not kept too hot. In an airy large Cattleya house, where the temperature and atmospheric moisture are not liable to sudden fluctuations, it does well, if not dried at the root during the winter.

**Trichopilia Galeottiana.**—This pretty and distinct species was recently in flower at Mr. Bull's. It is not perhaps so showy as some, but well worth a place. The spikes each bear about two or three flowers, the sepals and petals of a greenish yellow tint, the lip whitish spotted with crimson. It is an easily-grown, free-blooming plant, and requires a place in the Cattleya house as near the glass as possible, but shaded from the direct rays of the sun. The plants may be repotted in spring or after blooming, using clean pots and an ordinary description of compost. It requires abundance of water while growing and to be kept just moist while at rest. It is a native of Mexico and was introduced in 1859.

**Oncidium pumilum.**—This is a somewhat rare little species, very pretty and attractive, but not large enough to find favour among present-day Orchid growers. It has rather thick leaves, each about 6 inches in height, and its blossoms are produced upon erect branching scapes. They are so densely set, that it would seem impossible to put a straw between them anywhere, and are bright golden yellow and brown in colour. It was flowering freely in Messrs. Veitch and Sons' nursery at Chelsea last week, and is growing in small pans suspended from the roof of a fairly warm house. Anyone liking small-flowered and quaint kinds would do well to give this species a trial. It is a native of Brazil, and was introduced in 1824.

**Catasetum Bungeorothi.**—This is one of the finest species in the genus, its beautiful and singular blossoms never failing to attract attention. The flowers are pure white after being

open a little while, and last long in good condition. The best place to grow it is a light, almost unshaded part of the East India house, where the sun is allowed to shine on the glass after closing time in the afternoon. Grow it in pots of peat and Moss and allow plenty of water at the roots as long as growth is active, diminishing the supply by degrees, in autumn and in winter keeping them well on the dry side. The culture of *C. Bungeorothi*, in short, does not differ much from that required for the deciduous *Dendrobiums*.

**Cypripedium Charlesworthi.**—There is a very large stock in all sizes of this plant at Clapton, one house being almost filled with it, and among the plants in bloom a good deal of variation is apparent. The distinct rosy white dorsal sepal and the pure white staminode are the most distinct characteristics of this species. The plants are oftentimes a little disappointing, for when the blooms are first open the fine colour on the sepal is very noticeable, but it fades considerably with age. It is a fairly popular plant by now, though perhaps it has not quite fulfilled our expectations when first imported by Charlesworth and Co. from the East Indies. A plate of a good representative form was given in *THE GARDEN*, April 13, 1895.

**Vanda cœrulea at Gunnersbury House.**—According to my views, *Vanda cœrulea* is the most beautiful of all the *Vandas*, and when seen at its best no Orchid meets with greater favour. Without being actually particularly difficult to cultivate, it is yet seldom seen in a presentable condition in private gardens. In common with other kinds of Orchids, this species has its likes and dislikes; in other words, it fails badly in some positions and grows almost like a weed in others. Mr. Hudson, at Gunnersbury House, has not long taken it in hand, but has already formed a group of which he may well be proud. Most of his plants were bought as imported, and established in baskets after being received. Both position and treatment seem to agree well with these *Vandas*, and the roots—which I invariably take note of first when examining Orchids—are plentiful and in a particularly happy state—a sure index to a healthy, free-flowering top-growth. The plants, without being actually exposed to direct sunshine, are yet suspended where abundance of light and genial air reaches them, anything like a strong, dry heat not suiting these or any other *Vanda* I have ever grown. The baskets are surfaced over with live *Sphagnum Moss*, a proof that the plants are receiving abundance of water during the growing season, and the exact treatment required. A snug corner in a gently heated house is where the best of Mr. Hudson's plants are located.—W. I.

#### ODONTOGLOSSUM URO-SKINNERI.

This very distinct and beautiful Orchid is a strong, vigorous-growing species bearing long strap-shaped leaves almost like those of a *Zygopetalum*, and the flower-spikes appear at the base of the pseudo-bulbs. These often grow nearly a yard in height, and just now are very showy in many collections round London and elsewhere. The blossoms open successively upon the scapes, and are each 3 inches across in the better forms, of a greenish yellow ground, covered with brownish markings on the sepals and petals; the lip is a pretty bright rose, irregularly streaked with white. The culture of *O. Uro-Skinneri* may be safely taken in hand by anyone. It will be noted that the roots are of a more fleshy character than those of the usual run of *Odontoglossums*, larger, and therefore more easily injured, and this fact should be kept in mind when repotting or otherwise disturbing them. The peat used in the compost for *O. Uro-Skinneri* should be of the best quality, and plenty of large, rough pieces of crocks or charcoal should be introduced with a little clean *Sphagnum Moss*. Break the old pots with a hammer if the roots are likely to be much entwined about the drainage and sides, and in repotting keep the base of the plant a

little above the rim. Owing to the character of the roots noted above, a pot of fairly good dimensions compared with those of the plant may be used, but this must be thoroughly drained and a couple of inches only of compost allowed, except for very large plants. In a house kept nicely moist and duly shaded new roots will soon be in evidence, and the plants will soon take water freely. Few Orchids require more water when in active growth; hence the reason for care in the compost and drainage. While the growths are young and soft little or no water should be given overhead, but when the foliage commences to harden, light dewings are very beneficial both in keeping down insects and also replenishing the atmosphere just around the plants. A soft brownish scale is apt to attack this plant, and should be sought for and kept under. Sponging carefully and often with clear tepid rain water will keep the plants clean without using any strong insecticide, or if the plants are really dirty, a little soft soap and tobacco water may be mixed with it. *O. Uro-Skinneri* was sent home in 1854 by the gentleman whose name it bears, he having found it growing upon rocks at Santa Caterina, near Guatemala.

**Angræcum articulatum.**—The free-blooming character of this species is well shown by a large batch now in flower at Messrs. Hugh Low and Co.'s nursery at Clapton. There are hundreds of plants, apparently only semi-established, or, at all events, not very long imported; but they are covered with spikes of the pretty white blossoms, each with its spur about 4 inches in length. It is not a difficult plant to grow, thriving well in any description of house, provided heat and atmospheric moisture abound. While not liking a dense shade, a little must be allowed, or the foliage is sure to be injured. Pots, baskets or suspended pans suit it well, the receptacles not being larger than will take the plants easily. Clean *Sphagnum Moss* and charcoal only are required as compost. Good drainage is necessary, as the plants take a lot of water when in active growth.

**Chysis lævis.**—This is certainly one of the finest species in the genus, and was recently in flower at Mr. Bull's. The stems attain, on the strongest plants, a height of 15 inches or 18 inches, and the drooping raceme of flowers occurs from the young growth. The sepals and petals are yellowish, with a brownish tinge at the base; the lip brighter, with reddish spots and blotches. Its culture is not difficult, yet requires care, especially during the early part of the season. It is not possible to flower it well unless the growths are well ripened in autumn. Yet the young shoots and foliage are at first very easily injured by strong sunlight. The plants are best grown in the *Cattleya* house in a compost consisting of equal parts of peat and Moss, a little good loam being added for strong plants and plenty of crocks in a finely broken state. Good drainage is necessary and a thin compost, there being no need to raise the plant above the level of the pot's rim. Allow plenty of water at all times when growth is active, reducing the supply in autumn, in winter giving only just sufficient to keep the stems plump. *C. lævis*—so called on account of the smooth lip—is a native of Mexico and first flowered in England in 1840.

**Lælia xanthina.**—Although not so showy as many others in this favourite genus, this species is extremely pretty and quite distinct. The stems grow over a foot in height, with a single leaf on each, and the spike usually bears about four flowers, each 4 inches and upwards across. The edges of the sepals and petals being turned back give them the appearance of being narrower than they really are. In colour they are yellow, sometimes with a median line of brownish green, and the lip is yellow, becoming paler at the edge and having several radiating lines of crimson-purple in the centre. *L. xanthina* is not so strong or so vigorous rooting as the majority of species, and consequently should be placed in medium sized

pots only, these well drained, and a thin layer of compost suffices. Equal parts of peat and Moss with sufficient hard material to prevent closeness will suit it well. Water must be judiciously given, especially during winter, the quantity required during this season being very small. Even when growing freely, it is wise to let the compost get well on the dry side before giving fresh supply, and then to water thoroughly. The flowers appear at various times during the summer, and last about three weeks if kept cool and dry.

#### EPIDENDRUM FRAGRANS.

This species and the nearly related *E. radiatum* and *E. cochleatum* are all now in flower, and each has its distinguishing characteristic. The last, the oldest species of them all, in fact one of the oldest known *Epidendrums*, a quaint and singular Orchid, worthy of cultivation where this class of plants is cared for. In habit it is very like *Cattleya* of the labiata section, the pseudo-bulb erect, carrying one or two leaves, from the base which the flower-spikes spring. This bears seven blossoms about 3 inches across, the lip being inverted and shell-like—hence the specific name—in colour a deep purple-maroon. The sepals and petals are spreading, greenish white, having pretty effect against the purple of the lip. The shape and colour of flower *E. fragrans* and *radiatum* are similar to each other; indeed, the only difference apparently is the looser habit of the larger blossoms of the latter species. The colour is similar to that of *E. cochleatum* on the sepals and petals, the purple of the lip being brighter with more blue and less crimson about it. The culture of this group of plants is not difficult. The *Cattleya* house suits them well, a light position, only shaded from the direct rays of the sun, being chosen. If possible it is best to keep them to an annual cycle of growth and rest, but this is not always easy, especially with *E. cochleatum*, which sometimes grows away in an unaccountable manner when least expected. The style of growth and manner of rooting give a clue as to the best compost and size of pot, as these are not unlike those used for the evergreen section of *Dendrobiums*, such as *D. densiflorum* and its allies. While not liking the deep pots that the noble thrives in, the small pans used for deciduous kinds make the treatment too poor, and it is well to strike a medium between these. From time to time growth is pushing at the base in spring, and the blossoms are past the plants require a large quantity of water, both at the roots and in the atmosphere. This must be diminished by degrees when the bulbs are fully made up, and although in winter they need not be actually dry, yet little moisture is necessary. A cool, fairly dry house suits them best, *E. fragrans* especially; if in winter this is wintered in heat it fails to blossom properly.

**Oncidium crispum grandiflorum.**—As distinct from the type, this variety has much larger flowers, of greater substance, and usually a narrow margin of bright golden yellow to all the segments. This makes it a very fine thing, and plant I recently noted was carrying four spikes with an aggregate of something like seven flowers. To grow this Orchid well, a light, most unshaded position should be chosen for it, and the plants may be grown in shallow baskets with a thin layer of rough open compost. Plenty of water while growing and a moist atmosphere are essential; in winter, or whenever growth is quiet, give much less.—H.

**Oncidium lanceanum.**—A fine lot of the *Oncidium* is now in flower at Clapton, considerable variation being noted among them. The flowers of a good typical form will be about 2 inches across, the sepals and petals greenish yellow, with chocolate blotches, the lip varying in colour from almost a pure white to a deep violet-purple. Those of the latter colour make a fine show and may be considered the better forms. *O. lanceanum* has not the best of charac-

as a garden Orchid, but if good, healthy, well-leaved plants are obtained at first, and they are not unduly disturbed, not much difficulty will be found in their culture. It likes plenty of heat and sunlight and a moist atmosphere while growing.

**Cymbidium tigrinum.**—This pretty and sweet-scented Orchid I noted in flower this week. Unlike the *Lowianum* and similar species, it is a small compact grower, seldom growing more than 9 inches high. The racemes are short, bearing about three flowers, greenish in ground colour, with crimson spots. The lip is white, with regular purple and crimson markings. It need not be grown in so large pots or so strong a compost as the large growing kinds, equal parts of peat and Moss suiting it well over abundant drainage. It must not be dried when in flower or at rest, and while growing freely it takes a full supply of moisture. It does well at the cool end of the Cattleya house, and was introduced from the Masserim Mountains in 1864.—R.

**Oncidium triquetrum.**—The blossoms of this species, very pretty, though small, are produced on spikes each containing from a dozen to fifteen. They are rosy white in ground colour, sometimes having a pure white margin to the segments, and these are spotted and blotched with crimson. The plant is of tufted habit, the leaves about 6 inches high and bearing no pseudo-bulbs. To grow it well it should be placed in shallow pans of rough fibrous peat, with very little moss, over good drainage. A light position should be chosen at the cool end of the Cattleya house, and the roots must not be dried off. It is a very old species, having been referred to over a century ago, and is a native of Jamaica.

**Lælio-Cattleyas.**—This rapidly extending genus already contains many of the finest artificially raised hybrid Orchids in existence, some of the later varieties of *L. C. Canhamiana*, for instance, being among the showiest. *L. C. Canhamiana albida* is a fine large flower, the progeny of *Lælia purpurata* and *Cattleya Mossiae*. The sepals and petals are nearly pure white with only a very faint flush of rose, while the lip, as may be imagined by its parentage, is deeply tinted and very finely marked. *L. C. Stella* is also very handsome, with deeply-tinted outer segments and finely undulated lip. This is the result of crossing *Lælia elegans* and *Cattleya crispata*. *L. C. Sphyræ* is an exquisite flower, the plant of dwarf and fairly robust habit. It is a cross between *Cattleya Mendeli* and *Lælia xanthina*, and in its fully developed lip and the distinct yellowish tint of the outer segments unites the best characteristics of its parents in a pleasing manner. All hybrids raised between these genera seem to possess a robust constitution, a fact that augurs well for their future popularity.

#### DENDROBIUM STRATIOTES.

In its best forms this rare species is very beautiful. It has straight, erect, stem-like pseudo-bulbs, stiff-looking and formal. It grows about 2 feet high, the leaves being about 6 inches in length, and the racemes of flower cur at the top of the pseudo-bulbs. These carry several flowers, each about 3 inches across, the widest part, which is from the point of the lip to that of the dorsal sepal. This, with the dorsal sepals and petals are more or less undulated, pale greenish yellow, the lip three-lobed, the front one heart-shaped, the side ones standing erect; it is pure white in front, streaked with purple. These flowers appear at various times during the summer and autumn, and last several weeks in good condition. Like all the New Guinea Dendrobies, *D. stratiotes* delights in a strong, moist heat and plenty of light while making its growth, and I recently noted some very fine stems in a large Croton house here, apparently, very little shade was allowed even in the height of summer. But

it suited this *Dendrobium* as well as one or two of the nigro-hirsute section that were growing with it. If grown in the ordinary East India house the plants should be placed as near the glass as possible, and as its habit hardly fits it for baskets, the pots must be suspended. These need not be large, in fact, the roots do not thrive in a great amount of compost. Clean Sphagnum Moss, with a little fibrous peat and plenty of crocks and charcoal, will suit it well, and the base of the pseudo-bulbs must not be buried. The plants may be repotted when new growth is starting, and the most critical time with the watering is when the young shoots are a few inches high before they commence to root independently. Too much moisture then or cold water will cause them to rot at the base, back breaks having then to be relied on if these are produced. Still, with ordinary care this will not happen, and when once growth gets well away it will be very rapid. Resting the plants is another detail sometimes mismanaged. These plants are quite unlike the *Moulmein* and other Indian kinds, and if forced to rest by withholding water when they are starting to grow, they soon show their dislike to the treatment. Let them rest in summer if they are inclined, but never try and force them to do this or to grow. A drier atmosphere for a few weeks is recuperative to them in early summer, or at any time when the growth is not active, but when once the shoots are seen on the move, then let them have the advantage of a stimulating temperature, be it summer or winter. If yellow thrips is carefully kept under by sponging and the use of the vaporising fumigator, little trouble will be found with any other insects. Root moisture is necessary the whole year round, more, of course, when top and root growth are most active. *D. stratiotes* was introduced by M. Linden, of Brussels, whose collector found it in New Guinea or some of the nearly adjacent islands in 1885. H. R.

#### SHORT NOTES.—ORCHIDS.

**Masdevallia macrura.**—This is a free-blooming interesting species I have noticed in flower this week. In the best forms the blossoms are nearly a foot in length, the sepals long and tail-like, of a greenish-yellow tint with small purple spots. It blooms at various seasons and should be grown in peat and Moss with the warmest section of the genus.—I.

**Lælia elegans Mastersi.**—There are many beautiful forms of this variable Orchid differing greatly in size and colour, but this is very distinct. The sepals and petals are almost pure white, only a faint flush of rose being noticed, while the finely formed lip has in addition to the blotch in front a distinct margin of violet-purple on the side lobes. A nice plant of it was recently in flower with Mr. Bull at Chelsea.

**Oncidium prætextum aureum.**—In the matter of colouring this fine species does not vary so much as many others, but this is a distinct variety. The usual brownish blotches and margin have almost disappeared, and in their place there is a kind of faint marbling of orange such as is seen on some varieties of *Odontoglossum Schleiperianum*. It does well in a light position in the Cattleya house, and should never be dried off.

**Oncidium tigrinum.**—Already the branching scapes of bright yellow blossoms produced by this *Oncid* are in full beauty. It makes a capital plant for keeping up a display now that Orchids are getting past their best, and one never seems to have too many of it. The flowers are delicately scented, the blade of the lip a bright yellow, the other segments rather small. It does well in the cool house in medium-sized pots of peat and Moss, and needs moisture all the year round.

## KITCHEN GARDEN.

### GARDEN PEAS—1897.

This season as a whole has not been one of the most favourable for this crop. During the early months the cold winds kept growth in check to such an extent that it was late before gathering was general, but when once a start was made Peas for a time were plentiful, but of late in this district they have become scarce. Amongst those of recent introduction *Early Morn* may be considered an advance in the large-podded varieties. With me this grew to the height of about 4 feet, and was ready for use soon after *Exonian*. *Carter's Forcing* is a dwarf prolific kind and very early, coming into use about the same time as *Chelsea Gem*. The pods are straight and of a deep green colour, and the peas of excellent flavour when cooked. *Carter's Seedling* is another variety with straight, deep green pods, growing to the height of 4 feet, of robust constitution, and free habit. *Danby Stratagem* grew about 4 feet high. The foliage and pods were of a deep green colour, the latter hung in pairs all along the sides of the rows. *Majestic* also was tried, and this grew to the height of the last named, but was not nearly so prolific. *Magie*, a variety sent out by Mr. Eckford, is a good Pea, its robust foliage and deep green pods being very conspicuous. A row of each about 60 yards long was sown in a field; the ground was of but poor quality, therefore they did not attain the same height as those sown in the garden. About sixty varieties in all were tried, including many of recent introduction from various raisers. As a Pea for podding and withstanding the dry weather *Veitch's Main-crop* stood first. It is no doubt an excellent variety either for garden or field, as its robust constitution prevents an early attack of mildew, which often plays sad havoc in dry weather. *Sutton's Invincible* was also first-class, likewise *Conqueror*, *Prize-winner*, *Dwarf Defiance*, *Peerless*, and *Windsor Castle* sent out by the same firm. Dwarf Peas for small gardens are a great advantage, particularly where they can be depended upon for their productiveness. Amongst the late ones of this class *Autoerat*, *Late Queen*, and *Michaelmas* are the three best. All have a good constitution, and may be relied on as being productive. Tall Peas have gone out of favour, especially where there is a difficulty in getting stakes to support them; there are, however, some first-class varieties amongst these that are well worthy of cultivation, notably those of the *Ne Plus Ultra* type, the flavour of which is excellent. They are far more certain to give a crop than the dwarf ones, not being so subject to the attacks from fly; their growth being much more rapid, less chance is afforded for this pest to harbour in the points of the growths. There is one drawback even where stakes are plentiful, for in exposed situations the haulm is often blown about by the high winds and spoiled.

Busted Park, Uckfield. H. C. P.

**Peas and drought.**—The notes from "S. H." at p. 102 are to the point. I find it advisable to mulch before the stakes are put to the Peas. This season I soaked the mulching with manure water occasionally. Regarding sorts, I am at one with "S. H.," and consider some of the big-podded kinds a delusion. It seems strange that the big-podded kinds should find so much favour with judges.—DORSET.

**Lettuce Continuity.**—I was pleased to read a note of praise on this Lettuce by "E. B. C.," page 101. I do not think this Cabbage Lettuce is so well known as it should be. I tried it when first sent out some years ago, and found it not only first rate from an eatable point of view, but also for withstanding the drought, and not running to seed. In gardens of limited size one sometimes finds it a difficult matter to keep up a supply of good crisp Lettuce, owing to the fact that no sooner does the majority of sorts arrive at maturity, than running to seed takes place.

Continuity, on the other hand, remains intact and of good flavour for a long period. It grows to a large size in good soil, and is of a peculiar bronzy appearance outwardly.—J. C.

**Potato Carter's Record.**—In summers like the present, when the majority of mid-season varieties of Potatoes ripen prematurely, the tubers only swelling to about one half their normal size, any new sort which does well, in spite of a dry root run and parched atmosphere, is sure to find favour, especially with those whose gardens are of a light, porous nature. Of new varieties recently tried, Carter's Record has given me great satisfaction. I planted the tubers with a view to lifting for mid-season supply, but the growth was so rapid and the tubers ready for lifting in such a short time, that I feel sure it might, with certainty, be planted as a first early. It crops well, is of good colour, and first-rate flavour.—C. C. H.

**Onion Record.**—I am very much impressed with the general character of this Onion. So many of the well-known strains of the Spanish type are very flat, the bulbs, though of fairly large circumference, being very light. Not so, however, with the deep-bulbed varieties, of which Record is a good form. It grows under good cultivation to a large size, is of fine globular form, and a grand Onion for exhibition. The fine glossy skin which it has gives it additional beauty, and the exhibitor will find in Record just the Onion he needs for making a mark either as a single dish or for collections. With me it has stood a dry season well and will undoubtedly be largely grown.—GROWER.

**Late market Peas.**—What has struck me for many years is the fact that market gardeners, as a rule, and also farmers who yearly grow a certain acreage of Peas, put all their eggs into one basket, and sow only for gathering during June and July. All observant people must have noticed how scarce good Peas are during the month of August; even at seaside towns, where good vegetables are appreciated and readily bought, the supply is just as poor. At this season Cabbages and Cauliflowers are not at their best, the heat of summer being, as a rule, too great for them. This fact leaves consumers of vegetables in towns little to choose beyond Scarlet Runner Beans and Vegetable Marrows. If such good dry-weather Peas as Prodigy, Stratagem and Omega were grown for producing during August, they would find a ready sale and well repay the grower.—GROWER.

**Garden Turnips.**—The soil is now so heated that if but sufficient moisture be furnished, seed of the Early Snowball sown at once, and again just at the close of the month, will germinate quickly. The bulbs thus produced may not from the second sowing be large, but they will be very fresh and even delicious eating. Still further, they will endure frosts much better than larger ones, and finally, if not otherwise used, will give nice tops in the spring. To get bulbs of fair size to stand the winter, a sowing of the Red Globe may be made at once also. If the recent rains have been general germination will be very rapid. It is much better to sow seed in shallow drills than broadcast, also to sow thinly, as the labour of thinning after growth is so much lessened. Those who like yellow Turnips, and they are exceedingly pleasant eating, should make a sowing of the Golden Ball.—D.

**Turnips in hot weather.**—I never remember to have seen Turnips fail so completely as during the last few days owing to heat and drought, as, no matter how well watered, say once or twice a week, after one day's exposure they showed signs of distress. I fear, no matter where sown, the roots will be poor and flavourless, and if grown under trees they run badly. Now is a good time to make up losses. With a genial rain and the earth so warm, the seeds will germinate in three or four days and the roots be fit for use in a month. For present needs a quick-growing variety, such as Snowball, may be sown, and a good breadth of Yellow Globe or Golden Ball will be good for later supplies. Failing these, if white-fleshed Turnips are liked best, Red Globe and Green-top

Stone are excellent autumn varieties, as they keep sound so long and are superior in flavour to the flat roots with little tap root.—S. H.

**Potato English Beauty.**—I am pleased to see the note on this new variety (p. 85) by "W. I.," as it so fully confirms my own views as to the merits of the above. "A. W.," I find, also recommends this for its crop, in addition to good quality. As most Potato growers are aware, a dry, warm summer is favourable to the heavy cropping American varieties. English Beauty claims one of these (Beauty of Hebron) as one of its parents, with the result that there is a very heavy yield, and the other parent, Myatt's Prolific, adds to the quality, with dwarf top and earliness combined. English Beauty, just lifted (August 3), has given a splendid crop, and the quality is all that can be desired. From a very small quantity of seed I have a very fine yield. It can be lifted for use earlier than the Ashleaf. This is a great gain in gardens where much has to be grown in a small space.—P. F.

**Lettuce running to seed.**—I am obliged to "E. B.," Claremont (p. 101), in asking me to give Continuity Cabbage Lettuce a trial. I am able to confirm his remarks as to its drought-resisting qualities, as I recently saw this variety in a trial of Lettuces, and it was quite solid when many others had bolted. For several years I grew this variety and I liked it greatly, but some objection was made to its colour, a light coloured Lettuce being preferred, such kinds as Golden Queen being always asked for. For a season or two I have not grown Continuity, but intend to have some in reserve in future. Where Lettuces are needed in quantity, no one will find a better variety, and, I may add, if Cos varieties are needed, the Bath or Brown Cos sown for summer use is one of the best in hot, dry summers. This and the one "E. B." advises will not fail. In hot weather some of the summer Cos Lettuces bolt before half grown and the crop is lost, but those named are always reliable.—S. H. B.

**The American Potatoes.**—This has been an ideal season for such kinds as Early Rose, Beauty of Hebron, Puritan and other large growers. Owing to heat and drought, the amount of moisture generally found in these kinds is less and the quality superior. We often see these varieties objected to, and in wet, sunless summers they are not good. Much, however, depends upon the soil and position where grown. If the soil is light and poor or at all shallow, Early Puritan is excellent, and need not be discarded, even in wet seasons, if lifted early. For heavy clay soils I would not advise these kinds, as they are subject to disease. Neither should they be grown under trees, no matter how good the soil, as if the season is at all wet it is fatal to these kinds. I have noted they are very heavy croppers, and this makes them valuable market varieties, as they can be lifted early and find a ready sale. Grown in fresh land yearly they give a good return, but should not be crowded, owing to the robust top-growth. This year from light soil these American varieties are of splendid quality when cooked.—G. W. S.

**Vegetable Marrows.**—When the fruit committee were invited to examine in Chiswick Gardens a couple of Vegetable Marrows that had presumably been sent from the Levant, that body found very poor products, such as would be classed in our lists as very second-rate. It does seem evident that improvements in these edible Gourds come very slowly, we might almost say do not come at all. With the exception of that most useful variety, Pen-y-byd, the best and most prolific of its class, nothing particularly distinct has been introduced for many years. The Custard Cream Marrow or Gourd, once so much favoured, seems to have lost favour altogether, and the long, tubular-formed fruits are most in request. But these, as vegetable food, give very poor material, consisting, as they do, of about 85 per cent. of water. Without doubt, the best food is found in some of the so-called Squashes. One was the Ohio variety, that used

to be much grown some years ago. It is, however, a coarse grower, and a worse fruiter, the fruits being yellow. There seems to be a prettiest wide field open to anyone, who has leisure to strive to produce amongst Marrows some variety that is as good and much more attractive than is any one we at present possess. He seldom the bush varieties are met with, although they produce very white, handsome fruit. Probably they do not crop so continuously as the free growers, yet these cover a maximum of ground, and give but a minimum of fruit. Generally, Marrows are eaten far too large, and in the production of these large fruits, no doubt the plants suffer a severe strain, which checks productiveness.—D.

## STOVE AND GREENHOUSE.

### SUMMER TREATMENT OF CALLAS.

I was very much interested in the remarks of "A Midland Grower" recently contributed to *THE GARDEN*, concerning a method of culture the above that I recommended a year ago. It is interesting to know that success has been achieved by what, to me at least, is not at all a new method, seeing I have practised it for a dozen or fifteen years. And while I have no desire specially to persuade gardeners to alter their modes of culture, one cannot refrain occasionally from putting forth a system which decidedly minimises labour to some extent at least in summer, and at the same time provides much earlier supply of blossom than is possible under the best means of culture by any other system. Again, the system advocated by me of simply laying the pots on their sides, or making a stack of them in any out-of-the-way corner, should have some weight with the gardeners who have not too much assistance or much room at command, and yet are expected to produce flowers at almost any moment. A gardener with limited space for planting such things in the kitchen garden, or equally good place, should be only too glad to know that quite as good if not indeed better and finer blooms can be obtained, if instead of planting such things in a deep, prepared trench of rich soil, he merely lays his plants for six weeks at least on their sides. In gardens that are under-manned a few batches of winter flowering plants that could not be dismissed from all attention culture would be a boon indeed. And in truth as it came to me a few years ago, when growing several hundred plants of these Callas. So very old gardeners who saw these hundreds of plants scorching to death, as they termed it week by week in the great heat of the Jubilee year, 1887, prophesied many things concerning the future of my plants, none of which were ever realised. Independently of the saving of time, and the assurance that good spathes would be had weeks in advance of those from the planting-out system, is the fact that the plants that are thus dried off are so much dwarfed and more compact. There are also a freshness and vigour about them never seen in the bigger, coarser specimens that have been luxuriating in rich soil all the summer long, when they should have been enjoying a well-earned rest and flowering steadily all the previous winter. Given the rest and change that I have come to regard as almost a necessity, the corns are more than the average of stored-up energy ready to commence flowering again. The plants blooming as they usually do under six weeks from potting up again, and the pure white massive blooms are the best answer as to wisdom or otherwise of the system. E.

## GREENHOUSE AZALEAS.

The greenhouse Azalea is one of the most popular of indoor plants. With good treatment plants never fail to do well, and to outlive a greater portion of other hard-wooded things grown in pots. In fact, Azaleas are amongst the longest lived of the various tribes of greenhouse plants. In proof of this I may instance several large collections that are in the hands of some of the market growers near London, many of the specimens in which are known to be twenty years old. They consist mostly of the

carefully cared for, it usually takes two years to bring them round. After all it may be said that there is some plea to justify this way of treating Azaleas, inasmuch as most of what has been written on their cultivation is to the effect that the turning-out process is the right course to follow. Another source of weakness that Azaleas, in common with most other hard-wooded plants, suffer from is want of sufficient nutriment. In the case of pot plants of the numerous kinds that bear partial shaking out and repotting annually, the old material which has become

in some form. That old Azaleas can be kept for a long time full of strength and vigour I have proved with specimens that have remained undisturbed in the same soil for ten years, and at the end of the time they made as good wood as when they were young. Peat of even the best quality is not rich enough to enable Azaleas to make the growth they should do. The assistance that is required in this way to either get young Azaleas on quickly or to keep up the vigour of old plants is much more than seems to be generally supposed. When ordinary manure water is used for old specimens it should be given once a week during the time that the plants are making their growth, and up to the time the wood is approaching a hard, mature condition and the buds are prominent. After this stage has been reached it is doubtful if manure in any shape does not do more harm than good.

Regarding the new varieties of Azaleas, many of which have been sent from the Continent within the last score of years, it is doubtful if they are any improvement on the well-known older sorts. Some of them are an advance in the colour and also in form of their flowers, if we accept the florists' circular outline as the standard to aim at. The flowers in the variety figured are salmon-scarlet flamed with white. The plant illustrated has been grown in a thoroughly natural way, hence we get the shoots loaded with blossoms.

GROWER.

A naturally grown plant of *Azalea Verraeana*.

White and Fielder's White, which is only slightly different from the original sort. The plants in question are full of vigour and make spots from 8 inches to 15 inches in length annually, only a small percentage of which fails to flower.

The weakening effects which turning out-of-doors has on plants whilst making their growth may be seen in hardy shrubs that have been overwintered in pots under glass when treated in this way; the partially formed shoots do not thicken, the immature leaves look yellow and sickly, and when the plants are again planted out and fairly

exhausted is to a great extent got rid of and its place supplied by new. With Azaleas and other things of a like description, the nature of which is such that they will not submit to be treated in this way, the roots remain for years in the same soil, and unless something is done to make up for what the roots extract from it, the whole becomes so poor that the plants cannot do more than exist in it. This is what takes place with old specimens that, after being put into pots as large as it is convenient to give them, by-and-by become dependent on what they receive in the shape of manure in

**Begonia Worthiana.**—This Begonia which is largely used in the flower garden is interesting from the fact that it still remains so popular, while the different varieties raised about the same time have in nearly every case disappeared from cultivation. The early history of Begonia Worthiana is given in the French journal *Le Jardin* for August 5, from which it appears that this variety originated as a seedling from *B. boliviensis*, and was raised by M. Barré, gardener to M. Worth, at Puteaux, in all probability in 1869, as it was described by M. Carrière, and by him named *B. Worthiana* in 1870. As *B. Sedeni*, which was the first hybrid tuberous-rooted Begonia raised in this country, was distributed in 1870, it will be seen that *B. Worthiana* stands out as one of the earliest hybrids of this class.—T.

**Bouvardia leiantha.**—This is a pretty and bright old greenhouse plant not often met with. Its habit is distinct from that of the garden hybrids belonging to the genus, such as are now grown in immense numbers everywhere for cutting. The corymbs of flower are not so large as those of the hybrids, but of a pretty soft scarlet colour that is very attractive, and these are very freely produced all through the autumn and early winter. Indeed, there is hardly a month in the year when flowers may not be looked for, and in the west of

England it is often used for planting out during the summer months.

**Zonal Pelargonium Oreste.**—We have had many distinct Pelargoniums sent to this country by French raisers, among those of recent years being *Souvenir de Mirande*, which was the commencement of a distinct and now popular section of single-flowered zonal Pelargoniums. A couple of years or so ago M. Lemoine, of Nancy, sent out a zonal Pelargonium—*Alliance*—remarkable for its speckled blossoms, and the above-mentioned variety *Oreste* is in the same way, but with its distinctive features more pronounced. The ground colour of the flower is a kind of lilac-pink, dotted

profusely, especially on the three lower petals, with bright purple. The dotting is far more dense towards the centre of the flower than it is at the margins. This variety presents such an uncommon appearance, that it will be sure to attract attention, although it can scarcely be regarded as a particularly showy form. Being such a decided break away from existing kinds, this will doubtless be employed by the hybridist in the production of new varieties. *Pelargonium Oreste* is one of M. Lemoine's raising, and was sent out by him in the spring of this year. As far as my experience extends, it does not appear to be particularly vigorous.—H. P.

**Fuchsia Countess of Aberdeen.**—This distinct plant should make a most effective group. It has pure white blooms, which are small, but produced with such remarkable freedom that a complete mass of pearly drops results. It grows into a close bush no more than a foot high. As a pot plant it is a striking object, so unlike any other *Fuchsia* that all who see it are charmed.—H.

### LILIUM NEPALENSE.

This Lily is certainly one of the most distinct members of the entire genus, and forms a very attractive object in the greenhouse, for to be seen at its best it needs that amount of protection. A great deal of interest was attached to this Lily when it was first shown in flower by Messrs. Low on September 11, 1888, for whether it had been previously introduced is at least an open question, and from the various rumours of what *L. nepalense* was like, no one was prepared to see such a beautiful and distinct Lily. It is now generally well known, but a fair amount of individual differences exists in the case of this Lily, as well as in many other species. In some the chocolate-purple centre extends farther down the flower than in others, while the lighter coloured reflexed portion varies a good deal in its shade of yellow or greenish yellow. While this Lily can be readily flowered in a satisfactory manner if good imported bulbs are obtainable, it is really a very difficult species to cultivate, as the second year the display of blossoms will, as a rule, be few and far between. From this circumstance, continual importations are necessary to keep up the supply, and as they are collected in a wild state and not cultivated for the purpose, as is done in the case of the Japanese kinds, it is very probable that *L. nepalense* will soon get much scarcer than it was, as has already happened in the case of the *Neilgherry Lily* (*Lilium neilgherrense*). *L. nepalense* is a native of Upper Burmah, and other species from the same region are *L. sulphureum*, *L. Bakerianum*, *L. primum*, and *L. Lowi*. Of these, *L. sulphureum* still reaches this country in considerable numbers, *L. Lowi* crops up occasionally, while the other two are quite rare. A notable feature about these Burmese Lilies is the great general resemblance that the bulbs bear to one another, for although one may select some individuals with a certain amount of confidence, yet in the case of others it is quite impossible to speak with any degree of certainty till growth commences. *L. sulphureum*, as a rule, has larger and darker coloured bulbs than the others, but small ones of this species are very puzzling. In the case of *L. nepalense*, and, in fact, all the above-mentioned kinds, the bulbs should be potted as soon as received, which usually happens in the first two months of the year. Pots 5 inches or 6 inches in diameter will be sufficient for even the largest bulbs, as, in common with all Lilies, overpotting must be avoided. The pots should be well drained, and a mixture of loam, peat, and sand forms a very suitable compost. In potting, the upper part of the bulb should be about half an inch below the surface of the soil. If the soil is kept fairly moist, the roots at the base of the bulb will soon become active, but it is often some time before the shoot appears above the surface. The shoots of this Lily are stont, but few in number, and while in the case of some Lilies a great quantity are pushed out at the base of the flower-stem, in this

species they are not at all numerous. After potting, a cool greenhouse temperature, such as that in which *Pelargoniums* thrive, will suit *L. nepalense* well. During the growing season the principal care will be to keep the plants clear of aphides, as they quickly do a considerable amount of injury if allowed to congregate among the young unfolding leaves. H. P.

### BOUVARDIAS.

Good flowering plants in pots are not over plentiful at this season of the year. Although *Bouvardias* are usually regarded as late autumn and winter flowering plants, they may be had in bloom nearly throughout the year. One-year-old cut-back plants are best for early summer blooming, but early-struck cuttings make good plants for flowering in August. The variety most suitable for summer flowering as a pot plant is *Candidissima*, with pure white flowers. This forms a very dwarf and compact plant, and if stopped evenly, all the shoots will come into bloom at the same time. *Jasminiflora* is another good white, and *Jasminoides paniculata* may be recommended, being very free-growing and dwarf in habit. *Reine des Roses* is perhaps the best pink for summer. Grown under the same treatment it will come into bloom some weeks before most varieties. *Mrs. R. Green* is a general favourite. It varies a little in colour, but at its best the colour is a very pleasing shade of salmon pink. *President Cleveland* is by far the best scarlet we have, and I am surprised that the other scarlet sorts are kept in cultivation. The oldest scarlet variety, *Hogarth*, is still in demand. The double variety of this, *A. Neuner* (white), and *President* (Garfield) (pink) include all the doubles worth growing. Several other singles might be named. *Humboldtii corymbiflora*, though not suitable for pot work, is very useful for cut bloom. This flowers well when planted out in the open, but as the bloom is so easily damaged by wind or wet it is more useful when grown under glass. To keep up a succession of bloom the plants must be potted in a good rich compost, and after the pots are well filled with roots, manure may be used freely. No shade whatever should be given, and if watering is properly attended to, the hottest sunshine will do no damage.

In growing those recommended for pots, it is important to propagate as early in the year as possible. The plants should be potted in light porous soil and grown on in warmth during the early part of the season, and later on they will do well in cold pits, the lights being taken off in favourable weather. Stopping the plants requires careful attention. Each time they are gone over all the shoots should be stopped, and each time they should be stopped back to within one joint of the previous growth. Although *Bouvardias* enjoy hot, dry weather, they must not be allowed to get too dry at the root, and the syringe should be used freely, which will go a long way towards keeping off insects. Clear soot water may be used, but this must not be applied when the sun is out. H.

### MARGUERITE CARNATIONS IN POTS.

THESE are grown for late autumn and early winter bloom, and very useful they are at that time, when Carnations generally are over, and so many things in the outdoor garden are past their best. They are, however, equally serviceable during the spring months, and it is possible to have a good supply of Carnations up to the time they begin to flower in the open ground. I do not consider this race of Carnations of much service for midwinter bloom: they form buds freely in the autumn, but the blooms do not seem to have much substance when they open and quickly fade. From the beginning of March onward they come good in form and colour, and have that delicious fragrance which is almost entirely wanting during the dull winter months. The culture of the *Marguerite Carnations* is remarkably simple, consisting in putting them out in early

spring in well-worked, fairly enriched ground, a lifting and potting them late in summer or early in autumn. Many sow the seed in early spring in warmth, but I much prefer to sow in July early in August in a cold frame. The seed germinates freely at that season, and the young plants can be kept in a cool house through the winter coming into the open air in spring, without having been subjected to the debilitating effect of artificial heat. No hardening off is necessary, as is indispensable in the case of plants raised in heat February; and if planting out for the summer months is to be practised, the young plants can be set out a month or six weeks earlier than otherwise be the case. Some grow these Carnations in pots during the summer, but I am decidedly in favour of putting them into the open ground. Healthy young seedlings put out early in April will grow into specimens large enough for 7-inch pots, and they will be crowded with buds by the close of the summer. Early planting admits of early lifting, the plants being large enough to pot up by the middle of August. Flower-spikes will be thrown up, when the plants are doing well, early in July; but they will have to be pinched off, as flowers are not required before October, just as outdoor things are mostly over, and the formation of side growth is thereby encouraged, so that compact leafy specimens with abundant foliage down to the rim of the pot are obtained. From the beginning of August the flower-stems should be allowed to put up, as these will give a crop of bloom during the autumn and early winter months. If the weather is dry, it is advisable to give a good watering the day previous to lifting. Pots only large enough to contain the roots should be used, as the object is to get the plants as pot-bound as possible in winter. The small amount of fresh soil necessary should be very fine, so that it can be worked among the roots. If the plants are stood in a cold frame, shaded from hot sun, and kept rather close for a few days, they will soon make new roots, and can then be exposed to the full sun. I have had plants treated as above recommended, the roots of which could hardly be got into 8-inch pots, and which gave a constant succession of bloom from November to July. The colours, too, are really good, ranging from pure white to the darkest crimson, and they have the true Clove scent.—J. C. B., in *Field*.

## ORCHARD AND FRUIT GARDEN

### EARLY PEARS.

THE *Hessle*, or *Hazel*, as it is more often called, was years ago planted in great quantities; indeed, it was the chief fruit in market garden. Around the metropolis there are still many old gardens with trees of this variety, which rarely fail to fruit. This early Pear is in season in September, and is an enormous cropper. Early varieties should not be grown to the exclusion of late varieties, but with a garden of any size few early fruits are most useful, such varieties as *Jargonelle* and the small, but very early *Doyenné d'Été*, which is one of the very first Pears ripe, being fit for use in July. It is small, but refreshing, and of good flavour when gathered a few days before it is ripe; indeed this remark applies to the *Hessle*, the *Jargonelle*, and most of the early kinds.

The newer *St. Swithin* is one of the earliest Pears I have grown, and a note on early Pears would be incomplete without referring to this variety. This season it was ripe the third week in July, and a few fruits were earlier. *St. Swithin* is a medium-sized fruit if well grown, but, owing to its free-bearing qualities, it should be well thinned. In appearance it is not unlike a small *Jargonelle*, and, like that variety, is of poor quality if allowed to hang till the fruit are fully ripe. I have it in cordon and bus

form, and it never fails to give a good crop, but cordon trees are the earlier. As regards the quality, it is variable. I consider it superior to the Hessele, and a few fruits should be

am now gathering very nice fruits of excellent quality and of grand colour. For some years I grew Waterloo in pots, and found it one of the best, but never remember to have seen it so good on walls as this year, the flavour also being first-rate. On a south wall this variety was ripe on July 16, and the trees on the west aspect have provided fruits since that date. The fruits from the west wall are much finer than those from the south wall. There is one thing these early Peaches need, and that is severe thinning, as the fruits lack size if at all crowded. I prefer this variety to Early Alexander for walls, and it is more reliable as regards crop. With me it rarely fails to finish fruits of good colour and size. G. W.

**Strawberry runners.**—The season has been one of the worst on record as far as my experience goes, as regards the rooting of the runners, the excessive heat and drought having checked growth. The earlier runners did fairly well, but made more progress. I am sure where the plants bore fruit the runners will be late. Fortunately, we had a nice rain on the 8th, and things will improve greatly. One will need to exercise patience as regards planting if earlier runners from special plants were not procured. I am a strong advocate for reserving a few plants or rows for runner production, not fruiting these, layering early, and planting also, as plants in their permanent quarters will do grandly and get the benefit of the much-needed rains. I am sure large growers will experience a difficulty in getting an ample supply, as runners on certain varieties are very scarce. I prefer a plant of medium size with a single crown to those larger newer varieties with several crowns.—G. WYTHES.

**Apricot trees in hot weather.**—Although trees in very many gardens are this year minus fruit, the crop for next year will to a great extent be jeopardised if the roots are allowed to become too dry, and thus the wood and fruit-buds improperly developed. No wall fruit trees suffer sooner from insufficiency of root moisture or show it quicker than Apricots. If the leaves droop and assume a bluish tint, it may be concluded root-dryness is the cause of it. I have seen trees which showed such symptoms one day reconp themselves and even improve in colour by the next after a good soaking of water. If by any means possible an extra effort should be made to do them justice in the way of manurial waterings between now and when the foliage changes, as the rest the trees are having this year, though causing temporary uneasiness to the grower, ought to result in stouter wood and an improved condition generally, and consequently better crops in 1898.—J. C.

**The Loganberry.**—I, like Mr. Clark, was much interested in the remarks made on this American fruit in a recent issue. I procured two plants early in the spring, also two plants of the

Mayberry and two plants of the Strawberry Raspberry. I potted them up in good loam and placed them in cold frames. They have all grown into good plants. I have now planted out the two first in a warm border, and hope next year to get good results. One of the Loganberries bore about a dozen fruits, something like a dark-coloured Raspberry, but longer. These were of a brisk flavour, but very pleasant. The Mayberries have made good growth, but no fruit has shown on them, but on one of the Strawberry Raspberries three flowers have appeared, so that I hope to see the fruit this year. The foliage of the last plant is very pretty. With me it does not seem likely to make nearly so large a bush as the two former.—W. TOWNSEND, Sandhurst Lodge.

FRUIT TREES FOR NORTH WALLS.

In most gardens walls having a northern aspect are only used for the cultivation of the Morello Cherry, which, I think, is a pity, as in many parts of the country other subjects, such, for instance, as choice late dessert Plums, succeed admirably on north walls, to say nothing about Red and White Currants and dessert Gooseberries. Where Morellos are in demand as late as they can be had, it is then necessary to accord the trees a position where they will be shaded from the sun during the hottest part of the day, and such a position with the necessary amount of shade they experience when grown on a north wall. For the earlier supply, Morellos may just as well be grown as bushes as not, for they bear exceedingly heavy crops grown in this form, while the individual fruits are quite as large, and they hang for a long time if netted over. If this is done, the space they would otherwise occupy on the walls can be utilised for the growing of Plums as indicated above. Those who have to provide a large and varied dessert through the autumn months know full well the value of having a few trees of choice kinds of dessert Plums to fall back upon when indoor fruits other than Grapes begin to become scarce. Such kinds as Coe's Golden Drop,

Pear Hessele.

gathered daily; these will be fit for use in a day or two. Left on the trees they are mealy and poor-flavoured. Another very early Pear and little known is the Lawson. This was shown at a recent meeting of the Royal Horticultural Society. It is of good size, not unlike Beurré d'airgeau in colour, but a second quality fruit. It should not be allowed to ripen on the trees. The well-known Williams' Bon Chrétien, a larger and more melting Pear than the Hessele, has of late years taken the place formerly held by the Hessele, and being a larger fruit and ripe at the same season, is doubtless more profitable, but is not so reliable a cropper. The value of these early fruits is that they can be gathered a few at a time, thus prolonging the season. When the bulk is gathered the coolest storage should be given them. The Hessele Pear cannot be classed as first-rate, but it is valuable, as it thrives in positions in which better or later kinds would not give any return. The fruits may be termed below medium size, greenish yellow when ripe, and such spotted with russet, flesh juicy, sweet, and pleasant. In some soils the fruits are gritty near the core, and after housing require to be eaten quickly.

The tree is a pendulous grower, and even when grown for shade or ornament is well worth space in a small garden, as it is a pretty object when in bloom, being as fine as our best flowering trees or shrubs. Most of these very early Pears are grown as standards, but I have seen them made good use of in other ways. They may also be grown as espaliers, or horizontally trained along the sides of walks, and when grown in this way give much finer fruit and of better quality.

GROWER.

**Peach Waterloo.**—I am much pleased with the above variety this season on a west wall. I

Pear Williams' Bon Chrétien.

Jefferson's and Ickworth Impératrice will hang in good condition quite as long as the Cherries if covered with coarse muslin or very thin tiffany as a protection against birds, wasps, and flies while they are ripening. I have frequently gathered Golden Drop in the first week in November, and although the fruits have been

somewhat shrivelled, the flavour has been exceedingly rich and sugary, and, I need hardly add, greatly appreciated when sent to table.

No special culture is needed for growing Plums on such a position, and as a rule, owing to their flowering later than their brethren out in the open and those on walls having warmer aspects, they escape the effects of spring frosts and invariably set good crops of fruit. Last winter I planted cordon trees of the newer varieties of Plums on a north wall as an experiment, and hope to prove a few of them another season. This is an excellent way of clothing a wall quickly, and awkward portions of the wall, such as buttresses, lend themselves to the growing of cordons. Fan-trained trees also give abundant crops of fruit, and a favourite plan of mine is to plant these 12 feet apart, with a cordon between every two trees, not necessarily of the same variety, but so selected that the fruit will ripen about the same time on account of affording them protection against bird and wasp attacks. I have heard and read of early Pears being grown against north walls, but never put the matter to the test; but Plums will and do succeed admirably, and where north walls are of considerable extent and the climate suitable, I would strongly recommend that a portion of the same be devoted to the growing of dessert Plums for late autumn supply. Gooseberries are also a very profitable crop when grown on north walls, and the fruit may be had much later than when grown on bushes. The best way to grow these is as cordons with from three to five branches, which should be trained perpendicularly in the same manner as upright cordon Pears or Plums. Currants of both the red and white varieties bear most profusely grown in the same way, and come in useful after the fruit on the bushes out in the open garden has been gathered. Where autumn-fruiting Raspberries are grown, these late Currants are then doubly useful, as they can then be utilised for tart-making in addition to being useful as an adjunct to the dessert. A. W.

#### POTTING FORCING STRAWBERRIES.

The potting of Strawberries for forcing may be later than usual this year, but there need be no fear of poor crops if the plants are not over-potted. I am aware many growers like to get their plants into the fruiting pots at the earliest possible date, but, after some years' experience, I have come to the conclusion one may pot too early, as if the plants make a second growth and show flowers freely before the winter, they do not force so well the next spring. I find plants potted, say, early in August quite early enough, as they make one crown, this a good one, and the embryo flower-truss is dormant till started for forcing. I know it is an easy matter to thin the crowns, but not in the case of all varieties, as some split up so badly that it is impossible to get one strong crown when the plants are potted up very early. On the other hand, I do not advocate delay, as, unless the plant fills the fruiting pot with roots before being housed or placed in the winter quarters, there will be a collapse if such plants are forced hard, as, having few roots, the crowns will fail to swell when the plants are called upon for increased exertion. I think what may be termed the middle course is a safe one. At one time I was under the impression one could not pot too early, but a severe failure convinced me of my fault, and I am not sure if too early potting with certain varieties, such as Vicomtesse H. de Thury, is not the cause of so many weak trusses. Far better have one or two strong ones, and not a mass of useless ones not strong enough to bear the fruit when set. Doubtless the cause of failure is that the plants have lost vigour owing to the roots having exhausted all the food in the soil. Much depends on the locality where the plants are forced

and, of course, how forced. If not required too early, there is ample time for the plants to grow if potted as advised. If runners are not strong, much better use a smaller pot and get one strong single crown. I have advocated early potting, and I am a great believer in a fair-sized plant and the usual Strawberry pot. I have found there is no gain in coarseness, and would prefer the medium course after a severe trial of the various kinds usually forced. Doubtless my remarks would not apply to plants needed to fruit, say, in January or February, as here the cultivator would need to get the earliest matured plants. I have seen splendid results from very late potting, but much depends on how the plants are wintered and forced. G. WYTHES.

#### SCARCITY OF PLUMS.

This is the general cry in this part of the country, and when we find such varieties as Orleans fetching 20s. per bushel in the market, it is a sure sign that they are scarce. There is no doubt that for several years there has not been so short a crop, as but very few trees in exposed situations are carrying any fruit, while those in more sheltered positions have only a few. Some varieties, however, are much more prolific than others. This is owing either to their flowers not being forward enough to be injured by the late spring frosts, or because they are hardier. On looking over the plantations here, I find that Early Rivers, Orleans, The Czar, Victoria, Stint, Wyedale and Bush or Waterloo are carrying by far the best crops. Some of these varieties are but little known, and on that account are not so extensively grown as they deserve to be. The Czar is a most prolific early kind, of fair size, having a dark skin. It is seldom that the rains cause it to split unless allowed to hang till over-ripe. Where a quantity is required for preserving, this should be largely grown. Stint is rather a new variety of medium size, coming into use early, in August. This with me is most prolific both as a bush and against a wall. Victoria is so well known that it requires no description; a tree or two should always be planted against a north wall, in which position a full crop is generally grown. Wyedale—a variety far better known in the north than in the south—is of medium size and keeps good till quite late in the autumn, often plump till the middle of November. The heavy rains do not seem to affect its hanging like some other of the late kinds. This season, though so unfavourable for most varieties, the trees are carrying a fair crop. Bush or Waterloo is a fine late Plum that seldom fails, and even this season it is no exception. Turning to trees growing against walls, strange to say, those on a northern aspect are by far the best, as many on walls facing south have scarcely a fruit. Coe's Golden Drop, Jefferson's, Washington and some others are particularly conspicuous in this respect. In the southern counties it is advisable to plant such varieties against a north wall, as the autumnal rains do not seriously affect them when ripe. Plums as a rule are fairly hardy, a few degrees of frost taking but little effect on the expanded flowers. When there are from 8° to 10°, as we sometimes have for several hours together, there is but a poor chance of saving them from injury. By planting as before advised, the blooming period is often retarded, so that there is less risk in this respect. A row of Victoria that was shaded by some tall Apple trees is now carrying a full crop, while trees more exposed have scarcely a fruit on them. Plums are far more useful than Pears, as they may be used for a variety of purposes; therefore it is well to allot the choicer kinds positions on walls in preference to the latter, as they usually give a greater return for the labour expended upon them. Most of the hardier kinds may, however, be depended upon to give a supply of good fruit when grown as bushes and protected by a belt of trees to ward off the cold winds. H. C. P.

Busted Park, Uckfield.

#### TREATMENT OF YOUNG VINES.

REFERENCE was lately made to the class of borders that market-growers have to be content with, and which answer surprisingly well. There is no disputing the fact that the treatment of young Vines varies considerably, and it is equally certain results are also most variable. I hold that planting strong canes, or any supposed to be large enough to produce bunches the first season, is quite a mistake, yet it is often done. Even as supernumeraries they are a failure. If purchased they cost too much, and in any case they rarely give enough good bunches to pay for the trouble taken with them while the start, as far as forming stout canes is concerned, is frequently deplorable. Vines do not move well out of 10-inch pots, but they might be made to produce a crop if kept in their pots and liberally treated at the roots, and that is what I would do with them. I have long advocated keeping supernumeraries, or those that are to be cropped heavily for two seasons or so, well away from those intended to be permanent, because they greatly interfere with their progress. Supernumeraries ought not to be planted at all; they are not wanted. All that is required is to make a good start with permanent Vines, and these may then be freely cropped the following season. Pampered young Vines do not often develop into really good serviceable rods, and may easily prove the opposite. A gross start—such a result when extra strong canes are planted and duly cut down—is objectionable. Either future progress is somewhat on a par with the commencement, long-jointed, pithy canes resulting or else they cease growing so soon after the first burst, waiting for further supplies of sap from roots which have to be formed, that the wood becomes hardened and not much further progress is made that season. Short, well-ripened canes, not much larger than the stem of a clasp pipe, and strongly rooted in either 5-inch or 6-inch pots, are, in my opinion, much the best for planting in all positions where the sunshin can reach them, and no Vine ought to be planted, where it can possibly be avoided, in a dark place. There are no stagings along the fronts of market growers' houses, no planting between coils of hot-water pipes and from walls, and no bringing canes through from the outside. These difficulties private gardeners have to contend with, and they greatly interfere with a good start being made. If long canes must be planted, by all means plant them, but I have a great objection to long, naked stems, and like to have my Vines on a flat border where they do not suffer from contact with hot water pipes and are favoured with much of the light and sunshine going. A few words as to

#### WHEN TO PLANT.

October is given as a good time to plant ripened canes, as in this case the Vines have chance to form a few fresh roots before they go to rest, starting stronger in the spring accordingly. I have nothing to urge against this practice, and little or nothing to say in favour of it. If the border was ready and the course clear then I might plant in the autumn, but it has usually answered my purpose to plant in the spring. Supposing the young Vines were raised in the spring previous, duly topped, as they should be when about 2 feet long, and arranged outdoors all the summer, these would be harvested late in the autumn, or cut back to within 3 inches of the pots, and wintered in a cold house or frame. Early in February they would be started into growth in a temperature of about 55°, and directly the buds commenced moving, the time will have arrived for planting

When turned out of pots, these small Vines should be found particularly well furnished with roots compared with their size, and these ought to be washed or shaken clear of soil so that the roots may be spread out flatly and evenly in the soil. Thus treated the young Vines start moderately strongly and keep growing from the first, developing into fine fruiting canes the same season. If larger Vines were planted, I would yet advise cutting them down to near the ground, so as to have an even swelling throughout and no stunted lower portions of stem. Vines raised from eyes started, say in January, may be planted the following April or May with a good prospect of their becoming strong enough to give bunches during the next season, but not if Tomatoes were in full possession of the house at planting time. The "cut-backs" planted in March and grown from the first in gentle heat more than hold their own with the Tomato plants on each side of them, and eventually gain the upper-hand.

Market growers crowd their rods more than thought desirable by private gardeners, but they do not invariably plant the young Vines thickly. They have to study the Tomatoes. The majority of their houses are span-roofed and the Vines are planted on both sides. If disposed at a distance of 4 feet apart, there is good space for a row of Tomatoes midway between for two years, and half rows during the third season. The Vines are not arranged exactly opposite each other, but are triangled; this does not interfere with the lines of Tomato plants, because the pathway is in the middle. Eventually each rod is taken clean over an arched trellis, or from one side to the other, and they are then not more than 2 feet apart. In some instances the rods are not taken any further than the apex of the roof, and in this case a second cane is laid in after Tomatoes can no longer be grown in theinery. Personally, I prefer the arched trellis, or what amounts to be the same thing, training up longitudinal wires passed through long eyes screwed into the sash bars of the roofs and across Bamboo canes—a decidedly cheap and convenient arrangement, obviating the use of high steps and keeping the Vines well away from the glass at the hottest part of the roof. So far I am in agreement with the authorities, except perhaps with regard to the homely trellis. Where the difference comes in is in the matter of

#### STOPPING AND PRUNING.

In Mr. Barron's admirable treatise on the "Grape Vine" occurs the following passage: "Once fairly started, young Vines are all the better for the first summer, to be allowed to grow and ramble pretty freely, with as little stopping and pruning as possible. The more leaves and shoots developed the more roots produced and the stronger the foundation laid for the future plant." The writer of this paragraph is far from being alone in his views upon the free growth of young Vines, but I have ways fought against it, though admittedly in minority, and the more experience gained the more thoroughly convinced I become that Mr. Barron and those who follow the lines he has laid down are wrong. Fortunately, the average market grower is not tempted to allow his Vines to "ramble pretty freely," for the simple reason that his rent-paying Tomatoes would suffer from undue shade. Why allow so much growth to form only to cut it all off again? His rambling growth may be the means of promoting the increase of roots, it does so in fact, but they are of the wrong character—course and rambling, whereas it is abundance of root fibres that I prefer to find, as these and these only conduce to the formation of stout,

short-jointed hard canes, which will last as long as those in charge may desire them. This unrestricted growth is so much wasted vigour, also leading to a loss of fertility in the border and in particular a loss of time. The idea reads prettily, but there is nothing in it.

In March, 1896, I planted about fifty small cut-backs, and grew Tomatoes in pots between them in the way usual among market growers. Out of these three only are not carrying bunches at the present time. The strongest are furnished with six bunches each, or weighing on the aggregate not less than 9 lbs. weight; others have four bunches each. In addition to producing these bunches every Vine has formed long leading canes that any gardener might be proud of, the older portion of the rod also swelling satisfactorily. Those planted on the opposite side of the house in 1895, and cropped equally heavily last season, are now furnished with an average of twelve bunches each, these also being full of vigour and forming strong leading canes. There is nothing remarkable about the border, as this was only so much manured and trenched ground, prepared with neither more nor less ceremony than many gardeners bestow on their Strawberry beds. I shall be disappointed next season if these older Vines fail to mature less than twenty bunches each. I attribute this success largely to having never allowed the Vines to grow to waste. Timely stopping has invariably been practised, this applying to both leading and lateral growths. If the young Vines or the leaders on those planted longer are weakly, they are topped when about 4 feet long, while those that grow strongly are topped at a height of 5 feet to 6 feet. All lateral shoots from these young canes are stopped beyond the first leaf, and the breaks from these also just beyond the first leaf. Treated in this way the canes swell evenly and strongly, but there is no premature loss of primary leaves as frequently happens when the lateral growths extend and swell. It is the first formed leaves that do the best work, and only on stopped Vines do these develop properly and survive to the end of the season. All the winter pruning required in the case of one-season canes is to shorten these lightly, or only to the extent of removing the ends that have pushed out growths from buds that should have remained dormant till the following spring. I find the Vines carrying three bunches were shortened to within 3 feet to 4 feet of the ground, and those more heavily cropped were left to a length of about 5 feet. Those too weak to bear fruit were cut down to within 6 inches of the border. All have 6 feet leading canes of fresh growth. W. IGGULDEN.

**Melon notes.**—Melon Gunton Orange will not set with me. Is it a very shy-bearing variety? My attention was called to it by several notes in THE GARDEN. All the other sorts, like Hero of Lockinge, Conqueror, Scarlet Premier and others, thrive well and set freely. The fruits of Gunton Orange turn yellow one or two days after setting. The plants of Gunton Orange are, I think, the strongest in the whole house. Frogmore Orange, also grown for the first time, cracks badly and will be discarded. I fancy that the best white-fleshed variety is still the old Hero of Lockinge. Which is the best scarlet-fleshed Melon?—R. K., *St. Petersburg*.

**Nectarine Early Rivers.**—This new Nectarine is this season much finer, the quality being excellent. My first fruits were really earlier this season than last. I had a nice dish on the 24th of July and gathered daily until the 7th of August. The fruits have been remarkable for their splendid colour in addition to their size. There can be no question as to the earliness of

Early Rivers, and I have trees on west and south walls, in each case planted side by side with Lord Napier, a favourite variety with me. The newer variety is equally good, and as regards earliness of great value, and deserves all that was said in its favour when sent out. Those who have a demand for fruit at this season may with confidence plant Early Rivers where Nectarines do well, as it is a good grower, makes splendid wood, and with me does not crack like some kinds. It sets very freely on both aspects named. My trees are dwarf trained in both cases.—G. WYTHES.

**Fruit crops on the south coast.**—This has been a most disappointing year for fruit growers—at least, in this locality, for the promise of spring, as far as abundance of bloom was concerned, led me to hope that a record year was at last to smile on the fruit grower, but cold winds, rains and late spring frosts proved too much for the tender bloom, or rather for the embryo fruits, as Plums, Cherries and other stone fruits appeared to be setting remarkably well. They did not swell away kindly, and soon began to assume a sickly yellow look and fall to the ground. A more complete failure of all hardy stone fruits I never remember. Pears flowered magnificently, but there is a very scanty sprinkling, the only kinds that have anything like a crop are the small common sorts. Apples that, fortunately, did not flower until more genial weather prevailed are a good crop and promise to swell to a good size. Bush fruits have been thin crops. Strawberries that are grown in large quantities about here were plentiful, but very soon over, and growers did not realise any of the fancy prices they were expecting in Jubilee year, for after the first week of gathering prices dropped lower than they usually do. The late frosts cut off the earliest and finest blooms. Sir J. Paxton still holds foremost place as a market sort, Royal Sovereign not travelling so well.—J. GROOM, *Gosport*.

#### RICH, BUT TENDER APPLES.

I was pleased to see in Mr. Iggulden's remarks on the Apple crops in certain counties mention made of that old highly-flavoured, but now seldom met with, dessert Apple Margil. Many years ago this Apple was grown as dwarf bush trees in an Essex garden in which I was employed. For my part I prefer it to either Ribston or Cox's Orange, but the tree requires good culture, otherwise it usually becomes affected with canker. The Paradise stock suits it best. The trees in question occupied a sunny position and were planted in warm, well-drained soil, having been lifted 2 years after planting to keep the roots close to the surface. In gardens where this and other small, but deliciously flavoured Apples are esteemed, it would, I think, be a good plan to grow them by themselves, and give them this special treatment, as they seldom can be induced to yield in a satisfactory manner under rough and ready treatment. In this section may be classed that at present comparatively little-known conical Apple American Mother. This Apple has a somewhat soft flesh, but will keep firm and in good condition for a considerable time after it is gathered, but it must have a warm, well-drained root-run to do it justice. Fruit well exposed to the sun will sometimes take on a beautiful streaked appearance. The Melon Apple of America, a December to March Apple, much larger than the two preceding sorts, pays for special treatment and position. It has a rich, soft, melting flesh, and must be left on the tree as long as possible. Baddow Pippin, also known as d'Arcy Spice, is well worthy of any trouble which may be bestowed upon it. I have heard a wall recommended for these rich, but tender kinds, but my experience is that wall culture for Apples of any kind is an unsatisfactory undertaking, although well-laden trees are now and then met with. An east wall can scarcely be called suitable, and on either south or west aspects in hot summers, and particularly where the subsoil is not of a marly nature so as to retain moisture, insects, in-

cluding red spider and American blight, are almost sure to attack them. Some may say water can be artificially supplied, but this is easier said than done, where work, as is the case in most gardens at this particular season of the year, is too plentiful. Supposing the roots never to suffer from lack of moisture, burning of the fruit by the sun has almost invariably to be contended with in a greater or less degree. I have a tree of Annie Elizabeth occupying a hot, sunny aspect on a west wall, and this summer, just as the pips were forming, the exposed side of nearly every fruit on the tree was burnt as with a hot iron, all fruits so affected being, of course, useless.

C. C. D.

#### STRAWBERRIES FOR A MIDDLESEX GARDEN.

Will you kindly tell me what Strawberries you consider most suitable for our garden? I rather fancy Royal Sovereign, President, and Noble.—M. I.

\* \* \* If the soil is not at all heavy you will require a free-growing kind, and as you say in your note you fancy Laxton's Royal Sovereign, we do not think you could do better. It is a good flavoured variety with grand cropping qualities. We certainly do not advise Noble in addition to Royal Sovereign, as owing to the latter named being as early as Noble, quite as prolific and a better fruit, why grow an inferior variety? Noble previous to the advent of Royal Sovereign was valuable on account of its earliness, but with Royal Sovereign equally early there is no need to grow both, Noble being a softer and poorer fruit in comparison. Royal Sovereign claims Noble as one of its parents, King of the Earlies, a very rich early fruit, being the other, and as it possesses the vigour of Noble it will do well in an ordinary garden soil. Royal Sovereign is not at all expensive. President, a grand old variety, is one of the most useful Strawberries grown, on account of its good flavour and solid fruit. It is a midseason variety, fruits large, and colour very bright. It rarely fails, but, as noted in the article referred to, the best fruits are obtained from young plants. No matter what variety is grown, it is well to plant early, using good material and giving attention to the preparation of the soil. Strong plants are a little more costly at this time, but they give much better returns. Many of our Royal Sovereign plants carried 3 lbs. of fruit each. At 1s. 6d. a lb., these well repaid for labour, as the land after the Strawberries were cleared off was in splendid condition for the next crop of a different nature.—Ed.

#### STRAWBERRY LATEST OF ALL.

I would strongly advise "R. D." not to discard Latest of All Strawberry, and to give it another trial, as on heavy land it should do grandly. There may be something wrong with the soil, or drought may have been the cause of failure. This year I have some hundreds of plants, and they have given splendid crops of large fruit and first-rate flavour. My plants were mostly grown on north borders. The soil is light and none too rich. I am unable to say why "R. D.'s" plants should be so unsatisfactory, but a dozen is a small number, and in a lot of 500 I have had no fungus of any kind, and with such a dry season I fail to see why "R. D.'s" plants should be so affected if they were well rooted. Possibly Latest of All will not be so good the first season, as it is not a strong grower. It makes few runners, but gives very fine fruit the first season and in quantity the second. I note at page 75 "A. D." gives a splendid character to Latest of All, and it deserves it, as during the month of July it has been invaluable. For years I grew Laxton's Jubilee for late use. This in wet seasons mildewed badly, and was not equal in quality to the Pine section, which fruited at the same time. With the advent of Latest of All I have had no difficulty. I am pleased to see additional testimony at pages 95 and 96, and to see "J. C.'s" and Mr. Hagon's notes on

the value of this variety. It certainly resembles British Queen in having green or unripened fruits. On the other hand, I have this season noticed other kinds known as good-shaped vary greatly in this respect, especially some of the earlier kinds. To some extent the severe frost in May would be answerable, and the severe drought after in this part of the country may have affected the later fruits. I intend to double my stock of Latest of All this year, but plants will be late, as runners are difficult to procure.

G. WYTHES.

#### PEACH BLISTER.

THERE is invariably some of this to be seen on open-air trees of Peaches and Nectarines every season, but it is not often the attack is so severe as it was this spring. Experts inform us that this blister is caused by a fungus known as *Exoascus deformans*, and give full descriptions of the disease accompanied by supposed remedies. The descriptions are correct enough, but the remedies given are doubtful. What mystifies gardeners is the fact that the leaves on trees under glass, whether the houses are heated or not, are never affected by the disease, nor have I ever observed it on trees under wall cases. It is also a noteworthy fact that trees moved from under glass to open walls are not affected by the blister for at least two years, and very little of it is noticeable on trees at Longleat that have been moved into the open still longer. Undoubtedly cold cutting winds are responsible for much of the mischief done, these, it may be, damaging the tender young leaves and rendering them an easy prey to the disease. That the disease germs are resting on the trees in readiness for an opening would appear only too evident, or how else are we to account for the comparative immunity from attack enjoyed by those trees moved from under glass? It is further plain enough that they are powerless in the case of strong healthy foliage, or how comes it that well-protected trees do not suffer from the disease? I have never had any experience with carbonate of copper and the like on Peach trees, but if any of the readers of THE GARDEN have sprayed their trees both before and after the flowering periods with any of these poisonous preparations for combating the spread of fungoid diseases, they will render good service by publishing the results. I have most faith in screening the trees in the spring from cold easterly winds by means of blinds made of frigi-domo for choice, and, failing these, with doubled or trebled fish-nets hung loosely over the trees, keeping them at a safe distance from the walls by the aid of long rods. Glazed copings with running blinds are the best form of protection, as in this case no harm will result by leaving these open all day long while the cold winds prevail. It is worthy of mention that many Peach and Nectarine trees against south walls in the west of England lost nearly every leaf from this blister, yet they have recovered surprisingly, being well furnished with fresh, healthy young wood, while the crops are quite up to the average. In one garden not far from Bridgewater Peach trees on a south wall were badly attacked by blister, while those on a south-west wall, and therefore less exposed to chilling easterly winds, only suffered slightly from it.

W. INGULDEN.

**Peach Early Grosse Mignonne.**—The true early variety of this fine Peach is now—August 7—ripe in an unheated house. It is a fine showy fruit of exquisite flavour, the deep pale flesh slightly streaked with red. I have not a heavy crop, as the tree has grown rather too strongly,

but as it has to be shifted this autumn and is healthy and well ripened, I hope the slight check given will induce it to form more fruitful wood. It comes in very useful just after Hale's Early, to which it is much superior in point of quality.—H

**Plum jam.**—It may not be generally known that the best of Plum preserve is made from under-ripe fruit. Many people are so anxious to secure their fruit in a perfectly ripe state, and no doubt Plums are often what is termed dead ripe when the jam is made; consequently it is never so good, nor does it keep so well. A gardener I knew being without Green Gages himself was forced to buy for preserve-making. When the fruit was sent home he found it to be in an under-ripe condition, and was afraid the jam would not be satisfactory, but to his surprise when made it was delicious, after which he always endeavoured to gather Plums required for jam in an under-ripe rather than an over-ripe condition.—C. C.

#### SHORT NOTES.—FRUIT.

**Melon Ingestre Hybrid.**—I have grown the Melon for the first time this year, a friend having given me a few seeds of the true stock. I grew the plant on the cordon system, allowing two fruits to plant. The skin is of a bright golden colour and the flavour was excellent.—DORSET.

**Apples and Pears for pots.**—I should be very glad to learn the names of a few sorts of Pear and Apples considered the very best for pot culture. Considering our short summer, the sorts ought to be rather early.—R. K., *St. Petersburg.*

## GARDEN FLORA.

### PLATE 1132.

#### UTRICULARIAS.

(WITH A COLOURED PLATE OF *U. LATIFOLIA*.)

THE species of this singular genus are worth place in every collection of plants, their curious flowers having much the appearance of those of some Orchids. The Bladderworts thrive best in a mixture such as most Orchids like, viz. fibrous peat and a little sand, and are increased by separating the little bulb-like appendage that adhere to the stems and roots during summer. They do best when hung up to the roof. During growth they require a good supply of water with somewhat drier treatment when at rest. The following are the best known kinds:—

**U. ENDRESI.**—This plant should be grown in shallow suspended basket in a little peat and Sphagnum. It is deciduous, and in winter should only receive sufficient water to prevent the rhizomes shrivelling. It will winter well at the coolest end of the stove or East India Orchid house. As soon as it starts into growth it should be suspended from the roof at the warmest end of the house and kept constantly wet until the flowering is over and the foliage begins to decay. It should not be fumigated with tobacco at any time. The flowers are pale lilac.

**U. MONTANA.**—In this the flowers are pure white with an orange palate, and larger than those of U. Endresi. The temperature of a Cattleya house seems to suit U. montana. U. Endresi requiring a little more heat.

**U. HUMBOLDTI**, given a first-class certificate by the Royal Horticultural Society on April 12, 1892 is distinct. The flowers are larger than those of U. montana, of a pale lavender-blue colour, the spikes long and slender, the foliage broad and of considerable texture.

**U. LONGIFOLIA.**—This, by mistake named U. latifolia in our plate to-day, was also certificated on April 12, 1892, by the Royal Horticultural

\* Drawn for THE GARDEN in Messrs. Sander's nursery, St. Albans, by H. G. Moon. Lithographed and printed by J. L. Goffart.

1192. *Delphinium* *latifolium* L. var. *roseum* G.

Society. It is quite distinct from U. Humboldtii the flowers smaller, of a pale mauve shade, spike short and erect, foliage long and narrow.

## THE WEEK'S WORK.

### KITCHEN GARDEN.

**AUTUMN CAULIFLOWERS.**—As the Pea season draws to a close a good succession of Cauliflowers proves most valuable in affording a variety and maintaining the supply until the early Broccoli is ready. For this purpose Autumn Giant is by far the best, as after it once gets a start and given good ground it generally grows freely during the brief summers, and turns in at the season required. The earliest batch of plants will have arrived at that stage when an occasional dose of manure-water will prove of great assistance, as it not only stimulates growth, but the produce is of the finest quality when the plants are helped in his way. As a further means to secure this, frequent surface hoeings should be resorted to, though they may not be required for the destruction of weeds, but these, like all other crops, are greatly improved when a loose surface is maintained between the plants. This crop often follows early Potatoes and other things as they are cleared off south borders, for the reason that ground is scarce at the time the plants are ready for putting out, but it does not always prove a suitable position during a hot, dry September, as the flavour of the heads is not so mild, and they do not last long in a good condition. They may be preserved, however, for several weeks after they are ready for use by lifting them carefully and burying the roots rather deeply under the shade of a north wall, though it is not recommended to disturb the plants if it can be avoided during bright sunshine, or when the ground is very dry. Rather take advantage of a dull showery day, when if a good watering is given afterwards the plants will not feel the effects of removal so much.

**BROCCOLI.**—These together with the different Kales will now be making satisfactory progress, and a final hoeing should be made between the rows, in readiness for moulding the stems up a few inches before the plants become too large, when the work can be done more easily without damaging the leaves. It is not too late even now to put out more Kale of the dwarf curled varieties. These will make sturdy little plants before winter, and form a good succession to those santed earlier. Indeed, I have often found that small plants put out now remain uninjured during the most severe winters, when taller plants with smaller stems have collapsed. Where a late sowing was made of the dwarf varieties of Savoys and other things, a few hundred plants put on a spare piece of ground will be almost sure to come in useful before spring, and the site will be available by the time it is required for spring cropping. Such plants may be put out rather thickly and may be used as greens at any time, but it would be useless to trust to Broccoli in the same way, unless it should be a few late Model, if the plants are well grown, and hardly sufficient late kinds were put in at the right time. I have just finished planting good breadths of Little Pixie and Hardy Colewort Cabbage. Both of these are most useful winter crops, and as it is not desirable to retain the plants for affording sprouts in the spring, close planting is resorted to, and they are pulled up as required for use. This is a capital crop to follow second early Potatoes, and the plants may be put in as these are lifted without the labour of manuring the ground for them. Little Pixie is somewhat smaller and considered not quite so hardy as the Colewort named, and on that account should be used first. The plants are put out two foot apart, with 15 inches between the rows.

**SPRING CABBAGE.**—It is most important that good seed beds filled with healthy plants should be in all gardens at this season, so that the desired number of plants may be put out next month. As before explained, it is not wise to trust to one sowing to produce all the plants re-

quired, and at least three lots of seed should be put in. The last sowing is generally valuable for producing plants for spring planting, and the seed should be put in towards the end of the present month. If the young plants grow freely, it is a good plan to prick them out about 6 inches apart, burying their stems up to the seed leaf and treading the soil firmly round them; they are then better able to withstand severe frost, and much time is saved. Recent showers have greatly assisted the seeds to germinate, but unless the soil is kept in a moist condition by rain, watering the beds must be resorted to, or growth will be slow and the plants become stunted. Some well-decayed manure has been worked into a piece of ground ready to receive the first batch, by which time it will have become settled and in good condition when the plants are ready for putting out. Dust the seed-beds occasionally should there be any sign of fly attacking the plants.

**LETTUCE AND ENDIVE.**—Sowings of both these are made at the same time as the above, and practically treated in the same way. It is always desirable to have plenty of plants to draw from, not only for autumn planting, but for standing through the winter to be planted in warm situations next March. Another sowing will be made shortly of Hick's Hardy White and Lee's Immense, which will remain undisturbed until spring. Thin sowing is very necessary, as when the young plants come up too thickly they often decay owing to wet weather, and more are lost in this way than through frost. South or other warm borders will have to be prepared for pricking out a quantity of each at once. It is not necessary to dig in manure if the ground is in fairly good order, but after forking it over it should be made rather firm by treading, and a good dusting of wood ashes afforded on the surface before planting commences. The firm soil will prevent to some extent grubs attacking the roots, while the wood ashes will assist to ward off slugs. Any pits or frames that are available should be got ready to receive as many plants as possible. Fresh soil should be placed in these if necessary, so that the plants are brought well up to the glass. Where there is plenty of frames, some of them may be filled at once with young plants and the lights only used to protect them during severe frosts; others, of course, will be required for the storage of larger plants, which will be lifted and stood close together on the approach of bad weather.

RICHARD PARKER.

### FRUIT HOUSES.

**POTTING FRUIT TREES.**—Pot fruit trees from which the crop of fruit has been gathered should be attended to without further delay, whether it is in the shape of a shift into larger pots or tubs, or root-pruning and top-dressing that is needed. The potting of these trees is best done while the trees still retain their leaves, as new roots are then more quickly emitted, and, as a natural sequence, the trees recover in a much shorter time, particularly when they have to be severely dealt with. Trees which are now in medium-sized pots will benefit by having a shift into larger-sized ones, provided they are already well rooted and do not make gross growth. Those which had a shift early last spring will merely need knocking out to ascertain whether the drainage is in good working order, and perhaps to add a little top-dressing if the surface soil needs removing. Trees which are already in the largest-sized tubs or pots are more difficult to deal with, as no shift can be given these. If healthy, an annual root-pruning is very beneficial, especially in the case of pot Figs, and by these means the balls can be kept within bounds, and the benefit of a little new soil can be given them at the same time. I am no advocate for severe root-pruning in these cases, and merely advise the removal of all thick, fleshy roots found coiled round the outside of the ball and among the crocks, retaining all the small fibrous ones. By doing this, and

patiently picking out as much of the old soil from among the roots as is possible under the circumstances, room can be found for the introduction of a little new soil, from the crocks upwards, and if this is carried out annually, trees of this description can be kept in a healthy bearing condition for a number of years. The old mulchings and top-dressings applied while the trees were in full growth will be full of roots. These must be sacrificed, and all roots, soil, &c., must be removed down to the original level or a little below it if possible to allow of a little new soil being applied. In each and every case the balls of roots should be in a thoroughly moist condition before being potted; therefore, a good soaking of water should precede the operation. Use clean pots, tubs and drainage, and cover the latter with fibrous pieces of turf to prevent the finer particles of soil from getting amongst and choking it up. Be careful to ram the compost firm in every case, also when top-dressing, and immediately after well water to settle the soil among the roots. Trees which have had to be severely handled will be best put into a cold house and shaded for a time, and have an occasional dash overhead with the syringe to prevent the foliage drooping. Others which have been merely shifted or top-dressed may remain where they are outdoors, but the precaution should be taken to prevent worms from gaining ingress at the crock holes. When many trees of this description have to be operated upon, a general survey should be made to ascertain the number, and then a pretty good estimate will be gained as to the quantity of compost that will be required. As but limited quantities of this will be needed, comparatively speaking, it should be of the best description. Good fibrous loam of a calcareous nature is the best for pot trees. Loams containing but little fibre may have wood ashes, old plaster or lime rubble pounded up fine mixed with them to ensure porosity, bone-meal being added also at the rate of a 10-inch potful to every barrow-load of loam. This is the only manure I advise being used with the compost, as the requisite amount of feeding necessary can always be applied from the surface during the season of growth.

**POT VINES.**—Young Vines intended for planting or for cutting back and growing on another season for forcing early the following year should now be sufficiently advanced to allow of the pots being raised out of the plunging material. In a few weeks' time they may be taken outdoors and placed in a sunny position, either against a wall or hedge to finish the ripening of both wood and foliage. In the meantime see that they get ample supplies of water, and the same when placed outdoors. If trained to stakes fixed in an upright position the canes will need no further support when removal takes place, but if trained to wires, then they must be either fastened to the wall or tied to the hedge. Should the hot weather continue, boards placed in front of the pots or a little loose litter worked round them will keep the roots cool and considerably lessen labour in the way of watering.

**POT STRAWBERRIES.**—The early potted plants are making good progress, the soil being already well filled with roots. In a short time feeding, in the shape of weak guano water, may commence, or, where liquid manure is plentiful, this may be given instead. Keep all runners suppressed, and turn the pots round frequently, if standing on ashes, to prevent the roots catching hold. As growth proceeds, give each plant more room by thinning out, and syringe them freely towards sunset when the day has been parching hot. Successional batches should be accorded more room as they make more foliage, and attend to them in every particular as advised for the early lot of plants. The latest lot of all should be potted, if that has not already been done, and give the plants the benefit of an open space where they will experience full sunshine and a free circulation of air. If enough plants have been secured both for pots and planting, a line or two of the kinds which find favour for forcing should be planted

by the sides of walks or in any convenient spot, for affording runners for pot work another year. In order that these may grow strongly, so that plenty of robust runners will be afforded in the spring, the ground should be in good heart and quite free from shade.

**FRUIT ROOMS.**—The present is a good time in which to carry out any alterations and repairs, also the cleansing and painting of these structures. In addition to whitewashing walls and ceilings, the shelves and all woodwork should be well scrubbed with strong soda water, to destroy all mould germs which may be, and are very likely, present, if any fruits were allowed to decay last winter or spring. After this, any painting that is necessary may be done, and, if carried out at once, the same will become hardened and the strong smell have passed away before the general ingathering of the fruit takes place. Grape rooms should also be overhauled and cleaned in the same manner, and if any structural alterations are necessary they should be carried out forthwith.

**FRUIT GATHERING.**—Much time will be taken up now and for some time to come where fruit-growing is carried on to any extent, whether the produce is consumed at home or marketed. In addition to Peaches, Nectarines, and Apricots, which should be looked over every other day, Plums are now ripening, and Morello Cherries should be gathered for bottling. Plums are best gathered fresh from the trees, as if kept long they become unwholesome. The first-named fruits will take no harm if laid out thinly on an airy shelf in the fruit room, and will, in fact, keep in good condition with their flavour unimpaired for nearly a week. The early kinds of Pears, such as Doyenné d'Été, Citron des Carmes, and Summer Beurré d'Arenberg, are improved if gathered a few days before they are ripe and placed in the fruit room. Souvenir du Congrès, Williams' Bon Chrétien, Clapp's Favourite, and Beurré de l'Assomption should also be treated in like manner, but these are much later than usual this season, and will not need gathering yet. The earliest varieties of Apples, especially the dessert kinds, are best gathered direct from the trees, as they lose flavour and go flat if stored. Apples for market must be gathered before they become too ripe, otherwise they bruise badly if they have to be sent any distance, and a considerable loss in value is the result.

A. W.

## TREES AND SHRUBS.

### HICORIA PALLIDA.

*HICORIA PALLIDA* is nearer to the Nutmeg Hickory than to any other, but while the Nutmeg Hickory (*Hicoria myristiciformis*) has many characters which ally it to the Pecan and Bitternuts, this has characters which show close affinity to the White Hickory. The sterile flowers of *Hicoria pallida* are only from the base of the shoot of the year, while in the Nutmeg Hickory they are from separate lateral buds as well. The twigs, which are even more slender than in most forms of the Pignut, are purplish brown in colour and usually smooth, although some collected in South-western Georgia are tomentose toward the tip around the base of the terminal buds. The oval buds are sharply pointed: the lateral buds are similar to the terminal ones in shape and general appearance, but are somewhat smaller. The fruit, as in most of the Hickories, varies much in size and shape, being sometimes almost globular, and again nearly pear-shaped.

From its habit *Hicoria pallida* might be called the "Black Jack" of the Hickories, for it seldom exceeds 40 feet in height, and is often not over 18 feet or 20 feet, with a proportionate trunk diameter of from 8 inches to 15 inches. The very slender upper branches are erect and closely crowded, forming a narrow,

oblong crown; but the lower ones droop so low, that on isolated trees their extremities are only a few feet above the ground. The trunk, too, is always short, even when the tree is growing under the most favourable conditions, most of the branches spreading from a point only 15 feet or 20 feet above the base of the trunk. The grey bark is thick and firm, with deep and rather broad fissures separated by broad ridges, its general appearance being like that of the White Hickory, but rougher. In the summer, when in foliage, it bears a close resemblance to the White Hickory; in the winter the slender twigs make it more nearly resemble the Pignut. The heart-wood is brown in colour; the sap-wood nearly white; and I was told by persons who had used the wood that while much inferior to the White Hickory in those properties that make good hickory, it is equally as good as that of the Bitternut. The tree, however, is too small and too uncommon to be of importance economically. Even in the mountains of North Carolina, where I have found *Hicoria pallida* most common, it is exceedingly local, occurring at widely separated places, seldom more than a dozen trees being found at the same station. It prefers a poor, dry soil, and I have usually found it on sandy soils, although not always. In the mountains of Virginia and North Carolina it is associated with the Red Oak, the Rock Chestnut Oak, the Pignut and White Hickory, and ascends in the mountains of North Carolina as high as 4000 feet above sea-level. In South-western Georgia it is found growing with the White Hickory, Post Oak, Dogwood and Long-leaved Pine on a good loamy soil underlaid with marl and limestone. In Eastern North Carolina it is found on the littoral sand dunes at Wilmington, growing with the Sand Oak (*Quercus Catesbeii*), the Spanish Oak and the Red Cedar; while near by are the Water Oak, Live Oak, Laurel Oak and Bays. On the sandstone ridges of Central Tennessee it occurs with the Scrub Pine, Chestnut, and with the Oak and Rock Chestnut Oak. Its distribution, so far as I have observed, is from Southern Virginia and Eastern North Carolina to Middle Tennessee and South-western Georgia, but it is probably more extensively distributed, and should be looked for in Eastern Kentucky and Northern Alabama.

This tree was first discovered in the spring of 1895 near Chapel Hill, North Carolina, where, after two seasons' search, I have been able to find only three specimens. The summer after discovering it at Chapel Hill, while examining on horseback the forests of the western portion of North Carolina in the preparation of the description of the woodland of North Carolina in Bulletin No. 6 of the North Carolina Geological Survey, I found this tree in several other places in that State. The following spring it was found in South-western Georgia and Eastern North Carolina, and more recently in Tennessee. Having no good description of the Nutmeg Hickory or specimen for comparison, for a long time I considered *Hicoria pallida* to be that species, or at most a variety of it. The Nutmeg Hickory, however, does not occur in North Carolina, although indirectly credited to this State in the recently published "Nomenclature of the Arborecent Flora of the United States."

From what is now known of it, *Hicoria pallida* seems to be another localised South Appalachian species.—WILLIAM WILLARD ASHIE, in *Garden and Forest*.

**Pavia macrostachya.**—This so resembles a Horse Chestnut, that most people think it to be that. It is now in bloom in our pleasure-grounds

(middle of August). It is quite a small bush and not in a favourable position. To those who have not room for strong growing subjects this is well adapted, as it is not fast growing. I remember seeing a fine plant of this in full bloom in the grounds at Croome Court, Worcestershire.—DORSET.

**Ceanothus Gloire de Versailles.**—As a shrub to be grown in ordinary positions there is none amongst the Ceanothuses that has proved more useful than this. Some of the species are very tender and can only be grown against a wall, and even then are killed by such frosts as those of February, 1895, but *C. azureus* will stand on the hardest winters if the ground is covered with a thick layer of dry leaves. It is from this species apparently, that the variety *Gloire de Versailles* has been derived, but, compared with the species it is a more robust grower and has larger racemes of flowers, and is, indeed, in every way superior. There is now a large group of it in flower at Key and the feathery racemes of bright blue flowers are very pleasing, not only for their own beauty, but also because they are so different from other shrubs in flower now. It requires to be pruned pretty hard back each spring; a hard winter will do this, but during such winters as the two last it is only the soft tips of the shoots that are killed. Close pruning encourages a compact and shapely habit, and even with it our plants are 4 feet high. It strikes quite readily from cutting.—B.

**Spiræa Bumalda var. Anthony Waterer.**—The most important group of the *Spiræas* that flower in July and August is the one that constitutes the japonica (or callosa) group. To it, among many others, belong the fine varieties *ruberrima glabrata*, and *Bumalda*, but it is to the variety *Anthony Waterer*—a sport from *Bumalda*—that the first place must be given, for none equals it in its richness of colour. Its name alone suggests a high degree of merit, for it was sent out by an amateur named after the late Mr. Waterer, of Knap Hill, than whom a more exacting critic of tree or shrub has never lived. From *Bumalda* itself it does not differ in habit or foliage, having the same neat compact habit and dark green toothed leaves, and showing the same peculiar tendency to variegation. Its flowers are of a richer, brighter red, and lose much of the purple tinge that belongs to the ordinary *Bumalda*. In 1895, in the early part of the season which was very dry and hot, it lost a good deal of its brightness of colour, and it was not till later, when the rains came, that it showed its great superiority. But last year and this it has been very fine and realises all that has been anticipated of it. If the old blooms are removed as they fade, it will keep in beauty till October.

**Calophaca wolgarica.**—Although this shrub has been in cultivation more than 100 years, it is only rarely that it is to be seen now-a-days. A sun-loving plant, it has during this and the last few summers flowered profusely, and has proved itself a really handsome shrub for sunny positions. A few of its racemes are still bearing flowers, but it was about a month ago when it was in full beauty. It gets its specific name from being found in Siberia near the banks of the Volga. It is a leguminous shrub, 2 feet to 3 feet high with pinnate leaves each 3 inches to 4 inches long. The short-stalked leaflets (of which there are usually seven pairs and the odd terminal one) are orbicular, about a quarter of an inch in diameter, and covered on both sides with a greyish tomentum. The number and small size of these leaflets give the shrub a very distinct and pleasing character, and they serve admirably also as a contrast to the racemes of yellow flowers. These racemes are axillary, 4 inches to 6 inches long, and carry six to ten flowers of a papilionaceous character; they are deep yellow, and on the standard petals are stained with a still darker, reddish tinge. In fine seasons like the present, seed is formed plentifully and the pods, each 1½ inches long, together with the calyxes and flower-stalks, are covered with short, dark brown glandular bristles. It grows naturally in dry arid regions, and, like many shrubs

that character, I find it difficult to raise from seed. The seed germinates freely enough, but the young plants are very apt to damp off the first winter. This is indeed one of the few instances among shrubs where grafting is advantageous. Worked on standards of *Caragana arborescens* 3 feet or 4 feet high, it thrives admirably, and in being thus elevated it assumes naturally a sturdier and graceful habit. The common *Lahurman* has also been recommended as a stock.—B.

**Itea virginica.** This North American shrub well merits the recent note in THE GARDEN, though it has somehow acquired the reputation of being a poor plant, it is when in good condition really a pretty shrub, and one whose late season blooming is in its favour. It forms a freely branched, compact bush that reaches a height of a yard or so, but it will flower freely when not more than a couple of feet high. The flowers are small, but borne in closely packed cylindrical racemes which from 4 inches to 6 inches long. They are white and bear a certain amount of resemblance to those of the North American *Clethras*, which are still later in blooming than this *Itea*. Botanically, however, they are quite distinct, the *Itea* being a near ally of the *Escallonias*, while the *Clethras* belong to the *Ericaceae*. The *Itea* succeeds best under the conditions most favourable to what are commonly known as American plants; that is, a fairly moist spot, a soil containing a admixture of peat or well-decayed leaf mould, and a position fully exposed to the sun's rays, though if shaded it does not flower so profusely as a sunny spot. In the autumn the leaves die off brightly coloured. This *Itea* in a native state extends from Pennsylvania to Carolina, and was introduced into this country in 1744.—T.

**Indigofera Gerardiana.**—There is a mass of this shrub about 14 feet across in the arboretum at Kew, which is one of the most attractive of the woody things in flower at this date. When grown in the open it mostly dies back to the ground each winter, sending up the following summer a luxuriant thicket of slender, graceful stems 2 feet to 3 feet high, clothed plentifully with rich dark green pinnate leaves, from the axils of almost every one of which there is produced a raceme of deep-purple flowers. These racemes are each 4 inches to 6 inches long, the larger ones bearing several dozen closely-set flowers. The racemes at the base of the shoot are over before those near the top are expanded, and the flowering season lasts, in consequence, from July almost up to the time of the first frosts if the weather remains open and sunny. For this reason, as well as for the exceeding grace of its foliage, this shrub deserves more extended notice. Its only defect is that it is late starting in spring. When grown on a wall its stems survive the winter, and it forms a stout woody stem several feet high. It is a native of the Himalayan region and can be propagated by means of cuttings put in this month, and also by seeds when the summers are sufficiently sunny for them to ripen.

**Eucryphia pinnatifolia.**—This is, perhaps, the most beautiful of all hardy shrubs in flower now; certainly none is more striking. There is a group of plants near the Cactus house at Kew, forming a mass about 5 feet through and 4 feet high, very finely in flower. They have been in their present position—which is not a very sheltered one—for several years, and the species has therefore proved itself quite hardy in the neighbourhood of London. Whatever disasters the winter of 1894-95 may have brought to many exotic shrubs, it left the hall-mark of hardiness on those that survived, and this shrub was one. Each flower is 3 inches to 4 inches across and pure white; there are four wedge-shaped petals, and in the centre is a large tuft of yellow stamens. It suggests at once a very noble Christmas Rose (with petal short) and a *Hypericum*. The leaves are alternate and the leaflets number three or five, and are of a dark lustrous green. For the south of England, at any rate, this *Eucryphia* is a most valuable addition to our July and August flowering shrubs. Bentham and Hooker place the

*Eucryphia* in the great Rose family, but other authorities have placed them with the *Hypericums* or the *Saxifragas*.

**Hibiscus syriacus.**—The different varieties of *Hibiscus syriacus* have been long regarded as desirable flowering shrubs, from the fact that the blossoms are borne during the latter half of the summer when hardy shrubs in bloom are but few in number. Such being the case, it is somewhat singular that the first time any variety of this *Hibiscus* received notice from the Royal Horticultural Society was as recently as July 27, when two varieties were given awards of merit. Both of them are single-flowered forms, one (*Painted Lady*) being very little known, while the other, *eclestis*, is of French origin, and has been long grown in this country. There are numerous other varieties both single and double, and a few of the most distinct when brought together will form a very interesting group, and one, too, whose most effective stage is at the end of July and in August. This *Hibiscus* is perfectly hardy, and succeeds best in a rather deep soil of a loamy nature. It is very essential that the soil is not parched up during the summer, as the plants quickly suffer from drought, the leaves turning yellow and dropping off, while the flowers do not expand in a satisfactory manner. Among other desirable qualities possessed by this *Hibiscus* is the fact that it will succeed in the neighbourhood of towns better than many other shrubs.

## CHRYSANTHEMUMS.

### CHRYSANTHEMUM NOTES.

TAKING the flower-buds is an item of culture that will be almost general now; at least, with those who cultivate the plant on what is called the "big bloom" system. To produce flowers of large size, considerable time must be given for the buds to develop. If, for instance, we allowed the plants to perfect their last natural flower-buds—which are known as terminals—that usually appear in September, the time between that state and blossoming would be too short in the case of almost every variety of note. Growers, therefore, are now (early August) on the watch for a flower-bud at the point of each shoot, which may be almost hidden by a cluster of growths around it. Unless in the case of a few varieties this flower-bud should be retained on the plant and the little growths pinched away. This bud is known as the crown bud; it comes at varying times until about the second week of September. Viviani and Morel, Charles Davis, Mme. Carnot and Australian Gold may be named as producing fine deep blooms from late-formed flower-buds, but it is not wise to defer selecting buds of other Japanese kinds as they appear from now. Crown buds, again, are chosen for the growth of large deep blooms of the incurving class of *Chrysanthemums*, and later or terminal buds in the case of the different types of *Anemone* (single and pompon). What little manipulation of growth is required should be done in early spring. For example, that splendid Japanese kind, *Mrs. H. Weeks*, may not be expected to develop fine blossoms from late buds. These being very late to show themselves naturally, one cannot obtain them, even in August, without having topped the growth of the plant. Those handsome show flowers, *Mrs. F. Jameson*, *Mrs. John Shrimpton*, *Dorothy Seward*, *John Neville*, *W. G. Newitt* and *Mrs. W. H. Lees*, are others which will be disappointing if flower-buds cannot be had soon. In every variety that I know the flowers resulting from late buds will give blooms comparatively finer in colour. For other purposes than large blooms, therefore, the grower may wait for this formation in the natural manner.

### FEEDING.

That *Chrysanthemum* plants are generally over-fed with rich manures either in solid or liquid form I have not the slightest doubt. In looking through collections I see this every year. Such over-fed plants look taking to the eye, with their large, deep green leaves and gigantic stems, but rarely do such specimens produce satisfactory blooms. Badly-formed ones or those of a broad, flat nature are usually the result. The wood of *Chrysanthemums* must be firm, short jointed, and well ripened to give flowers of a high standard. At the same time it is hardly possible to keep the plants in a healthy growing state throughout the season without more or less feeding. The plants get yellow and contracted in growth when the large pots become full of roots if assistance be not given; and especially during the trying hot weather lately experienced. I would feed the plants, not for the purpose of obtaining big wood, but only to retain a healthy look in the leaves. Soot-water is excellent for this. Some sorts again really resent strong manures—*W. Seward*, *Mme. Carnot*—in fact all the whites—*Col. Smith*, *Hairy Wonder*, and the incurved varieties generally. When light, sandy soils are employed the need for stimulants is comparatively great, as such become impoverished early. Liquid manure from the farm-yard is not easily beaten and Peruvian guano has the constituents required by *Chrysanthemums*; whilst the approved fertilisers, of which there are so many, may be used with safety, always remembering weak doses and often are the proper rule to follow. Some assistance may also be rendered by the aid of a top-dressing of soil; an inch or so as a surface covering will be quick in producing top roots. Do not, however, make the soil over-rich with concentrated manures, or it may have the opposite effect.

### INSECTS

are not over numerous with me, the plants being in an open position, but earwigs are generally plentiful. These should be trapped; they do much damage among the soft points of the shoots, and often spoil many blooms. Pieces of the stems of the Broad Bean placed among the leaves are a good harbour for this pest. Prompt action in the matter of tying the shoots securely saves one the disappointment of many losses, the results of months of labour being easily spoiled by high winds. It is curious how several of the more popular varieties become addicted to some disease or decay which appears to affect their constitution in an unaccountable manner. Thus we find the leaves of that fine sort *E. Molyneux*, which are normally large, small, curled, and thin in substance. *Viviani Morel* and *Charles Davis* suffer in a similar way. Nothing less than a change of stock will alter this, and even then I have known them again take the disease in a year or two. I daresay there is something in the idea that high cultivation weakens the constitution of plants, and that in time they die out. The family of incurved sorts known as the *Queen* is another case. Many good cultivators have expressed the opinion that they, too, are past, and cannot be grown so fine as they once were. *Mme. Carnot* has a tendency to lose the leaves, even when the best means have been taken to prevent it. I notice also that a variety said to be a seedling from it, *Baronne Ad. de Rothschild*, has a similar, or rather an aggravated form of this tendency. At first spots are seen all over the leaves; these increase in size until finally decay sets in.

H. S.

**Chrysanthemums at Sydney, N.S.W.**—At the meeting of the floral committee of the New

South Wales Horticultural Society, the following colonial seedlings, raised by Mr. G. Kerslake, were awarded first-class certificates during the past season: F. McQuade.—Japanese; tips of petals slightly incurving; colour bright terracotta, amber reverse. Mr. J. H. Horton.—Japanese reflexed; colour bronzy yellow, centre paler. Miss Mary Underhay.—Japanese; petals broad and incurved; colour primrose-yellow.—C. H. P.

## FLOWER GARDEN.

### THE EDELWEISS.

THE Edelweiss (*Leontopodium alpinum*) is perhaps one of the most popular plants of the alpine flora, and the one plant of thousands that the average mountain tourist is most anxious to discover. Interesting the plant is undoubtedly, though beyond this it possesses but few attractions from a decorative point of view. Of course its correct home is the rock garden, where it should be planted in not too rich soil, yet quite firm. The plant is seen always to good advantage if rather freely grouped in colonies in the rock garden. The plant may be grown with complete success when a few strong seedlings are firmly planted in a narrow chink of rock, so placed that a deep fissure of gritty or sandy loam may be assured for the roots to ramble in. Plants in pots may be grown and flowered when the collar is tightly wedged between some pieces of stone or old mortar. At this season of the year I have frequently received parcels of the plant by post merely wrapped in a bit of Sphagnum Moss and some oiled paper, and in this way they travel well. But whether these collected plants will continue to succeed under cultivation in our lowland gardens depends as much on the way they have been lifted as upon any subsequent treatment on arrival. Assuming such plants do come to hand, and possessing a fair amount of fibrous roots, there is no better way of starting such things than by planting them not too deeply in coconut fibre and sand. Many plants that frequently rot, and that rapidly, when placed in soil will start new roots quite quickly when planted in this simple way: Give one good watering when planted, place in a rather shaded place and not a stuffy, ill-ventilated frame, and leave them alone for a week at least without further moisture. In this way scores of rare alpine plants have been treated after a long journey with a good deal of success. On the other hand, those who have no opportunity of obtaining plants direct from their mountain home will find seeds by far the best method of obtaining a stock. Indeed, seeds must be looked to for perpetuating the stock also, for the plant is not always a success when divided. On the other hand, it may be grown from seeds with perfect ease, and though I have grown the plant with success, I am bound to say I have never been able to obtain such results as I saw a few years ago in the gardens of Pusey House, Berkshire. Here the Edelweiss was treated as a biennial, large beds being edged around with it. The plants grew with considerable vigour, making tufts of leaves over a foot high and flowering abundantly. In this way a succession of plants, to flower each year, was maintained, seeds being harvested in great quantity. The plant produces tufts of hoary or woolly leaves from which issues the flower-stem, usually not more than 4 inches or 6 inches high. The true flowers are small and inconspicuous, yellow in colour, and set as it were in a star-like whorl of woolly, oblong leaves,

rendered white or nearly so by the density of the down-like tomentum that covers them. To this peculiar and interesting character the plant owes much of its popularity.—E. J.

Mr. Jas. Epps, Junr., Upper Norwood, who kindly sent the photo from which the illustration was prepared, writes as follows:—

I enclose a photo I have taken of a fine mass of Edelweiss that I have at the present time in flower in my garden. I have made the bed on a steep slope facing the S.W. and quite in the open. The plants have grown freely. Last year the plants also flowered freely, seed ripened, and this year numbers of young plants have become established. Some of the plants have ten to fifteen blooms.

**Layering border Carnations.**—Many gardeners layer their entire stock of border Carnations annually, and when well rooted transplant the whole batch separately, but while agreeing that the finest individual blooms are secured in this way, I maintain that the most attractive masses of bloom are secured by layering one-year-old plants and allowing the layers to remain where they are. Of course only a portion of the stock need be treated in this way, and the best effect is produced when these are together in beds or borders. I have had a grand show of the Burn Pink on plants treated in this way, also Celia and Lord Rendlesham. For cutting and

The Edelweiss in a garden at Norwood. From a photograph sent by Mr. Jas. Epps, Junr., Norfolk House, Beulah Hill, Upper Norwood.

for use in bouquets, I do not think there is a more useful variety than the Burn. It also has a grand constitution.—J. C.

**White Cactus Dahlias.**—There are several so-called white kinds, but a really good one has yet to be introduced. Mrs. Peart has blooms of nice shape when caught true, but it is very uncertain. I find the better flowers come through planting the old tubers instead of young spring-struck plants. Mrs. F. Fell is a kind that blooms very freely, but it is scarcely pure white or Cactus-shaped. Salisbury White and Harry Freeman, although most useful for a supply of cutflowers, are not good types of the shape desired. Keynes's White is the nearest to perfection; this, however, will not be grown generally until next year; meantime it may be noted as a sort likely to be greatly esteemed.—S.

**Good outdoor Fuchsias.**—The little Dun-robin Bedder is a capital dot plant for small beds, as effective here as the stronger varieties are for beds on a larger scale. Some two dozen plants that were saved over from last year and planted on a long narrow border on a carpet of Manglesi Geranium have developed into fine bushy stuff, and are flowering very freely. I have not as yet left it out through the winter, but the character of the plant would seem to indicate that it is hardy, or, at any rate, that it would be safe

with a heavy mulch of half-decayed leaves. General Roberts is a capital outdoor sort, a form a very attractive bed with alternate plant of white Marguerites or Hydrangea paniculata which, by the way, is flowering early this year and throwing very fine heads, or it may be planted freely on a white carpet, such as Centaurea Veronica incana. Duke of Edinburgh and the old Rose of Castile are in their respective colour as good as General Roberts, and another splendid variety not so well known is Annette. This form bushes and pyramids almost perfect in shape and flowers so freely that on well-bloomed specimens very little is seen of the foliage. It is season for Fuchsias, and they are certainly among the most attractive things in the flower garden. E. B. C.

**Statice latifolia.**—It is worthy of note that seedling plants of the great Sea Lavender are very considerably in their time of flowering, a fact that their value for cutting is thereby enhanced. With the view to strengthening the stock of this very useful plant, I sowed a packet of seed in autumn of 1895. The young plants are throwing up some huge panicles this summer, and it is interesting to watch the respective development. On August 2, for instance, one had its delicate lavender flowers well expanded, the type being very good and individual blooms of extra size; another had its buds well advanced, and yet another showed a perfectly green panicle with

sign of bud expansion. Bearing in mind the deep-rooting tendencies of Statice, it is advisable when growing from seed to transfer the seedling at an early stage to the spot they are destined permanently to occupy, and either to bastard trench or very deeply dig the site. They show to advantage in a bed of considerable size, and by way of contrast some clumps of a highly-coloured Pentstemon or Montbretia can be planted with them. If the object is quite as much to secure an effective display in the bed as to obtain a supply for cutting, individual panicles may be lightly staked to keep them clear of the ground.—E. B. C.

**Large plants of Western American Erythroniums.**—As stated in my article on Erythroniums, I do not believe that there is any difference in the average size of our Erythronium outside of *E. purpurascens*. Taking each species at its best development, I am fast learning the measures of size of any of our Liliaceae are of little value. The size depends on conditions, and the supposed dwarf species often takes on an immense development when just the right season and soil conditions occur. A striking instance of this came to my knowledge this season. Sereno Watson in his revision described two varieties of Erythronium grandiflorum. *E. grandiflorum* var. *parviflorum* was, as its name indicates, rather

lwarf in scape and small in flower. Among other regions, it occurred in the Blue Mountains of Eastern Oregon. One of my collectors found and collected it in these same Blue Mountains this season, and there were many stalks 2 feet high, with one 3 feet in height; and while four or five flowers were common, a maximum of ten was attained. The bulbs were immense. These fine dimensions do not indicate to my mind a larger species, or even a larger strain, but simply congenial surroundings. I recently saw stalks of *Erythronium revolutum* 2 feet high.—CARL PURDY, Ukiah, California, U.S.A.

**Feather Grass and Poppies.**—The informal border of hardy flowers gives us at times many unrehearsed effects of the most pleasing kind. One of these this year has been a combination of the Feather Grass (*Stipa pinnata*) and some scarlet Poppies. The latter are self-sown seedlings originally from the Shirley strain of varieties of *P. Rheas*, and are of a brilliant crimson. Nothing could be more delightful than the appearance of these glossy fluttering flowers, among which stood the ilcey plumes of the Feather Grass. The glowing colour of the Poppies enhanced the delicate beauty of the Grass, which in its turn opened the brilliance of the "Corn Rose," as the Poppy has been called.—S. ARNOTT.

**Erythroniums.**—In my article on *Erythroniums* published in THE GARDEN June 5, p. 408, two varieties of *Erythronium revolutum* were left without a name. One was the fine cream-coloured form which Sereno Watson in his revision called the type of *E. revolutum*. By Mr. Baker's decision the purple-flowered form is the type of *E. revolutum*, and Watson's type is left nameless. I know of no more appropriate name than *E. revolutum* var. *Watsoni*. The early-flowering form between *E. giganteum* and *E. revolutum* I will call *E. revolutum* var. *præcox*. The plate in *Botanical Magazine*, t. 5714, is the white form of *E. revolutum* var. *Watsoni*, and differs in no other respect except that var. *Watsoni* is creamy and the other white. The white one is my *E. revolutum* var. *billurum* in THE GARDEN of June 5, 1897.—CARL PURDY.

**Dahlias and earwigs.**—Probably many gardeners, both amateur and professional, are finding earwigs troublesome among the Dahlias, and the following hints, both as to staking Dahlias and trapping earwigs, may be of use in the future. I grow about 350 Dahlias, and, with a view to lessening expenses, I have this year staked with about 5-ft. bamboo canes (these cost about 1s. 6d. per dozen, as compared with 2s. 6d. per dozen for althia stakes). But the bamboos also make capital earwig traps. The first 5 inches or 6 inches of the cane will be probably hollow, and into this the insects creep after their night's feeding. I therefore cut into the cane just above the first joint and make a hole large enough for an earwig to get out. Every morning I examine these canes, and by the light shining in at the hole that has been cut I can see every insect inside, and by blowing strongly down the hollow, the earwigs will run into, or be blown into, a bowl or bucket held there for the purpose, and may then be easily killed. In this way I have kept the earwigs from destroying the blooms and also kept down the cost of stakes.—R. W. FOOT.

**Single Hollyhocks.**—Few persons will dispute the opinion expressed on page 99 that single hollyhocks are more ornamental than the double ones, for they possess a grace and beauty of their own which are totally wanting in the more lumpy double blossoms. Single flowers, too, seem to be gaining in popularity, for they crop up in many gardens, and in most instances are in good condition. The writer of the above-mentioned article concludes with the hope that someone will take the single Hollyhocks in hand and improve them largely, while he says "selection may do much, and intercrossing perhaps more." Where any system of crossing is followed it should be borne in mind that we have a most beautiful Hollyhock in *Althæa ficifolia*, of which a coloured plate appeared in THE GARDEN

January 12, 1895. The drawing was made from a plant that flowered in the herbaceous ground at Kew, where a short time since this species was remarkably showy. *A. ficifolia* forms a sturdy growing plant that in vigorous examples will reach a height of nearly 6 feet, the large leaves being five to seven-lobed, while the blossoms, which are each about 4 inches in diameter, are of a beautiful light clear yellow, in all respects totally different from those of the ordinary garden varieties. If single Hollyhocks are taken in hand by our hybridists, this charming species will doubtless play a part in the production of new forms.—H. P.

**Phlox Coquelicot.**—This Phlox, which has attracted a good deal of attention of late, owing to the brilliant colouring of its blossoms, seems to be but little known, while, judging by the catalogues, very few, if any, of our nurserymen have it in stock. It is therefore worthy of note that this variety is one of the many triumphs of that eminent hybridist, M. Lemoine, of Nancy, by whom it was sent out in 1896, and in whose catalogue it occurs among the varieties of 1896. On July 27 the members of the floral committee of the Royal Horticultural Society met at Chiswick to take under consideration the Pentstemons, Cannas and Phloxes growing there. The variety Coquelicot on this occasion received an award of merit, an honour bestowed on some other varieties from the same raiser, viz., *Evening*, rosy salmon, with a violet eye; *Tourbillon*, very large flowers of a rich salmon-carmine tint; and *Beranger*, soft salmon-pink, rayed with white, and a violet centre. There are now so many bright and effective varieties of this class of Phlox, that there is no excuse for planting the dull lilacs and washed-out purples that are so often seen.—H. P.

— We see that the Phlox Coquelicot has been much noticed and appreciated in England by your having twice published paragraphs about it in your paper. Its origin is as follows: We obtained this plant from seed and put it into commerce in the autumn of 1895 as a novelty. It appears in our last catalogue under the heading of "Varieties of 1896," p. 76. The plant the flowering of which has been noticed at Kew came directly from us.—V. LEMOINE ET FILS, Nancy.

CARNATIONS.

THE article in your issue of 7th inst. is interesting from an American point of view, but it is not very practical for this country, as the type of flower that is admired in America is totally different from that which we consider beautiful here. Take any of the best of the American Carnations. They have all papery petals with the roughest possible edges; they are most of them, it is true, nicely scented, which is a great thing in their favour. If an amateur wishes to please his own fancy only, he may, of course, indulge in American or other saw-edged varieties to his heart's content, but should he wish, as most amateurs, and professionals also for that matter, do, to be successful in the exhibition tent, it is imperative that he discard anything of this sort. He must see that his flowers are (1) perfect in form; (2) that the petals lie flat all round, with perfectly smooth edges; (3) that the calyx is unsplit; (4) that the colours are bright; and (5) that the stems are strong and able to support the blooms well above the plants, bottles, or glasses, as the case may be, without support.

Unless these few suggestions are carefully complied with the exhibitor may never expect to catch the judge's eye. If the grower can afford time and space to grow seedlings, by all means let him do so; but he must consider himself indeed fortunate if from the best seedlings procurable he can select five per cent. that are an improvement on existing varieties. Carnations have been so improved of late years, thanks to the efforts of the president of the National Carnation and Picotee Society, that each year the type gets higher and the restrictions more difficult to cope with. Amateurs may, however, take this as a

golden rule, that it is of no earthly use their placing any American or rough-edged flowers in their show stands in any high-class competition, for the judges will simply ignore them.

The authority I have quoted above evidently favours the undressed flowers, as he gives valuable prizes each year for flowers grown exclusively in the open air and that have not been touched by tweezers. These, therefore, have to be the strongest and best border varieties to stand any chance in a large public competition. I do not care for the large, split, tweezered and collared flowers, but in this I am, I believe, in the minority. It is, as in many other things, a matter of taste.

These remarks apply quite as much to the plants that are now being grown so extensively for winter blooming. We have as yet no winter exhibition of Carnations, but each season the varieties are improving and the number of winter-bloomers is increasing, so that by-and-by we may perhaps have a National show and a Midland show in January as well as in July.

H. W. WEGELIN.  
*St. Marychurch, Torquay.*

**Cactus Dahlia Cycle.**—The demand for this new type of Dahlia is causing the introduction of a large number of new kinds, and it will not be long before some discrimination is required, as among Roses, Chrysanthemums, and other popular flowers. The object of this note, however, is a great improvement in its colour. This is bright rich ruby-red. The form, too, most liked, is seen in this variety, which is striking and handsome. Its habit of growth and freedom of flowering place it in the list of the choicest.—S.

**Carnation Pride of the Garden.**—This is a hardy and free-flowering variety, and one that should be grown in all gardens where plenty of bloom for cutting is needed. The colour is a rich rose, which shows up well from a distance. This variety makes plenty of grass, so that a good stock of young plants can soon be raised. One-year-old plants layered and allowed to remain undisturbed the second year made a brave show, producing hundreds of their elegant rosy flowers. Pride of the Garden should be grown where ground is limited and only a few varieties can be accommodated.—J. C.

**Species of Hemerocallis.**—Having recently observed a question on this subject (p. 112), I consulted "Index Kewensis" and the "Kew Hand-list of Herbaceous Plants"—the two most recent and most trustworthy authorities—neither of which recognises the thousands of pseudo-botanical names given on no authority to plants by nurserymen and gardeners. I find that each of these authorities gives five species of *Hemerocallis*. "Index Kewensis" recognises *H. Dumortieri*, *H. flava*, *H. fulva*, *H. Middendorfi*, and *H. minor*. The "Hand-list" omits *H. Middendorfi* and gives one additional, *H. Thunbergi*, so that these two authorities together recognise six species in all.—C. WOLLEY-DOD, *Edg. Hall, Malpas*.

P.S.—I have known *H. Dumortieri* called *H. aurantiaca* in nurseries.

SHORT NOTES.—FLOWER.

**Michauxia campanuloides.**—One does not often see this quaint-looking and showy biennial. Perhaps it is that being a biennial it does not find much favour. These biennials are certainly disappointing plants. You think you have them established and you find to your disgust that you must begin sowing them afresh. There are some of them which seed very freely and reproduce themselves.—D.

**Helesium grandiflorum vel striatum.**—On going through the interesting garden of Mr. C. J. Grahame, of Wrydeclands, Leatherhead, I was struck with a plant, although its flowers were passing off, which he told me he had received under this name—*Helenium grandiflorum*. I cannot quite make it out, either from catalogues I have or in Nicholson's "Gardener's Dictionary."—H. H. D.

**Crium Powelli.**—This, which was raised by Mr. Powell, of Southborough, near Tunbridge Wells,

was given to me some three or four years ago. It has grown vigorously with me, and has withstood our severe winters without any protection, though I think I should be inclined to give it a little covering next winter of either Fern, Pine needles or cocoa-nut fibre. The height is from 2 feet to 3 feet.—D. D.

**Dryas octopetala.**—This very pretty native plant, with its delicately cut foliage and pure white blooms with yellow stamens, may be induced to flower all the summer if the seed-pods are picked off. My clump of it, which was sent me by a friend from Galway, flowered early in the spring, and is now (August) covered with its pretty blooms. It is certainly worth the little trouble of picking off the seed-vessels to get it to flower so continuously. It will vie with many of our alpine plants both in its foliage and flower, and is certainly more easy of cultivation than many of them.—D. O.

## ROSE GARDEN.

### HYBRID PERPETUAL ROSES.

This is the largest section of our Roses, and to many the most desirable, their colours being the brightest, and in most cases they are delightfully scented. The Hybrid Perpetual Roses as we now have them are the result of much crossing, hybridising, sporting, and other developments and methods of raising Roses, and originated in the first instance from the crossing of the China with Bourbon Roses. The general name "Perpetual" to all of this class is a misnomer, as many are not at all perpetual; but some varieties, more especially some of our oldest Roses, keep on blooming up to the month of November. Amongst the old H.P. kinds one may instance especially La France and Charles Lefebvre, and amongst newer varieties, Viscountess Folkestone and Victor Hugo as true perpetuals; whereas Mrs. John Laing, Margaret Dickson, Gabriel Luizet, General Jacqueminot, and many other H.P.'s do not usually bloom after the month of August—at all events, it is quite the exception when they do so. There is one advantage which H.P. Roses possess over their more aristocratic relatives the Teas, and that is they appear to have no marked preference for locality or position. Give them a fair start by good planting, and they will do equally well on heavy or light land, in warm or cold positions, on the side of a hill or on a dead level. Naturally they will bloom earlier when they have every advantage, and they will be heavier in petal off heavy land, but, taking them all round, H.P.'s will do well in almost all localities and situations where the air is pure and where they have been properly planted.

There is still great divergence of opinion as to what is the best stock on which to grow Hybrid Perpetual Roses, although it is usually allowed that Teas grow best on the Brier. The Brier, however, is the best of all the stocks. Some consider that maidens on Briers develop their first blooms too late in the season, and therefore those rosarians who use this stock are handicapped when they grow maidens extensively for exhibition.

Which are the best Hybrid Perpetual Roses to grow? That is a question which might lead to controversy, as our Rose lists alter annually. Each year a few (very few) good, apparently new, Hybrid Perpetuals are brought out. Some last in favour a year or two, some even longer, but the great majority are relegated to the dust-heap or given to friends who grow Roses in a casual sort of way. Few Hybrid Perpetual Roses have been brought out of recent years which can be said to equal and none to excel our oldest favourites. No doubt many good ones have been produced, notably Mrs. John Laing, Captain Hayward, Marquis

of Downshire, Marquis of Londonderry, Gustave Piganeau, Jeannie Dickson, Sir Rowland Hill, Viscountess Folkestone (best of all), Her Majesty, Margaret Dickson, most of which will permanently hold their positions, but are they better or more reliable, or will they supplant such varieties as A. K. Williams, Baroness Rothschild, Charles Lefebvre, La France, Marie Baumann, Comte de Raimbaud, Mme. Gabriel Luizet, Alfred Colomb, Dupuy Jamain, and General Jacqueminot? Certainly not. But there is a marked peculiarity in regard to the new Roses brought out; we seldom see a really first-class new dark and distinct red Rose. There are too many new Hybrid Perpetuals of various shades of light and dark pink, and too much alike. We do not want Roses of these uncertain lighter colours, but of decided shades

without exception the dark red Hybrid Perpetual Roses are sweet-scented, the want thereof being principally confined to some of the pink varieties, as Merveille de Lyon, Susanne Rodocanachi (here figured), and Duke of Edinburgh.

**Rose Mme. Edouard Helfenbein (Tea).**—This season has again shown the value of the lovely Tea Roses. At the commencement of August, when most of the Hybrid Perpetuals are devoid of all blossom, these grand Roses are beautifying our gardens and filling the air with their fragrance. The above variety is a worthy addition to the very vigorous non-climbing Teas, of which Marie Van Houtte and Mme. Lambert are good examples. The colour of the variety under notice is of the shade generally known as old gold; the centre of the flower is tinged with

Rose (H.P.) *Susanne Marie Rodocanachi*. From a photograph by Messrs. Byrne and Co., Richmond, Surrey.

of red, as the brilliant scarlet of Duke of Teck or Cheshunt Scarlet, or such whites as Margaret Dickson. We already have too many pink Hybrid Perpetuals similar in shade and shape, and between which at times even experts can hardly discriminate.

Another quality which of late years has not been considered a *sine qua non* in producing new Hybrid Perpetual Roses is that of scent. Surely of all qualities the Rose should not be scentless? It is the crowning point in a good Rose, and the greatest defect of two such good Hybrid Perpetuals as Baroness Rothschild and Her Majesty. Who would prefer either of these even in their greatest glory to a really good La France or a Mme. Gabriel Luizet, sweetest of all Hybrid Perpetuals? Almost

salmon shade, with fawn-coloured outer petals. Perhaps the flower is too rough or irregular in form for exhibition, but for the garden it is super and I can highly recommend it.—E.

**Rose Beaute Inconstante.**—Perhaps the variety, on account of its wonderful colour, is the most attractive of all the semi-double Teas. It is of an indescribable shade, and to say it is coppery red is not doing full justice to the Rose. A large amount of orange pervades the flower. As its name implies, it is variable; sometimes the blossoms on one plant are partly coppery red others of a pink and fawn colour. Possibly to propagate constantly from the shoots bearing highly-coloured flowers would in time fix the latter and most pleasing colour. Although it has this variable character, everyone should possess this variety. The perfume is delicious. It is,

stander grower, excellent alike for bush or standard. Under pot culture most of the blossoms are of the high-coloured coppery-red shade. It was raised by M. Pernet-Ducher, who has given Gustave Regis, Caroline Testout, and other rising novelties.—E.

**Roses losing colour.**—I see many letters in THE GARDEN asking the reason of certain Roses not appearing in their proper colour. I enclose an example of Crimson Rambler in which the twig was broken before flowering, and the flowers at the end have come quite pale, whereas just behind the break an off-shoot has come on which the flowers are of the natural colour. Of W. A. Richardson I have four plants on a brick wall. Last season I had a few pale-coloured flowers; this year not more than 1 per cent.—C. W. COWAN, *Weyfield, Penicuik, N. B.*

**Rose Souv. de Catherine Guillot (Tea).**—I would be difficult to name a more beautifully tinted Rose than the above. Its colour is scarlet orange, suffused with salmon, the edges of the petty buds heavily lined with earmine; a most lovely combination. It has a fairly large petal, but the flower is not full enough for exhibition; however, as a garden Rose it is destined to take a prominent place. This variety has a very attractive feature in its reddish wood and foliage, which certainly tend to enhance the vividness of its lovely-coloured flowers.—PHILOMEL.

**Rose Climbing Captain Christy.**—Yellow, red, and white climbing Roses we have in abundance, but pale pink varieties are not very numerous. In the above variety we have an ideal climber. The dwarf form is in almost every garden in the land, and the climbing sport of this grand Rose would also find a place. There is very little difference, if any, in the flowers of the dwarf and the climbing forms. The latter will make shoots fully 5 feet in length each season, and when well established it flowers abundantly. It also makes a splendid variety to grow as a standard, the fine long shoots gracefully drooping with the blossoms which they produce.

**Rose Eclair (H.P.).**—The very expressive name given to this Rose by its raiser is certainly well merited. Its brilliant, flashing, velvety crimson blossoms are most effective. Probably there is no Rose to equal it for doubleness, and it makes a grand front-row exhibition flower. It is a globular form, not very large for a Hybrid Perpetual, but the petals slightly reflex at the edges, which gives the bloom a very distinct character. Its flowers are produced rather sparsely, but it is a good grower, and if budded on the seedling or cutting Brier, its lovely colour is much more glowing. It is also a very fragrant variety.

**Roses in Midlothian.**—This has been the best season for Roses experienced for several years, but the following have proved as useless as before. Buds come in plenty, but on opening, the flowers are distorted so as to be quite worthless. Suzanne Marie Rodocanachi and Mlle. Eugénie Verdier among Hybrid Perpetuals, and Marquise de Salisbury among Hybrid Teas are the worst offenders. Before discarding the groups of these sorts—eight or ten of each, dwarfs—I should be glad of any hints as to whether anything can be done to make them flourish as well as Dr. Grill, the Hon. Edith Gifford, Madame Odéane Guinoisseau, Rubens, Marquise de Yvrens, and many others growing alongside of them.—J. M.

**Rose Helen Keller (H.P.).**—For general usefulness this Rose will rank nearly equal with Mrs. John Laing. For the last week or two it has been one of the showiest among the H.P.'s. It produces fine strong shoots, which are crowned with bunches of four and five blossoms, and a distinct feature of the variety is that these blossoms expand almost simultaneously, a fact not to be lost sight of. Helen Keller reminds one, in the exquisite high-centred, perfectly formed flower, of that almost forgotten variety, Emilie Husbarg. Its flowers have just the same silvery tinge to the petals, but the ground colour is a

much deeper pink than in that good old kind. Another useful attribute of Helen Keller is its sweet perfume. This quality is doubly valuable in such a lovely Rose.

**Fragrance of Roses.**—I enclose a few remarks on the fragrance of Roses. I have long collected all the old Roses, not only for their beauty, but for this very virtue, their great sweetness of perfume. Of course we have the pleasure of their presence for a much shorter time, but no garden, however small, should be without them. Many of the old ones are lost to us, but I have found treasures in old villas in Italy, often in those hid away in the mountains, many also are preserved in old Scotch houses, but there is one I have searched for in vain—the single Moss—though I still hope to find it, and that also would be a sweet parent. "Ridge-wood's" comment on "D. T. F.'s" note (p. 80) is true, but the difficulty of judging of the comparative fragrance of Roses is not insurmountable, and we must allow that much of the perfume of the old Roses can no longer be found in the beautiful hybrids of the present day. If we fill a glass with the sweetest of these and another with the Rosa biflora officinalis (Redoute's Rose des Parfumeurs), all doubt would vanish. Or who would make pot pourri with the sweetest of our new beautiful friends? The scent of the old ones remains long after their beauty has faded. This Rose (biflora officinalis), the one used in all the old pharmacies in Italy, is called in Tuscany the Rosa di Maggio, and is also the one grown on the Shipka Pass in the Balkans for attar of roses. I think we should all sympathise with "D. T. F.," and wish with him that the Roses of the future should possess the lovely gift of sweetness. How would it do to use Rosa biflora officinalis for this purpose?—C. L. S.

THE BROUGHTY FERRY ROSES.

This year the Roses at Broughty Ferry are from three weeks to a month later than last year; hence the simple explanation of their absence from the National Society at the Crystal Palace and Norwich and other great shows. The plants, however, are in superb health and vigour, and the time lost through the cold spring will be added to the other end of the blooming season, probably extending the Rose harvest well into the winter. Though the Rose season is late, in these nurseries the budding season is early, and was well-nigh finished at the time of my visit. The Roses are mostly on the Brier or Dog Rose, and though the Perpetuals are not so large as on the Manetti at Colechester, the whole of the Roses are a very even lot of the most promising character. A unique system prevails in these nurseries of obtaining a fine supply of maiden blooms throughout from very early breaks from the dormant buds. Almost immediately on the heels of budding, the Briers, which are specially robust, are pegged down level with the ground through the use of bamboo canes pegged down strongly over them. This system facilitates the taking of the buds and forces them into growth and bloom in a few weeks from their insertion. Garden Roses—Briers, especially the Penzance Sweet Briers, Polyanthas, and other rambling old-fashioned Roses—abound, and make a brave display on each side of the main walk from the public road into the nursery. Most of the leading sorts are worked in breaks or masses by themselves, which adds greatly to the interest and instruction of a ramble through them. Crimson Rambler has found a grand companion here in the new Perpetual Polyanthas, yellow Tea-scented Roses, Aglaia, Anne of Gierstein, as also a charming Sweet Brier with single dark crimson flowers, succeeded by a profusion of clustered bunches of heps. Bardou Job is almost single, glowing crimson. Brenda is another chaste Hybrid Sweet Brier, single, white. Maiden's Blush is peach. Euphrosyne or Pink Rambler is a capital companion for Aglaia or Yellow Rambler. Flora Melvor is a charming single white Rose with striking foliage. Janet's

Pride, almost single, white, tipped with crimson, is one of the earliest and most striking Briers. Lord and Lady Penzance are also among the cream of the Hybrid Sweet Briers, the former a single form, passing to yellow; the latter a soft tint of copper with a metallic lustre, steeped in fragrance. Moss Roses, the white and red Cabbage, the three Waltham climbers, York and Lancaster, &c., were also largely grown.

D. T. F.

**Roses unhealthy.** Could you kindly tell me what disease affects my Roses at this time of the year? It attacks all kinds alike. They lose all their foliage, leaving only the bare stems, making them very unsightly. The foliage is first attacked with a small spot or several spots. These appear to enlarge and spread over the surface of the leaf and finally the leaf-stalk. The leaves, stalks, &c., fall off. In some varieties it takes the colour of iron-rust. The soil was very carefully prepared before the Roses were planted. The sub-soil here is very strong clay, but in parts of the garden there is a great quantity of old mortar rubbish. In preparing the beds I have the worst of the clay removed to the depth of 2 feet or 3 feet, and good loam and cow manure mixed with the best of the remaining soil. The plants are often watered, and should they have insect pests in the spring, syringing with one or other of the insecticides recommended.—J. C., *Herts.*

\* \* \* These Roses are undoubtedly suffering from the effects of a check in their growth, caused possibly by the excessive wet in the early part of the year. We should say "J. C.'s" soil is too heavy, and should recommend that a good portion of the heavy clay be burnt and then thoroughly incorporated with the remainder. Roses on the Manetti stock are much addicted to this rust. There is no better stock than the seedling Brier for such soil as "J. C." has to deal with, as it induces a continuous growth instead of early maturation, as in the case of plants on the Manetti. The artificial watering of Roses is often the cause of much evil. We would rather frequently transplant Roses to newly-trenched land, then with frequent hoeing little or no water would be required even in the worst season. To obviate this rust and black spot, overcrowding should be avoided, and at pruning time the growths must be well thinned; this would allow of a free circulation of air, and consequently good healthy foliage, sufficiently sturdy to withstand attacks of fungoid disease, would result.—ED.

BANANA-GROWING FOR THE MARKETS.

The headquarters of the Banana trade in Nicaragua is Bluefields, until recently the capital of the Mosquito Reservation. For the planter with small means—that is, with a capital of £200 upwards—I know of no occupation so certain to realise a decent income as growing Bananas, provided that the plantation is within easy reach of the sea, and there are steamers to carry his produce to New Orleans, New York, or London. That is of prime importance.

The Banana is cultivated from suckers springing from the roots of an existing tree, generally known as the "stool." These suckers are detached and planted. They strike, and shoot up so fast that it is no great exaggeration to say that you can see them grow. In a year or less the planter harvests the first crop. The Banana has no trunk, but a soft, fibrous, so-called stem, composed of the leaf-stalks rolled one over the other, which grows to from 10 feet to 20 feet in height, and withers after the fruit has ripened. The tree is seldom known to seed. The roots, however, furnish shoots or suckers year after year, until the stool is exhausted. The purple flowers appear on long spikes,

springing from the cluster of leaves which appear to open out from the stem. The flower-spikes are often 4 feet long, and the bunch of fruit which succeeds the blossom comprises from eight to twelve dozen Bananas, weighing from 30 lbs. to 60 lbs. The leaves are from 6 feet to 10 feet long, and from 1 foot to 2 feet wide. When the leaves are newly opened, the tree has a most graceful appearance. For successful cultivation, a cool, rich, and moist soil is required—the alluvial deposits of the river bottoms or the higher land where rain is abundant or water plentiful. Bananas grown on high ground are said to be finer than those of the valleys. In preparing a plantation the trees and brushwood should be cut down, and after lying a month to dry, burned, and the ashes spread over the land. The suckers, which, being very abundant, may be purchased at a low price, are then planted at a distance of from 12 feet to 15 feet apart, or say 200 to the acre. In Mexico, as will be seen presently, they are often planted much more closely, 1000 plants to the acre being common. After the first crop is harvested the stems should be cut down, chopped into short lengths, and heaped round the roots, whence spring the new suckers. A proportion of these only are allowed to grow from the stool; the remainder are removed and sold, or planted elsewhere. The suckers grow as by magic, and bear fruit within the year. It will be seen, therefore, that a large plantation may be formed with the greatest ease, while by judicious management and attention to the time of planting the suckers, a constant succession of crops is secured and fruit gathered every week throughout the year. All that is required as regards after-cultivation is an occasional weeding, say, twice during the year, and the removal of suckers and uprooting of barren stools. When the stems cease to bear fruit, or the fruit is poor, the sooner the roots are dug up and a new sucker planted the better. The expenses of the necessary cleaning and replacing are very small. The only careful work required on a plantation is in handling the massive bunches. This must be done so as to avoid bruising them, or a small black spot will appear, followed by rapid decay. Care is also necessary in gathering the Bananas, but experience has taught the native labourers, when cutting the stems, to gauge the blows so that the first will cause the ponderous bunch to droop slowly until it nearly touches the ground, when another cut severs it from the tree. The Bananas are then collected and carefully loaded into a cart, boat, or railway truck, as the case may be, and conveyed to the nearest port to await the arrival of the fruit steamers plying between Bluefields and New Orleans. Sometimes they are packed in waste cotton from the Ceiba tree, but this is not general. The average price, if sold on the plantation or at the port, is 25 cents U.S. currency (or 1s. 0½d.) per bunch, while if carried to New Orleans they realise from 30 cents to 50 cents per bunch. Some of these Bananas, like a proportion of those grown in Costa Rica, find their way to England *via* New York, and when sound often realise from 7s. to 12s. per bunch; but if intended to be carried so far they must be packed carefully and in a very green state. In the year 1894-95 upwards of a million and a half bunches of Bananas, worth £240,000, or an average price of about 3s. per bunch, were imported from Costa Rica. The value of the Bananas imported into the United States from Nicaragua in a single year has exceeded 600,000 dollars.

At the plantation on the Rama River where I was staying I obtained the cost and profits of plantations of various sizes. The figures given

below relate to one of twenty acres in extent. Land may be purchased at 5s. the acre, or leased at an annual rental of 5 cents native currency (1½d.) upwards. The outgoings are calculated in native currency; the profits in that of the United States.

TWENTY ACRES.—FIRST YEAR.

Dr.	£	s.	d.
20 acres of land at 2 dols. 50c. an acre	...	5	0
Surveying and titles	...	4	0
Clearing	...	40	0
4000 suckers at 25 dols. per 1000	...	10	0
Planting at 10 dols. per 1000	...	4	0
Weeding at 7 dols. per acre	...	14	0
Harvesting: Forty days' labour at 75c. per day	...	3	0
Total cost	...	£80	0
To balance	...	128	6
		£208	6
Cr.	£	s.	d.
4000 bunches at 25c. U.S. currency each on the plantation	...	208	6
Profit	...	£128	6

In the second year two bunches may be expected from each stool, or 8000 in all, of the value of £416 13s. 4d. While the cost of cultivation in the second year will be, for two weedings, £28; removing overplus of suckers, £4 (the cost of which may be covered by their sale or recouped by planting them out); and harvesting, £6—total, £38. The profits of the plantation, therefore, for the second year will be £378 13s. 4d. This will continue until the stools are exhausted, when they must be grubbed up, and suckers planted in their stead. With the plants 15 feet apart the suckers may be planted between them when the first signs of exhaustion appear, so that there shall be no break in the yield of the plantation. As each stool sends up from six to ten stems by the end of the third year, it is possible to reap that number of bunches from each original tree, and four or five stems are sometimes allowed to produce fruit. But the bunches will be much finer if only two stems are permitted to mature; the others, if not sold or required for extending the plantation, should be cut off high up, or bent down, so as not to cause excessive bleeding from the stool, in which case the stool will not only yield finer fruit, but remain in vigorous health much longer than if allowed to exhaust itself.

In a recent bulletin, issued by the Bureau of the American Republic at Washington, it is stated that sixty-nine acres of land will yield 54,000 bunches of Bananas, worth, in the market, a minimum price of 37½ cents U.S. currency, or about 1s. 7d. per bunch = £4275; but I cannot agree with so large a profit. In British Honduras, which offers facilities even superior to those of Mosquito, with the inestimable advantage of a stable government, the profits of a Banana plantation are said by Mr. Morris, assistant-director of Kew Gardens, to range from £12 to £15 an acre after the lapse of eighteen months. But the Banana can be most profitably grown in connection with other crops, for which it serves as a shade plant. For india-rubber, the cultivation of which promises such magnificent profits, it affords admirable shade; also for Cacao, Coffee, Vanilla, &c., as the Banana plantation can be so regulated that it will provide shade all the year round. In Mexico, where 1000 suckers to the acre are often planted, the profits appear to be very

large. The figures given by Sir Henry Dering in a recent Foreign Office report would show that the total cost of cultivating an acre of Bananas, including the purchase of the land, £6 1s. 10d., and the return for the first year £27 1s., a profit of £20 19s. 2d. per acre; while the cost for the second year is under £3, and the return £54 2s., a profit of £51 2s. per acre.

Sir Henry Dering also supplies a mass of information, the greater part of which is equally applicable to British Honduras. We append few extracts:—

The Banana will grow in almost any soil except that composed almost wholly of sand or calcareous matter. The best soil is a warm, well drained, but rather moist, deep loam. The best elevation is 700 feet to 1500 feet above sea-level, but many varieties do extremely well at a moderate elevation in the mountains, provided they are protected from the withering blasts of high winds. The sucker, when planted, should be about 2 feet over all, and four to six months old. It should be placed in a specially prepared hole and when the land is poor a little manure can be put at the bottom of the hole. After planting the earth should be firmly pressed down by the feet all round the sucker. In seven months long spike bearing clusters of flowers, surrounded by coloured bracts, shoots forth from the cluster leaves, and minute Bananas soon appear at the base. During the growth of the plant the land must be kept free from weeds.

Before the plant throws out its flowering stems suckers will make their appearance. While the plant is young all these should be cut away except one. Afterwards, when the stool is matured, from three to five stems may be allowed to grow, which at three or four months old may be sold or transplanted to a new plantation; but on no consideration should a larger number be allowed to shoot up if fine bunches of fruit are looked for. After the stool has borne a crop or two, the earth should be loosened round the stool and manure or decayed leaves and Banana stalks forked in, the whole being moulded up with surface soil. With proper cultivation, a rich soil and a suitable climate, the first crop may be gathered in ten or twelve months from the time of planting, and at all times thereafter.—R. LAND W. CATER, in *Chambers's Journal*.

MOWING BY STEAM.

ANYTHING which lessens labour in gardens will be gladly welcomed. The steam lawn-mower is certainly a great saving of time, and it is much easier to work than an ordinary horse machine. It is very simple and not at all unwieldy, the engine and boiler being fitted on the top of a large or main roller. The machine is so nicely balanced, that it can be turned with more ease than a horse machine. The boiler is composed of a series of copper tubes (sixty in number), a copy fire-box, and the pressure is up to 300 lbs. Water is fed to the boiler by a brass force pump, fitted passing through a heater, and is delivered at a temperature of 180°. The steam is generated in the boiler by using ordinary petroleum, which is burned in the fire-box by a burner similar to that of an ordinary naphtha lamp. The oil is forced to the burner by compressed air, and to start the engine a very ingenious pump is used. The machine when at full working is attached to the gear and gives no trouble. Oil is forced to the burner at a pressure of about 15 lbs. Perfect combustion is obtained, with little smell and scarcely a smoke when in full working. I like the machine on account of its ease in working and the way it does its work. The chimney, which is about 7 feet high, is over the boiler.

The makers give the cost of working as 1s. per hour. Our machine certainly costs more, but it will work six hours without fresh oil. An ordinary labourer works the machine, and I learnt its management in three days. A man

working steadily can do as much work with the chine in one day as would take two with a horse worker. There is no great stress on the worker. I admit he must be active to keep up with the chine, which can be stopped as quickly as a horse drawn by a horse. A 25-inch machine weighs 9 cwt. Ours is a 30-inch, and weighs 14 cwt. I also find it extremely useful for rolling. It forces water grandly by attaching a rotary pump with suction and delivery hose. This is a grand addition, as water can be thrown 50 feet, and at the rate of 2000 gallons an hour. It is invaluable in seasons like the present. The makers also use the engine for various purposes, but I have not done so other than described. This machine is patented by the Lancashire Steam Motor Company, Leyland. G. WYTHES.

## NOTES OF THE WEEK.

**Rosa rugosa Blanc de Coubert** is a very handsome form of this Rose, with blossoms 5 inches across, of the purest white. It is free flowering and perfectly hardy.

**Carnation Sir Wilfrid Laurier** is among the Carnation novelties of the coming year. It is a flower of exceeding purity, a non-burster, while its habit is vigorous. The handsome pure white blossoms are very freely produced.

**Lobelia Carmine Gem.**—This lovely plant is one of the most striking of the herbaceous section of Lobelias, the colour very rich and bright, and flowers freely produced on long spikes. These only-cultivated plants are worth the attention of gardeners generally.

**Bougainvillea spectabilis** is now very attractive with its wreaths of rosy-purple flowers in the greenhouse, where it still occupies a front rank among the climbers. The rich colouring is not attractive, and if not quite unique among greenhouse plants, is still indispensable.

**Verbena venosa.**—Too frequently the rush and novelty does away with many of the tried and useful garden flowers, and this plant has certainly suffered in this way. Quite hardy and easily increased, it may be variously employed in summer with good results either as a groundwork or in mixture with other plants.

**Fruit crops in Lincoln.**—The South Lincolnshire fruit orchards suffered severely from a gale on Wednesday the 17th. In exposed places many trees were almost entirely stripped, and as the fruit is yet unripe, much of it will be unsalable. Most crops are deficient this year, and the loss to growers will be heavy.

**Lematis campaniflora.**—A singular species from Portugal, having numerous small, drooping flowers of a bluish-white shade, on climbing stems. The smallness of its blossoms and their peculiar form render it an attractive species. The large plants are now flowering at Kew, where it is found as hardy as any.

**Fourcroya in Cornwall.**—I am sending you a photo of two plants of *Fourcroya gigantea*. I regret the plants being so close to a dense background of shrubs, which prevents their showing up so distinctly as they otherwise would have done. M. SANGWIN, *Trelissick*.

\* Nobly-grown plants, fine in form.—Ed.

**Lilium Henryi.**—A large group of this Lily is now nicely in flower at Kew, though scarcely so lately in the stems as a year ago. This, however, to some extent may be due to the fact of the buds having broken up, or possibly suffering from the heat of last year. At the same time it is the most beautiful Lily, and one that cannot fail to impress lovers of this unique class of bulbous plants.

**Kniphofia nobilis.**—This is a noble plant in every way. When in a cut state much of its beauty bearing is modified, and doubtless this fact has weighed with the floral committee of the Royal Horticultural Society a week ago, when the plant

failed to obtain an award of merit. That it is one of the grandest of the whole race no one with knowledge of the plant will deny. At the same time it is one of the most striking in colour, and in this respect most valuable.

**Agapanthus umbellatus albus.**—Few of the nearly hardy plants are so useful as the well-known blue form of this, and where large examples exist these create a fine display on many a terrace garden; indeed, it is rather surprising how often the blue form is used for this purpose with no apparent attempt to substitute the pure white form above noted, which indeed is a most useful and valuable kind of the same easy culture as the type.

**Lagerstrœmia indica.**—I quite agree with what is said on this noble shrub by "H. P." (p. 82). I find that it is much more hardy than is generally thought. I have got in my garden a specimen 2 yards to 3 yards high, which was planted against a sheltered wall looking due south more than twenty years ago. It is covered in winter with straw, and every year it blooms profusely. Just now it is a mass of pink flowers. The climate in Geneva is far from mild.—M. MICHELI, *Geneva*.

**Victoria Regia.**—This is now flowering at Kew. It is, we think, more vigorous than usual—at any rate in the large handsome leaves, and particularly so in the depth of the upturned margin. As seen in the fine condition here, it is truly a noble species, equally so in the monster leaves of several feet diameter, and blossoms something like a foot across. Perhaps one of the most remarkable features is the rapid annual growth of the plant when the right temperature is maintained.

**Kniphofia Macowani.**—If this plant can boast of any special merit at all, it certainly must be in its dwarf habit and great freedom of flowering. At the last meeting of the Royal Horticultural Society Mr. Pritchard had quite a large bundle of its pretty and useful spikes, sufficiently small indeed to be of service in a cut state, while its dwarf habit will make it valuable in beds or borders. For a dwarf race of these plants there is still plenty of room if the flowers are bright and freely produced.

**Nelumbium speciosum.**—This handsome aquatic is now flowering beautifully at Kew. On stems nearly 7 feet high are the giant rose-coloured blossoms that are nearly 10 inches across. These handsome blossoms are exceedingly beautiful. Of nearly the same height are the large leaves, these being well-nigh 2 feet in diameter. Apart from the sumptuous blossoms to which we refer are others to follow shortly, judging by the well-developed buds that are nearly full grown.

**Montbretia crocosmiæflora.**—It would be difficult to name any flowering plant suited to the border so pleasing and beautiful as this. The slightly arching spikes give the plant a special value at this season, when a few good clumps are particularly attractive in any garden. Such things indeed merit special treatment, and those who can afford to place a barrowful of loam, peat and leaf soil in about equal parts, with the addition of some manure, to each clump will have an abundant reward in the rich display of flowers in after years.

**Carnation Mrs. Tudway.**—I beg to enclose a few blooms and grass of Carnation Mrs. Tudway. I sent three dozen blooms to the Royal Horticultural Society on the 10th inst., but can see no mention of them in any of the gardening papers. I consider it one of the best hardy Carnations, as it will stand for years without layering and throw flowers abundantly annually. It is the last to come into bloom, and grows about 3 feet high.—A. G. BOOKINGS, *Oldown House Gardens, Almondsbury, Glos*.

\* \* \* A fine, dark, clove-like plant with grass such as is rarely seen.—Ed.

**Lematis heracleifolia.**—This is a most remarkable species from China, with pale blue

blossoms, that individually are not unlike the recurring pips of some Hyacinths, especially those of a pale porcelain shade. The foliage, on the other hand, as implied in the specific name, is widely distinct from that of any other Lematis. It is a non-climbing species, and just now a bed is filled with it at Kew, where the plants are flowering freely. The flowering stems, very peculiar in form, produce large clustered heads, and smaller later sprays of the singular flowers on stems about 4 feet high.

**Lilium tigrinum splendens.**—On the grass at Kew, not far from the Victoria Gate, may now be seen a large group of this Lily, surrounding a colony of *Araucaria imbricata*. In the distance the effect is very good, though less so on a nearer view of the plants. Some years since we were struck by a much more imposing arrangement of Lily and *Araucaria*. In this instance, however, it was the pure Madonna kind, sending up its snowy spires amid the deep, dark green of the *Araucaria*, that produced one of the most striking and effective groups we have ever seen in a garden.

**Campanula G. F. Wilson.**—This pretty hybrid Bellflower still continues to produce many of its distinct blossoms, though more freely in those instances where a slight top-dressing was given after the main flowering earlier in the season. But even this does not compare with that portion of the stock that was divided and transplanted in the month of March. All these have bright fresh tufts of leaves and are flowering profusely, though of course the division of the plants interfered with their blooming at the right season. The gain, however, comes in maintaining a good succession of flowers.

**Two new Bamboos.**—I have received from Japan this spring two Bamboos, which appear to be new to western gardens. 1, *Phyllostachys fulva* (Japanese name, *Ogon chiku*)—a *Phyllostachys* of the same type as *P. nigra*—not yet sufficiently advanced for me to be able to describe it in detail. It promises to be very ornamental. 2, *Arundinaria metallica* (Japanese name, *Kan'eyama Daké*, or *Shakutan chiku*), a dwarf species, closely allied to *Arundinaria Veitchii*. Both these species should, from their geographical position in the Japanese islands, prove hardy in the average English climate.—A. B. FREEMAN MITFORD.

**Hydrangea paniculata grandiflora.**—In the open bed this fine plant is now flowering freely, the pure white panicles of blossom being well formed and of large size. In the greenhouse the heads of blossom are even purer, and among other plants most effective. For the large conservatory this handsome shrub is worth growing in large tubs. The plant will bear rather hard as well as close pruning, and where this is carried out and the plants are growing in a deep bed of soil, some noble heads of bloom are the result. Liquid manure may be employed as soon as the trusses are well in sight.

**A hybrid Poppy.**—I enclose some flower buds and leaves of a hybrid Poppy which has flowered in my garden for the first time this season. It appears to be *Papaver rupifragum* × *orientale*. The flowers are similar to those of *P. rupifragum*, but from 3 inches to 3½ inches in diameter, and are produced at intervals along a stem from 2 feet to 3 feet in length. Many of your readers have no doubt seen a similar hybrid from Mr. Carrington Ley's garden, but in his plant the flowers are produced singly at the end of the stem, in the same way as in *P. rupifragum*, and are of a deep orange-red colour.—E. C. BUXTON, *Coal Dorr, Bettws-y-Coed*.

**Asclepias tuberosa** is noted in THE GARDEN of July 31 as being "one of the most distinct plants in flower now." The same applies to it, as I see it frequently wild by the wayside in New Jersey. Perfect exposure to all the sun possible seems of more importance than special composts; indeed, here are magnificent plants growing with little or no soil at all on stony railway slopes or along the fringes of rocky woods, and the most casual observer cannot fail to note their beauty

with flowers so distinctly rich in colour. Its relatives prefer swampy ground, and are also very abundant in this district, but they cannot compare with this one in point of beauty even in all their natural luxuriance.—A. H., *Madison, N. J.*

**Eryngium planum var. celestinum.**—This pretty Sea Holly is one of the neatest habited of its kind, while the pretty globular heads that form the chief attraction in these plants are very freely produced. When in the mature state the colour is attractive, and small sprays are very useful in vases or epergnes. At the present time in the rock garden and border it is very pleasing.

**Polygonum Baldschuanicum.**—Notwithstanding that this species has been flowering profusely for some time past in the herbaceous ground at Kew, it is worthy of note at the present moment that it is in no wise exhausted by the heat and drought of the present year. As has been stated previously, it is a climbing species, possessing among these plants a claim to very considerable popularity. The elegant sprays of blossom are white, with just a faint tinge of pink that produces a very pleasing result.

**Lupinus arboreus.**—In the very light and warm soils of the Thames valley, this plant succeeds admirably, and never fails year by year to produce a most welcome display of its blossoms. Of its liability to go off occasionally I have not the same experience as Mr. Arnott, though severe frost will at times with old examples play considerable havoc. To the uses given at page 124 and of its value in the shrubbery I would like to add its adaptability to cover a west wall with but little trouble. For years I had a very fine example in this position, where it luxuriated in quite common soil, and the severest frost left it unharmed. It does not receive due attention in gardens, and though naturally shrubby in habit has a very pretty effect on a wall.—E. J.

**The Prairie Rose (R. setigera).**—The writer of the paragraph concerning this Rose in THE GARDEN of July 31 (p. 92) must surely have made mid-day observations of it only to have come to the conclusion that the flowers lack fragrance. I would class the Prairie Rose among the sweetest of Roses, and I know of nothing more delightful than a bunch of its clusters cut in the early morning while yet fresh with dew. At day-dawn and in the evening the bushes here scent the air for yards around. In the bright sun, however, the flowers wilt and are scentless. In the house the buds continue to open and the clusters keep fresh several days. The Prairie Rose should be planted where it can have free scope, and it is doubly valuable for its lateness of blooming.—A. H., *Madison, N. J.*

**The fruit crops in Cambridge.**—There is an extraordinary falling off in the chief part of the Cambridgeshire fruit harvest this year. Green Gages and other kinds of Plums, for which the district is famous, are almost a failure. Orchards from which, in a plentiful season, tons of Green Gages have been consigned in a single night to the London and other markets have in some cases practically none at all this year, and in most instances such a very slight crop that the enhanced market price cannot possibly recoup the numerous growers who cultivate this famous fruit. Pears, on the other hand, are abundant, and Apples, in many cases, are fairly plentiful, though it is not always the best sorts that are most prolific, and nothing in this direction will quite make up to the district for the loss in the harvest of Green Gages and other kinds of stone fruit.

**Clematis Viticella alba.**—It is very difficult to find a reason why such a good, useful and free-flowering summer climber is not more generally seen. Now and again a large plant is seen many feet high completely laden with its pure white blossoms. One very fine example we have seen of late occupying a south-east wall has been a perfect sheet of its pure white flowers for nearly 30 feet high and some 12 feet or more in width. That the plant has occupied the same position for some considerable time there is little doubt. Notwithstanding its position, which does not impress

one as being the most favourable, the plant flowers abundantly for weeks each year in July and August. Singularly enough, little sunlight reaches the plant, owing to a rather thick shade of Birch and Chestnut from an adjoining garden. This fact in nowise prevents the plant flowering abundantly each year.

**Lilium auratum rubro-vittatum.**—There is no more beautiful Lily in the whole genus than this, though it cannot be described as the most useful or the most easy to manage. It is but rarely indeed that any imported bulbs of it ever give a second bloom in this country. Under these circumstances, any Lily that holds a position quite unique among its kind is worth a special effort to obtain home-raised stock, and, if possible, to procure good flowering bulbs at home. To achieve this, a beginning must be made with scales of the variety in question, which should of course be secured from a reliable source to start with. Having detached the scales, place them in a cool and not too damp cellar in rather moist cocoa-nut fibre, and allow them to remain for some time. By making a start in the coming autumn with fresh scales a few small bulbs may be secured in the following year, to be grown like seedlings for a time. Of course it will take a few years of patient working and waiting, but if successful, all this will be repaid, and if not, some interesting information should be gleaned by the experiment in the hands of any intelligent amateur gardener.

**Notes from a Cornish garden.**—Heavy rain this last week has rather spoiled the flowers, but this summer flowers have been very good. As I write, Callirhoe involucrata is flowering well in the rock garden by the side of Tournefortia heliotropioides, which wintered out. Cyananthus lobatus is a mass of bloom, and Arctotis speciosa and A. aspera var. arborescens seem to thrive on a sunny bank, where also many of the Mesembryanthemums are still flowering. In the south border Hunnemaunia fumarifolia has been bright ever since June, and a single flower of Gerbera Jamesoni, now fading away, has been out three weeks. On the south wall Cassia corymbosa is a blaze of yellow. The white Swainsonia was planted out last August, and is now covered with bloom. Nandina domestica is at its best, and Eucomis punctata and Amaryllis Holfordi are both in flower close to the wall. Senecio Heritieri has been much admired here this year. Rudbeckia laciniata never did better. R. pulcherrima is good, but R. speciosa is not flowering so well. Lobelia Feuillei has many spikes of flowers. Malva lateritia is bright, and Phylisal Franchetti wintered out, and seems to have a very strong habit. The seedling Pentstemons are splendid, and show marked improvement in size and shape on the old varieties. Cyclamen hederifolium has been in flower in the grass since July 26, and Colchicum autumnale has been in bloom just a week.—C. R.

**Paris Chrysanthemum committee.**—The fourth issue of the bulletin of this committee has recently come to hand. Among its contents are a list of the officers of the committee, the names of the members composing the society's floral committee, regulations and schedule of prizes for the forthcoming show in November next, several short articles upon Chrysanthemum subjects, and a list of the members of the committee, among whom we notice such well-known Chrysanthemum specialists as Messrs. Brunt, Calvat, Charmet, Cordonnier, Conillard, Crozy, Daupias, Délaux, Fatzer, Heraud, Hoste, Lacroix, Nonin, de Reydellet, Rozain, Boucharlat, H. de Vilmorin, &c.

**The weather in West Herts.**—Taken as a whole, the past week has been about reasonable in temperature. There occurred one cold night, that preceding the 13th, when the exposed thermometer fell to within 7° of the freezing point. Although the temperature of the ground has fallen since the beginning of the week, it is still 3° above the average both at 2 feet and 1 foot deep. During a thunderstorm on the afternoon

of the 18th nearly a quarter of an inch of rain fell, and for eight minutes was falling at the rate of 1½ inches an hour. No measurable quantity of rain-water has now come through either percolation gauge for over five weeks, and not at all for eighteen days. Since the 4th the wind has blown almost exclusively from some point the compass between south and west.—E. J. *Berkhamsted.*

**Fungus on Saxifrages.**—Herewith I send you rosettes of Saxifrage attacked with a fungus which eventually kills the plant and is very contagious. I originally had it on a plant I bought and from that plant it has spread all over the garden, but only on the leaves of encrusted Saxifrages. I suppose the spores fly about in the air or do you think the spores may be in the soil and get up to the leaves through the roots? I think this because you can generally see the "spores" forming in the centre before it breaks open on the surface of the leaf to release the spores. I should be greatly obliged if "G. S. S." can tell me what it is, and if there is any cure.—LORDSWOOD.

\*\* No doubt the fungus on your Saxifrage has spread from the one infested plant, the spores being carried about by the wind. I do not imagine for one moment that the spores are in the soil. When a spore falls on a leaf under suitable conditions it begins to germinate and penetrates the skin of the leaf, and the fungus grows and creases within the leaf. Then at a certain period of its growth the reproductive organs are formed on the surface and spores are produced, which are wafted about by the wind. I should pull up plants which are badly attacked and spray others with Bordeaux mixture, which is made as follows: Dissolve 1½ lbs. of copper sulphate in little warm water, slake 1 lb. of freshly-burnt lime and make it about as thick as cream with water, then strain it through coarse canvas and the copper sulphate, add 11 gallons of water and stir thoroughly. Spray twice at an interval of four or five days. Next year keep a sharp lookout for this pest, and as soon as you notice it spray all the plants and again in a week's time G. S. S.

#### HONOURS FOR GARDENERS AND FARMERS.

I THINK the note (p. 116) rather severe on gardeners. Doubtless, from the writer's point of view, it is not an honour to accept an award or of merit, but as the recipient of the honour (not any way solicited or expected), I briefly give reasons for accepting the same. I consider it a Jubilee honour, and I fear the writer at p. 116 overlooks this. Again, is it not well to encourage merit? I do, and hope the honour will not be used in a swaggering way. I am of opinion horticulture has not received its proper recognition during the Queen's reign. When we see the medals and honours given to soldiers, sailors, statesmen and others eagerly accepted—indeed, looked for, perhaps the writer will be less severe on gardeners who have had so little done for them.—G. W.

\*\* We were not severe, we hope. It was the general effect of orders of merit that was criticised; and there are the loss of time, the money wasted and the disappointment of many to be thought of. Many of those who had the medals are our friends, and we feel sure no better choice could be made, but it was, and we hope always will be, the pride of all good gardeners to love their work for its own sake. Besides, in other walks of life than our own it is notorious that the bestowal of academic and like honours is not in the end for the good of art, and that in the end is the question.—ED.

**Celestial Sweet Brier.**—Do any of the readers of THE GARDEN happen to know the name of which at one time occurred in *Rosae* books? I now fail to trace it, and shall be grateful for any information.—ROSA.

**Name of fruit.**—*Chas. Simpson.*—Apple, Canada head.

## ORCHIDS.

### VANDA SUAVIS.

The habit and general appearance of this noble orchid render it an attractive plant whether in flower, while the delicacy of the blossoms is not surpassed by any in the genus. While looking through the fine gardens at King's Weston, near Bristol, recently, I noticed a fine plant of it in flower. It is a large specimen, bearing two racemes of about twenty flowers each, the individual blooms of fair size and richly tinted. To grow this Vanda well, a airy large house is best, and one kept at an intermediate rather than a very high temperature. Here growth will be quite free enough, and as the plants can be arranged at a considerable distance from the glass, a heavy shade is not required. Thus the growth made is of a lid character, not liable to be easily injured, and, owing to this, the winter temperature can be kept low without danger and the plants rest. If kept at a minimum of 50° they will take no harm and are far more likely to bloom freely than if kept warmer. All this class of Orchids require plenty of room for root and top growth; the pots or baskets used may therefore be fairly large. Good drainage, too, is essential and an open compost. Nothing but Sphagnum Moss and charcoal must be used for the latter, the charcoal being most useful in lumps as large as a hen's egg for large plants, and for smaller ones in proportion. When repotting or rebasketing, the base of the stems will sometimes be found to have decayed and the removal of the worst parts is advisable. If a large specimen becomes unhealthy without apparent reason, it may in early spring be shaken clear of the compost and examined. If found in bad condition, let every part of it be well washed and place it in a smaller receptacle of clean crocks and charcoal only for a few months, this often causing the emission of fresh young roots and having a good effect upon the future health of the plant. It is at this time that a little more warmth and

a closer atmosphere is desirable—a kind of convalescent treatment, in fact. But when growth is again active and roots are being freely produced, the plants may again have their usual treatment, as growth made in too much heat is not usually satisfactory. A good deal of the leaf-dropping common in Vandas during winter and early spring is attributable to this cause. The plants having attained a good hold of the new pots, a surfacing of Moss may be given, and this may be added to as occasion requires, always adding these to plenty of charcoal or placing the two materials in layers. It is good policy to take off a young piece or two of this Vanda occasionally and set it growing by itself, as should anything happen to large, old specimens, these may by judicious massing be made to take their place in a few seasons. Indeed, it is questionable whether any advantage accrues from keeping very old plants, for the further the heads get away from the compost, the weaker the growth and fewer in comparison are the flowers produced. If by placing a plant against a wall and providing a hold for the upper tiers of roots these could be kept healthy and fresh, no doubt the condition of the plant could be maintained almost indefinitely, but in most cases this is impossible, or, at least, not convenient. The state of the atmosphere has considerable effect on the well-being of Vandas. They like moisture, they like a free supply of fresh air, and in limited quantities ammonia, which may be generated by frequent damping with soot water, or sprinkling scot and lime in places out of sight in the house. Given this continually, there is no need to be always swilling the roots with water. By all means give enough to keep them healthy, but let them seek it themselves, as indicated by the fresh green tips of the roots before watering heavily in spring. V. suavis is closely related botanically to V. tricolor, the chief difference being in colour. It is a native of Java, occurring at considerable elevation often near the coast, and was discovered by Mr. Thomas Lobb, who sent it to Messrs. Veitch in 1846. R.

**Oncidium dasytyle.**—The dark purple callus upon the labellum of this Orchid renders it easily distinguished from all other species. It is a charming and free-flowering little plant frequently met with in good order. The pseudo-bulbs, slightly furrowed, are each about 1½ inches high, this dwarf, compact habit rendering it suitable for cultivation in small pans or baskets. In a light part of the Cattleya house, with abundant moisture while growing and a distinct resting season, it is usually satisfactory.

**Cattleya Warneri imperialis.**—This is a very fine variety of C. Warneri, and a plant of it was in flower recently with Mr. Bull. In size it is much superior to the type, and the colour is magnificent, the lovely crimson-purple on the front lobe being especially rich. It does well at the warmest end of the Cattleya house, and if suspended from the roof all the better. The plants must be induced to rest as far as possible during late autumn and winter.

**Dendrobium Vannerianum.**—This is a very pretty hybrid Dendrobium raised by Mr. W. Vanner, of Clislehurst, and the result of crossing D. japonicum with D. Falconeri. It retains much of the shape of the latter fine kind, but the colour is different. The sepals are long and lance-shaped, and upon a pure white ground there is a very faint margin of purple, this tint being repeated in an apical blotch on each petal. The lip is also white, with a light yellow disc, this being more or less marked with a very bright purple. A plant of it was recently in flower at Messrs. Veitch's.

**Cattleya Mossiæ Reineckiana.**—There are many fine sub-varieties of this Cattleya, as indicated by its being so freely exhibited, but one of the brightest and best I have seen was recently in bloom with Messrs. Veitch in the Chelsea nursery. The outer segments were of the purest white, the finely-shaped lip having the usual yellow area, but the purple streaks about this were very distinct. The flowers were large and of great substance, and altogether, it is one of the finest and most chaste Cattleyas in existence. It requires the same treatment as the typical form.—R.

**Oncidium macranthum hastiferum.**—Although not so bright as the typical O. macranthum, the colours (yellow and brown) in this variety are very nicely blended. The plant is not quite so

strong growing as the typical form, but equally free-blooming, the long, scandent scapes having a fine appearance loosely arranged among other Orchids. Plenty of water at the roots and a cool, moist atmosphere all the year round are essential to its successful culture. Care is necessary that insects do not eat the young roots that often appear above the compost fine.

**Angræcum falcatum.**—This pretty little species is seldom seen, but it has an exceptional interest in that it is not a native of the African continent or islands, but Japan, where it was discovered many years ago. It is, in fact, one of the very oldest known kinds, and, unlike the other species in the genus, requires cool or intermediate treatment. It grows only a few inches high, and produces a small bunch-like spike of flowers from the upper part of the stems. These are yellowish white, with a curved spur about 2 inches long. It should be allowed a light, fairly sunny position, and be grown in clean Moss and charcoal in small baskets or suspended pans.

**Masdevallia Harryana.**—The blossoms of this fine species are now getting past their best, but I noted several fine varieties in bloom this week. One of the best of these is M. H. violacea, having a distinct violet-purple tint in place of the deep crimson of the type. Its culture may be almost exactly the same as for all in this section, and it is not difficult. August is the safest time to repot, using a thin compost of peat fibre and Sphagnum over good drainage. By this means the plants take a good hold of the compost before winter, and are not, therefore, so likely to suffer from any check that may then be experienced.—H.

**Oncidium curtum.**—Several fine plants of this species have recently come under my notice, one in a neighbouring collection carrying seven of the brightly-tinted spikes. In this condition it is a really fine Orchid and worthy of all care. It is a native of Brazil, consequently it needs more warmth than the Peruvian kinds. In a medium-sized pot or basket of good open compost it does well, and may as regards its growth be classed with such as *O. Forbesi* and *O. crispum*. It delights in copious moisture both in the atmosphere and at the roots while growing, and may be kept just moist when at rest.—H. R.

**Cattleya Harrisonæ.**—This pretty plant I noted in good order at Malmaison. There are several varieties of it, but the type is as pretty as any of them. The flowers occur on the apex of the young growth on erect racemes, and are individually about 4 inches across, the rosy sepals and petals reflexed and showing off the lip, which has a dense yellow eye, to perfection. No particular difficulty will be found in its culture provided the plants are healthy for a start, but many species have greater recuperative powers. An ordinary Cattleya temperature and good open compost are requisite. It is an old Brazilian species, and was introduced by Mr. Harrison in 1836.

**Spathoglottis Fortunei.**—This fine species I have noted in flower in several places recently. Each flower is about an inch and a half across, and eight or nine are produced on each spike. The sepals and petals are bright yellow, the lip having brownish tips to the lateral lobes. After flowering, this plant soon begins to lose its foliage, and the water supply must then be gradually diminished, until during the winter months very little indeed is required. At this time the plant may be grouped in a cool, fairly dry house, but a little more moisture and warmth are necessary when growth is active. It may be grown in pots or pans in the usual compost recommended for terrestrial Orchids. It is a native of Hong-Kong and was sent to Chiswick by Fortune about the year 1844.

**Cattleya crispa.**—A fine plant of this old species is now flowering with Capt. Belfield, of Malmaison, Frenchay, near Bristol. It is in good health, about a couple of feet across, and bearing thirty fine flowers. Although the lip of this species is not so finely developed as that of many

known kinds, it has a charm of its own in the undulate crisped margin and bright bit of colour. It flowers, too, at a season when first-rate kinds are getting over, and this alone should be sufficient to make it more popular. It is not exacting in its cultural requirements, and if a few of the large old specimens that used to be common enough were now exhibited, they would surely command a good deal of attention. The flowers are of medium size with narrow segments, pure white on the sepals and petals, the lip bright purple. It first flowered in England in 1826, in the autumn of the same year that it was sent from Rio de Janeiro by Sir Henry Chamberlain.

**Cypripedium oenanthum superbum.**—This is one of the best Cypripediums of the week, and is in bloom in many places. It is one of Messrs. Veitch's hybrids, and the reverse cross to that which gave the typical *C. oenanthum*, viz., *C. insigne* Maulei and *C. Harrisonianum*. The leaves are only slightly variegated, but the flowers are large and handsome. The dorsal sepal is deep reddish purple at the base, passing to nearly white at the margin, the entire segment being overlaid with lines of rosy purple spots. The petals are clear brownish yellow at the base, merging into a much deeper tint above, while the lip is a rich vinous purple externally, with a yellow spotted throat. As may be imagined by the parentage, it is a strong, robust grower and thrives well in an intermediate temperature, provided the roots are in good material, kept moist, and no insects allowed about the foliage.

**Dendrochilum filiforme.**—The graceful pendent racemes of flower produced by this Orchid have been not inaptly described as like gold filigree chains. Not only are they charming in appearance, but delicately scented, and they make a distinct and charming addition to the species now in bloom. Some nice plants I noted in flower last week were carrying each about twenty spikes, and the effect of these hanging from the young green growths was very fine. They appear in the earlier stages of the plant's development; consequently when in flower the roots should not be dried. The plants are of a tufted habit, with small pseudo-bulbs and narrow green leaves, and they thrive well in a moist, warm house, planted either in baskets or small suspended pans. Plenty of water must be allowed even after the blooms have fallen until the growths are quite complete, when less heat and water necessary. Thrips are fond of the rather succulent foliage and bloom, and are apt to put in appearance when the flowers are just opening. The usual remedial measures should be taken for their destruction and every endeavour made to keep them out of the house. *D. filiforme* first flowered in England in 1841, having been sent home to Messrs. Loddiges by Cuming a few years earlier.

#### ZYGOPETALUM GAUTIERI.

THERE are few more attractive species than this in this somewhat extensive genus, and it is, perhaps, as easy as any to grow when well established. In habit it resembles the *maxillare* and *rostratum* section more than *Z. Mackayi* or *Z. crinitum*, but it is more robust than either of the first-mentioned kinds. A plant I noticed in flower recently was carrying three spikes—twenty flowers in all. Each of these is about 2 inches across and has a fine deep purple lip. To grow it well there is nothing to beat a large piece of Tree Fern stem, the roots having a great affinity for this material and thriving well upon it. Once established in this material the most ordinary treatment suffices to keep it in good health, simply because the rhizomes do not carry the young leads out of the way of a root-hold. When they are inclined to leave it, it is only necessary to tie or peg them down, while when they grow over the edge of a pot or pan it is more difficult. Rafts, too, are excellent if the stems cannot be obtained, and if the leads are placed a good distance from the edge the plants go on almost indefinitely. These of course must be lined with

a little compost of some kind, equal parts of Moss and peat serving as well as any. The rhizomes may easily be pulled down to the raft by passing a wire between the rods, and, owing to the free circulation of air obtained, the roots do well under this mode. Of course the great advantage in either of these ways of cultivating it—that disturbance need not be frequent, but grown in pots or pans, on the other hand, they so require a shift owing to the reasons above noted. Perhaps the best time to replant is when the young shoots are starting, as new roots generally appear about the time the plants are in bloom and these give them a hold on the new material. No dry resting season is necessary, but a thorough ripening of the pseudo-bulbs is conducive to free flowering. This ripening is different to that of *Dendrobium* for instance, and is brought about more by a plentiful supply of fresh air than by excess of sunlight, which would be detrimental to the foliage. The worst insect enemies are spider or brown scale, but neither of these is troublesome in a moist atmosphere properly balanced. An intermediate temperature suits it well, such as a shady part of the Cattleya house. It is a native of Brazil, introduced in 1868.

**Oncidium Kramerianum.**—This beautiful Butterfly species is seldom without a flower open and plants having several spikes may be said to be constantly in flower for at least eight months out of the twelve. I have seen it in flower several collections during the week, and natural a good deal of variation exists, but there is not single one that could not be described as good. It is easily grown in a suitable temperature, and likes abundant atmospheric moisture, especially while growing freely.—R.

**Cypripedium niveum.**—This beautiful species is now in bloom, and is one of the prettiest in the genus. From prettily variegated foliage the flower-spikes rise about 8 inches and the blossoms are nearly pure white, the only colour being few spots of purple. It does well in the warm house in a shady, moist position, and may be grown in small pots of peat and moss with a little limestone. Messrs. Veitch first imported this plant about 1868 from some of the islands about the Malay Peninsula.

## KITCHEN GARDEN.

### PEAS OF MEDIUM HEIGHT.

TAKING one year with another and judging the Pea crop in the aggregate, it appears to me that the best results are obtained from a good selection of varieties of medium height or, say, which run from 2½ feet to 3½ feet. These are certainly the Peas which give the least amount of trouble combined with good crops, and there are now in cultivation a sufficient number of good and distinct varieties of this type to bridge the whole season through, so that neither the very dwarf nor the very tall varieties need be grown unless desired. One of the earliest in the section is *St. Osyth Gem* which closely follows *Chelsea Gem*, but is quite distinct from that popular variety and runs about 3 feet high. The haulm and pods are of a very dark green colour, as are the Peas themselves, and the flavour is excellent and well in advance of the most early Peas. To follow this nothing can beat *Dr. Maclean*, an old favourite and one of the best of Peas judged from any standpoint; it has the merit of doing well in all sorts of weather, and this is a characteristic which it shares with other variety of a similar type, viz., *Gladiator*, very hardy and good cropping Pea which, however, requires sugar. After the above-mentioned are over there is a wide selection, including such fine varieties as *Carter's Seedling*, a very deep green, free cropping, and large podded variety of the best quality; *Veitch's Main Crop*, very similar to the foregoing in all respects, and *Carter's Majestic*, with paler coloured pods and Peas of

ne flavour and full in the pod. Danby Stratagem, which is probably a taller and better coloured selection from the old Stratagem, must also be included amongst these main crop varieties, and its chief characteristic, in addition to the good qualities of its progenitor, is that it is continuous fruiting and stands the drought well. Included also among the Peas of medium height and of high quality are Senator, a very free cropper, and, for the latest crop, Autoerast, a Pea that will hardly be surpassed for late work, and which has with me entirely ousted another good late Pea, viz., Sturdy, which for some years provided the latest crops. In these notes I have not exhausted the list of this section of Peas. Possibly there may be others as good as those I have named. My object has been to draw attention more closely to the value of Peas of this type for gardens generally.—J. C. TALLACK.

**Cauliflower Eclipse.**—This is a grand dry weather Cauliflower for late summer and early autumn cutting. Until I first grew it I found it difficult in making the summer Cauliflowers meet those of autumn, and could never entirely depend on doing so in spite of frequent sowings. At Walscheren, but with Eclipse to fall back on these difficulties have disappeared. I have now (August 16) been cutting for some weeks from this variety, and shall do so until the Autumn plant comes in. In habit Eclipse appears to be intermediate between the two varieties mentioned above, but the heads have none of that looseness often to be met with in Walscheren, and are quite solid and large, without being coarse.—J. C. TALLACK.

**Globe Artichokes and drought.**—The Globe Artichoke suffers badly in hot, dry summers unless well fed, watered and mulched, but even with these precautions red spider attacks the joints and ruins the healthy foliage, thus crippling the growths. It is well at this season if the joints are at all distressed to cut the bearing stems within a few inches of the soil. By doing this new growths are encouraged and the plants in a better condition before winter sets in. When much exhausted during the summer months they need a little extra care from now till October. Even this, there will be a full crop well into the autumn, and in many gardens late Artichokes are appreciated when choice vegetables are getting past their best. Few vegetables will repay for liberal supplies of liquid manure better than Globe Artichokes at this season, and the plants will take stronger doses than many others. Failing this, a dressing of well-decayed manure with copious supplies of moisture will assist the new growth and build up new wood for winter. Plants in any way neglected now make a late growth. This growth is soon injured in severe weather.—H. B.

**Cabbage sprouts.**—I am not sure that "C. D." (p. 120) would advise us to grow Cabbage sprouts in preference to Cabbage. I have for some years followed the practice of growing Coleworts even for November and December supplies, and I find the Coleworts more valuable than Cabbage sprouts. I am aware it is an easier matter to cut over Cabbages that have produced heads and allow these to produce shoots, but these are their best are not equal to a well-grown Colewort, and in my opinion much inferior to an autumn Cabbage. It may be asked, what is an autumn Cabbage? My reply is, Cabbages sown for use from October to Christmas, such as Sutton's Little Gem or Favourite. These grown specially for autumn use are far superior to those cut over, which may be termed sprouts. Again, we have the St. John's Day and Christmas Drumhead, splendid types of autumn Cabbage and well worth special cultivation for winter supplies. These are very hardy and of good quality. When once sown they will be much liked. I think allowing plants to produce sprouts robs the soil, as the Cabbage is a gross feeder. I admit that to leave plants which have produced heads is the simplest plan, and where labour is scarce it is commend-

able, but for quality I would advise autumn or winter Cabbage, not sprouts.—S. M.

**Sugar Peas.**—These are much liked on the Continent, but rarely seen in our gardens; indeed, as regards novelties in vegetables, we are very conservative, and year after year grow the same things and pay little attention to new kinds. I am aware the Sugar Pea can scarcely be called new; it is well known abroad; but in a dry season like the one we have just passed through this Pea is well worth growing, as, gathered in a young state, it can be cooked whole or cut up like the French Bean. The best way is to cook the pods whole, but of course they must not be allowed to get old or stringy. In a young state they are very fleshy and of excellent flavour. I am surprised a vegetable of so good quality should be so little grown in our gardens, as many would prefer it to Broad Beans or even the Scarlet Runner. There are several varieties, some much thicker than others, with broad pods, and the grower must not expect fine Peas, but size and substance of pods are the points aimed at. Culture is simple. Sow thinly in good land and every three weeks or a month to give a long supply. I prefer the pods cooked whole, not cut in any way; they are delicious if young.—G. W. S.

**Onion Record.**—I am sure many will agree with "Grower's" good opinion of this Onion at p. 136. I think if the writer had seen the splendid bulbs staged at the great show of vegetables at the last November exhibition of the National Chrysanthemum Society, he would have been delighted with such perfect specimens and so many of them. I do not place too much value on the variety named simply because it is an exhibition kind, but for its general utility, as I find Record one of our most valuable Onions. Its perfect shape and excellent quality make it a desirable kind for all gardens. Like "Grower," I much admire its fine globular form, and I notice these shaped bulbs, no matter how large they are grown, are superior keepers to the flat ones. I saw sound bulbs of this well into April. This shows its value, and when grown with only ordinary culture it is one of the best, as there is no difficulty in having it good late into the spring. Last year I sowed it at this date and with great success, as our roots, with only ordinary culture, are very fine, and were not affected by the heat and drought as badly as the spring sown. In gardens much troubled with the grub it is an excellent practice to sow seed in the autumn and finer produce is obtained.—G. WYTHES.

**Pea Model Telephone.**—This new Pea tried this season proves a wonderfully prolific variety, and a valuable introduction for sowing early. It is a main-crop Pea, but I advise it for what may be termed a second early, as, if the cultivator divides the season into four, this variety is specially good to follow the first earlies. It is a selection from the original Telephone sent out some years ago, and a good variety too, but this is superior. A few growers of the older Telephone found a difficulty in getting a true stock. With Model there is a better growth, and as regards crop, it is much superior to the older form. With me it only grew 4 feet high, but doubtless the heat and drought were answerable for this, as I saw it at least 5 feet high in heavier soil. There are from nine to ten peas in a pod, and the quantity of pods for such a large Pea is wonderful. I am not a great lover of coarse things, but Model Telephone is not coarse, as the peas, though large, are of excellent quality, while the plants are more vigorous.—G. WYTHES.

**Vegetables at Shrewsbury.**—These garden products are always seen in great force at Shrewsbury when the annual exhibition of the Shropshire Horticultural Society takes place. But whilst the western district of England seems to be specially favourable to vegetables, and cottagers undoubtedly show up well, local growers of the gardener class seem somewhat afraid to enter into the open classes in competition with some who have made very high reputations as growers and exhibitors. The first-prize collection

in Messrs. Sutton and Sons' open class was, to his credit be it said, won by a young gardener from Wales, beating some famous antagonists, and that fact should encourage some others to enter the lists in the open classes another year. In Messrs. Webb and Sons' open class the prizes went to Pope, of Highbere; Bowerman, of Hackwood; and Wilkins, of Henstridge, respectively; and in Messrs. Sutton and Sons' class, Pope, Bowerman, Waite, and Wilkins took the other prizes, so that the southern men almost exclusively held the field. That fact shows that in spite of the long drought experienced vegetables can be grown as finely south as anywhere in the kingdom. Although no collection was perfect, yet in each collection some had perfect examples, as, for instance, Fester's, of Wales, Tomatoes, Pope's Cauliflowers and Peas, Bowerman's Potatoes and Runner Beans, Wilkins' Celery, Waite's Cucumbers, &c., all of which if in one collection would have presented a degree of excellence unbeatable. The best average collection, undoubtedly even, refined, good, was Pope's, which took Webb and Sons' first prize.—A. D.

**Large Peas.**—I am pleased "W. S.," Wilts, in his excellent article on Peas (p. 118) noted the value of large Peas. I had never heard of anyone objecting to them. I am aware for special purposes there may be a demand for small Peas, but have never found any difficulty, as if small Peas are needed we can gather before they are fully matured. On the other hand, cooks will not have the small, round, white Peas, and I do not grow them. I should think that the large Peas "J. C.," objects to must have been extra large or past their best, as the new varieties are, in my opinion, a great boon to the grower. Stratagem is still one of the best Peas grown. It may be termed large if the white rounds are taken as the right size for use. For many years I have noticed these large green pods stand drought well, and this is a point worth attention where Peas do not thrive well.—L. M.

**Pea Danby Stratagem.**—Having for many years grown the older Stratagem, I was curious to test the newcomer against the old, and so grew the two side by side. I have come to the same conclusion as Mr. Crawford, viz., that the newer kind is an excellent selection. As most growers know, unless there is rigid selection of the seed stocks, there is a tendency to go wrong. Stratagem Pea of late years has been excellent, but there appears to be more vigour in the newer kind, and an absence of pale pods. It is a fine early pea, and this is a great gain; it is a splendid cropper, and of first-rate quality. It crops close down to the soil, and the pods are mostly produced in pairs, the haulm of a deep green, strong and vigorous. For years I forced the older variety on account of its cropping, as when gathering commenced it gave quantity in addition to quality. The Danby being earlier will make it more valuable.—G. WYTHES.

**Late market Peas.**—There are a few reasons, well known to market growers, why they do not grow breadths of late Peas, as suggested they should do by "Grower." I have put the same question to market gardeners frequently, and always obtained the same replies. The first is that the land occupied by Peas is always needed for filling up as early as possible with succession crops. That could not be done in the case of late Peas such as would be giving crops through August. Of course, it may be said that the rows might be placed wide enough apart to enable plants to be put out between them early, but everyone familiar with market field Pea pickers know that plants so put out have such rough treatment, apart from their being half starved by the earlier crop, that they seldom pay to stand after the Peas are removed. Then there is the undoubted fact that the ordinary town consumer soon tires of Peas, or indeed of any other green vegetable, and a month of Peas usually satisfies his requirements. Then the Runner Beans come in, and these become such formidable competitors in the market with late Peas, that the price even of a good fresh sample

of the latter is low. Then, so far as London is concerned, the classes who can afford to pay higher prices are largely out of town. Possibly it might pay to grow late Peas in the neighbourhood of watering-places. There is, too, a good deal of risk attached to late Peas, arising from possible drought or attacks of mildew. Market fields are at the most ploughed only from 10 inches to 12 inches deep, and late Peas cannot withstand drought in such cases as those in gardens can. As late Peas, none excel Antocrat, Late Queen, and Latest of All.—A. D.

**Potato Up-to-Date.**—A good deal of interest is felt in the ultimate turn-out of this late strong-growing Scotch-raised Potato. It is one of Mr. Finlay's, who gave us The Bruce and some others, and undoubtedly has the Magnum Bonum blood in it. The Bruce is almost a reproduction of Magnum Bonum, indeed in top and tubers is scarcely distinct. However, it is not the only one put into commerce that shows the Magnum parentage. Up-to-Date has some diverse features, although it still has the strong tall top growth with which the Magnum race has made us familiar. The tubers should be more pebble-shaped and more even in size; indeed, the comparative evenness of the tubers so far seems to have been one of its special recommendations. I have it growing on one brash at Surbiton, beside Syon House Prolific, Chancellor, The Bruce and numerous fine varieties, but at present there is no prospect of the tubers being ready to lift earlier than the second week in September.—A. D.

**Spinach.**—Will a "Midland Grower," who refers to a Spinach named The Carter at page 119, kindly say in what respect this variety differs from others in commerce? There was a first-rate and most complete trial of all the divers Spinach in commerce conducted at Chiswick two years since, and the result was to define but three really distinct varieties only, each one having both round and prickly seed. The Flanders, which is the old commerce variety, is generally grown as summer (Round-seeded) and winter (Prickly-seeded), though differing only in young seed. The second is the large-leaved Viroflay, or, as also called, Victoria, now well known in commerce, and one of the largest leaved and finest of the various Spinach. The third is the Long-stander, a very distinct form, the leaves being stout, very green, rather rounded, and the plants less apt to bolt off to flower than either of the others. Now, does The Carter differ from either of these? If so, then let us see it growing at Chiswick, that its merits may be widely known. Anything new and distinct is ever welcomed, if it be also good; but praising old things under new names is rather trying.—A. D.

**Pea Autocrat.**—In a season when many vegetables have failed it is well to note the merits of any good variety. Autocrat has been most useful, as the crop was a full one, and though our soil is very light, the quality was excellent. For some years I have grown the above, and I have advised others to do so in these pages, and the longer I grow it the more useful I find it, my only objection to it in the past being its price. Now, Autocrat is within everyone's reach, and a grand mid-season or late variety it is. It is not unlike Ne Plus Ultra in colour, with the same good qualities. It is of a robust growth, which enables it to resist drought and mildew. It should be sown thinly to get good results, and then there is a grand crop. I use it for July and August supplies, and though the latter sowings have turned in earlier than needed, owing to the heat and drought, there is no lack of pods and of the best variety. "W. S." (p. 118) notes that Autocrat has done well with him.—G. WYTHES.

**The yellow Turnip.**—In few gardens are Turnips sent to the kitchen of good quality, say from January to May. This is owing to many of our white-fleshed varieties getting too coarse in rich garden soil and not standing the winter well. In the northern parts of the country there is less difficulty, as the yellow-fleshed varieties are in constant demand all the year round. If

anyone interested in the market supply in our large northern towns attempted to grow white varieties he would have a poor sale. The yellow-fleshed kinds are more solid, and I consider them superior in quality to many of our white kinds. Doubtless, for early spring sowing the white varieties are superior, being earlier; but for succession crops and for winter supplies the yellow-fleshed are more useful, as they remain solid longer. One yellow variety I grew last season stood drought splendidly. I had it under the name of Green Top Yellow Scotch, and although the white varieties soon got hot and tough, this variety, with a longer tap-root, was excellent and did not run. I am aware climate in a measure is answerable for the excellent qualities of the yellow varieties, and I may add soil also. There is no lack of really good yellow varieties; the Orange Jelly, Yellow Perfection, Yellow Malta and Dobbie's Golden Ball—the last a splendid type for present sowing—are all good and worth a trial where winter Turnips are required in quantity. Even in warm soils for storing, or a winter crop to remain where sown, the yellow varieties are less injured by wet or frost. A sowing made now and another a month hence will give roots from October to March, or later. Huge roots are not needed, but medium-sized, or even small for the latest supply. Where Turnips are stored, it is much better to place in the open, with just enough covering to keep out frost, as when placed in a warm store they grow out and soon become flavourless. When sown in autumn the seeds soon germinate in moist soil. For keeping till spring I advise a later sowing.—G. W. S.

**Feeding Asparagus.**—Many take care to supply a liberal quantity of artificial manure, salt, and so on to their Asparagus beds in the spring months, while growth is small and new roots are comparatively few in number, but entirely neglect them after the grass gets a fair height during August. But this is just the time when the roots can assimilate plenty of food, there being an abundance of roots working near the surface. It can, with a little care and trouble, be spread broadcast over the surface of the beds in spite of the abundance of top growth, and if a little salt is mixed with the manure it will destroy any young seedling weeds that may spring up after the rains, for nothing looks worse than an accumulation of weeds and rubbish when the beds are mown over in autumn, to say nothing of the impoverishment by such things.—J. C.

## ONIONS.

A COTTAGER who hardly ever fails to secure good crops of Onions was this year rather puzzled as to the cause of some of the plants going off when about one-fourth grown. The disease, as he termed it, appeared for the first time last year. On pulling up some of the affected bulbs I found that the roots were nearly all decayed, but an examination with the pocket lens failed to reveal any signs of disease or insect pests; the roots seemed simply to have withered away. I found that, contrary to his usual practice, this man had not roughly dug his ground in winter, but had waited until spring, had then dug it in the usual manner, sowing the seeds right away. In this way the soil had not been exposed to the sweetening influences of frost and wind, and, although naturally light, was too close and sour for the roots to work freely in. It is well to ridge up ground intended for Onions early in the winter, so that every particle of the top spit is subjected to atmospheric influences in the winter season, as Onion seed should where the maggot is troublesome be sown in February. The cottager above referred to sows, if possible, early in the month, and I have not in twenty years seen a bad crop of Onions in that garden, although the locality is much infested with the grub. It would seem that, with the soil in a very sweet condition at sowing time and an early start, the young plants get too large for the grub to injure much. If the soil is al-

lowed to remain untouched through the early winter months, unless February is remarkably fine, there is no chance of thoroughly sweetening it before March, and after a wet winter it is frequently the end of that month before it is really in a fit condition for the reception of seeds. If the roots cannot work freely in the soil from that time they appear above ground, they are liable to come into a stunted condition in a time of heat and drought later on. When the plants get checked in this way they are almost certain to fall a prey to the maggot in districts where this prevails. J. C. B.

**Potato Sharpe's Victor.**—My seed Potatoes are always well greened. At lifting time they are laid out on an asphalt walk for a week or fortnight if favourable. Then they are put into shallow boxes, stood in an open shed, and kept as cool and given much light as possible until planting time. I plant Sharpe's Victor as early in February as I can. As soon as the tops are through the ground I stick Pea-rod in slanting direction amongst them, and it is very seldom frost does them any harm.—T. COCKERILL.

**Feeding Seakale.**—Those who force Seakale and rely upon home-grown roots will find the much finer crowns are obtained by feeding free at this season. I find that after prolonged heat and drought, with the rainfall there is such liberal growth. Food given now is of great value in swelling up the crowns and furnishing full-sized crowns for forcing. Sewage in a diluted form an excellent food. Failing this, liquid manure from stables is a grand fertiliser, as this latter contains saline matter which is good for plants. Nitrate used now is specially good and as a top-dressing at the rate of 3 cwt. per acre is one of the best and quickest acting food we have. Nitrate of soda is of special value in poor soils, used before growth is too far advanced and if used in wet or showery weather its effect is soon seen. Fish manure is a valuable food when moisture can be given to wash the food into the soil. This manure mixed with nitrates or sulphate of potash is one of the best fertilisers, but given alone is of great value applied at the rate of 5 cwt. per acre. Seakale often suffers in dry seasons, and unless moisture is given freely growth is checked, and for plants grown for open air supplies food given now is of great value in building strong crowns.—S. M.

**Planting winter and spring vegetables.** Gardeners and others are often perplexed as to the best course to pursue with their young Colewort and Cabbage plants in hot, dry autumn being afraid to transplant on account of the extreme drought. In such seasons the great advantage of sowing thinly and thinning out the seedlings freely when quite small is seen, as even left until slightly larger than ordinary planting out size they take little harm; whereas when crowded together they must go out or be spoiled. Much may be done to help on the young plant after removal by a little timely preparation, such for instance, as drawing out good deep drills 10 days previous to planting and filling them with water several times. If the ground is fairly deep and in good heart this will usually suffice, but where the reverse is the case the plan adopted by some with their Broccoli, Brussels Sprouts, and Kales of making a thick paste of clay and water and dipping the roots in previous to planting may be practised even in August and September. A good deal of trouble in transplanting such things as Lettuces which are intended for cutting in early winter in the open border is saved by sowing where they are to remain, and merely thinning out to the required distances. In large gardens where extensive large quantities are required this plan, of course, would not answer, but in gardens of limited size the case is different. I find Coleworts sown on north border are doing far better in every way than those occupying a west or even an east aspect, and the plants will doubtless lift much better. Of course, wherever practicable it is always advisable to plant immediately after rain.—J. C.

## FLOWER GARDEN.

## THE CULTURE OF CALOCHORTI.

CALOCHORTI are natives of a vast region in North America, stretching from far east of the Rocky Mountains to the Pacific Ocean, and from Northern Mexico to British America. From the sea-coast and islands they grow from

*debris* are respectively the chosen homes of certain species. Several choose the blackest and stickiest of clays. One is found in salt meadows and many in grassy meadows. In

## THE CULTIVATION

of the species, it is only to be expected that experience will vary much. I have at different times tried nearly every known species in many

Wallace, in his notes on their culture, has properly outlined the best treatment in this respect. My experience more and more emphasizes the fact that no success with them need be expected unless drainage is good. More failures can be attributed to faulty drainage than to anything else. In the growth of Calochorti I commenced with the idea that the nearer I imitated the natural soil the better. The latter idea is a mistake. I have tried many soils. Their home is in a mountainous region where a great variety of soils is obtainable. I have gradually come to the use of three mixtures. Along our river banks there is a winter deposit of sandy silt. This is excellent Calochortus soil, but not so good as the next. I find the best results follow from the use of about one half half-rotten spent tan bark with one half sandy or clay loam. The tan bark rots slowly and gives a loose, well-drained soil, which will not pack. This suits all Calochorti and gives a splendid bloom and firm, well-ripened bulbs. For English growers many substitutes will occur. I know of but one disease to which Calochorti are subject. This is a mildew, the "Lily leaf ash." It attacks them in the spring, just before the flowering stalk appears. It attacks the leaf tissue, and in a week entirely destroys the leaf and injures the bulb. In their susceptibility to the attacks of the fungus Calochorti vary greatly. All of the species having a single glossy radical leaf, such as the *C. albus*, *C. elegans*, *C. nitidus*, and *C. Weedi* possess, are entirely free from its attacks excepting that *C. Weedi* is rarely touched. This includes all of the Star Tulips and the *C. nitidus* group. Of the Mariposa group proper, *C. luteus*, *C. Vesta*, *C. venustus* var. *purpurascens* and *C. venustus* var. *citrinus* are exempt, *C. luteus* var. *aculeatus* and the *Eldorado C. venustus* are nearly so, with *C. clavatus*, while all of the desert species, such as *C. splendens*, *C. Kennedyi*, *C. Palmeri*, *C. Gunnisoni*, *C. Nuttalli*, *C. macrocarpus*, and *C. flexuosus* are subject to it, some as *C. Kennedyi* to such an extent as to make their successful culture very near hopeless unless some cure can be found for this mildew.

I have planted hundreds of good *C. Kennedyi* bulbs, have had them come up and make a splendid leaf and root growth through the winter and early spring, and yet have never flowered one. I notice that there is a great difference in the degree to which lots of Calochorti from different localities are affected by this mildew. I believe that there is reason to hope that strains of each variety may be discovered which to a large extent will not suffer from it. Thus the beautiful *Calochortus venustus* var. *roseus* is very much injured by it, while the very similar *Eldorado venustus* is but little troubled, and *C. Vesta* not in the least.

While the amateur may prefer to try all sorts and get his experience for himself, I believe that the ordinary grower will appreciate a list of the

## BEST GROWERS

among the Calochorti, as well as a collection representing all sections of the genus. For such I would recommend the following:—

In the globular-flowered Star Tulips, *C. albus*, white, *C. pulchellus*, yellow, and *C. amoenus*, rose-coloured, are all thrifty and beautiful. Among the open-cupped Star Tulips, *C. Benthami*, in yellow, and *C. Maweanus* var. *major* are the best. There is, however, a race of giant Star Tulips, sturdy plants 9 inches to 16 inches high, with large flowers of the same delicate style as *Maweanus*, which, although rare now, will soon quite displace the smaller

Flowers of the rarer Mariposa Lilies.

9000 feet to 9000 feet altitude on the peaks. Some are natives of the intensely hot deserts of Southern California and Arizona, and some grow in the moist meadows of Oregon in a climate differing but little from that of England. Montana and other states of the inland region the species indigenous there have to bear a low temperature as 40° below zero. In the soils in which they naturally grow there is as much diversity. Clay, sand, loam and rocky

soils and situations. The winter climate of Ukiah is quite wet, with the thermometer often at 20° to 24°, and sometimes as low as 15° above zero. Often the Calochorti leaves are frozen till they crackle, but I have never known any injury to result. In spring there is abundant rain until their flowering time. Our mid-summer is perfectly dry. Perfect drainage is the first essential to success. A well-drained soil is best for all sorts. Mr.

ones. These are *C. apiculatus*, straw-coloured, *C. Greenei*, blue, and *C. Howelli*, yellow. *C. lilacinus*, a lavender-coloured sort, is a splendid grower and very desirable. In the next section, *C. nitidus* is a fine hardy and very beautiful plant, combining the attributes of Star Tulip and Mariposa. In the *C. Weedi* set, *C. Plummerae* is best. Nearly all of the *C. splendens* group are subject to mildew; *C. splendens* var. *atroviolaceus* seems the hardiest. Of the *C. venustus*, the true Butterfly Tulips, *C. Vesta* is by far the best grower. It is a sort which has great vitality, can be propagated very rapidly by offsets (three or four a year), and grows well in any well-drained soil. I saw a fine instance of its comparative vigour in the garden of Mr. Luther Burbank, of Santa Rosa, California. A set of about a dozen species had been planted in a bed of rich soil, with summer watering, two years ago. Of the set, one *C. Plummerae*, and two *C. venustus oculatus* survived, but the row of *C. Vesta* had quadrupled and showed a solid mass of immense blooms. *C. venustus* var. *purpurascens* is almost as good a grower, and the two are by all odds the easiest *Calochorti* to grow. *C. venustus* var. *citrinus* in lemon is very thrifty, rather more so than *C. venustus oculatus* in white, or the Eldorado strain in all colours. *C. Lyoni*, *C. splendens*, *C. Palmeri*, *C. Gunnisoni*, and *C. Nuttalli* are all subject to the mildew. That grand plant *C. clavatus* is a fine grower and much thrifter than the foregoing. *C. aureus*, *C. Kennedyi*, *C. flexuosus*, and *C. Nuttalli* are apt to give little satisfaction, beautiful as they are. *C. macrocarpus* is in the same list. *C. luteus* var. *concolor* is rather better, although not so good as *clavatus*. *C. luteus* is a very thrifty little plant, but not to be mentioned with *C. venustus* var. *citrinus*.

I have found that by very late planting I can bring sorts to flower which planted early invariably succumb. I planted such species as *C. Nuttalli*, *C. Lyoni*, *C. splendens*, and *C. venustus roseus* in February this season and had a magnificent bloom. I had the same experience a year ago. It would seem that when planted early they reach a standstill period in late winter and cannot resist disease, while planted late they are, in full growth at the critical period.

CARL PURDY.

Ukiah, California, U.S.A.

**Gypsophila paniculata.**—A very nice point was raised at the recent exhibition of the Midland Carnation Society at Birmingham. There was a class for floral arrangements or designs for a dinner-table. Ferns or any other foliage may be used, but Carnation and Picotee blooms only allowed. There were seven of these tables, and in most of them *Gypsophila paniculata* was employed. The question raised is a very nice one: Was it in accordance with the schedule that *Gypsophila paniculata* be used, seeing that the schedule distinctly states "Carnation and Picotee blooms only?" The matter came before me as the superintendent of the show, and I held that the *Gypsophila* was employed solely as a light and graceful-foliaged plant; that from the floral point of view it had no value whatever; and as its use had been permitted in the past, I should allow it on that occasion. This view was held by Mr. Robert Sydenham, and there was no disqualification. At the same time I am free to admit that the *Gypsophila* is a flowering plant, that it is shown as such in a collection of bunches of perennials, and that it would be well if its use were made permissive in the future in order to prevent any objection being raised to its employment.—R. DEAN.

**Improvement in Cactus Dahlias.**—The taste for Dahlias other than the lumpy masses of colour of the old show varieties, as they are called, has led to the production of the more useful and

beautiful Cactus-shaped kinds. The transformation has been rapid when one thinks of the sorts so popular even a few years back. But a season or two ago it was thought that in *Gloriosa*, *Matchless*, and the like a standard of excellence had been reached which could not possibly be improved upon. Who, however, that has the means of comparison would now consider these the best types? The former looks heavy beside a variety called *Starfish*, and the latter the same compared with the newer *Harry Stredwick*. The grace and lightness of formation lately gained are decided advances, and when new shades of colour are obtained with this desirable form, then indeed there will be a race of lovely Dahlias. It is pleasing to note size has not been the leading point. To my mind, if a Cactus Dahlia measures much over 4 inches in diameter it becomes heavy. Another noticeable trait in the newer kinds is the habit of throwing their blossoms out on long wiry stems. Shortness of the flower-stem detracts from the merits of many otherwise beautiful sorts—*Delicata*, *Lady Penzance*, *Countess of Radnor*, for example. The growth of the plants in the later sorts is an advance in its healthy, bushy character. We require more freedom of flowering in some instances, or rather every flower should come double. This is not the case yet with too many varieties which exhibit an eye or disc in the centre if not severely disbudded. *Earl of Pembroke* is a perfect type in the matter of free flowering.—H. S.

**Carnation Carolus Duran.**—In his *Carnation notes* from Woking, "H. S." (p. 125) mentions having been much disappointed with the above Carnation, which he, presumably, met with for the first time in the collection under notice. Evidently there was something radically wrong with the plants in question, for, whatever may be its faults, *Carolus Duran* is one of the healthiest growers and best formed flowers among apricot-coloured Carnations. Its shade of colour is not so striking as that of *Mrs. Reynolds-Hole*, but for all that it is distinctly pleasing. In season it is later than the majority of summer Carnations, and only comes on as the others are getting over; indeed, it is with me now (August 18) at its best, and will go on flowering for weeks to come. In habit it resembles the more moderate growers among the Tree Carnations, as it grows about 2½ feet high and flowers all up the sides of the main stems. The flowers are very full, and a burst calyx is very rarely met with on a healthy plant, except when it has been very severely disbudded, which it resents. I would not have troubled you with this defence of an old favourite had I not so often praised it in your pages. I must say, however, that I think "H. S." has based his objections on very slight knowledge of the variety, and that it is not quite fair to condemn a valuable border Carnation on the strength of a failure to bring out its best points under pot cultivation. Let "H. S." grow it in big groups in the border where he can cut it by the armful at a time with stems a foot or more in length, and I feel sure that he will then neither condemn its growth, form, nor colour. This seems to me the only true way to judge the qualities of a border Carnation.—J. C. TALLACK.

**Mosaic culture in the Fatherland.**—The Germans are good planters, and their town gardens are very gracefully arranged, but when they come to the phase of bedding out called mosaic culture the effect is appalling in its ugliness and stupidity. This *bonne bouche* is reserved for the very best positions in often charming cities and well-planted parks, and is put down in front of the finest buildings, and as a centre-piece of the garden art in the parks at fashionable "baths" like Homburg and Wiesbaden. It is never pretty in colour as a whole as seen at mid-summer, the plants mostly being of a sickly purple or other ugly colour, and any form and freedom of growth the plants might naturally show are cut down, as in our own case, by the scissors and fingers. A flower gardener who is ambitious of competing in design with the poorest kind of carpet-makers may find many designs as hard and mechanical as could be

imagined, but dissociated wholly from true art. To those who think this a matter of taste, we say no; the error of it should be a matter of common sense. These designs are wrong, ugly, and oft ridiculous, because the designer thinks of pattern and not of form and beauty, and forgets he is dealing with living things. The garden is degraded when we resort to conventional complexities, which are right enough on flat surface like panels, carpets, and pavement. The people who produce these—among the best of which the *cloisonné* work of the Japanese—could do nothing better with such surface, but the gardener deals with living things, often more beautiful in their natural forms than anything made by man. The only result got by putting plants in such mosaic is masses of colour, which could be better got by grouping and massing in natural ways.—Field.

#### CARNATIONS AT BOOKHAM.

THE collection of choice border Carnations in the Edenside Nursery of Mr. James Douglas, at Gre Bookham, is perhaps the most complete of the kind. A year ago Mr. Douglas had some three long houses devoted to his favourite flower. These in the short space of twelve months we found inadequate for the accommodation of forthcoming novelties, and a new house about 100 feet in length and 18 feet wide has been built during the present summer expressly for the novelties all sections. The novelties alone are a wonderful lot, the spacious house being filled from end to end, each kind arranged in one huge block. We cannot fail to strike one on seeing this remarkable set of novelties the size of blossom, with vigour and robust constitution, that prevails. Especially is this so in the yellow ground and fancy kind which are increasing in favour every year. Indeed, it would be difficult to conceive anything more handsome in its way than *Voltaire*, raised by Mr. Martin Smith and distributed a year ago. A similarly high standard prevails throughout.

In the yellow grounds there are several novelties for this year, all of great merit. *Badmint* is particularly good, handsome in form and size of blossom, the petals well formed and of a clear yellow, with a deep red margin. *Empress Eugénie* is considered one of the very best of its kind, and is a most distinct flower with rose edge. *Dervi* has a primrose ground and a margin of lilac-roses this is one of the largest flowers. *Miss Ali Mills*, raised by Dr. Colby Sharpin, is an exceptional flower, most beautiful in form, deep yellow, and margined with rich scarlet. Another kind, *Stanley Wrightson* (Douglas), has large massive flowers and heavy scarlet edge, which among the general collection, *Ladas*, Mr. Nigg is perhaps the most remarkable of all; *Mrs. Douglas* a beautifully refined flower; *Xerxes*, *Voltaire* already noted; *Golden Eagle*, a fine deep colour ground; and *Eldorado* were conspicuous.

Sells are a more numerous class as also a strong and important one, and generally in demand. Among these we noted some especially good scarlets, foremost among them being *Lady Hindley*, a brilliant and striking flower of the richest scarlet with petals of exceptional form and substance. *Lamplighter* is another very fine bright scarlet clear and good, while *Mrs. McRae* is of dark hue and said to be an improvement upon *Haye* scarlet in colour. *Belladonna* and *Boadicea* are both high-coloured flowers, the latter especially vigorous. *Garrick* is quite distinct, a rich ruby red, while the form is all one could desire. No is certainly the darkest yet raised, in colour an exceptionally dark maroon-crimson, while the flower in form is well nigh faultless. In the pin and salmon-pink shades there are some special good things, at the head of which we must place *Endymion*, a really magnificent Carnation, exquisite both in form and colour, and of a lovely salmon-pink shade. *May Yobe* is very pleasing in a shade of reddish-pink, the flowers sweetly fragrant and very handsome in form, while the growth is strong and vigorous withal. Scarcely an Carnation can surpass *Regatta*, more particular-

its perfectly neat form, while the rose-pink of its wipers renders it in this respect most pleasing, and Minerva, a clear deep pink well, up to exhibition standard so far as its full flowers and fine wipers are concerned, completed the most worthy of this ever-important shade of colour. In the shades of flesh, Ibis and Cassandra—which also a late flowering variety, and for this reason both including in every selection—are conspicuous. Equally so is the lovely Lady Nina

and I have not been at all successful with it. I was in a neighbour's garden the other day when I saw a plant of it with a whole sheaf of flowers open. No particular pains had been taken with its culture, and I can only imagine when it is now so constantly raised from seed that the seedlings vary in this quality of free flowering, and that my friend had got one of the best of them. I have tried with my own plants the various plans which have been suggested in THE GARDEN for inducing it to flower freely, but in vain. As is usual in most directions about culture, you get the most varied recommendations, and I can only conjecture that soil and situation have induced growers to make these recommendations. One says, do not disturb the plants at all, while another says, pull the plants to pieces. Both plans have been equally ineffectual with me.—D.

**Iceland Poppies.**—At page 127 "R. D." has a note on these showy and useful flowers, recommending them for table decoration. When gracefully and lightfully arranged with Gypsophila or some light grasses, few things can surpass them on the dinner table or in vases. The white and yellow or orange blend well, or they have a charming effect arranged separately, lasting fairly well when cut and placed in water at once. They are not amongst the best things for sending to a distance, not travelling well unless special care is taken in packing. A little care is needed in raising the plants, a shaded position and specially prepared bed being best, sowing in May or June and transplanting in early autumn for next summer's flowering. They are capital subjects for mixing in the herbaceous border.—J. C.

NOTES ON LILIES.

THERE is one family of plants which persistently asserts itself at this season of the year, viz., the Lilies. Here, for instance, is a grand spike of that most valuable acquisition *Lilium Henryi*, the stem from 6 feet to 7 feet high, crowded with a cluster of brilliant orange-coloured flowers copiously spotted with dark chocolate-brown. This, which is in truth both in structure and form an orange-coloured speciosum, is likely to become one of our most popular Lilies; it has a grand constitution and is perfectly hardy. Some of the Lilies are, of course, past, but many of them have done exceptionally well, as, for example, *Lilium candidum*, and yet we are hearing continual complaints of its failure. I had a visit the other day from my neighbour, the poet laureate. He somewhat envied the condition of my bulbs, and said that he had lost all of his; yet, midway between him and me there are some cottagers' gardens on the brow of the hill, facing due south, with a hot, sandy soil, and there the plants are more vigorous than my own, the stems being between 4 feet and 5 feet high and crowned with a profusion of large, well-formed flowers, so that, considering what a dry season we have had and the position of these bulbs, I cannot resist the conclusion that we cannot grow them in too dry and warm a situation. These plants receive no sort of care, are never watered, and yet, as I have said, they are full of life and vigour. There is another white Lily about whose hardiness I am not quite sure, although some growers assert that it is perfectly hardy. I mean *Lilium philippinense*. In form I think it is one of the most elegant of the longiflorum type of Lilies, the tube being nearly a foot long and very elegantly shaped. Its habitat would at first sight seem to throw a doubt on its hardiness, but, although found in the Philippine Islands, it grows at an elevation of 8000 feet, and so may probably be like some of the plants found in East Africa, perfectly hardy; it is very dwarf, and, if hardy, will do admirably for the front of any bed. There is

another well-known Lily which has been exceptionally good this year, viz., *Lilium crustaceum*, or as the older generations always called it, *Isabellinum*, a name which seemed to indicate its hybrid origin. It is very easily grown, and I am often surprised that a plant at once so stately and so beautiful is not more widely used; its apricot-coloured flowers are very attractive. *Lilium Leichtlini* has flowered very well with me this year, and is certainly a very pleasing flower, but it does not seem to have a very strong constitution; I have frequently lost it, but this year it seems to have done very well indeed. *Lilium superbum*, or the Swamp Lily, as it is sometimes called, has had a hard time of it in this dry weather; my plants are alive and flowering well, although those who have been accustomed to see it 6 feet or 8 feet high will hardly recognise it in my dwarf plants.

A CHARMING EFFECT.

*RHEXIA VIRGINICA* and the distinct *Muhlenbeckia complexa* are now both at their best out of doors. The above heading was suggested by an accidental mixture of a wild sort. Nothing, as it struck me at first—and I have been many a time to look at the beautiful blend—could be more charming. The *Muhlenbeckia* is well known as having a resemblance to a climbing or sprawling mass of Maiden-hair Fern with black stems and fawny green foliage. If there is anything by which it can climb as a twiner it climbs, otherwise it runs rapidly on the surface and becomes a capital foil for any sort of short, late summer-flowering plant or bulb, especially the *Colchicums*. In the present case the *Rhexia* had been placed near some strong plants which had covered the ground, and now the *Rhexia* has come through and at a stature of 9 inches is mingling its clusters of big rosy carmine flowers with the more sombre hue of the creeper. But the brightest of touch of colour is given by the curly filaments of

*Calochortus fuscus.* (See p. 157.)

*Calochortus flavus.* (See p. 157.)

the sheeny flowers of the *Rhexia*; they are of the brilliant golden yellow that almost seems to turn twilight to sunlight. I try to be a contented man, but I wish I had the space and other means to make up a big group of these plants to light up the garden in the latter half of August, when, as we well know, there is a great want of brightness.

The *Muhlenbeckia* will grow almost anywhere, but a sheltered nook is advisable, as the severest

blush or pale peach shade, and a flower of considerable merit, though not a novelty of the present year; indeed, it is freely grown in northern districts, and that deservedly. In the somewhat rare shade of cinnamon there are but few, therefore Mrs. Colby Sharpin is doubly welcome for its exquisite rich shade of this colour all for its superb form. This variety has obtained the highest possible honours as a show flower, and makes a conspicuous object even among the host of meritorious things at Bookham. Another conspicuous novelty is that named Mrs. James Douglas, which Mr. Douglas regards as the best Carnation he has yet raised." The colour is rich carmine-rose, the flowers large and of perfect form; indeed, as we recently saw it, the flowers were handsome in the extreme. Pure white kinds are not numerous in this collection this year, and Mr. Martin Smith's new Silver Standard may be taken as the best of these.

The above is far from a complete list, even of the novelties to be seen at Edenside, for some kinds, as yet in insufficient numbers for distribution, are necessarily omitted here. Adjoining the house of new varieties is another of equal size, and equally meritorious for the rich collection it contains. Here, again, the fancy kinds, and also the yellow ground varieties, were in strong force, which, with the selfs—mostly the novelties of a year ago—make a most sumptuous feast of the Carnation. In the open nursery a large space is devoted to seedlings, many very fine, while those that even bear a mark for further trial are very few and far between. E. J.

**Teuchera sanguinea.**—We are continually being complained of this not being free flowering,

winters have been known to kill it. The *Rhexia* has special requirements. The bed should be sunken so as to get plenty of moisture, the soil well decayed peat or leaves, and, of course, as it further decays and settles, should be replenished with fresh mulchings. This plan will very well suit the tubers of the *Rhexia*, as the younger ones often come near the surface than would otherwise be good for them in keen frosts. To grow these two plants together as indicated, the creeper, of course, would get the same sort of black soil, and this would do well, because the foliage would be all the more luxuriant, as it should be, for showing off flowers of such high colour as those of the *Rhexia*. J. Wood.

*Woodville, Kirkstall.*

#### SHORT NOTES.—FLOWER.

**Cactus Dahlia Princess Ena** is one of the newest varieties. The colour is a striking shade of amber, the blooms of medium size, full and nicely formed, the petals narrow and pointed, and the habit of the plant dwarf. It is, in fact, one of the shortest in my collection.—H. S.

**Cactus Dahlia Mrs. Frances Fell.**—I am not at all pleased with this variety, although much has been said of its merits. It is supposed to be white, but the blooms here are dirty in colour and very heavy in build. The Cactus form, too, is absent, and the long ungainly flower-stems do not add to the beauty of the plant.—H.

**Cactus Dahlia Charles Woodbridge.**—This variety was introduced last year, but I only saw one flower of it at the Dahlia show. It is unquestionably the best of its colour, and indeed one of the most perfect sorts yet raised. Its colour is crimson, with a purple glow. This is most vivid and rich. It is dwarf in growth and has particularly fine foliage.—S.

**Cactus Dahlia Bridesmaid.**—This is a decided improvement, being a distinct and most delicately tinted kind. It has a primrose-yellow ground, tinged with rose, and in form the blooms are perfect. The plant is sturdy, throwing the flowers up on long stems, unlike the older variety of somewhat similar tints, *Delicata*. A Dahlia bloom which is hidden amongst leaves, however pretty itself, is useless either for cutting or as a showy object in the garden.—H.

**Cactus Dahlia Fusilier** is about the best of last season's novelties, and it is one of the earliest to bloom this year. The shape and colour (coral-pink) are beautiful. I find the buds require thinning, the plant producing more than can develop perfectly. Its blossoms are thrown well away from the leaves.—H.

**Pompon Dahlia Zoar.**—This is a charming little flower, perfect in shape and delicate in combination of lemon and pink. Apart from its blossoms which come most abundantly is the dwarf habit of the plant. It does not reach 2 feet in height. Anyone desiring a bold and pretty group will do well to make a note of this little-known variety.

**Cactus Dahlia Harry Stredwick.**—This is a very dark crimson-coloured variety of much merit. In form it may be classed among the best types. The blooms are produced on long foot-stalks; therefore they are not hidden by the leaves—a fault of not a few otherwise beautiful kinds. The plant is of medium height and has stout foliage.—H.

**Cactus Dahlia Starfish** is a fine new variety. The blooms have the narrow pointed and twisted petals so much admired in this class. The colour is a vivid scarlet. Its flowers are full and borne very freely, whilst the habit of growth is all that can be desired. The raiser describes it as being the most perfect of Cactus Dahlias, and I think it well deserves this recommendation.—H.

**Cactus Dahlia Matchless.**—Few Dahlias are more admired than this almost black variety. One of its chief merits is the abundance of blooms each plant gives. My plants are literally covered with flowers and they form striking objects. One can scarcely point out an improvement in a

Dahlia of this shade of colour, although time may bring a kind with less flat and heavy-looking petals.—H.

## ORCHARD AND FRUIT GARDEN.

### MILDEW ON VINES.

EIGHT Vines in my viney are badly covered with mildew and to a less extent with what I believe is rust. Early in July, or perhaps it was in June, there was a little mildew, and I gave the gardener sulphur. I was then away from home for several weeks, and on returning found leaves and bunches of Grapes all thickly covered with mildew. The gardener says it is too bad to be dealt with. The Vines are Black Hamburg, Alicante, and two white kinds. They have done well for twenty-five to thirty years. What is the cause, and what the remedy?—H. D. R.

\*\*\* Mildew is very bad in many vineries this season, but it is to be hoped there are few such cases as above described, or where it is thought the Vines are not worth restoring to a healthy condition. If the Vines owned by "H. D. R." are feeble and the young growth promises to ripen indifferently, then it might probably be the most economical in the end to root them out, and also to remove the whole of the border, a thorough cleansing of glass, woodwork (this should be painted), walls, including the foundations, being followed by the formation of a new border and the planting of young Vines. This would mean a considerable amount of work and expense, and entail the loss of a supply of Grapes for one season only. Vines from twenty-five to thirty years old need not necessarily be worn out, and if those under notice have formed moderately strong lateral growth and the wood promises to ripen satisfactorily, these might be restored to a healthier, profitable state next season, only a few traces of mildew being observable. In this case there would not be a loss of crop. If this is the line decided to be taken, an attempt should be made to check the progress of the mildew at once. Supposing the bunches now hanging are worthless, all ought to be cut and the Vines freely syringed with some mildew specific, diluted and applied as advised by the vendors, repeating the application a week or ten days later. It must be understood that if these mildew specifics touch sound bunches they will greatly disfigure them, and they should not, therefore, be recklessly used by other readers who may be troubled with mildew on their Vines. In all instances where mildew is on the Vines, but the bunches are worth saving, its progress may be arrested by sulphur fumes generated by means of the hot-water pipes. Paint the latter with a mixture of flowers of sulphur and skimmed milk, close the house after sunset, and make the pipes as hot as possible. The fumes ought to be almost unbearable to anyone going into the house, otherwise they will not be effective. If applied when there are no berries to crack, the house may be shut up in the daytime and the temperature raised to 130° for a short time with advantage.

Vines rooting into new soil are usually in the most profitable condition, and a fresh width of border would benefit "H. D. R.'s" Vines greatly. This part of the work of renovation ought to commence soon, or while yet there is time for the new soil to become partly occupied by roots before the leaves cease their functions. Fork away all the old border up to within a yard or so of the stems of the Vines, preserving the bulk of the roots unearthened and further

removing the surface of that portion of the border saved so as to bare the roots. It is not necessary to completely form a new border this autumn, but a width should be added to hold the old roots after they have been freely pruned and the rest added piecemeal in later years. A particular mixture is absolutely necessary, but fresh fibrous loam from an old pasture is very desirable, chopping this up roughly and adding a sprinkling of wood ashes, mortar rubbish, nearly fresh horse manure and half-inch bone. Failing turf, the border may be formed with a mixture of fresh loam and garden soil in equal parts, with enough mortar rubbish, "burnt bake" and horse manure to keep it porous; after years, the other essentials being supplied by some special Vine manures used at the rate advised by the vendors. The portion of the border should be top-dressed with a rich mixture of soil and manures of the character just described, and neither this nor the new soil containing old roots regularly distributed through it must be allowed to become dry for the next twelve months at least.

The improved root-action, which is certain to follow a change of soil, will aid the Vines ward off disease and insect attacks, and largely contribute to the production of greatly improved crops. At the same time it must not be wholly relied upon to keep mildew off. When the Vines are at rest and have been duly pruned the rods should be cleared of loose bark, and severely scraped, and following this with scrubbing with hot, soapy water prior to dressing with Gishurst compound applied according to instructions given on each box, and, failing this, flowers of sulphur may be freely rubbed with a soapy brush. A few disease germs may escape all this painting, white-washing, scrubbing and change of soil, and if the first time patches of mildew that show on the leaves are overlooked they will quickly spread all over the Vines again. A close look-out must therefore be kept in the spring, and any small patch found be at once either coated with fresh flowers of sulphur or be damped with diluted mildew specific applied with a sponge. A rush of cool air admitted through front ventilators on a bright day in the spring is liable to introduce mildew, while a sluggish moist atmosphere is most conducive to its further spread.—W. I.

### NEW STRAWBERRIES.

THERE is a long list of names at p. 127 of which may be termed new varieties, and even then will so long a list such kinds as Laxton's Leader, one of the best, I consider, and superior to Monarc is omitted; also the newer Mentmore, a Strawberry we shall hear more of. My object in adding "D. T. F.'s" note is to give those a place he overlooked, and I think he will pardon my remark if I do not set the same value on some that he does. I have this year grown Leader in good number and it is a very fine strawberry, well worth a place in all selections for its crop and size. I am aware in giving size as a recommendation I am on dangerous ground, but I have yet to learn why a good-sized fruit, if it is of good quality, should be condemned. I have never seen large fruits objected to. It is all very well to condemn size if quality is lacking; but I look upon large Strawberries as a great boon to growers who need Strawberries in quantity, and I have never heard any objection to a fine dish. "D. T. F." I am pleased to see, gives Laxton's Royal Sovereign a place among the new kinds. It is well deserving of this on account of its forcing and open qualities. It will grow where others fail. I show my opinion of its worth this year, and have added another thousand to my stock for forcing, as it is equally early as the Vicomtesse H. de Thury, and there is size with a heavy crop. Mentmore is a new variety of this year

and was given an award early in June. This is a valuable fruit, following Royal Sovereign. It is a deep crimson colour, handsome, and of good quality. The growth is robust, and it is a fine main-crop variety. This was raised by Messrs. Weston, who have others, new ones, which I doubtless have heard of in time. Mentmore's parents were Noble and British Queen, and they are well known, the one for free growth and size, the other for quality.

"D. T. F." names Mr. Allan's valuable seedlings and the newer Lady Suffield. I have not grown the last-named, but if equal to Lord Suffield will be valuable. Again, we have four from Mr. Carmichael, and here my remarks must be brief. I have only seen fruits once, and not at the same opportunity of seeing growing plants as "D. T. F." A great deal depends upon growth, as in some soils some varieties do not thrive. Veitch's Perfection has this season proved really grand fruit, and though not large there is quality. I trust it will be found a free grower what may be termed a bad Strawberry soil. I note it is not recommended for forcing, and this is important, as growers will not be disappointed. There are plenty which force. Another good point of Perfection is that it travels well. This, like most of the new seedlings, claims British Queen one of its parents. I have not noted the new evens' Wonder, a fruit sent out for forcing chiefly, and another of more recent introduction, Early Giant, a very large fruit. Some of "D. T. F.'s" names I have no knowledge of. It may be urged at this great increase in numbers will be bewildering. Soils vary so much that one season's trial must not condemn any new kind. I find in our light soil I must grow young plants, also must growers. Many are in a position to give a few varieties a trial, and these can give us the result of their work. The Royal Horticultural Society devote much time and space to trials, which are a great help to those who cannot grow a few things.

G. WYTHES.

#### TRANSPLANTING FRUIT TREES.

THE time is at hand when this work will have to be attended to. Large trees that have to be moved either from one house to another, or from the outside to new structures need care, if a season's crop is not to be lost. On no account should the tree be left until the leaves fall. It is much better to be too early than too late, but as soon as the foliage on the older wood is ripe no time must be lost. New borders should be made some few weeks in advance of lifting to give them time to settle. The soil must be firmly packed, and in most cases it is necessary to use a rammer, the soil being fairly dry and not likely to clog. I have known growers recommend outside borders being left until planting time, because they are likely to get soaked by autumn rains; but such a plan will not recommend itself to anyone who has observed the effect of loose borders, on young trees more especially. If properly firmed any ordinary rains will not harm them, and should a downpour occur it is easy to lay a few boards or old shutters over them to throw off the moisture. According to my experience in various soils and different counties, I find covering quite unnecessary. For borders close to hot, dry walls I find a greater depth of soil is required above the drainage than in any description of peach house, where the borders are usually wider and come in for more frequent watering. A depth of 2 feet would be ample in either case were water supplied in sufficient quantities as often as needed, but the less of spring and summer work often causes trees to be neglected outside, and in such cases an additional depth of 6 inches is advisable. The most suitable for Peaches has been often described in THE GARDEN, and all I need say is, be sure that plenty of lime is applied if this constituent is not present in the soil. Less complaint of the fruit dropping while stoning would be heard if this were always attended to. Burnt and charred garden refuse, too, are valuable

additions, but manure of any kind should be excluded. It is easy enough to feed the trees from the surfacing found to be necessary, this, too, having the effect of keeping the roots well up. After carefully lifting each tree, any long thong-like roots may be shortened back, making a clean cut sloping upward, but all small fibres must be carefully retained, and damaged as little as possible. Bruised or twisted roots must be cut back to where they are sound, and as much soil as possible kept about the ball. A good soaking of water before lifting is necessary should the soil be at all dry. Have a strong mat or large bag ready spread out upon a hand-barrow to take the tree, and pull this up afterwards, tying it around the stem to keep the ball of soil intact. Have the holes a foot larger every way than the size of the ball, and after spreading out the roots carefully with an upward slant, cover them with a little fine moderately dry soil before filling in, laying each tier out separately. The upper tiers ought not to be more than 2 inches under the surface, and when all is finished and firmly trodden in, give a thorough soaking of water to settle the soil round the small roots. If the weather is very hot and sunny, shading should be given both to trees outside and under glass, but the less this is used the better. Damp the trees overhead daily in dull weather, and twice daily if bright, this serving to keep the foliage fresh to the last, and ensuring plumpness of the wood. With regard to pruning either of young or old trees, no greater mistake is made in fruit growing than cutting hard back, always provided that the trees have been carefully lifted and planting not unduly delayed. All that is needed is to remove weak or badly ripened ends of shoots, and when the time for disbudding comes round in spring, if anything unsuitable to produce fruitful wood has been left, the shoots may be rubbed off and the faulty wood subsequently removed. When the shoots have finished up naturally with good triple buds at the end it is simply ruinous to cut them back. These few details carried out carefully, the lifting of larger trees may be safely attempted, and in most cases it may be done without loss of crops.

T.

#### MODERN GRAPE GROWING.

WITHOUT entering into the vexed question of elaborate *versus* simple, inexpensive Vine borders, this paper would yet be incomplete without some reference to that portion of my subject. And here, let me add, that what may be correct in the case of a private garden would, if attempted by a market grower, be altogether wrong, because uncalled for and far too expensive. When the bulk of Vine roots are to be found in a half dead state, deep down in a cold, water-logged soil, the value of the crops produced is very low indeed. In anticipation of this difficulty, it has long been the fashion to excavate deeply both for the foundation walls and for the borders, concrete floors, abundance of drainage, extra deep drains and the like following as a matter of course. Some of these precautions are not quite unnecessary, especially seeing that the Vines in private gardens are supposed to remain in a productive state for a long time, say from twenty-five to fifty years. My sympathy is with numerous gardeners who are not allowed to do what they think best with Vines in an unprofitable state. They must not think of rooting them out and starting afresh, nor can they produce enough fresh soil for the purpose of putting new life into the stale borders, which the Vine roots take every opportunity of escaping from. It is no fanciful compost that Vines require, but what they thrive in is good, sweet porous soil, the very opposite of half the borders in the country. The initial mistake made by so many of us has been this sinking the foundation of the

houses and borders so much below the ordinary ground level, thereby inviting the very evils we are most anxious to avoid. Market growers ought, however, not to take a great amount of credit to themselves for having avoided the errors of their brethren private gardeners. It was necessary, as previously intimated, that first drove them to avoid deep borders, excessive drainage and such things. If it had been absolutely necessary to form borders on the old lines comparatively few Grapes would have found their way to the markets other than the surplus from private gardens. Only those who have ever excavated for the deep foundations laid in correspondingly deep drains, and moved the mass of soil necessary before the site was ready for the new borders, have any conception of the amount of labour entailed and the cost of the whole work. Whether market growers are justified in rushing to the other extreme, and merely planting on the top of the ground that is to serve as a ready-made Vine border, may be questionable from a private gardener's point of view, but it answers surprisingly well all the same.

It is considered that ordinarily good land drainage, or that which is sufficient for hardy fruit trees, is good enough for Vines, any way, that is all many of them get, and they seem happy enough. Naturally, soils and sub-soils vary greatly, but no person with any experience would think of pitching upon a mass of heavy, clayey ground for growing Grapes extensively, unless prepared to go to some extra expense in fitting it for such work. From choice, I prefer either a sandy or gravelly, light, clayey loam, and would avoid as much as possible black spongy soils as well as tenacious clays. Some of the best Grapes I have yet grown were produced by Vines rooting in ground considered well adapted to the growth of cereals, especially Wheat, and noted for the grand crops of thistles that had been in possession from time immemorial. There was no extra draining done, nor a cartload of loam added. The preparation consisted of bastard trenching, good solid manure being added to each spit, and a dressing of burnbake and half-inch bones forked into the surface. This was neither more nor less than a good preparation for Tomatoes, and as a matter of fact the Vines had to share the border with Tomato plants for three successive seasons. It is true the latter were ostensibly in 10-inch pots, but the roots quickly found their way into the border underneath, and derived much of their support from it. To all appearances the Grape Vine does not suffer greatly from association with Tomato plants, and the latter are happy with the Vines so long as they are not unduly shaded.

The old notion that a Vine ought to be treated like a colt, or worked very lightly, if at all, during the first three or four years of its life, is quite exploded as far as market growers are concerned, though it is evident enough it dies hard in the case of private gardeners. There is no analogy between the two, and why they should be similarly treated passes my comprehension. If early cropping of Vines effectually stopped all further sound progress, then that would be a good reason for working them lightly for the first three or four years, but it does not necessarily do anything of the kind. Gardeners of my acquaintance have been so well pleased with the condition of their super-numeraries after they have produced two or more heavy crops, that they have actually preserved them and cut out what were intended to be permanent rods, but which had been unduly pampered and failed to crop satisfactorily accordingly.

There is more to be said on the subject of the treatment of young canes than can be crowded into one short article, and for the present I will not attempt it. The career of market-growers' Vines is supposed to be brief, but again I say not necessarily so. It is true they crop them sometimes lightly, but more often heavily during the first year after planting (I know where there are some that were planted in February, 1896, and which are now carrying six good bunches apiece, and others in the same house a year older with twelve bunches on each), but there is no good reason why these rods should not be as serviceable and as full of vigour twenty years hence as any very lightly cropped at the outset. It is all a question of management. If the heavily-cropped young rods form strong leaders and swell satisfactorily throughout, this to me is proof positive that they are not being badly used. In reality it is those Vines planted in rich borders, thought essential by some gardeners, that are the least equal to the strain of heavy cropping, and the first to require rest, renovation of border and other restorative measures. The market grower plants in comparatively poor soil, as compared with the great stacks of turves private gardeners are frequently enabled to plant in, and does not forget that good living must accompany hard work. Rich top-dressings, liquid manure and abundance of water are applied to their Vines, these serving to keep the roots active near the surface, and to sustain the Vines in excellent health in spite of the extraordinary crops they are expected to produce. When from various causes the Vines do fail to produce remunerative crops, no time is lost in trying to nurse them back to a more profitable condition, but they are rooted out and Tomatoes are grown in their place. In anticipation of this breakdown of the Vines, other houses are planted, and the work of keeping up a heavy, regular supply goes on. Enormous quantities of Grapes are put on our markets by foreign and home growers, but, thanks to the ever-increasing demand for them and the simple methods of culture now in vogue, they pay fairly well, even if the average price is 1s. per pound.

W. IGGULDEN.

#### RENEWING FRUIT TREE BORDERS.

THE time arrives, sooner or later, when the renewing of fruit tree borders becomes imperative, particularly in connection with fruit culture under glass, as, owing to the circumscribed area of such borders, together with the demands of the roots and the frequent necessity for applying large quantities of water, the soil, in course of time, becomes exhausted. When this should be done depends entirely on the condition of the soil comprising the borders, and this can only be ascertained by careful examination, commencing at the surface and sampling the same right down to the drainage. When a loam of good quality is used, in the construction of fruit tree borders, the necessity for renewal occurs at less frequent intervals, but when a loam of inferior quality only is to be had, the renewal of the borders every few years becomes an absolute necessity, that is if fruit of first-rate quality is looked for. Loam, as is well known, varies very much in character, some being full of fibre and some almost destitute of it, or containing such a small proportion that it soon becomes worn out and inert. Borders constructed of loam containing plenty of, or a fair proportion of, fibre will remain in good condition for many years, but when they are made up with loam of inferior quality the necessity arises for either

partially or entirely removing them at much more frequent intervals. Such cases as those just mentioned are by no means infrequent, and, however troublesome and inconvenient the matter may be, the inevitable has to be faced, for it is useless to expect good results once the soil becomes exhausted.

Now, the wearing out of the principal constituent of fruit tree borders shows itself in an unmistakable manner on the subjects growing in them, not all at once, it is true, but, generally speaking, in a gradual manner. The symptoms will, of course, vary according to the kind of fruit, and none will show it more quickly than the Vine and Peach. These symptoms when first noticed, whatever form or shape they may take, will at once convey to the mind of the cultivator the idea that all is not right, and the sharp practitioner will at once commence an investigation by examining the border, and according to the condition in which he finds the compost, so will he formulate his plans, whether the renewal has to be done wholly or in part, and make preparations accordingly.

The best time for carrying out this kind of work is undoubtedly in early autumn, but it is not always convenient to do it then, in many cases on account of not being able to get the crops cleared in time. However, when it can be done early and while the Vines or trees, as the case may be, still have leaves on them, it certainly is more advantageous from more points of view than one, as the fact of their still retaining their foliage leads to root action being set up at once, and by the time the leaves fall the new compost will contain numbers of new roots, which greatly accelerate their re-establishment. In any case such work should be done if possible before winter sets in, and incidental matters, comprising the haulage of the necessary materials, such as loam and old lime rubble, for correcting the former when heavy and retentive, wood ashes, charcoal, and drain pipes and rubble for the drainage, should be done in the meantime. In low-lying and damp districts where the sub-soil is apt at times to be charged with water, a flooring of concrete should be put in, if one does not already exist, to keep the superfluous moisture back, and the sand and lime should be ready for doing this with as soon as the old border has been removed. Where nothing but light or friable loam can be had, it is an excellent plan to add a little marl, clay or turf from the sides of roads, or even road scrapings to such for growing such subjects as Peaches and Nectarines, only they should be thoroughly dried and well pounded up before they are mixed with the loam. Wood ashes are easily made by charring refuse wood, such as the prunings of fruit trees and shrubs, &c., which should be in a green state, and after the fire is once started, it should be partially smothered down to prevent the materials from blazing freely, otherwise the mass will be reduced to nothing but fine ashes. Old bricks and brickbats form the best material for placing over the drain pipes to make the foundation for the border, and they should be broken to three sizes, using the finest grade as a matter of course for the top layer. Bricks or brick rubble are much warmer than stone for this purpose, and besides this, stone is not easily procured in many places.

The loam should be dug and carted at once to a convenient spot, and as handy to the spot where it will be required as possible. Preserve enough whole turves for covering the drainage with, also for building up the fronts of borders when the latter are above ground level and have no retaining wall. The remainder should be roughly chopped, after which add the

various ingredients deemed necessary. We mix the whole together and throw the mass into a long ridge-shaped heap, and let it lie in that condition until required for use. As loam varies so much in character, they must be dealt with according to their merits; no hard and fast rule can be laid down as to what should be added to them to make them fertile, but the materials mentioned in this note act in a beneficial manner, and with the exception of lime rubble, which should be used for medium or heavy loams alone, they can be added to all classes of soils alike. Both charcoal and wood ashes are great helps in keeping the compost open and sweet, while they absorb and retain a great deal of moisture which the roots soon discover by the way they both penetrate and cling to the particles. Manures, such as crushed bon and bone-meal, may be added in varying quantities according to the quality of the loam, but the quantity used should not exceed 1 cwt. of the latter for every ton of soil. For Vine borders a manure can now be purchased called Vine border compound, which contains all that is necessary both for the present needs of the Vines, and for several years to come. This can be highly recommended, while it saves the trouble of buying and mixing the necessary manure at home.

In any case every requisite should be ready to hand, and the work undertaken as soon as circumstances will permit, and as success depends so much on the operation being quickly performed, the necessity of being thoroughly prepared is quite obvious.

A. W.

## GARDEN FLORA.

### PLATE 1133.

#### LATHYRUS SPLENDENS.

(WITH A COLOURED PLATE.\*)

THIS is a perennial Pea with four-angled stem about a dozen feet long, slender pinnate leaves and erect axillary peduncles, each bearing from six to twelve large carmine-red flowers. It is native of Southern California, where it was discovered about twenty years ago, but it does not appear to have attracted the attention of horticulturists until a year or two ago, when Mr. Orelt, writing in *Garden and Forest*, drew attention to its merits as a garden plant. While wild it is usually found creeping over bushes and when in flower it thus presents the illusion of a grand flowering shrub. It is known in the United States as "Pride of California." In 1894 Professor Greene, of the University of California, sent seeds of it to Kew. They were sown under glass, and when strong enough the plants were placed in the open air. Here they grew fairly well, but failed to flower. In April 1895, one of the seedlings was planted in a bed of sandy soil in an airy greenhouse in which Cape bulbs are grown. Here it grew vigorously, forming a thick tangle of Sweet Pea-like stems. No flowers were produced until the spring of this year, when in March buds appeared in almost every leaf axil of the young shoots, and for about three months there was a continuous display of beautiful flowers, such as are represented in the accompanying plate. The colour is unlike that of any other Pea flower known to me. Thus grown this *Lathyrus* is a first-rate greenhouse plant; it is perennial, stands London fog, and yields a large and continuous crop of richly-coloured flowers in spring.

\* Drawn for THE GARDEN in the Royal Garden Kew, by H. G. Moon. Lithographed and printed by J. L. Goffart.

LAMPROUS FLORIDA

The strongest of the shoots got somewhat "rusty" after flowering, and were therefore removed, but the plant is now again in vigorous growth, and will no doubt be equally good next year. Seeds were ripened by the Kew plant; here are also seeds of it offered in the catalogues of American and other nurserymen.

Mr. Sturtevant writes that in his garden at Los Angeles, California, this *Lathyrus* usually flowers in February, but sometimes it begins in October and continues all winter, producing its greatest amount of bloom in February and March. In a note recently communicated to the *Gardeners' Chronicle* by Dr. Franceschi, of California, it is stated that this plant is not common in California, growing only in San Diego at the extreme south, and also in Lower California. Although a native of the desert high region of the interior, it adapts itself freely to liberal watering, provided it has sufficient drainage, and in this case it will keep growing and blooming all summer. It ought to prove hardy under the same conditions as answer for Fremontia and Ronneya. In the warmest parts of the United Kingdom it is worth trying in the open air, and, judging by its behaviour at Kew, it would probably prove an ideal plant for such gardens as that of Mr. Haubury at Wentone. It does not appear to be happy under cultivation in the northern States of America, where one would expect it to grow and flower as freely as the Sweet Pea does here.

W. W.

## THE WEEK'S WORK.

### FRUIT HOUSES.

FIGS.—Pot trees will have been relieved of their second crop of fruit ere now, and should, therefore, be got to rest as early as possible if required again or early forcing. If the wood is ripening well, the pots may be stood outdoors in the full sun under the shelter of a hedge or wall, but if yet immature, keep them under glass or in the house in which they have been growing during the summer. Here, under the influence of full sunshine and an abundance of air, the wood will soon mature, without which it is useless to look for fruit next season. The trees should be relieved of all green fruits which may have formed while the second crop was ripening, and if the inner part of the bushes has been allowed to become rounded with young shoots sent up from the base, these should be cut away; or if too much wood has been allowed to develop in any part of the tree, thin out the same at once, cutting out that which is weak and sappy. Before the leaves are shed, repot or shift these trees into larger pots as the case may demand, and until the leaves drop, keep them moderately supplied with water. Repotting is best done now, as new roots are then formed in the fresh compost before the trees go to rest. Planted-out trees started early in the year should now be ripening their wood. This should also be thinned out if too much has been laid in, and all fruits above the size of Currants should be pulled off. Give all the air possible, and, as the blight ripens, gradually reduce the supply of water at the roots. Root pruning of trees which have got into an unsatisfactory condition should also have attention now, and if the failure has been caused through rampant growth being made, and a too rich border, curtail the roots by confining them to borders of limited extent. This and the substitution of soil of a poor character, in lieu of that already composing the border, will bring them back into a fruitful condition. In such cases as these the compost should consist of alcareous loam and lime rubble alone, using the latter in the proportion of one-sixth of the whole. Light loam may have marl or pulverised clay mixed with it with advantage, and in all cases the compost should be made very firm. Trees, the roots

of which are kept within limits by brick walls, or those growing in borders of limited areas which are kept in place by means of turf walls, are always the better for having their roots shortened back with a medium of new compost, and new turf walls built for them to root into another season. It is astonishing what a small amount of soil the Fig will flourish in when restricted if well fed from the surface during the season of growth. The wood made in such cases is always of a most fruitful description, because the roots cannot ramble away from home, and this is the true secret of success in Fig culture under glass. I have a tree at the present time which covers about 360 square feet of trellising, the roots of which only have about 2 cubic yards of soil to grow in. This tree carries two crops of fruit annually, the second, of course, not equalling the first in point of size, but they are none the less appreciated on that account. Trees in other houses ripening their second crop of fruit should not be neglected in the way of watering, but the syringe had better be withheld and damping down reduced to a minimum, or discontinued altogether if the situation is a low one, otherwise the fruits will spot and decay. The house should also be aired abundantly during fine weather, but when wet admit a little air at the front only, and turn on a small amount of heat to keep the air dry and circulating through the house. Late houses, from which only one crop will be gathered, should be freely aired during the day, especially if unheated, and the fruits are commencing to ripen. When such is the case, syringing and damping must necessarily cease. Moisture must, of course, be supplied to the roots to keep the fruits swelling up to the last, but discontinue feeding when they commence to soften, otherwise size will be gained at the expense of flavour.

PEACH HOUSES.—As the crops are cleared from the trees in successional houses, thin out the wood as directed in a previous calendar, and take steps to give them a thorough cleansing with an insecticide if they need it. In any case a good hosing or a wash with the garden engine now and again is always beneficial to the trees, as it enables them to retain their leaves until the latter have fulfilled their proper functions. Open all ventilators to their fullest extent, and see that the borders receive as much water as they require, giving established and aged trees diluted liquid manure now and again if it can be spared. Houses in which the fruits are ripe and ripening must be kept dry when the weather is fine, but on wet days and cool nights a little fire-heat will be needed, especially in cold districts. Look the fruits over daily, or every other day, and if this is done but few of them will drop, while those gathered will be of better flavour than if allowed to remain on the trees until dead ripe. Fruits on trees in late houses will be fast swelling, and as the Peach crop outdoors is admittedly a short one in the majority of cases, the value of these late fruits will be considerably enhanced. Good feeding is essential, whether the borders are inside or out, or both, to enable the fruits to attain full size, as such varieties as Exquisite, Late Admirable, Princess of Wales, Sea Eagle, Goshawk, Pine-apple, Pitmaston Orange, Victoria, Humboldt, and other choice Peaches and Nectarines will swell to a very large size if generously treated. As the nights generally get much cooler after this time of the year, syringing must be done more cautiously, as the leaves should always be dry before night. If this cannot be ensured, syringing had best be confined to the mornings, and if the trees are clean this will be sufficient to keep them so. A little air may be kept on through the night, which should be gradually increased as the day wears on; when bright, and if necessary to hurry the crop to maturity, close with sun-heat in the afternoon. If, on the other hand, it is desirable to delay the ripening as long as possible, keep the house fully ventilated. Keep all gross growths suppressed, and laterals pinched in regularly, to cause an equal flow of sap, and if elevating the apex of the fruits to-

wards the sun has not had attention, it should be done before the fruits become too heavy and they begin to soften. Where this has been done, fully expose the fruits by pushing or tying the leaves on one side, so that the sun may shine full upon them and ensure high colour.

LATE POT PEACHES.—These will require much the same treatment as the permanently planted trees, only they will need water much oftener. Feeding either with artificial or liquid manures should be pursued up to the time the fruits commence to ripen, and then cease. After this give pure water, and no more than is necessary, because if over-done the flavour will be flat and insipid. As the trees are cleared of fruit cut away all superfluous wood, and when the leaves show signs of ripening get any rotting or tubbing done, and keep them under cover until the leaves drop, with the house amply ventilated if the autumn should prove wet. If fine and warm, they will be all the better for being stood outdoors.

A. W.

### KITCHEN GARDEN.

KIDNEY BEANS.—So long as a good supply of Scarlet Runners is forthcoming there is little demand for the dwarf varieties, but those who have to keep up a good supply of choice vegetables know the value of these in the autumn, when the former are cut down by frost, which often happens in September, long before other things less tender feel any ill effects from a low temperature. To guard against a break in the supply it becomes necessary to again resort to pot or frame culture. The latter is certainly to be preferred for autumn crops, if the frames are provided with only a small amount of hot water pipes. Where such pots or frames are not at command, pots or boxes must be used, so that they can be transferred to a warm house, when it becomes necessary to use artificial heat. It is better to make an early start, so that the plants will make sturdy growth during the coming month with as little protection as possible, whether they are to be grown in pots or planted out in pits. This is better than waiting until the outside supply is cut off and then resorting to hard forcing. Heated pits in which a crop of Cucumbers or Melons have recently been produced may be used with advantage. The same soil will grow a good crop of Beans without further trouble, beyond forking it over and affording a good watering if necessary. There is no comparison between plants grown in this way and those in pots, as regards the yield. Of course the lights are dispensed with as long as possible, and only replaced at night when there is danger of frost, or to ward off heavy rains; even then fire heat should be withheld if possible, and only applied when really necessary. Select dwarf-growing varieties, such as Earliest of All, which is most suitable for this treatment. If pots or boxes have to be used, these should be filled with a rich holding compost, which should be made moderately firm before sowing, as this assists the formation of sturdy growth, and the plants will not require watering so frequently. Good drainage is very necessary, but it would be safer to stand the pots in a cold frame, so that they do not become over-charged with moisture after heavy rains. Sowings recently made on warm borders will prove most valuable for late supplies, if a frame or some other temporary protection can be afforded as the nights become colder. Indeed, it would be wise to have sheets of tiffany, or some other light covering, ready for placing over both the dwarf and the taller kinds, as a slight protection of this kind may save the plants from one early frost, and they will go on bearing for weeks afterwards.

VEGETABLE MARROWS.—Like the former, these often succumb to one early frost, which is very disappointing when perhaps for weeks afterwards the weather remains fairly mild, and for the want of a little timely attention their season is so much shortened. Seeing that we have a long time before us when there will be only a small variety of outside vegetables to select from, it becomes

necessary that we should retain the summer ones as long as possible. A framework of stakes can be easily arranged round the bed on which the plant are growing in such a way that mats may be used immediately frost is expected.

**SPRING-SOWN ONIONS.**—The time has arrived when these should be got out of the ground, carefully harvested, and stored away in their winter quarters. Much depends on the way the bulbs are ripened to insure them keeping properly through the winter. In most beds a good proportion form thick necks, and longer time is necessary to mature them properly. It is a good plan to go over the bed and bend such as these over with the back of a rake; a few hot days afterwards will cause the tops to wither, when they can be pulled up and placed under cover, spreading them out thinly so that they can get plenty of air and become firm before they are stored away. The small silver-skinned varieties should be carefully ripened before they are used for pickling, to insure them being both crisp and clear in colour. Other vegetables used for mixed pickles, such as Cauliflowers, French Beans, Gherkins, Radish pods, &c., should be sent into the kitchen while they are plentiful, leaving Red Cabbage for some weeks later, as this is generally preferred after it has been subjected to a little frost.

RICHARD PARKER.

## FRUIT AND VEGETABLE CROPS.

### SYON HOUSE, BRENTFORD.

THE fruit crops in this neighbourhood are not up to the average, and if we take the most useful one, the Apple, it is much below the average. There is, I regret to say, in many instances trees without a single fruit, whilst a few have a full crop. The Codlin varieties are the best this season, and this is remarkable, as I have observed these varieties fruit very freely one season and fail the next. Keswick Codlins are good. Manks Codlin, grown largely in this district, is, I might say, a failure. Lord Grosvenor and Lord Sutherland are bearing heavy crops, and a few late-looking kinds, such as Lane's Prince Albert and Alfriston, have excellent crops. Dessert Apples are not at all plentiful. King of the Pippins has only half a crop, the valuable Russets none at all, and late keepers of all kinds will be very scarce. We have only a few Blenheim's, but early kinds, such as Devonshire Quarrenden and Irish Peach, are a full crop. Lady Dudley is fine both in crop and size of fruit. Pears, like Apples, are much under average; the early kinds are best. Williams' Bon Chrétien and Margaret Marillat are our heaviest croppers. Louise Bonne of Jersey, which rarely fails with us, is good, and I notice a few trees in the district bearing well on walls, but bush and standards are poor this season. Our young trees on west walls are good. Such kinds as Marie Louise, Conference, Durondeau, and Beurré Diel have full crops, with a fair quantity of Pitmaston Duchess and Soldat Laboureur in bush form. I regret we have but few late Pears, and, unfortunately, such second-rate varieties as Beurré Bachelier and Clairgeau are laden, whilst there are no Doyenné du Comice. I had this season the poorest crop of Apricots I have had during the past few years. The frost and hail ruined the fruit early in the spring; the best was the Large Early. Peaches and Nectarines are excellent both in crop and quality. They have done well where well attended to with moisture. Amsden June was the earliest Peach in the open. This was very good, and I am pleased to note we now have a good companion Nectarine in Early Rivers. This is a grand acquisition, large, good, and hardy.

I had splendid fruits in quantity before July was over. All kinds of Peaches and Nectarines are good, the trees clean and ripening up the wood well. I never saw Lord Napier produce such fine fruit in the open. I feed and water freely and allow young trees to grow freely, never checking when there is ample wall space. Plums are a failure. I have these as cordons, bushes, and on walls, and have scarcely any fruit. Victoria, usually abundant, is poor. I have a few Gages, Golden Drop and Prince Englebert. Damsons are very scarce indeed; the Farleigh variety is the only one giving any fruit. Cherries had a nice crop and good fruit. Such varieties as Early Rivers and Governor Wood were excellent. Morellos were an average crop, but few fruits. I grow a large quantity of these, but they did not come up to the usual standard of quantity. Small fruits, such as Strawberries, exceeded our expectation. I had a fine crop. I only fruit young plants, in most cases treating them as annuals. Royal Sovereign is the heaviest cropper. It is good on a light soil, and Lord Sutherland with Latest of All did grandly. Raspberries, though plentiful, were soon over, owing to heat and drought. Superlative was the most reliable cropper. Currants and Gooseberries were an average crop.

Vegetables have suffered much from drought, and in light soils, unless given special culture, were poor. There was no difficulty in getting early supplies, as, owing to a mild winter, spring Cabbage was early and good. There was no lack of good Broccoli, and Asparagus was abundant. Peas, owing to drought, were soon over, and unless special attention was given to variety to suit the soil the crop was poor. Potatoes have been good, but early kinds were not very plentiful. In many cases they were cut by frost, and drought affected others. Later ones promise well in deeply cultivated land, and so far I have seen no disease. I fear, unless we get genial rains, we shall have a scarcity of good winter vegetables, as the plants make poor progress. The soil is very dry at the time my note is written, but with rain growth would be rapid.—G. WYTHES.

### SOUTHERN.

**Aldenham House, Elstree, Herts.**—The fruit crops in this district are poor, especially Apples, Plums, and sweet Cherries. Morellos are good. Apricots good. Pears average. Small fruits good, particularly Gooseberries. Strawberries plentiful and good. Nuts very abundant. Vegetables are good. Potatoes clean and free from disease.—E. BECKETT.

**Old Warden Park, Biggleswade.**—Apples under average, but the fruit is generally good and the trees are clean and healthy and making excellent growth. Pears are under average. The fruit is generally good, but rather small, the trees very clean and healthy and making fine growth. Plums are very thin on bush and standard trees, but better on walls with a south aspect. The fruit is clean and good and the trees healthy. Cherries under average, not much grown except Morellos, which are good. Peaches and Nectarines on unprotected walls are a good average crop, the fruit very fine. Apricots under average. Gooseberries and Currants very thin. Raspberries are an average crop. Superlative is the best variety grown here.—G. R. ALLIS.

**Luton Hoo, Beds.**—In this district Apples are under average. Pears are better, but these too are not up to average. Peaches on the open walls are very thin. The same applies to Apricots. Plums and Cherries on the walls are slightly under average, on the standards none. All bush fruit has been scarce. We have had a short season of Strawberries; the crop was light, but the quality was all that could be desired. With the exception of Apples, there was a good show of fruit in

the spring, but the cold early months of the year proved too much for a good set. Added to this the severe hailstorm which broke over here on June 24 played such havoc as to permanently injure what fruits were left on the trees.

With the exception of Cauliflowers, all vegetables have been good.—GEO. H. MAYCOCK.

**Elmstead Grange, Chislehurst.**—Fruit crops in this locality cannot be called a success the bloom in many instances being damaged by late frosts and the hailstorm of June 6. The latter played havoc with Apples, Pears, &c., the few remaining on the trees bearing the marks to this day.

Vegetables, notwithstanding the dry season and the above-mentioned hailstorm, have done remarkably well. Peas, early and second early, have been a splendid crop; later and taller varieties have suffered from want of rain. Winter vegetable look fairly well, but require copious rains to put them on.—J. BLACKBURN.

**Olandon Park, Guildford.**—Fruit crops in this garden and in the district are far below the average. Apples are very small owing to dry weather, and fruit on trees that are bearing a fair crop are infested with maggot and falling of wholesale. In some places near here you may see an orchard here and there bearing good crops, but they are few and far between. Pears are very scarce, but what there are appear to be good Espalier trees have done best with me this season there being scarcely any on the standards. Plum are very light all round. Peaches and Nectarines are much below the average, but will, I think, be fairly good, as they have finished stoning and are swelling fast. The only way I can account for the scarcity in this garden and adjoining district is the late frosts, as there was plenty of bloom on all kinds of fruit trees.

Vegetables, taking the dry weather into consideration, are very good, but everything need rain badly. Early Potatoes were light, owing to their being cut back by frost. Mid-season varieties are very good and late Leeks very promising but I am afraid if wet sets in it will cause disease. Winter stuff of all kinds looks wonderfully well in most places.—H. W. BLAKE.

**Mentmore, Bucks.**—Apples are only a poor crop, although a few varieties are bearing freely such as Worcester Pearmain, Stirling Castle, Sea ton House, Calville Boisbunel, large and very fine Ecklinville, Mr. Gladstone, Jefferson's, Oslin, Ribston Pippin, large and good on young trees Prince Albert, Lord Sutherland, Yellow Ingestre and Keswick Codlin are all bearing a good crop. The trees are growing very freely and are free from blight of any kind. Pears are about half a crop on walls, standards, and bushes. Peaches and Nectarines about the same. Apricots very poor. Nuts a heavy crop. Small fruits of all kinds abundant and good.

Potatoes are small, but good in quality and free from disease. Beans and Peas abundant and good. The soil here is a strong loam resting on chalky clay, so that a dry summer is always best, and hence all kinds of vegetables have been abundant and good.—JAMES SMITH.

**Cliveden Gardens, Maidenhead.**—Pears, Apples, and Plums are a poor crop. Cherries are a failure. Strawberries and all bush fruit are above average crop. Peaches and Nectarines on walls outside excellent. Apricots made average.

All vegetables are very good. Potatoes very clean and no disease.—A. B. WADDS.

**Yattendon Court, Newbury.**—Apples about half a crop. Some varieties, as Lord Sutherland, Warner's King, Tower of Glamis, and Ribston Pippin are good, and in our village I have seen some good crops of common Apples. Of Pears we have a fair crop. Victoria and Pershore Plums are good. Cherries on standards a failure. Morellos on wall fair, but troubled with black fly. Currants and Gooseberries about half a crop. Raspberries and Strawberries a very good crop. I may add that we sprayed Pears and Plums twice with a diluted Bordeaux mixture and Paris

reen, and I find that what is safe for Apples, Pears, and Plums, injures Cherries.

Vegetables good. Early Peas a wonderful crop, 2 feet higher than normal height. Cauliflowers fine. Onions, Carrots, Parsnips good. Potatoes an excellent crop, free from disease and of good quality.—R. MAHER.

**Harewood Lodge, Sunninghill.**—Apples a total failure with me. Pears a trifle better, and on walls in many places good. Plums over average. Gooseberries very abundant. Red Currants fairly good, black very scarce generally. Raspberries scarce. Apricots partial crop only.

Peas were abundant and good up till last week in July, when all late sown ones collapsed through mildew in spite of being sown in spacious trenches and liberally supplied with water. Dwarf Beans very abundant. Early Potatoes are satisfactory, but late ones are suffering from want of rain. The same remark applies to all the Brassica family, club being very prevalent.—C. DEAVIN.

**Cassiobury Park, Watford.**—Apples are under average. Pears almost a failure, and Plums poor. Peaches and Nectarines good crops on walls. Cherries almost a failure; Morellos under average. Apricots under average. Small fruits average. Strawberries and Nuts are average crops.—CHAS. DEANE.

**Royal Gardens, Windsor.**—This is by no means a good Apple year in consequence of the sharp frost on May 6 (8°), and the succession of wet, cold days whilst the trees were in bloom. Of early cooking varieties we have an average crop, but of later or long-keeping sorts the crop is generally light. The same may also be said of lessert varieties. The sorts carrying the best crops are Lane's Prince Albert, Rosemary Russet, Frogmore Prolific, Paradise Pippin, and the Codlin varieties. We have every form of trained tree, but I cannot say that any one particular form is bearing better than another. Pears are a long way from being a heavy crop; at the same time, I am told by visitors who call that we have our full share. It is rather singular that the best flavoured varieties, such as Thompson's, Doyenné du Comice, Fondante d'Automne, Williams' Bon Chrétien, Gratioli of Jersey, &c., are the scarcest. Plums, I am sorry to say, are quite a failure. Damsons the same. Peaches out of doors are excellent, both as to crop and quality of fruit. Nectarines the same. Apricots are bearing a specially heavy crop of excellent fruit, and the trees looking healthy and well. In spring our Peaches, Nectarines, and Apricots are well protected by tiffany blinds until the fruit is well set and the trees were well furnished with foliage, and during the summer they are frequently washed with the hose and well mulched and watered in hot weather. Cherries in the open quarters have been a failure, but on the walls they have been splendid, and, as we have trees growing on every aspect, the season for this favourite fruit is prolonged to the utmost. Some of our best sweet Cherries are picked from trees growing on a north wall. Gooseberries are about half a crop. Black Currants almost a failure. Raspberries moderate crop, and Nuts generally good.—OWEN THOMAS.

**Wrotham Park, Barnet.**—There was an abundance of blossom on the Apple trees, but only a poor crop on the whole; in fact, in some gardens there is scarcely an Apple. Here we have a very partial crop, some varieties heavily laden with good fruit, others with either none at all or only a few, but good samples. The best here are Stirling Castle and Lane's Prince Albert, then come Worcester Pearmain, Cellini, Lord Grosvenor, Bess Pool, Duke of Devonshire, May Queen, The Queen; all these are bush or pyramid trees and young, having in fact all been planted within the last seven years. Keswick Codlin and Dr. Harvey among the old standard trees are carrying heavy crops. Pears also blossomed well and on the whole are an average crop of good fruit. Here on young trees on a west wall we have nice crops of Williams' Bon Chrétien, Beurré Diel, Easter Beurré, Bergamote d'Esperen, Winter Nelis,

Josephine de Malines, Doyenné du Comice, Pit-maston Duchess, Beurré Clairgeau, and Marie Louise. On the Plums there was plenty of blossom again, but very little fruit on the whole, Victoria being the best crop. Grand Duke, Archduke, Rivers' Early, and Old Orleans are also carrying a few nice fruits; all these, however, are on an east wall. The bush and standard trees in the garden have nothing at all on them, this in a great measure being due to the birds—bullfinches principally—devouring the buds in early spring. Peaches are about an average crop, although they did not require much thinning this season, many of the blooms and small fruit being cut by the frost and cold winds so prevalent last spring. Much of the foliage is badly blistered. Figs are rather over an average crop this season here, and the fruit promises to be fine. In the case of sweet Cherries, a splendid blossom was followed by almost a total failure in the crop. The frost completely spoilt all chance of any fruit. Only one tree here had any fruit at all—a May Duke on a south wall. Morello were better—an average crop of good quality. Among the small fruits, Red Currants were much above an average crop and very fine, as also White. Black, on the other hand, were very much below the mark and the fruit poor in quality. Gooseberries very uneven—in some places plentiful, in others scarce. Strawberries over an average crop and very good, but the season short. Waterloo stood the drought well here and gave some very fine late fruits. Raspberries a failure on light soils, as here; better on heavier ground. Apricots very poor, although there was a good show of bloom, but they, like the Peaches, suffered from the frost. Filberts are an unusually heavy crop, and Walnuts are very scarce.

Vegetables taken altogether are very good, Potatoes yielding well and up to the present showing no signs of disease. Peas have been plentiful and good up to now, but the hot, dry weather has brought mildew, and, unless from the latest sowing, which may give a few pickings, they are practically over. Carrots and Turnips are poor in some places. Onions, Beet, Parsnips, and the winter crops are all looking very well. Runners are doing very well, though they were rather late in coming in.—G. RINGHAM.

**Claremont, Esher.**—The fruit crop of 1897 must be described as slightly below the average, although the expression is really applicable to a few things. On the whole, there is not much to complain of. Apples are very thin, absolutely the worst crop I have ever known; tree after tree, alike of bushes, pyramids and standards, being without a single fruit. Apricots are thin, but the fruit is large and of excellent quality. Dessert Cherries were a good crop, but Morellos below average. Plums are also much below; the best results are from a south-west wall on a south-easterly aspect, where most of our trees are. A bitter wind played on them continuously for several days when the bloom was expanded, accompanied by frosty nights. Pears are barely half a crop. There was plenty of bloom and the set seemed right, but three parts dropped when about the size of marbles. Peaches and Nectarines are very good; indeed, on a stretch of wall 150 yards long there is not a single failure. Figs and Nuts are both above average. Small fruits have been well up to the average, with the exception of Black Currants. Insect pests have been rather troublesome, but aphid in various forms, also red spider—that is strongly in evidence on our light, sandy soil—have been kept in check by heavy and repeated washings. Earwigs are the worst enemy on the Peach wall, but the bean traps were put in early and thousands have already been captured.

Vegetables were never better. All roots were looking clean and healthy, and the greater part of the winter-green crop was just planted when the first heavy storm came, and gave everything a grand start. Potatoes are a heavy crop, but the disease, I am sorry to say, is making its appearance. Remedial measures in the way of cutting off and carefully clearing away every particle of haulm

are resorted to as soon as there is any sign of ripening.—E. BURKELL.

**Bearwood, Woking.**—This is the worst season we have had in this neighbourhood for years. Apples, Pears and Plums are quite a failure, and owing to the drought the fruits are very small and maggoty. Peaches and Nectarines are a thin crop; Apricots the same. Cherries bad. Bush fruits have been a poor crop and small, and owing to the continual cold weather in blooming time, everything got much injured by blight. Strawberries have been an average crop. Many of the earlier sorts got much injured by the sharp frost in blooming time. Our best Strawberry for our general supply is the British Queen. Early sorts are Keens' Seedling, Noble, Viet. de Thury. Sir Joseph Paxton is grown for market in the open rather largely.

Vegetables have been fairly good up to the present time, but are now giving up from want of rain. Potatoes, early and second early, are good; late sorts, I fear, will fare badly.—J. TAGG.

**Wrest Park, Amptill, Beds.**—Apples are under the average. Cherries, too, poor. Damsons a very light crop. Apricots much lighter than in 1896. Plums average on walls, under average on standards. Peaches good average crop all over. Nectarines average crop on early and late trees. Pears on walls and standards are over the average. Strawberries of all varieties a good crop. Gooseberries average. Currants very good average crop, and Raspberries average.

Vegetables very good in the garden, but much in need of rain, as Broccoli, Cauliflower, Peas and Carrots are now suffering from the long spell of drought.—GEORGE MACRINLAY.

**Elvetham Park, Hants.**—The fruit crops generally were very promising here until May 12. On the above date we registered 10° of frost at 9 p.m., which continued throughout the night, proving disastrous to the Apples and Pears, with the exception of Pears on the wall trees, which are carrying a fair crop. The Strawberries would have shared the same fate had they not been covered over with straw in the evening; being thus protected, a very good crop was secured. Gooseberries, Currants, Raspberries, and Plums under average. Dessert Cherries fair crop, Morello Cherries very good. Apricots fair crop. Peaches abundant.

Vegetable crops are satisfactory. Peas, both early and mid-season, have done well. Late Peas are beginning to feel the effects of the recent dry weather. I grow Ne Plus Ultra largely for latest supply. Broccoli with few exceptions stood the winter well. I finished cutting Model on June 8. I always take the old precaution with Broccoli in the autumn in having a trench taken out on the north side of the rows, heeling the plants over, taking care the stems are covered up close to the lower leaves, this being a check to root action, and thus making the plants more hardy to withstand the winter. Autumn sown Cauliflowers have done equally well, coming in a few days after the Broccoli were over. Early Potatoes have done well this season and are free from disease.—G. MITCHESON.

**Falconhurst, Edenbridge, Kent.**—The fruit crop in this locality falls very short of the average, and is in some cases almost a failure. The appearance of the trees in the spring gave promise of very heavy crops, but the frosts, accompanied by north-east and east winds which we experienced on no less than ten nights during May, played havoc with them. Peaches and Nectarines being seriously damaged, more by the east wind than frost. From June 1 to August 7 the drought and hot sun caused the bush fruit to ripen early and drop off wholesale. The total rainfall for that period in this district was 2.18 inches as compared with 6.27 inches for the same period of last year. Apples are a very thin crop, fruit small, and some trees a total failure. Pears are a better crop, but the fruit is very small. Peaches and Nectarines are scarce. Plums and Damsons are a thin crop. Cherries were poor, while Figs are extra good. Black Currants were a good heavy crop with me, but scarce in the district;

Red and White were plentiful. Gooseberries are under the average. Raspberries were a good crop, but the fruit was small. Early Strawberries were very good, but later varieties were not at all satisfactory, the fruit being small and the crop soon over. Nuts and Filberts plentiful.

The drought and heat combined have in many instances proved too much for vegetables. Potatoes are a good crop, and free from disease, so far as early sorts go. If rain comes now I am afraid it will be too late to do late kinds any good, but might cause disease. Early and second early Peas were very good, but main-crop Peas a failure. I have some late ones looking very well, and if rain comes they promise to yield well. Broad Beans were a good crop. Runner and dwarf have grown well, but set badly. Onions, Carrots, Beet, and Parsnips are plentiful, but very small. Tomatoes are a splendid crop, the fruit of fair size and plentiful. Globe Artichokes were never better. Every kind of Brassica is stunted, and I doubt if a good many will be worth saving. Winter and early spring vegetables will be very scarce in this district.—A. CANNON.

**Theydon Grove, Epping.**—The fruit crop in this garden and neighbourhood, as far as I can ascertain, is the poorest we have had during the nineteen years I have been here. The late spring frosts did serious damage to all kinds of fruit, and the severe hailstorm throughout Essex of June 24 destroyed what prospects we had. Peaches and Nectarines outside are very light. Apricots the same. Plums very few. Pears on the wall a good crop; standards none. Apples, what few there were, were destroyed by the hail. Strawberries, Raspberries, Gooseberries, Currants, and Morello Cherries promised well, but the greater part destroyed by the hail.

The vegetable crops suffered very much from the hailstorm; up to that time they looked very promising. The Asparagus, early Peas, and Potatoes were good, but Peas from the date of the storm are a failure. Beans, Marrows, and other late vegetables are recovering. The second early crop of Potatoes is very light, as the haulm was quite destroyed.—GEORGE HEWITT.

**Caddington Hall, Dunstable.**—The fruit crops in these gardens and immediate neighbourhood are rather under the average. Apples are very scarce. Pears are plentiful here and also in the district. Plums very thin. Prunes are very thin. We had a very poor crop of Gooseberries and Red Currants. Black Currants about half the usual quantity. Raspberries were a fair crop. Strawberries were an abundant crop.

The vegetable crops in these gardens and neighbourhood are, on the whole, very good, though we have suffered considerably from the drought. Rain is very much needed for the winter vegetables. Early and second early Potatoes very good crop and free from disease. Late kinds want rain to finish off growth. Cabbage and Cauliflower have been very good. Peas, Beans, &c., have been good crops and the quality excellent.—W. STANTON.

**Buxted Park, Sussex.**—Apricots on walls facing S.E. were good, particularly Moor Park, while those on other aspects suffered severely from the late spring frost. Peaches I never saw cut up so badly as they have been this season. The blister was so bad in the early part of the summer that not a leaf was to be seen without it, the consequence being that there is no fruit of any account. Trees on south-east walls suffered most. There is no difference in this respect between those said to be hardy and the more tender kinds. Pears on walls are carrying fair crops, while standards and bush trees have scarcely a fruit on them. Plums are a partial crop, some varieties being loaded, while others have not a fruit. Orleans, Victoria, Blue Gage, Coe's Golden Drop, The Czar, and a few others are the best. Apples are also a partial crop, some kinds being plentiful, while others have not a fruit. The best are Stirling Castle, The Queen, Hawthornden, Pott's Seedling, Lane's Prince Albert, Warner's King, Ecklinville, Cox's Pomona, and Irish Peach. Currants, both Red

and Black, were good, but Gooseberries were only a partial crop. Raspberries were abundant, particularly Prince of Wales and Superlative, but the dry weather caused them to very soon go over. Nuts, Filberts, and Cobs are good, but Walnuts are a failure.—H. C. PRINSEP.

## TREES AND SHRUBS.

### THE WISTARIA.

ALTHOUGH written many years ago, since which time great numbers of plants have been introduced into this country, Loudon's words, "that this plant may truly be considered the most magnificent of all our hardy climbers," is just as applicable at the present day as it was when the above was written, for it has not been surpassed or even equalled since then. The Chinese Wistaria is so well known that nothing further need be said as to its general appearance, except that the large massive clusters of lilac-purple blossoms are in colour very distinct from anything else in bloom at that time. It is generally

The Wistaria on a balcony. Engraved for THE GARDEN from a photograph.

treated as a wall plant, where it will soon cover a considerable space, but it may also with advantage be employed in other ways: for instance, being of such vigorous growth it will rapidly make its way into a neighbouring tree if opportunity occurs, and in this way some charming and picturesque effects may be produced. Again, it may be used for covering an arbour, screen, or anything in that way, a good instance of which is to be seen at Kew, where there is a large circular arrangement of iron-work completely clothed with this Wistaria, which in spring attracts everyone. True, the blooms are in an exposed position sometimes injured by late spring frosts, but in a general way this seldom happens, and when it does take place we often get a scattered number of flowers later on, while the beautiful pinnate foliage renders it an attractive climber throughout the summer. Though we seldom see any other but the Chinese Wistaria it is by no means the only

member of the family available, there being among others a pure white counterpart of it which, as far as my experience extends, appear to be equally free-flowering with the type, so that a charming effect might be produced by planting the two in close proximity. The double-flowered variety has been frequently figured and the subject of many notes, but it is greatly inferior to the ordinary form, and may be at once passed over. Another species is *W. multijuga*, which has been described as producing racemes of blossom over 2 feet in length. This certainly reads very attractive, and it is by no means a misrepresentation; but as a set off the individual flowers are smaller and of paler tint, while there is also a much greater space between them than in the case of the common kind, to which in ornamental feature it is much inferior. The oldest of the Wistaria is the North American *W. frutescens*, which was introduced during the early part of the last century, but at the present day it is rarely seen though very desirable, for it does not attain the dimensions of the others, and may therefore be grown in a more limited space, while the flower do not expand till those of all the rest are past. In this species the flowers are borne in shorter and denser racemes which are erect, or partially so. They may be trained to a wall or treated in any way similar to the other kinds, while being much less vigorous than any of them, it forms a very ornamental specimen if planted in the open ground trained round a few sticks, and the allowed to grow at will. Another feature possessed by this Wistaria is that the blossoms are pleasantly fragrant. Wistarias, as a rule, do not transplant readily owing to their stout, deep, descending roots; still, from this very circumstance they are enabled to resist drought, and will consequently succeed better in dry sandy soils than many other classes of plants; but, for all that, they much prefer a good deep loam.

**Cedars of Lebanon in Norfolk.**—So far as I know, Norfolk is not so famous for Lebanon Cedars as Essex, Kent, and Sussex but I recently saw some very fine old specimens at Beeston Park, near Norwich. One measuring one I found it to be some 25 feet in girth at the base, but, unfortunately many of the far-reaching limbs had died and had been sawn off close to the body of the tree. There were several others much higher than this one, but they had never had a fair chance so far as furnishing their bottoms was concerned, on account of being too thickly and closely surrounded by other trees. Their towering heads, however, showed well from a distance. It is a mistake to plant Lebanon Cedars amongst other trees. They should stand out boldly by themselves where their full beauty can be seen.—C. C. H.

**Summer-flowering shrubs.**—The yellow Spanish Broom is now charmingly in bloom, and there are many golden blossoms on various *St. John's Worts* (*Hypericum*). *H. Moserianum* is a good thing and worth general planting. Several masses of *Berberis stenophylla*, moved last spring, are now charmingly in flower. It is nice to have the flower now, even though the beauty in spring may be lost. I suppose the moving had some effect, though it is not uncommon for this and *Darwinia* to bloom in autumn. The Tamarisks are in bloom now, and a plant on a wall has attained large proportions. It is a pity the *Ceanothus* are not perfectly hardy. I have lost them so many times that I have ceased to plant them. An archway in an amateur's garden covered with the white *Clematis flammula* and the purple variety Jack-

anni was very pleasing; the blending of the colours and the training were perfect. Both these are hardy, and it would be better to plant known hardy things that will grow than tender plants which die. I hear of nurserymen selling thousands of these plants in pots annually. The reason for the large demand is that owing to the system of propagation being faulty many plants die, and have known these plants purchased by the same parties time after time, with the hope of getting them established at last. Jackmanni is one of the hardiest, and if propagated by cuttings or layering the plants soon get strong, and do not die. Two American trees, the Buckeye tree and the Calabash, are summer-flowering trees of distinct character. The Hibiscus and the Irish and Mediterranean Heaths may be added to the list of shrubs in flower.—E. H.

#### FRUIT CULTURE IN SWITZERLAND.

THE Swiss Horticultural Society, a new association comprising French and German groups of the societies and committees of horticulture and free societies of twenty-two cantons held a "pomologic congress" on September 24 last at Geneva at the time the national exhibition was held there, and the congress was presided over by M. Marc Richeli. M. Charles Baltet, of Troyes, who forty years earlier inaugurated the first French pomological congress at Lyons, was among those who took part. He writes in the *Revue Horticole* as follows:—

Fruit tree cultivation in Switzerland well deserves a special study. The fertile plains of Helvetia, the presence of lakes, together with the mountain slopes and elevated plateaux are productive of extremely varied results. In all such places the cultivation of fruit trees is carried on, and the markets and export trade are supplied therefrom. The conferences and exhibitions held in towns and villages and fostered by the state, by societies, and by the cantonal or communal administrations have had the effect of at once encouraging and locating planters, with the result that new orchards of considerable extent, in addition to the more modest garden, have been formed, and also plantations have had the benefit of a more enlightened system of cultivation, pruning and grafting. In reputation the produce of the Valais takes first rank, then next those of the Vaudois and the Geneva canton, next Friburg, Thurgovia, Zurich and Ticino, the last-named enjoying advantages as regards sun. In many districts the grower's aim has been to produce as well a good travelling fruit for exportation wholesale to, amongst others, the cider districts of near countries, like Northern France and Southern Germany, where it is used sometimes by itself and sometimes with other kinds. Among the Apples grown for this purpose we have—

*Aargauer Herrenapfel*.—A late-bearing kind.  
*A beignets*.—From the Jura (Vaudois), a plump, open winter Apple.  
*Blanche à côtes*.—A sweet preserving and cooking Apple.  
*Bachelette*.—A good eating Apple, from the Jura (Vaudois).  
*De Fer*.—Native of Gros de Vaud; a good keeping Apple.  
*De Prince*.—A firm, juicy Apple; will keep for a year.  
*Françoise*.—From Vaud; aromatic in flavour and good for all purposes.  
*Gros Bohnapfel*.—Much grown in Canton Fribourg.  
*Hausuli*.—Long well known in the market.  
*Palmapfel and Sauergrousch*.—Varieties which fit in the lower valleys, such as Grindelwald, and good for drying.  
*Quiken*.—A pretty fruit, originally from Wurtemberg.  
*Paradis d'Automne*.—Sweet; for preserving and cooking.  
*Petite Tardive*.—A white Apple; keeps long; rust tree.  
*Pomme Coing*.—Good for baking, preserving, and cider-making.  
*Pomme Rose*.—A popular fruit for garden, orchard, and market.

*Princesse de Wurtemberg*.—Very late and robust.  
*Reinette Bovarde*.—Handsome and good winter fruit from Canton Vaud.  
*Rose de Virginie*.—Quick grower; handsome and early fruit.  
*Rouge douce*.—Good cooking fruit; keeps till July.  
*Usterapfel*.—Yielding 100 bushels the tree.

In general, the trees which produce these diverse varieties, and which combine the qualities of robustness and fertility, are happy alike in the field and by the roadside. Experience has taught the cider-making peasant the superior virtues of the following: Reine des Reinettes, Reinette de Caux, Reinette d'Osnabruck, Reinette Baumann, Reinette de Châtagnier, Calville de Dantzig, Saint Nicolas, together with Bohnapfel Breitacher, Fraurotacher, Spatlauber, Spitzweisser, Waldhotter well known in the lists of cider Apples beyond the Rhine, the last-named variety often heading the list of fruits destined for the cider press. At the same time, the cultivator does not forget the Gelber Jacobs Apfel, a cooking Apple so much in demand in Thurgovia for cider making, that there is a proverb to the effect that "He who knows not Jacob's cider is no Thurgovian."

In the cantons Thurgovia, Friburg and Lucerne, sparkling beverages are manufactured from Pears and Apples, and in many districts it is the custom to combine these two fruits, and thereby increase the yield of juice. Cider is of daily consumption in the household, the hotel and the inn. In speaking of

#### DESSERT APPLES

we cannot omit mention of two delightful Apples—Transparente de Zurich (an ivory-white Apple) and De Laet (with its delicate dead-white and scarlet skin). The trees of both, generally dwarf in growth, are good bearers, and offer a stout resistance to the winter frosts. Our own Reinette Ananas, with its reddish brown skin, is fertile also in the Valais; and we may now find cultivated, at an altitude of nearly 3500 feet, Russian Apples like Borowitzky, Antonowka, Titowka, Alexandre, as also some Canadian kinds.

The Pear also has its local varieties as well as those which are propagated by grafting. Thus we have

*Barbeyron*.—A from December to January fruit, delicious when cooked.  
*Botzi et Chaune*.—Fruits for drying and cooking.  
*De Frauler*.—Latest as regards vegetation.  
*Gelbmöster and Guntershauser*, which are popular in Argovia.  
*Gelbe Mostbirne*.—A robust tree on the high mountains of St. Gall, Appenzell, and Thurgovia cantons.  
*Lederbirne and Schwartzwalder*.—Hardy trees in the severe winter frost, growing at a height of over 3000 feet.  
*Loup, Mirzler, Grosse blanche de Champagne, Normande blanche ou verte*, which are a good addition to the juice of the cider Apple.  
*Thiersbirne*.—Yielding nearly two hogsheads of cider the tree throughout the whole of Eastern Switzerland.  
*Wasserbirne*, which, growing as large as an Oak tree, produces a light coloured and abundant Pear.

The Pear tree de Maude is propagated everywhere. The tree, which attains gigantic proportions in Savoy and the French and Swiss Alps, produces as much as from 800 to 1000 litres of cider. We can recommend as a good "all-round" Pear one of the most common in Switzerland, the Längler or Kannenbirne, or sometimes known as d'Estranguillon, which has always been a favourite for cider, baking, and preserving. Like the Pear Goliath, the Laustieglerin of Thurgovia is grown both for drying and for alcohol. It is a tree which bears at 200 years of age. There are many kinds which, like the last, are good for various economic purposes, and which fringe the roadsides of German Switzerland. Most of these are described and figured in a pomologic work published at Saint Gall, now out of print, but of which a new edition is expected shortly. It is our hope that a result of the pomologic sessions the congress may be to fix the value and to revise, if necessary, the nomenclature of the various species

in general cultivation. Besides the country orchards we should mention those gardens of dwarf or half dwarf trees which have been planted by cultivators of acknowledged skill with fine, good varieties of each season's fruits for the table. These plantations are fed from the nurseries of Swiss, French or German growers. Williams', Louise Bonne, Beurré, and Doyenné do wonders in them, and Pear trees, like Urbaniste, Baltet père, Josephine de Malines, are found to withstand the extremes of climate.

The espaliers of these gardens offer a whole series of Peach trees bearing fruit large in size and good in quality, scattered over the sheltered hillsides or in the vineyards. The Syrian Peach known as de Tullius and some native types are produced from the kernel. The climate of the Valais is as good for the maturing of the fine late sorts of Peach, Calville Blanche Apples in the open air and the Malvoisie Grape as the Lyons region is.

The Cherry tree does well in these districts, and in order to supply the requirements of the distilleries, it is found profitable to plant good kinds of Kirsch Cherries, such as Noire Commune des Avants, de Sovertz, de Montreux, à Queue Rouge, la Rouge Commune (which is a good fruit for drying), la Péquenette (which does well even in clay soils), and some unnamed local kinds. Cultivators of these have their own little nurseries for supplying their needs. Some Cantons plant the Kirsch Cherry, and orchards of these trees are found along the roads leading to la Béroche, in Canton Neuchâtel, whilst others massed on the slopes and plateaux of the mountains help largely to increase the revenue derived from rural industry. Dessert Cherries, like the White Heart, the Black Cherry and the Black Heart Cherry, succeed either as bushes or as standards. In the environs of Lausanne, the Chevanne, a black Cherry, is chiefly used for preserving. A white heart Cherry called Napoleon does well at considerable altitudes, as does also the black du Righi Cherry, which ripens in July.

For table, cooking, drying and distilling purposes, the Plum is in great demand, and we ourselves observed numerous unnamed varieties of white, yellow, red and purple Plums being brought to market. We were assured that Plums like Quetsche de Bâle, Berudje (or Béronge), and Méchelette can hold their own against the imports from Servia. There is, for example, the de Bacon, a tree which bears at an altitude of over 1000 feet, and has a disposition to naturalise itself by offshoots and seed like the Berudje; also there is the Baconette, with the synonym of Mirabelle Rouge, and Monsieur Rouge of proved robustness. Plums like Reine Claude, Mirabelle, and Monsieur hâtif are found profitable to grow on the plains and the hillsides even in the shade. Its fine foliage and the fact of its fruit demanding shelter makes the Apricot a suitable tree for cultivation near dwelling-places, where it is seen ornamenting the hotel yard and the villa approach. In certain gorges and slopes it is generally a fertile tree. As we follow the Rhône valley we note the fine Apricot orchards near Saxon-les-Bains, and the sale of the fruit is never at a standstill. Close to lakes, it is also favourably placed. We have only to mention the wild Grenadier at Sion, on the sunburnt slopes of the Tourbillon, immediately above which the eternal snows form an unexpected contrast. That decorative and most abundant bush, the Cognassier de Portugal, has its place in the orchard; it is at once useful and ornamental. The same valley is from Bex to Brigue crowned with forests of Chestnut trees. If the Chestnut is insufficient in quantity to supply the needs of consumers, France and Italy are at hand to make good the deficiency; whilst as regards nuts, domestic trade and commercial requirements are fed from the produce of the plains, the hillsides, and the mountain hollows, although the imported nut is no stranger. It would not be possible to fix the nomenclature of the dry fruit, as the seed does not reproduce the types. Nevertheless, the example of Dauphiné grafting the Walnut has already found imitators

in some of the Swiss cantons, where good late sorts are propagated, like Mayette, a dessert fruit: Chaberte, used in oil manufacture; and de la Saint Jean for the market.

As regards the smaller fruits, Gooseberries, Currants, and Raspberries, although scattered over the fields, vineyards, gardens, and orchards, the demands for the table, economic or domestic purposes, are not sufficient to make it a profitable industry. Our own good kinds of Gooseberry—Fertile, Versaillaise, and Holland—are found here, as well as some Currants and Raspberries. Not to speak of the glasshouse culture, which shows a tendency to expansion, the Grape is found not only on the garden trellis or espalier, but also in a high state of cultivation in vineyards on the shores of the lake of Geneva, at Montreux, Vevey, Clarens, Lausanne, and in the Valais, in the territory of cantons Neuchâtel and Fribourg. The Pineau Grape comes to the table under the names of Salraguin Klevez and Cortailloid. Our Chasselas Doré—called Fendant Roux and often Gut-Edel in the high Rhine valleys—has attractions for the wholesale dealer, of which the canton Vaud has had fruitful experience. Le Chasselas is the foundation of the Swiss white wines. La Valais sends out large quantities of the best Grapes in boxes, whilst retaining the smaller fry for the factory, which, as a certain outlet, has encouraged landowners and farmers to extend and improve the open-air and covered vineries. The canton Ticino, in the Piedmontese region, the fertility of the valleys in which is well known, exports by the lake of Lugano large quantities of wine and Grapes, to be used, as regards the former, in the manufacture of sparkling wines. The Vine is now gaining in importance in this comparatively warm country. Seconded by the action of the sun, the chalky nature of the soil is a stimulant to the fertility of the Muscats, Frankenthal, Lignan Blanc, Avarengo, Malvoisie, Gros Guillaume and other Vines producing Grapes of fine quality. The manufacture of the raw fruit into various preparations has made great progress in Switzerland, so that the grower has now in the factory an assured and profitable outlet for the fruits of his toil. The attitude of the federal and cantonal administrations is favourable to the establishment of factories and distilleries.

**Removing boiler.**—I should feel obliged by advice on the following subject: I have two small vineries (one to come on in July, the other in September), a small greenhouse in the centre, and the other side a small stove house, and an orchard house for Peaches in June, heated by about 650 feet of piping. I consume annually about eighty chaldrons of coke. This seems to me enormous, owing, I am led to believe, to the size of boiler which was originally placed there to heat, when built, four other small houses, two on either side. I contend that it would answer my purpose to remove the boiler and have a small one placed there to heat 700 feet of piping—A. A. W.

\* \* This is a rather awkward subject to advise on, especially seeing that "A. A. W." does not state what kind of boiler he has in use. It certainly seems wasteful, and a smaller one unless not equal to keeping up the heat without hard driving, would be the most economical. With large boilers much may be done towards economising fuel by a judicious use of fire dampers, but the boiler complained of evidently swallows up more fuel than ought to be necessary with the amount of piping to be heated. If "A. A. W." will describe his present boiler we will endeavour to advise him upon changes that may be desirable.—Ed.

## STOVE AND GREENHOUSE.

### STREPTOCARPI.

THOUGH the fine hybrid strain of *Streptocarpus* now in commerce has been distributed for some years, it is but rarely that one meets with a good batch of plants. This does not arise from any difficulties that their cultivation presents, for, given a suitable position, they are as easy to grow as the commonest of greenhouse plants, and certainly we have hardly any other plant that gives such a splendid return for the little trouble spent over them. Personally, I think that their introduction was one of the greatest boons ever given to the gardener who has not the command of much heat, as they flower continuously from May to September, and even later, in unheated greenhouses without giving the trouble of raising successional batches, and the delicate colouring and quaint tracery in their flowers are a continual source of pleasure to all who see them. I like best of all the

flowering scapes. As a cut flower used with delicate greenery they are delightful, and, once got into position, there are but few things more lasting, which is a great consideration to those who have much of this work to do.

### CULTIVATION.

My method of treatment differs in time of sowing from that generally recommended, as I prefer to sow in a cool house late in spring rather than in heat earlier in the year, for the latter method gives more trouble and more risk of losing the tiny plants in the early stages. Sown in carefully prepared seed pots with a inch or so of finely sifted loam and leaf mould freely mixed with sand, on the surface, and placed in a shady corner away from draught in a cool or temperate house, the seedlings come up quickly. They should never be allowed to get dry, and the seed-pot should be covered with a sheet of glass from which condensed moisture should be wiped daily. Damping off is more frequently the result of dryness below than of anything else. When the seedlings go

*Streptocarpus* plants four years old. From a photograph sent by Mr. Chas. Jones, Ote Hall Gardens, Burgess Hill, Sussex.

white grounds with blue or purple pencillings, but there are also many delicate self shades of heliotrope and light or dark purple that are very beautiful. One peculiarity I find is that it is the flowers of lightest shades that are borne on the tallest and finest scapes, and it is not uncommon to be able to cut scapes of the white grounds at least 10 inches high and with as many as twelve flowers and buds on a scape. The red and rose-coloured flowers are not so generally satisfactory, though they contain some beautiful varieties, but the percentage of plants which have to be discarded for poorness of colour or dwarfness of habit is higher among these shades than among the whites and purples. *S. Wendlandi* is rather an awkward type of plant, but it bears tall, many-flowered scapes of blue flowers that are very useful, and a new strain of hybrids between this and *S. Dunni* is likely to be much sought after. Hybridists are still busy among the *Streptocarpus*, so that nothing like finality has been reached, and we may look for plants of faultless habit combined with tall free-

big enough to handle they are pricked off in pans filled with equal parts of loam and leaf mould, and removed to a frame containing spent hot-bed where they are kept shaded all summer. A few of the strongest plants are potted off into 3-inch pots during the early autumn, but the majority are left in the pans all winter and wintered in a house that has a minimum temperature of 38° or 40°, keeping them fairly dry at the root till March, when they are potted into their flowering pots. The secret for this shift is similar to that recommended above except for the addition of about one quarter its bulk of finely broken and well decayed cow manure, and it is to the latter that I attribute the robust and healthy growth made by the plants. After potting, water must be given in gradually increasing quantities, but at no time must the soil be allowed to get sodden. To the position selected for the plants when growing and flowering I attach some importance and I never think they look well or do well when mixed with other flowering plants, though

do both when grown amongst Ferns. In own case they are grouped at the west of a tall lean-to house facing north, and on a bench which is covered with an or two of cocoa-nut fibre, and here they flower with the utmost profusion, the only attention they require being watering and occasional picking over to remove the seed-pods, which form quickly and weaken the plants if left on. The requisite conditions for well-being of the plants are a cool, moist room, freedom from draught, and plenty of light without direct sunshine; in fact, the conditions which make our Maiden-hair and other delicate Ferns look their happiest will do the same with the Streptocarpus. This spring, having many surplus plants on hand, I formed in order to the main path of a large house by lining on edge two 4-inch planks at 4 inches apart, filling up the intervening space with peat and loam, in which I put the surplus stock. Here the plants have done very well and provided quantities of flowers for cutting, besides adding greatly to the appearance of the house. The only insects which trouble Streptocarpus are green fly, white fly, and mealy bug; the two former may be easily dealt with by spraying with nicotine insecticides, but the latter if allowed to establish itself will surely kill the plants, as there are no successful means of getting rid of it from plants with woolly leaves and a close-growing habit. Given cool treatment throughout, however, mealy bug should not get a standing; the danger arises through raising the seedlings in a hothouse among other plants already infested with the pest.

The illustration shows three well-flowered examples grown by Mr. C. Jones, gardener to Mr. H. Woods, Ote Hall, Burgess Hill, Sussex. These plants were each four years old and measured 3½ feet across. They were in 10-inch pots, and at their best at the end of the month of June. There were then on them 150 more flowers than at the time the photograph was taken.  
J. C. TALLACK.

**Plumbago capensis.**—The remarks by "H." (122) on the treatment of this useful but much neglected plant, are well worth perusal, as showing the usefulness of it when grown in pots. As a pot plant my experience of it is but limited, but I have proved it to be a capital subject for covering trellises in conservatories and cool corridors, though, as "H." says, a little warmth suits it best. Planted in a fairly rich loamy compost it quickly covers a large space, and when in bloom in autumn its pale blue flowers are very attractive. I have a large plant on a conservatory wall, and each spring I cut it back to several eyes from the base, removing altogether the weaker growths. Soon breaks away again and the growths are allowed to fall down naturally.—GROWER.

**Calceolaria alba.**—What may be accomplished with this perfectly beautiful species as a pot plant was well shown at the Royal Horticultural Society, on Tuesday last, by a group of several plants in a circular basket, the importance of which may fairly be estimated by its receiving a first-class certificate. The species, a native of Chili, has been in cultivation for half a century or more, yet has been little known to gardeners generally. Several notices of this beautiful species, as also a coloured plate last year in THE GARDEN, have brought the plant more prominently into notice, and now Mr. J. T. Bennett-Poë, of Ceshunt (gardener, Mr. Downes), has proved its value both as a pot plant or cut flower. The perfectly grown plants shown by Mr. Poë were compact bushes laden with blossoms, these being borne on much-forked heads in considerable profusion. The elegant sub-shrubby character of the plant, with numerous linear leaves that are minutely serrated at the margin only, add beauty

to the plant, which, while nearly hardy, is not sufficiently so to render it of permanent worth in the garden. As a cool greenhouse plant, however, there is plenty of room for it, or even in beds in the open all the summer long.

SOCIETIES AND EXHIBITIONS.

ROYAL HORTICULTURAL SOCIETY.

ONLY a very small number of exhibits were brought together on this occasion. The most conspicuous exhibits were a large group of Caladiums from Messrs. John Laing and Sons, Forest Hill, hardy plants from Messrs. Wallace, of Colechester, an extensive and very interesting collection of twenty dishes of Cob Nuts and Filberts from Messrs. Bunyard and Co., Maidstone, a large collection of fruit from the Dowager Lady Fricake, Fulwell Park, a group of hardy Heaths from Messrs. Veitch and Sons, and groups of Orchids from Messrs. Sander and Messrs. Veitch and Sons. From Sir Trevor Lawrence came an enormous spike of Grammatophyllum speciosum.

Orchid Committee.

A gold medal and first-class certificate were awarded to Sir T. Lawrence for

GRAMMATOPHYLLUM SPECIOSUM.—A gigantic form producing spikes upwards of 7 feet in length, and carrying upwards of sixty flowers, each about 6 inches across the sepals and petals by 1 inch in breadth, the ground colour being rich golden yellow, heavily spotted with rich brown; the lip pale yellow, lined and suffused with brown. Two flowers are produced at the base of the spike, which are not fertile; the ground colour greenish yellow, with darker brown markings. Although an old species, it is somewhat difficult to induce it to flower freely, only two instances of its having previously flowered in this country having been recorded, viz., with Messrs. Loddiges, of Hackney, in 1851, also with Mr. Farmer, of Cheam, in 1858.

Awards of merit were adjudged to the following:—

LELIO-CATTLEYA JUNO (C. Mossie x L. majalis).—The sepals and petals deep rose, suffused with a darker shade of colour, the lip rich purple, shading to yellow, lined with purple-brown at the base, the side lobes pale rose, shading to yellow. The flower is intermediate in character between the two species, but the habit of growth resembles C. Mossie. From Mr. N. E. Cookson, Wylam-on-Tyne.

LELIO-CATTLEYA ANDERIANA (bicolor x elegans).—The sepals and petals are nearly white, slightly suffused with rose at the base, the lip deep velvety crimson, with a white blotch and margin in front, the side lobes pale rose, shading to purple, lined with white at the base, the colour rose-purple, with a white blotch at the apex. The lip has the elongated character of C. bicolor. It is remarkably free-flowering; the plant exhibited carried four flowers on the spike. From Mr. R. J. Measures, Cambridge Lodge, Camberwell.

GOODYERA ROLLISSONI.—A lovely form, with deep velvety green and yellow foliage. It is remarkably free growing and a most desirable variety. From Mr. W. Bull, Chelsea.

Messrs. J. Veitch and Sons, King's Road, Chelsea, sent two fine forms of Cattleya Atalanta, a good form of C. intertexta (C. Warneri x C. Mossie), a large, bold-flowered variety with deep rose sepals and petals, the lip deep rose, veined and suffused with rich crimson-purple in the centre, shading to rich orange-yellow at the base; Lelio-Cattleya Nysa (L. crisa x C. Warszewiczii), a lovely form with pale rose sepals and petals, the lip rich crimson-purple, heavily fringed at the edges with light rose, the side lobes white, shading to rich yellow and deep crimson at the base; L. C. Parysatis (Boweringiana x pumila), intermediate in character between the two parents, with three flowers; Cypripedium Melanthus (Hookeri x

Stonei), a distinct form, the dorsal sepal pale green, suffused with yellow and lined with brown, the petals greenish yellow, lined and spotted with dark brown, the lip greenish yellow, suffused with brown; and C. Janet (Spicerianum x glanduliferum), taking a great deal of the characters of C. Spicerianum in form and colour, with the twisted characteristic of the other parent in the petals (silver medal). Messrs. F. Sander and Co. sent a small group consisting of Catacsetum Chrystianum, a distinct form with deep rich brown sepals and petals, the lip brown, mottled with green and heavily suffused with dark purple hairs at the margin; C. fimbriatum with ten flowers, Lelia amanda, Cattleya Gaskelliana virginialis, a nearly white form with a slight tint of rose in the centre of the lip; Lelio-Cattleya Robini Measures (parentage not recorded), the sepals and petals pale lemon-yellow, the lip yellow, suffused with rose-purple, with a deeper shade of yellow at the base; and L. C. Sanderiana, a variety very similar to one previously noted under the name of L. C. Elstead Gem.

Sir T. Lawrence sent a distinct species of Cymbidium with pale green sweetly-scented flowers, and Lelio-Cattleya Janet (C. intermedia violacea x L. pumila), a lovely form, with pale rose sepals and petals, lip crimson-purple in front, which extends round the margin of the side lobes, the latter rose, shading to yellow at the base.

Mrs. Briggs, Bury Bank House, Acerrington, sent Cypripedium Hereules (venustum x Stonei) with two flowers. Mr. R. J. Measures exhibited the rare Masdevallia Lowi, a most distinct variety, the sepals and petals white at the tips, spotted with purple, and shading to yellow at the base. The plant carried eleven spikes of flowers. Mr. C. J. Ingram sent a form of L. Dominiana, Lelio-Cattleya Ruby Gem (C. Lawrenceana x L. C. elegans), the sepals pale rose, petals rose, heavily suffused with a darker shade of colour; lip rich crimson-purple, shading to white in the throat; and Cypripedium gracile (Haynaldianum x Swavianum), a graceful form with three flowers.

Messrs. H. Low and Co. had Lelio-Cattleya Canhamiana, L. C. Aurora, and a fine form of Cypripedium Alfred Hollington with three flowers.

Floral Committee.

A first-class certificate was awarded to—

FICUS RADICANS VARIEGATA.—This is a very pleasing variety, dwarf and bushy in habit, with pretty mottled foliage, grey-green and white. It appears to be a strong grower, and is a highly attractive plant. From Mr. W. Bull.

Awards of merit went to the following:—

CACTUS DAHLIA AMBER.—The colour is very charming, being shades of bronzy yellow. The form is fairly good, the petals narrow and pointed, but not twisted, and the bloom is slightly inclined to be coarse. From Mr. J. Stredwick, Silver Hill Park, St. Leonards.

CACTUS DAHLIA NIGHT.—A very dark velvety maroon, of excellent form and a very taking colour. It is not unlike Matchless, but has a better centre. It should make a good exhibition bloom. From Mr. J. Stredwick.

POMPON DAHLIA HYPATIA.—This is a variety of good form, with a close, hard centre. The colour is quite distinct, being a pinkish terra-cotta, shading almost to bronze yellow at the centre. From Mr. C. Turner, Slough.

POMPON DAHLIA VESTA.—A shapely white; certainly an improvement in form on most of the existing whites, but spoiled by a defective centre. From Mr. Turner.

POMPON DAHLIA PIRYNE.—A pretty variety with yellow petals, shading to scarlet at the edges. The form is generally good, but the centres appear to be not quite reliable. From Mr. Turner.

SHOW DAHLIA MARJORIE.—A very pretty flower, amber-yellow, the older petals faintly tinged with pink. The form is good, but the centres slightly uneven. From Mr. Turner.

The principal exhibit in this section was a large group of Caladiums from Messrs. John Laing

and Sons. The plants were not generally of great size, but were in good condition, well grown and of brilliant colours. A few of the most striking plants were the charmingly variegated *C. E. Dahle*, *Michel Buchner*, a particularly handsome specimen of *Louis Van Houtte*, *Baron Adolphe de Rothschild*, *Princess of Teck*, *Flammant Rose*, a very bright variety; *Raymond Lemoine*, very fine, *P. Klein* and *Mrs. Laing*. From the same firm came also a very pretty group of *Crotons*, every plant in which was a model of symmetrical growth and all were well coloured (silver-gilt *Flora* medal). A nice group of plants, chiefly *Begonias* and ornamental foliage plants, was shown by *Mr. P. Purnell*, *Woodlands*, *Streatham Hill*. The arrangement was tasteful and effective (silver medal). *Mr. T. S. Ware*, of *Tottenham*, made a gorgeous show with a collection of *Dahlias*, containing pompons and *Cactus* and decorative varieties. Among the pompons the best bunches were *Eurydice*, *Tommy Keith*, *Mrs. W. Besant*, *Mars*, *Darkness*, *Lilian* and *Juliette*. The *Cactus* section contained good examples of *Valkyrie*, *Mrs. A. Beck*, *Matchless* and *John Welch* (silver medal). *Messrs. W. Wallace and Co.*, *Colchester*, staged a beautiful collection of *Liliums* and *Gladioli*, making a very brilliant bank of colour. Varieties of *Lilium speciosum* were well shown, also *L. auratum*, *L. Maximowiczii*, *L. Batemannii*, *L. tigrinum splendens* and *L. tigrinum flore-pleno* (silver medal). *Messrs. Veitch and Sons* had a very delightful exhibit, viz., a collection of hardy *Heaths*. The varieties shown were *Erica Mackayana*, *E. vulgaris variegata*, *E. v. aurea*, with very good foliage; *E. v. Hammondi*, a very strong-growing white form; *E. vulgaris fl. pl.*, a very lovely variety, free-flowering and of very sturdy growth, the colour also very charming; *E. cinerea alba*, *E. vulgaris Allporti*, a handsome variety of darker colour (silver medal). *Mr. W. Bull*, *King's Road*, *Chelsea*, sent plants of *Musa superba* and of *Ficus radicans variegata*.

A few new *Roses* were shown by *Messrs. Wm. Paul and Son*, *Waltham Cross*, viz., the new *Tea* *Empress Alexandra of Russia*, *Aurora*, a pretty pink bedding and decorative *Rose*; *Waltham Standard*, a new red *Hybrid Perpetual*; and *Queen Olga of Russia*, a new *Hybrid Tea*.

#### Fruit Committee.

An award of merit was given to

MELON FROGMORE SCARLET, a scarlet flesh fruit, large, oval, nicely netted, and of excellent quality. It is a cross between *Duchess* and the old *Beechwood*. Sent by *Mr. O. Thomas*, the *Royal Gardens*, *Frogmore*.

The exhibits before this committee were not numerous, but interesting. Fruit was shown well by *Messrs. Rivers*, *Bunyard*, *Elliot*, *Wythes* and *Rickwood*, and some excellent vegetables came from *Mr. Lawrence*. Some excellent *Grapes* were staged by *Mr. Elliot*, gardener to *Capt. Macdonald*, *Hurstide*, *West Molesey*, consisting of the varieties *Foster's Seedling*, *Madresfield Court* and *Gros Maroc* (silver *Knighthall* medal). The *Dowager Lady Freake* (gardener, *Mr. Rickwood*, *Fulwood Park*, *Twickenham*) sent thirty dishes of fruit, consisting of *Apples* and *Pears*, *Peaches*, *Plums*, *Nectarines*, *Currants* in variety, and *Black Hamburg Grapes*, with *Morello Cherries* (silver *Banksian* medal). *Mr. G. Wythes*, *Syon House*, *Brentford*, sent thirty *Melons*, the chief variety being *Middlesex Hero*. The fruits were beautifully netted. This kind was given an award in 1895. The same exhibitor sent a new seedling *Melon*, *Thames Bank*, but not ripe. *Mr. Willard*, *Holly Lodge Gardens*, *Highgate*, sent a new seedling *Melon*, a white flesh, but the fruit was not quite at its best—a promising kind. *Mr. McIndoe*, *Hutton Hall*, *Guisborough*, *Yorks*, sent a dish of *Japanese Plum Burbank*, a very prolific variety. *Messrs. Rivers and Sons*, *Sawbridgeworth*, sent black and white *Grapes*. *Graskiska* is a very sweet, refreshing *Grape*, not large, but good, amber-coloured berries and very free-bearing, and *Directeur Tisserand* is a blue berry, round and distinct. They also exhibited three boxes of *Plums* grown on pot trees—splendid

fruits, the varieties being *Late Transparent Gage*, *Golden Gage* and *Monarch*. These were given a cultural commendation. *Messrs. G. Bunyard and Co.*, *The Royal Nurseries*, *Maidstone*, exhibited twenty dishes of nuts—*Cob* and *Filberts*, very fine, and varieties worth special notice. The *Atlas Cob*, *Webb's Prize*, *Duke of Edinburgh*, *Pearson's Prolific*, red and white *Filberts*, the *Kent Filbert* and the purple-skinned *Filbert* were most noticeable for size and quantity, and the collection was most interesting.

Vegetables were well shown by *Mr. F. Robinson*, gardener to *Mr. V. Lawrence*, *Elstfield House*, *Hollingbourne*. There were very good exhibits of *Excelsior Onions*, *Standard-bearer Celery*, *Bunyard's Scarlet Perfection Carrot* and good *Student Parsnip*, *Potatoes* in variety, *Hill's Prize Runner Bean* (a nice dish), excellent *Cheltenham Green-top Beet*, *Sutton's No. 1 Cucumber*, *Walcheren Cauliflower*, and other good dishes (silver *Banksian* medal). A collection of *Cucumbers* (eighteen fruits) came from *Mr. W. Kemp*, *Barnes*, the variety being *Covent Garden Perfection*. *Mr. Corbet*, gardener to the *Marquis of Normanby*, *Mulgrave Castle*, sent seedling *Tomatoes Royal Sovereign* and *Mulgrave Castle*. Doubtless these will be tried at *Chiswick*.

The *Veitch* prizes for flavour in *Apples* were given, first, to *Mr. Wythes*, *Syon*, who had a dish of *Irish Peach*, and second, to *Mr. Herrin*, *Dropmore Gardens*, for *Lady Sudeley*. *Mr. Wythes* was given the second award for *Jargonelle Pears*, but by the rules the award was vetoed, as he had it on the previous occasion for the same fruit.

A most interesting lecture on *Plums* was given by *Mr. A. Pearson*, of *Chilwell*, *Notts*, who alluded to the value of the fruit on account of its hardiness and its freedom on a north aspect in moist soil and in exposed places. In noting new varieties he remarked what good kinds the *Messrs. Rivers* had given us, mostly from seed, but a few had been obtained from suckers. He dwelt on budding and grafting, the former being the most suitable, as trees treated thus were not so liable to canker. He described the varieties of stocks for the work, and advised a good dwarfing stock for these fruits. When the cuttings are needed for grafts they should not be in active growth, but nearly dormant. Many growers, on the other hand, took their cuttings direct from the trees. *Plums* should not be too closely pruned, and wall trees should be trained horizontally, not fan-trained, the shoots pinched when growing rather than pruning with the knife. Thinning the fruits was often neglected. It was important to do the thinning early. He gave instances of immense crops of fruits obtained by market growers in favourable localities, and noted the value of jam factories in the districts named, and used in this way the *Plum* gave a good return. For market, *Rivers' Early Prolific*, *Victoria*, *Kirke's*, and many others gave a splendid return when well grown and sent with care to preserve the bloom. For dessert, *Jefferson's*, *Early Transparent*, and *Green Gage* were doubtless the most profitable. There was a demand now for fruit for bottling. The smaller fruits were best for this purpose. He dwelt on the various kinds grown in the midlands and the various aspects needed for certain varieties. He mentioned that the *Prunes*, which did so well at *Mentmore*, did not succeed in many other places. There should be greater care in the gathering of these fruits and in selection for certain soils. He alluded to the *Japanese Burbank* shown that day and to other *Japanese* kinds. The chairman, *Mr. Bunyard*, added some excellent remarks on planting, grafting, and the value of the *Golden Gage*, *Pond's Seedling*, *Victoria*, and *Frogmore Prolific* *Danson* and other interesting matters connected with the culture of *Plums*.

**National Chrysanthemum Society.**—The members of the general committee of this society held a meeting on Monday evening last at *Anderton's Hotel*. *Mr. T. W. Sanders* occupied

the chair and was, considering the season of year, well supported by his brother officers and members. The business was mainly formal of a routine nature. A vote of condolence to the family of the late *Mr. R. Owen* was confirmed and the vacancy on the floral committee caused by his death was filled up by the appointment of *Mr. Gleeson* to the vacancy. A report was submitted as to the annual excursion, which was pronounced to be, as usual, a most successful affair. It was resolved that the society's medals awarded at the forthcoming September show should be the same way as at the other shows of the season. So far as miscellaneous exhibits are concerned, twenty-five new members were elected, and *Higham Hill* and *Barnstaple Chrysanthemum Societies* were admitted in affiliation.

#### THE NATIONAL CO-OPERATIVE FESTIVAL.

AUGUST 20 AND 21.

This festival, which brings into a common centre the leaders and members of the various co-operative societies in the country, extends throughout the week, the most interesting part of it being a large flower show which took place on Friday and Saturday of last week at the *Crystal Palace*. It has been the practice hitherto to hold the flower show in the nave of the building, but, as that occupied by the *Imperial Victorian Exhibition* huge tent was erected on the garden terrace, 500 yards in length by 40 feet in width, and this the various exhibits forming the flower show were staged, where they were seen to much greater advantage than in the building, where also they suffered much less from heat. It was not only a very extensive exhibition, but of general excellence.

On the first day the fruit grown under glass was staged, some good collections being placed upon the tables, the produce very largely of growers or well-known amateurs. Saturday brought the most interesting part of it, the produce mainly of the gardens of working men—self-taught growers, who have gained their knowledge by experience learned in the course of culture. A portion of the show came from all parts of the country, and comprised twenty-nine complete collections of vegetables, forming in the aggregate 174 dishes; of these, one entry came from *Scotland*, two from the midlands, three from the west of *England*, five from the north-west, eight from *London* and its suburbs, and ten from the south of *England*. The counties are grouped in eight different districts, so that the collection grown in a certain area compete by themselves and thus a favourable part of the country gain no advantage over one of a colder and less genial character. Saturday's display was made up of over 1000 entries; among them were 298 dishes of *Potatoes*, many of them of the high quality; of *Beans* there were 130 dishes, *Beet* seventy-eight, of *Cabbage* twenty-nine and of garden *Turnips* seventy-seven; but the particular vegetables, owing, it was said, mainly to the inclemency of the season, lacked their usual quality. Everything else was decidedly good. Of *Cauliflowers* there were few entries, as it is a season between the early types and the later autumn varieties; of *Celery* there were thirty dishes, some of it remarkably good; *Peas* were represented by sixty-four dishes, the *Duke of Albany* and *Autocrat* types being most in evidence; *Vegetable Marrows* by ninety-one. As it is not only an improvement in quality, but it is made quite clear that the range of varieties widens also; the best of each is what is sought and cultivated.

There were excellent plants also, many of them brought with great care from long distances. The finest specimens of *Ferns*, including some of the choicer *Maiden-hairs* and others, *Coleus*, *Begonias*, delightful pots of *Harrison's Musk*, admirable flowering *Begonias*, *Fuchsia*, *Lilies*, *Pelargoniums*, &c. *Annuals* grown in pots made a brave display, though many, no doubt

been taken up from the ground and placed in for the purpose. Pot plants numbered nearly but cut flowers reached to 637 entries, and most popular with these co-operators are Dah-Marigolds, Roses, Asters, Sweet Peas, Migotte, &c. The show, Cactus and Pompon was excellent, and African Marigolds very It was satisfactory to note that there were six entries made by working women and ty-nine by the children of artisans in the es set apart for them. All the time the show open to the public the tent was crowded with ors, who appeared to be deeply interested the exhibits. Perhaps no other exhibition of kind draws to it so much of human interest his one of co-operative products. It always acts an enormous crowd.

the Italian Court within the Palace could be an exhibition of photographs of "Gardens of taste," shown individually and also in collec- for, for which prizes are offered. Many of these sisted of workmen's town gardens, cottagers' country gardens, window gardens, floral porches, oery, hanging baskets, &c., ten classes in all, he professional photographers were invited to el collections of garden views and sylvan ces, and prizes were awarded for these also. My a useful hint was conveyed by these, as they represented what human hands had wrought ssisted Nature to display in the way of delight- subjects.

he principle of co-operation has undoubtedly ed largely into our social and industrial yems, never to get out of them again. Some of eading advocates may be deemed visionaries n their projects regarded as crude, but it does ar probable that, were the principle more ly introduced into industrial organisations, ay of the labour wars between employers and oyed might be prevented. This is a consum- nion devoutly to be wished, and if the results of his annual festival and flower show tend towards a tter understanding of labour and social ques- es, and a more cordial intercourse among rkers and their masters, then it is a movement h, if it does not command full adherence, may excite and draw to it the sympathies of the omunity.

## NOTES OF THE WEEK.

*Ladiolus brechleyensis*.—The bold spikes of his old garden plant have been singularly effective of late, and, in spite of many choice hybrid kinds, the bold scarlet of this well-known plant is as much admired as ever. A splendid plant for shrubby borders.

*Egonia Knowsleyana*.—For grouping freely in the conservatory this is a most pleasing variety, bearing its elegant white and rose-tinted blossoms in considerable numbers. So free indeed is its growth, that many useful branches could be secured when cut flowers are in request. In this the small sprays would be very charming for use.

*Lymphæa Marliacea ignea*.—This lovely hybrid is now flowering splendidly at Kew in the lately aquatic tank, its richly-coloured blossoms spading out in all directions. The colour is remarkable as well as pronounced—a shade of bright ro-crimson, inclining possibly to an intense hue whage. It bears a continued succession of glow- ing blossoms for weeks together, floating on the surface of the water, and is most valuable.

*Lymphæa tuberosa* var. *flavescens*.—This very pleasing variety, now flowering abundantly in the open water, where its large, pale creamy yellow blossoms are most attractive, and associated with the brighter tints of the more recent hybrids, the effect is indeed beautiful. The species is a native of North America and quite lately in British gardens, of easy culture, and readily increased by division of its tuberous roots when dormant.

*Antiana Andrewsii*.—For moist or very shady positions this is a capital plant in groups,

and of considerable value at this time in the bog garden, where so few things of its colour can be found. Where there is no bog garden the plant may be grown with perfect success in similar positions and soil to the Trilliums, Dentarias, *Cypripedium spectabile*, and such things. In a shady spot at the foot of the rockery the plant grew and flourished for some years in succession.

**Carnation Mrs. Tudway.**—I have sent you a plant of *Carnation Mrs. Tudway* for you to see its habit and constitution. It was layered in August, 1896, and planted out the following October. I planted out 300 and not one went off during the winter. I planted out 500 of the old Clove, and lost about 100 plants.—A. G. HOOKINGS, *The Gardens, Oldcorn House, Almondsbury*.

**Tufted Pansy Ardwell Gem.**—This old variety is just now flowering exceptionally well, and although there are several distinct acquisitions in yellow sorts in the newer varieties, this sort flowers consistently. Small pieces planted out in the spring have now attained to large proportions, the rich green creeping style of growth being literally covered with bloom. It is a pity that the constitution of some of the newer sorts is not equal to the variety under notice.—D. B.

**Chrysanthemum Bronze Bride.**—This is one of the first of the early-flowering pompons to flower this season. The colour in its early stages is a rich reddish bronze, and is especially effective when a few plants are grouped together. With age the blooms pass to a light bronze colour. A good feature in this plant is that when the flowering season is over the plant may be cut down, when new growths break away freely from the base, and these each give a number of blossoms of excellent form and colour. The height rarely exceeds 2 feet 6 inches.—D. B. C.

**Campanula garganica hirsuta.**—This is a pretty kind that flowers profusely during the summer months. The plant flowers when given a position not too hot or dry in the border or rock garden. Its trailing, tufted habit, however, is best suited to the latter position, where its masses of somewhat starry blue and white flowers are singularly effective and pretty. The typical species is also a valuable plant for the same reason, and not less so the pure white variety, which is not nearly so plentiful as it deserves to be, and difficult to obtain true to name.

**Nertera depressa.**—The pretty orange-scarlet berries of this plant are now approaching maturity, and among very dwarf subjects it is quite distinct and, for the time being, effective. Given frame protection for the winter and fresh potting in the early spring with returning growth, success may be assured. Potting should, however, be done some time before the inconspicuous little blossoms appear, and if divided at all the gardener should be lenient, or the set of berries will be meagre. When the plant is in flower, plenty of air should be given to encourage a free set of berries.

**Gentiana asclepiadea alba** (White Willow Gentian).—Some fine tufts of this graceful Gentian are now flowering abundantly in the rock garden at Kew. The position is a somewhat shady one, and here in the cool, uniform conditions thereby ensured the plant grows and blossoms freely. A mixture of the blue and white forms of this plant with graceful stems, that doubtless suggest its popular name, growing 2½ feet high, has a decidedly pretty effect in the rock garden or in any spot at once cool and shaded. The plant is at home there, and in deep moist soil of peat and loam luxuriates.

**Three stove climbers.**—I herewith send you a spray of three good stove climbers—*Schubertia grandiflora*, *Passiflora princeps*, and *Aristolochia elegans*. *Passiflora princeps* is growing in a 12-inch pot and has not been potted for four years, and we are seldom without plenty of flowers; there is now over fifty rhizomes on it. *Schubertia grandiflora* is very rarely seen, but it is one of the

best climbers to grow where plenty of white flowers are required; it will commence to flower early in the spring, and continue till very late in the autumn. A. G. HOOKINGS.

\* \* \* Handsome flowers, all well grown.—Ed.

**Lilium speciosum Melpomene.**—When freely grouped in the garden in partially shady places this is one of the most handsome, as also the most desirable and useful of all the forms of this section. Vigorous of growth, free and abundant, as well as reliable in flowering, it yields a grand profusion of its richly coloured blossoms. These latter are of great substance, the rich crimson hue that predominates being freely spotted with white, the margin of the petals being also lined with white. This very handsome Lily is now flowering freely, and is very conspicuous in a mass.

**Tufted Pansy Magie.**—This variety, sent out by Mr. S. Pye last year, is now at its best. The cooler and moister weather of the last fortnight has suited it. All through the season the flowers have been highly prized, as they were freely produced and are of a shade of colour somewhat new. The colour is a pleasing shade of rose, with a light suffusion of crimson in the centre and on the lower petal. The flowers are of large size and of circular form, with a very neat yellow eye. This variety has growth which is fairly dwarf and compact, and on this account should supersede that formerly much-prized sort, *William Niel*, for bedding.—D. B.

**Abelia rupestris.**—A charming and pretty rock shrub or wall plant of comparatively easy culture, and bearing a profusion of pale pink and white blossoms. Though by reason of its specific name it is called the Rock *Abelia*, it is very rarely indeed so employed, but, at the same time, a rather sheltered spot should be given it where the proximity of a large piece of rock would afford some protection. Flowering, too, quite late in summer, it would assist in keeping the rock garden more attractive, while the general effect of such beautiful things judiciously placed would prove a step in the right direction.

**Abutilon Golden Fleece.**—This variety has the merit of providing a rich profusion of blossoms of a beautiful golden tint and considerable size. During its period of flowering, which ranges from early in June to the end of October, or even later, the old-established examples produce many hundreds of flowers. As a greenhouse plant for the roof this variety has but few equals, and its flowering propensity appears endless. A capital idea of the value of the plant may be gathered from a good-sized example in one of the greenhouses at Kew. Where an abundance of useful flowers for small glass is required, this kind is worth some attention.

**Phygelius capensis.**—For a position fully exposed this distinct and useful autumn-flowering perennial cannot be regarded as absolutely hardy, and should be well mulched each year. At the same time it would be advisable to root some young plants for wintering in frames in the event of the old plant being killed by the frost. Freshly rooted plants are also more vigorous, and take to the soil readily when planted in good ground early in April. A few cuttings could be inserted as soon as procurable, and these, in sandy soil, root readily. Bright-coloured subjects such as this are always valued in late summer and autumn when the yellow-flowering composites appear to hold sway in the garden.

**Chrysanthemum Little Bob.**—This excellent old pompon is flowering well already this season, its charming little blossoms of bright crimson standing out conspicuously from among other varieties of the same flower. Although flowering so early in the season, it is not to be despised in the least, but rather should be more widely resorted to for planting in clumps in the hardy border, or in small beds by itself. The plant is dwarf and free growing, and rarely exceeds 18 inches in height. It is wrongly named in one or two instances in the trial of early-flowering *Chrysanthemums* at the Royal Horticultural Society, Chiswick, being

there described as *Scarlet Gem*, which is really synonymous with the variety under notice.—D. B. C.

**Tufted Pansy Britannia.**—So much has been written about the need of a really true blue tufted Pansy, that all interested in the distribution of a novelty of this description should welcome it. The colour is indeed a rich and deep shade of blue, and, like other Pansies of this shade of colour, the hot and trying weather of July and early August caused them to be anything but pretty. Now, however, this variety is simply superb, and may be considered a magnificent addition to these plants if a position can be given to it where partial shade can be secured, more especially during the hottest part of the day. The flowers are rather large, circular, and deeply veined. This variety is also fragrant. Free habit of growth characterises this sort.—C. A. H.

**Symphyantra pendula.**—A good summer plant for the rock garden, too rarely seen in anything approaching good condition. It is a plant easy to accommodate in a light, warm soil, and the small fragments that one sees occasionally must not be taken as representative of this species, which will reach a diameter of 2 feet, or even 3 feet, when well grown. Thus seen, it is very attractive either as a front row border plant or on an easy slope in good soil in the rock garden. The large pendent blossoms are creamy white and nearly 3 inches long. A good plan is to raise a few seedlings and plant out at 6 inches apart, with the object of forming a goodly-sized patch. At Kew just now the plant is in fine form in the hardy plant department.—E. J.

**Sea Lavenders.**—So many persons now use the bloom of *Gypsophila paniculata* for vase decoration, and use it so commonly also, that already some occasional and yet pleasing substitute for it is asked for. Nothing I know of furnishes that substitute so pleasingly and abundantly as do the *Statice*s. When clumps of these hardy plants are established, and they do remarkably well on mounds or rockwork, they give great clusters of beautiful small bluish flowers in large racemes. Not only may these be used with exceeding grace with other flowers, for the bluish tints are almost neutral, but gathered now and stood in vases without water they keep bright for months, as *Everlasting Flowers* do. Everyone who wants such things should get plants of *incana*, *latifolia* and *Lemoniana*, for they are all good.—A. D.

**Spiræa Anthony Waterer.**—Those who have *Spiræa Bumaldi* should also secure plants of this rich, deep crimson-carmine flowered variety. It is well worth pointing out that where a few plants are grown, one or two pinched back in the summer induce later bloom, and that is valuable, especially where rich colour is desired in cut flowers. Small clusters of bloom cut well and are very effective. As these *Spiræa*s are shrubby and very hardy they are easily grown, as are any other deciduous shrubs, but they are naturally dwarf. They like a semi-peaty soil, that being indeed the natural character of the Knaphill soil where these shrubs thrive so well. A few plants put out thinly into a bed, various *Lilium*s being planted between, or clusters of *Hyacinthus candidus*, give very pleasing garden decoration with very little trouble.—A. D.

**Tufted Pansies.**—I have but just seen the large collection of these growing at Long Ditton, where during the season comparatively little rain has fallen. The plants were small ones put out in the spring, and the majority have now grown into masses. The following few I noted as remarkably effective, not only in colour, but having done wonderfully well, forming dense masses of leafage and bloom: *Nellie*, rayless, pure white; *Primrose Dame*, pale lemon; *Lord Elcho*, rich yellow; *Florizel*, bluish-lilac, a marvellous mass of a lovely hue; *William Haig*, colour of *Archie Grant*, but flowers of better form, a beautiful variety; *Blue Gown*, pale blue, and *True Blue*, a rich blue. All these seem to make first-rate masses and are singularly effective. It is only by seeing these plants thus grown that their

suitability for massing can be accurately determined.—A. D.

**Perennial Sunflowers.**—It is one of the misfortunes of these hardy plants that they increase too rapidly. If not kept in check they become a positive nuisance, apart from which they grow so tall and bloom so profusely that but a few plants in a garden seem unduly to dominate everything else, and yellow prevails everywhere. How much is this the case where largely grown it is easy to realise just now. It would be a good thing if all the tall, coarse, weedy growers were at once destroyed, and one-half the stock of all others also, as nothing tends so much to depopularise any family of plants as their too all pervadence. Perennial *Aster*s, with their generally blue tints and many so tall, are fast getting into the same category. Unfortunately these are things which diseases seldom trouble. They survive, not because the fittest, but because so robust, elbowing myriads of better things into obscurity.—A. D.

**Rudbeckia laciniata Golden Glow.**—Though this plant obtained the award of merit at a recent meeting of the Royal Horticultural Society, the flowers presented were scarcely as meritorious as one could wish either in colour or form; in both of these it seems inferior to the more freely cultivated *Sunflowers*. Whether the plant is as yet hardly established in gardens or not is not quite clear, though so far as English gardens in the south are concerned, the plant would appear the reverse of happy. Members of its genus are usually quick at establishing themselves in our gardens, and unless this one improves in the coming year we shall be inclined to regard it as an over-rated plant. Of a dozen or more blossoms in the Drill Hall recently only two were passably good, which, seeing these emanated from widely removed growers of hardy plants, does not speak much in its favour. We trust so distinct a variety will eventually prove a success.

**Cobæa scandens.**—A short time back an excellent photograph appeared in *THE GARDEN* showing a porch clothed with *Cobæa scandens*, and a note was appended thereto explaining how easily and quickly such clothing could be effected with this climber. I have been using it this year to cover some wires at the back of a cold house, and the growth made was so rapid that I was induced to take one or two measurements to verify the above statement. The seed, it may be noted, was sown singly early in February in small pots, the latter being plunged in a bed of leaves giving out a gentle warmth. The place being hardly ready when the young plants had filled the small pots with roots, a shift was given into 5-inch pots, and they were planted the first week in May. On August 2 the leading shoot of one of the plants had attained a length of 30 feet, and the superficial area covered by the same plant is 120 square feet. Naturally, a little trouble has been taken in the way of training and tying, but not very much, and I think the case affords an apt illustration of the ease and rapidity with which bare places can be clothed with this very quick-growing climber.—E. BURRELL.

**Hailstorm at Acton, Gunnersbury, and neighbourhood.**—On Wednesday last (August 25) about noon a terrific hailstorm burst over this immediate neighbourhood, accompanied with heavy peals of thunder and most vivid lightning. The damage done in Acton is most grievous to witness, more especially amongst the many market florists of the district. A hurried visit paid to Mr. Humby's nursery in the Mill Hill Road revealed such a destruction amongst growing plants still standing outside and in broken glass as could scarcely be credited were it not seen. A large number of *Chrysanthemum*s, which in the morning were the picture of health, were broken down, other things also suffering extensively. When seen six hours after the storm had burst, hailstones by the barrowload could be gathered up, many of these as measured then being fully an inch in diameter. In this district, too, there are many very pretty villa gardens which are com-

pletely denuded of their flowers and the foliage completely riddled. The foliage of the trees, also stripped off so as to cover the ground quite thickly, some trees being almost bare. Of nurseries besides that quoted have also suffered, notably Mr. Pike's, the *Carnation grower*. At Gunnersbury the damage is not nearly so apparent. I am glad to say; the hailstones here ranged to the size of nuts. Of these there was an enormous quantity. In all probability we shall see more signs of the injury to growing crops in a few days' time. The *Aucuba* shoots sent are from villa garden in Acton.—J. HUDSON.

**Seedling Verbenas.**—When but a few days since I was looking over the beds of seed-raised *Verbenas* in Messrs. Sutton and Sons' nursery, Reading, I could but remember the exceed trouble involved in the propagation of many *Verbenas* half a century since, when these plants constituted so important a factor in the sum of bedding arrangements of that date. What trouble was involved in procuring proper shoots, make cuttings, and even then how difficult to induce them to strike if wiry, and how ready they damped off if too young and sappy. Certainly it was wisest to keep stock plants in all the summer, and these, wintered in a cold house, provided mildew was kept at bay, would furnish very good cuttings to root in the spring in heat. Yet what a large amount of trouble was involved. Now things are, indeed, changed, by purchasing a packet of mixed seed, if a mixed bed of *Verbenas* be desired, or getting seed packets of distinct colours, if preferred, it is easy to obtain in that way beautiful varieties that long way exceed in quality and colouring the best named varieties of half a century since. There were blues in Messrs. Sutton's beds that almost vie with the hue of *Salvia patens*, rich were they, and as to blooming power were wonderful. So also the scarlets, so fine yet from seed so alike. Then there were whites, roses, maroons, and other colours, all charming as to indeed make one wish for a garden in which to grow from seed these lovely things. How one sees in such plants, in *Petunias*, *Lobelias*, *Phlox Drummondii*, *Stocks*, *Asters*, *Margolds*, and dozens of diverse things, a summer floral wealth, and all obtained by mere sowing of a few packets of seed.—A. D.

**The weather in West Herts.**—The weather of the past week has again been about seasonal in temperature. The days were cool for the time of year, while the nights, on the other hand, were mostly warm. The ground temperatures had fallen, but are still slightly above the average both at 2 feet and 1 foot deep. Rain fell on every day but one during the week, the total amounting to nearly 1½ inches. There occurred very heavy downpour shortly before 7 o'clock the morning of the 25th, when for ten minutes rain was falling at the mean rate of over an inch an hour. On each of the last five days some water has come through both the percolation gauges. Previous to this no water at all had come through either gauge for three weeks; no measurable quantity for nearly six weeks. The winds were, as a rule, rather high, the direct again being some point of the compass between south and west.—E. M., *Berkhamsted*.

#### BOOK RECEIVED.

"Report on the Phenological Observations 1896." By Edward Mawley, F.R.H.S.

**Rosa biflora officinalis.**—Will "C. L." say where this can be obtained?

**Names of fruit.**—W.—1, Yorkshire Green; 2, Roundway Magnum Bonum; 3, Cellini probably; 4, please send again; 5, Cox's Orange Pippin; 6, W. Calville.

**Names of plants.**—H. O. W.—*Virginian* *Phytolacca decandra*.—W. Harding.—*Brachyphyllum calycinum*.—C. Stewart.—1, *Pavia macrostachya*; 2, *Gleditschia triacanthos*; 3, *Viburnum Lantana*; 4, *Arbutus Menziesii*.

## FERNS.

### TODEAS AT FRENCHAY.

ARRANGED in a low lean-to house at Malmaison, Frenchay, near Bristol, is a capital collection of these charming Filmy Ferns. They were collected personally by Captain Belfield, the present owner, many years ago in New Zealand, and a healthier, more thriving lot of plants could be difficult to find. They are principally two species—*T. superba* and *T. pellucida*, the last-named lovely kind being represented by many immense specimens, one of which is over 7 feet across. The age of the plant is shown by the large root-stock, which on the large plant is several feet in circumference, and the leaves are beautifully fresh and green. The house is an annexe to a large temperate fernery, and is, of course, entered from here only; consequently drying wind never reaches it, while the aspect and the heavy shading used combine to keep up that cool, moist atmosphere in which all these Ferns thrive. A winding path runs the entire length of the house, and the large leaves of the *Todeas* look remarkably well in prominent positions upon the rockwork, with which the house is lined on each side. The plants are evidently in good hands, and what is even more important, in a house that suits them well. Mr. Rye says it is not unusual to enter to find the fronds covered with hoar-frost, but presumably, owing to the damp atmosphere and the fact of the surface of the fronds never being dry, no harm results.

**Davallia fijiensis.**—A nice specimen of this fern is very ornamental, and such an one I noted recently at Malmaison. The finely divided fronds grow about 18 inches high, and are broad and deeply arched, the hairy rhizomes having a very quaint appearance. *D. fijiensis* is not a difficult fern to cultivate, and is much more elegant than the common Hare's-foot (*D. canariensis*). Like all the *Davallias*, it dislikes a close or heavy root-pan, but delights in rambling about over rough masses of cork or charcoal. It is suitable for

hanging baskets or for suspending on large cork blocks, such as are often used for *Platycerium alcicorne*. If grown in pans these must be well drained, and the rhizomes planted in a compost consisting of rough lumps of peat and loam, with charcoal and small crocks liberally added. A moist atmosphere is congenial to its growth, the plants thriving well in a shady position in the stove.—R.

### SUBSTITUTES FOR WATERING IN DRY SEASONS.

THE best substitute for watering in a dry season is a deeper and better working of the land with more manure or compost. In a dry season artificials are of no use, simply because without moisture the plants cannot take them up. A plant with its root confined must of necessity suffer from drought if its wants are not supplied, but placed out in the open, and the ground well broken and exposed and, if possible, manured, the watering-pot, except in special cases, such as transplanting, or special crops such as Celery, which is to a certain extent a marsh plant, need not be so much used even in dry weather. Mulching is a substitute for watering and is only second in importance to the deepening of the root-runs. When mulching is mentioned it is commonly understood that a covering of manure is placed over the roots on the surface of the soil, but where manure or compost cannot be had, an inch or two of loose soil, though it does not afford the nutriment which manure gives, has pretty much the same effect in checking evaporation and keeping out the intense heat. A hard baked surface cracks, and the moisture issues out of the fissures in the shape of vapour, but a loose surface prevents cracking, and so the moisture remains in the land, and is added to by what is known as capillary attraction. And this explains how the crops on a freely stirred soil flourish whilst others on hard baked land fail. Then the loose friable surface being in an absorbent condition to a certain extent gains fertility from the at-

mosphere. During all the late drought where the hoe has been run through the surface often—and the oftener the better in reason—the plants have attained their full development without a drop of water. The sunshine is the most glorious gift the cultivator of the soil receives, and if it does harm it is because the matter is not properly grasped, and the right measures for its utilisation taken. E. H.

## CHRYSANTHEMUMS.

### EARLY-FLOWERING VARIETIES.

THE first to bloom is *M. G. Grunerwald*, the plants of which have been a mass of colour for some time in the open border. It is of a pink shade, but varies, some of the blooms fading to a bluish-white. This is very free flowering. *Mme. Marie Masse* has flowers of a better colour than *M. Grunerwald* and more bushy growth. I think it an excellent early kind. In whites there is little to choose between *Mme. Desgrange* and *Lady Fitzwygram*. Perhaps the latter is the purer white out of doors, but both of them require the shelter of glass to bring the colour out free from a yellow tinge. *Flora* is a very showy border sort. Its yellow blooms are bright, and the small flowers are borne in great freedom, so as to become a fine mass. *G. Wernig* is also a capital yellow. *M. Dupuis* is good in the bronze shade. Taking the habit of the plant, with its free-flowering qualities and its earliness, it is one of a very few really useful early kinds. Notwithstanding the large number of new varieties that have been brought into cultivation, the choice of sorts worth growing is extremely limited. *Sam Barlow*, a salmon-pink flower, is a useful kind. *Mlle. Eulalie Morel* is of a somewhat similar shade and very good, but it blooms rather late in September. A good early red is wanted. *Roi des Precocees*, the best, is a bit late; so, too, is *Harvest Home*. The last-named is rather a tall grower. Except *Flora*, the sorts named are Japanese Chrysanthemums. This variety is a pompon. Others with a wealth of small blossoms useful as border varieties are *Blushing Bride* and

Bronze Bride. These are very free: La Petite Marie, a dwarf-growing white; Little Bob, crimson-brown; Mignon, yellow; Piercy's Seedling, a capital bronze.

Ryecroft Glory is a valuable early variety, but seldom flowers outside before frost sets in. It is, however, first rate as a pot plant. The growth is naturally bushy, and quite massive specimens may be obtained in small pots. The flowers are rich deep yellow under glass. For the various purposes for which plants are used in decorations this *Chrysanthemum* should be grown in quantity. Emily Silsbury may be called a white companion to the above. The blooms are larger and more ragged. The habit is not so bushy, but it is equally free flowering. It is likely to become popular as an early kind for pot culture.

H. S.

#### RIPENED WOOD AND THE BUDS.

I HAVE had several opportunities lately of noting the difference between the flower-buds on soft growth and those on stems that are thoroughly ripened by exposure. From the latter the flower-buds seem to be thrown up, as it were, by the solid force behind them, right away from the foliage. The peduncles are stout and the buds clean, sure indications of gigantic blooms to follow. By the time these burst into colour this leaves immediately below them will be large, firm and leather-like in substance. The flower-buds at the points of sappy growth appear limp and unkindly. Many have a tendency to remain stationary, as if the vigour of the plant is wasted in leaves. The foliage in an opposite direction to that of well-ripened wood is smaller as the tips of the shoots are reached. Such growth will certainly not produce the desired solid well-formed bloom. Over-feeding in the early or growing stages of the plant's growth is a cause of this sappy wood; also being stood too closely together or otherwise coddled in a shady situation. Anyone is able to grow *Chrysanthemums* up to midsummer, but it is after that period the test of good culture comes in. I have seen an instance in which the variety *Mme. Carnot* has stems now 9 feet high. These plants have been fed with stimulating manures, as well as growing in rich soil, the whole summer, and although they are large, abundant, and of a fine healthy green, I shall be surprised if the blossoms are at all satisfactory. The stems carry the leaves too far apart, and the growth is much too soft to produce any other than flat ungainly flowers. If plants have been exposed to the full rays of the summer sun, firmly potted and not stimulated with manures, they respond in a remarkable manner to the showery weather which generally prevails in early September. It is then we may assist, by top-dressing and otherwise, the developing buds. A weekly dose of some approved fertiliser will work wonders by bringing the roots to the surface. But use these aids in weak rather than strong applications each time. Most that I have favoured, such as *Ichthemic* and *Thomson's*, may be sprinkled on the surface in the proportion of a tablespoonful to a 10-inch pot. The safer plan, however, is to mix an equal quantity of sifted earth and then put it on in the above quantity. Guano, soot, and sulphate of ammonia or nitrate of soda are best used in the liquid state, but the latter require very great care. I would not use them at greater strength than half an ounce to two gallons of water. They are quick in action and cause the buds to push up fast, and have also the virtue of adding brilliancy to colours in flowers.

**HOUSING THE PLANTS.**—The proper time to put *Chrysanthemum* plants under glass is when there is danger from frosts, or as soon as the flower-buds burst and the florets show colour. Subject to these conditions, they are best outside, because no indoor treatment we can give is so favourable to the swelling buds as are the natural dews. I have attempted to hasten the bud development by placing backward plants under glass, but believe that such treatment really retards them. The moment colour is seen in the blossoms there is no better means of preventing decay of the early florets than keeping them quite free from

moisture. It is well, therefore, to have a greenhouse ready to shelter these early blooms as they advance, but allow the bulk to remain out some time longer. The end of September is a good general time for housing *Chrysanthemums*, for rarely does frost occur before that date—at least, enough to do harm. Taking the plants under cover gives us an opportunity to thoroughly clean them. The pots may be washed and decayed leaves removed. Those that have a touch of mildew on the leaves may be dusted with sulphur. Oftentimes green-fly is lurking on the under sides of the foliage, to spread in great numbers when under glass. A dusting of tobacco powder will destroy this. Keep the greenhouse airy and cool as possible by throwing open every ventilator, and for a few days let the roots be on the dry side. This will get the plants accustomed to their new conditions.

H. S.

**Chrysanthemum Thistle.**—For those who need light elegant varieties of *Chrysanthemums* for cutting, Thistle is most useful. It certainly is not one of the most showy of its class, "small Japanese," but its extreme lightness in a great measure atones for this. Of a lemon shade, it makes a pretty vase arranged with a little greenery. I find, however, that to grow it well a lightish, open soil and extra well drained pots are necessary. Last year my plants were grown in such a medium and gave satisfaction, flowering well. This year a heavier loam was used, and although suiting the general run of varieties, Thistle does not seem at home in it, the foliage presenting a somewhat sickly appearance and growth being slow. Care will be used in watering to give them every chance of recovering, but I am not at all sanguine of that, and shall in future use a light soil.—C. C. H.

**Early Chrysanthemums in a vase.**—With the advent of September the early *Chrysanthemums* come into blossom space. The handsome flowers of the *Mme. C. Desgrange* type are, during this season, generally at their best, and these flowers, if cut with long stems, are invaluable for decoration where an arrangement of an artistic kind is wanted combined with blossoms showing the highest cultural skill. What is prettier and richer in appearance than a vase containing nine to twelve large flowers of the light yellow *Mrs. Burrell*, or the deeper shade of the same colour as seen in *G. Wernig* and *Mrs. Hawkins*? Let either of these sorts be arranged by itself, and the rich green foliage of the plant is all that is needed for the embellishment of the vase. Those desiring still further enrichment, and a more striking finish, may obtain it by using a few fronds of the feathery *Asparagus plumosus*, these to overhang the side of the vase. The chaste white flowers of *Mme. C. Desgrange* answer the same purpose and make a magnificent decoration for the drawing-room or hall. A few sprigs of *Prunus Pissardi* or any purple-coloured foliage make a pretty contrast and a welcome change. In this case, too, *Asparagus* foliage may be used, but only those of the lightest shade of green. The one essential in these simple arrangements is never to crowd the flowers together. A really handsome vase may be arranged with just a few flowers, each blossom standing out quite distinct from its neighbour, so that all its good points may be seen. A batch of plants should always be grown for this purpose.—D. B. C.

**Azalea indica.**—Formerly there were few gardeners who did not stand their *Azaleas* out of doors in autumn with a view to securing a thorough maturity of the new wood, and doubtless the idea was a correct one, though in more places than not now-a-days one sees the plants left in the greenhouse all the year round. Of course by non-removal much labour is saved, and the fine display of bloom to be seen in the large nursery houses each spring is ample proof that the open-air treatment may be dispensed with, providing abundance of air is given night and day. Feed-

ing *Azaleas* would years ago have been looked upon with suspicion, but many now make a rule feed either with very weak farmyard liquid, or sprinkling some approved fertiliser on the surface of the pot and watering it home, and a marked difference is soon perceptible both in the vigour and colour of the new growth as compared with plants that have no stimulants given them.—J.

## PUBLIC GARDENS.

### ROSES IN PUBLIC PARKS.

I AM aware it requires a certain amount of courage to advocate the more extensive employment of *Roses* for decorating the public parks of our large cities, but I think the time has arrived when something should be done towards removing the reproaches often heard at the apparent neglect of our national flower in these places; and when we consider the immense popularity which the *Rose* has attained in our country, it is surprising that no attempt is made to use it more extensively. I daresay the vitiated air will be one excuse for this neglect, but I am firmly convinced that *Roses* could be grown in the parks from June to September without fear of permanent injury to the plants. It is a well known fact that shrubs having shiny foliage resist to a great extent the impurities floating in the air, and in the China, Tea-scented, and Hybrid Tea-scented *Roses* this style of foliage is very common. Although *Finsbury Park* is situated amid healthier surroundings than many of its rivals, it has, nevertheless, to contend with many disadvantages compared to country gardens, yet Mr. Melville has successfully employed the *China Roses* as bedding plants, and in beautiful they appear when massed in this way. If, therefore, the *Chinas* can be so used, why not the more refined *Teas* and *Hybrid Teas*? As the season is fast approaching when the matter should be taken in hand, perhaps a few ideas on this subject will be admissible.

In the first place, I would suggest that the plants to be used should be grown in pots somewhat expensive method, but I think the extra expense will be more than saved in the end, as I am persuaded that plants so grown for part of the year in a purer air would well repay any extra trouble taken to produce them. Old year-old plants from the open ground should be procured, of the freest-flowering and sturdiest of the *Tea*, *Hybrid Tea*, *China*, *Hybrid Perpetua*, *Polyantha*, *Bourbon*, and *Rugosa* classes. In potting of these should be commenced early in October. As it would be absolutely essential that these plants to be grown in a pure air, my suggestion is that the park authorities should rent or buy a plot of land right away in the country where land is cheap and the air pure. Eight-inch pots would be the best size in which to put the plants the first year, and the compost should consist of good unsifted fibrous loam, with some artificial manure of a lasting nature, and little charcoal dust added. After potting, stand the plants in the open upon a bed of ash until about November. They should then be plunged over their rims in coal ashes in a cold frame, taking care to keep lights night and day until the sharp frosts come. About the commencement of March the plants should be sparingly pruned, still keeping them in the pits and preventing injury from severe frosts. *Roses* in this dormant state will stand few degrees of frost. Keep the plants dry after pruning, and when young growths are about 2 inches long give a good soaking. We come now to a very critical time with them. In the forward state a few degrees of frost will cripple the first blossoms; therefore put on the lights every night. If the plants are injured to the hardy treatment they should be good, sound healthy plants by the end of May, with a quantity of flower-buds showing. These plants can then be taken from their country home, and

edded out in prominent and sunny positions in the parks. If these beds were previously well drained and filled with good fibrous loam, with some well-decayed cow manure added, the plants would quickly lay hold of this, and the result would be some splendid sucker-like growths owned with grand trusses of flowers.

As to the style of plant to employ, little need be said. To the clever superintendents, styles and methods will speedily present themselves, and if the dwarf or bush form, or the pyramidal pillar form be employed, they may be made very attractive. We are far behind our Continental and American friends in this matter. Certainly our climate is better than ours in many respects, but I should imagine that all large cities have the usual amount of injurious air to contend with, and it is no uncommon circumstance to meet with plantations of Roses in the parks and gardens of continental cities and those of the States. I am not aware that they remove their plants in the autumn, but, in my opinion, for London and cities of lesser magnitude, the practice would be decidedly beneficial, if more costly. The advantages would predominate, for the beds filled with the Roses in summer could be rendered interesting in winter and spring by bedding out small cineraria and bulbs. Roses grown in the manner suggested would be available for this treatment for several years, and a larger pot for them, as they required it, would be an item of small consideration in such establishments. Just imagine what a bed would be like containing, say, 50 to 100 plants each of such lovely Roses as La Francee, Augustine Guinoisseau, Camoens, Marie Vanhoutte, Caroline Testout, Captain Christy, Mrs. J. J. Grant, Viscountess Folkestone, Gloire des Olyanthis, Mme. Laurette Messimy, Souvenir de la Malmaison, Marquise de Salisbury, Mme. Ernest-Ducher, Anna Ollivier, Mme. Hoste, Souvenir du President Carnot, Grand Due de Luxembourg, Enchantress, Mme. Abel Chatenay, Mme. Bruant and such-like kinds. They combine usefulness of habit, fragrance, and, indeed, all the qualities that one looks for in a decorative ant. I gladly broach this subject for the consideration of responsible authorities, and trust they will give the matter the attention it deserves. I feel sure that it only requires a careful consideration of the advantages to be derived by the more intensive use of these lovely Roses to ensure complete success.

PHILOMEL.

## KITCHEN GARDEN.

### NOTES ON VEGETABLES.

ALTHOUGH far from being the most attractive element in gardening, there is no part of it that of greater importance than is vegetable culture. We have learned to more fully estimate their value as healthful food, and in the doing have also in a remarkable degree improved them as both food and garden products. Good gardeners have now learned also to find in vegetable culture much that is at once very interesting and pleasurable. This gratification is largely been induced by the beauty as well as high quality found in vegetables to-day, and they compare surprisingly to their advantage with the vegetables of but 30 to 40 years ago. Apart from their domestic value as food, vegetables have become most important market subjects also, and myriads of persons find in their growth means to a prosperous livelihood. The range of vegetables, too, is exceedingly wide. Literally they serve to satisfy all tastes, and those whose pleasure is found in profitable gardening, whether for a livelihood or for recreation, derive from their products pleasure from which the ordinary consumer of market vegetables is debarred, seeing that the former is always command greater variety, the best kinds, exceeding freshness, and the satisfaction of consuming one's own products, which,

too, is of great value, as well as adding much to the pleasure incidental to their consumption. The amateur's chief trouble, perhaps, in seeking to make from seedmen's lists suitable selections is found in the multiplicity of varieties which in these lists abound, varieties that are added to each year. On the other hand, the gardener finds very much of interest, amounting almost to excitement, each year if he obtains but a few diverse sorts, and by growing a variety of each kind of vegetable each year eventually succeeds in securing the very best to suit his requirements. Whilst main crops should always be of well-established varieties, trial rows of newer ones prove to be useful and instructive. Everyone who gardens, no matter whether amateur or professional, has to learn at the outset certain fundamental principles of culture. Soil must not be shallow, but deeply worked, and this is done by trenching. In that way roots run deep, and find moisture from which in shallow-worked soil they are excluded. Then the soil, which is, after all, but a store or larder, must be amply furnished with plant food in the form of various manures, and although repletion is as wasteful to plants as to animals, yet plants know better than animals do what is good for them, and take up only what they need. Still, this may be done too grossly, and therefore the best average results come from deep trenching, allied to moderate manuring, yearly performed. But manures vary very much, as these are useful in proportion as they contain phosphate, potash, and nitrogen, the primary constituents of plant life. Any manure, so-called, in which these elements are absent is practically worthless. This fact shows that soil may be amply manured in a way, yet be half starved. Fairly fresh animal manures, non-fermented, and artificial manures of guaranteed quality are best for all purposes. When seasons are dry, however, these manures applied in liquid form are the most acceptable to plants, as all roots absorb food only through minute root hairs, and these can absorb only in liquid form. Hence, again, the importance of watering crops freely in dry weather, for when the soil is very dry, even if there be ample manure in the soil, if water be not present to divert the mineral elements, plants cannot utilise them. Plants of nearly all descriptions, but vegetables especially, being quick growers, need ample water as well as plant food. These facts serve to show that the primary needs of vegetable culture are deeply worked soil, ample plant food, and abundant moisture to enable plants to utilise that food. The primary vegetables grown in gardens are, of roots, Carrots, Beet, and Parsnips, all tapering ones and long keeping, and round or bulbous roots, such as Turnip-rooted Beet, Turnips, and Onions, and of tuberous roots, Potatoes, Jerusalem and Chinese Artichokes. Of fruit-bearing ones we have Peas, dwarf and runner Beans, and Broad Beans, Tomatoes, Cucumbers, and Vegetable Marrows. Of stem plants, usually blanched to render them tender and edible, Leeks, Celery, Asparagus, Seakale, and even Mushrooms, whilst of leaf or heart plants we have Cabbages, Kales, Savoys, Brussels Sprouts, Broccoli, Cauliflowers, Spinach, &c., and Lettuce and Endive of salads. Beyond these there are numerous lesser ones in great variety, so that even of kinds, apart from varieties of each, the range or selection is great. Herbs, too, are useful products not to be overlooked. In the good culture of all these things there is found an enjoyment and satisfaction no other form of recreation furnishes.

D.

**Peas and green fly.**—I can confirm the statement made by your correspondent as to tall Peas

escaping the green fly this season. I have grown this year for the first time Chelsonian. It is a Pea advertised to grow 6 feet or 7 feet high, and I have no doubt that in an ordinary season it would even exceed that height. Other well-known dwaffer varieties, such as Satisfaction, Rentpayer, and Maincrop, were badly infested with fly, but Chelsonian entirely escaped it. It has a stout haulm, vigorous growth, plenty of pods, and is first-rate for table. The pods are square at end, thin in substance and packed with Peas. Anyone anxious to try the newly-introduced varieties should include in their selection Chelsonian.—S. F.

**Winter Cabbages.**—The value of these cannot be too highly estimated. Those who can now have nice strong plants of Ellam's Early, Flower of Spring, or any other small precocious variety, and will put them out 15 inches apart on some good ground, giving the plants a good watering to start them, may find as reward at Christmas and in January, if the winter be fairly open, that they have plenty of nice little heads to eat. A sowing of seed of Ellam's Early and l'Etampes, the finest of second early Cabbages, made at once will give plants to go out about the middle of October, soon enough to furnish nice hearts in March, April, and May if all go well with them. Small plantings and often should be the maxim of Cabbage growers.—A. D.

**Potato Early Regent.**—It unfortunately happens that so many persons regard Potatoes more for their size, and the way they fill the bushel, than for their general excellence and suitability for table use. I have just been lifting amongst others Early Puritan, White Beauty of Hebron, Supreme, and other early varieties, and the one named above, Early Regent, gave me a better crop of tubers, of more even and useful table size. None give better quality. In relation to Potatoes generally there is no feature more needed than greater evenness of shape and medium size with plenty of tubers. The big-tubered varieties are of little service to anyone, as no one cares for large ones, and they command but a poor price in the market. On the other hand, a good crop of fine, medium-sized tubers is not only the most economical, but sells best also.—A. D.

**Tomatoes and the disease.**—I recently inspected a large span-roofed house in a private garden in which Tomatoes were grown. Formerly the gardener used to plant each border with plants in an upright position, training them to stakes, but has now abandoned that system, preferring to plant close to the front light, and train them up a wire trellis, similar to Vines, his reason for changing being that when grown thickly together in an upright position it was difficult to check growth, and disease was much more rampant. Grown in a slanting position under the roof glass, each plant received a full amount of sunshine and fresh air, growth was firmer and disease not half so troublesome, and even if it did appear, it was much more easily dealt with. At the place under notice Challenger was found to be much more addicted to disease than some others, and for that reason would not be so much grown in future. The house was built over the ordinary garden soil, which, with the addition of a little bone-meal, suited the Tomatoes well.—J. C.

**French Bean Canadian Glory.**—This is a distinct type of dwarf Bean, and may be classed as of special value in dry seasons, as the pods are produced in great quantity, and when cooked are of excellent quality; indeed, I find the flavour superior to some of the older kinds. It may be asked, do we require so many distinct kinds of Beans, either runners or dwarfs? and I reply, yes, especially if the new ones are good and prolong the season. The value of Canadian Glory is that it is a fleshy pod, compact and stringless—that is, devoid of stringy material, which makes it more suitable, as it is so soon prepared in the kitchen; indeed, if cooked in a young state it may be cooked whole, and is sure to become a favourite

in large establishments. In addition to the last-noted quality, it is a very precocious variety, being one of the earliest Beans I have grown, and, unlike many others, does not become tough in dry weather. Of course, it is well to gather the pods regularly, as if allowed to run to seed the plants lose strength, and if this is done the plants bear an enormous crop of Beans, and will provide dishes for a long season. The Beans when cooked are much liked for their good colour in addition to their quality.—G. WYTHES.

**Watering Asparagus.**—Asparagus, in common with other good vegetables which depend upon this season's growth for next year's supplies, may with advantage get assistance at this season, as heat and drought have affected the growth of the plants. Those who can give moisture freely, or irrigate, are in a good position to build up a strong crown for the next season. Drought in the case of Asparagus is fatal to the good growth of the plant, as unless a robust top-growth is made, there will be weak crowns and small grass next season. Food given now must be given freely, as the season of growth will soon be past, but no one need fear feeding a little later than usual, as, the soil being warm, with a liberal supply of moisture, growth will be later than usual, and in light soils food and moisture may be given liberally till the end of September. Newly-planted beds have suffered from drought, but these, given food now, will be benefited, and beds, if at all old, and which may be forced early, will make larger crowns if given liquid manure freely. We flood our beds if the liquid can be spared; failing this, a dressing of nitrate of soda, fish manure, or even guano well watered in will be efficacious.—G. W.

**Carrot Summer Favourite.**—I had this superb variety on trial this season, and am very pleased with the quality and the way this root matures, as it is superior to the Short Horn, to which type it belongs, but is of a thicker build, without much top, and is a splendid summer variety in gardens where quality and quantity are needed. The colour of Summer Favourite is distinct from most others—bright cochineal-scarlet—with a very small core for the size of root, and few Carrots are more shapely. For exhibition purposes it will take a leading position on account of its size, shape and colour. I am not a lover of the long Altringham type of Carrot, and prefer those of the Intermediate type; in fact, I fail to see the utility of large gross roots for home use, and the size of the one noted is what I admire, while for early spring sowing it is very good, as it soon comes to maturity. I notice any Carrot with a small core or centre is earlier than those which have a large core, and with early Carrots time saved is important. Of course, the same reasons which make it a valuable early variety stand good for autumn supplies, as when sown for late use the roots are sweeter than those sown in early spring.—G. WYTHES.

**Cucumbers, &c.**—Without doubt, the very best results in the matter of good fruit crops from these plants, as also from Melons and Tomatoes, all three having now in low span or lean-to houses very similar treatment, are obtained when the soil is placed in shallow troughs or boxes, as it is now so well understood that restriction of root area into good, sweet turfy loam is far more conducive to fruit production than is the furnishing of too much soil area. In addition to this, the roots, being near and under control, are easily fed from the surface, and in that respect all the needs of the plants are easily supplied. One of our most successful Cucumber and Melon growers, who plants usually two crops yearly in the same houses, and who also has grand crops of Tomatoes, uses shallow, movable troughs. These consist of broad open trellises about 16 inches wide, to the sides of which are fastened stout, clean boards 7 inches deep. Thus a trough 6 inches by 16 inches is furnished. The troughs are laid along over the bottom pipes on cross-bars, and the open trellis is first covered with pieces of rough turf, the compost following, and is slightly heaped in the

centre. Plants are put out in single rows about 15 inches apart; they soon grow fruit, and having carried a good crop are removed, the soil is taken out, the troughs cleaned and whitened with lime, then refilled with soil and plants, and a second crop is taken. That treatment of course applies to Cucumbers and Melons only; the grower in this way never suffers from eelworm. I have in several places this season seen remarkable crops of Tomatoes grown in shallow boxes, feeding with artificial and liquid manure, and keeping the plants heavily cropped over a long season.—A. D.

**Onion Silver Ball.**—Of late years considerable additions have been made to the varieties of Onions; indeed, few vegetables show greater improvement both in variety and culture, such sorts as Record and Ailsa Craig being now grown for their size, and they have their uses, for when cooked as a vegetable they are superior to the imported bulbs. I have seen huge Onions objected to, and I do not advise their growth, but a few special bulbs for the purposes of exhibition are valuable, as the varieties mentioned are noted for their mild flavour. Silver Ball is not a large grower, but is specially suitable for early use. It is a pretty bulb, of medium size, pure white, and of very mild flavour. It is not recommended for keeping, but for supplies during the summer. In shape it is a perfect ball, not a flattened root, and its bright silvery colour makes it a nice contrast to the other varieties. I have found it to be a remarkably quick grower, and seeds sown in the autumn at this date give very early supplies the following summer. It is much liked for cooking on account of its size, fine texture, and mild flavour, and for the purpose named its maturing so quickly makes it valuable.—G. WYTHES.

**Climbing French Beans.**—Whatever faults may have been found with this type of Bean when first introduced, it has fully justified its advent, and I am prepared to place them in the front rank for quantity, quality, and earliness, three cardinal points of great importance to those who need early vegetables of the best quality. During the prolonged heat and drought of July, and early in August, the Climbing French Bean has given us a splendid lot of pods, young, of good shape, and just the kind desired in the kitchen. They are less stringy than the dwarf Bean, and, what is so important to those who need quantities, they are more lasting, they produce freely, and are less influenced by heat and drought, while the quantity which can be gathered from the plant is wonderful, as they give supplies when the dwarf kinds fail. I am induced to class these as superior to the runner Bean, for they are much earlier, require less space, and are, in my opinion, more productive. For gardens of limited size they are invaluable, as where the dwarf varieties cannot be sown often, a row or two of the new climbing type will furnish a liberal supply till cut down by frost.—G. W.

**Pea Michaelmas.**—This is one of the newer introductions, and one worth a special note for its crop, lateness, and good qualities. Like all the best autumn Peas, it is of a deep green, and, unlike some very early ones, it remains good a long time, and is noted for its splendid flavour. If I can compare it, I should describe it as a dwarf Ne Plus Ultra. It has the good qualities of the old favourite, at the same time is dwarfer and quite as prolific as that variety. Though only 2 feet to 3 feet high, it bears profusely to the bottom of the haulm. The habit and strength of haulm denote its good qualities, and last year when on trial in our light soil it exceeded our expectations, as it cropped for so long a season and gave Peas of splendid quality. It is not a very large pod, but may be termed above medium size, and is filled with large Peas of a deep green colour, remarkable for their sweet flavour. It is free from mildew and has no disease of any kind, this freedom from mildew being a strong point in its favour, as so many late-growing Peas mildew badly. This year this variety has stood the heat and drought well. It is very vigorous,

extremes of weather affecting it little, and, being what may be termed a continuous cropper, it bears a long time.—G. W.

**Pea Maincrop.**—Defects in the Pea crop have been found out this year, and any new variety which held its own may be grown in future with confidence. Requiring a good number of Peas during June and July, I am always on the alert to find the best for our light gravelly soil, and last year I was so pleased with the cropping qualities of Maincrop that I grew it more largely this year, and it was specially good, standing heat and drought and podding grandly, without getting yellow, tough, and flavourless, as some of the midseason varieties quickly do in dry year. Maincrop gave us nice green pods to the last; the haulm continued green and was not infested with mildew, showing it to be an acquisition as dry-weather Pea. In colour it much resembles Ne Plus Ultra, but the haulm is more robust branching, and the pods larger, thicker, and longer; but let me advise intending cultivator not to sow too early. It does not like too much cold or wet in its infancy, as the variety appeals to me to be more of a late kind than a midseason, but sown from April to June it is a grand Pea and of superior table quality. I am a great lover of this class of Pea with a dwarf growing Maincrop being 3 feet in height. These dwarf kinds are readily cultivated, needing less support and space.—G. W.

**Record Onion.**—When I grew this variety both from glass-raised plants, dibbled out, and from an ordinary spring sowing, I found it to be late in ripening that practically it did not ripen at all. That was on light ground at Richmond last year. Differing in this respect from several other varieties, I could not yet classify it at all. Judging by the reference recently made to fine sample bulbs shown under the name of Record at the Westminster Aquarium last November, I am very much puzzled to determine whether the splendid bulbs in question were the true Record or had been grown by mistake under that name, as these bulbs were unquestionably Ailsa Craig. And I was even then, when seeing them, all more puzzled because what I have previously shown as Record was of a flattish nature. What is the parentage of Record? Has it any of Tripoli blood in it? Onion varieties come so fast, or, perhaps, to put it more correctly, our nomenclature grows so rapidly, that it is hard to keep pace with it. I could but have my sympathy with a seedsman who the other day showed me his bulb stock of a dozen assorted diverse ones, when he said, "We want for customers just about three or four types, one round and flat, white, and a good crimson, one that satisfies all requirements. As to so many becoming a nuisance."—D.

**Physalis Franchetti.**—Having been one of the first to recommend this great Bladder Cheese from Japan in THE GARDEN, and having been the cause of many disappointments from those who have far failed to grow and fruit it freely, I should like to say that I recently saw it luxuriant and fertile in a rock bed at Carton, Maynooth, co. Kildare. It there forms a fresh green, spreading mass of stems, the tallest of which are about 3 feet high, and bearing fruits and flowers freely all the upper leaf axils. Some of the swollen calyces, though not as yet coloured, are larger than any figure of this plant that I have seen, and much larger than any ripe specimens I have had under my notice. Not only is the plant much taller and more robust than P. Alkekken but its leaves are of a much lighter and brighter tone of green, giving to the plant quite a fresh and distinct appearance. A deep, rich soil and stones seems to suit this fine new introduction admirably at Carton, so those who have hitherto failed, myself included, may ultimately succeed. The plant grows so easily and rapidly from seed that a good strong stock may soon be obtained.—F. W. B.

TREES AND SHRUBS.

THE AMERICAN DOGWOOD.

(CORNUS FLORIDA.)

THIS is one of the most beautiful of our spring-blooming trees. We American readers of your noble journal have often wondered to see so little mention made of this lovely tree, and to see it does not flourish with you as in the United States, for so fine a plant cannot be unknown to English gardeners. This specimen was planted some twenty-five years ago in a best stone clay soil, and is now some 14 feet

The fruit, in bunches of brilliant red drupes, is almost as showy as the blossom, so that this hardy small tree should be planted for its autumn effect almost as much as for its vernal glory.—MARY L. S. PERKINS, *Oatfield, East Walnut Hills, Cincinnati, Ohio.*

\* \* \* It has often been planted, but we never saw it flower. Do any of our readers find it flowers well, and where? The illustration shows a very handsome tree and strange to English eyes.—Ed.

**Ampelopsis and Ivies.**—A very showy wall may be had by planting alternately Ampelopsis Veitchi and Golden Ivies. During the season of

tenaciously to the brickwork that snow and wind have no power over them.—C. C. H.

STOVE AND GREENHOUSE.

TUBEROUS-ROOTED BEGONIAS AT LEWISHAM.

THE increasing popularity of the tuberous-rooted Begonia both for the flower garden and the conservatory is due to a very large extent to the energy of the leading specialists, who, during recent years, have given us many fine kinds. Notably among these is the display made by Mr. Jones at the Rycroft Nursery, Lewisham, where

*The American Dogwood (Cornus florida). From a photograph sent by Mr. J. L. Stettinius, Oatfield, East Walnut Hills, Cincinnati, Ohio.*

high by 17 feet across, well branched to the ground. The flower buds, which are formed the previous season in clusters at the tips of the twigs above the tree, begin to open about the 1st of May in the latitude of Cincinnati. The first leaves of the involucre grow very rapidly and turn white (there is also a pink form) as they develop in size, until the whole plant is a mass of snowy beauty, before the true leaves are grown to full size, and one can easily fancy the tree covered with great white butterflies when open wings 3 inches to 5 inches across. Its grace and beauty cannot be well described, but must be seen.

growth the brilliant golden shade of the Ivies and rich green of the Ampelopsis form a pleasing contrast, while later in the autumn the beauty is enhanced by the rich crimson shade of the latter. The one drawback of such an arrangement is that the Ampelopsis lose their leaves during winter, causing the wall to have a somewhat patchy appearance. The small-leaved Golden and Silver Ivies, besides being very attractive, give far less trouble than the large-leaved, coarser sorts, which require frequent clipping in to induce a neat, close growth, and they can now be purchased at such a reasonable price that a long reach of wall may be quickly covered at a little cost. A few tacks given to the plants when first planted is all that is necessary, as they cling so

special pains have been taken to keep the stock up to a high standard of excellence. Special attention has been given to raising those kinds which have stout erect footstalks, thus dispensing with the aid of stakes for displaying the individual blooms. Of course there were sorts to be seen where the drooping form of growth was specially recognised, but in these instances they were perpetuated for the special purpose of using them for baskets, or any form of planting where the drooping character of the growth would be valuable. The double flowers were of a high order of merit, an immense number of seedlings possessing flowers of exceptional size and beauty, and promising to supersede others now thought highly of. The Camellia form of double flower

certainly appears to be the more desirable one to perpetuate, and of these there was an excellent assortment. The heavy double flower does not compare favourably with the neater blossoms of Camellia shape and a single eye. Some of the colours too were quite novel, and cannot fail to create a greater interest in the flower. The variations in the different self colours appeal to almost every taste, orange, buff, salmon, rose, red, scarlet, vermilion, yellow, white, and intermediate shades of colour being represented in the many beautiful things seen. The fancy or margined flowers have also made a marked advance, the colouring of the margins in several instances being almost unique. A real gem has been raised this season, the ground colour being a pretty shade of yellow with a striking margin of reddish-crimson. This seems likely to be the forerunner of a new race, and will be welcomed as a contrast to those fancy flowers with a white ground. The best display is made in a large house 103 feet by 25 feet, a grand mass of double varieties being arranged on the centre staging, while the staging all round the sides is filled with smaller plants of the doubles and singles too. Other houses are devoted to the raising of stock, and a large structure is set aside for the purpose of seed saving, and where many interesting experiments and crosses are each year carried out. Over 100,000 seedlings are planted out and potted up this season.

#### DOUBLE FLOWERS.

Conspicuous among the double flowers was a variety named H. J. Jones. This is an immense vermilion-scarlet of Camellia form. Another flower of similar form was Beauty of Belgrove, colour somewhat resembling La France Rose. Mrs. Walter Finch, a bright crimson of exquisite form, was also much admired. Viscountess Cranbrook is an unusually good sort, rosy pink flower with large white centre. Miss Clara Walker calls for special comment; this is a double blush-pink shaded salmon with cream centre. Princess of Wales is a new flower of large size, colour, blush-pink, fine erect footstalks. Jubilee White is a very neat flower with erect stems, Camellia form and free flowering. A very pleasing bright pink is Mme. Garde, the flower is prettily crimped at the edges and is also large. Another Camellia-shaped flower is Triumph, colour bright crimson, nice habit. A grand yellow of good form is Yellow Queen. This variety is free flowering, and is considered to be the finest yellow Camellia-shaped flower in cultivation. A flower of a lovely flesh colour is Olive Smith. Rycroft Favourite is a variety of a pleasing shade of bright pink beautifully fringed large full flower on erect stems. An effective flower is Marginata, having salmon-blush flowers, neatly-edged light pink. One of the best white Camellia-shaped flowers is White Queen. A flower of exquisite shape is Miss Dolly Fell, pure white, with crimped edges and erect stems. Rycroft Salmon should prove a fine exhibition plant, with large salmon-rose flowers standing out well above the foliage, and with a nice branching habit. A light primrose flower of a drooping form of growth is Mrs. Stottart, and this should make a good plant for baskets, &c. Lady Guest is a bronze-yellow, with salmon-pink margin, nice dwarf habit. A good bright crimson is B. R. Davis, a very effective flower. Mottled Beauty is a slightly mottled flower, colour bright pink, mottled white, quite distinct. A plant with good branching form of growth and invaluable to the exhibitor is Victory; this is a salmon-scarlet. The foregoing are a few of an immense number of high-class flowers seen here.

#### SINGLES.

The singles are very fine indeed, several of the best being named. Those deserving special notice are Mrs. G. P. Linford, pink, white centre; Maud Surman, pure salmon; Echo, apricot; Rycroft, apricot; Novelty, margined, bright red on a white ground; Beauty, magenta-pink, light centre; and Mars, deep vermilion. C. A. H.

*Encephalartos villosus*.—I have had a plant of *E. villosus* for twenty-six years. The fronds

are 6 feet long, though the root has not developed much, which I attribute to the gardener cutting off the fronds when they change colour. It is now in flower. The flower is 18 inches high, with a series of scales like a Pine-apple. Is this rare? Is there any particular treatment? Is the plant likely to die? Is it worth while to photograph it?—J. W. B.

\* \* \* The stem of the *Encephalartos* in question increases very slowly, and the fact of the fronds being cut off when they change colour would have no effect on the growth of the stem, as presumably it is only the very old fronds that are treated in this way, and they have lost nearly the whole of their vitality. In the case of an established specimen it occasionally flowers, but plants of this class are now so little grown that its flowering, though not exactly rare, is decidedly uncommon. No particular treatment is needed during the flowering period. It is not at all likely to die, as the crown of young leaves will push the cone on one side and develop without any check. As it is not often seen in bloom, a photograph of it would be interesting.

#### GREENHOUSE AZALEAS.

THE note on greenhouse Azaleas (p. 137) is very opportune, for there are at least two items connected with these Azaleas to which special attention needs to be now directed. One of these is that where Azaleas of this class are kept out of doors particular care must be paid to the watering, as towards the end of the summer, with occasional showers and frequently heavy night dews, both of which tend to make the surface of the soil moist, there is far more danger of the plants suffering from drought than during the height of the summer, when one is not so likely to be deceived as to the state of moisture around the roots. The second item to which attention may be directed is that very soon the importations of these Azaleas from Belgium will reach this country, and an opportunity is then given of increasing one's stock if required. As a rule the earlier importations reach here about the latter half of September, and it will be found advantageous to obtain them as soon as possible afterwards, as the plants can then be treated according to one's requirements; whereas, if kept in stock by dealers anxious to sell them, and the plants are obtained late in the season, one does not know the treatment to which they have been subjected during the interval between their arrival in this country and the time they were sold. They are frequently sold in quantity at the various auction rooms, but obtaining them in this way is a somewhat risky matter, for though the plant is likely to die if the roots are once allowed to get thoroughly parched, yet the injury may not be seen for a few days, particularly if the soil has been moistened meanwhile. Of course, plants that have stood about in sale rooms and such places, often in draughty passages, are far more liable to suffer in this way than those which have been sent direct to a nurseryman and properly attended to on their arrival without delay. The Azaleas sent from abroad are lifted from the beds in which they have grown and packed together as closely as possible in order to economise the expense of carriage. Then directly on receipt I prefer to unpack them and soak any that are at all dry in a tub of water, so that the ball of earth is moistened completely through, then they are stood on the floor of the potting shed and sprinkled overhead. The following day they will be in good condition for potting, using for the purpose good sandy peat. Care must be taken to work the soil thoroughly around the roots, but it need not be rammed down to the extent that some think necessary for the cultivation of Azaleas. An examination of the imported plants with their luxuriant growth will show that Azaleas will both grow and flower well even when the soil is of a far more open and loose nature than most imagine. As the Azaleas are planted out in Belgium, the balls of earth are frequently very irregular in shape, and unless they are some-

what reduced, pots out of all proportion to plants will in some cases be required. When happens one need not be afraid of reducing roots to reasonable proportions, as no injury thereby caused, provided the plants receive reasonable attention afterwards. When potted I prefer to keep the plants in a frame the lights of which are kept rather close for a time, and shaded during bright sunshine. An occasional syring overhead will tend greatly towards keeping foliage fresh until the roots recover their normal activity. In about a fortnight they will become to a certain extent established, when more may by degrees be given and the shade lessened till they can do without it altogether. After this they will require the same treatment as established plants. In alluding to the fact that Azaleas do not require such very hard potting I of course refer to the freshly imported plants that have been lifted from the ground, as in the case of old-established plants the ball of earth gradually gets exceedingly hard; so if they are shifted and the new soil is not made correspondingly firm, the plant would be simply starved to death, as all the water would percolate through the new soil, leaving the ball of earth quite dry. In old plants, however, potting is very seldom needed. H. J.

#### BORONIA SERRULATA.

It is not often that one sees a good specimen of this *Boronia*, and it must be admitted that greenhouse plants require so much skill and patience to bring to specimen size. Even in the days when this class of plant was in high favour, and when huge plants were shown in splendid condition at the London exhibitions, a really first-class specimen in perfect health was rare. My leading growers were apparently unable to induce perennial vigour in this *Boronia*, and gave up the culture for that of other things more reliable. My plants are so telling in a collection of stove and greenhouse plants, and for this reason the exhibitors of them have been anxious to secure a good specimen of the *Boronia serrulata*. There is but little difficulty in cultivating this species up to a certain age. With a little more care it is necessary for Cape Heaths one may count on reasonable certainty on inducing a free, heavy growth. The cultivator's real trouble begins with what is called the three-quarter specimen. What it really is that without apparent effort carries off this *Boronia* at a certain age has not been quite satisfactorily determined. The attack is so sudden and at times so violent that in less than a week a plant that from its infancy has been a picture of healthy vigour is completely ruined. More frequently the attack is only partial, a branch or two giving out and the remainder of the plant remaining quite healthy. It rarely happens, however, that a plant is of much use after it has once been attacked in this way. The partial defoliation deprives it of its value for exhibition purposes, and sooner or later it collapses entirely. The seat of disease is apparently near the soil, thus intercepting the flow of sap, and causing perfectly healthy portions of the plant to shrivel. As so much dreaded enemy almost invariably does its work in the dull months of the year, it is safe to assume that damp in some way is the predisposing cause. It is possible that if that portion of the stem which touches the ground through the winter months be kept dry, the danger would be minimised. A successful grower of hard wood greenhouse plants once told me he had in a great measure proved this to be the case. He made a point of growing on his plants to specimen size, either from cuttings of his own striking, or from quite small plants when obliged to purchase them. Before re-potting from 2½ inch pots he sawed round the pot some 2 inches below the rim. When the plant was placed in a larger pot the upper portion of the severed pot was retained intact, and this remained throughout the period of time required to bring it into specimen size. The advantage claimed for this plan

ROSE GARDEN.

THE YELLOW BANKSIAN ROSE.

I AM forwarding you a photograph for reproduction, if possible, to show your numerous readers how well this Rose flowers in the favoured climate of Devon. The plant was photographed early in May, 1893. Though it blooms most profusely each year, I, too, find that the white kind is very shy in flowering. It does not grow so freely nor so strongly. I prune the plant every year after flowering, and tie in all I can in the way of young growth without crowding. The very strong shoots I dispense with, unless required to fill up, then I shorten to about half their length. Unlike your correspondent (see THE GARDEN, July 24), I do no further pruning in the spring, though no doubt his method is a good one, as it is conducive to keeping the growth close to the wall. Banksian Roses require a wall due south, even in this part

Especially care must be taken to secure perfect drainage, as the roots of this Begonia are easily injured by excess of moisture. The compost should be used in a moist but not wet condition, and should be firmly pressed in, as this Begonia never attains the dimensions that many plants of a similar nature do, growth being comparatively slow. Considerable caution in repotting is indispensable. If a plant is given a greater amount of fresh soil than the roots can take possession of in the course of the growing season, there is much danger of their coming into an inert condition, and the probability is that when the dull days arrive the foliage will take on that yellow lustreless appearance which too frequently mars the beauty of this species. Plants that are repotted after blooming should get as small a slift as possible, as they have not so long a season of growth as young ones repotted early in spring. Another most important item is a free admission of air whilst avoiding draughts. Where plants are wintered in span-roofed structures, enough air can through the winter be admitted from the top ventilators. In the spring when cold easterly

when so desired water could be given without wetting the collar of the plant, so that the condition of the stem could be maintained in a semi-dry condition. In this way he asserted that the small collapse to which such things as Boronias, Pteleas, Hedaromas and some Cape Heaths are liable would be almost entirely averted. This individual had some very fine specimens, which remained in good health, to my knowledge, for several years, and many of them were grown right from the cutting. The most successful propagator of Boronia serrulata I ever knew took cuttings from plants that had made growth in a light airy house, in a temperature of about 50°. The cutting pots (6 inches) were about two-thirds filled with drainage, a little rough material being added on that, and then filled with finely-sifted, washed peat to within 2 inches of the top, finishing off with silver sand. The pots were plunged in a tan bed, the cuttings were covered with bell glasses, which were removed dry every morning. In this way about 90 per cent. of the cuttings made roots. When rooted they were gradually inured

The yellow Banksian Rose in Devon. From a photograph by Mr. J. Mayne, Bickton Gardens, Salterton, Devon.

of England, to flower them well, as we had one until recently on a west wall, but not a single flower appeared, consequently it was removed to a south aspect. J. MAYNE. Bickton, Devon.

winds accompany bright sunshine much injury is frequently done to this class of plant, and care must be taken that the cold air does not directly pass on to the foliage. J. C. B.

**Gloxinias as market plants.**—I was recently much struck at the display of small, exceptionally well-grown plants of Gloxinias exposed for sale in Norwich market. The plants occupied pots about 3 inches in circumference and each carried from three to four fine highly-coloured blooms, the price asked being 6d. each. They were seedlings of this year's growth, being sown in March and grown on in a brisk moist temperature, care being taken to harden them well off before bringing them out into the open air. Very few who purchased them would be able to do anything with them the second year, but if they only remain in good condition for a few weeks, which with care they will do, they are well worth the money asked for them. The strain was one of the best I had ever seen, the colours of many of the flowers being exceedingly beautiful.—J. C.

**Rose Mrs. James Wilson (Tea).**—This is a good Rose that appears to be a combination of The Bride and Marie Van Houtte. It has the lovely carmine shading of the latter variety, but its globular flowers of pale lemon colour somewhat resemble The Bride, although there is an absence of the pointed outer petals peculiar to this variety. Mrs. James Wilson is a vigorous variety, and although the flowers do not always open well, it is nevertheless a serviceable Rose. P.

**Rose Duke of Connaught (H.P.).**—At the present day Tea and Hybrid Tea Roses claim rather the larger portion of our attention, but we must not entirely forget our old and useful friends the Hybrid Perpetuals. The above-named variety for garden decoration is quite first-rate. Its colour is a peculiar fiery crimson, with rich vel-

the general atmosphere of the house, and then into small pots in sandy peat. They were kept in the propagating house until the roots began to work freely in the compost, and were then removed to cold frames, being shaded from very hot sun, carefully watered and sprinkled overhead in the morning on fine days. By the autumn they were well established in their pots, and were in good condition for shifting into 4½-inch pots the following spring. Peat of the very finest quality must be used for this Boronia. It should not be cut, but pulled to pieces by hand into lumps about the size of a Cob-nut, adding one-sixth of coarse silver sand. The end of March or beginning of April is the best time for repotting in the earlier stages of growth, but later on it should be done when the flowers fade, and just as the young growths are pushing. After potting, a somewhat close atmosphere should be maintained, but as soon as the roots begin to work into the new compost and growth is being freely made, abundance of air must be given. A little shade from hot sun is beneficial, but this must be reasonable, and must not in any case be overdone.

vety shading; the form of flower is almost round. It makes good vigorous growth, not rampant, but quite strong enough, and its flowers are freely produced in summer and autumn.—P.

**Rose Joseph Bernacchi** (Noisette).—This is an excellent climbing Rose of fairly vigorous habit. It has fine long buds of a pale cream colour; in fact, both in bud and blossom this variety somewhat resembles that grand variety *Mme. Hoste*. Any gardener who has large demands for Roses with long buds, for bouquets or button-holes, would find in *Joseph Bernacchi* a really useful kind, and it can be cut with fine long stems, which are so essential to the proper display of any Rose.

**Rose Comtesse Panisse** (Tea).—This pretty variety is certainly deserving of more popularity. It is a good grower, making good solid wood and thick leathery foliage. The colour is a pleasing shade of flesh-pink mingled with rose and a distinct coppery shading. The petals are almost wax-like in texture, a fact which enables this Rose to withstand the rain better than many of its more delicate-petalled relatives. The flowers also show up well, being borne upon good stiff stalks, and are generally seen in corymbs. It is not a show Rose and the blossoms are only of medium size, but I can strongly commend it as a garden variety.—PHILOMEL.

**Rosa Pissardi**.—The true kind bearing this name is a lovely semi-double Rose for the garden. It is a very continuous flowering kind, almost as much so as *Stanwell Perpetual*. The paper-white flowers, which are about 2 inches across and generally appear in corymbs, contain two and three rows of petals. These flowers when expanded have a striking resemblance to the Musk Rose *Eliza Werry*, but the difference in the varieties is marked in the tiny buds, those of *R. Pissardi* being elongated and pale pink in colour, whereas *Eliza Werry* has buff-coloured buds, smaller, and almost round. *R. Pissardi* has pretty lanceolated foliage of a bright green colour. It is a strong grower, but of compact habit, enabling the flowers to show to great advantage on the plant. This variety has the sweet fragrance of the Dog Roses.—P.

**Rose Eugene Furst** (H.P.).—It appears strange that some of the best Hybrid Perpetual Roses for garden decoration remain in comparative obscurity. Perhaps this will not be so when the National Rose Society institutes an autumnal Rose show, and also gives more encouragement to the display of useful Roses which perhaps are devoid of finish, as looked at through their critical eyes, but which, nevertheless, surpass some of their more refined relatives for garden decoration. The above Rose is a case in point. One rarely meets with it at an exhibition, but it is to my mind one of the best crimson Roses for cutting. It never fails to yield a good supply of flowers of a vivid scarlet-crimson colour, and especially is it useful during the month of August, when there is rather a dearth of Hybrid Perpetual Roses. It is a good vigorous grower, equally useful for bedding, to grow as a pillar Rose, or as a standard.—P.

**Semi-climbing Teas under glass**.—During a recent visit to the gardens of Hatfield House I was astonished to see that lovely Rose *Sunset* clambling away up the sunny side of the Camellia house as though it were a real climber. The plant was fully 10 feet high and covered with a mass of splendid blossoms, which Mr. Norman doubtless found very useful for cutting. The plan adopted at Hatfield, of planting out these dwarf Teas and using them as semi-climbers, is a very good one. One can thus obtain a supply of useful flowers without the inconvenience of the over-luxuriant growths of the real climbers. *Sunset* was not the only variety employed, for that good old kind, *Niphetos*, appeared just as vigorous, and one almost questioned the need of a climbing *Niphetos* when the old variety could be so successfully grown. I should mention that the conservatory in which these Roses were growing had the sides entirely of glass, so that abundance of sun was given to the plants, which doubt-

less considerably assisted in producing the effect described. Other excellent varieties for similar treatment would be *Kaiserin Augusta Victoria*, *Perle des Jardins*, *Anna Olivier*, *Bridesmaid*, *Catherine Mermet*, *Marie Van Houtte*, *The Bride*, *Mme. Lambert*, *Mme. Hoste*, *Souvenir du President Carnot*, *Medea*, *Belle Siebrecht*, *Mme. Charles*, *Souvenir d'un Ami*, *Caroline Testout*, *La France*, *Duchess of Albany*, and *Mme. Abel Chatenay*.—P.

**Rose Papa Gontier**.—As a winter Rose this is very popular with the market growers in Worthing and neighbourhood, where large areas covered with glass, devoted to the cultivation of a few popular classes of plants, occur in all directions. It belongs to the Tea section, and, like many others of its class, as the flowers are not very double, it is more attractive in the bud state than afterwards. The buds are really charming, being particularly long and of a pleasing bright rosy-crimson colour. It meets with a ready sale and possesses the great merit of developing its blossoms throughout the winter in less heat than most of the other varieties; indeed, in too high a temperature the blooms lose their richness of colouring. This Rose was, I believe, sent out by *Nabonnand* over a dozen years ago, and our American cousins were the first to find out its value for flowering under glass, as occasional notes used to appear in the horticultural publications on the other side of the Atlantic, while it was as yet almost unknown in this country. Judging by the numbers now grown, it would appear to have become quite an established favourite. *Rose Papa Gontier* is another illustration of the fact that a plant may be in cultivation for years before its merits are recognised, a very striking example of which is to be found in the case of the now popular *Pelargonium F. V. Raspail*, which was sent out by *Lemoine* as long ago as 1878, yet it almost dropped out of cultivation, and then some years afterwards bounded into popularity.—H. P.

## FRUIT AND VEGETABLE CROPS.

### SOUTHERN.

**Warlies Park, Waltham Abbey**.—The fruit crop here and in the district this year is very poor. Apples are very much under average and the fruit is a poor sample. *Keswick Codlin*, *Manks Codlin* and *Lord Suffield* among the kitchen, and *Irish Peach* among the dessert, are the only varieties I have bearing. Pears are a little better, but not up to the average; the fruit is a fair sample, especially on the walls. Plums, with the exception of a few on the walls, are a failure. *Damsons* the same. *Gooseberries* are over average. *Black Currants* average. *Red Currants* under average. *Raspberries* under average. *Peaches* on walls are not up to the average and the fruits are small. *Apricots* are an average crop and the fruit good.

On the whole, this has been a good vegetable season, and most of the crops are above average. *Potatoes* have not been so good with me for several years, the tubers being of a nice size and shape, clean, and entirely free from disease. All root crops are good; so are all the *Brassica* tribe, with the exception of *Canfliflowers*, which have suffered very much from the hot weather we have had lately.—WM. CLARK.

**Caversham Park, Reading**.—Neither for quantity nor quality will the fruit crop in this district compare favourably with those of the past five years. Apples are fairly good, and some varieties, such as *Devonshire Quarrenden*, *Cockle Pippin*, *Cox's Orange* and *King Pippins*, are heavily laden, while on several trees of *Blenheim Orange* there is no fruit whatever. Pears are about an average, but I fear the quality will be poor. Plums are bad, as are also *Cherries*, with the exception of *Morellos*, which are good both in quantity and quality. *Peaches* on walls are good. *Raspberries*, *Currants* and *Gooseberries* are under the average, but *Strawberries* were very

good owing to being mulched early. *Nuts* are very good, and *Figs* on walls promise to do well.

Early Peas were exceptionally good, but season and late varieties are poor, as also Beans. Green crops generally are bad, and toes are small and below the average. On roots sown early have done well, and all kinds promise a good return, but are sufficient from the prolonged drought.—W. MILES.

**Arundel Castle, Sussex**.—Apples are under average. *Cox's Orange Pippin*, *Cox's Pomona*, *Lane's Prince Albert*, *Lord Suffield*, *Keswick*, *lin*, *Cellini Pippin*, *New Hawthornden*, *Mundi*, *Stirling Castle*, *old Nonsuch*, *Peach*, *Hambledon Deux Ans* and *King of Pippins* are carrying the best crops. *Pear* under average. *Beurré Bose*, *Beurré Duchesse d'Angoulême*, *Eyewood*, *Duronde*, *Catillac* and *Uvedale's St. Germain* are carrying heavy crops. Plums are a failure both on standards and walls. *Peaches* and *Nectarines* are an average crop, some trees badly infested with spot. *Cherries* average. *Cherries* poor. Small fruits average. *Black Currants* good. *Nuts* and *Strawberries* over average.

Vegetable crops looked well until end of last fortnight have checked Peas and Beans. *Potatoes* are full of disease, both early and late kinds. Disease appeared in the neighbourhood at the end of June, earlier than I have known it previously.—E. BURBURY.

**Basing Park, Alton, Hants**.—The fruit crop is under the average. Some of the trees have fair crops where they are protected from the north and east winds and screened by trees. I attribute the failure to frost in May and June, which destroyed the crops, and particularly where they were exposed to the cold winds. Many of the trees have good crops on the south side of the trees. The Apples have dropped much of late from the dry weather and cold nights. Pears are good average crops on the walls on protected trees, but they are dropping much from northerly winds. Plums are almost a failure. *Cherries* not more than half average. *Peaches* poor, and *Nectarines* under average. *Strawberries* not more than half a crop; all early blossoms were cut off by frost, and the hot and dry weather caused the fruit to drop early, and the Strawberry season was soon over. The *Gooseberry* crop was under the average. *Black Currants* were a good crop. *Raspberries* under average, quite small. *Black Currants* under the average, but fruit fine and good. *Lee's Prolific Black Currant* is the best. I will grow no other, as that always gives a good crop of first-class fruits of a fine flavour.

Vegetables have been good this season where they have had plenty of water and where the soil is good and rich.—W. SMYTHE.

**Eaglehurst Castle, Fawley**.—Apples are carrying heavy crops, excepting a few trees that bore very heavily last year. *Raspberries* were not so good this year, either in quantity or size of fruit. Owing to the drought last year they did not produce such fine canes. *Gooseberries* were the best crop we have had for some time. Plums are very scarce here this season, some trees carrying only one-third of a crop, others none. *Apricots* were only a moderate crop, also *Peaches* and *Nectarines* outside. The *Strawberries* here bore very heavy crops. The soil grows are *Sir Joseph Paxton*, *King of the Earth*, *President*, and *Dr. Hogg*. *Royal Sovereign* planted last autumn and it produced some fine fruit this season. *Sir Joseph Paxton* and *King of the Earth* do well here. Planting early in autumn, from plants layered in pots, gives the best results.—HENRY GARRATT.

**Hackwood Park, Basingstoke**.—The fruit crops in this district are very poor. Apples, I think, are the worst. *Lord Grosvenor*, *Lord Suffield*, *Potts' Seedling*, *Warner's King*, *Keswick* are the best. Pears are much under average. *Souvenir du Congrès*, *Louise Bonaparte*

sey, Mme. Treyve, Pitmaston Duchess, Beurré d'Orgerau, Beurré Diel, and Winter Nelis have a fair crop. Plums almost a failure, even the Victorias. Peaches and Nectarines very few. I never remember to have seen the trees blistered so badly as this year. Apricots a failure. All small fruits much over the average.—J. BOWERMAN.

**Waddon Gardens, Winslow.**—The fruit crops in this district are rather below the average. Early in the season there was every promise of good crops, but a long spell of cold, cutting winds and late frosts destroyed most of the bloom, so that with the exception of trees in sheltered positions the crops are very poor. Apple trees in sheltered positions have borne well, especially the following varieties: Keswick Codlin, Cox's Orange Pippin, Bismarck, Peasgood's Nonsuch, Emperor Alexander, Mr. Gladstone, and King of the Pippins. Pears, on the whole, are a poor crop. Plums in sheltered positions fair. Gooseberries and Currants have borne plentifully, and in this immediate vicinity been quite free from the caterpillar of the Gooseberry sawfly. Strawberries have been an exceptionally good crop, excellent in quality and large. The varieties that do best with us are the following: Royal Sovereign, President, Scarlet Queen, and Laxton's Latest of All. Raspberries have cropped abundantly, especially Superlative, which I find does better than any other variety.—J. MILSON.

**The Hoo Gardens, Welwyn, Herts.**—Apples are under an average crop. Pears average. Plums under the average. Cherries a good average crop, especially Morellos. Peaches and Nectarines are good and the trees healthy. Apricots are very poor. Small fruits are heavy and of good quality. Strawberries very good. Nuts of all kinds a most remarkable crop.

The first and second early Potatoes are small, but the later varieties appear to give larger tubers.—C. E. MARTIN.

**Midbrooke Park, Sussex.**—The Apple crop is below the average. Some varieties are bearing heavy crops of clean-skinned and equal-sized fruit. All the trees of Blenheim are bearing full crops. That useful Apple, Forge, is bearing heavy crops, more especially upon old trees. No Hawthorned on espaliers is cropping very freely; no fruit upon standards. Lane's Prince Albert and all the different sorts of Codlins are bearing good average crops. Apricots above an average crop, fruit large and of first-rate quality. Cherries (sweet) almost a failure. Morellos an average crop, but small. Figs are an average crop. Black Currants above an average crop; fruit extra large. Red and White Currants fair average crop, but the fruit rather small. Gooseberries an extra heavy crop of fruit. Blackberries good average crop. Medlars below an average crop. Nectarines poor. The trees suffered very much from blister during the cold east winds. Pears and Nuts very plentiful. Peaches good average crop, but fruit smaller than usual. Plums almost a failure upon wall trees and standards. The only sorts bearing fruit are Prince Englebert, Red Magnum Bonum, and Victoria planted upon a west wall. Quinces an average crop. Raspberries a plentiful crop, Superlative bearing the best crop and Prince of Wales coming next. Strawberries above an average crop, but owing to the dry weather the crop was soon over. Present stood the drought better than any of the other sorts grown. Walnuts very few. Damsons none.—WM. CHRISTISON.

**Topmore, Maidenhead.**—The fruit crops generally are somewhat under the average in this, the South Bucks district. The greatest loss will be found in the scarcity of Apples, which are not bearing a crop. There are exceptions; for instance, Blenheims are quite heavily cropped in the Burnham district, two miles distant on lower ground. I noted, however, that last year these trees were fruitless, and this may account partly for their crop this. The trees may possibly have had more strength in the blossom and able to withstand

cold winds and frosty nights better than others that had cropped freely the previous year. The blossoming of trees was profuse in all instances, but why an occasional orchard is to be found well cropped in similar situations to those just the reverse, I am unable to explain, unless the facts above stated have some bearing on the question. Bush trees on the Paradise stock have generally cropped better than orchard trees, a few varieties, as Grenadier, Lord Grosvenor, Lane's Prince Albert, Lord Derby, Ecklinville Seedling, Worcester Pearmain, and Bismarck carrying good crops. Pears are almost a failure; an occasional tree may be found cropping fairly well. Peaches and Nectarines on walls are excellent as regards crop, and the trees very healthy. Severe thinning of the fruits has been necessary. Apricots are very poor, and the same may be said of Plums both on walls and standards. Both Morello and sweet Cherries on walls are, and have been, plentiful, but on orchard trees the crops were generally very poor. Gooseberries and Red Currants were plentiful. Black Currants are about half a crop. Raspberries promised to be good, but the dry weather which set in at ripening time was too much for them and half the crop dried up from want of moisture. Nuts are very abundant.

The vegetable crops have been generally excellent, although Peas, Beans, and other subjects are now feeling the effects of the continued dry weather. Potatoes are cropping abundantly, and very little disease is apparent up to the present.—C. HERRIN.

**Woodhatch Lodge, Reigate.**—Apples are under average. The varieties that are cropping well are Stone's, Warner's King, Bess Pool, Stirling Castle, Prince Albert, Wellington, Hornmead's Pearmain, Duchess of Oldenburg, Allen's Everlasting, King of Pippins, Cox's Orange and Blenheim Orange. Pears are under average. A few espaliers on a wall have good crops. Plums are a failure. Gooseberries under average. Currants (Black and Red) are poor. Raspberries average, especially good being Superlative.

Peas have been good this season. Chelsea Gem, Earliest Marrow, Exonian, Veitch's Main Crop, Autocrat and Chelsonian have cropped well. Beans have done well, and all the green crops are looking well. Potatoes will be a light crop, but at present they are free from disease.—C. J. SALTER.

**Kingston, Surrey.**—Very erratic are Apples in this locality. Some growers have none; others, especially on old trees, have plenty. The Codlin family give the best results, although Prince Albert, Blenheim Pippin, King of the Pippins, and some small fruited have in some localities cropped very well. It seems probable, in spite of adverse reports, that Apples will be fairly plentiful after all for a time, but we shall find them scarce and dear at the close of the year. Pears, too, vary very much, the earliest and most common forms being plentiful, whilst the larger and best ones are scarce. Plums and Damsons are almost a failure. Seldom have there been fewer of these stone fruits. Apricots have been thin, but Peaches, Nectarines, and Cherries are, or have been, fairly abundant. Bush fruits, too, have been pretty plentiful, the thinnest crop having been Black Currants; Gooseberries have been the best. Raspberries also have been abundant, and the Strawberry crop was far more abundant than was at first anticipated would be the case. Walnuts vary, from some trees absolutely fruitless to others elsewhere full of fruit, and small Nuts are in the same category.

The vegetable crops have on the whole been good, though in shallow soils drought has told adversely. Potatoes late, are yet robust and healthy on deeply-worked ground, and so far there is little evidence of the disease. The early ones have quite ripened and present a very fair tuber crop. Peas have been very good, and mildew has given little trouble; in many directions fine crops have been obtained. Runner Beans have suffered from lack of air and root moisture, and bloom has fallen, but that has now been checked. Onions have never been finer or cleaner than this year. Beets and Parsnips are capital and clean,

but Carrots are only moderately good and the foliage is rusty. There is neither Onion maggot nor Celery fly anywhere this season.—A. DEAN.

**Waddon House, Croydon.**—Fruit and vegetable crops in this district, as a whole, have been unsatisfactory, the late frosts and hot, dry weather being very unfavourable, as the subsoil is very bad as a rule. Apples under average. Pears very few. Peaches and Nectarines over average and good. Gooseberries average. Currants under average. Strawberries about average in the district, although mine were under, owing to all the early fruit, also bloom, being cut off with frost on May 13.

Vegetables have been very good, especially early Peas, Beans, Cauliflower and Cabbage.—J. HARRIS.

**Strathfieldsaye, Hants.**—The fruit crops in this neighbourhood are fairly good. Small fruits have been plentiful and good in quality. Strawberries extra heavy crops of even-sized berries, of first-class flavour. Raspberries a full crop, especially Superlative, which is a vigorous grower and heavy cropper. Magnum Bonum is also a fine yellow Raspberry of extra flavour and good cropping qualities. Black Currants have been fine in size and crop, such sorts as Lee's Prolific and Black Naples doing best. Red Currants have also been a full crop; the sorts which do best here are Red Dutch, Mammoth, Fay's Prolific. Of White Currants, the best crops are got of White Dutch, White Versailles and cut-leaved White Dutch. Gooseberries have not been so heavy a crop as usual in this district. Cherries on walls and standards have been very good, the fruit clean and good in flavour. Plums and Damsons are a light crop and the fruits poor. Apricots are an average crop. Pears are rather a thin crop, but the fruits are swelling into a good size. Apples are also under an average crop; Lane's Prince Albert, Duchess of Oldenburg, Blenheim Orange and all the Codlin types are good. Nuts are plentiful and good.

Vegetables are an extra good lot, especially where watering has been attended to. Potatoes are a heavy crop, free from disease and of first-class quality. Peas have been fine, especially Boston Wonder, Ne Plus Ultra, Duke of Albany, and several of Sutton's Marrowfat Peas have done well this year. Cabbages have been plentiful and good. Onions, Carrots, Leeks and Celery are good crops, and now rain has come winter vegetables will soon fill their quarters. Our rainfall for January was 2.37; February, 3.84; March, 4.65; April, 1.53; May, 1.14; June, 2.04; July, 1.67. Total, 17.24.—J. W. McHARTIE.

**Wyeombe Abbey.**—The crops of Apples, Plums, Damsons, and Cherries are very short in general. Peaches and Nectarines an average crop. Pears above an average. Bush fruits generally are an average crop, although in some places there was a deficiency of Black and Red Currants. Nuts are very abundant, and Walnuts a fairly good crop.

All crops of vegetables are excellent this year, the Potato crop being exceedingly good, and at the present time but very little disease abounds in this locality.—G. T. MILES.

**Wakehurst Place, Haywards Heath.**—The fruit crops in these gardens have not been good. Apples showed well for bloom, but, on the whole, there is a very irregular crop. The best are Early Red Margaret, Red Quarrenden, Cox's Orange, Ribston Pippin, Worcester Pearmain, Lord Suffield, Warner's King, and Sandringham. Pears are very poor, and Plums on walls much below the average. Cherries are not extensively grown, and the crop is poor. Strawberries have been a fine crop and of good quality. Royal Sovereign and John Ruskin are carrying fine crops, but I much prefer the former. Raspberries are good average, but soon past owing to the drought. Gooseberries below the average. Red Currants good, also Black. Nuts are an abundant crop, and Walnuts very good.

Vegetables have done very well, except Cauliflowers, which have been almost a failure. I

have found the following Peas succeed best: Early—Sutton's May Queen, Veitch's Chelsea Gem. For succession, Prodigy, Criterion, and Maincrop; and Ne Plus Ultra for late use. Potatoes are good, and quite free from disease.—A. DREWETT.

**The Gardens, Stoke Court, Slough, Bucks.**—Apples and Plums are a poor crop with the exception of one or two kinds. Pears are about half a crop, Marie Louise, Beurré Bo-cé, and Doyenné Boussoch being fairly well cropped. Cherries half a crop, but good fruit, both Morellos and sweet Cherries. Peaches, Nectarines, and Apricots are very good, trees healthy and fruit fine. Waterloo and Amsden June I sent to table July 15. Red, Black, and White Currants very good. Raspberries and Strawberries excellent. Gooseberries very good. Nuts abundant and good.

Peas have done wonderfully well. Beans, Runner, French, and Broad, have done well. Carrots, Onions, Parsnips, Beet, Artichokes are good. Potatoes excellent crop, and free from disease at present. Cabbage, Brussels Sprouts, and Broccoli are very much affected with club at the root.—F. W. BEEVERS.

#### EASTERN.

**Livermere Park Gardens, Bury St. Edmunds.**—The fruit crops generally this year are light, though there are no absolute failures. The irregular way in which Apples and Plums are fruiting is curious, for many trees are carrying heavy crops side by side with others absolutely fruitless. Of Apples, early varieties such as Manks and Keswick Codlins, the old Nonsuch, Devonshire Quarrenden, and White Juneating have heavy crops, as also have the old Hawthornden and King of the Pippins; Ribston Pippins are a fairly heavy crop and the fruits extra fine. Others that may be mentioned as carrying fair crops are Lemon Pippin, Emperor Alexander, and Warner's King. Varieties other than those mentioned are either fruitless or carrying a very much below average crop. Pears are a good crop all round, but much in want of moisture. Peaches and Nectarines on a south wall were blistered almost to death and the crop is very light; on a west wall their condition is much better. Plums on walls are a light crop, as the trees were caught by a sharp frost while in blossom, the best in this position being Washington, Goliath, and Reine Claude de Bayay. In the open some trees, notably Early Prolific, Belle de Louvain, Victoria and Orleans, have heavy crops; other varieties are very light. Damsons, Apricots, Figs, and sweet and Morello Cherries are much below the average; the latter, however, carried a tolerable crop of very fine fruits. Currants of all kinds, Gooseberries, Medlars, and Quinces are average crops. Grapes (outdoor) are a good crop, and promise to finish well. Raspberries are a full average crop; Walnuts and Filberts over average. Undoubtedly the crop of the year was Strawberries; these I never had finer and the crop was immense, as rain came just in time to swell the fruit, and during the gathering season dry weather prevailed.

Among vegetables, Potatoes in gardens have done well, but in fields the yield is poor, drought having much affected the crop. Disease appeared early here and caught one plot of Snowdrop before the crop could be lifted; only a few tubers showed the disease at lifting time, but many have shown it since, though the same variety from another plot hard by, lifted at the same time, was not affected. Onions, transplanted from boxes, are fine in spite of the drought. Tomatoes are doing well and ripening early, and the earliest with me, both on walls and trained to stakes, is Carter's Outdoor, a free-cropping, corrugated variety of good quality, and reminding one forcibly of the old Large Red, but much earlier. The root crop generally is good, as, too, is the Celery crop, but the latter has to be kept well watered. Kales of all kinds are backward, but will have plenty of time yet to make good progress, growth with

these in autumn being generally rapid. Peas, with the exception of early sowings, have not carried very heavy crops, or rather the crops on most varieties have not lasted long, but the quality has been good and insect pests not so prevalent as they were last year. Taking vegetables generally, they are very good where growing on deeply worked soil.—J. C. TALLACK.

**Shrubland Park, Ipswich.**—We in this neighbourhood have cause to remember the inclement spring of this year. Night after night we were visited with severe frost just as the fruit trees were in full bloom. The result is that the fruit crops, as regards Apples and Pears and all stone fruits in this garden, and so far as I have seen in this neighbourhood, are, with few exceptions, very light. Strawberries were fairly plentiful, but as many of the first blooms were destroyed by frost, the fruit was much smaller than usual. Gooseberries and Currants are plentiful; Raspberries scarce. Filberts, Cobs, and Walnuts are heavy crops.

As we have been favoured with plenty of sun and a fair quantity of rain, all vegetable crops are looking well. Peas have been exceptionally good. Early Potatoes are also good; quite free from disease. Since the moister weather set in on the 7th I find that disease is showing itself on the late varieties of Potatoes.—G. TAYLOR.

**Diddington Hall, Huntingdon.**—Apples very thin indeed. Pears a good average crop on walls, thin on standards. Peaches and Nectarines about half a crop, healthy and clean. Plums and Damsons a complete failure. Walnuts, Cobs, and Filberts a very heavy crop, the best I have had for years. Gooseberries rather thin, but fruit large and clean. Currants, both Red and Black, very thin. Strawberries a splendid crop, but soon over, owing to the excessive heat. I still find Keens' Seedling and Noble the best early kinds for preserving. For table use Royal Sovereign and Sir Joseph Paxton, and for late use Waterloo and Oxonian are the best.

Potatoes on early borders good and quite free from disease; the earliest and best was Ring-leader, followed by Duke of York. Onions sound and clean, but small. Peas, early crops extra good, late crops light and suffered from mildew. Beans an excellent crop. All the Cabbage tribe are sadly in need of a good soaking rain.—T. LOCKIE.

**Babraham, Cambridge.**—What promised to be one of the best crops of fruit of all kinds has in some cases fallen much below the average. Apples are much below. Some sorts have a crop, the most noticeable being Lane's Prince Albert. This variety seems to have withstood the frost better than any other. Some of my Apples, the above variety and Ecklinville in particular, had their buds entirely stripped by bullfinches and tits. Plums are the worst crop we have. They were a long while in bloom owing to the cold winds, and then to finish them off a sharp frost appeared after rain. Victoria, Rivers' Prolific, and Czar seem to be the only varieties bearing. I have several acres planted on some higher ground, the trees not having been planted long, but I notice that most of these are carrying a few. Damsons are about the same as Plums. Pears are a little better. Some sorts are carrying a crop, but I find the choicer sorts have failed. Cherries were pretty good. Apricots not good, but I am of opinion the loss to them was from want of water more than the weather. Gooseberries and Black Currants are not much more than half a crop. Strawberries, Red Currants, and Raspberries were very good. Nuts very plentiful. Quinces I never have seen so scarce as this year. Peaches and Nectarines are, as usual, carrying good crop. Of course the trees are always protected from frost when in blossom. I had Nectarine Precoce de Crocels ripe end of July on walls.

Tomatoes are doing well this year; Sutton's Perfection and Best of All are excellent. Vegetables of all sorts have done well. Peas I have never seen do better; the crop on Earliest of All was wonderful. Gradus is a good second early;

for a later variety Sutton's Peerless is a splendid sort, the flavour being excellent, and Veitch Extra Marrow is all that one could desire. These varieties only growing about 3 feet must take the place of all such kinds as the Duke of Albany. While these excellent varieties are of the very best quality I hear complaints of their being too large, and Peas about the size of Sweet Peas are asked for. Potatoes are very free from disease as yet the early kinds ripened off very quickly, and the crops are not so heavy. Cabbages were very early this year. I cut in quantity end of March good heads of Ellam's. The root crops in fields will be the best seen for some years.—J. HILL.

**Hardwick, Bury St. Edmunds.**—The fruit crop around this neighbourhood cannot be considered satisfactory. It is the worst season for Apples I have known for many years. The different kinds of Codlins, Duchess of Oldenburg, Hawthornden, and a few other kinds are pretty good; still much of the fruit of those kinds is falling off through maggot, and Ribston, Blenheim Warner's King, Court Pendu Plat, Fearn's Pippin, and many others are almost a failure. Pears are somewhat better; the fruits are small and, I fear, will not come to any size. Apricots are few and far between. There was a good show in bloom, but the frost during April quite spoiled the prospects in our garden. Peaches and Nectarines are fairly good and may be considered an average. Early Cherries were pretty good, but Morellos a very light. Many of them fell during the storm time. Plums are light; a few kinds, such as Early Orleans, Victoria, Monarch, Prince Engbert, and Ickworth Impératrice are fairly good, but Golden Drop, Jefferson's, Goliath, and Gages are almost a failure. Strawberries have been good all round, the best season I have seen for some time. Raspberries pretty good, but fell small through the drought. The different kinds of Currants and Gooseberries are very good.

Early Potatoes were very good, but second early and the late kinds have suffered through the dry weather. I hope the rains that we have just had will not be too late to help them. The early kinds of Peas were very good, but the late kinds have suffered very much from the dry weather.—B. MARKS.

## GARDEN FLORA.

### PLATE 1134.

#### THE LILY OF THE VALLEY.

(WITH A COLOURED PLATE OF CONVALLARIA MAJALIS, FONTIN'S VAR.)

IN figuring such an exquisitely sweet and lovely woodland flower as this, no apology is necessary. There may be newer and rarer flowers in our gardens, but we certainly possess but few, if any, wild plants which are at the same time so dainty in all their ways and blossoming and there is, perhaps, no native wild flower that is so universally grown in gardens of both rich and poor all over the country as is the Lily of the Valley. We do not remember that it has ever received a first-class certificate from any society, and it seems to be one of the few plants that has escaped being figured in the embracing *Botanical Magazine*. Of course it has its usual niche in all the floras, and Hooker tells us that it is found in "woods from Moravia to Kent and Somerset, ascending to 1000 feet in the north of England, naturalised in Scotland and Ireland, flowering in May and June. Its general distribution is Europe, North Asia, and North America, and it is also met with in North China and Japan. Its chaste modes and sweetness alike recommend it to all taste

\* Drawn for THE GARDEN in Messrs. Laxton nursery at Bedford by H. G. Moon. Lithographed and printed by J. L. Goffart.

ASHEM  
1847

LILY OF THE VALLEY (FONTIN'S VAR.)

and it is perhaps a blessing that it has so far escaped the attention of those who like to improve on Nature by rearing variations in form, size, or habit, or colour. It is essentially monotypic; there is nothing in the whole world of plants quite like it, its nearest relatives being the twin-leaved *Smilacina* and the graceful Solomon's Seal (*Polygonatum*). The plant certainly does vary, but it is within very narrow limits, the range of its variation being in inverse proportion to its extensive geographical distribution. There are tall and dwarf, broad-leaved and narrow-leaved kinds, and some forms are a little earlier or more sensitive to artificial heat than others, this depending to some extent on the climate and soil in which the roots or crowns are, or have been, grown. There is a giant kind with semi-double flowers rarely seen, there is a poor and puny rosy triple form, and a kind having golden yellow ripens on its foliage. Commercially, the plant is become of late years very important, and especially since Mr. Jannoch, of Dersingham, (tr. T. Rochford, of Turnford, and other growers of its flowers for market have made of such a gigantic speciality.

In Germany the culture of Lily of the Valley is an industry of considerable magnitude, and the Berlin "crowns" are considered finer than the French or Dutch-grown produce, and these are most largely cultivated by all the extensive growers. The forcing of Lily of the Valley for its flowers has proved so remunerative, that refrigerator chambers have been in some cases utilised in retarding the crowns, with heated forcing pits to forward their growth, and in this way it is now quite possible to produce plenty of flowers every day in the year if need be instead of merely during the two or three spring months when it was formerly in season. The ground and climate near Berlin seem particularly well suited to the culture of this plant, and it is curious to note that the Berlin crowns are valued far more highly than are those from Hamburg and other localities.

The best varieties are Berlin, Dutch, Victoria and Wallace's, and even the common wild types soon improve as grown in the Berlin soil. By the best crowns stout spikes of from fifteen to twenty-five bells are produced. As we have said, but little, if any, attempts have been made to improve the Lily of the Valley from seed. As a rule it increases vegetatively by its numerous underground stolons, but now and then, as at Traffan, Kildare, and elsewhere, spikes of soft permilion berries succeed the snowy flowers and open good seeds from which some variations might naturally be expected, not but that the plant, as wild or as well grown, is beautiful enough as it is. The following account by Mr. M. Wakefield in the *Spectator* of June 5, 1897, of the Lily of the Valley as still existing on the acre in the woods of Arnside Knott may interest those who have never seen this plant so happy and luxuriant in its native haunts, woodland and wilds.

The woods where this fairy-flower has elected to dwell in such profusion cover perhaps three or four hundred acres of ground, and the beds of Lilies are literally all over them, spreading in patches from a quarter to a whole acre. Above them grow the Nutwood, the Dog Rose, and the Bramble, while here and there the Firs and Yews give the scene a quiet distinctive dignity. Below the trees there is nothing but cool, broad, shady lanes and the little bells of the "Maiblume," as the Germans call our Lily:—

The stooping Lilies of the Valley  
That love with shades and dews to dally,  
And bending droop on slender threads  
With broad hood leaves above their heads,  
Like white-robed maids in summer hours,  
Beneath umbrellas, shunning showers.

Not a sound can be heard except the bird's song; verily a place to dream in, and perhaps it is true, as is said, that the scent of the Lily of the Valley has a narcotic influence, for fancies and imaginings take possession of one's scent-soothed soul. The Lilies seem a cool, pure world of themselves; far away, indeed, are the stress and turmoil of the real world, for at this moment nothing seems real save acres of Lily of the Valley—at any rate, for half an hour! Through a cutting in the wood the mighty and well-beloved outlines of the hills stand clearly against the horizon from Coniston Old Man to Kentmere. Helvellyn, Fairfield, and Red Screes rear their heads straight in front of us. Mountain peaks in the distance, and Lilies of the Valley all around us, verily "a sight for a sair cen." We do not need Gerarde's famous dejection of the blossoms, which he says is "good against the gout and comforteth the heart;" the comfort enters into us with the sight of the fells and the scent of the flowers. We make no dye from our lovely Lily leaves, beautiful colour though it be. We distil no famous aqua aurea from their bell-like flowers to preserve us, as in olden days, from contagious maladies; the Lily beds of Arnside are just the joyous playground of children and a dreamland for their elders. And the tide covers the golden sands with its deepest blue of southern hue, the birds are quieting one by one, while the Arnside Lilies, as the old sixteenth-century herbalist put it, "comforteth the heart."  
F. W. BURIDGE.

## THE WEEK'S WORK.

### HARDY FRUIT GARDEN.

**STRAWBERRIES.**—Planting should be brought to a close as speedily as possible, especially if these plants are expected to give returns in the shape of a crop of extra fine fruit next year. Keep the hoe at work amongst previously set-out plants to prevent weeds from growing, and pinch out runners as fast as they appear. Should September prove warm and dry, these plants will make good headway and growth must not sustain a check through dryness at the roots. The training up of the remainder of the old plants should be brought to a conclusion, and a mulch of manure used between the rows at the first opportunity that offers. Red spider has been so rife among plantations this year, that it is necessary, where a wholesale cutting away of the leaves has had to be done, to induce the crowns to make a fresh crop of leaves as speedily as possible. This the mulch and the effects of the copious rains of the past fortnight will speedily bring about if attended to at once.

**WALL TREES.**—These should have a final look over as far as regards pinching and tacking or tying in, as the case may be, for little growth will be made after this date. Where too much wood has been laid in a tree, no matter what kind of fruit it may be, thin it out at once and give the remainder a better chance of becoming thoroughly ripened. Peach and Nectarine trees bearing but scanty or no crops at all should, if they have made an abundance of wood, be kept drier at the roots. Artificial watering had better be discontinued, and to induce the trees to ripen their wood properly, remove the mulching from the alleys so that the sun's rays can have free play on the border. Trees which have made extra strong growth should be root-lifted, but of this more anon.

**GENERAL WORK.**—The heavy rains which have fallen of late have saved much labour in the shape of watering, and all fruit trees without exception will be sufficiently moist at the roots for some time to come. In districts where the rainfall has been slight, especially if the soil be light, watering will still need attention, and all trees bearing heavy crops should have all they require. In woodland districts, netting of choice Pears and Apples will have to be done, as tomits are extremely numerous and destructive this season. This is easily managed in the case of walls, but it

is not so easy a matter with bush trees; nevertheless it will be the only means of saving the fruit where these destructive pests prove troublesome. Shooting them is an effectual remedy, but they keep so close amongst the trees that it is almost impossible to hit them without damaging either the crop or the trees. Take nets off Gooseberry and Currant bushes as fast as they are cleared of fruit and store away for future use when dry. Attend to the ingathering of fruit, especially Pears and Apples of the earlier kinds. A good way to ascertain when they are ready is to lift one or two of the fruits with the hand, when if the stalk parts readily from the tree, gathering may be done with safety, and none should be gathered unless they do so. The warm rain has had the effect of causing myriads of weeds to spring up in fruit quarters as well as other parts of the garden, and they must at any cost be kept under. The hoe should therefore be kept at work, and if the showery weather of the past few days continues, the quickest plan is to rake the weeds off, as the roots will only catch hold again if left on the ground. Note should now be made of actual requirements in the shape of fruit trees and bush fruits for the coming autumn, so that orders may be placed early in the nurserymen's hands when a personal visit and selection of trees cannot be made. This greatly facilitates matters, and the purchaser can then depend on his trees being despatched as soon as lifting can be done with safety.

**LIFTING AND TRANSPLANTING.**—Where this has become necessary, either through unfruitfulness consequent on rank growth, or from want of vigour through being planted too deep, or from poorness of soil, or through crowding, necessitating the removal of every tree planted too close together at the outset, it may be carried out either towards the end of the present month or early in October. Trees carrying fruit must of necessity wait until the crop has been gathered, but once that is done there need be no further delay. Trees which have to be procured from a distance cannot, of course, be lifted until the leaves fall, but at home it is not necessary to wait for this to occur, and so long as the trees have ceased to make growth, the fact of their retaining their leaves is an advantage, as it induces the roots to send out new fibrils at once, with the result that the trees are partly re-established before winter sets in. The great aim in practising lifting with regard to unfruitful trees is to check exuberant growth, which leads to the production of fruit-buds in lieu of a superabundance of wood-buds, and once the trees are brought into subjection and made to bear fruit, the very fact of their bearing generally prevents them from getting out of bounds again. If lifting was only more generally practised we should not hear so many complaints about unfruitful trees. Lifting comes under two headings, one of which may be termed partial lifting, in which case a portion of the roots are laid bare, according to the necessities of the case, but the tree remains stationary in the same position. In the other case, or that of actual lifting, a good ball of soil must be preserved on the roots, so that the tree may be lifted out bodily and transported to another part of the garden. This point cannot be too strongly insisted on, as, unless lifted with a good ball of soil attached, the trees would suffer so severely, that it would take them two or three seasons to recover from the shock. In the first case, a trench should be opened out 2 feet wide all round for bush and pyramid trees, and in a semi-circular form for wall trees, at some distance from the stems. This distance will vary according to the size and age of the trees, but, as a rule, the trench should not be opened nearer than 4 feet, and it is but seldom that it is necessary to go further out than 8 feet, 6 feet generally being the usual distance. As the soil is removed, all roots met with should be carefully preserved and pegged back out of the way until no more are found. If there is a suspicion that the tree possesses tap roots, a drift or tunnel should be driven underneath, and when it is found, cut the root off close up to the ball. If

any other strong roots are found striking straight down into the subsoil, follow them as far as is practicable, then cut them through, and when filling in again lay them out in a horizontal position. The roots laid bare in the process of digging the trench should be examined, when all strong ones may be shortened back, and the mutilated portions of the weaker and fibrous roots trimmed off. They will then be ready for laying out afresh, either in soil of a poorer description than that in which they have been growing, if it is necessary to administer a check, or in a richer compost if it is necessary to impart fresh vigour to the tree. The roots must be laid out nearly level, and at various levels also, as the filling in of the trench proceeds, so that the topmost roots will be about 4 inches or 5 inches under the surface. In no case should any of the ends of the roots be allowed to take a downward direction, for this will only lead to future trouble, and those in charge of the lifting should pay particular attention to this matter. Before finally filling in the trench give a good soaking of water to settle the soil amongst the roots, and let it drain a few hours or a day before finishing off. When trees have to be lifted bodily and moved to another place, the same care is needed to preserve all the roots found when opening out the trench, as in the above instance. After this the soil should be gradually worked away with a five-pronged fork until a ball of soil is left from about 2 feet to 3 feet in diameter, and the roots should be pegged or fastened back out of the way. The ball must be tunnelled under and unseated before attempting to lift the mass out of the hole, and if the soil is at all loose it would be well to prevent a possible mishap by enclosing the ball in a strong mat or some old bagging and fastening it round with cords. A hole should be dug in readiness to receive the tree, so that no delay occurs, and the same rules observed in laying out the roots, and watering the soil also before finally filling in the trench, as given above. A mulch of some description, but preferably that of strawy manure, should be applied to the surface in all instances after lifting, this being a conservator of both warmth and moisture. A daily syringing of cold water for a week or two is a great help to wall trees after lifting has been done, as it freshens up the foliage and enables the trees to retain their leaves much longer.

A. W.

#### KITCHEN GARDEN.

**LEEKs.**—It is not too late even now to make a further plantation of these, where there is a continuous demand for them, as they will form a succession to those planted in trenches some weeks ago. The early batch will now be growing strongly, and soil may be drawn round the stems so as to have them blanched and ready for use by the end of October. If the roots are required for exhibition they should be fed up with frequent waterings of liquid manure. Few plants absorb more moisture from the ground than these; therefore it is almost impossible to over-water them when there is an absence of rain.

**CELERY.**—Recent rains have improved this crop wonderfully, the foliage being of good colour and so far free of disease. Continue to draw more soil round them as growth develops, it being better to do this piecemeal than burying them with a great depth of soil at one time. There is a danger of the early lot running prematurely to seed, owing to the check received during the dry weather. Where there is a danger of this the plants should be used up at once, or it will soon become useless.

**GENERAL WORK.**—Beyond making the usual sowings of Cabbage, Spinach, Turnips, Lettuce, and Endive, September is considered a quiet month in this department, but there are few gardens in which much of the winter's work might not be pushed forward with advantage, especially in backward districts and where the ground is naturally of a heavy nature. In some gardens the ground is so retentive that, unless it is turned over before it is sodden by autumn rains, it is late in spring before it is in a fit condition to do

so, and much valuable time is lost in getting in the different crops. The sooner such ground can be turned over, when present crops are cleared off, the better, as it gives a long season for exposure to weather and is the more easily worked in the spring. The present is also a good time to prepare different composts for dressing the ground as it becomes vacant. Ashes produced by burning garden rubbish of all kinds, mixed with soil that has accumulated from different sources during the summer, are more suitable for some soils than farmyard manure, and now is a good time to prepare this for winter use. In the case of ground cleared of spring-sown Onions, we generally clear the surface of weeds and give it a good sprinkling of gaslime. This is allowed to remain on the top most of the winter before it is dug in, when it is sown with the same crop the following spring, and we have little trouble with maggot. Besides having made a late sowing of Parsley for standing through the winter, we have recently cut all the main lot over, as the foliage being gross, it could not withstand bad weather. The new growth will be more sturdy and will not turn yellow like the former after a lot of rain and snow.

RICHARD PARKER.

### ORCHARD AND FRUIT GARDEN.

#### FLAVOUR IN EARLY APPLES.

THOUGH of late years there has been a considerable number of new Apples added to the list of these early fruits, we have failed to get good quality, as most of them are second-rate, and a small percentage not worth growing, if flavour is considered. Last year I was much surprised to see Worcester Pearmain given a first prize for flavour: doubtless the dish in question was staged under advantageous circumstances, and may have been the best, but certainly such was not my impression. I would at any time prefer an Irish Peach, the old Devonshire Quarrenden, and Duchess of Oldenburg to the Apple in question; but, as everyone knows, tastes differ. Still, although the Worcester Pearmain may be a good market fruit, it certainly cannot be classed as one of first-rate quality. Doubtless its free-fruited qualities have made it a favourite, but I am sorry to see it recognised as a sort deserving of special merit, in the way of prizes for flavour, when there are so many superior. I think the newer Lady Sudeley, if gathered at the right moment, far better as regards flavour. This has a brisk, refreshing taste, with a spicy aroma, which is lacking in the one noted above, and the newer variety is most handsome and the tree a rapid grower. With me it has never failed to fruit since the year after planting. Of course, I do not place Lady Sudeley on the same footing as Cox's Orange; indeed, there are no early Apples that one can, but if eaten direct from the tree it is not lacking in good flavour. This variety needs less pruning than some; it bears so freely on the points of the shoots, that much fruit is lost if hard pruned. A fruit much liked by some growers is the Irish Peach, but I think where Lady Sudeley is grown there is no need to plant this old variety. I admit few early Apples are superior to it in flavour, but, owing to its free cropping, the fruits are not large and do not keep long. I have noted how curious the larger Lady Sudeley grows, and the Peach is somewhat similar. Those who prefer a solid fruit will find none equal to the old Devonshire Quarrenden. This, grown on the Paradise stock in bush form, is an excellent early Apple, and does well in light or well-drained soil; on clay it is not so reliable. The usual method of culture with this variety was large standards,

but grown thus the fruits soon bruised in wind weather and then decayed quickly. Grown in the form advised and on the stock recommended the fruit is very fine, and its grand colour and rich flavour makes it a general favourite. A few words will describe Mr. Gladstone, an early showy fruit. This is somewhat like Worcester Pearmain for quality, and is very prolific on the Paradise stock, and where Worcester is grown there is no need to include the newer form, though Mr. Gladstone is the earlier of the two. We have a very showy Apple, much liked on account of its very bright colour. The fruits have a rich bloom on them like Plum, and the tree is a grand cropper and known under two names, Duchess of Gloucester and Duchess Favourite. The fruits are very shapely, though not large, and if gathered direct from the trees, are of fair quality and keep longer than some very early kinds. Another very showy Apple is Red Astrachan larger than Duchess, and, like it, beautiful, coloured and not deficient in quality for an early variety, if eaten direct from the tree. This is less valuable than Duchess if stored, as it soon becomes mealy. This is in season at this date (August 23)—rather earlier than usual. A brisk, sprightly fruit is Summer Golden Pippin, also known under the name of Yellow Ingestre, a small fruit, firm flesh a golden yellow when quite ripe, and much liked by those who prefer a solid, brisk flavoured fruit. There are, I believe, two, if not more, varieties of the Summer Pippin, a some are much larger and greener, but stock and soil will influence these fruits. The true form is a good standard fruit, and though ripe early in September it will keep well into the winter. I have not noted the value of Duchess of Oldenburg as a summer fruiter. This is a class of Apple many persons like, and is in some catalogues classed as a cooking fruit, but if grown in bush form on the Paradise stock it is well worth a place on the dessert table; the fruits are of medium size, with a brisk acid flavour. This is much liked by many, and the tree is a constant bearer and grows freely in almost any soil; in fact, it may be classed as a good town Apple, as it rarely fails to crop under adverse conditions, and is in season in August and early September. There are others—in deed there is no lack of variety—but I have noticed those noted for cropping, with the best quality and earliness combined. By growing these early varieties in bush form anyone is able to get an early supply; at the same time large quantities are not needed, and with small trees there is an early supply with finer fruits.

G. WYTHES.

**Apple Potts' Seedling.**—Further experience of this fine Codlin Apple proves that it is worthy of more extended cultivation, and should be planted by all who require cooking Apples of first-rate quality during September. The fact that in the scarsest seasons Potts' Seedling usually bears more or less fruit, enhances its value, and as it succeeds well in smoky districts in the vicinity of towns, amateurs should include it in their list. It succeeds well either on the Paradise or Crab stock. It is a great favourite in Norfolk.—C. C. H.

**Apples and Pears for pots.**—"R. K." having asked for the names of a few Apples and Pears suitable for pot culture, I have much pleasure in submitting the names of six varieties of Apples and nine of Pears, all of which I should imagine would succeed well in the climate of St. Petersburg. If I have named too many Pears, "R. K." can make a selection from the list below, and I may add that they all produce fruit of large size and of first-rate quality. When purchasing

the Pears, trees on the Quince stock should be asked for, as these give by far the best results when grown in pots. Both the Apples and Pears are arranged in their order of ripening. Six Apples: Beauty of Bath, Lady Sudeley, Washington, Melon, Cox's Orange Pippin and Peasgood's Nonsuch. Nine Pears: Beurré de l'Assomption, Clapp's Favourite, Williams' Bon Chrétien, Beurré d'Amanlis, Gratioli of Jersey, Thomson's, Beurré Superfin, Duchesse d'Angoulême and Doyenné du Comice.—A. W.

**Nectarine Early Rivers.**—This will undoubtedly become a great favourite amongst gardeners who require ripe fruit early in the year. Mr. Shingler, the gardener at Melton, thinks very highly of it, and as grown there it does equally as well as Lord Napier, so far as cropping is concerned, while it has not that objectionable habit of turning soft and rusty as if from sunstroke which Lord Napier has. Grown in a pot at Melton it has borne a good crop of fine, highly-coloured, deliciously flavoured fruit, and more trees will be planted in future. In Early Rivers, Elruge, Rivers' Orange, and Violette Hâtive we have four Nectarines ripening in the order named, which for hardness of constitution, freedom in cropping and general good quality cannot, I think, be beaten.—J. C.

**Strawberries for forcing.**—Where fruit is required in March the forwardest batches for introducing into heat during November will have been potted. Some growers are careless as to where they stand their plants, sometimes placing them on a bottom minus ashes, with the result that the balls become infested with worms, and the holes in the base of the pots stopped up with soil. Some of the most successful growers use the sides of the kitchen garden walks, placing boards, or, better still, trellises for standing the pots on. All superfluous water can then escape and a good circulation of air is secured. More room should be given as soon as the plants approach one another in growth, crowding having a weakening effect. Liquid manure diluted to about a fourth of its natural strength is a capital stimulant for Strawberries, but soon does injury if given too strong where the plants are confined to pots.—J. C.

**Peach Lord Palmerston.**—Few gardeners who have had any experience with this Peach would care to plant it where table Peaches alone are required, but where there is plenty of house room and fruits are used for sweets in the kitchen, a tree will be found very useful, as it is a capital cooking variety and a prodigious bearer. I lately saw a tree of this variety at Melton Constable carrying an enormous crop of extra large, fine-looking fruit, which Mr. Shingler informed me would chiefly be used for culinary purposes. Many have been tempted to plant Lord Palmerston from seeing a dish of it at an exhibition, only to find that they had made a mistake, so far as quality was concerned. I never grew Lady Palmerston, but have been told that it far surpasses Lord Palmerston in quality. Perhaps some reader of THE GARDEN has proved it.—J. C.

**Strawberry runners in 1897.**—Mr. Wythes recently noted how unsatisfactory Strawberry runners are this season, being not only late, but small and inferior. This, I am afraid, is the case in most places, and market gardeners will in many instances find it difficult to muster sufficient runners with which to furnish the allotted areas. I recently saw in market gardens in East Anglia large Strawberry beds which had borne fruit this year, and so bronzed and wizened were they, that scarcely any runners could be got from them. I, like Mr. Wythes, strongly advocate the system of planting a percentage of plants annually for runner production, and although in many gardens it may for want of room be difficult to do this, market growers with their larger areas could easily do it, and would undoubtedly find it to pay well.—J. C.

**Apple Devonshire Quarrenden.**—I do not think there are many young trees of this good old dessert Apple planted now-a-days, people appar-

ently going in more for the larger, softer, and indifferent keeping varieties, which, in fact, require to be eaten almost as soon as gathered from the tree. The soil and climate of East Anglia seem to suit this Apple well, and, judging from the quantities of it now being offered for sale at the various seaside towns, it would appear that some of the old trees are still yielding good crops of fruit. In light, warm soils the true Devonshire Quarrenden becomes red nearly to the core, is deliciously sweet, and will keep good for a considerable time, which is saying a good deal for an autumn dessert Apple. Intending planters should be careful to purchase their trees from a reliable firm, as there is a larger and inferior variety of Quarrenden which seldom colours up well.—GROWER.

**Apples in East Anglia.**—East Anglian orchards, in common with those in most other parts, seem to have suffered from the cold winds which prevailed in May last. In travelling through Cambridgeshire and Norfolk I noticed orchard after orchard quite bare of fruit. I learn that the show of blossom was one of the best seen for years, but that it succumbed to the bitter blasts of spring, which were actually worse than frost, crippling the fruit in its infancy, so that where trees did hold their fruit in the first instance most of it fell later on. The majority of the trees one sees with fruit on appear to be small, old-fashioned varieties, having extra good constitutions. Plums are equally as scarce, fruit of what appeared to me to be the old Orleans selling in Norwich for 6s. a stone. Altogether this great scarcity will be keenly felt both by growers and consumers.—GROWER.

PLUM NOTES.

ALTHOUGH the Plum crop as a whole is a decided failure, and there are stretches of wall with absolutely no fruit to be found, several of the best kinds are bearing fairly well and a supply of fruit has and will be available alike for dessert and ordinary cooking, the failure being in the large quantities usually supplied for preserving. I have both Rivers' Early Prolific and Early Favourite, and recommend the latter. It is quite as early as Prolific, an equally sure cropper and a decidedly better Plum, good ripe fruit, if not up to the standard of the Gages, being acceptable for dessert very early in the season. I do not know how it does on heavier soil; here the annual growth made is very slight; it takes the tree years to reach the top of a high wall. I have not grown Rivers' Stint. What is the difference between this and Early Favourite? The Czar is a decided acquisition, coming in just after the early and before the mid-season Plums, and no more certain cropper—not even Victoria—is to be found. As cooking Plums, to the two already named may be added Victoria, Pond's Seedling, and Pershore, the last on account of its colour and the admirable preserve it makes. I do not grow a later cooking Plum than Pond's Seedling, for the reason that Coe's Golden Drop is a great and consistent cropper, and furnishes plenty of fruit alike for dessert and the kitchen all through the latter part of the season. Where, however, a greater variety is required, Diamond and Imperiale de Milan are good cooking sorts for September and October. Oullin's Golden Gage is one of the earliest of the *bona fide* dessert Plums, and if to this are added Transparent and the old Green Gage (true), Jefferson's and Golden Drop, a few of the very best are secured. Denniston's Superb I am compelled to omit, for, although free on some soils, here it is very shy. The soil being on the light side, I am compelled when planting young trees to excavate rather deeply and fill up with the heaviest soil obtainable; a little of the same soil is put on as a top-dressing every autumn, with a mulch of manure in the spring if the weather seems likely to be hot and dry. Enemies are spring frosts, grey aphid, and blackbirds. For the first-named I manage enough fish netting to put on a double thickness, and this is generally sufficient protection unless the visitation is exceptionally severe, whilst the

same netting is utilised against blackbirds, that always commence an attack on the Plums when the small fruit is over. The grey aphid is a troublesome enemy, and multiplies faster than any other of the species. Fortunately, it is more easily killed than the black form. I think quassia extract is about the best remedy; other insecticides may be even more efficacious in the way of sudden death to the fly, but the great point about the quassia is its safety. In the hands of an inexperienced workman an extra dose will not be detrimental to young shoots or foliage.

E. B. C.

BLACK CURRANT MITE.

Will you kindly inform me if there is any remedy for the Black Currant bud mite? My bushes are badly infested.—R. H.

\* \* \* The Currant bud mite (*Phytoptus ribis*) each year becomes more destructive, and unless drastic remedies are applied Black Currants will soon be a thing of the past among many market growers. It used to be considered one of the most profitable fruits to grow, but, owing to the bud mite, farmers of my acquaintance have had good reason to think differently of the value of Black Currants, and have cleared whole breadths of bushes off the ground. All classes of growers are strongly advised to keep a close look-out for first attacks and to take measures for the prevention of the spread of the mite. The mites are so small as to be undiscernible to the naked eye, a powerful lens being needed to see them, yet if they take possession of the buds they arrest natural development of growth, an abnormal swelling of bud taking its place. In the spring when it is seen, a certain number of buds fail to burst into growth, and are much swollen. The shoots bearing these should be cut off and burnt, or if there is only a bud here and there affected, these only may be removed and burnt. Neglect or fail to persevere with these precautions and the time may arrive when the bushes will be so badly infested by bud mites as to be quite worthless, and only fit for a bonfire. Owing to the protection afforded by the bud scales, there is no reaching the mites after they are once in possession, but experts give remedies of a preventive nature. The best of these is a preparation of soft soap, soda, and sulphur. Dissolve 4 lbs. of soft soap by boiling in eight gallons of water; boil 8 ozs. of caustic soda and 1 lb. sulphur in a gallon of water, then mix all together and boil gently for about half an hour. When wanted for use add twelve gallons of water, heating and applying it at a temperature of 100°. Spray the bushes with this preparation in November and again in February, doing it thoroughly. This, coupled with the timely removal of all swollen buds that are seen, will rid the bushes of the mites. I should also advise "R. H." to start a fresh plantation with young bushes from an untainted source, and on ground well away from the affected bushes. If his remedial measures prove of no avail he will then have his new clean bushes to fall back upon.—W. I.

**Mulberries.**—These, in common with the majority of fruits, appear to be scarce this season, and, even where trees are carrying fruit, much of it is deformed and small for the time of year, and will never swell to its normal size. Many have no idea of the richness of Mulberry jam, and it is a great pity that more young trees have not been planted during the last half century to replace those that are fast disappearing. A semi-shaded position suits Mulberries well, but they like a moist root-run. Those who have only a few fruits on their trees will do well to protect with fish netting, as blackbirds and thrushes will take them even while in a red unripe state.—C. C. H.

**Pear Beurre Giffard.**—In the interesting article on early Pears which appeared in the issue of the 21st, mention is not made of that most excellent dessert Pear Beurre Giffard. I do not think this variety is generally known, although it deserves to be, as, independent of its general good

quality, it does not decay so quickly as many of the early autumn Pears, Citron des Carnes for instance. Beurré Giffard is a medium-sized fruit, of handsome appearance, having a red cheek on the side exposed to the sun, the flavour being exceedingly rich and melting. It grows rather irregularly, but succeeds well grown as a cordon on the Quince. In shape it much resembles Jargonelle, and is in season from the end of August to the middle of September. It is a good Pear for exhibition on account of its extreme hardness.—J. C.

**Peaches and Nectarines in pots.**—There is a capital lot of Peaches and Nectarines in pots in one of the houses at Melton Constable, Mr. Shingler's treatment differing somewhat from that usually given. The pots are plunged in a narrow border along the front of a lean-to house, trained trees occupying the back wall. The pots are let into pans so as to prevent the roots going down into the border and encouraging rank growth, and each season all roots which grow over the sides are cut off close to the pots. The trees are left plunged all the year round and mulching annually practised. By this means the trees are kept within bounds, growth being moderate and becoming well ripened in autumn, and if necessary feeding can easily be practised. Many of the stronger growing shy-fruited varieties are rendered more fertile, while such well-known sorts as Elruge, Pine-apple, and Rivers' Orange bear so freely that liberal thinning of the fruit is necessary.—J. C.

#### GRUB IN APPLE AND PEAR LEAVES.

Would you kindly tell me what the enclosed leaves are attacked with? All my Apples and Pears on the walls are every year attacked in the same way. This season they have been worse than ever. The walls are built of hard whinstone. One wall faces south-west and one wall south-east. I have watered the trees all along in dry seasons, but never could stop this trouble. I have watered now and again with liquid manure from farmyard. Plums are never affected.—A PERTSHIRE WRITER.

\* \* This is one of the worst instances of injury done by the Pear tree blister moth (*Lyonetia clerckella*) I have ever met with. Although the popular term would imply that it is an insect pest affecting the Pear only, it has been found, as in the case under notice, that the Apple and also Cherry are liable to be attacked by it. In order to be able to cope with this insect, its life history must be inquired into. A certain number of perfect moths, which, being so small—not measuring more than one-third of an inch across the expanded wings—are never heeded, pass the winter in crevices in dry walls, among dry leaves, and such like. In the spring these deposit their eggs on the young leaves, into which the newly hatched-out grub eats its way, causing a small blister at that spot and mining round it, eating away the pulp to a circumference of one-eighth to one-third of an inch in diameter. In some instances these dark brown patches are so numerous as to coalesce, and the injury done to the leaves is severe enough to cause them to drop wholesale. While the tiny grubs are at work, or say during May, June, and the early part of July, it is only by close observation that they can be discovered, and by the time the patches change to a dark brown colour, the change from the larvæ stage to the perfect insect has taken place and fresh broods of moths are at work laying more eggs. Once the grubs have entered the leaves, nothing can be done to save the latter, and prevention must be the order of the day. Preventive measures should consist in a thorough clearance of all rubbish from about the trees, and the stopping with fresh mortar of all crevices or lurking places in the walls. This should be followed in the spring by frequent spraying of the leaves with either soap-suds, a decoction of quassia chips and soft soap, or other form of insecticide not strong enough to damage tender leaves, but sufficiently distasteful to the moths. Once a week is not too often to spray with the selected insecticide, doing it only once

or twice in the season proving next to useless. A close look-out should also be kept for any signs of the moths having done their work in spite of the sprays, and all blistered leaves found ought to be at once gathered and burnt. "A Perthshire Writer," having once inadvertently allowed the moths to get the upper hand, will have to be most persevering with his work of prevention, but may succeed in getting rid of the pest in the course of two or three seasons.—W. I.

#### FRUIT TREES ON NORTH WALLS.

I AM pleased to see A. W." (p. 139) point out the value of north walls for fruit trees, as in a season such as we have passed through, with much heat and drought, north walls are doubly valuable. I find we can secure excellent crops of Cherries from such positions—I do not mean Morellos, but the best kinds—whereas on warmer aspects in such a season, and on light soil, the fruits are soon over. I admit that a few of the better Cherries, but only a few, do not thrive as vigorously as one could wish, but these are not numerous. Many of the Bigarreans and Heart Cherries do well, and a few of the Dukes. These latter make less wood and gum more, but there is a large number to select from. North

*Stapelia bufonia*. From a photograph by Mrs. McDonell, Edgware Road, London.

walls in favoured localities are too useful for growing merely Morellos. I note "A. W." advises Plums, and these do better on this aspect than on a warmer one in certain districts. I am aware there is less protection in the spring, but when once the crop is set the after growth is much cleaner, as on a warmer wall the trees are frequently badly attacked by fly and difficult to keep clean. Most of the Plums will do on a north wall; in fact, they like this position during July and August, and there is a great gain in retarding a portion of the crop grown in this way. "A. W." fully notes the advantages of Plums grown thus, and I may add Pears also, as I find this year our best crops are on a north wall. In places where Apples of the best quality are needed for dessert, I have seen very good results obtained by utilising a north wall. Treated thus, special culture may be given, and thinning is a simple matter. If cordon Pears are grown, it is well to plant the free-growing early kinds, if the situation is

exposed, and strong plants. The best crop of Gooseberries I ever had was grown on a north wall 8 feet to 9 feet high, with the trees trained as double cordons. When once the top of the wall was reached these gave little trouble beyond spurring in and netting over to protect from birds. Grown thus the trees give us fruit for weeks after those in the open were past, as they last well if trees are kept close in to the wall. No matter what variety of fruit is grown, it is well to keep the trees close to the wall and give shelter in the way of a good coping if possible. G. WYTHES.

#### THE CARRION FLOWERS.

(STAPELIA.)

THE genus *Stapelia* is an extensive one, as sixty or more species are known, but many of them are not in cultivation. Except in botanic gardens or in the collection of some specialist, they are rarely seen, one objection to them being the unpleasant odour of the blossoms, which is exactly like carrion, and, the petals being thick and fleshy, they often become infested with maggots after being expanded a few days. Nearly the whole of them are natives of South Africa, and consequently they require greenhouse temperature in this country, with a dry atmosphere during the winter months. They are not deep rooting; hence the pots in which they are grown should be thoroughly well drained, or pans may be used for their culture. Sandy loam, lightened by an admixture of leaf-mould and brick rubble, will suit these Carrion Flowers exactly, and during the summer they may be watered with moderate freedom, but in the winter greater care must be exercised, for it is not advisable to parch them up, while an excess of moisture is likely to prove fatal. Notwithstanding the fact that *Stapelias* are no longer popular at the present day, they are wonderfully interesting and, in a way, beautiful their quaint starfish-like flowers being, in some cases at least, marked in a most remarkable manner. One species, *S. gigantea* claims a place among the wonders of the vegetable kingdom, as the comparatively huge blossom is shaped like a five-pointed star, foot or more across, and the marking is equally strange. The ground colour is a pale tawny yellow, marked in a zigzag manner with reddish transverse bars, and the entire flower is densely covered with hairs. Its odour is a vile as any of the others, so much so that when in bloom it must be covered with a bell glass in order to allow of a near inspection of the blossoms, or if stood on a shelf with a ventilator overhead the stench is a good deal lessened. This *Stapelia* has flowered several times in cultivation, and a first-class certificate was awarded it by the Royal Horticultural Society in the autumn of 1891. It is the only member of the genus that has ever received such recognition. *S. bufonia*, whose general appearance is well shown in the accompanying illustration, is a much smaller flower than the last, but strangely marked, as the specific name of *bufonia* (toad-like) would imply. Other species that may be mentioned are *S. Planti*, *S. pulvinata*, *S. primulina*, *S. Asterias*, *S. variegata*, *S. Simsi*, *S. grandiflora*, and *S. deflexa*, of which a characteristic illustration was given in THE GARDEN, January 30, 1892. A great many of the Carrion Flowers were introduced during the latter years of the last century or the earlier ones of the present. The general appearance of the *Stapelias* when growing would suggest a near relationship to the Cacti or Euphorbias, instead of which they are allies of the Hoyas and other Asclepiads. H. P.

FLOWER GARDEN.

BORDER CARNATIONS.

"Many men—many minds."

Northern gardens Carnations are now at their best, making a glorious show in borders when boldly massed, and still more delightful when planted in raised beds, so that the long flower-stems may fall over, garlanding the stone or the woodwork with a flowery drapery rich in colour and redolent of spicy odours. No flower has been more killed by kindness, or, to say, than the Carnation, for the florist has taken it in hand and reduced it to his standard of uniformity, till half its charm and more than half its beauty have been smoothed away. Year by year it is very instructive as well as interesting to buy some of the many varieties which are so loudly praised, either to show or by their raisers, and (were it not rather expensive luxury) to watch the seedling out, both by death and by the deliberate pulling up as worthless, of at least three-quarters of these dearly-bought novelties. It is curious to notice how indiscriminate the praise of some folk is. They lump together the most delicate florist's flower with a bold border variety, till none but the most expert can understand how such failure will result from following such a selection, or rather, I might say, conglomeration. Individually, I have a horror of the prim florist's flower as a border plant. It is all very well "pulled" out and dressed for exhibition after having been specially grown and severely shrouded in order to impart special vigour. But, just plant one of these show beauties in the open garden, and see the result! The wonder is that so many still grow the Carnation at all after having been so bitterly disappointed. Were it not for the robust vigour of Cloves and beds of seedlings, we should hear, I fear, little or nothing of this fragrant flower. It rejoices in the cool northern air, and prefers the freest breath of heaven to the sheltering sufficiency of suburban gardens. In such a season as this the Carnation is peerless in the north, where no black thrips destroy the beauty of the opening petals, and where drought is not felt so keenly as in warmer soils and situations, and we may well be thankful for its beauty. First and foremost of the borders come the fragrant Cloves in each three-year-old clumps, laden with heavy flowers, which show to greatest perfection if grown in big boxes on the top of a Jasmine-covered retaining wall and allowed to hang down, mingling their sweetness with the stars of the white Jasmine. In Spain, in the Magdaine, in Italy, and along the Riviera this plan of growing Carnations is so common and so much admired, it is always a matter of wonder to me that it is never adopted in England, where they will do quite well, and brave severe winters fully exposed when once established.

To my mind, the proper definition of a border Carnation is one that will endure for at least three years in the same place, and give an increasing abundance of flower.

This cuts off nearly nine-tenths of the varieties catalogued, because there is no need to recur to nurseries in order to renew one's plants. There is no doubt a strong temptation to nurserymen to grow varieties that require special attention, but I think that when once a good collection of hardy border Carnations is established, the amateur will readily experiment with new sorts, in the hope he may find something which will make a permanent addition to his borders. To-day I will not talk more about old favourites, but note down the behaviour of various newer Carnations which will, I think, remain in our gardens. There are many gains, especially in selfs and yellow grounds, but fragrance is sadly deficient in most, so that I hail with delight a specially sweet white—Mrs. F. Gifford—which should be worth a trial, from all accounts. Three years ago I was much fascinated by a yellow ground with pink tips called Cowslip, which has proved an excellent border variety. This year there are two others—one, Voltaire, and the second, Eldorado, deeper and fuller in colour. Of these, for gardening purposes Eldorado is much the better, strong and sturdy in habit and most telling in a border. Voltaire is the nearest to the florist's model, and intermediate in colour between Cowslip and Eldorado, and apparently a more delicate variety, so that, personally, I should discard Voltaire and grow Cowslip and Eldorado. The Dey is another yellow and red Carnation, but muddily in tone, to my fancy; it is good in habit and thin in petals. Cardinal Wolsey, Sir John Falstaff and Geo. Cruikshank are all deep tones of red and yellow and good border plants, but they do not specially appeal to my sense of beauty. The much-praised yellow ground Mrs. Sydenham is quite worthless as a border plant. Of apricot shades, there is one (Winifred) which seems a great addition to the border; it is excellent in habit, apparently hardy, and bears abundant flowers, delightful in colour and shape. Pasha comes next to it in excellence, and Nabob, The Hunter, Carolus Duran and Mrs. Hole are all a long way behind in a border. Of pure yellows, there is still nothing that surpasses Germania, which does so well here on a bank where no winter damp can linger; but the robustness and freedom of Duke of Orleans make it useful, and the number of secondary blooms down its long straggling flower-stems is remarkable. Hanging over the edge of a retaining wall, Duke of Orleans, Hayes' Scarlet and Mephisto make a brilliant mass greatly admired by visitors. Neither Corunna nor Miss Audrey Campbell are improvements in any way, as far as my experience goes, but their lemon-yellow colour is pleasing. Of soft pinks, Duchess of York is the best here, promising to make a good mass, but Burn Pink (or Duchess of Fife, as it is often called) is so bad to beat that I am content with it. Of scarlets, Sweet Brier is good, and so is Paradox and several others. King Arthur is always the most wonderful flower in the garden, but it is not a true border variety; it needs annual propagation and is

particular in its requirements. Still, it is so grand, it is worth a little extra trouble. So far as I have seen, there is no dark border variety to come near Mephisto. Uriah Pike positively refuses to grow outside with me, and Duke of York is not so rich in colour or so vigorous. White and rose-coloured border Carnations are so abundant, that it is hard to say this or that only should be grown. Still, I must say that a three-year-old plant of Ellen Terry is a joy and a possession; the huge white flowers are so abundant, the growth so vigorous, and on old plants the blooms are more refined and often do not split at all, so that it improves with age, like good wine.

Of fancies, I can only say "everyone to his or her taste." Few of them can make effective border plants, but now and then the quaint mixture of colours appeals to someone's sensibilities, and among a good batch of seedlings there will always be one or two worth keeping for one's own garden, if not worth putting into commerce.

E. H. WOODALL.

*St. Nicholas House, Scarborough.*

NOTES ON HARDY PLANTS.

*Sedum hirsutum* is more like a miniature *Sempervivum* in the arrangement of its foliage, and thickly beset with distinctive hairs, as the name suggests, but the flowers are like the finer *Sedum*, white and starchy, with big black anthers. The plant is not only of interest because so different to other species, but it is exquisitely beautiful when in flower, though its height is less than 3 inches. It is also perfectly hardy, as I kept it going many years in the open and growing on nothing but tufa. Pigeons and other birds appear to have a preference for it.

*Azalea procumbens*.—It is when we see this in late summer, with its small leaves and twigs of such glowing colours as orange and mahogany, that this pretty creeping shrub assumes its most effective and useful aspect as a garden or rock-work plant. It is pleasing all the year round, from its neat, close habit and evergreen character, and the flowers are an additional charm, but, so far as my experience goes, in a garden somewhat low in a lowland valley the clusters of blossom are very sparse indeed. I have therefore learnt to value it for the colour of its foliage just mentioned, and with annual top-dressing of peat and sand I am rarely disappointed.

*Primula Rusbyi*.—This is one of the latest species to vegetate and flower, the latter often occurring in the present month. As regards its propagation, it is easy enough if done with strong, healthy stock and at the right time; in fact, however strong the stock, it may not be pulled to pieces to advantage except in a leafy state in mid-summer. A fortnight ago I divided one piece, putting the offsets into little pots. I have just been to turn a few out to examine the new roots, for there was plenty of evidence of their existence beforehand. The new roots constitute clear and distinct white lines all the length of the balls, such as delight the gardener when working with precious material of this kind, and these results have come about in a fortnight. Of course the weather has been very warm and not too wet. No doubt all such hardy plants are better in every way when they are prepared to go through the winter with new and established roots under them. This is one of the most rare, beautiful, distinct, and hardy of the *Primulas*.

*Gaultheria procumbens* is now in its best form here; it has its maximum amount of character, with all its features displayed at once. The old deep green foliage contrasts with the shoots of the new foliage, which is a bronzy red. There are present the early crop of bright scarlet berries

in plenty and abundance of the waxy white bell-shaped flowers. The whole plant is only 4 inches or 5 inches high, but it forms an effective vari-coloured object without a single fault of any kind when well grown, which is easy enough to do in a half loam and half peat soil on the flat, where plenty of moisture can find it.

**Sedum corsicum.**—Without flowers, how very effective a group of this is when resting on a conspicuous point in full sunshine, where doubtless it gets those conditions needful for the development of its many pleasing tints. Of course, this variety of *dasyphyllum* does not withstand our wet winters, but it may often be brought through with a little shelter from wet and may be preserved in a cold frame kept dry in winter—a little care it is well worth. J. Wood.

Woodrille, Kirkstall.

#### SPIRÆA ASTILBOIDES.

This distinct *Spiræa* was first exhibited by Mr. William Bull, of Chelsea, in 1880, and distributed by him four years later. After that it soon worked its way into popular favour, and is now to be met with in nearly all gardens of any pretensions whatever. This *Spiræa* is now sent from Holland every year in large quantities, just as in the case of the older *S. barbata*, or *japonica*, as it is often called. It is altogether a larger and bolder plant than *S. japonica*, while the inflorescence is of a creamy-white tint and more lumpy than in that kind. It is a fine subject for greenhouse or conservatory decoration, but cannot be forced into bloom so early as *S. japonica*; indeed, it is most effective when simply protected under glass and brought on without any severe forcing. Out of doors, too, it is very attractive, a moist nook in the rockwork or some such a spot being just the place for it. When fully exposed, the young foliage is of a distinct bronzy tint, which imparts a very pleasing feature to the plant and contrasts markedly with the creamy-white blossoms. In 1891 a *Spiræa* was sent out by a Belgian nurseryman under the name of *S. astilboides floribunda*, and announced as a seedling from a plant of *S. astilboides*, which had presumably been fertilised with the pollen of *S. japonica* growing in close proximity thereto, and such is doubtless correct, as the newer kind is in general appearance about midway between the two. The foliage partakes largely of the characters of the two species, as the leaflets are larger and rougher than those of *S. japonica*, and at the same time they are of a much brighter green than *S. astilboides*, and do not become bronzed by exposure. The inflorescence is more in the way of *S. japonica* than the other, being more erect and of a whiter tint than *S. astilboides*. It is, however, a larger growing plant than *S. japonica*. This *Spiræa* received an award of merit from the Royal Horticultural Society in 1894. Both *S. astilboides* and *S. astilboides floribunda* have figured prominently at many exhibitions, grand masses having been several times seen at the Temple shows. H. P.

**Tufted Pansy Duchess of York.**—A few weeks since a note appeared in THE GARDEN with reference to a variation in some plants sent to me under the name of White Duchess, but which was sufficiently distinct from any other member of the family to make careful note of. From information recently acquired it is understood to be a sport from Duchess of Fife, the sport having originated in the garden of a small, but enthusiastic amateur grower in the neighbourhood of Chingford a few years since. The stock has evidently been widely distributed, as my plants were received from the nursery of a celebrated midland grower, and now I understand the plant is to be sent out under the name prefixing this

note by a firm in the south. The flowers are pretty, with a bright bluish narrow margin, the ground colour being white with a light suffusion of yellow on the lower petals.—D. B. C.

#### FLOWER GARDEN NOTES.

SOME rather interesting combinations in the way of summer planting, noted from time to time, and quiet, pleasing and effective in the way of contrast, may serve as a guide to another season's planting. Perhaps the most striking carpet for beds of *Lobelia fulgens* vars. *Queen Victoria* and *Firefly*—if, that is, the carpet may be an annual and not a permanent affair—is *Golden Harry*

little darker than that of *Sugar Beet*, but it is hard worth growing. If when planting the *Lobelia* a permanent bed, or, at any rate, one that will last for two or three seasons, is designed, a more enduring carpet than the *Pelargonium* will be found in several of the lighter-coloured *Violas* in *Veronica incana*. If the beds in which *Lobelia* are growing are to be occupied next year by other subjects, the plants may be lifted at the end of the season and packed together tightly in boxes or frames. They should be kept under such circumstances on the dry side, and protected from very severe frost. Hardy combinations, both effective and pleasing, have resulted with the association respectively of *Montbretias* and the *Fuchsia gracilis* with *Hydrangea paniculata*

*Spiræa astilboides.* From a photograph sent by Mr. Greenwood Pim, Monkstown, Ireland.

however *Pelargonium*, the taller plants some 30 ins. apart each way. These *Lobelias* are very vigorous this year, some of the stems being  $1\frac{1}{2}$  inches in diameter at the base, and with stems of this size the flower-spike, as may be imagined, is proportionately strong. I notice that varieties differ in the deep colouring of the foliage, and it is therefore well to put a small stick or label to the best types, that propagation, if required, can be made from them, the contrast with the lighter undergrowth being much more effective. There is a variety whose foliage, from a colour standpoint, is very
